CHICAGO, ILL., JULY 3, 1897.

No. 1.

ORIGINAL ARTICLES.

ON THE DEVELOPMENT OF THE CAUSAL TREATMENT OF TUBERCULOSIS.

BY EDWIN KLEBS, M.D.

CHICAGO, ILL.

I will not state in this paper the whole history of this question, which at its first commencement excited so much enthusiasm, and later caused so much disappointment to all concerned. As one of the few observers, having published detailed reports on the question ("On the Causal Treatment of Tuberculosis," Hamburg-Leipzig, 1894), I may be justified in expressing my regret that so many of the works on this subject, mostly in Germany, are written in the obscure and abbreviated style possibly appropriate for "vorläufige Mittheilungen," but not for definite scientific work.

Robert Koch, in his first paper on "Tuberculin" (1890), showed the effects of this substance on tuberculous rabbits, but never gave later detailed accounts of his experiments. Everyone wishing to work on the subject was therefore obliged to find his way in the dark. Indeed, the preparation of tuberculin was not published for a long time afterward. Finding that the often dangerous effect of tuberculin shown by Virchow, Hansemann and others was effected by toxins, I tried to eliminate those substances which I found unnecessary for the undoubted healing effect sometimes observed in tuberculin treatment. While Koch would avoid the faults of his first treatment by giving very small doses of tuberculin, his pupil, Dr. Carl Spengler of Davos, declares that small doses are not efficient. He also finds that the feverish reaction after the injection will not be necessary for the healing process. He says, in his pamphlet ("Ueber Tuberculin Behandlung," Davos, 1897, p. 7), "the small doses recommended before oftentimes may bring some relief to some phthisics, but for definite healing they are not sufficient. On tuberculous infected animals which should die in eleven weeks, the small doses do not work at all." The last is a valuable confirmation of the efficiency of the tuberculin for healing purposes, this sort of infection being very slight if guinea-pigs are used.

These results of practical experience, emphasized in 1897, are exactly the same proclaimed by me in 1894 as the results of experimental and clinical work. If now Dr. Spengler has not words for stating this fact, he can not be excused on the ground of ignorance, as I conferred with him at length, before he migrated to the camp of Dr. Koch. He may be excused, as he follows the method of his master, and we shall see that the latter is responsible for the suppression of facts, as yet not known in the German scientific world. The latest publication of Dr. Koch, in the *Deutsche Medicinische Wochenschrift*, April 1, 1897, has provoked the very justified reclamation of

Dr. Hans Buchner in Munich and his brother in Tübingen, regarding the preparation of his new tuberculin, the so-called TR. It has always been the custom in Germany, and I think in all civilized countries, to name the author of a method that one uses for a similar purpose. This conceded, we must ask if the Buchner method to procure the products of living bacteria by mechanical destruction of the cells can give substances more efficient for medical purpose, than the simple extracts made by watery or glycerin solutions of salt, acting on the killed bacilli? That will depend mostly on the agencies used for the destruction of life. I am very glad to hear, from Koch and Spengler, that they accepted my view that the cooking of tubercle cultures destroys a good deal of the healing substances. The substituted concentration *in vacuo*, for many years practiced in my laboratory, is the principle set forth in my book.

Spengler asserts that this new tuberculin of Koch, named TO (original "Tuberculin after Spengler" a somewhat curious expression for an improved tuberculin), gives higher febrile reactions than the former preparation. In consequence of the extreme danger connected with the use of such toxic products, it must be excluded from therapeutic use.

As I have shown in my book (1894), the action of the tuberculo-toxins lies in two directions, first in a depression of the heart action, shown by kymographic experiments on dogs and rabbits, animals much more resistant to the tubercular infection than men and guinea-pigs. I could also observe this same highly dangerous influence in tubercular patients, at first supporting the tuberculin treatment, but after some time showing very grave convulsions, probably effected by the impaired action of the heart. Further experiments on animals have shown me that these toxins have a highly cumulative action, probably due to the slow secretion of these substances. White rats, which are very resistant to tuberculosis, can be killed by this agent in thirty to fifty minutes under convulsions and cyanosis. I must emphatically declare that the TO must be rejected totally as a therapeutic agent.

The second deleterious action of these tuberculo-toxins is the local necrosis of the tuberculous parts, once held by Koch as the true healing action of his remedy. I have shown in my book that the tubercle bacilli develop rapidly in necrotic tissue, and have explained from this observation the rapid dissemination of tuberculosis after the tuberculin treatment. Regarding the cases observed in the pathologic institution of Virchow (1890 to 1891), it is difficult to understand how Spengler can suggest, in 1897, that these cases can be explained as a commencement of miliary tuberculosis preceding the injections. If he will reread the lecture on these observations, he will find cases in which the disease, before the treatment, never had a febrile character.

On this account I rejected the tuberculin treatment

and experimented to make the treatment innocuous by chemie elimination of the toxins. The tuberculo-cidin was the result of these researches, published in detail in my book. I stated that this substance not only killed living tubercle bacilli in the test-tube, but healed far advanced tuberculosis in guinea-pigs. In five years, hundreds of cases of human tuberculosis have been treated with very good results, in Europe and in this country. A milder acting form was the antiphthisin, which contains only substances taken from the fluid of the cultures—as I believe, mostly secretion products of the bacilli, toxic for its productions, but not for the human body. The good results of AP in very irritable forms of tuberculosis have been obvious; the killing power was demonstrated by experiments made in Asheville, N. C. (Win-yah Sanitarium). With these two products of tubercle culture we had very good results, as reported in this country by a vast number of most reliable physicians, using more than 50 liters the last year.

I undertook during the last two years renewed experiments on the question of immunization in tuberculosis. In 1876 I had found some indications in my experimental work, that even in tuberculosis this property was not absent. New proofs were brought forth in my book (1894), but sharply criticised by one of my severest critics, Dr. Lubarsch, formerly my assistant in Zurich. As Dr. Lubarsch has himself worked on immunization, his criticism may have made some impression.

Later I published my experiences made in this country on this question (JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, July 25, 1896; *Centralblatt für Bacteriologie*, Nos. 14 and 15, 1896), and am satisfied that Dr. Koch built up his new theory on the same principle, but, curiously, not remembering my work. As to the clinical support of this view, we may say that the long period of latency of the disease, as well as the results of causal treatment, accord fully in this direction. Koch is now searching for immunizing substances in the tubercle bacilli, as I did before. His TR, the crushed substance of dry living tubercle bacilli, will have this power of immunization. How much must be given in proportion to the weight of the patient, or the quantity of immunizing or only organic matter contained in his TR, is not noted in his communication. In some of his animal test cases the immunization is not finished, in others perfect. We would be very grateful to hear the history of these experimental cases. Without that the proof is not so positive. The responsibility of the physicians will be sustained alone by the reputation of the author, not disputable in all bacterial, but somewhat doubtful in therapeutic questions, as shown by the tuberculin treatment.

The manner of preparation of the TR involves some questions that should be answered before the treatment with this substance could safely commence. Living virulent bacilli are crushed mechanically so long as no tubercle bacilli can be detected in the obtained fluid. The rest of the indissoluble substance should be very small, and the fluid perfectly clear or opalescent. The addition of 10 per cent. glycerin should be sufficient for conservation.

1. If living tubercle bacilli are crushed and extracted, it is to be feared that some of them will remain. That they can be wholly eliminated by the use of centrifuge is doubtful, as the fluid is by no means a true solution, but a gelatinous soaked-up mass. The precipitation

by addition of glycerin, more than 10 per cent., noted by Koch, shows this clearly. In such a substance particles not much different in specific weight will not follow the centrifugal motion. Indeed, this substance contains, according to Koch, masses stainable by methylene-blue, consisting mostly of the bodies of tubercle bacilli freed from their fatty contents during the experiments. Are these bacilli, deprived of their fat, living or not? We do not know that and have no other means for deciding this question than the animal experiment, the infection. I have some reason for suggesting that in the living animal and in men tubercle bacilli are also present, which do not stain acid-proof with fuchsin, but stain after the method of Gram. The question arises whether the new TR will be tested in every animal experiment as to whether it is infectious or not?

2. For conservation of this fluid Koch adds to the crushed and centrifuged preparation 10 per cent. glycerin. But it is generally accepted that organisms grow very well in such a fluid. This is the more to be regarded as the manner of preparation does not guarantee the aseptic condition. The way of avoiding this difficulty should be published.

Experiments can only decide these questions, and they should be reported in a detailed manner. In these complicated experiments, in which the variability of animal life accords with the variability of microbic life and only one factor, the chemical product, can be made constant, without a greater number of scientifically varied experiments nothing can be decided. The whole material must be published, so that any one can judge from the evidence.

3. Lastly, we come to the comparison of the two existing methods for preparing immunizing and healing substances from the cultures of tubercle bacilli, the tuberculo-cidin and TR. Koch remarks in his last publication that the presence of fat in these organisms, which gives the substance the specific reaction, as shown first by me, hindered the extraction of tubercle bacilli. That this is not true is shown by experiments by the director of my laboratory in Strassburg, Dr. Ernest Klebs, who gives the following account:

ANALYTICAL DETERMINATION OF THE EXTRACT OF TUBERCLE CULTURES.

"Of five liters tubercle cultures exactly four weeks old and grown perfectly, I made the determination of organic substances in the fluid. The cultures after they were taken out of the incubator were first killed by ortho-kresol, then mixed and preserved in a room of normal temperature (January and February). The results of the analysis were as follows. (The glycerin was extracted in the platinum-crucible with ether and alcohol, 3 to 1, before drying the residue.)

1.	Extract 24 hours after killing the T. B.,	1.64 per cent.
2.	" 7 days " " "	1.71 "
3.	" 14 " " " "	1.86 "
4.	" 21 " " " "	1.88 "
5.	" 35 " " " "	2.20 "
6.	" 42 " " " "	2.44 "

The difference between analysis No. 6 and No. 1 is: 2.44—1.64=0.8 per cent. In six weeks in the liter of the cultures nearly eight grams more are gone in solution. That result is very remarkable, but I found nearly the same quantity, 7.9 per cent., last summer, as I wrote you."

In this last experiment the strongest toxin I ever received was obtained by concentrating *in vacuo*. Tuberculous guinea-pigs of 700 grams weight are

killed by 0.3 gram weight in less than twenty-four hours and 0.5 c.c. kills sound white rats of 150 grams weight in thirty to fifty minutes. It seems to be identical with the TO of R. Koch. After this result I can not think that by any method more soluble substance can be extracted from the tuberculin bacilli by a fluid containing 5 per cent. glycerin. The high toxic effect of this substance is defending the use for healing purposes, which view Koch seems also to accept by going over to the production of TR. All these extracted substances are contained in the tuberculocidin (TC), eliminating the toxins by precipitation with sodium bismuth iodid. The often repeated effect of this substance is that the higher temperature of tuberculous animals and man is suppressed and the tubercle bacilli are killed, the tuberculous tissue reabsorbed without formation of scars where the tissues are not wholly necrotized. That also the gravest infection of guinea-pigs can heal I have shown last year. (JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 1. c.) It seems to me to be of the highest value to compare the immunizing property of the tubercle bacilli extract made without crushing the T.B. and after crushing them as is made in the preparation of TR. In experiments on guinea-pigs, begun immediately after having received the publication of Koch (in April) on T. B. killed with kresol, 0.2 per cent., I have found no difference in the immunizing power of the extracts made by my method and by the method of Koch. The first seemed to be more efficient, but this may depend on a somewhat higher concentration. So I am sure that the precipitation with NaBiI₄ does not destroy the immunizing substance contained in the T. B. As to the question, whether living T. B. give more of this substance, it seems to me very questionable, for if this substance would be destroyed by the death of T. B. our preparations must have become totally ineffectual.

The difficulties in preparing TR from living T. B. lie, as I have shown, in the danger of the presence of some living T. B. in the fluid as long as the fluid is opalescent, by the presence of gelatinous matter. Within the last few days I have found a method of eliminating these certainly superfluous or dangerous admixtures, using the usual centrifuge, giving no more than 2,680 rotations per minute. By adding finely powdered carbonate of magnesia the fluid can be cleared up by a rotation of 2,000 per minute. All this gelatinous matter and with it some T. B. escaping the crushing is precipitated and included in the magnesia deposit. The experiments with these fluids will be begun now and will be referred to in due time. Addition of conservative fluids, as 0.2 per cent. orthocresol, will be tried in these experiments. The danger of contamination at the time of the preparation must be avoided, as far as possible, by always using fluids immediately after having centrifuged them with magnesia-carbonate. For human use such preparations must be avoided, but the theoretic question seems to be interesting.

Wire Springs to Hold open Operated Abscesses.—E. Braatz uses a small wire spring shaped something like a fancy W, or a spiral for deep abscesses, to keep the openings from closing after evacuation of the pus, thus facilitating free discharge. He has them made in various sizes, and if necessary, combines a rubber drain with them, which he always slits lengthwise, to secure better drainage. This is a return to the old spirals of Chaisaignac.—*Cbl. f. Chir.*, April 24.

GENERAL MEDICINE A SPECIALTY IN ITSELF: ITS RELATION TO THE RECOGNIZED SPECIALTIES, PARTICULARLY TO BACTERIOLOGY.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, at Philadelphia, Pa., June 1-4, 1897.

BY GEORGE BYRD HARRISON, M.D.

President of the Obstetrical, Gynecological and Pediatric Society; Professor of Diseases of Children, Columbian University; Senior Physician Washington City Orphan Asylum; Member of Attending Staff, Department of General Diseases Central Dispensary and Emergency Hospital, etc.
WASHINGTON, D. C.

I wish to urge upon you, as forcibly as I can, that the time has come when we should claim with all our energy that the department of medicine in which we are engaged (the noblest of all the divisions of the science, because the most comprehensive, and calling into play the intellectual faculties as none other can possibly do), is, and of right should be, a *specialty* in itself, claiming not only *recognition* from the "manipulative" (or otherwise limited), recognized specialties, but occupying toward them the position of a parent to children—a fostering care which they can not do without, unless they are content to be relegated to the domain of sciolism and quackery. These are strong expressions, but not too emphatic for the occasion. A brilliant medical man, of admirable attainment in the theory of medicine, of thorough hospital training and very considerable experience in private practice, told me (within a few weeks), that he had made up his mind to quit private practice and enter the Marine-Hospital Service. Having been out of the class-room so long, and with little time to prepare for examination, he had some misgivings as to his ability to compete with men fresh from their textbooks. But, he added, I have come to this deliberate conclusion, that the time is not far distant when none but the rich can afford to indulge in the practice of general medicine. He carried out his plan, and out of three places competed for by thirty odd applicants, took the first position and is now installed in that service. This illustration of what is likely to occur very generally, has struck me forcibly. If the present system goes on we will all be impelled to *quasi* specialism—which is as dishonest as modern homeopathy—or else to give up civil practice altogether.

Let us contemplate the picture as it is presented day by day. We call a laryngologist to a case, because under the Hippocratic oath we feel obliged to give the patient the advantage of manipulative skill and constant practice. Everything goes well with this individual, and we congratulate ourselves upon our consideration for the patient and his friends. Very soon we hear of another case in the same household, construed by the friends to be a suitable one for a specialist, and the specialist whom we have introduced is installed. Perhaps there may have been a shade of difference in the conditions, and with our superior knowledge of the qualifications of the various men engaged in this line, we might have preferred some one else to meet the phenomena which long acquaintance with the patient and his relations makes us more fit to interpret than any one else; but the man whom we introduced into the household takes not only precedence, but absolute *control* of the situation; we have not even an opportunity for remonstrance, much less of interference.

Again, one of our constituents, of advanced years, though in admirable health and gaining weight, goes to an aurist to have the cerumen (if there be an accumulation), removed from his ears. The specialist goes through the routine of ear syringing, and prescribes arsenic. The general practitioner is soon called to relieve the patient of violent herpes zoster induced by arsenic—for the patient is intolérant of all drugs, as his general physician well knows.

In another instance a gentleman of rheumatic diathesis has a lump on his forehead, which his physician is treating with iodine ointment and making light of, because the patient is syphilophobic and the physician has sifted the evidence and eliminated such a possibility. The doctor, unwilling to rob him by a consultation (there being no need for one), sends him to a specialist, with a note detailing treatment and asking if any should be added. He sees no more of his patient for months, and when he reports, is told that the surgeon diagnosed syphilis and prescribed iodide of potassium.

A distinguished gynecologist and obstetrician will attend a male hotel guest seized with cholera morbus, when general physicians are within easy call. The same gentleman will consult in a fatal case of septic dysentery, and perhaps next day perform abdominal section.

An eye case will be placed under the charge of a careless (or at least not well-selected) specialist, by the patient's friends, and loss of sight be the actual and logical result.

An aged person suffering from cophosis will be sent by some kind patron to an aurist, and encouraged by him to pay regular visits for a protracted period, when the general attendant, knowing the history of the case, could have predicted the result (negative except to the aurist), and have saved the patron needless and wasteful expenditure.

These illustrations could be multiplied almost indefinitely, but enough have been given to "point the moral." "My brethren, these things ought not so to be." We have a duty to the general public, a duty to ourselves, and an obligation also to the true and regular specialists, of whom we all know a few. These cases which I have cited are not fancy sketches, but (*mutatis mutandis*) living pictures actually observed day by day. They are not complimentary to our great profession; but they are facts, stubborn and hard to correct, but which we are bound to face and endeavor to correct; and moreover, they can be corrected, if we are true to ourselves and to the much-vaunted ethics of our Code. Indeed, it is through the Code of Ethics of the AMERICAN MEDICAL ASSOCIATION that they must be fought. There may be difference of opinion, and profitable discussion, as to the manner of correction, but our duty is paramount, if the prestige of regular medicine is to be preserved. I venture two suggestions:

1. Instead of prohibiting the specialist from so proclaiming himself, on his sign (as is now the rule of his special association), he should be *made* to do so. Then we could mark his errors, and deal with them ethically.

2. Our Code might be amended, so that a patient, presenting himself in a physician's office for the first time, should be asked who his regular attendant was, and after receiving treatment, should be referred to his attendant, in order that the treatment given might be approved and supplemented, or condemned; for, as

we have said before, by reason of superior knowledge concerning the individual's constitution, antecedents and environment, he is the best qualified judge of the situation. It is manifest that one division of our science should not be bound by the law of Hippocrates, if the rest are to be free lances—*ce va sans dire*.

But let us now consider certain aspects of the relations of general medicine and bacteriology, as it presents itself up to date—a science of inestimable value today, and of incalculable potentialities in the future. It is, however, greatly to be feared lest in some of its careless and unintelligent applications, it do more harm than good. In no direction is its inexact employment more disastrous, according to our observation, than in the diagnosis of diphtheria.

Through its instrumentality, the National Capital, at the very opening of the present Congressional year, was accredited with an "epidemic of diphtheria." From our own experience and practice, which is largely amongst children (though we repudiate any claim to reputation as a specialist in this line), the writer deliberately asserts that, for seventeen years, he believes the community has not been so free from diphtheria. This observation coincides with opinions expressed to him by many of the leading members of the profession here. The writer, besides his private practice, is and has for fifteen years been the senior physician of one of the largest orphan asylums of the city, whose children have *entrée* to the public schools, and whose inmates' friends visit them weekly. Within two years and a half, we have seen *one* case of diphtheria, and no case of fatal sore throat nor fatal laryngitis in our whole practice; and yet this has been heralded to the world as a plague spot. We have seen angina membranacea, follicular tonsillitis, herpetic sore throat, aphthous sore throat, etc., but these have all yielded promptly to antiseptic and aseptic measures with isolation and ventilation, coupled with appropriate general and local treatment, including stimulation and proper diet. We believe the disease has in no case been transferred from one member of the family to another. In all, there has been spontaneous tendency to recovery and actual recovery.

ON TRACHEAL TUGGING IN CONDITIONS OTHER THAN ANEURYSM OF THE TRANSVERSE PORTION OF THE ARCH OF THE AORTA.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, June 1-4, 1897.

BY HARRY TOULMIN, M.D.

INSTRUCTOR IN PHYSICAL DIAGNOSIS, UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA.

While serving as medical interne at the Johns Hopkins Hospital under Dr. Osler, some years ago, I became impressed by the frequency with which cases of aneurysm of the transverse portion of the arch of the aorta were accompanied by tracheal tugging. Desiring to know if this phenomenon might occur in other diseases or in health, I recently began to collect statistics, and desire to make today what, on account of the small number thus far examined, can only be called a preliminary report.

I found that results of work on similar lines had been published by Grimsdale¹ and by Ewart,² and a

¹ Practitioner, February, 1892.

² British Medical Journal, March 19, 1892.

short time ago F. A. Packard,³ in an article on "The Signs and Symptoms of Aortic Aneurysm," makes mention of some observations of his own in this connection.

In making up my tables the following points were ascertained in addition to tests for tugging: Nationality, age, sex, social condition, occupation, disease for which under treatment, condition of heart, shape of chest, and pulse rate. As nationality, social condition and pulse had no bearing in the cases I examined they will not receive further attention. So few females were examined that I shall omit such cases from the present paper.

In testing for tugging, both Oliver's and Ewart's methods were used during inspiration, expiration and while the breath was held. (I may say here that Ewart's method is the more delicate and less unpleasant to the patient.)

Positive results were classified under four groups: *A*, very slight up-and-down movement; *B*, slight up-and-down movement; *C*, distinct tugging; *D*, very marked tugging. The distinction is drawn between an up-and-down movement, because, as Dr. Packard remarks in the article referred to, the word tug is very aptly used and means more than mere movement. Ross (?) probably selected the word to convey a distinct pulling or tugging sensation.

In all, seventy-five cases were examined. Their ages ranged from 20 to 87 years. Nearly every occupation was represented, but by far the greater number were from the laboring classes. The diseases for which the individuals were being treated were as follows: Adherent pleura and pericardium, 1; aneurysm, abdominal, 1; aneurysm, thoracic, ascending aorta, 4; arterio-sclerosis, general, 3; asthma, 1; bronchitis, acute, 1, chronic, 6; cancer of liver, 1; cardiac valvular disease, 7; dilatation of aorta, 1; dyspepsia, 2; emphysema, 2; gallstones, 1; hemorrhoids, 1; hernia, 2; Hodgkin's disease, 1; hydro-pulmo-thorax, 1; laryngitis, chronic, 1; myocarditis, 1; nephritis, acute, 1, chronic, 9; no disease, 7; opium habit, 1; phthisis, 12; pleurisy, dry, 1, with effusion, 1; pneumonia, 1; rheumatism, muscular, 1, articular, 10; typhoid fever, 2.

In forty-four cases no up-and-down movement of any degree was detected. Nineteen cases belonged to group *A*. The ages ranged from 20 to 72 with an average of 41. With the exception of a clerk the occupations all required hard work. Two of the individuals were supposed to be well, 3 had cardiac valvular disease, 2 chronic nephritis, 1 right-sided pulmo-thorax, 2 phthisis, 5 chronic articular rheumatism, 1 pleurisy with effusion, 1 hernia, 1 dyspepsia, 1 aneurysm of the ascending aorta. The heart conditions were as follow: Aortic stenosis and insufficiency with mitral insufficiency and hypertrophy 1 case, aortic insufficiency 1, mitral insufficiency with hypertrophy 2, simple hypertrophy 4, two very marked; normal heart 11. There were 3 particularly large chests, 9 normal in size and shape, 1 with chicken breast, 4 long and narrow, 2 abnormally enlarged by effusion.

Group *B* contained five cases whose ages were 30, 40, 43, 62 and 65. Two were laborers, one a peddler, one a tailor and one a stevedore. There was one case each of Hodgkin's disease, hernia, chronic bronchitis, cardiac valvular disease and cardiac valvular disease with adherent pleura and pericardium. The heart

was normal in 3 cases, while mitral insufficiency with hypertrophy was present in the other two. In 4 cases the chest was large and well developed, in one long and narrow.

Group *C*.—Two cases belonged to this group; one was a laborer aged 42 with extensive phthisis, the other a saw-filer with phthisis and aneurysm of the ascending aorta. The heart was perfectly normal in the former, hypertrophied in the latter. In one the chest was long and narrow, in the other well formed, not phthisical.

Group *D*.—In five cases a very marked tug was obtained.

The following condensed table will show the different features:

Case No.	Age.	Occupation.	Disease.	Heart.	Chest.
8	82	Laborer.	Emphysema with old left-sided pleurisy.	Hypertrophied	Barrel-typical.
9	65	Laborer.	General arterio-sclerosis.	Hypertrophied supposed to have dilated aorta.	Normal.
59	50	Laborer.	Chronic articular rheumatism.	Normal.	Large.
62	60	Nurse.	Chronic nephritis.	Aortic-systolic murmur.	Normal.
65	51	Carpenter.	Aortic insufficiency, with dilatation of aorta.	Aortic insufficiency with hypertrophy.	Large.

The question of respiration in relation to tracheal tugging is quite an important one. In seventeen of the twenty-four cases belonging to Groups *A* and *B* the up and down movement was observed during *inspiration only*, while in five of the seven cases of Groups *C* and *D*, the tugging was not increased at all by inspiration, and there was only a very slight change in the other two. In other words, a simple up-and-down movement, if present is usually not altered by respiration. It is such tugging that we feel in cases of aneurysm of the transverse arch and not the simple, changeable up-and-down movement. If, then, we eliminate all the cases presenting this latter condition, we have remaining only seven cases out of seventy-five, a little over 9 per cent., in which tracheal tugging was present.

Studying these seven cases in greater detail, it will be observed that the heart was normal in only two of them; it was hypertrophied in four, with aortic insufficiency in one and possibly aortic stenosis in another. In the case of aneurysm of the ascending aorta, there was probably involvement of the transverse aorta, an interesting condition that Ewart suggested in his paper. We would expect to find tugging in both instances of dilatation of the aorta. It is a question whether we can account for its presence in Case 8 by the pulmonary condition. It is possible that adhesions might explain it. There seems to be no such reasoning to apply to the remaining two cases.

If satisfactory conclusions could be drawn from such a small number of cases we would say:

1. An up-and-down movement of the trachea occurs in many healthy individuals and accompanies other diseases than aneurysm.

2. In such cases the movement is much affected by respiration, in the majority of cases being present during inspiration only.

3. In a very small percentage of cases distinct tugging of the trachea may be present without involvement of the aorta either by aneurysm or simple dilatation.

ON THE BACTERIOLOGIC EXAMINATION OF THE STOOLS IN TYPHOID FEVER, AND ITS VALUE IN DIAGNOSIS.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY MARK W. RICHARDSON, M.D.

BOSTON, MASS.

[From the Laboratory of the Massachusetts General Hospital, Boston.]

Ever since Gaffky, in 1894, succeeded in cultivating upon artificial media, the bacillus discovered in typhoidal tissues by Eberth, many efforts have been made by bacteriologists and clinicians to isolate the organism from the fluids and excretions of the living body, notably the blood, urine and feces. Up to 1891 the investigations of a Pfeiffer; Simmonds, and especially Karlinski, had shown the task to be apparently a very simple one. Unfortunately, however, the value of the results of these observers is open to very serious doubts; for the methods employed in proving the cultures thus obtained, were, according to our present standards, entirely insufficient, and it is more than probable that a great many of the bacilli thus isolated were not typhoid bacilli at all, but others of the same group, most probably varieties of the colon bacillus.

In investigating stools the greatest difficulties have arisen from the other bacteria present. These have been a disturbing element, first, because their colonies often markedly resembled those of typhoid, and secondly, because, in their growth, they often completely liquefied gelatin before the typhoid organisms had a chance to grow. This latter difficulty could be obviated by the use of agar-agar, but even then the colonies lacked a characteristic appearance, and many had to be picked up and verified in the hope that one or more would prove to be typhoid.

To overcome this objection, Chantemesse and Widal, in 1887, added to ordinary gelatin 25 per cent. carbolic acid, and claimed that, by this means, the growth of all organisms except typhoid, was inhibited.

Holz, in 1890, could not confirm these results. He devised a medium which combined the advantages of potato and gelatin. This medium was naturally acid in reaction, and this acidity prevented the growth of a number of bacteria. Moreover this inhibitory power was still further increased by the addition of .03 per cent of carbolic acid. Upon this medium both colon and typhoid bacilli grew, but the colonies were said to be easily distinguished.

In 1895 the subject was again taken up, and this time by Elsner. Elsner considered the potato-gelatin of Holz the best medium devised up to that time. The appearance of the typhoid colonies, however, was not, in his opinion, sufficiently distinctive, especially when the carbolic acid was added. Elsner made a long search for a substitute for carbolic acid, and finally hit upon the iodid of potash in the strength of 1 per cent. The formula for this gelatin was as follows: An extract of potato ($\frac{1}{2}$ kg. to a liter of water), was boiled with 10 per cent. of gelatin. The medium was then given such an acidity that 10 c.c. was neutralized by from 2.5 to 3 c.c. of a deci-normal soda solution. Then, just before using, 1 per cent. of potassium iodid was added. Upon this gelatin, typhoid and colon bacilli were practically the only bacteria which grow. Occasionally proteus and other liquefying forms were seen, but they rarely gave any trouble. After twenty-four hours at the room temperature, only colon colonies were to be seen, and these, viewed under a low power

of the microscope, were round, coarsely granular, brownish-gray, and sharply defined. The typhoid colonies rarely appeared before the end of forty-eight hours, and these were small, pale, less sharply defined, and with very fine granulation. Elsner experimented with thirty typhoid and colon cultures, and never failed to differentiate them easily. He also examined the stools in seventeen typhoid cases with fifteen positive results.

Since the appearance of Elsner's publication the method has been practiced by a number of other observers, with very considerable success. It has not been at all uncommon to find the typhoid organisms as early as the seventh day of the disease, and, though the bacilli disappear rapidly from the stools with the beginning of convalescence, they have been found as late as the thirty-sixth and forty-first day after the temperature had reached the normal point. Indeed, the method has been more successful, for Remlinger and Schneider claim to have found typhoid bacilli in the stools of five non-typhoidal patients, a leucemia with fever, a case of acute miliary tuberculosis, a case of acute dysentery, and two chronic malarias. Further, these observers had similar success with samples of water and dust taken indiscriminately from the surrounding country. The results are most remarkable, but I think they must be accepted with great reserve until they are confirmed by other observers.

My own investigations upon this subject were undertaken primarily with the purpose of testing the Elsner method as such; later my object was to compare it with the newly discovered serum-reaction, to see whether there might not be cases, where, with a negative serum test, the bacilli were to be found in the stools; finally, I decided to determine the accuracy of the observations of Remlinger and Schneider as to the ubiquity of the typhoid bacillus. Before enumerating my results I wish to state that the latter part of my experiments were carried out upon a new agar medium devised by Capaldi. This is made up as follows:

Aq. dest	1000.0
Witte's peptone	20.0
Gelatin	10.0
Mannit (or grape sugar)	10.0
NaCl	5.0
Chlorid of potash	5.0

Boil and filter. Add 2 per cent. of agar-agar, and make alkaline with 10 c.c. of normal soda solution. Boil, filter and sterilize. In eighteen hours the typhoid colonies are seen as small, round, colorless and transparent in contrast to the larger, more opaque, brownish, colon colonies. This medium is far easier to make up than the gelatin, and my results with it have been very satisfactory. Its advantages are:

1. No chance for liquefaction.
2. The typhoid colonies are much larger, and thus more easy to pick up. With the gelatin the colonies were often so small that it was impossible to make inoculations from them.
3. Colonies are ready for examination in eighteen hours rather than in forty-eight or seventy-two.

The only difference in procedure is, that with the agar, the plates are first poured and hardened. The suspected material is then spread upon their surface, whereas with the gelatin, the material is thoroughly mixed with the medium while the latter is melted. Although the two methods were used in my investigations, the results, for the sake of simplicity, will be considered together.

In all there were examined 109 stools in forty-nine different individuals. Of these forty-nine cases, thirteen were typical typhoids in the febrile stage, and in these thirteen cases fifty-five stools were investigated. The isolation of the typhoid bacillus was accomplished in ten out of the thirteen cases: in nineteen out of fifty-five stools. In one case the bacilli were found on what was said to be the fifth day of the disease, but the history was somewhat indefinite, and disease was probably further advanced. Two cases were positive on the eleventh day. In the other seven cases the typhoid organisms were first discovered on the twelfth, twentieth, twenty-third, twenty-seventh, twenty-eighth, twenty-ninth and thirty-sixth day respectively. Seven out of ten cases were positive on the first examination. In these cases, therefore, it is impossible to say how much sooner the organisms might have been found had the stools been received earlier. In the three other positive febrile cases the bacilli were isolated only after several examinations, on the twentieth, twenty-seventh and twenty-eighth days.

In testing the typhoid cultures obtained from these positive cases the bacilli were examined in: 1. The hanging drop—size, shape and motility. 2. Gelatin slant and stab cultures. 3. Litmus milk. 4. Sugar agar. 5. Peptone solution (for indol). 6. Potato. 7. Bouillon. 8. Two test solutions of Capaldi and Proskauer. 9. Reaction to typhoid serum.

Of the three negative febrile cases, one was unsatisfactory because the stools could be examined but once, and that on the sixth day of the disease: the other two were typical typhoids, and one went through a relapse as well. Although six stools in one case and eight in the other were searched and that, too, by both methods, Elsner and Capaldi, I was never able to isolate the typhoid bacillus. All these thirteen cases gave well marked serum reactions at least two days before the typhoid organisms could be recovered from the stools. We see therefore, that, as far as this series of cases goes, the serum reaction proved itself far superior as a diagnostic aid. There are cases reported, however, such as those of Biggs and Park, Breuer, Achard, Cahill and Thoinot, where the serum reaction did not appear until late in the disease, till convalescence began or perhaps till the occurrence of a relapse. In such cases it would seem as if a bacteriologic examination of the stools would be of great value, for the appearance of bacilli in the dejections of the second week is a quite common occurrence. In fact Kolle has reported two cases in point, where the serum reaction was obtained first on the sixteenth and seventeenth days, but where the bacilli were cultivated from the stools on the tenth and eleventh days.

To continue with my own cases—two stools in two cases of doubtful typhoid were examined with negative result. These two cases never presented any serum reaction, and were practically convalescent when investigated. Twenty-three stools of thirteen convalescent typhoids were examined with but one positive result, and that on the first day after the fever had disappeared. Seventeen stools of seventeen non-typhoidal cases were all negative. Included in this series were cases of grippe, pneumonia, sepsis, meningitis, otitis media, endocarditis, gonorrhoeal rheumatism and neurasthenia. Furthermore, the intestinal contents of twelve individuals were secured at autopsy and examined, this series of observations being undertaken in order that, in case of a positive result, there might be no doubt as to the diagnosis. The patho-

logic examination in these cases showed them to be absolutely non-typhoidal in character, and the bacteriologic cultivations never revealed any typhoid bacilli.

From the foregoing, it will be seen that the dejections of twenty-nine non-typhoidal individuals showed no typhoid bacilli. Moreover, when we add forty-seven similar stools examined by Pollac, Chantemesse and Courmont, we have a total of seventy-six with not a single positive result. This experience is, certainly, very different from that of Remlinger and Schneider, who found the specific bacilli in 50 per cent. of the non-typhoidal stools investigated. The only case supporting Remlinger and Schneider which I could find, was one referred to by Chantemesse as occurring in a person whose occupation was that of caring for typhoid patients.

Conclusions: 1. The isolation of typhoid bacilli from the dejections of persons sick with typhoid fever is, in the great majority of cases, a practicable procedure.

2. With the appearance of convalescence, the organisms disappear rapidly from the stools. They persist, however, for several weeks: this is important as regards disinfection.

3. The value of the serum test is, in most instances, greater by reason of its simplicity and its earlier appearance. In those cases, however, where the specific blood changes necessary for the serum reaction do not appear till late in the disease, till convalescence begins, or till the occurrence of a relapse, the bacteriologic examination of the stools would be of great value.

4. The results of Remlinger and Schneider, who declare the typhoid bacillus to be a ubiquitous organism, could not be confirmed by the writer.

CLINICAL REPORT ON SERUM DIAGNOSIS IN TYPHOID FEVER.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association held at Philadelphia, June 1-4, 1897.

BY E. BATES BLOCK, M.D.

ASSISTANT RESIDENT PHYSICIAN JOHNS HOPKINS HOSPITAL, BALTIMORE, MD.

The work upon serum diagnosis in typhoid fever, which I shall report, was begun with Dr. Camac in October 1896, at a time when most of the cases in the Hospital were either far advanced in the disease or convalescent, so that my first experience was with cases in which the diagnosis had been previously definitely determined. In some of these cases the blood was given to me for examination without any knowledge on my part of the clinical diagnosis, while in the majority of the cases I was thoroughly familiar with the clinical course of the disease before the tests were made. I have since had occasion to test many cases in which the diagnosis was uncertain. I thought it best to omit in this report the examinations of specimens sent me from cases outside of the hospital, as I can not in every case be sure of the clinical diagnosis. Thus, there are included in this report, only the cases which were in Prof. Osler's wards in the Johns Hopkins Hospital, and of which we have careful clinical records from the date of admission well into the period of convalescence. It is believed that in this way the sources of error were reduced to a minimum.

In making the test with the fresh blood serum, the method suggested by Grunbaum,¹ with slight modifications, was fol-

lowed. The blood was removed from a vein of the forearm with a hypodermic syringe and placed in a Nuttall bulb, on ice, until the serum had separated from the clot. A portion was then sucked up to the first mark on a graduated tube which has another mark corresponding to sixteen times the volume indicated by the first mark. Bouillon was then sucked up with the serum until the second mark was reached. The fluid was then blown out into a watch glass, thoroughly mixed, and again sucked up, the process being repeated several times to insure thorough mixing of the bouillon and serum. The emulsion of typhoid bacilli is prepared by taking a platinum loopful of a culture grown on slightly alkaline agar, then carefully rubbing it up with a drop of the bouillon against the side of a test tube containing one c.c. of bouillon, and subsequently mixing it with the whole amount. A drop of the serum bouillon mixture and a drop of the emulsion of the typhoid bacilli are then thoroughly mixed on a cover-slip and examined at once as a hanging drop.

Of the twenty-two specimens of typhoid blood serum examined by this method, eighteen gave a reaction which was unmistakable. Of the three cases which gave only a slight reaction all except one subsequently gave a reaction by the dry method, which was quite sufficiently marked for diagnostic purposes. In the remaining exceptional case there was total absence of agglutination, when tested by the dry method, nine days before the second examination. As the latter was positive in its result, it may be suggested that, although the reaction was hardly more distinct than is seen at times in non-typhoid blood, its absence at one period and presence at a later one may well have awakened the suspicion of typhoid fever. The tests were made upon the third and upon the eleventh days of the relapse, which occurred twenty-three days after the end of the first attack. During this interval the agglutinating properties may well have disappeared entirely from the blood.

In many of these cases the macroscopic test was used, the blood serum being diluted sixteen times before inoculation with the typhoid culture. Although it was found satisfactory in every case, from the fact that it requires more time, and greater care to prevent contamination, the microscopic test, which is equally striking, is to be preferred.

In order to test the point whether the bacteria were killed or not, cultures were taken both from the macroscopic and microscopic preparations and a growth of the typhoid bacillus invariably followed. The number of organisms inoculated was, of course, large.

In making the test with the dried blood our method does not differ essentially from that employed in other laboratories. The blood is obtained by pricking the ear, which has previously been thoroughly cleansed, and a large drop is allowed to run down a glass slide which leaves a streak composed for the most part of serum alone while the solid constituents form a clot at the bottom of the slide. The thin film of serum is then moistened with distilled water and a drop placed upon a cover-slip. This gives, invariably, a dilution of more than ten parts of water to one part of serum. It is very essential in case water be used that it be distilled, for we have found in testing non-distilled waters that most variable results are obtained with the same specimens of blood. In most of the tests, the typhoid emulsion was prepared from a slightly alkaline agar culture from twelve to twenty-four hours old, as in the serum test. An oese of this is then thoroughly mixed with a drop of the diluted serum, on the cover-slip, and examined at once as a hanging drop. A given quantity of serum seems capable of affecting only a certain number of the bacteria, so that a reaction which is very unsatisfactory when a large number of organisms are used, may become quite marked

when the number is reduced. Conversely, the clumping is unsatisfactory if too small a number of organisms be used.

By the dried blood method, specimens from thirty-nine cases of typhoid fever were tested, and, in these, eighty-five examinations were made. In thirty-six cases the reaction at some period of the disease was quite sufficient for diagnosis, while in three the reaction remained doubtful. One of these cases was considered under the discussion of the serum method. The two other cases were quite atypical and there is a possibility of their not having been typhoid fever; one of them was tested on the fourteenth day of the disease, and the other one on the twenty-second and twenty-fourth days. Of the eighty-five examinations made by this method, seventy-two were sufficiently marked for diagnosis, while thirteen were not. The latter are, however, readily accounted for by the fact that the tests were made either near the beginning or at end of the attack, in every instance excepting the two above mentioned as being atypical. The thirteen examinations were made in seven cases, from one to four examinations being made in each case. In only three of the specimens was the reaction entirely absent either at a very early or very late date. In the remaining specimens a slight reaction was observed, which was not, however, considered sufficient to establish the diagnosis.

In the cases in which both the serum and dry methods were tested at the same time the difference was found to be very slight. By both methods, considered together, a hundred and seven tests were made in forty-six cases of typhoid fever. The percentage of failures in these cases was 6.5, while the failures in the specimens amounted to 15.88, the latter percentage being partly accounted for by the early or late date at which the specimens were taken. The earliest date at which we have obtained the reaction is the sixth day of the disease.

If we make allowances for the slight variations in the reactions due to the differences of dilution and time, we may say that the reaction is found to increase gradually as the disease advances, and to decline with the defervescence or during convalescence.

In nearly all of these cases the preparations were watched for thirty minutes and then examined at short intervals for a few hours, and again on the following few days. I omitted to note separately the motility in each case, but it was always taken into consideration in estimating the reaction as "marked" or "partial." Where the term "slight" is used (see table) the reaction as compared with specimens of non-typhoid blood that gave a similar reaction, should be considered insufficient for diagnostic purposes; however, it was always greater than that found in the majority of specimens of normal blood. In nearly every case control preparations were used, the importance of which precaution can not be emphasized too strongly. These consisted of a hanging drop from the cultures employed, without the addition of serum, and with the addition of normal serum. This is especially demanded in every case in which the least doubt exists.

In all of the cases tabulated the reaction of the culture medium used was slightly alkaline. In a number of cases comparative tests were made, using strongly acid, neutral and alkaline bouillon. The acid culture did not show a precipitate of dead bacteria, or preëxisting clumps as often as the alkaline culture,

Case No.	Temp.	Severity.	Day of Disease.	Motility.	Clumping.	Time.	Method.	Remarks.

and the bacteria seemed more motile and the clumping more rapid in the former.

We have found the test valuable in many cases which were not typhoid fever but in which the early symptoms left us in doubt. When in these cases the reaction is slight, it remains for the comparison of subsequent specimens to render a decision definite, while the specimens which give no evidence of the phenomena, after a careful examination as late as the tenth day of the disease, may, in our experience, with reasonable certainty, be considered as not being typhoid fever.

Especial interest attaches to tuberculosis, which sometimes leaves the physician in doubt as to the true diagnosis. In this disease we have found the reaction of value, in excluding at an earlier date than it might otherwise have been possible, cases of tuberculous meningitis, tuberculous peritonitis, and even pulmonary phthisis in which the physical examination revealed nothing in the lungs. Another group of cases, in which it is often of value, is malarial fever, and short febrile diseases which often simulate more or less closely the early stages of typhoid fever.

Among the results which I have found confusing are the presence of the reaction in one case of pernicious comatose malaria, one case of diabetic coma (both tested by the serum method with a dilution of sixteen parts of bouillon), and one case which was probably scarlet fever, in which the patient was also comatose (tested by the dry method). It is a rather singular fact that these three very diverse diseases gave the reaction when in a comatose condition, while repeated examinations failed to reveal it in a large number of other cases of malaria, and in several other cases of diabetes, and of scarlet fever.

In the course of my studies, I have employed cultures of the typhoid bacillus obtained from three several sources, and have noted differences in the reaction obtained with active blood in the different cultures used in parallel tests. One of them even occasionally failed to react at all with specimens of blood that gave a marked reaction with another culture. The same result was obtained by Achard and Bensaude, and Widal and Sicard,² although they did not believe that the difference was constant. The time which should be allowed for the reaction will depend upon the degree of dilution. In a dilution of one part of serum to sixteen parts of bouillon thirty minutes seems quite sufficient, while, as Professor Welch remarked, if the dilution of one to fifty be adopted, two hours should be allowed.

The following cases are interesting as illustrations of the value of the test in the diseases mentioned above.

Case 1.—D. B. was admitted with delirium, and no history was obtained. The blood did not give the agglutination reaction, and there was a leucocytosis of 23,000. On the next day the following history was obtained from the doctor who had previously attended her. She had complained for twelve days of severe headache, slight stiffness of the neck and nervousness. The temperature ranged between 100 and 102.5. The patient had epistaxis twice, pain in the abdomen, and twenty to thirty spots on the abdomen which were identical in appearance to rose spots: she had been delirious since the day before admission. The physical examination revealed very little. The subsequent development of inequality of the pupils, taches cérébrales, the rigidity of the arms and neck, the presence of phosphates and sugar in the urine led to a diagnosis of tuberculous meningitis, which was confirmed by the postmortem examination.

Case 2.—W. W. was admitted for pleurisy with effusion. Eight days after admission the temperature rose, the highest

point reached, being 104. The fever gradually rose and slowly declined, reaching normal on the eleventh day. The clinical symptoms as well as the Widal reaction were very suggestive of typhoid fever. The boy had epistaxis, a palpable spleen, malaise, anorexia, a coated tongue; the pulse was dicrotic, and his urine gave the diazo reaction. This case serves as a type of several similar cases in which the existing complications might be sufficient to account for most of the symptoms present, but the distinct reaction of the blood was serviceable in establishing the diagnosis.

Case 3.—G. K., a boy with cystitis was admitted complaining of headache, weakness, abdominal pain, epistaxis, slight diarrhea, anorexia, vomiting, fever, and continuous chilly sensations. The diagnosis of typhoid fever was established by the agglutination test, and the subsequent course of the disease verified this diagnosis. It was a mild attack and the temperature reached normal on the tenth day.

Case 4.—J. L. had typhoid fever in November, 1895, and returned in November, 1896, with headache, weakness, anorexia, and had had two chills before admission. His urine gave the diazo reaction. The agglutination test was marked and of distinct value in confirming the clinical diagnosis. The question here arose as to whether the reaction could have been due to his attack of the year before, and was answered by the return of the patient three months later complaining of having had a chill and fever, headache, and pain in the back and limbs. The urine gave the tests for bile, but not the diazo reaction. The continued high temperature for a few days gave rise to suspicions of a third attack of typhoid fever, as well as cholecystitis, but the former was excluded by the entire absence of the agglutinative reaction.

Case 5.—S. J. was admitted to the hospital for a streptococcus infection of the arm. Six weeks after admission the patient had a slight chill and the temperature rose to 103. There was slight headache, the tongue was coated, anorexia, diarrhea lasting three weeks, and the spleen was enlarged. The temperature for over three weeks ranged between 102 and 104. The examination of the blood gave very marked clumping and total loss of motility. This case is interesting from the fact that the general condition of the patient was not at all suggestive of typhoid fever, and despite the symptoms enumerated above, the diagnosis of typhoid fever could not have been satisfactorily made without the agglutination test. Cultures from the stool and blood did not show the typhoid bacillus, while Dr. Walker obtained the streptococcus repeatedly from the arm lesions.

Case 6.—E. R. was admitted complaining of headache and pains over entire body. There was nothing of importance in his history, but the loss of appetite, coated tongue, palpable spleen, dicrotic pulse, diazo reaction in the urine, prolonged high temperature for six days before the test was applied, and the absence of malarial parasites in a number of blood examinations led to the diagnosis of typhoid fever. The Widal reaction was tested on the eighth day of illness and was totally absent. The subsequent demonstration of estivo-autumnal malarial parasites in the peripheral blood and spleen proved the test in this case a most important aid in excluding typhoid fever.

THE SERUM DIAGNOSIS OF TYPHOID FEVER.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, at Philadelphia, Pa., June 1-4, 1897.

BY A. R. GUERARD, M.D.
NEW YORK, N. Y.

The following is a summary of the methods employed and the results obtained in the use of this test in the Health Department of New York city up to May 1, 1897, including a collective investigation of the results obtained by the principal observers up to the present time, taken from the published reports on the subject.

It is now nearly a year since Widal published his first communication on the serum diagnosis of typhoid fever. Charrin and Roger, Gruber, Pfeiffer and Kolle, and others, had previously observed the phenomena described by Widal, viz.: the immobilization and

agglutination of the respective bacilli in the blood serum of animals artificially immunized against infection from the bacillus pyocyaneus, the cholera vibrio and Eberth's bacillus, and Pfeiffer had suggested that a differential diagnosis of typhoid fever might be made by means of the serum of animals immunized against typhoid infection. But to Widal unquestionably belongs the credit of having brought the subject clearly and prominently before the profession, and of having on an extensive scale made the first application of the serum test for the diagnosis of typhoid fever. An additional impetus to the work in this newly discovered field of bacteriologic investigation was given by Wyatt Johnston of Montreal, who introduced the use of this method of diagnosis in municipal laboratories, suggesting that dried blood should be employed instead of fluid serum. Since that time the serum test for the diagnosis of typhoid fever, owing to its scientific interest and practical importance, has attracted the attention of bacteriologists and physicians in all parts of the world; and so rapidly has the interest in the subject increased, that we can today hardly take up any well-known medical journal, foreign or domestic, without finding some reference to Widal's test.

In September, 1896, investigations on this subject were begun in the laboratories of the Health Department of New York city, and in the latter part of October, the Board of Health issued an announcement to the physicians of the city, describing the Widal serum test and requesting that physicians having cases which presented symptoms suggestive of typhoid fever should send specimens of the blood daily, or every other day, until the nature of the disease became clinically established. Directions were given for preparing the specimens of blood, and arrangements were made so that physicians could obtain the glass slides for collecting the blood, with circulars of information and blanks to be filled out with histories of the cases, from the various health department depôts throughout the city. The facilities thus offered to the physicians for determining the value of the serum test for the diagnosis of typhoid fever, were quite largely utilized, and in March, 1897, the Health Department published a report prepared by Dr. Hermann M. Biggs, pathologist and director of the bacteriologic laboratories, and Dr. Wm. H. Park, assistant director of the hospital laboratory, of the methods followed and the results obtained up to January, 1897.

During the last four months comparatively little experimental work on the subject has been carried on in these laboratories; but in the results obtained in the daily routine work of the laboratory, no reason thus far has been found to change the methods which were originally adopted, nor the conclusions which were reached when the first report was published.

Methods employed for making the test.—Various methods have been followed by different observers in making the serum test. In Germany to a large extent the macroscopic or test-tube method has been employed, considerable quantities of serum being mixed with a young culture of the typhoid bacillus or with a sterile broth, which is then inoculated; it being claimed by some that many reactions which are missed under the microscope are distinctly apparent in the macroscopic test. In France, on the contrary, the microscopic or hanging drop method seems as a rule to have been preferred. (Some observers use both methods. When large quantities of serum are required,

as for the test-tube method, it is withdrawn by venesection of a vein at the elbow, or by deep puncture of the tip of the finger; smaller quantities of serum, as for the hanging-drop method, are easily procured by pricking the tip of the finger or ear with a needle and allowing the blood to coagulate.) The blood for the test has been used in three ways: fluid serum, and fluid and dried blood. The most commonly used is the fluid serum, separated from the blood by coagulation or by means of the centrifuge, and collected in narrow glass tubes, capillary tubes or graduated pipettes. The dried blood has been employed almost exclusively in this country and in Canada (as suggested by Wyatt Johnston of Montreal), being collected on glass slides or paper. The fluid serum is now preferably used in the health department laboratories, and is derived from blisters produced by means of cantharides plasters.

In a large majority of the tests made in our laboratories, however, the dried blood is still used; but whenever it can be obtained, the serum from coagulated blood or fly blisters is preferred. Ordinarily the reaction is watched under the microscope in the hanging drop, this method having been found to give the most satisfactory results. The macroscopic method has been seldom employed, and then only for the purpose of comparing the results with the routine method.

For the dried blood test the blood is obtained by pricking the tip of the finger or the ear, after first thoroughly cleansing and sterilizing the part, and two or three large drops are collected on a glass slide and allowed to dry. In preparing the specimen for examination the dried blood is brought into solution by mixing it with about five times the quantity of water. Then a drop of this decidedly reddish mixture is placed on a cover-glass, and to it is added a drop of a fifteen to twenty-four hour bouillon culture of the typhoid bacillus. The two drops after being mixed should have, according to Dr. Park, a faint reddish tinge, the color being the guide to the amount of dilution necessary. The cover-glass with the mixture is then inverted over a hollow slide, which is greased around the edges to make it air-tight, and the hanging drop examined under the microscope, preferably by gaslight, with a high power dry lens.

The fluid serum is obtained in two ways: 1. Directly from the blood, by pricking the tip of the finger or the ear with a lancet-shaped needle, the blood as it issues being allowed to fill, by gravity, a capillary tube having a central bulb. The ends of the tube are then sealed by heat or wax, and as the blood clots, a few drops of serum separate. This method of obtaining blood serum has been found to possess the advantage of rapidity, but also to have this disadvantage, namely, that the serum thus separated is apt to contain more or less blood cells, which somewhat obscure the field when the liquid serum is immediately mixed with the culture, and which cause clumps of detritus if the serum is allowed to dry. The same thing occurs with dried blood even to a greater extent. 2. The serum is obtained from a blister as follows: A piece of cantharides plaster the size of a five cent piece is applied to the skin at some spot on the chest or abdomen. A blister forms in from eight to eighteen hours. This should be protected from injury. The serum from the blister is collected in a capillary tube, the ends of which are sealed. Several drops of the serum can be easily obtained from a blister so small that it is prac-

tically painless and harmless. The serum thus obtained is clear, entirely free from blood cells and admirably suited for the test. The results obtained with serum from blisters have been entirely satisfactory; nor does this method of procuring the serum cause any discomfort to the patient. Though Widal was the first to observe that the serum from blisters gave the same reaction as blood serum, no one but ourselves, so far as is known, has used this mode of obtaining serum for the test in routine work.

There are several advantages and disadvantages in the employment of dried blood or serum for the serum test. Dried blood is quickly and easily obtained and does not deteriorate or become contaminated. It is readily transportable, and seems to be of nearly equal strength with the fluid serum in its agglutinating properties. The great objection to its use, however, is that there is no way of determining the amount of dilution except by the color, and this can be only roughly and approximately done. Unless diluted with a sufficient quantity of water, at least five times its bulk, it is too viscid to be used. Serum, on the contrary, can be used in any dilution desired. By making use of a graduated capillary pipette, this can be accurately measured. The only disadvantages in the use of fluid serum are the slight difficulty in collecting and transporting it, and the delay in obtaining it when a blister is employed (eight to eighteen hours). But these trivial objections are more than compensated by the greater accuracy of the results obtained.

The typhoid cultures used for the serum test.—The larger number of the tests made in the laboratories have been made with an eighteen to twenty-four hour broth culture of a typhoid bacillus of considerable virulence obtained some time ago from Pfeiffer. Other less virulent cultures have also been employed, but though the reactions in all of them have been fair, the most characteristic reactions have been observed with the more virulent Pfeiffer culture. This fact of the distinctness of the reaction being in proportion to the virulence of the culture employed in the mixture has been observed by Kolle, Fraenkel, Grünbaum and others. In order to get a marked characteristic reaction, therefore, it is important to use for the test a culture not over twenty-four hours old in which the bacilli are not too numerous, but rather isolated and actively motile, and the degree of whose motility is known. Some observers prefer to use the water of condensation or a diluted emulsion from an agar culture; but in our experiments a bouillon culture has been found to give the best results.

The dilution employed in the test.—It has been observed that the blood serum of some healthy persons and those suffering from other diseases than typhoid fever, at times produces identically the same effect upon the typhoid bacilli as is caused by typhoid serum, viz.: immobilization, agglutination and agglomeration of the bacilli; the only difference being that in typhoid fever, as a rule, the reaction occurs in higher dilutions, that is, after the addition to the cultures of smaller quantities of serum, than in non-typhoid diseases, or when the same dilution is used it occurs more quickly and completely with the typhoid serum. The serum test is therefore quantitative, and not qualitative.

The results obtained in the laboratories show that in cases of other diseases than typhoid fever and in healthy persons, a reaction may occur in more concentrated dilutions than 1 of serum to 10 of culture,

and that even in a 1 to 10 dilution, occasionally a *delayed moderate* reaction may take place. But very rarely, except in typhoid fever, has a *complete* reaction been found to occur in a 1 to 10 dilution within *fifteen minutes*. When dried blood is used, the slight tendency of non-typhoid blood in 1 to 10 dilutions to produce agglutination is increased by the presence of the fibrinous clumps derived from the blood cells.

Some observers, however, as Gruber and his followers, Grünbaum and Durham, Kolle, Stern, Fraenkel and others, maintain that a considerable proportion of non-typhoid and normal blood serums give a characteristic "typhoid reaction" in a 1 to 10 dilution in one to two hours. Thus, out of seventy cases examined by Stern, twenty were found to give a marked reaction in a 1 to 10 dilution in one hour; five in a 1 to 20 dilution; two a very slight reaction in a dilution of 1 to 30; but none gave a reaction in a 1 to 50 dilution. It is therefore recommended by these observers that a dilution of not less than 1 to 30 and up to 1 to 50 should be used, in order to avoid all possible source of error in this direction.

But as stated before, we have seen no adequate reason to abandon the method originally adopted by us, and we still adhere to the reaction given by the 1 to 10 dilution, believing that, although rarely a non-typhoid blood will give a definite reaction in this concentration, we are able thus to include a large number of true typhoid reactions which would be excluded if a higher dilution were required.

The method of procedure now employed is as follows: The test is first made with 1 to 10 dilution of serum or blood; if complete clumping and immobilization of the bacilli occur immediately, or within fifteen minutes, it is considered satisfactory and a positive diagnosis is rendered; if not, serum obtained from a fly blister is requested and a careful determination of the rate of reaction and the dilution at which the reaction takes place, is made. If possible such examinations are made repeatedly at short intervals. A reaction occurring later than fifteen minutes or in a less dilution than 1 to 10, is never reported as positive.

The short time allowed for the reaction to take place, combined with this comparatively slight dilution, in our opinion seems to form a desirable middle ground, which includes a larger percentage of correct diagnoses than is obtained by a higher dilution. As the percentage of all positive reactions, not typhoid, excluded by the 1 to 10 dilution in fifteen minutes, is very large, and as the number of typhoid bloods or serums, which do not give a positive reaction at a much greater dilution than 1 to 10 is considerable, it has been deemed inadvisable to exclude them by adopting a higher dilution for the standard in our routine work, the number of false diagnoses thus made being very small compared with the number of true typhoid diagnoses.

We depend much upon the rapidity with which the reaction takes place, and upon the character of the reaction. The "personal equation" enters largely here into the conclusion reached in the examination, and also the peculiarities of the culture of typhoid bacillus to which the observer has become accustomed. (Such is the opinion expressed by Dr. P. H. Hiss, Assistant Bacteriologist Health Department Laboratories, New York City.)

Results of the serum test in the diagnosis of typhoid fever. Up to May 1, specimens of blood or serum, or of both blood and serum, from between

three and four hundred individuals have been subjected to the Widal test in the health department laboratories. Of these the diagnosis of typhoid fever was confirmed or excluded by the clinical course of the disease and by autopsy, in 271 cases. Of 162 of those finally believed to be typhoid fever, 118 gave a marked positive reaction and 44 gave no reaction, in a 1 to 10 dilution. Ninety-eight cases finally believed to be non-typhoid gave no reaction, and eleven cases remaining in doubt, but in which the probability of typhoid was not excluded by the clinical diagnosis, gave a partial or feeble reaction. Thus of the 271 cases of suspected typhoid examined, 129 gave a positive, and 142 a negative reaction—47.6 per cent. positive and 52.4 per cent. negative: 72.8 per cent. of the cases finally believed to be typhoid gave a marked positive reaction with the Widal test, on the first examination.

These cases were examined between the third day and the end of the fourth week of the disease. The greatest number of positive reactions were obtained during the second and third weeks. The cases which gave no reaction, though finally believed to be typhoid fever, were mostly examined early in the disease, during the first and second weeks, and it is not unlikely that in some of these cases a reaction might have appeared later, had repeated examinations been made. For example, in hospital cases in which the blood was frequently tested, a definite typhoid reaction was present in 88 per cent. of the cases at some time during the illness. As a rule the reaction, if occurring at all, appeared before the fourteenth day, but in two cases it did not appear until the middle of the fourth week.

This delayed reaction in cases of typhoid has also been observed by others. Durham reports two cases which gave no reaction up to the seventeenth and eighteenth days of the disease; Stern mentions a case in which there was no reaction until the fourteenth day; Fränkel examined eighteen convalescents from typhoid, with negative results from the third to the fourteenth week of the disease; Kolle cites two cases of typhoid, bacteriologically confirmed in whom the serum reaction was not manifest until the sixteenth and seventeenth days. One case examined in our laboratories, which showed not only the symptoms of typhoid, but from the blood of the spleen typhoid bacilli were obtained, never gave any reaction, though repeatedly examined during the course of the disease.

Widal has recently made some interesting investigations into the agglutinating power of the blood serum of typhoid fever patients during the course of the disease in cases of recurrence and during convalescence, which have an important bearing on this subject. In a communication published in *La Semaine Médicale*, February, 1897, he states that "in five out of twenty-one cases examined the agglutinating power did not exceed 1 to 100. In eight it varied between 1 to 100 and 200; in five others, between 1 to 100 and 400; in the remaining three cases the agglutinating power was very high, being 1 to 800 at the end of a severe attack which had lasted for forty-seven days. It was 1 to 1,500 the fourteenth day of the disease, in another case in which apyrexia set in on the nineteenth day. The last case is the most interesting of all. The agglomerating power reached the extraordinary figures of 1 to 11,000 and 12,000 during the first days of an attack of typhoid fever, yet the disease was only of average

severity and the hyperpyrexia subsided within eighteen days from the onset." On the other hand, Widal "met with some grave cases with only slight or medium agglomerating power. In one case, for instance, with a fatal termination, the agglomerating power was never higher than 1 to 50 and varied, toward the end, between 1 to 5 and 1 to 10."

"These figures show," says Widal, "that although a low agglomerating power is usually observed in mild cases, the gravity of typhoid fever is far from always being proportional to the agglomerating power."

"The curve of the agglomerating power during the entire course of the disease varies considerably in character in different cases. Sometimes the agglomerating power is low at the onset of the disease, rising gradually during the stationary period; this is most frequently the case. At other times this power remains the same during the entire course of the disease. Again, it may decrease during the decline, and even during the stationary period of the disease. In one case the agglomerating power was lowered toward the middle of the disease, rising during the period of decline and again decreasing when convalescence set in. In one instance it was higher at the beginning of convalescence than at the end of recrudescence, but it soon fell.

"As a rule, the agglomerating power decreases more or less rapidly during convalescence. In some cases it falls very slowly and when once reduced it may persist for months and even years; at other times the decrease is surprisingly rapid."

Widal thinks that these results show that the agglomerating reaction generally decreases in intensity at the beginning of convalescence and even during the period of the decline of the disease, a fact which in his opinion proves the truth of his previous statement as to its being mainly a reaction of the infection period.

Convalescent cases examined.—Of twelve cases (examined in our laboratories) who had recovered from typhoid fever, three gave a marked reaction in the third and fourth month after convalescence, two a moderate, and three a slight reaction; one gave a doubtful reaction after one year, one a slight reaction after five years, and two gave no reaction after three and fourteen years respectively.

Healthy persons examined.—The blood serum of over one hundred healthy individuals tested, in no instance ever gave a definite reaction in a 1 to 10 dilution.

Other diseases than typhoid fever examined.—In eighty-seven cases examinations have been made of the blood of persons who were suffering from other diseases, such as tuberculosis, rheumatism, appendicitis, malignant tumors, diphtheria, scarlet fever, measles, leprosy, meningitis, leucemia, etc. The serum from only one of these gave a positive reaction and in this case the final diagnosis was doubtful.

Of forty-three cases recently examined for suspected typhoid fever, but which were finally believed to be non-typhoid, one gave a positive reaction with a 1 to 10 dilution, and turned out to be endocarditis complicated by malaria; in another case, which was that of a boy who had been sick only three days with a fever from which he rapidly recovered, the blood gave a reaction on the second day of the fever. The point of interest in this case is the fact that at the time of his illness four members of the family were sick with typical typhoid fever. Another case of this

TABLE—Giving the results of serum diagnosis in cases of clinically typical or suspected typhoid fever, in convalescents, of those who have suffered from other diseases and in healthy subjects, and the test used with dilutions.

Reporter.	Number of cases of typical or suspected typhoid tested.	Day of disease when tested.	Reaction.				Number of convalescents tested.		No. of cases other than typhoid tested.	Number of healthy subjects tested.		Test used and dilution.

series gave a well-marked reaction in a 1 to 5 dilution, but only a faint one at 1 to 10. It proved to be miliary tuberculosis.

The effect of typhoid serum upon other bacilli.—From experiments made by Dr. Hiss, a number of varieties of motile bacilli other than the typhoid bacillus are developed by the serum from persons suffering from typhoid fever, even when the serum is used quite highly diluted. These bacilli are also clumped, but to a much less extent than with the serum from some persons ill with other diseases.

Collective investigation.—In order to arrive at some general idea of the total results obtained by different observers, in the use of the serum test for the diagnosis of typhoid fever, a collective investigation has been made from the principal published reports on the subject.

In a total of 1,738 cases of typical or suspected typhoid fever reported as having been examined by forty-two different observers, 1,416, or 81.5 per cent. gave a decisive positive reaction, and 12 cases a partial or feeble reaction. In 234 cases finally believed

to be non-typhoid there was no reaction, and 46 cases in which the clinical diagnosis of typhoid fever was finally confirmed, or 2.6 per cent., failed to give the typhoid reaction at any time. These cases were examined at different periods from the second to the sixtieth day of the disease. The positive reactions were obtained, as a rule, during the second and third weeks, a few as early as the second and third day from the onset of the disease.

Of 92 convalescent cases reported as having been examined at varying periods after convalescence from the first week to the thirty-seventh year, in 48 a positive reaction occurred and in 44 there was no reaction. In only one case reported by Widal was the reaction present as long after recovery as the seventh year, the majority of the cases showing no reaction after one year. Of other diseases than typhoid fever, 816 cases were reported with only 36, or 4.6 per cent., positive and 780 negative reactions.

Numbers of healthy persons have been examined with the serum test, but the data from the results obtained from these examinations are too incomplete to

give any accurate statistics of the results; but the general statement is made that in very rare instances has the blood of healthy individuals ever been found to give a positive reaction with the typhoid bacillus in dilution of 1 to 10, or over. (The methods employed by the different observers in making the serum tests are almost as numerous as the number of those who have made them—macroscopic and microscopic tests, fluid serum and fluid and dried blood, and dilution varying from 1 to 10 to 1 to 50, and over, being used together or separately. There have naturally been some contradictory results obtained under these circumstances, but on the whole the general consensus of opinion is distinctly in favor of the practical value of the serum test.)

General conclusions.—From an analysis of the results which have so far been obtained in the application of the Widal test, it would seem, in the first place, that the serum reaction is by no means specific, in the strict acceptation of the term. In the second place, it is evident that this test has certain limitations in its practical utility, and that unless properly applied with a due appreciation of these limitations, it is liable to lead to false conclusions. The chief precautions to be observed in making the serum test are: 1. The virulence of the typhoid cultures employed. 2. The dilution of the serum. 3. The time limit for the reaction. The culture should be of high and known degree of virulence and the bacilli actively motile; the dilution should be in the proportion of at least 1 to 10, with a limit of fifteen minutes for the reaction to appear. Others recommend a dilution of 1 to 30 or 50, with a time limit of one to two hours, but according to our judgment, there is no special advantage to be gained by using these higher dilutions. The possibility of error, which in either method is sometimes unavoidable, is in our method at least on the right side. It is better to err occasionally in giving a false positive diagnosis than by a negative result to exclude perhaps many true cases of typhoid. In our collective investigation it was found that sixteen of the forty-two observers had used the higher dilutions, 1 to 20 to 1 to 50, while twenty-six have adhered to the original 1 to 10 dilution of Widal. It should be remembered, however, that, aside from this possible source of error, the reaction may also be due at times not to a present but a past case of typhoid, so mild in character that it has been entirely forgotten. The absence of a reaction in any single case does not necessarily exclude the diagnosis of typhoid fever, as the reaction may be delayed till late in the disease. But if on repeated examinations no reaction appears, it is strong presumptive evidence of the absence of typhoid fever.

Dried blood and fluid serum give very much the same results, but there is a decided advantage in the use of fluid serum, because the proportions in the mixture with the serum can be more accurately determined. The best mode of procuring the serum is by means of cantharides blisters.

When the subject of the serum diagnosis of typhoid fever was first brought before the public, it was hoped that at last the long-sought infallible diagnostic test for typhoid fever had been discovered, which was at once rapid, simple and suitable for clinical use at the bedside. With the non-fulfillment of these hopes, some physicians have come to look upon Widal's test as practically useless for diagnostic purposes. But, nevertheless, the results which have been obtained by

many different observers with an extended application of this method of diagnosis, would seem to warrant the conclusion that, in the hands of the expert bacteriologist it is capable of rendering valuable assistance to the physician, along with the other signs of typhoid fever, in a large majority of cases, although, like other signs of disease, it is sometimes wanting, or indecisive.

(In the preparation of this paper the first report on the subject published by the Health Department has been largely drawn upon. It is also desired to thank more especially Drs. Hiss and Baldwin, Assistant Bacteriologists of the Department, for information furnished regarding the recent results obtained in the Health Department laboratories.)

CLINICAL REPORT ON SERUM DIAGNOSIS IN TYPHOID FEVER.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY S. S. KNEASS, M.D.

WM. PEPPER CLINICAL LABORATORY,
PHILADELPHIA, PA.

I desire to very briefly report the results obtained from a number of examinations made for Widal's reaction in various diseases.

The method I have employed is that devised by

Dr. Wyatt Johnston, the use of the dried drop of blood. It is true that this method does not lend itself to an exact determination of dilution of serum employed; and in a few of the cases fresh blood with exact dilutions was used. A few drops of blood were mixed with ten times the amount of distilled water in the white corpuscle pipette of a Thoma-Zeiss hemocytometer, centrifugated, and the clear liquid thus obtained added to the bouillon culture to the required dilution. For the dry method, however, an agar culture of the bacillus, twenty-four hours old or even less, was employed and the mixture of this with the serum examined directly under the microscope, in a hanging preparation. Even with the dried blood, however, an approximate estimation may be obtained by roughly estimating the original amount of blood and rubbing it up in twice that quantity of distilled water or bouillon with a flat platinum needle. One or two drops of this are added to nine or eight drops of water, in which has been mixed a small quantity of the culture, this giving a dilution of 1:10 or 1:20. The error of this method really increases the dilution and hence does not invalidate any positive results. The hanging drop is examined for at least thirty minutes and oftener for much longer. The 1 in 10 dilution I have regarded as a minimum and generally, for diagnosis, have made use of a higher one.

The reaction is not considered complete until all motility has ceased and until agglutination has reached its maximum. Of 103 cases examined, 45 were submitted with a diagnosis of typhoid fever, 43 gave a complete Widal's reaction in from three to twenty minutes. Two were negative; these were typhoids who were convalescing from mild attacks of the disease at the tenth and forty-third day from the fall of temperature.

Forty-three cases of suspected typhoid fever were sent to me, and the result of Widal's test was confirmed in 38; in 14, with a positive reaction, the course of the disease proved it to be typhoid; in 24 with negative reaction it was not. Of the remaining 5, 2 were positive and 3 were negative; 1 of the positive and 1 of the negative were sisters who had the symptoms of very mild attacks of typhoid fever. The blood of one examined about the second week, gave a complete reaction in fifteen minutes; two weeks later no reaction occurred in either. The clinical diagnosis remained in doubt. Of the remaining cases no history could be obtained and the clinical diagnosis also remained in doubt.

Fifteen cases of diseases other than typhoid fever were examined with uniformly negative results. Quite a number of tests were made with typhoid serum and specimens of the colon bacillus, but in no case was there complete loss of motility or agglutination. There seems to be no very definite relation between the strength of the reaction and the severity of the attack. Only in a general way can one say, that with very mild cases the agglutinative power of the serum may be less and comparatively transient.

I quote briefly a couple of cases which are significant. H. came to the hospital with symptoms of typhoid. He had some diarrhea, abdominal tenderness and tympanites, persistent fever and slight splenic enlargement, but no spots. The temperature remained about 103 and was little affected by baths. There were also some pulmonary symptoms, but repeated examinations of the copious sputum failed to reveal the presence of the tubercle bacillus. An

examination failed to give Widal's reaction. The postmortem showed pulmonary and renal tuberculosis. There were no intestinal typhoid lesions and splenic cultures remained sterile.

The other case was one of meningitis. Widal's reaction was present, and the course of the disease showed it to be a case of typhoid with a meningitis due possibly to typhoid infection.

About twenty cases were examined at periods of from one day to nine months after the disappearance of the fever. In four of these, of eight, fourteen, fifteen and forty-three days respectively, the reaction was incomplete or altogether absent. (Two of these had shown a reaction during the febrile period.) The others were all positive. Those which had also been examined during the disease, showed an increase in the time required before the reaction was complete. Cases in which a relapse took place show this more markedly. In one case on the fifteenth day the reaction was complete in three minutes; on the twentieth day, with normal temperature, in five minutes; on the twenty-seventh it took thirty minutes before the motility of the bacilli ceased. A relapse occurred shortly afterward and on the third day of this the time of reaction was three to five minutes. The other cases showed the same thing. It might seem that very little immunization had taken place and that the agglutination of the bacilli kept pace with it; that the reaction should be regarded not as a phenomenon of infection but rather one in some way connected with the production of immunity, a by-product of immunization. (The experiments of Wright and Semple seem to point to the same thing. The blood of their patients who had received increasing doses of dead virulent typhoid cultures, showed the gradual appearance of the Widal reaction increasing hand in hand with the immunity.)

The earliest period in the disease at which the reaction was found was the fifth day. In four it was absent or incomplete on the sixth, seventh, tenth and eleventh days, but was present on the fifteenth, seventeenth, twenty-third and twenty-fourth days respectively. Its maximum did not always correspond with the height of the infection.

Care must be taken to distinguish between a complete positive reaction and what has been called a pseudo-reaction—a partial reaction. In this latter I have never found a complete cessation of motility of the bacilli, even when the agglutination has been fairly well marked. Another source of error may be noted. If instead of using one stock culture from which to make the fresh inoculations, they are made directly from one tube to another in successive generations, the culture gradually loses its power to react to the typhoid serum. It may be that such reinoculations increase the virulence of the bacilli and that virulent bacilli do not agglutinate as well as the non-virulent ones. This was certainly shown to be the case in the cholera reaction by certain German experiments (Pfeiffer).

The few cases that I have examined have been uniformly positive in their results, if we leave out those few in which there was no clinical diagnosis, or in which it remained doubtful. The reaction seems to be specific in character, inasmuch as it occurs only with the bacillus typhosus and only in cases of typhoid fever. Its value as a means of diagnosis is undoubted. Two things must be remembered, however. The fact that it rarely appears before the fifth day of the disease,

and, as has already been pointed out, that it may be retained for a long time after convalescence, some cases being reported in which it existed for years afterward. Such a case, with febrile symptoms, might be mistaken for a light typhoid attack by the examiner, if the fact of the previous attack were not in the clinical history.

LARYNGEAL PERICHONDRITIS COMPLICATING TYPHOID FEVER.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, at Philadelphia, Pa., June 1-4, 1897.

BY M. H. FUSSELL, M.D.

PHILADELPHIA, PA.

Perichondritis as a complication or sequel of typhoid fever has been known since the beginning of the present century. Nevertheless, the text-books upon medicine, with rare exceptions, make no mention of the fact. Perhaps all of the books speak of laryngitis or of ulceration of the larynx, but very few of perichondritis as the result of this ulceration. Osler has seen but two cases, both of which recovered. Hutchinson quotes Greisenger as an authority for its occasional presence. Strümpell says the disorders which attack the less superficial structures of the larynx are fortunately rare. Chief among them is laryngeal perichondritis. This complication is justly regarded as of bad omen, and may lead to the rapid development of laryngeal edema with great obstruction. Greisenger and Betke were among the very first to study this condition; they made studies of the condition of the larynx in persons who had died of typhoid fever, and Greisenger says that ulceration of the laryngeal mucous membrane occurs in about one-fifth of the fatal cases, while Hoffman found it in 11 per cent. and Betke in 12 per cent. (Inaugural thesis by Plagemann, 1879, on "Laryngo-typhoid.") Plagemann goes on to say that while many cases of ulceration recover without other symptoms than those of laryngitis, the cases which go on to edema and consequent stenosis usually are the result of perichondritis. He believes that the cases are always due to the local effect of the typhoid poison upon the larynx. Most authors believe that there is always an antecedent condition of the larynx upon which is engrafted the severe ulceration and consequent perichondritis. About 1878 to 1881 there seems to have been a desire on the part of the graduates of medicine in France and Germany to write on the laryngeal complications of typhoid fever. Many excellent essays may be found among the theses of that period; to those of Plagemann, Campe, Blasing and Atherac the writer owes most of his statistics.

The frequency of laryngeal perichondritis may be judged from the fact that in 2,000 autopsies of typhoid cases reported in the *Münchener Medicinische Wochenschrift* for 1891, there were fifteen cases.

The case here detailed was seen by me in consultation at St. Timothy's Hospital, Philadelphia.

The patient, an Italian, male, aged 30 years, was seized with what proved to be an unusually severe attack of typhoid fever in December, 1894. In the very beginning of the attack there was much hoarseness, and in the course of the fever he developed pneumonia.

After five weeks the temperature fell to normal. About six days after this a friend brought him an apple, which he ate, core and all. Almost immediately he was seized with a severe attack of coughing

and signs of laryngeal stenosis. I saw him on the third day afterward. He was suffering extremely from stenosis of the larynx and begged for relief. Examination of the larynx showed nothing but an edema; no ulcerations in any part. The region of the thyroid cartilage was swollen externally and extremely painful to the touch. The urine was normal. The lungs showed no signs of disease. Examination of the sputum showed an absence of tubercle bacilli. A diagnosis of perichondritis was made, tracheotomy advised but refused, and a blister was placed over the larynx. Two days afterward I saw the patient again. The edema of the larynx had largely disappeared, but the stenosis was quite as great as on the former occasion. The laryngoscope showed a pale mucous membrane with a decided narrowing *below* the cords. The

Perichondritis of larynx, case of typhoid fever.

tenderness over the larynx still existed. The diagnosis seemed to be correct, and a tracheotomy was again urged, but refused. The patient died on the seventh day after the beginning of symptoms of stenosis of the larynx. At the autopsy the left lung was found to be the seat of an old pleurisy; the lungs were erepitant throughout, heart normal, kidneys normal. The intestines showed healed typhoid ulcers, as here shown. The larynx was removed entire. The interior was filled with a frothy muco-purulent matter; there was no ulceration of the cords, but a small mucous polypus, the size of a pea, on the left side just at the junction of the false and true cords. Section through the *posterior* angle of the thyroid cartilage showed a large perichondrial abscess filled with

pus. The cartilage was necrosed. The abscess extended about one-half an inch on each side of the posterior median line. The anterior portion of the thyroid cartilage and the neighboring cartilage appeared normal.

This case would seem to indicate that there is much force in the view of certain authors that the laryngitis from which the perichondritis occurs is one of the primary lesions, for here hoarseness and general respiratory distress were among the early and continuous symptoms. However, careful examination of the larynx showed only the abrasions spoken of, and in no sense an ulcer which was in any way comparable to a typhoid infiltration.

The infrequent occurrence of perichondritis as a complication does not excuse the carelessness of writers on medical subjects in ignoring its occurrence. We are all familiar with the frequent laryngitis which accompanies the fever. Treatment of the laryngitis will often abort a more serious ulceration and perhaps perichondritis. Diagnosis is exceedingly difficult. Many of the authors believe that cold has a decided causative effect; this seems scarcely probable, however, when at the present date cold baths are used so extensively and laryngeal complications are certainly no more common than formerly. When a perichondritis exists and the general condition of the patient will admit, the only proper course is relief by tracheotomy.

THE RATIONAL ANTISEPTIC TREATMENT OF TYPHOID FEVER.

Presented in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, at Philadelphia, Pa., June 1-4, 1897.

BY H. A. WEST, M.D.

PROFESSOR OF GENERAL AND CLINICAL MEDICINE, UNIVERSITY OF TEXAS;
SECRETARY TEXAS STATE MEDICAL ASSOCIATION; VICE-PRESIDENT SOUTH TEXAS MEDICAL ASSOCIATION.
GALVESTON, TEXAS.

Probably no infectious disease has been the subject of more careful research than that of typhoid fever. There is none upon which the literature is more extensive, and about which there has been greater unanimity of opinion as to its natural history and therapeutic indications. If there is any one fact, in regard to this disease, which has been considered by all who are entitled to be regarded as authorities upon the subject as definitely settled, it is that typhoid fever belongs to the class of self-limited diseases. While various claims have been made, at different times, to the discovery of plans of treatment which are effectual in the abortion of the disease, there is no drug or combination of drugs which has received general recognition as having the power of effecting a specific cure. So, when assertions which revolutionize our conceptions of this ubiquitous and omnipresent evil are persistently and repeatedly made, removing it from the category of self-limited diseases, and placing it in the class which can be cut short by medicines, it behooves us to carefully scrutinize the evidence upon which such claims are made and put them to stringent proof.

I am skeptical as to the abortive powers of any drug in the treatment of typhoid fever; briefly for the following reasons:

1. It is a specific infectious disease and with the exception of malaria there is no other of this class which can be jugulated by the action of drugs.

2. The long period of incubation, and prolonged

insidious onset characteristic of the disease give ample time for the infectious microorganism to pass beyond the intestine into other tissues and organs, where they can not be reached via the gastro-intestinal canal.

3. There is no evidence to prove the potency of any medicine for the destruction of the pathogenic agent in the intestinal canal when given in doses which would not be toxic to the infected person.

4. There is no drug known to me, which we can introduce through the circulation, that will destroy the typhoid bacilli after they have reached the glandular organs.

5. My own experience with the formulæ which have been extensively advertised as specifics, has not been such as to substantiate the claims made for them by their authors.

The object of this paper, however, is not to combat the use of any particular combination of antiseptic drugs, for that question can well be removed from the sphere of debate, and may be relegated to the arbitration of the sick room, where it will soon be settled beyond any doubt; but rather to prevent what I conceive to be a rational basis of antiseptic treatment of the disease under consideration, involving a far more comprehensive *modus operandi* than the mere action of drug upon the typhoid bacilli. The antiseptic treatment of typhoid fever begins at the mouth and ends at the bed pan.

Experience has abundantly verified the necessity for a liquid and easily digested diet, which is requisite for the following reasons:

1. Impaired masticatory powers, muscular weakness and degenerations are characteristic and early results of the typhoid toxin and affecting the muscles of mastication as well as others, this first process of digestion is inhibited. Oftentimes the effects of the toxius of the disease upon the nervous centers is to interfere with mastication even if the muscular power was not diminished.

2. Impairment of insalivation, from diminished secretion and weakened digestive power of salivary glands. Hence starchy foods, especially those requiring mastication, are likely to undergo fermentation, and as an antiseptic precaution should be either prohibited or used in such forms as to facilitate their digestion.

3. There is impairment of the motion of the tongue and other muscular structures of the mouth, conducing to the retention and decomposition of particles of food, which are likely in various ways to contribute to infection.

4. The same muscular weakness and tendency to stupor which interferes with mastication also impairs deglutition, especially of solids, particles of which are apt to pass into the air passages (swallowed the wrong way) and become the carriers of infection, and the fruitful sources of secondary inflammatory processes as pharyngitis, laryngitis, bronchitis, catarrhal and croupous pneumonia.

5. These various functional disturbances, aggravated by the use of solid food, are likely to cause other inflammatory and suppurative processes as parotitis, disease of the middle ear, etc. Hence, a rational plan of antiseptics should begin with the selection of such foods as are best adapted to the weakened functional capacity of the patient, and which are least likely to be left between the teeth or upon the gums, where they are likely to undergo decompo-

sition and become the media of infection, and any plan of antiseptic treatment which does not include such regulation of the diet—the use of the tooth brush, as well as other cleansing and disinfectant measures applied to the mouth—appears to be fatally defective.

6. *Acute gastro-adenitis*.—It is, I think, generally admitted, that the stomach is involved to a greater or less extent in every case of typhoid fever no matter whether the case be mild or severe. The terms gastric and catarrhal fever, as frequently applied to the disease, indicate the constancy of gastric complications. Dr. Wm. H. Thomson speaking upon this subject says: "It is by no means the glandular tract of the intestine only which suffers, for recent researches show that in no disease except in gastric cancer is the peptonic power of the stomach so decreased as in this fever. Dr. Samuel Fenwick of the London Hospital, (*Lancet*, June 11, 1887) reports four cases of marked atrophy of the stomach in typhoid fever in which he scraped off the whole of the gastric mucous membrane and proved that the average weight was only 580 grains, while the average weight of the same membrane in seventeen patients who had died of other diseases was 1,035 grains, showing that in typhoid fever the stomach loses nearly half its bulk. Nor is there merely loss of bulk; there is also impairment of functional activity, for in seven cases of typhoid fever he made an artificial gastric juice with the mucous membrane of the stomach and found that the average amount of coagulated albumin was only one grain, while the amount ordinarily dissolved by the same in those dying of other diseases, as phthisis and pneumonia, was four grains. In two of the typhoid cases, the gastric membrane had lost its peptonizing power entirely, so that the albumin was quite unaffected by the artificial gastric juice made from them."

Resulting from this gastro-adenitis we have a deficiency of secretion, especially of hydrochloric acid, and as this is one of nature's most powerful antiseptics, its inadequate elaboration is followed by fermentation and putrefactive processes in the stomach with all their evil consequences. The secretory functions of the stomach are not the only ones involved, for as the muscular structures are generally affected, this coat of the stomach does not escape, so we have motor incapacity added to the other functional disturbances. As Dr. Thomson truly states, "we should bear in mind that in every case of typhoid fever, we have to deal with a stomach which is reduced to the weakness or even more than the weakness for digestion of the stomach of a newly born infant."

Therefore, we should not only abstain from loading a stomach with strong solid foods, but it is vitally essential for the well being of the patient, to carefully adapt the quantity and quality of the food to the digestive capacity of the patient. Not only so, but it is requisite also to aid stomach digestion by the administration of hydrochloric acid, pepsin and the like, as well as to stimulate its motor activity by nuxvomica; these remedies are antiseptics in the widest acceptance of the term, and any plan of treatment which ignores these well established conditions and fails to remedy them by a properly regulated dietary, and the administration of such antiseptics as above indicated is fatally defective.

7. *Secondary intestinal disturbances*.—The sali-

vary and gastric glands are not the only ones damaged in secretory capacity, in this disease: for the disturbed circulation, the anemia, the pyrexia and presence of the toxins in the blood, have a similar deleterious effect upon the secretions of the liver, pancreas and intestinal glands.

The disturbance of function and inflammatory conditions thus accounted for, are explanatory of various intestinal symptoms which otherwise might be attributed solely to the direct effects of the specific lesions, and any plan of treatment which leaves out of view these secondary infections and functional disturbances of intestinal digestion, is to my mind fatally defective.

In the consideration of the utility of drugs for the purpose of intestinal antiseptics several factors require investigation. 1. At what period of the disease does the evidence prove that the typhoid bacilli penetrate beneath the mucous membrane into the glandular tissues? Upon this subject it would be reasonable to suppose that absorption of the bacilli goes on during the period of incubation, for the symptoms of the onset can only be thus explained: the mere presence of the pathogenic organisms in the lumen of the intestinal canal would not account for the anorexia, headache, malaise, dizziness, muscular and mental weakness and fever. However, we are not left to conjecture on this point. Murchison² quotes Trousseau as stating that enlargement of the agminated and solitary glands is found on the fourth and fifth days, while Chomel and Louis held that it did not commence until the seventh or eighth days, but expresses his own opinion, founded upon postmortem investigation, that glandular enlargement commences with the disease and continues to progress until about the ninth day. Speaking of the mesenteric glands, Murchison states further, that these glands are invariably enlarged, their appearance varying according to the stage of the disease at which death occurs. *They begin to enlarge at the very commencement of the fever, and go on increasing in size, contemporaneously with the intestinal glands, until about the twelfth or fourteenth day.* 2. Conceding that the bacilli multiply after reaching the intestine, penetrate the mucous coat, invade the lymph channels, passing into the mesenteric glands and entering the blood, through which they reach the spleen and other organs, is it rational to suppose that antiseptic medicinal agents acting upon the intestinal canal could cut short the disease by any effect upon the bacilli? 3. Conceding that it is unreasonable to expect any direct curative effects by the action of drugs upon the bacilli, the question arises, can such drugs be beneficial in other ways, and what is the rational *modus operandi*? In addition to the direct action of the typhoid bacillus, we have to take into consideration the coöperative effects of the absorption of septic material into the blood from the intestines, and complications due to other microorganisms which find a more favorable soil for development in the tissues and organs of a patient whose power of resistance has already been reduced by the fever. So then, a rational system of antiseptic treatment of typhoid fever involves, in addition to those measures of prophylaxis already mentioned, which are of greatest importance, the use of other means for the prevention of septic absorption and complicating processes.

Before speaking of the utility of antiseptic drugs,

¹ Trans. New York Academy of Medicine, 1891, p. 28.

² Murchison: Continued Fevers, third edition, pp. 617-631.

I wish to emphasize and reiterate the statement that a proper adaptation of the diet to the conditions produced by the disease is of far more importance than the use of any drug or combination of drugs in the pharmacopeia. It is in the intestines that the accumulated evil effects of mouth and stomach indigestion are felt with greatest force, hence abdominal pain, tympanitic distension, diarrhea, absorption of ptomaines, to say nothing of the increased danger of hemorrhage and perforation, can not be obviated when the diet is neglected, no matter what medicines are given. Intestinal antiseptics may be promoted by the free use of water by the stomach, mechanically washing out and cleansing that organ and enabling it to empty itself of accumulated products of imperfect digestion. An abundant supply of diluents are also useful in other ways, viz.: by stimulating secretory activity of the skin, kidneys, lungs, intestines; by promoting the discharge of excrementitious products, and in preventing septic complications.

Similar results are obtained by occasional careful cleansing and disinfectant irrigations of the large intestine, which are especially useful when either constipation, diarrhea or tympanites indicate the presence of intestinal irritants. The same indications can be met by sweeping out abnormal intestinal contents from above, by the cautious administration of mercurial and saline purgatives. I use the word *cautious* advisedly, for the increased susceptibility to the action of cathartics in typhoid fever is well understood, and in my opinion the persistent and continuous use of purgatives is not only unnecessary, but bad practice. I have observed hypercatharsis from a seidlitz powder, and have had to discontinue capsules containing small doses of calomel and podophyllin because of the excessive intestinal peristalsis. A small dose of calomel (say half a grain every half hour until six doses are taken, followed in two hours by 2 dr. of sulphate of magnesia if bowels do not move) will have a good effect at the outset and may also be required during the progress of the fever. When the bowels are obstinately constipated, it is better to move them by daily enemata of glycerin than by the repeated use of purgatives by the stomach.

Before prescribing any one of the long list of antiseptic drugs, several questions must be favorably answered: What effect will the medicament have upon the appetite and digestion of the patient? Will it produce nausea, vomiting, or in any way interfere with nutrition? If the reply be affirmative the drug should not be used. Next, granting that absorption of the drug does not occur in the stomach, to what extent can we reasonably expect to destroy pathogenic microorganisms or prevent the formation and absorption of ptomaines, in a tube of such great length as the intestinal canal, without giving them in such large doses as to poison the patient?

If called upon to testify as to my personal knowledge concerning the positive value of antiseptic drugs in the treatment of typhoid fever, I fear my testimony would not add much to their reputation, for the reason that it has been my custom to use these remedies in conjunction with hydrotherapy and with other remedial measures, according to the plans as heretofore specified in this paper. I can, however, call to mind a few cases where a distinctly good effect appears to have been produced. A boy 4 years of age, treated last summer, showed a disposition to excessive elevation of temperature in spite of the most active

and persistent use of cold baths; under 3 gr. doses of thymol, given every three to four hours, the fever was reduced and he finally recovered. On the contrary, I have in other cases found the fever apparently not affected in the slightest degree by this remedy. In addition to thymol, I have used the various preparations of bismuth, subcarbonate, subnitrate and salicylate; when the diarrhea is severe these are useful. Salol and sodium benzoate have also been beneficial in similar conditions.

Other drugs of this class, which have been used with asserted good results, are phenol-bismuth, ichthyol, beta-naphthol, betol, benzo-naphthol, hydro-naphthol, magnesium benzoate, carbolic acid, creosote, turpentine, chlorin, iodine, camphor, chloroform and quinin; this is but a partial list, the very fact that they are so numerous tending to verify the observation that none of them are entitled to be regarded as specifics. They may fulfil useful purposes, but a rational system of antiseptic treatment of typhoid fever should include a careful attention to all these methods of regimen which an abundant experience has demonstrated to be essential.

One word as to the necessity of attention to the hygiene of the sick room as an antiseptic measure. An instance in point is that mentioned by Koreynski and Gluzinski,³ who mention a ward, previously occupied by many surgical cases, wherein a number of patients affected with enteric fever were afterward placed. Great mortality from septicemia, pyemia, phlegmonous inflammations, etc., ensued, and dust from the ward showed the presence of staphylococcus aureus, and the streptococcus pyogenes citreus and albus. After thorough disinfection of the ward these septic complications disappeared. No plan of antiseptics is complete, which does not include a complete destruction of the typhoid bacilli after their escape in the dejections.

THE TREATMENT OF TYPHOID FEVER.

Read in the Section on Practice of Medicine at the Forty-eighth Annual Meeting of the American Medical Association held at Philadelphia, June 1-4, 1897.

BY JOHN N. UPSHUR, M.D.

Professor of Practice of Medicine in the Medical College of Virginia; President Richmond Academy of Medicine and Surgery; Honorary Fellow of the State Medical Society of West Virginia.
RICHMOND, VA.

I have been influenced in the selection of a subject for this paper, not by the fact that its discussion has been neglected, nor because the medical mind for many years has been lacking in appreciation of its importance or failed to elaborately consider the best therapeutics for its management, but because concurrently with the development of much that is beneficial, errors and misconceptions have crept in. I believe, in the minds of many men, there is a vagueness of conception of the skilful treatment of typhoid fever, which in this advanced age with its wealth of clinical observation and literature, is deplorable. Therefore, I will endeavor to discuss the subject as fully, yet as concisely and practically as possible.

Prophylaxis.—Being an infectious disease we can not be too careful in using every means to prevent its spread. The case itself should not be allowed to become a focus of infection, the greatest care should be exercised in disinfection of the dejections, ventilation and cleanliness. Care also should be exercised in disposing of the dejections and urine, that neither

³ Centralbl. für Klin. Med., 1892, p. 829.

drinking water nor milk be infected. The free use of such chemic disinfectants as experience has taught us will absolutely destroy the bacilli, will prevent the spread of the disease. After adding the disinfectant, prolonged exposure to the sunlight is essential to perfect disinfection. In the country, free additions of quick lime and then burying far from all water supply will be efficacious. The bed linen and clothes of patient should be thoroughly boiled with a strong solution of bichlorid. The bed should be protected by a rubber sheet. When the case has terminated the room should be thoroughly disinfected for at least two weeks before it is occupied and furniture washed with a solution of bichlorid, 1 to 1000. In fatal cases the body should be enveloped in a sheet and moistened in a solution of bichlorid, 1 to 1000. If prevalent in an epidemic form, all milk and water should be boiled and no uncooked food eaten. The source of the infection should be sought for in the water or milk supply or faulty plumbing, and if possible corrected. All faulty sanitary arrangements by which the water supply, milk or other articles of food may be contaminated should be remedied.

General management of the patient.—I desire to emphasize at the outset the importance of *absolute rest*. So important do I believe this to be, that I am sure that I have seen it make the difference between life and death to neglect the precaution of perfect quiet to both body and mind. The patient in the beginning should be placed in as comfortable a room as possible; well ventilated, free from all possibility of continued exposure to infection, and in bed, as soon as the prodromes manifest themselves. Those patients who do not give up until forced to, are the most troublesome, and taking journeys for the purpose of reaching home is fraught with the greatest danger. The rule of using bed pan and urinal should be enforced. The patient should be protected from drafts and the covering varied with changes of temperature; the bed linen and clothes of the patient changed sufficiently often to keep them clean, though prudence must be exercised to avoid too great unrest to the patient. The nursing should be quick, systematic, absolutely free from every disturbing factor. Patients should not be left alone, especially if at all delirious; suicidal impulses may develop and life be lost as the forfeit of too little watchfulness. Sufficient pure, cool water is to be given in amounts not large enough to oppress the patient by the aggregate quantity taken, yet sufficient to relieve thirst. The diet should be liquid, nutritious, easily digested and the most explicit directions as to time and quantity administered. Gastric indigestion, curds in the stools and increased diarrhea indicate over-feeding. Milk is the best of all foods for the typhoid fever patient; it should be given in small portions at stated intervals and in such form as is most agreeable to the patient. The diet may be varied by animal broths, liquid peptonoid preparations, oyster or clam soup. Dull and soporific patients must be aroused to take food at proper intervals, but those sleeping sweetly and naturally should not be disturbed, but the food administered when they awake. Solid food should not be allowed for a week or ten days after return of temperature to normal and then very cautiously. Alcohol should not be recklessly administered in the beginning of an attack: in young, vigorous subjects it is not necessary. In those subjects who have used it habitually a moderate amount should be given from

the beginning. In cases in which diarrhea, tenderness, tympanites, great prostration, feeble first sound of the heart, dicrotic pulse and nervous symptoms exist, it should be freely given, whisky or brandy being the best form for its exhibition; if urine be albuminous and contains casts it should be given cautiously.

Mild cases require no treatment beyond rest and quiet treatment in bed, the heart being all right and no evidence of serious intestinal lesion. The bowels should be kept open by simple enemata of salt and water or glycerin and water. However, care should be exercised in even the mildest cases, as relapse may be of serious character, and a case free from danger or complication at the outset develop into one of serious nature. The headache usually requires no treatment, as it spontaneously disappears during the second week, but if it causes much suffering may be palliated by cold compresses or the ice cup to the head, with quiet and exclusion of light. Such preparations as phenacetin, etc., may be used in small doses, but I deprecate most decidedly the use of the coal-tar derivatives at any stage of the disease, as being too depressant. Sleeplessness may be controlled by sodium bromid in the earlier stage of the disease. When coma vigil comes on, no remedy is better than opium: it strengthens heart action and tends to remedy the cerebral congestion. Somnolence is to be treated by alcohol, both internally and by sponging. Ether hypodermatically in 10 minim doses is of advantage. The preparations of ammonia are used, but are inferior in action. Nervous symptoms are to be treated by such agents as musk, asafetida, valerian and ice cap, which must not be left on too long for fear of too great depression. Tremor, supposed to indicate deep intestinal ulceration, is to be treated by full doses of alcohol. Vomiting is not very common, but when it occurs in the beginning of an attack, if obstinate, nourishment by the mouth should be suspended. Iodin, in one-drop doses, is an admirable remedy, or a drop dose of creosote in a teaspoonful of cherry laurel water. Nausea may be controlled and nourishment administered at the same time, by giving a mixture of milk, white of egg and lime water prepared as follows: Add the white of one egg, whipped up to a stiff froth, to a tumbler of milk, mix well and then add a wineglassful of lime water. It may be given in quantities of a tablespoonful to half a tumbler, cold. Locally apply mustard plaster or turpentine stupes to epigastrium.

Constipation, if prolonged is not necessarily an evidence of mild intestinal lesion. I much prefer two or three loose actions per day. It is to be relieved by enemata of warm soapsuds and salt, carefully administered every second day. Laxative drugs are to be avoided, as they may cause perforation of the bowel. Diarrhea should be treated, when excessive, by regulation of quantity and quality of food, and if this does not prove efficient, a small dose of bismuth subnitrate after each stool or a teaspoonful of paregoric may be all that is necessary. If stools are very offensive salol or some simple antiseptic may be given. Dry tongue with sordes on the teeth and tympanites indicate the giving of water freely and the exhibition of turpentine. I can not too highly commend the action of turpentine. The tympanites in the latter stages of the disease, associated with coma vigil, picking at the bed clothes, dicrotic pulse, cold clammy skin, restlessness, all indicating passive congestion of

the brain, vasomotor paresis, are to be controlled by a commanding dose of opium. The tinct. opii is the best form of administration. The marvelous benefit from this remedy under such conditions is most pronounced, and I have more than once seen a patient rescued from a most perilous state. Furthermore, in cases of threatened heart failure, while we rely upon free administration of alcohol, no remedy exceeds strychnia in value as stimulant. Often used in alternating doses with nitroglycerin the patient is tided over a most critical period, the strychnia strengthening heart action, the nitroglycerin diminishing the contracted ischemic vessels and lessening resistance to heart action. In extreme cases, where there is prolonged collapse, the strychnia may be given hypodermically, reinforced by nitrite of amyl by inhalation.

Intestinal hemorrhage. indicated by a sudden fall of temperature and symptoms of collapse is to be treated by hypodermics of strychnia, atropia and ergot, with turpentine stupe to abdomen, enemata of ice water, absolute quiet of the bowels and the patient and diet reduced to a minimum for several days.

Peritonitis demands free use of opium by the mouth or morphia hypodermically; if the patient survive the bowels should be controlled. This lesion is usually due to perforation of the bowels, and coming during the latter stage of the disease or during convalescence the question of celiotomy for its repair has been raised, but I am of opinion that it is not justifiable, except that these cases are usually hopeless under other means, and a small percentage have succeeded.

The patient's attention should regularly be called to the necessity of emptying the bladder, as in the usually lethargic state the inclination is often not recognized. Catheter should be used if necessary. Chest complications and such others as may arise should be treated symptomatically.

Fever.—Numerous drugs have been used with the object of abridging typhoid fever, but all clinical experience shows the effort to have been fruitless. We can, however, in a measure control the temperature. The Brand treatment commends itself by the record of a reduced mortality, but careful examination of the methods strikes me that it is one involving such a state of unrest to the patient that it can not be free from serious objection. Yet with such authority testifying to its beneficial results I would be slow to condemn it. Free sponging with alcohol and water is of great comfort to the patient and I have found it efficient in reducing temperature. I can not too earnestly condemn the use of the coal-tar derivatives; their exhibition is fraught with danger because of their depressant effect on the heart. When the fever has progressed to that point where there is an increase in the length of the remission, during the latter part of the third week, I have seen great benefit in hastening the resolution of the fever by the administration of quinin in doses of gr. x., given at midnight: Care should be exercised, however, that it does not prove too depressant in its influence on the heart.

Serum treatment.—The results thus far obtained are not sufficiently definite, except from the standpoint of diagnosis, to be conclusive, and from the present outlook do not promise much in the future.

I can not close the consideration of this subject without a review of the so-called abortive and antiseptic

treatment of typhoid fever. Because I believe many men have been misled by the claims made for this method, and because I believe it to be not only thoroughly irrational, but fruitful of harm, both to the patient by the use of a faulty method, and also to the doctor in engendering a habit of unscientific routine. Let us look carefully at its method of application and the claims it sets up in its bid for professional favor and endorsement.

The Woodbridge treatment, or abortive treatment of typhoid fever, as described by Dr. John Eliot Woodbridge, makes claims of such brilliant results that one is startled and the question arises, have I been groping and blundering all these years? Let us analyze the claims made for this treatment. In the outset, I desire it understood that I have *never* tried it, not because of a spirit of prejudice or unfairness, but because, upon careful consideration, the brilliant results claimed, to my mind, disproved the facts and I did not feel willing to trifle with the life of my patient by uncertain experimentation. A knowledge of the nature and cause of the disease as fully established by the ablest thinkers of the day, making it a matter of impossibility to believe the results, no doubt honestly claimed as being possible, unless the day of miracles had returned. I would cordially commend the creditable industrious and earnest research of the originator of this treatment, but believe at the same time that he has drawn erroneous conclusions, and that there must have been errors of diagnosis. We have no evidence of proof given, except the bold assertion of success by himself and others, and the testimonials are not worth any more than the testimonials given by hundreds to the so-called cancer cures, kidney cures, *et id omne genus*. We are told absolutely nothing of the mode of cure by this routine practice in the use of formulas one, two and three. The author of this treatment tells us that he has had no death from "typhoid, malarial, or any continued fever for twelve years—for sixteen years before a death rate of 17 per cent." One case given is of pneumo-typhus, treated like typhoid fever. Why? Grave cases seen on the twelfth day, up in four or five days, cured by a single visit. Cases of intestinal hemorrhage, bad hygienic surroundings, well on the twelfth or thirteenth day. Solid food allowed cases on the fifth day. One case of a medical gentleman able to see patients in his office. Case of old lady with preëxisting Bright's disease, complicated by repeated intestinal hemorrhage. All kinds of adverse conditions; no restrictions as to diet, exercise, bathing, yet no death! "The patient should be put on the treatment when first seen; if you await pathogonomic symptoms, will not always succeed in aborting." Does not the question of correct diagnosis of many cases claimed as cures arise here legitimately? The patient is said to have been cured before a positive diagnosis can be made. I ask in all fairness, would claims of success in any other known malady, based upon such evidence as this, be considered as aught but the assertions of an enthusiast? Nor is this all; this treatment for typhoid fever is to be applied when the patient applies "for treatment for diphtheria, la grippe, or any pathologic condition which would be benefited by intestinal or antiseptic treatment," and this is given as proof of the abortive treatment of typhoid fever. Furthermore, let us look more closely at the formulas and method of administration. First, I notice the necessity of careful compounding of

these formulas; very good, but I also note that, as prepared and furnished the profession by Parke, Davis & Co., they are better than if obtained anywhere else; a nice advertisement for that firm, and not exactly in line with the Code of Ethics of this ASSOCIATION. Formula No. 1, dose one tablet every fifteen minutes for twenty-four or forty-eight hours; (quantity of medicine taken in that time, calomel, guaiacol-carbonate, menthol, each 12 grains, eucalyptol q. s.). Formula No. 2, same only smaller dose, with the addition of thymol; to be given for several days until, during the period of administration, "five or six, not less, free evacuations of the bowels are secured." On fifth or sixth day Formula No. 3 is commenced, given every three or four hours, alternating with tablets Nos. 1 and 2. All this washed down "with copious draughts of distilled or sterilized, or if indicated, some good laxative or diuretic water." Just think of it, the annoyance of such frequent dosage and no time for sleep. When will the stomach take and tolerate nourishment? The constant unrest of such copious purgations, to say nothing of so apparent a fact as the exhaustion incident to it! Now "this treatment begun early, none other needed." It has failed in no instance, if seen before the eighth day. In the hands of other men, with 800 cases treated, there were only 9 deaths. Eliminate all ordinary causes of death except hemorrhage and perforation, and minimize these. One case is cited when patient died because of too small a dose, having received it every three hours instead of every fifteen minutes! Finally, I note many of these cases had treatment begun on tenth or twelfth day, normal temperature on nineteenth to twenty-third day. This proves nothing, because many cases that never have this marvelous treatment have normal temperature as soon as this.

Finally, we are told, "this language is unintelligible to the greatest thinkers." Is it not strange that after two years no authority has yet endorsed or commended this treatment? The more we know of the etiology and pathology of this disease, the less we feel inclined to try it. The issues are too serious, the stake too important to be made the object of such experimentation, and to renounce the convictions of years, enforced and established by long experience. I would be glad to have convincing proof of the brilliant results claimed, and be able to approach the treatment of my cases of typhoid fever with the assurance of its harmless nature and certainty of cure, but with expression of greatest regard for Dr. Woodbridge's earnest and honest efforts, I frankly tell him his assertions of success must partake more of the positiveness of a true scientist, backed by the evidence of correct diagnosis, other than that of bald assertions.

A recent writer says: "Intestinal antiseptics, in so far as the pathogenic organisms of enteric fever are concerned, is directed against specific germs not present in the bowels prior to the breaking down of the intestinal lymph elements, and is therefore largely inoperative; general antiseptics, if by that we are to understand a germicidal influence upon bacteriologic forms diffusely implanted in the lymph tissues throughout the organism, is a vain fancy wholly unsupported by facts. The parasite is more resistant to such influences than is the host. Clinical and pathologic considerations are alike opposed to the whole subject of the antiseptic treatment of enteric

fever." (J. C. Wilson in Loomis-Thompson, "American System of Practical Medicine," Vol. i, p. 222). Again, "the antiseptic treatment has not a truly rational basis, while the extravagant claims of its advocates discredit their results." (Tyson's Practice, p. 46).

Treatment of convalescence.—Great care should be exercised during this period. No solid food should be allowed for a week or ten days after return to normal temperature. The diet should be restricted to milk, milk toast, eggs, animal broths. At the end of a week after return to normal temperature the patient may be allowed to sit up for a short period, increasing the time each day, and care should be exercised as to exertion. It must be remembered how much the heart muscle has suffered, and that it requires some time for it to be restored its original integrity. Over exertion, too, may cause a relapse. Should a relapse occur, no special treatment is required, but the treatment is the same as in the original attack.

PREGNANCY COMPLICATED BY OVARIAN AND FIBROID TUMORS. REMARKS UPON INDICATIONS FOR TREATMENT.

BY L. H. DUNNING, M.D.

INDIANAPOLIS, IND.

It is not my purpose to enter into a systematic or profound discussion of the subject indicated in my title. It is rather to remark in a practical way upon the indications for treatment, and to give point and emphasis to my remarks by a few illustrative cases, that this paper has been written.

The presence of an ovarian tumor during pregnancy is a menace to the life of the patient. Abortion is not so prone to occur as in case of pregnancy complicated by a fibroid tumor. The dangers appear in consequence of serious happenings to the cyst and by the irritation produced by the presence of the tumor. These happenings may be mentioned in the order of their frequency: 1, peritonitis with adhesions; 2, suppuration of the cyst; 3, torsion of the pedicle; 4, gangrene of the cyst walls; 5, hemorrhage into the cyst.

In an able article by Mangiagalli,¹ of which a summary is given in the "Annals of Universal Medical Sciences" for 1894, he shows that primary suppuration of the cyst is of frequent occurrence. Of 150 ovariectomies, 5 were done during pregnancy and 11 soon after the puerperium. In 5 of these 16 cases, there was primary suppuration of the cyst; in 2, there was torsion of the pedicle with peritonitis; torsion of the pedicle, suppuration and rupture of the cyst in 1, and hemorrhage into the cyst in 1.

Playfair² has shown the great danger to the mother in allowing pregnancy to go to full term. He says, that, "Of 13 cases of delivery by the natural powers which I collected in a paper on 'Labor Complicated by Ovarian Tumors,' far more than half proved fatal."

Contrast these results with those obtained by Russian surgeons under operative measures, as shown by Gordon in his report of 1894. There had been up to that time 204 ovariectomies performed during pregnancy, in Russia. Twenty-one cases could not be followed. In 7 cases the uterus was wounded and 2 died. Of the remaining 176 cases, 164 recovered completely and 122 of these went on to full delivery. Twelve died.

We have thus 183 cases operated upon with 14 deaths, a fatality of .076 per cent., which is but slightly above the mortality occurring when the operation is done in non-pregnant women. The consensus of opinion as I read it in the literature of the last few years is decidedly in favor of removing the tumor as soon as diagnosed. Due regard must be given to the condition of the patient.

In our own case it was my belief that the combined shock of delivery and ovariectomy, in the exhausted condition of the patient, would speedily have proven fatal. Early operations, before complications arise, are to be resorted to, not only because less dangerous to the life of the patient, but also because less liable to induce abortion.

I can find no authority whatever in the late textbooks, nor in recent journal articles by eminent writers, justifying an expectant treatment in cases of ovarian tumor complicating gestation. Prompt action is an imperative duty. A correct diagnosis is all-important and is not infrequently effected with difficulty. Fortunately, in some instances, the pregnant woman and the attendant physician both possess the knowledge that the tumor was present before pregnancy occurred. With this clue it is not difficult, as a rule, by palpation and percussion, to determine the presence, size, shape and location of the neoplasm. A distinct, circumscribed, fluctuating tumor, located to one side or above the uterus and changing its position with the growth of the uterus, may with little hesitation be declared an ovarian tumor, especially if it can be moved independently and is attended by none other than pressure symptoms. When suppuration occurs in such a cyst it is attended by a most profound effect upon the patient. Fever appears, and later, chills and night-sweats supervene. Torsion of the pedicle induces necrosis of the cyst walls or hemorrhage into the cyst cavity. In the former case fever and exhaustion gradually develop, and in the latter, shock, amounting in many instances to collapse. In all such instances the indications are for immediate interference.

I shall not attempt a review of the recent literature of pregnancy complicated by fibroid tumors, but content myself with stating what I believe to be the consensus of opinion of authoritative writers.

Pedunculated subserous fibroid tumors, unless large or adherent in unfavorable locations, give rise to few symptoms during pregnancy. When very large, however, or adherent, they sometimes induce pressure symptoms leading to impairment of the general health of the patient, and may even threaten life. Only under such circumstances do they call for extirpation, or induction of abortion.

Interstitial tumors of the body and fundus of the uterus seldom produce marked symptoms during pregnancy. It can not be denied, however, that when associated with pus tubes and pelvic adhesions, as they not infrequently are, the growth of the uterus is attended by pain, and sometimes general peritonitis and septic symptoms appear. Under the latter mentioned circumstances hysterectomy is indicated, but is attended by much danger to the mother.

Fibroma of the cervix not infrequently impedes labor and demands an extirpation of the tumor before delivery can be effected. That the presence of a small, pedunculated, submucous fibroid does not always induce abortion is demonstrated by our sixth case.

Hoffmeier³ contends that the presence of a fibroid in the uterus does not tend to induce abortion, but the reported experiences of numerous other observers does not accord with his views.

That the presence of endometritis predisposes to abortion is generally conceded. Any one who has examined the endometrium, in uteri removed for fibroma, must have noticed the almost universal presence of endometritis of the glandular or polypoid forms. In this morbid condition of the endometrium may be found a prolific source of sterility and of abortion. When it exists in pregnancy the decidua vera becomes thickened and abnormally vascular, so that hemorrhage is prone to occur and abortion result.

I think it may be stated as a rule that fibroid uteri which do not well tolerate the presence and growth of the fetus and growth of the uterus, abort, so that it is safe to adopt a non-interference plan so long as gestation proceeds normally.

If we may truly estimate the views of the profession by the articles published of late in journals and books we may safely say that there has been during the last three years a rapid rise and gradual decline of the sentiment favoring hysterectomy and myomectomy in uterine fibroids complicating gestation.

The operation is new in this country. Long⁴ in 1894 was the first American to deliberately extirpate the uterus in a case of fibroid tumor and pregnancy.

Hysterectomy should be the operation of choice when the tumor is of the pedunculated, subserous variety and when it is not too deeply imbedded in the uterine wall.

I wish to report the following cases as bearing upon the subject under discussion:

Case 1.—Mrs. A., aged 35 years; mother of four children. The last one was born Dec. 15, 1896 (two and one-half months ago). She was aware that she had a small tumor before she became pregnant. It grew somewhat during pregnancy, so that at term she was unusually large and suffered much from pressure in the upper portion of the abdomen, which region the tumor occupied during gestation. After delivery the tumor filled the lower portion of the abdomen, extending above the umbilicus. The child was born in a normal manner, weighed four and one-half pounds, was perfectly formed and healthy. The mother nursed the child and both did well. The tumor grew rapidly after delivery and when she came to me was much larger than a gravid uterus at full term. It was extirpated Feb. 26, 1897, two months and eleven days after delivery. There were many adhesions. The sac was adherent to the anterior abdominal wall in front, while the intestines and omentum covered the upper and posterior surface of the tumor. The adhesions were so recent that no difficulty was experienced in separating them, and the patient made an excellent recovery.

Case 2.—Mrs. B. was referred to me July 11, 1895. There was present a large interstitial fibroid of the uterus, and the patient was three months pregnant. She had borne one child since the tumor was discovered, and as the tumor was growing the patient felt uneasy, fearing lest the large size of the tumor might interfere with delivery. In view of the progressive emaciation of the patient and steady growth of the tumor, and her great anxiety, I favored operation but did not strongly advise it. Active interference was rejected. The patient went to full term and was delivered in a normal manner of a healthy child.

Case 3.—Mrs. C., March 29, 1896, had been in labor between one and two days, but had made little progress. Her abdomen was enormously distended and the upper portion contained a cystic tumor. After examination I concluded to attempt delivery first, and if successful operate a few days later. The os was dilatable and the head could be felt above the upper strait. Delivery was easily effected by turning. The patient was much prostrated after the delivery and I felt glad that we had not performed ovariectomy previous to the delivery. The patient rallied after a few hours and was doing seemingly well for five days, when suddenly symptoms of collapse appeared. She died two days later.

I am indebted to Dr. J. C. Webster, her attending physician, for the following facts: "The patient was tapped at the umbilicus March 20 and a considerable amount of fluid withdrawn. She was delivered on March 29. She lived until Sunday, April 4. On Friday before she died she suddenly collapsed but was kept alive until Sunday. An autopsy showed a hemorrhage into one of the compartments of the cyst. This hemorrhage was probably the immediate cause of the collapse and death. About two gallons of ascitic fluid were found in the abdominal cavity. The cyst wall had not been punctured when the abdomen was tapped. The tumor was multilocular. The cysts contained fluid of varying consistency, some thin, some thick and gelatinous. The tumor contained about eight gallons of fluid. The peritoneal surface was studded by a vast number of small cysts. I do not believe she could have survived an ovariectomy."

Case 4. Mrs. D. Came under my observation when three and one-half months pregnant. I was called to consider the advisability of extirpating a fibroid tumor of the uterus. The tumor was small, not larger than a lemon, and in the anterior wall of the uterus. The patient was greatly agitated and desired an operation. I declined to remove the tumor. A few weeks later, viz., April 1, the patient came to my sanitarium still desiring an operation. The tumor had not grown, though the pregnant uterus had gradually and normally developed since my visit. The patient had felt motion a few days previously and the movements of the child continued active during her two weeks' stay in the sanitarium. During the patient's stay at the sanitarium she manifested marked nervous symptoms of a hysterical nature, but they gradually subsided and very nearly disappeared. Finally she concluded to remain in the city until after her confinement and went to a friend's home to await the event. Dr. Hodges assumed charge of the case. Soon after leaving the sanitarium she began suffering from uterine pains which seemed to indicate an impending miscarriage. She finally miscarried the latter part of May. Nothing untoward occurred at the time of miscarriage except that she was excessively nervous and made a slow recovery. I saw her Sept. 27, 1896. The tumor had diminished in size, at that time being scarcely larger than a walnut without its hull.

Case 5.—Mrs. E., aged 19 years. Married and mother of one child which died when eight months old. She and her physician gave the following history: During the last months of pregnancy she was unusually large and suffered from dyspnea, but the presence of a tumor was not suspected. After delivery she remained large and in a few weeks her physician had decided she had an ovarian tumor. It grew rapidly and was tapped three times. She was operated upon Sept. 3, 1896, eight months after delivery. There were most extensive adhesions of the sac to the peritoneum, intestines and omentum. The tumor was large, it and its contents weighing sixty one pounds. It was a multilocular ovarian cyst of the glandular variety. She made an uninterrupted recovery and is now seemingly in perfect health.

Case 6.—Was one of pedunculated, submucous, fibroid of the uterus. I saw the patient about two years ago. The occasion of my being called was a profuse hemorrhage occurring ten days after a normal delivery. The os was patulous so that I introduced two fingers into the uterine cavity, when I encountered a pedunculated fibroid as large as a small lemon.

The peduncle was probably an inch long and attached to the right of the median line upon the anterior wall of the uterus, while the uneven surface of the placental attachment was felt to the left. The tumor was friable, but the pedicle was firm. It was removed by torsion. The uterine cavity was irrigated with hot water and packed with iodoform gauze. No further hemorrhage occurred and the patient made an excellent recovery. The tumor was examined after removal and found to be necrotic.

Case 7.—Mrs. Z. was referred to me Dec. 3, 1896, with an interstitial fibroid tumor as large as a pregnant uterus at four months. She had been able to feel this tumor for thirteen or fourteen years above the pubic bone, and eleven years ago, two or three years after the tumor was first discovered, she had an accidental miscarriage at three and one-half months.

These cases are thus briefly reported to emphasize a few points I believe to be of practical value. They tend to show that a pregnant woman having a fibroid tumor is prone to miscarry, but that the presence of the tumor is not a menace to life, while the presence of an ovarian tumor complicating pregnancy frequently leads even in favorable cases to severe pressure symptoms, peritonitis with adhesions, and not infre-

quently (in less favorable cases) to the death of the patient.

INTRA-UTERINE AMPUTATION.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association held at Philadelphia, Pa., June 1-4, 1897.

BY M. H. FUSSELL, M.D.

PHILADELPHIA, PA.

The following notes and accompanying specimens are due entirely to Dr. Thomas W. Brockbank of Philadelphia.

I was called May 13, 1895, to attend Mrs. D., aged 36, healthy Pennsylvania German, mother of nine children, eight of which are living and healthy. Mrs. D. first menstruated at 15 years of age, has always been regular, and was married at 16. Her husband is

also of Pennsylvania German type and healthy. I found her in labor at the end of the seventh month of gestation; external palpation showed nothing abnormal; bimanual examination showed genital organs and pelvis normal; cervix three-fourths dilated; position L. O. A. with vertex presentation; membranes had already ruptured and the waters escaped. Dilatation was soon complete and under good uterine contraction the head advanced rapidly. The extension and rotation were normal and complete, body rotating one-half circumference. The head and shoulders having been expelled from the vagina the uterine contractions ceased. I passed my hand under the covers for the purpose of grasping the shoulders and completing the delivery, and in doing so I was attracted by a sharp substance coming in contact with my hand which indicated some abnormality. On making an examination I found that the left arm was missing from a point about one inch from the shoulder. A close inspection showed that the soft parts had appar-

ently been separated for some time, the end of the stump being entirely healed excepting a small central opening through which protruded a small sharp spiculum of necrosed bone. There was no bleeding or evidences of recent separation of the soft parts. After tying and separating the funis I made a vaginal examination in search of the missing arm, which I found in the lower portion of the uterus, the separated end showing appearances identical with the end of the stump. The placenta was normal and healthy in appearance. The child was fully developed for a seven months' fetus, except that it was cyanotic, which condition caused death forty-five hours later. The photograph herewith exhibited was taken after death.

The above brief description is made from notes taken at time of attendance. I have purposely refrained from any discussion as to probable cause of such phenomena, desiring to leave that part of the subject to the members of this ASSOCIATION.

I attended Mrs. D. again on May 26, 1896, at full term, at which time she was delivered of a healthy male child.

WHAT TO DO WITH THE WASTE WATER OF A COUNTRY HOUSE.

BY HARVEY B. BASHORE, M.D.

WEST FAIRVIEW, PA.

For the convenience of studying this subject, country houses are divided into three classes: 1. Those which have water service and use water closets for the disposal of excreta just as in the city. 2. Those in which the excreta are disposed of by some method of dry closet; sewers not being necessary, but some form of drain for carrying the waste waters from the kitchen sink, bath, etc. 3. Those which have no water service, no bath, etc., a condition found in by far the greater number of houses outside of the cities. In such a house a slop bowl should be put up in some convenient place, either in the house or outside, and connected with a surface or subsoil drain. In England, where much attention has been paid to the subject of draining isolated houses, the general opinion seems to be that some form of surface drain is the better. One described by Professor Poore, consisting of a perforated tin roof gutter suspended over the garden bed, I know from experience, is quite practicable. Another way is to dig a gutter about a foot deep and a foot or two in width. This, being properly graded, is lined with round river-stones or cobblestones, such as are used for making street gutters, and connected by a tin or galvanized iron pipe to the slop bowl, kitchen sink or bath. This is probably the cheapest, most durable, and most efficient drain that can be made, and as the waste pipe opens into the drain above ground, there is no need of a trap. In some places, however, on account of lack of suitable land, a surface drain may not be practicable, and we have to resort to a subsoil drain, which may be made by digging a trench about two feet deep and twenty feet long, supposing the drain to be from the kitchen sink for a family of four or five. The bottom of the trench must be graded so that there is a fall of something like five inches in the twenty feet, then a narrow board is placed in the bottom and on this tiles are laid with their ends one-half inch apart. Then broken stones or coarse siftings of ashes, etc., are to be thrown in about the tiles and the trench filled with earth. Connect the sink and the drain with a lead pipe at one

end, and at the other end a similar pipe lead to the surface and allow a free circulation of air through the drain—a very important point. These subsoil drains, although rarely causing much odor in the room, should be trapped as a precautionary measure. The waste from the bath may be disposed of in the same manner. For the disposal of the bedroom slops, a slop bowl connected to the same drain may be placed in the bath room, or wherever most convenient.

For the disposal of sewage from isolated houses, the only method is some form of surface irrigation modeled after the large city plants. Choose a suitable location, with sufficient slope, and build a shallow tank; from this tank extend a gutter through the field, and from this extend distributing gutters in the direction in which the sewage is desired to flow. The tank, of course, should be managed with an automatic flush and be discharged intermittently. If for any reason a surface tank would not be desirable, one may be constructed under the ground, if there is sufficient slope for its outlet.

The absorptive field should be planted with corn and not with vegetables.

GUMMA ON THE FACE, SIMULATING LACHRYMAL FISTULA.

BY ALBERT B. HALE, M.D.

CHICAGO, ILL.

Wherever there is connective tissue there we may find gummatous inflammation. I suppose this is an axiom in pathology, and yet it is one I am myself very often forgetting, so I am not guilty of disrespect if I assume that it is occasionally forgotten by others. The following case is given, therefore, to illustrate how careful one should be, not only in making an examination, but also in searching the history for some causal factor which may have been neglected in any treatment previously attempted.

Mrs. A. B., married, four children living, one born dead, was seen by me after she had been examined and treated for the last six months elsewhere. She complained of a sore on the nose just underneath the inner edge of the right lower lid, for which, she said, all kinds of washes, salves and injections had been tried without relief. The examination showed a swelling exactly over the location of the tear sac (right eye) with no acute inflammatory appearance, but with a hard infiltrated area of congestion extending into the surrounding tissues. In the center of the swelling was a fistulous opening with reddened edges, through which very little pus but considerable serum and granular débris escaped. The swelling was practically painless. To all appearances, there had been an abscess of the tear sac, but the patient reported no history of great pain and no pronounced discharge with immediate relief. On further examination it was found that a probe could be passed through the lower lachrymal punctum into the nose without appearing at the opening, and that a second probe passed through the fistula failed to come in direct contact with the first, but that, when they were made to rub against each other, there was normal or at least living tissue between them. A distinct history of syphilis could not be elicited, although she had had a sore throat before the eye was bad; but considering the indolent character of the swelling, its resemblance to a suppurating gumma, its resistance to ordinary antiseptic treatment and the suspicious circumstance

of a miscarriage and some sore throat, I made the diagnosis of gamma and gave the iodid of potassium .75 grams three times a day, and only a simple boric acid wash for cleanliness. Improvement began at once and at the end of six weeks the swelling had disappeared, the fistula had closed, lachrymation had ceased and a probe passed into the nose as easily as through a normal duct.

SURGERY ONE HUNDRED YEARS AGO.

AN HISTORICAL STUDY

BY DR. GEORGE FISCHER.

DEDICATED TO THE GERMAN SURGICAL ASSOCIATION.

TRANSLATED FOR THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION
BY CARL H. VON KLEIN, A.M., M.D.

VIII.—PROFESSORS OF SURGERY AND PRACTICAL SURGEONS
(WUNDAERZTE).

(Continued from page 1234.)

Ferdinand Leber (1727–1808) was of much more importance; we have already mentioned his services in the abolishment of torture. Hyrtl has erected a small monument to this true son of Vienna (l. c. xxxiv). Leber's father made wigs, while his mother was a midwife. He was educated in a Jesuit school and became the pupil of a surgeon, under whom he learned bleeding and plaster-making during the three years legally prescribed. A small inheritance made him independent so that he could devote himself to the study of surgery. Jaus instructed him in anatomy and theoretic surgery, while he studied practical surgery in the Trinity (Dreifaltigkeit) Hospital, and became the assistant practitioner there. Having become Master of Surgery, in 1751 he received a minor appointment as physician in Breitenfurt with a salary of one hundred thalers, and in the following year, through his patron de Haën, he was called back to Vienna as surgeon of the great Citizens' Hospital. Here de Haën held his clinical lectures, and in the difficult cases called Leber in consultation. He had at the same time supervision of the two great suburban hospitals, St. Mark's and Backenhaus. He understood how to use the rich school and opportunities, and while in this position he laid the foundation of his reputation as a practical physician. In accord with de Haën's desire he provided, at his own expense, a collection of anatomic pathologic specimens. In 1751 he became torture-physician and in 1761 professor of anatomy and theoretic surgery. A copy of a college note-book on anatomy which Hyrtl had the opportunity to inspect, contained an odd mixture of earnestness, humor and triviality. The scientific part was cut short and there followed anecdotes from his surgical practice and a flood of humorous, caustic thrusts—sometimes reaching an incredible degree of vulgarity—against all the ways and shortcomings of public life, especially in the realm of medicine; but with all this Leber was a good anatomist and his surgical chapters were very thorough and accurate. The surgical illustrations in his lectures were practical and intelligible. When, in 1772, the teaching of the medical faculty was modified by Baron von Störck, Leber was charged to take as the groundwork of his lectures the German translation of Winslow's "Exposition Anatomique" and Schaarschmidt's tables. This impelled him in the same year to publish an anatomic manual—"Lectures on Dissection," a very good compendium for that time. This ran through many edi-

tions and replaced the most popular text-books, such as Heister's "Anatomic Compendium," etc. His surgical practice claimed his whole activity. Until the founding of Joseph's Academy he was the only operator in Vienna. He relates, among other anecdotes, a case where he, without any assistants, performed a Cæsarean section in a dark room, and found the head so wedged in that in disengaging it the whole body of the mother was lifted up; she recovered in nine weeks. He had a great reputation as a surgeon and was much sought after by foreigners. In spite of his rough, bearish and forbidding manner he was generally beloved. All biographers testify that he was an honest, open, good-hearted man, strictly moral and religious, but extremely gruff. His dwelling was besieged by patients the entire day, he authorized several apothecaries to fill his prescriptions for the poor and charge them to his account. With Boerhaave, he said: "The poor are my best patients, for heaven pays their bills." In 1776 Leber became body surgeon to the empress, and as such was two years later ennobled. In 1786 he gave up the chair of anatomy, presented his fine anatomic collection to the university and until his death taught only theoretic and practical surgery. He was the recipient of various honors; the university conferred upon him the doctor's degree *honoris causa*; Emperor Francis I. increased his salary 500 guilders and bestowed upon him the gold medal of honor, with a chain. He died in his 81st year, leaving thirteen children; one of his biographers attributes to him thirty-six children as the result of thirty-six years of married life with one wife. Excepting an essay on surgical practice and observations on hemlock (1762) and several small surgical notes in Plenck's and Molirenheim's contributions, he wrote nothing. Most of these papers treated of surgical instruments, a part of which he had invented, a part improved: for example, a lens-knife, a curved scalpel for extracting bulbi, pharynx and polypus tweezers, a knife for operating on rectal fistula, a ligature needle for the art. intercostalis, a stethoscope, an ear trumpet, a urine receptacle, etc. His aspirator for emptying pleuritic effusions deserves special mention. Leber was also the first surgeon who (as I shall show in Chapter xvi) made known the cure for aneurysm through direct and indirect compression (1770), and first applied the indirect compression alone to an aneurysm. These services laid, in part, the foundation of the just claim of German surgery to originating indirect compression for aneurysms, although they forget that they have contributed nothing to the development of this method.

In sharp contrast to his meager literary accomplishment stood the mental activity of his colleague, *Joseph Jacob Plenck* (1732–1807). The latter, who was born in Vienna, was the most popular text-book writer of his time, and left almost no science untouched. Surgery and obstetrics, anatomy and medical jurisprudence, eye and skin diseases, syphilis and children's diseases, pharmacy and pharmacology, etc., are all treated by him in his more than forty elementary works, outlines, and the like, much of which was not original. (Haller accused him of copying the experiences of the obstetrician, Saxtorph, without giving the name.) Plenck had no importance as a surgeon, and his surgical works are without scientific value. They are as follows: "Samml. u. Beob. über Gegenstände der Chirurgie," 3 Th. 1769–1775; "Lehrsätze der prakt. Wundarzneiwissenschaft

2Th., 1774-1776; "Neues Lehrgebäude von Geschwülsten." 1769; "Pharmacia Chirurgica," 1775; "Auswahl der Chir. Arzneimittel," 1775; "Pharmacologia Chirurgica," 1782, u. A. Nevertheless he was a clever writer, who had the gift of expressing the kernel of his science in a complete and well-ordered, if somewhat exaggerated, manner, and kept himself abreast of the times. He owes it to this circumstance that his books were very popular in Austria for a long time for elementary instruction and ran through many editions. In the publishing of his compilations he found, "that in order to save many surgical notes from oblivion it was necessary that some man should have earnestness enough in his patriotic breast to take them up, taste to collate them and self-renunciation enough to expose himself to the prejudice of the critics." He resolved to be this man. The lions growled loudly, but it did no good. The contents remained meager. All his writings were addressed to German surgeons of the smallest measure of education. His work paused at this low stage, which is shown, among other ways, by the fact that Plenck never described the surgical remedies in a scientific manner, but only by their taste, smell and external appearance, because he feared that in any other way "he would shoot over the heads of his pupils." It is to be noted that he made many new remedies available, little known before, because at that time operations were preferred by the students, and they did not concern themselves much with the other departments of surgery. By grinding quicksilver with gum arabic he produced a preparation (*mercurius gummosus*), to be given mostly in the form of pills in syphilis, and this remedy soon became very popular. Plenck was for a short time in the beginning teacher of anatomy, surgery and obstetrics in Basel. In 1771 he became professor of surgery in the newly erected University of Tyrnau (Ofen), in Hungary, and from there went to Vienna as teacher of chemistry and botany in Joseph's Academy. There he became director of the army apothecaries, staff-surgeon, secretary of the academy, and for his services was elevated to the Hungarian nobility.

Contemporary with Plenck, *John Hunczovsky* (1752-1798) taught in Joseph's Academy. He was a man who devoted himself to his science with great zeal, but he had not the genius to elevate Austrian surgery. Born in Mähren and trained in the barber shop of his father, he came in his 20th year, poor in purse, to Vienna. There he was supported by the Princess Tarocca and the Countess Berghausen, and was sent by the former, upon Brambilla's advice for further training in surgery under Moscati at Milan. After two years, when his patroness had died, he returned to Vienna and became assistant to Professor Steidele, in the Spanish Hospital, afterward to Brambilla. The latter was much taken with his ambitious pupil, living in the closest relation with him, and in 1777 procured for him from Emperor Joseph the money for a foreign tour. For two years he remained in Paris, placing himself chiefly under the tuition of Louis and Sabatier, and visiting untiringly the Paris hospitals as well as the sessions of the Académie de Chirurgie. Then he lived a year in London, visited Pott, Else, Bromfield, Alanson, J. Hunter, and saw also the great marine hospitals in Portsmouth and Plymouth, and in 1780 went back to France, where he visited the hospitals of the various seaports. David in Rouen was never to be forgotten by him. At the end of this year he returned

to Vienna by way of Turin and Milan. When, about this time, the medico-surgical school was established in Gumpendorf, Brambilla appointed him teacher of anatomy, philosophy, medicine and surgery, and provided him with a large ward where he held surgical clinics. Three years later he obtained, in Joseph's Academy, the professorship of operations, obstetrics and municipal health regulations. He is said to have operated little. Full of enthusiasm for the new institution, he was tirelessly active, and enriched it with many pathologic specimens. In 1791 he accompanied the emperor, Leopold II., to Italy, and was made court surgeon. Gradually the relation to Brambilla, to whom he had been devoted, began to grow cooler, as Brambilla conducted himself more as a superior than as a friend. Hunczovsky became dissatisfied with the development of the academy; his zeal lagged. At an operation for fistula of the rectum he scratched the end of his forefinger, whereupon inflammation and suppuration of the lymphatic glands of the arm and of the axilla set in. His gradual recovery was interrupted by the death of his friend, the poet Blumauer; a renewed and violent fever was quickly followed by death. The only one of his works which is read today with interest is his "Medico-surgical Observations of Journeys in England and France" (1783). In this was drawn a good picture of the hospitals existing at that time; certain new methods of cure and new instruments of foreigners were also described, and especially the successful treatment of kyphosis by Pott, and the same physician's recommendation of opium, in case of gangrena senilis; the use of electricity in case of rheumatic swelling of the joints was indorsed. Besides this he translated "Genge's Interpretation of Hippocrates" (1777); wrote a treatise on surgical operations (1785); translated Hamilton's "Duties of a Regimental Surgeon" (1790); and, with A. Schmidt, founded a library of the latest medical and surgical literature for the royal imperial army surgeons (1789). I have shown that it was not Dzondi, in the year 1829, but Hunczovsky in 1789, who first described congenital neck fistula, and cured it by injection of alcohol or splitting of the passage. He himself had no notion of the importance of this discovery, since he does not say a word about its origin or rarity in his treatise on the deformity.

Raphael John Steidele (1737-1821), and Mohrenheim distinguished themselves more as obstetricians than as surgeons. Steidele acted as such, at first in the Spanish and Trinity Hospitals in Vienna, then as University professor he entered the General Hospital, and held surgical clinics. He recommended simplicity in surgical matters, as well in respect to instruments as methods, but he had so little self-confidence that he "did not dare to impart his ideas to other surgeons, and hesitated to enlighten them, since each had the same right to call upon his own experience." In his collections of notes (four parts, 1776-88), much surgical material, with the necessary diagnosis, was supplied; but nothing of any great worth. It redounds to his credit that he followed Pott's opinion and energetically contended for a prompt operation in case of strangulated hernia; generally, a very healthy condition developed from this treatment. His treatment of hemorrhages, in which he contended for a special blood supply to each part of the body, was, through the frequent repetitions contained in it, uninteresting. *Joseph von*

Mohrenheim (1799) was second surgeon, obstetrician and oculist in the medico-practical academy in Vienna, and from there was called to St. Petersburg by the Empress Catherine of Russia, in 1783, as court physician and professor. He published many interesting cases in his "Notes" (1780), and in the *Wienerische Beiträge*, a periodical founded by him (1781); but his reputation is based especially on a treatise on obstetrics, a beautiful work with forty-six copper plates (1791), which was compiled by him, on command of the Russian empress, "for the use of her empire."

A more vivid coloring is introduced into the portrayal of Austrian surgery by the monk's cowl, which the Bohemian, Joachim Wrabetz (born 1740), wore. He learned surgery in the mechanical way, and in 1762 was appointed to the Imperial Military Hospital in Prague. When again without employment he wandered over Hungary and finally entered the order of the Brothers of Mercy, which in 1768 sent him to practice in the Bohemian village Kukus, where there was a considerable monastery. Here he performed operations secretly, mostly at a time when the other brothers were tarrying at table; he is said to have successfully performed nineteen cataract operations, fourteen of them by incision. The villagers of Kukus looked upon him as a miracle of God and hung the altar of the Virgin with wax and silver eyes. Sent to Vienna three years later he passed the prescribed examinations and became chief surgeon in the Brothers' Hospital and performed many operations under the eye of Leber, by whom he was daily visited. Here was a surgeon who at least made an attempt to keep an account (in figures) of his activity. He operated upon forty cancerous swellings, ten cases of fistula of the rectum, fifteen harelips, twenty cases of strangulated hernia, four cases of lithotomy, with one fatal case (?). Several small members were amputated by ligature and four large amputations made, as well as one successful exarticulation humeri and genu. He opened all cadavers and made eighty-six arm injections. He took a great deal of trouble to free the brothers of his order from the superstitious belief that they and their patients were protected from contagious diseases through the intercession of the pope. In 1776 he was called by the bishop-prince of Speier to Bruchsal to establish a hospital. He first went to Paris, visited the hospital of his order, met Frère Cosme, who was living at that time, and became very intimate with Louis, who in general did not love surgeon-priests; he then conducted the building of the hospital in Bruchsal and taught anatomy and surgery. The bishop made him his private surgeon and from Rome he was appointed prior of his order, and in 1782 the degree of Doctor of Surgery was conferred upon him by the University of Freiburg. He then became extraordinary professor of surgery in Prague. Wrabetz was much criticized because he recommended the making of amputations by ligature, instead of with the knife and he practiced it with success, of which more later.

The other Austrian surgeons were quite unimportant. There was *A. Beul*, a professor of surgery in Joseph's Academy and successor of Hunczovsky and after Mederer's death chief army physician and director of the academy. He wrote on lymphatic swelling (1801). The professor of anatomy in Prague, *Klinkosch*, published a classification of hernia (1765). The master of surgery and teacher of anatomy in the

imperial academy of fine arts in Vienna, *Posch*, in a treatise on diseases of the teeth suggested the use of the magnet in cases of toothache and urged the lancing of children's gums in difficult teething (1761). *Posch* also invented the foot-bed, which bears his name, for the treatment of ankle fractures (1774). *Sim Zeller*, first obstetrician and chief surgeon in the maternity house and the hospital in Vienna urgently recommended the common sponge as one of the best appliances in hemorrhages, and further endorsed the use of cold water in operations and hemorrhages, as well as water dressings in case of wounds and sores (1797). In this simple treatise, which was opposed with sharp derision, he was endorsed by V. von Kern, whose activity as director of the surgical clinic in Vienna extended into the present century. Simplicity in the treatment of wounds in Germany was inaugurated in the Vienna school. Kern also recommended the use of cold water in cases of fresh cuts and amputations, and for bruises, gunshot wounds and sores he suggested warm water. In the latter class of injuries he limited the misuse of plasters and salves. He treated wounds and amputations simply and without bandage or suture. His colleague in Joseph's Academy, *Zang*, belonging rather to our own century, contributed a very valuable work on operations, "Darstellung blutiger Operationen" (1813).

As it was in the empire so it was in the other parts of Germany: the soil upon which surgery was cultivated was a flat and uniform plain. There were no towering peaks or gigantic rocks, no wildly foaming mountain streams driving everything before them. The landscape was here and there broken by gently rising hills which lent it beauty and animation, and upon these small heights there flourished in *German surgery* a small number of *talented teachers*, many *industrious writers*, and a few *good practitioners*. No *genius* had been born and the new ideas which alone could have given German surgery a new direction did not appear. Even the best German surgeons, as Bilguer and Theden, had so little self-confidence that they took learned physicians in consultation in deciding whether their works were worthy of publication. If any one believed that Germany possessed any great men who could be compared to the best surgeons abroad he was greatly mistaken.

(To be continued.)

SOCIETY PROCEEDINGS.

Medical Society of the State of Pennsylvania.

Minutes of the Forty-seventh Annual Session.

(Continued from page 1238.)

Drs. WHARTON SINKLER and F. SAVERY PEARCE of Philadelphia gave a paper on

A STUDY OF EPILEPSY

with special reference to auras and to some other unusual features.

Table 1 contained an analysis of the auras recorded in the 315 cases; 141 definite auras were recorded, or in about 40 per cent. of the cases. The most frequent aura was stomachic, in 15 per cent. The next most frequent was aphasia; next a "vague" sensation. The initial sensations or movements exactly determined in the given cases of idiopathic epilepsy was 53, or in about 17 per cent.

Unusual auras.—One case presented the sensation of a tight band being bound about the arm, and at times the attack could be stopped by constricting the member above this site. Another case presented the peculiar ophthalmic aura [?] of a hideous face which preceded the attacks of grand

mal. One case presented a peculiar odor of flowers ushering in the fit. Another case had odor of some indescribable substance which was associated with a sweet taste in the mouth.

Table 2 referred to the exciting causes in 315 cases as given by the patient or relatives. In 140 causes, were given, or in 46 per cent., convulsions of childhood most frequently; while fright, indigestion and injury were also commonly noted causes. Many other reflex sources were noted. It was considered that gastro-intestinal disorders were the exciting causes of attacks in many cases where the predisposition existed. It was particularly noted that puerperal convulsions seldom ended in epilepsy. Alcohol was considered a frequent cause, and specific disease not so frequent as assumed.

Table 3 was devoted to conditions of the heart, blood and circulation and to conditions of consciousness, semi-consciousness and sleeping spells (narcolepsy) and to the eyes and respiratory organs. These had no essential relation to the disease in question, unless associated with other lesions, or (as of the eyes) a remote nervous degeneration consequent upon prolonged idiopathic epilepsy.

Table 4 referred to intelligence, which was fair in 61 per cent., very bright in 19 per cent., poor in 17 per cent., imbecile in 3 per cent. The disposition was notably bad in 26 cases. Nutrition was good in 50, bad in 76, otherwise fair. Some peculiar delusions were noted in this table, as sequels of the attacks—such as turning into a skeleton; of God going to punish him for last act he did, ever so simple. There was one case bled in status epilepticus and one case bled after a severe attack, in both of which the blood was dark and hypertoxic. The urine of several cases after attacks showed a tendency to hypotonicity. The authors pointed out that Drs. S. Weir Mitchell and Stewart were restudying the subject of the blood and excretions and secretions in epilepsy and that no definite conclusions were arrived at as yet.

Table 5 recorded the number of attacks, the heredity cases complicated by chorea, cases with relaxation of sphincters, patients having conditions which excite attacks definitely determined (121). General muscular paresis was found in only 7 cases.

Table 6 detailed the time of day when attacks most frequently occurred. It was found that from 6 P.M. to 3 A.M. gradual attacks were most frequent. Next most frequent after 3 A.M. until waking hours, and least frequent in the day time.

It was given as a cause for night attacks that inhibition of the coordinating brain centers existed at night and that the fact of sleep itself being the most important factor in lessening this inhibition was suggested as allied to dreamstates in which the sensory apparatus is well known to play weird phenomena.

One case never had a day attack, excepting when asleep. Petit mal is probably not noted at night, because the patient is seldom awakened by it.

Table 7 referred to remissions. Several cases had one attack in four years; one had an attack in two years; two, three and four attacks a year only occurred in many cases. One case had the remarkable remission of twenty-one years, one of twelve years and others of varying intervals. Two cases died in status epilepticus. The rest of the table was devoted to the initial cry, which occurred in 16 $\frac{2}{3}$ per cent.; tongue biting which occurred in 21 per cent. The age at beginning of attacks was recorded in another table, as was also the duration. The authors then devoted consideration of diagnosis, prognosis and treatment, suggesting hypnotism as one of the newer means to be tried thoroughly. All reflex causes should be sought, especially gastro-intestinal.

MALPRACTICE SUITS AND THE REMEDY.

D. B. II. DETWILER, Williamsport—The success that has attended the efforts of designing patients in furnishing suits of malpractice to intriguing attorneys upon the more opulent of our profession, leads us in self-defense to propose a plan today for our protection, for your consideration.

The physician from the nature of his work is isolated, hence more amenable to the attacks of this class of robbing parasites than any of the learned professions. The onset is generally made upon surgeons, from the nature of their work; the injuries incident to life, many of which have been deformities that are inevitable, and they furnish specious pleas for this designing class of conspirators for speculative purposes. This combination requires no capital, and the division of profits with designing lawyers, is unfortunately in many cases so large as to excite the cupidity of those who have secured gratuitous service from their victims. This has become so patent that it requires no special illustration among our surgical associates. The case of Anna Dickinson against the borough of Pittston and the physicians who sought to help her by placing her in the State Institution for Insane at Danville, for her recovery

as directed by the law in such cases, has excited much comment and a large expenditure of money in its defense, which after four years litigation has terminated in an award of six cents damages, with the costs not arranged for. With a case as apparent as this, a brilliant public woman, with aberration of mind due to known causes, places the guardians of the public and the necessary physicians of standing, in litigation for \$150,000 while they were carrying out the plain duties of the law for the protection of the public. Such a possibility was not entertained by the framers of the laws for the protection of the insane, nor for the necessary medical supervision. Yet here were four years of litigation in the highest tribunal of the State, and two years ago it was fortunately not decided on account of the death of the wife of one of the juryman, which stood 8 to 4 for the plaintiff. It is now terminated. Who will reimburse these physicians for these four years of litigation because they carried out the letter of the law provided for the care of the insane? Who of us are exempt from any of these dangers? Accepting these facts, what is the remedy? It is in the more thorough organization of our medical men, the standing of shoulder to shoulder, and the general defense for the individual. Organization is the remedy. Its best illustration is that of the Granger. A few years ago there was nothing more feeble and now with its more solid organization there is nothing more influential nor stable in legislative work. They have vote and use them for their protection. We have from 8,000 to 10,000 physicians in this commonwealth who have intelligence and influence, yet when the medical examiners board was formulated by this body, there never was a more important measure for the protection of the health and lives of the commonwealth. It was absolutely ignored, defeated until the county societies under the leadership of our late President, Dr. McCormick, and his able corps of assistants, were so organized that its political influence was felt in the legislative halls and then only by the formation of these boards of examiners. Comment is useless. This body of representative men, each individual able at any time to control from 50 to 100 votes, so feebly coherent, that they have no political influence and unable to protect their members from this invasion of blackmailing intriguers. The State Medical Society should be to the individual member as the government is to its citizens, an ægis of protection. When Paul said "I am a Roman Citizen" the shackles fell from his limbs and the same protection is extended by the national government to its most humble citizen at home and abroad. This protection by the State Medical Society would bring under its banners every eligible medical man in the State. I would suggest that a special committee be appointed by this body to investigate all charges of malpractice with power to act. When a suit is instituted this committee shall investigate, and when not due to carelessness and incompetence, it shall take charge of the same. Employ counsel and defend the case with the best legal talent obtainable, with all the power of this great society and defray the expense out of its funds. In order to carry out this measure, a special fund should be created by a specific assessment upon its members. This State protection would make practical evidence of its power and deter these parasites in their nefarious work. When the litigation is due to the carelessness or incompetence of the practitioner the committee should after full examination leave the case to its own defense. With a more complete county organization, and the enrolment of every worthy medical man, there would not be a more powerful organization in this commonwealth than our grand old State Medical Society.

In the afternoon, Dr. W. E. HUGHES, Philadelphia, read the Address in Medicine, reviewing the general subjects which had been brought before the profession during the past year and the matters now most attracting the attention of the physicians.

Dr. J. E. WILLETTS, Pittsburg, read the Address in Ophthalmology. He devoted his paper to personal observations, antiseptics and anesthetics in ocular operations, perimetry and the corneal circulation. All applications to the eye, if they cause hyperemia of the conjunctiva, are to be avoided. Under this come formaldehyde and eucain. They have no advantage over hydrarg. bichlorid. The tendency to destroy the cutting edge of the knife with the bichlorid may be overcome by refushing the conjunctival sac with a solution of boric acid. Non-irritating antiseptics are essential. Eucain is a decided irritant; it must not be used. It may relieve pain, but increase the conditions that produce it. Cocain is the ideal anesthetic here. Frequent instillations into the eye are not needed and are bad, 3 drops of a solution 4 per cent. is what he uses for an extraction with iridectomy. Avoid a too profound anesthesia with cocain. Perimetry is only an important adjunct in ophthalmology. Without the ophthalmoscope ophthalmology would be an imperfect science. We can thus readily differentiate diseases. It has been thus developed that we can take the field of

vision with prisms; that there is no contraction of the field for transmitted light; that there is no contraction of the field for color; that all that is necessary for the normal retina to perceive color at its periphery is to receive the impression, etc.

The next paper was by Dr. F. S. NEVLING, Clearfield, on

BRIEF VIEWS OF LESIONS AND TREATMENT OF TYPHOID FEVER.

There are certain general features belonging to all fevers, as chill, followed by increase of the heart action, increase of heat, etc. The chill undoubtedly originates in some impression of a depressing character upon the nerves, most probably upon the great sympathetic and vagus nerves: the diminution of vital nerve force is followed by increased action of the heart, inducing an increased metamorphosis of the carbonized and nitrogenized material of the blood and tissues, producing increased diminution of carbonic acid gas by the lungs, and urea and uric acid by the kidneys and other secretory organs. The balance between the tissue metamorphosis and the excretion of effete material is not, however, always preserved, and the albuminoid material thrown into the circulation by the rapid disintegration both prevents due oxidation of the blood in the lungs, and acts as a peccant matter upon the nervous centers, obstructs the capillaries and induces that condition known as typhoid. The impression upon the nerves may arise from poisonous matter introduced into the circulation from without, or from matter generated within the circulation itself, or the impression may have a local origin from a wound or injury. Once the impression is made, the depressing influence applied to the nerves controlling the circulating organs, increased heart's action follows and increased heat from increased respiration, and increased tissue change.

Typhoid fever presents, however, distinctive elements that characterize and separate it from all other fevers. Its most distinctive features are its bowel lesions, its inflammation, ulceration, or sloughing of the solitary and agminate glands of the lower portion of the ileum and extending into the cecum.

There are some physicians who maintain that it is right to lock up the bowels and keep them locked up in typhoid fever, while others maintain that the looseness of the bowels present in most cases of typhoid fever is an effort of nature to throw off by these intestinal evacuations the sloughs and irritant poisons that aggravate the disease by being retained in contact with those glands. The latter view I think to be the most rational, not that I advocate the utility of an exhausting diarrhea, but object to the locking process. I furthermore think that cases in which these sloughs are retained in the bowels are more liable to hemorrhage and perforation, the result of the secondary lesion from inoculation by the retained sloughs causing deeper ulcerations of the bowels; but as catharsis in this disease is a delicate operation, easily started but controlled with difficulty, great caution should be exercised in the use of cathartics, and although I coincide with the opposition of the locking process and keeping locked, yet I hold the view that loosening, whether the result of the disease or the action of medicines, is a weakening process and should be restrained within due bounds in the treatment of typhoid fever. There are certain general remedies applicable in all forms, and special remedies adapted to each disease and calculated to meet their individual aberrations from health. Sponging and the bath to reduce febrile heat are general remedies applicable in all cases of typhoid fever, and suitable stimulants and foods for sustaining the heart's action are also general remedies. Among a great many practitioners alcoholic stimulants are preferred as best for sustaining the heart's action, by their absorption into the circulation directly reaching the nervous centers, and also for furnishing carbonized material to the blood for lung combustion, thus sparing the fat and tissues of the body, and further for their stimulant action upon the blood vessels, helping to prevent or overcome capillary obstruction and stasis. Turpentine is also a valuable stimulant, especially with regard to preventing and overcoming capillary obstruction, but it is so valuable as an eliminating diuretic as well as an antispasmodic, relieving the irregular contractions of the bowels and attendant pains, that its stimulant power is often overlooked.

Appropriate food is another general remedy: in the choice of diet three things are to be kept in view. First, the powers of digestion are enfeebled: we must, therefore, choose nutriment easy of digestion. Next the blood is loaded with albuminoid material from tissue degeneration, therefore the diet should not be too highly nitrogenized lest we add to the offending material in the circulation and increase the labors of the secretory organs. Third, the bowels are sore and irritable, therefore the food should be bland; and, again, the ileo cecal sphincter is ordinarily in an irritable or inflamed condition, and the

opening from the ileum into cecum narrowed, therefore the diet should be fluid. Milk commends itself as a highly valuable article of diet, being fluid, easy of digestion and not too highly nitrogenized. Glycerin has been introduced to the British professional public as a valuable article in the treatment of typhoid fever. It commends itself as being nutritious, bland, antiseptic, alterative, containing no nitrogen, and preserving its fluidity throughout the process of digestion. I can add my testimony to its value, having used it with advantage in my own practice in the treatment of typhoid fever. Eliminary remedies, as cathartics, diuretics, sudorifics, etc., have their uses. Cathartics, as I have already remarked, should be used with great caution in typhoid fever; owing to the predisposition to diarrhea already existing in most cases of the disease diuretics are of great value. Turpentine holds, in my estimation, the highest place, not only possessing diuretic properties of a high order, but controlling the pain and irregular spasmodic action of the bowels, preventing and overcoming capillary engorgement and stasis; conjoined with the above remedial agents I make use of chlorate of potash and chlorin for their known action in exciting secretion, keeping the tongue and mouth moist and free from sordes, thereby relieving thirst, promoting the patient's comfort and facilitating the act of swallowing, also for the well known disinfecting properties of the chlorin and its destructive influence upon the lower forms of vegetable and animal life. The course of treatment that I have adopted and found satisfactory, is as follows: Should the diagnosis be typhoid fever the treatment is begun by a bath or sponging of the surface followed by chlorate of potash one drachm, muriatic acid, chemically pure, one drachm, distilled water four fluid ounces, shake and add pure glycerin four ounces. Give one teaspoonful every three hours, with a strictly liquid diet, generally milk, beef tea, etc. Should pain in the bowels supervene, turpentine, ten to fifteen drop doses in mucilage of gum acacia, or dropped on sugar, at short intervals until relief is afforded. When the urine is scanty or mic-turition is difficult or painful, turpentine is also given in the same doses as an elementary diuretic. When stimulation becomes necessary it is carried out by means of milk punch, combining the alcoholic with the nutrient. Stimulation is deemed necessary as soon as the fur upon the tongue assumes a brownish cast, or the pulse loses its volume, or low delirium appears. The bath or sponging to reduce febrile heat is continued throughout the treatment and is used whenever the febrile heat is excessive. Under this treatment, strictly carried out, the cases seldom assume a severe type. The fever is commonly restrained within moderate limit, the tongue and mouth remain moist, the teeth and lips free from sordes, diarrhea is seldom excessive, hemorrhage from the bowels is rare, convalescence often commences in fourteen days from the onset of the disease, and seldom later than the fourth week. Of course remedies are used to restrain excessive diarrhea and produce sleep when wakefulness disturbs the patient. Intestinal hemorrhage, if it is slight, does not call for other measures of treatment than the most absolute rest of the patient, the restriction of his diet to substances being most readily digested and absorbed in the stomach and upper intestine, and even of that kind of food by all means not more than can be properly digested and assimilated. Food and drink are to be iced and lumps of ice held in the mouth and swallowed. The action of the bowels are to be as far as possible controlled. I never had but four cases of exceedingly serious hemorrhage. In one case the hemorrhage came on suddenly (during the first week) and was very large. The temperature fell at once from 104 to 97. Another patient had nine very severe hemorrhages during his extended illness. In these cases I gave aromatic spts. of ammonia and brandy as a stimulant.

Dr. W. W. KEEN of Philadelphia reported

THE REMOVAL OF AN ANGIOMA OF THE LIVER BY ELASTIC CONTRACTION EXTERNAL TO THE ABDOMINAL CAVITY, WITH A TABLE OF FIFTY-SEVEN CASES OF OPERATION FOR HEPATIC TUMORS.

He referred to a second case on which he has operated for angioma of the liver: a woman aged 53, whose health had been failing for five years; for three years she had noticed a tumor at the pit of the stomach, which pained her considerably. Upon examination a tumor was felt to the right of the median line midway between the level of the umbilicus and the ensiform cartilage. It was quite tender upon pressure, slightly movable in respiration, dull on percussion and measured 7.5 cm. in diameter. The diagnosis lay between a tumor of the liver, of the stomach, of the colon or of the omentum, although the symptoms did not point directly to any one particular organ. An incision extending from the border of the ribs to the level of the umbilicus in the middle of the right rectus

revealed that it was an angioma at the lower border of the liver. Such tumors are usually only discovered at postmortems, never having given rise to symptoms. Dr. Keen did not think it wise to attack it with the knife or to attempt to amputate it completely even by the Paquelin cautery, in view of the large vessels leading into it. Accordingly he cut down through the liver tissue obliquely on each side of the tumor so as to make an artificial pedicle for the tumor. The base of the tumor was then encircled with an elastic rubber tube. The tumor was then drawn through the abdominal incision, the wound being partially closed and an iodoform gauze collar packed around the tumor and below the elastic ligature. On the sixth day the rubber ligature was removed and as there was but a small pedicle left, this was divided by a pair of scissors without the loss of a drop of blood. Cicatrization became complete in fifty-two days.

Up to this date fifty-seven cases of angioma of the liver are on record with a mortality of 16.7 per cent. A table of all these cases by Dr. Geo. W. Spencer was presented with his paper. Age seems to have no special influence, but sex on the contrary is very striking; forty-one were women as against eight men. This disproportion is believed to be due to the constriction of the chest in women from their clothing.

The diagnosis in most of the cases was in error, and it was a striking fact that in a large number of the cases there was an area of tympany between the tumor and the hepatic dulness, which, naturally led to the conclusion that the tumor was not connected with the liver. The duration of the tumor, even in some of the malignant cases, is striking: ranging from less than a year to twenty years. There are twelve different varieties of tumors, the most common being syphiloma and hydatid cysts. The size varied from very small ones to the size of an adult's head.

Four methods have been employed for the removal of such tumors: 1, the ligature; 2, packing with gauze wet with hot water; 3, the cautery; 4, the elastic ligature. Not uncommonly two or more of these methods have been employed.

The conclusions reached by Dr. Keen are: 1, that tumors of the liver and even large portions of the liver can be removed without undue disturbance of its function; 2, that the escape of bile into the peritoneal cavity is not usual after such an operation; 3, that the two dangers of hepatic operations are sepsis and hemorrhage, especially the latter; 4, the removal of a tumor can be done by ligation, blunt dissection, the cautery, the knife or the scissors, or by a combination of these methods; 5, in case a syphilitic tumor is suspected, no operation should be done until after a full trial of anti-syphilitic treatment has been made and failed; 6, in all cases of doubt and, provided time allows, after a fair trial of anti-syphilitic treatment, an exploratory laparotomy should be done. If the case is unsuitable for operation because it is syphilitic, or by any other reason, the abdomen is to be closed and very rarely will any mischief be done.

Dr. Keen's paper provoked free discussion, entered into by Drs. Kane, Montgomery and others.

Dr. S. AYRES of Pittsburg followed on "A Case of Hemorrhage in the Left Frontal Lobe Simulating Hysteria."

Dr. C. HUDSON MAKVEN of Philadelphia gave the details of 200 cases of speech defects at the Polyclinic in Philadelphia, showing marked improvement under treatment.

(To be continued.)

Illinois State Medical Society.

Abstract of the Proceedings of the Forty-seventh annual meeting, held at East St. Louis, May 18, 19 and 20, 1897.

(Concluded from page 1196.)

SECOND DAY—EVENING SESSION.

In the evening the Society went to St. Louis, where a special session was held in honor of it at the Century Theater by the Missouri State Medical Association. At this session addresses were delivered by Drs. J. H. Duncan of St. Louis, R. J. Sloan of Kansas City and A. W. McAlester of Columbia, Mo.

THIRD DAY—MORNING SESSION.

SECTION THREE.

Chairman, Dr. O. B. WILL, Peoria.
Secretary, Dr. R. C. MATHENY, Springfield.

A symposium of papers was presented in this section on

THE DUTY OF THE MEDICAL PRACTITIONER TO THE STATE.

The first one was read by Dr. L. R. RYAN of Galesburg, on "The Accumulation of Vital Statistics." The author stated that the object of vital statistics was to classify and arrange the facts relating to the quantity and character of human life

under different circumstances, for the purpose of determining the effect upon it of each of these effects taken singly, or two or more of them acting together. The results so obtained would form an important part of the scientific foundations of sociology, political economy and preventive medicine. It deals with masses of men, not individuals, and its conclusions are for the most part applicable only to large bodies of people: yet its data are derived from individual records, and its results are accepted in many cases as a sufficient guide for individual action. One of the most interesting subjects was the relation of race and color to birth rate, to certain forms of disease, to the liability to certain forms of disease at certain ages. The author said this country was the great mixing ground of the races, and while the mixture is rapidly becoming so intricate as to make it almost impossible to distinguish the different strains, still there were many groups of men of distinct races among whom the record of disease and death would form valuable material for study upon this important theme. Accurate data with regard to death could only be ascertained by a system of registration of deaths, made at the time of death. Repeated experience has shown that 70 per cent. of all deaths can be collected at the end of a year for the preceding year by any present system of enumeration, and it is now well recognized that a complete registration of deaths can only be obtained by legislation which forbids a burial until a permit has been granted from a central office, which permit is issued only on the certificate of a physician, setting forth the cause of death, and other facts in connection with it which are of importance.

Dr. EMMA J. LUCAS of Peoria, dwelt upon "The Physician's Duty to the State in relation to Local Sanitary Affairs," saying that the competent physician finds that he has other duties than those of self and more work than was apprehended in the old-time expression "practicing physic." He has great duties to the community in which he lives, requiring of him no half-hearted service in the prevention as well as the cure of disease. While the speaker appreciates that the physician's duties are many, constant and tiring, yet because of the profession chosen by him this is only what he should expect. Furthermore, he is expected to be a person of superior parts as well as of superior moral character, and in the author's opinion the competent physician can always find time and patience to do one thing more.

Dr. R. C. MATHENY of Springfield, followed with a paper on "The Duty of the Medical Practitioner to the State in the Detection of Crime and Punishment of Criminals."

The only crime which the author considered in his paper was that of abortion, and he said that the criminals were those connected with its practice. The persons with whom the State had to deal were the woman and the aider, in case there is an associate. It was hardly to be expected that the civil authorities would ever be instrumental in dealing effectively with the woman who endeavored to defeat the timely fulfillment of her own pregnancy. The defeat of Nature's purposes by self-inflicted devices could not be successfully coped with. The efforts of the State and of morality must be in other direction.

The Chairman, Dr. O. B. WILL, read the final paper of this Section, which was entitled "Legal Control as a Factor in Restricting the Prevalence of Specific Disease."

The author stated that in establishing the value of legal control as a factor in restricting the prevalence of specific disease, account necessarily has to be taken of popular feeling respecting the matter, regardless of any legislative expression. Not only that, but the sentiment of those individually most directly concerned must be given due weight if effectiveness is to be expected. A healthy and tolerant public sentiment is found to be of the utmost importance in securing acquiescence in the adoption of any line of action so closely concerning individual freedom. As a factor in restricting the prevalence of specific disease, the writer looks upon legal control, as it is potentially represented in existing administrative bodies, as absolutely inefficient and worthless. At the same time, he is impressed with the conviction, born of personal observation and experience along the line under discussion as well as in eleemosynary investigations and work, that a properly organized effort, under authority of the State, with discretionary powers, and taking into active consideration the various elements of influence herein considered, could attain nearly all that is so badly needed, even in the most delicate relationships of life that concern public and individual health. Even male prostitutes, the confessedly most difficult class to dominate and the most dangerous to the community, can be reached and controlled by an authoritative and, at the same time, judicial organization working through the profession, while the sensitive class should be effectively reached through direct pressure under legal protection.

REPORT OF NOMINATING COMMITTEE.

Your committee recommends Galesburg as the next place of meeting. Recommendations:

For President—Dr. J. M. G. Carter, Waukegan.

First Vice-President—Dr. T. J. Pitner, Jacksonville.

Second Vice-President—Dr. J. T. McAnally, Carbondale.

Permanent Secretary—Dr. E. W. Weis, Ottawa.

Assistant Secretary—Dr. J. E. Cowan, Galesburg.

Treasurer—Dr. G. N. Kreider, Springfield.

Members of Judicial Council—Dr. C. C. Hunt, Dixon; Dr. Hugh T. Patrick, Chicago; Dr. C. DuHadway, Jerseyville.

Committee on Necrology—Dr. John H. Hollister, Chicago;

Dr. O. B. Will, Peoria; Dr. E. J. Brown, Decatur.

Committee on Medical Legislation—Dr. J. W. Pettit,

Ottawa; Dr. Harold N. Moyer, Chicago; Dr. D. W. Graham,

Chicago; Dr. Daniel R. Brower, Chicago; Dr. J. B. Maxwell,

Mt. Carmel; Dr. John B. Hamilton, Chicago.

Committee on Medical History, consisting of members of

forty years' standing—D. N. S. Davis, Chicago; Dr. Robert

Boal Lacon; Dr. Edmund Andrews, Chicago; Dr. E. Ingals,

Chicago; Dr. J. H. Hollister, Chicago; Dr. J. S. Whitmore,

Metamora; Dr. T. D. Fitch, Chicago; Dr. De Laskie Miller,

Chicago.

SECTION ONE.

Chairman, Dr. A. R. Edwards, Chicago.

Secretary, Dr. F. P. Norbury, Jacksonville.

SECTION TWO.

Chairman, Dr. J. L. Wiggins, East St. Louis.

Secretary, Dr. A. E. Halstead, Chicago.

SECTION THREE.

Chairman, Dr. D. R. Brower, Chicago.

Secretary, Dr. C. B. Johnson, Champaign.

The Nominating Committee further recommend that an appropriation of \$100 be made for the use of the Committee on Legislation.

Committee of Arrangements.—*Chairman*, Dr. J. F. Percy,

Galesburg; Dr. D. W. Aldrich, Galesburg; Dr. Delia Rice,

Galesburg, Dr. L. S. Lambert, Galesburg.

Committee on Medical Societies—Dr. C. W. Hall, Kewanee;

Dr. J. A. Baughman, Neoga; Dr. W. R. McKenzie, Chester.

Respectfully submitted,

D. R. BROWER, *Chairman*.

E. J. BROWN, *Secretary*.

The following resolution prepared by a sub-committee of the Nominating Committee, we respectfully submit:

Resolved, That the Illinois State Medical Society hereby extend a vote of thanks to Dr. John B. Hamilton of Chicago, for his eminent and efficient services rendered as Permanent Secretary of this Society for a term of five years.

C. C. HUNT,

E. P. COOK,

J. O. DECOURCY.

Committee.

On motion, the reports of the Nominating Committee and sub-committee were unanimously adopted.

Dr. E. P. Cook offered resolutions of thanks to the Committee of Arrangements and the people of East St. Louis, which were unanimously adopted, after which the Society adjourned to meet in Galesburg, the third Tuesday in May, 1898.

SELECTIONS.

Psittacosis. At Genoa, it is reported that fourteen cases of this affection, with eight deaths, have occurred. The last death was that of Signor Gavino, brother of the captain of the *Manilla*, in which the two infected parrots were brought from Brazil. Now Captain Gavino himself, his wife, and his daughter are under treatment for the same malady. The Genoa city board of health was not an hour too soon in its warning to the public against harboring these domestic pets, as from being sporadic the broncho-pneumonia they convey has assumed almost an epidemic form. Meanwhile, the susceptibility of the parrot to pulmonary disorders, above all, to tuberculosis, is being put *en évidence* by the medical journals, most of which refer to the classic treatise on the subject by Dr. A. De Gordon y Acorta, a physician of Havana. The malady, often hereditary in the bird, is invariably accentuated by the close confinement and the privations encountered during the voyage to Europe, where again, even if it arrives in fair health, it is for the most

part exposed to insanitary conditions, under which it often contracts tuberculosis and broncho-pneumonia from proximity to human sufferers from these ailments. In Berlin the profession has long been alive to the danger of harboring and petting the bird, the veterinary school there having had 154 parrots under observation, and 54 of them having been found by bacteriologic tests applied by Prof. Eugen Fröhner, to be laboring under advanced tuberculosis. The lesson, so familiar on the continent, is worth repeating in the British Isles, where the parrot is imported from nearly every tropic or sub-tropic colony, and where well nigh every one of its 355 species is typically represented. Dr. W. T. Greene of London, in the *Lancet*, May 8, commenting on the diseases of the parrot and canary bird, takes a very much more favorable view of that of the former as follows: "If a parrot is rationally treated, there is far less risk from its society than there is from that of the average dog or cat, and no one need be under any apprehension of contracting psittacosis, unless, as I have said, he or she should be stupid enough and disgusting enough to become voluntarily infected by the morbid secretions from an ailing bird; and as many of these are possessed of an immense fund of courage and endurance, and show no symptom of being ill until the last, it is well that all intimate connection with them should be strictly avoided, and if due care is taken in this respect no one need be under the slightest fear of contracting any complaint, but ordinary rules of cleanliness must not be ignored, and if they are, it is not the parrot, but its negligent owner that should be blamed for any untoward consequences that may follow. Other birds, besides parrots, are liable to epidemic disease that very readily become endemic, and is then transmissible by atmospheric infection to other animals and even to human beings. I refer to the dreaded 'canary plague,' which is a form of splenic fever, near of kin to the goal fever of former times, that had its origin in crowding and filth, as this terrible disease most undoubtedly has. Case after case has from time to time been brought under my notice, where a canary-keeper has lost his entire stock through incautiously buying a new bird at an infected shop, and once an outbreak occurs it can only be stamped out, like the pleuro-pneumonia of cattle, by instantly destroying every bird that shows the least sign of illness and burning the cages and everything connected with them: no form of disinfection is to be relied on in such a case, for even stoving has been found to fail. There is no doubt that this complaint, like the kindred disease known as chicken cholera, is due in the first instance to crowding in wooden cages saturated with the droppings of generations of birds often—too often—dieted on unnaturally stimulating food and kept at tropical heat, or above it, to ensure early broods. The spleen seems to be the principal seat of the disease; it is enormously enlarged and studded with points of white matter which are not tubercular but *sui generis*, and the whole system swarms with microbes. I know of one case of canary plague where some children who lived in the room where the cages were kept, contracted a feverish affection, accompanied by a rash that had a superficial resemblance to that of measles, but did not run the course of that disease, though taken for it by the medical attendant (not myself); however, the symptoms, which were not severe, the temperature not rising above 100 degrees F., quickly subsided when the children were moved elsewhere. Every one of the birds, however, about fifty or so in number, died; and after the room had been fumigated and the cages cleansed thoroughly, as was supposed, and disinfected, a new stock of birds was acquired, but quickly followed their predecessors, and then the fancier gave up in despair. But even the canary plague need be no bugbear for householders, if only due attention is paid to ordinary sanitation; but filth always has engendered disease and always will do so, but it sounds to me irrational to condemn the innocent victims when it is really those who by neglect or ignorance of

the common laws of health, and especially of the right way of managing birds, who should be blamed. There will be no psittacosis, or canary plague, or chicken cholera, either, if the subjects of these diseases are treated properly by the persons who have charge of them, and other pulmonary complaints are also usually due to some breach of a natural law.

The Pneumatic Tire for Doctors' Carriages.—Of the comfort of the rubber tire as applied to an ordinary carriage there can be no doubt, and the chief question therefore for those who are anxious to use them is as to whether they will wear. Of course, they require care in using and are somewhat expensive in the first instance, but against these items on the debit side must be set various points to their credit. We have recently received two very opposite accounts of the lasting powers of these tires, which we here lay before our readers. The first is the experience of a practitioner in Sheffield. He allows that, having procured a set of the tires in question, he found an enormous amount of increase of comfort from the absence of vibration and jolting, and in addition that the body of his carriage, a light coupé brougham, was saved a proportionate amount of wear. But, on the other hand, he found that they frequently burst, and although mended soon gave way again: that they threw up a quantity of mud, which injured the paint of the carriage; and that the brakes, though efficient, soon wore out. The other experience comes from a medical officer of health in a hilly part of Wales. He had the pneumatic tires fitted to an ambulance brougham, which in eight months traveled over 750 miles of hilly, rough ground without a puncture and with extreme comfort to the sick transported thereby. The brake blocks wear out in seven and a half months, but the tires themselves were but little worn by the brakes, although much cut by the roads. This latter seems a pretty severe test, and we are unable to account for the disastrous experiences of the Sheffield practitioner except by assuming that he got a faulty tire, for even with the greatest care anything manufactured sometimes fail, or else that the tires were not properly inflated before use and so got nipped between the road and the wheel. The increase of comfort is so great that though it may not be worth while for a medical man to run the risk of having his carriage laid up for long spaces of time, as happened to one who tried the tires, yet in the light of the Welsh experience they would seem to be quite worth a trial.—London *Lancet*, May 8.

Twelve Cases of Persistent Priapism. Dr. Arthur H. Ward of the London Lock Hospital tabulates twelve cases of this affection, and reports another from his own practice that appears to have been a spontaneous thrombosis of the corpora cavernosa. His case, A. A., aged 32, unmarried, was seen at the end of five days of continuous erection, with much pain and no sleep. He was a small, "weedy," weary-looking individual. Family history negative. No venereal record. He had no illness or serious accident, had always been temperate and had never lived abroad or suffered from ague. Eight days before admission he had had intercourse, but had noticed nothing unusual afterward. Five days before admission he got up at midnight to pass urine, having been asleep for some hours. On returning to bed erection of the penis occurred. This condition remained through the night unchanged, with much pain referred to the body of the organ. He went to work the next day, but afterward remained in bed on his back with the knees drawn up. Any attempt to turn on his side was followed by greatly increased pain. There were no emissions or sexual desires. The penis was hyper-erected, being almost in contact with the median line of the abdomen. The erection was confined to the corpora cavernosa, the rounded ends of which could be clearly felt through the substance of the glans, which, together with the corpus spongiosum, was perfectly flaccid. The corpora cavernosa were of almost wooden hardness, and

fluctuation could not be felt. Any attempt to depress the organ caused acute pain; the skin was normal and there was no localized swelling. The pulse and temperature were normal, the tongue was clean, and the urine was acid with no albumin. The heart and lungs were healthy. The left side of the abdomen was somewhat rigid and felt uniformly hard. The spleen was considerably enlarged, and its anterior margin could be felt near the umbilicus: no bruit or friction fremitus were present. The liver was apparently normal. There were large, soft, smooth glands in the groins, axillæ and sides of the neck; they were movable, painless and discrete; the skin over them was natural. There were no signs of local hemorrhage. The patient was not markedly anemic, and complained of no symptoms of that condition. On the third day there was little change. An inflammatory swelling was found over the corpus cavernosum near the crus, this subsided spontaneously. The penis became very gradually less painful and rigid, and about the seventh day fluctuation could be felt over the corpora cavernosa. The spleen increased in size and the notch could be felt at the umbilicus, while the lower border extended down to the crest of the ilium. On the tenth day the Clinical Research Association reported on the blood as follows: "Hemoglobin and red blood corpuscles 50 per cent. of normal. Proportion of white corpuscles to red 1 to 8. They are mostly of the large and not very sharply staining variety, but the eosinophile and granule cells are also increased. Poikilocytosis is not marked, but nucleated red blood corpuscles are occasionally met with. A few cells of doubtful nature, containing large splotches of material staining purple with methylene blue and eosin, are met with; these possibly are fragments of broken-down red blood corpuscles. The blood is typically leucocytic and would point to the splenic variety of the disease." By the end of the fourth week the priapism was much less, and the penis fell forward when the man stood up. He felt better in all respects and slept well without drugs. His condition continued to improve, and by the end of the eighth week the penis was almost normal. One or two indurated masses remained in the crura. On the morning before leaving the hospital the patient had a normal painless erection, which soon subsided. Two months later there had been no return of the priapism. The spleen was very much smaller and the condition of the blood improved. The patient had gained weight and seemed to be fairly well. The arsenic treatment had been pursued. This case was no doubt one of spontaneous thrombosis of the corpora cavernosa consequent on the blood condition and established by an ordinary erection. The extraordinary hardness of the parts at first could only have been produced by the distension of the cavernous tissue with a passive clot. This large mass would naturally disintegrate in a few days and then afford a sense of fluctuation, but the thrombosis of the emissary veins persisting would prevent any escape into the circulation and at the same time keep up the condition of erection. He regarded the inflammatory swelling on the right side as probably surrounding a blocked emissary vein. The indurated masses which were felt in the crura at the end of the case were probably portions of the thrombus, which had organized more or less completely. The iodid treatment was adopted with a view of promoting the absorption of the clots, and this process was probably assisted by the local pressure, which at the same time gave the patient considerable ease by preventing the extreme tension which any displacement of the penis caused. Dr. Ward determined to avoid making any incisions if possible, although no doubt the disintegrated clots might have been squeezed out through them. But sepsis in this situation was only too likely to occur, and in the patient's general condition might have been disastrous. Nothing short of actual suppuration justifies incisions in such a case, since even if sepsis be avoided, adhesions between the trabeculae must occur at the seat of the incisions and might cause distortion, while a septic condition would probably result in the entire loss of erectile power.—London *Lancet*, April 24.

The Diagnosis of Tuberculosis from the Morphology of the Blood.—In a paper on this subject, Dr. A. M. Holmes (*Med. and Surg. Reporter*, No. 2075, p. 757) concludes as follows: That the diagnosis of tuberculosis, from the morphologic appearance of the blood, rests upon the hypothesis that each individual has a biologic prototype in the leucocytes of his own blood. The leucocytes are independent organisms with functions analogous to those of the larger organism. That they pass through the stages of growth and decay. That disintegration of leucocytes may occur at any age. That the leucocytes are tissue-formers. That, as are the leucocytes, so is the individual. That tuberculosis is a disease characterized by tissue disintegration. That in tuberculous blood there is abundant cell disintegration, premature development, premature decay, and more or less deviation from the normal percentages of the various types of cells. That if there is marked disintegration in the leucocytes, it is with absolute certainty that we can predict a similar condition in the larger organism. That tuberculosis possesses a combination of blood appearances, from which a diagnosis may be made earlier than by any other means that we now possess. That these may be recognized under a high power. That they can be recognized even before the disease manifests itself in the individual. That they are sufficiently marked in tuberculous persons, or even in those with a strong tuberculous predisposition, to enable a diagnosis being made from the blood alone, without knowledge of the history or physical condition. That the real source of recuperative power is to be found in the leucocytes. That thus far no other pathologic condition has been found which presents similar appearances. That to secure an early diagnosis would enable many to avail themselves of favorable climatic changes, and thereby delay or even prevent the destructive results which would otherwise inevitably follow. And finally, that if future investigations confirm these deductions, we may look forward to a no distant day when, if we expect to detect tuberculosis in its incipency, we must study the leucocytes.

PRACTICAL NOTES.

Improved Gynecologic Massage. O. Beuttner recommends raising the pelvis in massaging the uterus and adnexa, as the organs thus become much more easily accessible to the operator, and the massage is much less fatiguing to the patient.—*Semaine Méd.*, May 26.

Local Injections of Antitoxin Serum in Diphtheria of the Eye.—H. Coppez communicates to the *Rev. Gen. D'Ophthalmol.*, May 31, the results of a series of experiments on rabbits in this line, from which he concludes that local injections of antitoxic serum are useful. The effect of the serum is much more rapid. In severe monocular cases a subconjunctival injection of the serum in the sound eye seems to be the best means to preserve the sight on that side.

Treatment of Cavities with Mixed Iodoform and Calomel.—Sprengel announces that equal parts of iodoform and calomel form a harmless and powerful antiseptic dressing for the cavities left after operating for tuberculosis of the bones, joints, tracheotomies, etc. It promotes the formation of a thin eschar, thus preventing the sticking of the dressings to the tissues. After hemostasis is secured, the powder is sprinkled over the walls of the cavity with a small pointed spoon and rubbed in with a gauze pad held in the forceps. As much as $4\frac{1}{2}$ grams can thus be applied without inconvenience. The wound is afterward kept open with a tampon.—*Cbl. f. Chir.*, February 6.

Edema of the Optic Disc.—Prof. A. Angelucci concludes from four personal observations and the results of others, that craniectomy in cases of edema of the optic disc produced by a tumor in the cerebrum or cerebellum, always improves the sight, but

this improvement only continues and progresses when the operation was completed by the extirpation of the diseased focus. For the cases when this is impossible, he agrees with Broca, Mauriac and Chipault, who insist upon the palliative treatment of papillitis associated with symptoms of cerebral compression, as craniectomy in such cases relieves the pain, retards the post-neuritic atrophy and blindness and prolongs life.—*Revue Gén. D'Ophthalm.*, May 31.

Cancer of the Larynx.—Schmiegelow states that there are few parts of the body in which a cancer remains localized so long as in the larynx, and that few radical operations are as sure of success as its removal when diagnosed in time. He urges the necessity of careful investigation with the laryngoscope as frequently hoarseness is the only symptom of incipient cancer in this locality. His experience and observations of thirty-four cases are described in a comprehensive article in the *Nordiskt Med. Arkiv.* of May 8. He has never removed the entire larynx. One case, aged 62, on which he performed thyrotomy and the excision of the right vocal chord, has shown no relapse in the four years since. A relapse in a case, aged 72, required tracheotomy later. One died in the course of the seven operations he reports in detail.

Favorable Effect of Franklinization on the Voice.—It was announced at the meeting of the *Acad. de Sciences*, April 5, that the singing voice after a course of Franklinization, if the vocal organs are sound, becomes clearer, more flexible, with increased volume and agreeability of tone, and is less easily fatigued. It is therefore to be recommended to vocal pupils and *débutants*, as it imparts an exceptional beauty to the voice. The singer is seated on an insulated stool, connected with the negative pole of a high tension static machine, and an electric brush held before his face. The effect is perceptible even after one sitting.—*Semaine Méd.*, April 21.

Subcutaneous Injections of Salts of Iron.—Prof. R. Lepine reviews in the *Semaine Méd.* of May 26, the important works that have established the fact of the positive absorption of inorganic iron by the intestines, and refers to the cases in which iron is imperatively needed, but is not tolerated by the stomach. He has treated such cases with subcutaneous injections of citrate of iron (3 to 4 c.c. of a 4 per cent. solution, equivalent to 0.12 to 0.15 gram of citrate), and has found it remarkably successful. He describes one case of grave anemia of gastro-intestinal origin, in which the improvement was prompt and truly marvelous. He warns against administering iron in this way to patients with diseased kidneys or with tendency to hemorrhages, cirrhosis, hemorrhoids, metrorrhagia, etc.

Hemorrhage from Sound Kidneys.—There are eight cases on record in which the kidney was removed for hemorrhage and found absolutely normal. Klemperer ascribes it to paralysis of the vasoconstricting nerves, which he treats with complete repose, predominant but not absolute milk diet and suggestion. If several weeks of this fail to cure, combined with hydrotherapeutics and local electric treatment, and there is danger from excessive loss of blood, the kidney should be explored, but if found sound it need not be removed at that time, as the exploratory operation alone may bring relief. *Deutsche Med. Woch.*, No. 8, 1897.

Acetonuria in the Mother Certain Evidence of Fetal Death. It has been Knapp's experience that the urine of the mother tested with Legal's reagent, in cases of suspected death of the fetus, always showed a remarkable amount of acetone when the fetus was actually dead. The *Presse Méd.*, May 22, recommends Chautard's test as simpler and more accurate for the purpose. It is merely a 1 to 2000 solution of fuchsin (0.05 centigrams of fuchsin dissolved in 100 grams water) discolored with sulphurous acid. A few drops of this solution added to a test tube containing 15 to 20 c.c. urine turns the urine violet if there is acetone present.

Treatment of Varicose Ulcers Without Repose in Bed.—With Aubouin's method the patient resumes his occupation without inconvenience or delay, and the dressings only need changing as the secretions find their way through the bandages. He first renders the limb antiseptic and dusts the ulcer with iodoform, xeroform of aristol or dermatol, smearing the adjoining eczematous region with Lassar's paste (pulv. starch and white zinc oxid each 20 grams, vaselin 40 grams). After this Unna's glue paste, melted, is applied over the whole limb. (Formula: Water and glycerin each 80 grams, gelatin and zinc oxid each 20 grams.) A starched tarletan bandage is applied outside of this with moderate compression and an outer bandage to prevent soiling, when the patient is dismissed to his usual occupation. The appearance of pus is the only indication for a change of dressings. They are easily removed after soaking in a warm foot bath.—*Presse Méd.*, May 19.

Occlusive Dressing with Aïrol Paste.—P. Bruns of Tübingen recommends his aïrol paste in the highest terms as an ideal dressing for sutured wounds. It dries rapidly and sticks closely, it is powerfully antiseptic and absolutely unirritating to the most sensitive skin, but its chief advantage is that it allows the secretions to ooze through it. He has been using it for six months, especially after laparotomies, herniotomies and ignipunctures, and has not had a single stitch-hole suppuration with it. He concludes with the statement that occlusion with aïrol paste insures in the simplest manner a flawless *prima intentio*. His formula is: Aïrol, mucil. gummi arab., glycerin, ãã, 10 parts; bolus albus, 20 parts. He uses it even in wounds with drainage.—*Beitrag. z. Klin. Chin.*, xviii, No. 2.

Strontium Lacticum in Bright's Disease.—Bronowski has confirmed Laborde's assertion that this substance has no toxic effect, even administered for a long period. After experimenting with animals, he administered it to thirteen cases of Bright's disease. Death from other complications followed in two cases, and one case was not affected by it either way, but the remaining ten were all either entirely cured or remarkably improved. His doses were 1.0 *pro dosi* and 6.0 *pro die*, in an aqueous solution. The strong diuretic effect was felt by the second day, especially in acute parenchymatous nephritis. The effect is much less powerful in the chronic forms. He adds that morphin diminishes the effect of the strontium, and ascribes its diuretic effect to stimulus of the N. splanchnicus, which dilates the renal vessels.—*St. Petersb. Med. Woch.*, May 22.

Formaldehyde and Its derivatives, Holzin and Steriform.—Rosenberg states that he has become convinced from recent investigations and experiments that formaldehyde is the most powerful bactericide we possess, and that it is by no means as toxic as generally supposed, which he proved by taking gradually increasing doses himself, for six weeks, without the slightest trace of harm. Nothing abnormal was discovered in the blood or urine at any time, although bacteriologic tests of the urine showed that it had been rendered absolutely sterile. Lessin's new test for formaldehyde detects it even in a 1 to 10 million dilution, and with this test free aldehyde was found in the urine after taking the formaldehyde, and even after remaining in a room they had been disinfected with it, which disproves the assumption that it can not pass into the blood without being resolved into formic acid. He also administered it to animals and to patients with tuberculosis, erysipelas, etc. (In tuberculosis having the patients inhale holzin, a preparation of 50 per cent. menthol, 3.5 per cent. formaldehyde and methyl alcohol.) He prefers the two derivatives, holzin a liquid, and steriform a solid, and an entirely new chemical substance, prepared with lactose, but differing from it in important particulars. (Formula: 5 per cent. formaldehyde, 10 per cent. sal ammoniac, 20 per cent. pepsin and the rest lactose.) Holzin is especially effective in disinfecting surgical instruments. He mentions an instance in which he operated

a tumor of the sheath of a tendon with the same instrument, unwiped and uncleaned, with which he had operated an extensive suppurating phlegmon an hour before, merely leaving the instrument in holzin during the interval.—*Therap. Woch.*, April 25.

Tuberculous Cystitis.—In treating this subject from an experience of 116 cases, Prof. Guyon emphasizes first of all the immense importance of general therapeutics, which applies to all forms of cystitis. There is not the danger of irritating the bladder in tuberculous cystitis that there is in other forms, hence the diet should be abundant and extremely nourishing. Creosote ranks first in the medicines. He has also found cod liver oil useful. Local treatment must be very cautiously applied as the bladder is exceedingly sensitive. It should be examined as little as possible and irrigation avoided. But the local treatment is extremely important and should be commenced from the first, confining it to very weak solutions. He found boric acid, etc., injurious in any form, and restricts himself to sublimate and guaiacol. The sublimate is more effective: it is beneficial even in very weak solutions and in merely suspected cases. Four out of 33 patients treated with it, were completely cured; five much improved and eight moderately. He begins with a 1 to 5000 solution, raising this to 1 to 3000, and reducing the strength at the slightest evidence of irritation. It must always be borne in mind that the bladder can not stand even the weakest solution in any form but gradual instillations 30 to 40 drops are enough: 50 the maximum. The general treatment should be continued months, even if all the symptoms have long ceased. The surgical treatment was high cystotomy in sixteen cases: one recovery: two improvements: seven deaths and six negative results. Better results were attained with perineal drainage. With this in seven operations five were very much improved, one died and one was not affected. Nine women cured *per urethram* were all very much benefited with one exception.—*Bulletin Méd.*, No. 4.

Camphoric Acid in the Treatment of Night Sweats.—Dr. H. A. Hare in the *Therapeutic Gazette*, March, reports that in the January issue of the *Edinburgh Medical Journal* Dr. Ralph Stockman has contributed a paper in which he notes the value of camphoric acid in the treatment of night sweats, and quoted considerably from foreign literature on this subject in support of his own clinical experience. Dr. Hare has on several occasions in papers which have been published, and every year to his class of medical students, emphasized the value of this remedy as an antisudorific. His first experience with it was in the wards of St. Agnes' Hospital during 1890-91, where he found, as Dr. Stockman has, that it controlled the sweats of tuberculosis in the great majority of cases and did not produce any disagreeable symptoms whatever, such as are usually caused by atropin and other powerful antisudorifics. He has pointed out that twenty grains was usually quite sufficient to control the sweat, provided it was given early enough to be absorbed before the time the sweat was reached; and he also pointed out, what other continental observers had previously noted, that as much as sixty grains of this drug may be given without deleterious effect. A continued large employment of camphoric acid in the six years that have succeeded this report has still further confirmed his high opinion of this remedy. Like every other remedy, it will fail in some cases, but no remedy has been met with which in his hands so universally succeeds. It may be given in cachet, dissolved in whisky or brandy, or placed in dry powder on the tongue and washed down with a little water or milk; but as it is slowly absorbed it should be given an hour or two before the time at which the sweat usually comes on. The writer has also found camphoric acid of great value in the treatment of idiopathic pytalism as it is sometimes met with in young children, as it controls the salivation without disordering the digestion.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, JULY 3, 1897.

LIFE INSURANCE FEES FOR MEDICAL TOUTS.

For at least half a century the American medical profession has been conscious of the great injustice done it in the matter of fees for life insurance examinations. Of late this feeling has been intensified by the wanton reduction of fees to medical examiners, while at the same time the salaries of presidents were increased by thousands. While life insurance companies do not appreciate physicians highly in their proper functions as medical men they seem to understand their commercial value as advisers of families, to judge from the following offer to a local member of the medical profession, from one of the larger New York life insurance companies:

Knowing that among your large acquaintance more than two-thirds are thorough believers in life insurance, and a person anticipating placing insurance, will listen to the advice of his physician, a large amount can often be earned in this way, without inconvenience or taking your time from your regular line of work. If the following proposition is received favorably kindly notify me by mail and I will place your name on our records both here and in New York as a representative of this Society, which is the largest and strongest financial institution of this kind in the world, pays its death claims more promptly, gives better results on maturing policies and more liberal contracts than any other company in existence. On business I may secure through letters, personal introductions or names furnished by you, I will pay you 25 per cent. of the first year's premium. Business that comes direct from you without solicitation by myself or agent I will pay a commission of 50 per cent. of the first year's premium. Will furnish illustrations of the results of policies at any age, per your request on any plan you may suggest. If you keep this proposition in mind, and take advantage of it whenever the opportunity presents itself you will find that at the end of the year your profits from this source will have been very satisfactory.

This is an innovation introduced from that "right little, tight little, island" whose ideal medical men, so free from commercialism, will, the *Medical Press* greatly fears, be contaminated by chance contact with Yankee-dollar-adoring medical *ὁι παλλοι* at the coming meeting at Montreal of the British Medical Association. This commission dodge has long been adopted in Britain by the shady life insurance companies satirized by Dickens in "Martin Chuzzlewit," whose lash the medical tout of those days did not escape, as witness the picture of the "Anglo-Bengalee" dinner:

The lunch was handsomely served with a profusion of rich glass plate and china, which seemed to denote that eating and drinking on a showy scale formed no unimportant item in the business of the Anglo-Bengalee Directorship. As it progressed the Medical Officer grew more and more joyous and red faced insomuch that every mouthful he ate and every drop of wine he swallowed seemed to impart new lustre to his eyes and to light up new sparks in his nose and forehead.

In certain quarters of the city and its neighborhood Mr. Jobling was a very popular character. He had a portentously sagacious chin and a pompous voice, with a rich huskiness in some of its tones that went directly to the heart like a ray of light shining through the ruddy medium of choice old burgundy. His neckerchief and shirt-collar were ever of the whitest, his clothes of the blackest and slickest, his gold watchchain of the heaviest and his seals of the largest. His boots, which were always of the brightest, creaked as he walked. Perhaps he could shake his head, rub his hands or warm himself before a fire better than any man alive and he had a peculiar way of smacking his lips and saying "Ah," at intervals while patients detailed their symptoms, which inspired great confidence. It seemed to express: "I know what you're going to say better than you do; but go on, go on." As he talked on all occasions whether he had anything to say or not it was unanimously observed of him that he was full of anecdote and his experience and profit from it were considered for the same reason to be something much too extensive for description. His female patients could never praise him too highly and the coldest of his male admirers would always say this for him to their friends, that whatever Jobling's professional skill might be, and he had a high reputation, he was one of the most comfortable fellows you ever saw in your life.

Jobling was for many reasons not last in the list, because his connection lay principally among tradesmen and their families, exactly the sort of person whom the Anglo-Bengalee Company wanted for a medical officer. But Jobling was far too knowing to connect himself with the company in any closer ties than as a paid (and well paid) functionary or to allow his connection to be misunderstood abroad if he could help it. Hence he always stated the case to an inquiring patient after this manner.

"Why my dear sir, with regard to the Anglo-Bengalee my information you see is limited, very limited. I am the medical officer in consideration of a certain monthly payment. The laborer is worthy of his hire; bis dat qui cito dat (classical scholar Jobling, thinks the patient, well read man) and I receive regularly. Therefore I am bound so far as my own knowledge goes to speak well of the establishment. (Nothing can be fairer than Jobling's conduct, thinks the patient who has just paid Jobling's bill himself). If you put any question to me my dear friend," says the Doctor, "touching the responsibility or capital of the company there I am at fault for I have no head for figures, and not being a shareholder am delicate of showing any curiosity whatever on the subject. Delicacy, your amiable lady will agree with me I am sure, should be one of the first characters of a medical man. (Nothing can be finer or more gentlemanly than Jobling's feelings thinks the patient). Very good my dear sir; so the matter stands. You don't know Mr. Montague. I am sorry for it. A remarkably handsome man and quite the gentleman in every respect. Property I am told in India House and everything belonging to him beautiful. Costly furniture on the most elegant and lavish scale. And pictures which even from an anatomical point of view are perfection. In case you should think of doing anything with the company I'll pass you, you may depend upon it. I can conscientiously report upon you as a healthy subject. If I understand any man's constitution it is yours. And this little indisposition has done him more good maam." says the Doctor, turning to his patient's wife, "than if he had swallowed the contents of half the nonsen-

sical bottle in my surgery. For to tell the honest truth one-half of them are nonsense compared with such a constitution as his." (Jobling is the most friendly creature I ever met with in my life, thinks the patient, and upon my word and honor I will consider it.)

"Commission to you, Doctor, on four new policies and a loan this morning, eh?" said Crimble, looking, when they had finished lunch, over some papers brought in by the reporter. "Well done!"

"Jobling, my dear friend," said Tigg, "long life to you."

"No, no; nonsense. Upon my word, I have no right to draw the commission," said the Doctor; "I haven't, really. It's picking your pocket. I don't recommend anybody here. I only say what I know. My patients ask me what I know and I tell 'em what I know; nothing else. Caution is my weak side, that's the truth, and always was from a boy. That is," said the Doctor, filling his glass, "caution in behalf of other people. Whether I would repose confidence in his company myself, if I had not been paying money elsewhere for many years, that's quite another question."

"The Anglo-Bengalee" swindled its policy-holders. The life insurance company, which pays its medical touts large commissions while refusing its medical examiners proper compensation, is, on the most ordinary business principles, in imminent danger of sharing a like fate. To secure proper risks rather than great increase in business is *the* duty of a life insurance company. Payment of commissions to medical touts rather than proper fees to medical examiners may conduce to the benefit of the agent or of the president, but it certainly does not to the best interest of the policy-holders. Moreover, it is a procedure calling for examination by the State into the financial condition of the companies practicing.

THE TRANSMISSION OF LEPROSY.

The transmission of leprosy is a question that has long been an open one and in late years, notwithstanding the discovery of its germ in HANSEN'S bacillus, there has been more or less conflict of opinion as to the dangers of contact and infection and also as to its possible hereditary transmission. As to its contagiousness there is at present little doubt; the experience of countries where it has been introduced is evidence enough of this fact; under favorable conditions, as yet imperfectly known, it must be almost malignantly contagious. A couple of Chinese lepers introduced into the Sandwich Islands less than forty years ago have infected at the present day twelve per cent. of the native population; a brief visit to the tropics has been known to be followed by leprosy without any actual consciousness of exposure, and other still more striking examples are on record. On the other hand, there are some who consider its contagiousness as slight, and believe that as a public danger its importance has been unduly magnified. The government commission in India not long since took this view, and considered the isolation of lepers, other than vagrants, unnecessary.

It is not essential that we should adopt the view advanced a few years back, that there is at the present time a general increase or spread of this affection, a "recrudescence of leprosy," that bids fair to reproduce the conditions of the middle ages in Europe and trans-

mit them also to America. Our faith in medical science ought not to fail us to the extent of our believing that such conditions could be reproduced at the present time. It may be that we have only had our eyes opened to the prevalence of a disorder that unrecognized has existed among us all this time, but which in our climatic and other conditions is hardly a serious public danger, though formidable enough to its occasional victims. Nevertheless, with its capricious contagion, its repulsive character and its practical incurability, it is serious enough for us to use all means to prevent its spread where it exists, and to welcome any new additions to our knowledge that may be available for this purpose.

One of the most recent contributions to this subject is that of Dr. KARL WEBER of Halle in the latest issue of the *Deutsches Archiv für klinische Medizin*, in which he gives the result of a search by the various histologic methods, of which he gives the preference to the carbol fuchsin stain of ZIEHL-NIELSEN, for the lepra bacillus in the different tissues and fluids of the body, with a special object of ascertaining what are the readiest ways by which it can be transmitted. His results were negative as regarded the blood from healthy tissues, the saliva and the urine, but the lepra bacilli were found more or less abundantly in the blood and lymph from the diseased parts, in the dermal scales, the lanugo hairs, the perspiration and the spermatid fluid. They were especially abundant in the skin in all its layers, and it seems clear, accepting his findings and conclusions, that there is no limit to the possibility of the dissemination of these germs. The question remains, Are they in a living condition and capable of producing leprosy? It would appear from the uncertainty of the contagion as well as from culture and inoculation experiments that the vitality or at least the activity of these organisms must be at a low ebb for most of the time or that unfavorable external conditions or excessive resistance of healthy tissue limit their pathologic propagation. Otherwise we could hardly limit the extension of the disease and it is this remarkable saving fact, for such it seems to be, that prevents us from becoming a world of lepers. As Dr. WEBER says: "It is indeed remarkable that considering the tremendous number of these bacilli, the danger of infection is relatively slight, and we can base this fact, lacking positive proof, only provisionally on the assumption that the bacilli are either already dead in the skin, or that if still alive, they pass through many alterations after being thrown off, that cause their death. It is also supposable, that special conditions are requisite for infection to be possible." The thought that a leper is constantly throwing off innumerable HANSEN'S bacilli from the surface of his body, wherever he may be, is an unpleasant one at best, and if it were supposable that they all or any considerable proportion of them possessed their full virulence and activity it would be unendurable. The

facts, however, that the contagion of leprosy seems to be very slight in temperate climates, and even in the tropics, as in Hawaii, it is confined almost entirely to the native and Asiatic races and the whites generally escape, that it is sometimes not even communicated between husband and wife or parents and children, notwithstanding the intimate relation in which they live, indicate that some special conditions that do not generally exist are requisite for its transmission. On the other hand the very slight exposure that sometimes appears to be sufficient for its contagion and its uncertain and lengthy periods of incubation leave an unpleasant uncertainty in regard to any and every exposure. There will be many important practical questions for the consideration of the Conference on Leprosy that is to meet in Berlin next October, and its conclusions will be awaited with interest.

There are of course other questions that are of scientific interest, such as the relations of MORVAN'S disease and syringomyelia and other affections to leprosy, but the really practical ones are those that bear upon its contagiousness and its transmission. It will be a satisfaction if enough can be added to our knowledge of the disorder to remove some of the uncertainty that at present exists.

THE LATEST THEORY OF SLEEP.

In the *Journal of Experimental Medicine* for May, there appears an experimental investigation upon the physiology of sleep, by W. H. HOWELLS of Johns Hopkins University. His experiments were made to ascertain the variations in the volume of the arm during sleep by means of a plethysmograph, and the results indicated a vasomotor dilatation in the arm, which the experimenter attributes to a relaxation of tone in the vascular apparatus of the skin, a diminished peripheral resistance in the skin area and a corresponding lower arterial pressure and blood supply to the brain. This interpretation of his results leads the author to adopt a theory of sleep which he thinks is new in some of its features, and which he states as follows: "The immediate cause of normal sleep lies in a vascular dilatation (of the skin) that causes a fall of blood pressure in the arteries at the base of the brain and thereby produces an anemic condition in the cortex cerebri. This condition of anemia, in connection with the withdrawal of external stimuli, causes a depression of the psychic processes in the brain cells below the threshold of consciousness." The fall of blood pressure, he goes on to say, is due to a relaxation of tone in the vasomotor centers, and normal awakening is due to a resumption of vasomotor tone, and this involves an incessant activity of this center during waking from stimuli of all kinds, resulting finally in its fatigue with renewed relaxation and consequent sleep. This is the rhythmic cycle—a loss and a resumption of tone in the vasomotor center.

If the fatigue is not extreme, sleep can only be induced by the withdrawal of stimuli and this is an ordinary condition in the production of normal slumber. It may be that a certain degree of fatigue of the higher centers has also its action, and these factors may be said to enter into the production of normal sleep. 1. "A diminution of irritability, caused by fatigue, of large portions of the cortical area. 2. Voluntary withdrawal of sensory and mental stimuli involved in the preparations for sleep. 3. A diminished blood supply to the brain, owing to a relaxation of tone in the vasomotor center and the fall of general arterial pressure thereby produced. This last is the immediate cause of sleep and must always precede it; the first is comparatively unessential, as was shown by STRUEMPELL'S well-known case where cutting off the remaining sensory avenues to consciousness produced sleep at any time.

In favor of his view HOWELLS finds that awakening is accompanied by an immediate decrease of peripheral vascular tonus as shown by his plethysmographic tracings, which also showed the same corresponding with the increase of intensity of the slumber, though later there was a variance which he explains on the assumption that the cells of the cortex regain their activity sooner than do those of the vasomotor center, the slow recovery of the latter from fatigue thus insuring the needed rest for the organism as a whole, which would not be gained were the cortical cells chiefly involved.

While he claims this theory as new, at least in part, he admits that a somewhat similar one was once held by MOSSO, and later rejected, and also by HEGER as quoted by DE BOECK and VERHOEGEN. HILL also has recently proposed the idea that sleep is due to cerebral anemia caused by relaxation of the vasomotor centers for the splanchnic area. He does not refer to the notion that sleep is due to cerebral anemia caused by loss of inhibition over the vasomotor centers by fatigue of the cortical cells, advanced by DURHAM and others, which, as a very similar vasomotor and cerebral anemia theory, might well have been noticed in this connection. The ideas of HOWELLS do not, moreover, exclude any such theories as those of RAMON Y CAJAL and DUVAL, inasmuch as they do not attempt to explain the ultimate cell changes in the nervous centers. With the little we have learned of the effects of fatigue upon nerve elements, there seems to be a wide range of possibilities in this direction. The possibility moreover of a special sleep-regulating center has been suggested and is still an open question.

The theory of HOWELLS contains really only one novel feature, if it be novel, namely, the notion of a vasomotor relaxation in the skin correlated with anemia of the brain. The relations of the two to each other as cause and effect are not demonstrated, and in this respect it is not a very important addition

to previous theories. As an experimental contribution, however, to the physiology of sleep the paper has its value.

THE DIAGNOSTIC SIGNIFICANCE OF HEMOPTYSIS.

It is by no means always easy to determine at once the source of hemorrhage when blood is ejected from the mouth. It is true that certain peculiarities of appearance serve to distinguish the blood as it comes either from the respiratory or the digestive passages. Thus blood from the lungs is likely to be frothy and florid in hue, while that from the stomach is usually dark and clotted from the action of the gastric juice. In the one instance the hemorrhage attends or follows cough; in the other it is associated with vomiting or regurgitation. It must, however, be borne in mind that blood from the lungs may enter the stomach and be rejected by vomiting, while blood from the stomach may be inspired into the larynx and trachea and be expelled by cough.

Even when in a given case it is recognized that the bleeding has its origin in the air-passages it may be difficult to decide its precise source. In the majority of cases no doubt such hemoptysis results from disease of the lungs, usually tuberculous in nature, but in a considerable number the responsible lesion is situated in some other portion of the respiratory apparatus. It must be obvious that the discrimination means a vast difference in prognosis and in treatment. To this aspect of the subject interesting consideration is given by Dr. DAVID NEWMAN in a recent communication published in the *British Medical Journal*, May 29, 1897, p. 1900.

In the course of this paper it is pointed out that the tissues of the upper air-passages have a very free vascular supply and are constantly exposed to injury, so that blood vessels already weakened by disease are exceedingly liable to rupture. Clinical experience has shown that hemorrhage not rarely occurs from very trivial lesions of the pharynx and the larynx, being often attributed to tuberculous disease of the lungs, even in the absence of discoverable physical signs. Under such circumstances the laryngoscope will in many cases disclose the real source of the bleeding.

It is to be remembered in this connection that blood may come from the gums or the mucous membrane of the mouth as a result of either local or constitutional morbid states. Among the latter may be enumerated hemophilia, purpura, scurvy and anemia. Apart from changes in the blood and blood vessels hemorrhage into the larynx or pharynx may result from acute inflammation, ulceration, varicose veins or aneurysms and vascular tumors. The most common local cause of hemorrhage from the upper air-passages is a dilatation of the veins in the pharynx or larynx. From this source the bleeding is generally

slight, although it may be persistent. Tumors composed of blood vessels are seldom met with in the nasal mucous membrane and very rarely give rise to hemorrhage of the kind under consideration.

In all cases of hemoptysis the important point is to discover the source of bleeding. The mode of escape of the blood and the impressions of the patient can not be relied upon for diagnostic purposes in a doubtful case, so that the use of the laryngoscope or of the rhinoscope becomes often absolutely necessary. The presence of blood in the trachea is not always a certain indication that the extravasation came from the lungs; it may have come from the upper air-passages or even from the esophagus or the stomach. In the absence of evidence of a lesion of the parts last named the bleeding may be safely attributed to pulmonary disease, even though there be no demonstrable physical signs; and on this assumption treatment should be adopted until unmistakable symptoms or physical signs render the diagnosis certain. Under rare circumstances the possibility of malingering or deception will have to be considered and proper allowance made.

THE LATE MEETING OF THE OPHTHALMIC SECTION OF THE AMERICAN MEDICAL ASSOCIATION.

This was of National importance; its members included physicians from every portion of the United States: in reputation for competent work and honorable conduct they were of the best; for unceasing devotion to the interest of the Section they could not have been excelled; in short, it was a representative body of working American ophthalmologists.

Its officers, led by the Chairman, Dr. GEO. E. DE SCHWEINITZ, presented a program of exceptional interest; including seventy papers, with discussions opened by persons selected for their familiarity with each topic. This gave the Section a careful study not only by the author of the paper but by one or more other member, all speaking directly to the same point. Ten minutes only was allowed to each paper and five to each person discussing the same, and no person could speak twice. As the Chairman impartially enforced these rules, the meeting moved forward with the regularity of clockwork, making tediousness impossible.

Over six-sevenths of the papers were completed in the time appointed for Section work without curtailing reasonable discussion.

Of the important subjects discussed, were ROENTGEN rays in ophthalmic surgery, with experimental researches for locating foreign bodies within the eye. Drs. H. F. HANSELL and WM. M. SWEET, presented this matter in such a way as to interest and instruct, by giving not only their own personal work, but that of others.

The discussion upon the implantation of a glass ball as a support of an artificial eye, showed that this procedure was gaining in popularity.

Dr. ROBERT RANDOLPH's paper on the Bacteriology of the Conjunctiva, with its discussion by Dr. HAROLD GIFFORD, placed before the Section scientific researches of a practical nature. It was shown that all the bacteria could not be removed from the conjunctiva by any means that would not destroy the same, though masses of the bacteria could be safely removed. Working details for the practical ophthalmologist were given.

Dr. E. A. DE SCHWEINITZ's paper upon the Best Methods of Sterilizing Ophthalmic Instruments was another contribution of original investigation valuable to all who use surgical instruments.

It suffices to mention the fact that Dr. H. KNAPP reported a study of one thousand cataract operations with comments, as all having to do with such cases will read it with profit. His discussion of many other topics greatly enriched the proceedings. Other phases of cataract operations were treated by papers as the after-treatment of cataract cases with especial reference to the use of germicides by Dr. J. A. WHITE of Richmond; The Best Methods of Preparing Dressings for Cataract Cases, by Dr. C. A. WOOD, etc.

Glaucoma was discussed in different aspects by Dr. D. S. REYNOLDS and Dr. S. D. RISLEY.

An interesting group of papers treated of special tumors of the orbit, and abscesses of the same locality.

Trachoma was considered in a series of carefully prepared papers; its surgical management; its medical treatment; the value of jequirity; the treatment of complications; the hygiene of trachoma; ten years with the surgical treatment of trachoma and the relative infrequency of trachoma in Southern California. Each participant in this series was especially qualified therefore by extensive experience that the total result was of high scientific and practical value. Alone these papers will be worth many times the cost of the Transactions of this Section.

Space fails to farther specify the exceptionally good work done by this Section.

It is permitted to say that the reason for this scientific excellence lies in the fact that its members work for the good of the entire Section equally with their own. There is not and has not been for years any wire pulling for official position. Provision is made by the rules for the selection of those who can best serve the Section and these are elected as its servants.

Reference to its social features must not be omitted as these are helpful to its development. All who have attended its social reunions feel that they are in the midst of a band of brothers working for the common good, and the advancement of their art. Old acquaintances are renewed and new ones formed, by those who have known each other by their published work.

Altogether the Ophthalmic Section of the AMERICAN MEDICAL ASSOCIATION is a model medical society. Other Sections are working toward the same end along similar lines; even the ASSOCIATION itself is tending thither. When these have become altogether like the Ophthalmic Section, membership therein will be prized most highly, and inability of members to attend the annual meetings will be regarded as a serious personal loss, loss of professional attainment and of professional fellowship.

The Chairman for the coming year is Dr. HAROLD GIFFORD of Omaha, Neb., the Secretary Dr. ROBERT RANDOLPH of Baltimore, Executive Committee Dr. EDWARD JACKSON of Philadelphia, Dr. L. HOWE of Buffalo, N. Y. and Dr. G. E. DE SCHWEINITZ of Philadelphia. The work of the Section republished from the JOURNAL with list of members, etc., can be secured from the secretary or from the JOURNAL office for one dollar.

CORRESPONDENCE.

Section Work at the Meetings of the American Medical Association.

PHILADELPHIA, PA., June 21, 1897.

To the Editor:—Your discussion of "*The Ideals of the Profession*" is a most moderate and timely one. It is, *unfortunately*, based upon the idea that the members of our profession invariably improve, as they grow older, showing by the end of the tenth year a well rounded perfection in science, arts and ethics.

If this were so, the suggestion to keep the younger men back till they had been in practice ten years, would be most valuable. *Unfortunately*, in some of us at least, time emphasizes our faults as well as our virtues, and there are no more blatant advertisers, none more ready to rush into print, in either the medical or the lay press, none more eager to be the first to report "something new" based mayhap upon a single case, than some of the so-called leaders of the profession who have been in practice for ten years or even a longer period.

Many a "modest youth" has blossomed into the obtrusive advertiser of older years.

Further, in these days of "*systems*" it is sometimes doubtful whether we are *always* getting original work from the busy "ten year olds." A dozen young men to make compilations from the journals and libraries, a shorthand, typewriting medical amanuensis "to lick" the copy into shape, and there is not much else left for the ten year graduate to do, but to affix his signature and perhaps read the paper, which he can also do by proxy.

As regards the regulation of the Section work, much can be done by a judiciously energetic chairman.

In this great and glorious republic of letters, everybody is at liberty to leave the room when the paper by a graduate of less than ten years is being read, while those older graduates (and perhaps some younger ones) who place their names and titles upon the Section program for advertising purposes only, can be cut off, by requiring that the chairman and secretary of the Section shall be imperatively obligated to exclude from the reading, and from the columns of the JOURNAL, all those who have not placed in the hands of the secretary of that Section upon the day of the registration of the meeting of the ASSOCIATION for that year, a copy of the paper to be read as a guarantee of good faith. The provision of a month in advance as it

now stands, is inoperative, because from the exigencies of a physician's work it has been found impracticable.

Yours truly, E. W. HOLMES, M.D.

The Vile Osteopathy Bill.

OMAHA, NEB., June 25, 1897.

To the Editor:—I am glad to see you publish the names of the senators who supported the vile osteopathy bill in your legislature. Now, if every doctor in Illinois (my native State) will cut the list out and paste it in his hat, and then fill his political pocket full of stones for the benefit of these creatures when they raise their heads above the grass, something practical will be accomplished. This form of "argument" is the only one that really reaches the vitals of the average politician. In the Nebraska legislature last winter our bill for an examining board was defeated, largely owing to the opposition of an Omaha senator, who was, immediately after, the nominee of his party for mayor of this city. At least fifty physicians at once organized in opposition to the gentleman and, in a close election, we had the satisfaction of seeing him defeated by 200 votes. We actually found that doctors have a good many friends who are willing to favor them if they will simply get out and ask for what they want, just as other fellows do. The trouble in the past has been too much modesty and too little uniformity of action. Our fight for an improvement in our medical law is all that kept osteopathy in the background in Nebraska. A bill was prepared and ready to introduce, but there were too many doctors on deck all winter to allow any crooked work. All honor to your governor and to those of South Dakota and Colorado for their sensible stand on this vicious bill. It seems to me that the doctors in those States should remember them most kindly for all time to come.

Respectfully yours, B. G. CRUMMER, M.D.

ASSOCIATION NEWS.

Recommendation of Section on Neurology. Report of Committee on President's Address.—Your Committee, to whom was referred the address of the Chairman of the Section, beg leave to report as follows: That they believe it expedient that the work of this Section should be divided and that the part dealing with Medical Jurisprudence should be included in the work of the Section on State Medicine or that a separate Section should be instituted to deal with the subjects included under the term Forensic Medicine. They, however, deem it inexpedient to take any action at this time regarding such a division.

They strongly recommend for adoption, the recommendation of the Chairman that the office of the Secretary of the Section so far as possible be made permanent. This can not be done under the By-laws of the ASSOCIATION, but the same result can be reached, if those who regularly attend the meeting of the Section reach a tacit understanding that the secretary is to be re-elected each succeeding year. This, we think, is the most important step to take to secure continuity in our work on some sort of stable membership for the Section. We feel that unless a certain number of men throughout the country interested in neurological science, are interested from year to year in the work of the Section, the largest measure of success can not be achieved.

We would further recommend that a small voluntary assessment be made annually upon the members attending the Section, which shall be devoted to postage and other incidental expenses of the secretary, while the transportation of the secretary to and fro from the place of meeting be paid from this fund.

We recommend for adoption the following:

Resolved, That the Section on Neurology and Medical Jurisprudence endorse the neural terms adopted by the American

Neurological Association, the Association of American Anatomists, and the American Association for the Advancement of Science, and so far as practical recommend their use in the work of the Section.

All of which is submitted,

C. K. MILLS,
C. H. HUGHES,
HAROLD N. MOYER.

Philadelphia, June 2, 1897.

Rush Monument Fund.—At the recent annual meeting of the American Medico-Psychological Association, the undersigned were appointed a committee to coöperate with a similar committee of the AMERICAN MEDICAL ASSOCIATION, to urge the completion of the project to erect a memorial at Washington to Dr. Benjamin Rush. Since then the semi-centennial jubilee of the latter body has been held at Philadelphia, and a feature of the occasion was the enthusiastic resolve to raise a fund of \$100,000 for the erection of such a monument as shall be creditable to its illustrious subject and to the great profession of which he was so distinguished a member. This action makes it all the more incumbent upon the American Medico-Psychological Association to contribute its full share to the accomplishment of this commendable National undertaking. Dr. Rush's prominence as an alienist whose views were far ahead of his time, and whose work on insanity was a standard authority in Europe, as well as America, for more than half a century after his death, makes it particularly our duty to honor his memory—first as one of ourselves and as a master in our special line of inquiry; and, further, because of his eminence as a teacher, writer and general practitioner and renowned Revolutionary patriot.

Your committee, therefore, most earnestly solicits your prompt subscription to the fund which, it is hoped, you will make commensurate with this Association's estimate of this great physician and psychologist.

Contributions may be made to any member of the Committee.

George H. Rohé, Sykesville, Md.; J. T. Searcy, Tuscaloosa, Ala.; John Curwen, Warren, Pa.; Benj. Blackford, Staunton, Va.; T. J. W. Burgess, Montreal, Can.; A. B. Richardson, Columbus, Ohio; Wm. M. Edwards, Kalamazoo, Mich.; H. A. Gilman, Mt. Pleasant, Ia.; Chas. P. Bancroft, Concord, N. H.; P. M. Wiese, Albany, N. Y.

Colorado's Contribution to the Rush Monument Fund.—Colorado has already fulfilled the pledge for a \$2,000 contribution to the Rush Monument Fund, made by Dr. Graham at the meeting of the AMERICAN MEDICAL ASSOCIATION at Philadelphia. At the meeting of the State Medical Society, June 15, the full sum pledged by Dr. Graham was immediately raised by individual subscriptions offered most generously and with great enthusiasm.

Competition for the Senn Medal. Pursuant to a resolution adopted by the Section of Surgery and Anatomy of the AMERICAN MEDICAL ASSOCIATION, June 4, 1897, I have been appointed by the Chairman, Dr. Reginald H. Sayre, as Chairman of the Committee charged with the awarding of the Senn Medal for 1898. The other members of the Committee are Drs. H. O. Walker of Detroit, Mich., and S. H. Weeks of Portland, Me.

1. A gold medal of suitable design is to be conferred upon the member of the AMERICAN MEDICAL ASSOCIATION who shall present the best essay upon some surgical subject.

2. This medal will be known as the Nicholas Senn Prize Medal.

3. The award shall be made under the following conditions: a. The name of the author of each competing essay shall be enclosed in a sealed envelope bearing a suitable motto or device, the essay itself bearing the same motto or device. The title of the successful essay and the motto or device to be read at the meeting at which the award is made, and the corresponding envelope to be then and there opened and the name of the successful author announced. b. All successful essays become the property of the ASSOCIATION. c. The medal shall be conferred and honorable mention made of the two other essays considered worthy of this distinction, at a general meeting of the ASSOCIATION. d. The competition is to be confined to those who at the time of entering the competition, as well as at

the time of conferring the medal, shall be members of the AMERICAN MEDICAL ASSOCIATION. e. The competition for the medal will be closed three months before the next annual meeting of the AMERICAN MEDICAL ASSOCIATION, and no essays will be received after March 1, 1898.

Competitors will address their essays to the undersigned.

J. McFADDEN GASTON, M.D., Chairman.

1½ Edgewood Ave., Atlanta, Ga.

SOCIETY NEWS.

Connecticut Medical Association.—The one hundred and fifth annual meeting of the Connecticut Medical Association was held at Hartford May 26 and 27. Among others, papers were read by Dr. M. M. Johnson on "The treatment of pus cases in appendicitis," and Dr. A. N. Alling on "Foreign bodies in the eye." The following officers were elected: President, Dr. R. S. Goodwin; vice-president, Dr. H. P. Stearns; secretary, Dr. Dr. J. La Pierre, treasurer, Dr. W. W. Knight.

Mississippi Valley Medical Association.—The next meeting of the Mississippi Valley Medical Association will be held in Louisville on Oct. 5, 6, 7 and 8, 1897. All railroads will offer reduced rates. The President, Dr. Thomas Hunt Stucky, and the Chairman of the Committee of Arrangements, Dr. H. Horace Grant, promise that the meeting will be the most successful in the history of the Association, and this promise is warranted by the well-known hospitality of Louisville and Kentucky doctors. Titles of papers should be sent to the secretary, Dr. H. W. Loeb, 3559 Olive St., St. Louis.

National Association of Military Surgeons.—The Association held its sessions at Columbus, Ohio, May 25 to 27. Dr. J. D. Griffith, Kansas City, Mo., was chosen president. The Doctor read a paper, before the Association, on the effects of the Krag-Jorgensen rifle with which he experimented at Forts Riley and Leavenworth for several years. His experiments show that loose earth is a good protection against these bullets, which penetrate steel, oak and solid earth. The numerous other papers presented will be published in the "Transactions." Kansas City, Mo., was chosen as the next place of meeting for 1898.

The Eleventh Congress of Anatomy was held at Ghent in April, with over 50 members in attendance from America, Japan and all the European countries. Schultze presented specimens of his "transparent embryos," for study of the skeleton, and described his method of preparing them. Laguesse described the histogenic development of the pancreas, and Unna the epithelial nature of nevus cells. Retzius called attention to a hitherto unnoticed convolution (apophysis) of the temporal lobe common to mammals, rudimentary in man. The most important of the numerous interesting contributions was K. v. Bardeleben's communication of the results of his extensive research in the Innervation of the Muscles. Henceforth new points for stimulus must be sought, instead of those now accepted, and he claims to have established a firm basis for future neurologic work. He has found a great number of hitherto unknown nerve ramifications in the walls and sheaths of the vessels, sinews, etc., some of which are so evident that it is remarkable that they have not been noted before. He states that each muscle nerve divides invariably into two branches, or the main stem sends out one branch abruptly. Each nerve also sends out one or more vasomotor nerves, usually just as it enters the muscle, rarely at its distal end. As the nerve reaches the muscle it sends out at least one returning branch toward the proximal end of the muscle. He also affirms the existence of an intramuscular plexus in all the larger muscles, and of dual innervation of the brachialis int., pectineus, lumbricalis III m., and III p., adductor magnus and hallucis, etc., mentioning thus eleven muscles with double innervation, some of which are already known. He queries whether the intramuscular plexus may not be the cause of the simultaneous

innervation of a whole muscle. Further details are given in the *Deutsche med. Woch.* of June 3 and his report is to form Vol. 2 of his Handbook of Anatomy.

Medical Society of New Jersey.—The one hundred and thirty-first annual meeting was held in the United States Hotel, Atlantic City, June 22 and 23, 1897. President T. J. Smith presiding. There was a large attendance of the prominent physicians of the State. The president's address was on "The Problem of Dependency," in which he urged the establishment by the State of a colony for epileptics. The society appointed a committee to consider the matter with power to act. A very interesting discussion took place on the question "In the treatment of appendicitis is the free use of the knife necessary?" Both sides were ably presented, but the large majority of the speakers believed that the knife was used too frequently. Able reports were presented on each of the following departments concerning the progress made during the past year: Medicine and Therapeutics, Surgery, State Medicine and Hygiene, Diseases of Nose and Throat, Eye and Ear, Bacteriology. Papers were also read on "The present status of serum treatment of diphtheria," by Dr. McAlister; "Infantile diarrhea," by Dr. W. E. Darnell; "Some of the effects of constipation and their treatment," by Dr. J. Daland; Third Vice-President L. M. Halsey's essay was on "Headaches, auto-intoxication a factor." Dr. L. F. Bishop read a paper on "Some important points in the treatment of pneumonia," and Dr. R. C. Newton on "A criticism of modified milk and present dairy methods." The prize this year for the Fellows' Prize Essay, \$100, was awarded to George Bayles, M.D., of Orange. Action was unanimously taken in favor of the Rush monument and against the antivivisection bill pending in Congress. The officers elected are: President, D. C. English, New Brunswick; first vice-president, C. R. P. Fisher, Bound Brook; second vice-president, Luther M. Halsey, Williamstown; third vice-president, John J. H. Love, Montclair; corresponding secretary, E. L. B. Godfrey, Camden; recording secretary, William Pierson, Orange, and treasurer, Archibald Mercer, Newark. The latter three were reelected. The personnel of the Standing Committee remains unchanged, although the time of service is modified. It consists of Drs. William H. Izard and Stephen Pierson for three years, H. W. Elmer and Henry Mitchell for two years, and M. Lampson and Charles Young for one year. Hereafter the sessions will last three days instead of two. The next will be held at Asbury Park on June 28, 29 and 30, 1898.

Colorado State Medical Society.—The twenty-seventh annual convention of the Colorado State Medical Society was held at Denver June 15 to 17. Many rare old books on medicine and chemistry were exhibited, and also surgical instruments, etc., of bygone days. Among these was the medicine chest carried by Dr. Livingstone on his African explorations. The following papers were presented: "The ancient and modern instruments used in diagnosis and treatment of diseases of the stomach," C. D. Spivak, Denver; "A case of nasal sarcoma," W. W. Bulette, Pueblo; "Treatment of Pott's disease of the spine," G. B. Packard, Denver; "Relation of diseases of the ear to those of the throat and nose," John M. Foster, Denver; "Electricity in diseases of women," Minnie C. T. Love, Denver; "Progress toward accurate therapeutics," J. T. Melvin, Saguache; "Post-abortive sepsis, with report of cases," P. E. Hyrup-Pedersen, Denver; "Report of surgical cases," Leonard Freeman, Denver; "An operation for appendicitis and its after-treatment," W. A. Kickland, Loveland; "Prophylactic gynecology," R. R. Walker, Paris, Texas; "The radical cure of hernia, with report of a case," Frank Pinney, La Junta; "The clinical uses of stethoscopic pressure," Henry Sewall, Denver; "Nasal polypi," P. F. Gildea, Colorado Springs; "Chronic lead poisoning," E. C. Hill, Denver; "A case of unilateral optic neuritis, complete recovery," George Cleary, Denver; "Removal of coal and powder stains from the cuticular integument," George W. Miel, Denver; "What infer-

ences may be drawn from cases of pulmonary tuberculosis reported to have originated in Colorado," S. G. Bonney, Denver; "Ichthyol in the treatment of diseases of the eye," D. H. Coover, Denver; "Medical customs of the Mexicans and Rocky Mountain Indians," M. Beshoar, Trinidad; "Puerperal mastitis," Laura Liebhart, Denver; "Two cases of tumor of the cerebellum," H. T. Pershing, Denver; "Colorado Springs up to date," R. K. Hutchings, Colorado Springs; "Prophylactic treatment of tuberculosis," Frank E. Waxam, Denver; "Insanity of adolescence," Frank P. Norbury, Jacksonville, Ill.; "Difficulties in the diagnosis of the states of unconsciousness," J. T. Eskridge, Denver; "The relations of malpositions of the macula lutea to heterophoria," G. Melville Black, Denver; "Diagnosis, prognosis and treatment of mastoiditis," W. C. Bane, Denver; "Some practical points gathered from sources wise and otherwise," Will B. Davis, Pueblo; "The character of pulmonary cases sent to Colorado," W. H. Campbell, Colorado Springs; "Migraine in Childhood," H. F. Hazlett, Pueblo; "Chloroform in labor," Kate R. Lobinger, Denver; "Treatment of uterine fibroids," I. B. Perkins, Denver; "Inequality of pupils observed at an altitude of 10,250 feet," E. T. Boyd, Leadville; "How does our school system influence the health and development of the child?" E. Stuver, Rawlins, Wyo.; "Thirty-five cases of appendicitis, remarks," F. M. Cochems, Salida; "Puerperal eclampsia," J. D. Rothwell, Denver; "Present status of serum therapy," Alfred Mann, Denver; "Physical signs of acute bronchitis," J. N. Hall, Denver; "Galvanism in ulcerative keratitis," R. F. LeMond, Denver; "Operative treatment in dislocations and fractures," C. B. Nichols, Denver; "Importance of diet in infancy," H. B. Whitney, Denver; "Shock from a medical standpoint," E. P. Hershey, Denver; "Use and abuse of the uterine curette," H. G. Wetherill, Denver; "An abdominal section on an infant sixty-four hours old," E. J. A. Rogers, Denver; "Surgical treatment of diseases of the gall bladder," Neil Macphatter, Denver; "Observations deducted from three years' work in fractures," F. H. McNaught, Denver; "Dental reflexes affecting the eye and ear," J. R. Robinson, Colorado Springs; "Some controverted points in medico-legal matters," J. H. Pershing, Esq., Denver; "The effects on bone of the new bullet used by our army," J. D. Griffith, Kansas City; "Methods and results in 450 cases of fracture of the bones of the forearm," C. A. Powers, Denver.

PUBLIC HEALTH.

Mortality of the Leading Diseases in New York City.—The records of the last year show that 9,600 deaths have occurred through pneumonia, which heads the list; then comes consumption, with 8,250; diarrheal diseases, with 5,900 victims, followed by heart diseases, which killed 3,840; Bright's disease, 3,270; bronchitis, 2,880; diphtheria, 2,370, and apoplexy, 1,950. The total depopulation by death last year amounted to 72,780.

Money for Famine Sufferers.—Bishop James R. Thoburn, chairman of the Interdenominational Distributing Committee of India, has received \$40,000 through Thomas Cook & Son, bankers. Thus far \$100,000 has been cabled. The fund for the suffering has reached \$180,000. Next week \$40,000 more will be cabled, and it is expected that the amount that will aid in relieving the starving people will reach \$200,000.

Scarlet Fever at Plainfield, N. J.—Only two new cases of scarlet fever were reported June 19. The city and State boards of health have traced the origin of the epidemic to a dealer, whose son while ill handled the milk. Under the supervision of the Health Inspector 500 quarts of milk ready for delivery were dumped into the sewer. The son was quarantined.

The Profession of Medicine a Department of the State.—Dr. C. F. Marks, the retiring president of the Queensland Branch of the British Medical Association proposed in his address that the medical care of the people should be part of a Public Health Department of the State. He suggested that a medical service for the whole colony be established, modeled somewhat on the lines of the Army Medical Service. The country should be divided into suitable districts having a senior and two junior men to each, with relieving officers and inspectors: salaries to begin at not less than £300 a year, and promotion to be by

years of service or for distinguished service on ballot of all the medical officers. Dr. Marks assumes that there are about two hundred practitioners in Queensland, with, roughly, an average income of £1,000 a year, and the population is about 500,000. A sum of 8 shillings per head of population raised by government taxation would give ample funds for the scheme, allowing for fair superannuation allowances. Such a scheme, he maintained, was the only remedy for the present abuses of lodges, dispensaries and hospitals. At the annual conference of the Political Labor League of New South Wales on January 26, it was moved and carried, "That the care of the public health being among the first duties of the state, the practice of medicine should be a national service, the country to be divided into medical districts in charge of government medical officers, whose services shall be absolutely free." The proposal met with general approbation.

The Report of the German Commission on Plague. The German Commission on plague at Bombay has issued a report which is dated March 19, and has appeared in the *Deutsche Medicinische Wochenschrift*. Professor Gaffky acted temporarily as the head of the commission until the arrival of Professor Koch from the Cape. It reached Bombay on March 8 and immediately began work in the Municipal Building, where a laboratory already had been provided by Dr. Bitter, the Egyptian Commissioner. There was some difficulty in obtaining an adequate supply of subjects, owing partly to the religious prejudices of the natives against postmortem examination and partly to the number of bodies taken by the commissions of the various foreign nations. But by the courtesy of the authorities and of Dr. Bitter, a pupil of Professor Koch, arrangements satisfactory to the German Commission were eventually made. It was very soon found that the bubonic virus in the great majority of cases penetrated into the human body through small lesions of the skin. The glands of the neighborhood then began to swell and, when the quantity of virus absorbed was not too large, they were able to retain and to destroy it. When the bacilli were present in large quantities they made their way through the lymphatic glands and were then found everywhere in the blood in the internal organs. This was the typical form of bubonic septicemia. When a gland suppurred the bacilli might be removed from the body, but a dangerous septicemia caused by streptococci might result. The bubonic bacilli were present in large quantity in the patient's urine and feces, and in this way the virus might become spread everywhere. In another group of cases the virus was apparently absorbed by the lungs and under these circumstances primary pneumonia was commonly found, the lungs containing plague bacilli along with diplococci and streptococci. It is obvious how dangerous the sputum of such patients must necessarily be. Primary infection from the intestinal canal was not observed in any instance, but sometimes it appeared to arise from the tonsils. The low standard of living of the native population, their dirty habits, and their objection to hospital treatment were very favorable to the great spread of the epidemic, but the Europeans were almost entirely exempt. After the new Epidemic Diseases Act of 1897 came into operation the authorities took more active measures, and the special commission under the presidency of General Gatacre, displayed praiseworthy energy in providing for the compulsory removal of patients to the hospitals and for the isolation of suspicious cases in the so-called segregation camps. The report states that for the purpose of a bacteriologic examination it was not sufficient to take a single drop of blood from the finger, as this method gave a satisfactory result only when the bacilli were present in very large quantity. An agar culture must be made in doubtful cases; the colonies were usually developed after forty-eight hours. The bubonic glands should not be punctured for diagnostic purposes, because of the risk of admitting the virus into the blood vessels. The commission found that if blood serum obtained from either persons or animals convalescent from plague was mixed in a test tube with a culture of plague bacilli it had a specific influence on them. Cultures of other bacteria treated in this way became opales-

cent throughout their whole extent, but the plague bacilli formed small coagula which, in course of time, fell to the bottom of the test tube, leaving the supernatant fluid clear. This so-called "paralysis" of the bacilli was identical with that observed in the case of enteric fever and cholera and led to the inference that artificial immunization might be possible, but the commission has not yet finished its researches on this subject. The commissioners state that they were unable to express a definite opinion as to the efficacy of the immunization methods of M. Haffkine and Dr. Yersin.

NECROLOGY.

N. P. JOYNER, M.D., was drowned in the St. Lawrence River during the forenoon of June 23, while going to Grindstone Island to attend a patient. The oarsman who stood up to adjust a sail, capsized the boat, but by clinging to it saved his own life. Dr. Joyner leaves a widow and parents in Kingston, Canada. His body was recovered.

R. J. GOODMAN, M.D., Sparks, Ga., June 16.—Josiah H. Dodge, M.D., Pana, Ill., June 24, aged 76 years.—J. H. Tanner, M.D., New Haven, Ill., June 24.—Joseph J. Boynton, M.D., South Framingham, Mass., June 17, aged 64 years.—Chauncey Clark Robinson, M.D., Milwaukee, Wis., aged 76 years.

JOSEPH WAGGONER, M.D., Ravenna, Ohio, died June 6, from an attack of angina pectoris, aged 75 years. He was born in Richmond, Jefferson Co., Ohio: was a graduate of Cleveland Medical College and had been in active practice since 1847. He was acting assistant surgeon, U. S. A., at Lincoln Hospital, Washington, in 1863 and a member of the AMERICAN MEDICAL ASSOCIATION, Ohio State Medical Society, Northeastern Ohio Medical Society and Portage Co., Medical Society.

BOOK NOTICES.

New Volume of Hare's System of Practical Therapeutics. A System of Practical Therapeutics by eminent Authors. Edited by HOBART AMORY HARE, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia. Volume IV. Octavo, pp. 1065, with illustrations. Regular price, cloth, \$6; leather, \$7; half Russia, \$8. Price of Vol. IV to subscribers to the System, cloth, \$5; leather, \$6; half Russia, \$7. Price of the System complete in four volumes of about 4500 pages, with about 550 engravings, cloth, \$20; leather, \$24; half Russia, \$28. Philadelphia and New York: Lea Brothers & Co., Publishers. 1897.

Dr. Hare's publications are so uniformly successful that it is almost enough to say of any book that he is the author of it to insure its favorable reception at the hands of the profession. In this case, where he appears as the editor of a system, his experience as an editor is not less valuable. It will be seen by the list that although a new corps of authors have been selected for this 4th volume, "the drum is in hands that know how to beat it." The great change that has taken place in therapeutics in the last few years makes it necessary for one to have at hand for reference the latest book on the subject, and among them the system edited by Dr. Hare has few if any superiors. In the present volume there are considered recent advances in hydrotherapy, tuberculosis, syphilis, typhoid fever and malaria, scarlet fever and measles, diseases of the nasal chambers, diseases of the uvula, pharynx and larynx. New facts in methods of treatment of diphtheria, asthma, bronchitis and whooping cough, abscesses and gangrene of the lungs, diseases of the heart, blood, liver, stomach and skin, and obesity, diabetes, peritonitis including appendicitis, etc.

Among the many valuable articles of interest we may refer especially to that of Dr. Metzger on the treatment of obesity, wherein he refers to his own experience in the treatment of obesity by the thyroid gland preparation, which experience he says is of the most satisfactory kind, none of his patients ever having had a complaint to make.

Dr. Parks in the treatment of diphtheria believes it is "no exaggeration to say that in diphtheria antitoxin we have a remedy superior to all others combined, and in no wise interferes with other treatment."

Dr. Ingals has an interesting article on the nasal affections, etc., mostly from a surgical standpoint.

We congratulate the editor on the publication of this great volume.

A System of Medicine by Many Writers. Edited by THOMAS CLIFFORD ALBUTT, M.A., M.D., LL.D., F.R.C.P., F.R.S., F.S.A. Volume III. New York: The Macmillan Company. 1897. 8vo, cl., pp. 1176. Price \$5.

Our cousins across the water have no intention of being left behind in the contributions to the medical literature of the period, and the present volume is a monument to the industry of the editor and the erudition of the contributors. The present bulky volume treats of the following subjects. viz.:

1. Epilepsy, actinomycosis, Madura foot.
2. Diseases of uncertain bacteriology: *a.* Not endemic. *b.* Endemic. Diseases not endemic are measles, scarlet fever, chickenpox, smallpox, mumps, whooping cough. Under this head also is included an essay by Dr. Craiger on the coexistence of infectious diseases. Under endemic diseases are described the climate diseases of India, typhus fever, dengue, yellow fever, dysentery, beriberi, Malta fever, epidemic dropsy, negro lethargy, frambesia.

3. Infective diseases communicated from animals to man: *a.* Glanders. *b.* Anthrax. *c.* Vaccinia. Foot and mouth disease, rabies, glandular fever.

4. Diseases due to protozoa: Malarial fever, hemoglobinuric fever, amebic dysentery. Diseases due to intoxications: Poisoning by food, grain poisoning, mushroom poisoning, snake poison and snake bite, alcoholism, opium poisoning and other intoxications, metallic and some other forms of poisoning, including poisonous trades. Diseases due to internal parasites: Psorospermiasis, worms, platyhelminthes and nemathelminthes, bilharzia, hematobia, hydatid disease.

Addenda: Sero-diagnosis of typhoid fever, supplement to the article "plague," addendum to "Yellow fever."

The volume is illustrated by 77 illustrations, 6 charts and map and a colored plate. The volume is fully equal in interest to its predecessors and is entirely trustworthy on the subjects mentioned.

The article of Dr. Joseph Fayrer on the climate and some of the fevers in India is a notable paper, and brings a vast amount of information which is not accessible to the majority of physicians.

In regard to climate, he quotes as appropriate to that of India Milton's description of the trying climate in "Paradise Lost":

"For hot, cold, moist and dry, four champions fierce,
Strive here for mastery and to battle bring
Their embryon atoms."

The limit of space alone prevents us from quoting more extensively from the volume.

Hysteria and Certain Allied Conditions. Their nature and treatment, with special reference to the application of the Rest Cure, Massage, Electropathy, Hypnotism, etc. By GEORGE J. PRESTON, M.D. Illustrated. Philadelphia: P. Blakiston, Son & Co., 1012 Walnut St. 1897. 8vo. Cl., pp. 298. Price \$2.00.

This book is to be commended for the reason that while there is no particular dearth of literature on the subject, recent literature is so scattered through the journals and the general text-books, that it requires labor to consolidate and bring it into view, although most of the text-books on practice of medicine as well as those on nervous and mental diseases contain chapters on the subject.

The author looks to the prevention of the disease with the most striking results. Much may be accomplished he says, "in the way of prophylaxis by the judicious education of body

and mind of children and great care should be exercised as to their physical development. The love of out-door life should be strenuously inculcated and every inducement to out-door exercise offered. The love of nature or fondness for out-door sports has saved many a life that was already predestined to hysteria. A great deal depends upon the systematic training of this class of children. Their education should be in competent hands and it should be supervised by some one conversant with the child's disposition.

The school hours should not be long but the child should be kept occupied while in school. Contests for prizes should so far as possible be discouraged. As the child grows older the reading should be carefully directed and sentimental literature be forbidden. There is much truth even if there is a little exaggeration in what Tissot says, "If your daughter reads novels at fifteen she will have hysteria at twenty." The development of the sexual life is a period especially to be watched, and children should have these matters explained to them as soon as they are old enough to understand. The morbid curiosity surrounding this physiologic question should be early replaced by a clear understanding of the principles of reproduction. It should be the great effort of those directing the education of the class of children of which we have been speaking to avoid all emotionalism and sentimentalism, to inculcate healthy views of life, to suppress the tendency to excess in matters social or religious and to implant the principles of sound morality."

"The vigorous out-door life of the English has developed a race in which there is very little hysteria, while the more artificial excitable life on the Continent has had the opposite effect."

Concerning the treatment of hysteria by hypnotic suggestion the author says that this treatment has "never realized the expectations that the early attempts in this direction promised."

As to drugs the author is somewhat pessimistic, although the bromids and the old fashioned anti-spasmodics were given an appropriate place.

Altogether we think the book a useful and valuable one on those subjects on which it treats.

Aphasia and the Cerebral Speech Mechanism. By WILLIAM ELDER, M.D., F.R.C.P. With illustrations. London: H. K. Lewis, 1897. 8vo. cl. pp. 259. Price 10s. 6d.

The greater part of this work consists of the (Edinburgh) University lectures of the author. It goes far to elucidate a difficult but very interesting subject. The chapters are:

1. Reception, retention and production of speech.
2. Reception, retention and production of speech roots.
3. Mechanism of speech as shown by its disorganization.
4. Clinical varieties of aphasia.
5. Auditory aphasia.
6. Conduction of aphasia.
7. Visual aphasia or word blindness.
8. Aphemia motor aphasia, Broca's aphasia.
9. Agraphia aphasia.
10. Disturbance of the music faculty, amusia, etc.
11. Aphasia from the surgical point of view.

The volume concludes with the bibliography and index.

The author points out how important it is for the surgeon to possess an exact knowledge of aphasia. He indicates that the study of aphasia will lead to correct knowledge which will clear up diagnosis of many doubtful cases. The book is full of interest, is printed on fine paper and in large type. We commend it.

Manual of Static Electricity in X-Ray. By S. K. MONELL, M.D., 8vo, pp. 614.

Since the translation of Arthuis book in 1871, by Etheridge there have been few English monographs on this branch of electricity.

The author has taken advantage of the fact that the static

machine affords the means of exciting the X-ray within a Crookes tube and has brought into the volume the reports of many cases to sustain his side of the question, besides that the careful technics given by the author will give new ideas to many who had considered static electricity of little or no therapeutic value. Chapters 10 and 11 are devoted to X-ray photography, to X-ray effects in general and detailed directions are given for its management, but the fact remains the same that the authentic photography, while frequently individually successful, has no success in the long run, but most persons who have used it have come to the conclusion that it permits many mistakes and much chagrin for people's benefit by employing a professional photographer to do the work, and in our large cities that is now entirely practicable, but before it becomes generally used the price must be reduced, as it is effectually necessary to make the exposure on three sides in order to obtain a correct notion of the exact nature of the case. For example, the writer a short time since in a course of treatment of the fracture of the thigh just below the trochanters, had a negative taken from before backward, which indicated a non-union, whereas in point of fact there was a vicious union which required to be chiseled before the fragments could be separated, the spur bone having formed exactly behind the overlap fragment. The exposure should be made from behind forward and from before backward in each case. Thus two negatives are always required, and a third one from a lateral point of view is sometimes desirable. All this is expensive at present rates, but it will doubtless be reduced in time.

The Disorders of Digestion in Infancy and Childhood. By W. SOLTAU FENWICK, M.D., B.S. Lond., M.R.C.S. Physician to out-patients at Evelina Hospital for Sick Children. 8vo, pp. 377. London: H. K. Lewis; Philadelphia: J. B. Lippincott Co. 1897.

At the beginning of summer the general practitioner and those especially devoted to diseases of children are particularly interested in all books of this class, especially if they are likely to furnish any desirable information which may lead to better results in the prevention and treatment of infantile diseases of the digestive organs, so rife during midsummer. The book, which is therefore a timely one, is written in admirable style, and the teachings of the author are judicious. He begins with the anatomy and physiology of the stomach of the infant and naturally the bacteriology of the subject occupies considerable attention, and afterward the diet in infancy and the disorders of digestion are taken up.

Photographs and drawings have been used in illustrating the book, which is up to date and well worthy of a place in a physician's library.

The publisher has done his part well. The illustrations are not mere copies of former books on the subject, but seem to be original.

MISCELLANY.

Tragedy at Bologna.—Dr. Augusto Obici, who recently went from Modena with the highest reputation to fill the chair of pathologic anatomy in the University of Bologna and had delivered his inaugural discourse to a delighted audience of students and professional colleagues, committed suicide by throwing himself from the Aposa bridge into the river beneath, a distance of 100 feet. Death was immediate. Professor Obici was just 30 years of age and had been suffering from profound neurasthenia.—London *Lancet*.

Vicarious and Other Hemorrhages.—Chipault recently treated hysteric bleeding from the mamma in a woman of 40. He mentions his astonishment at finding the mamma apparently normal under the blood-stained cloths. Strümpell describes some cases of spitting of blood after traumatism that were ascribed to tuberculosis until discovered to proceed from the

upper part of the throat. Hermann also describes cases of sudden vomiting of blood, mixed with mucus and saliva, in hysteria, or consecutive to a disappointment, such as the non-arrival of a letter. But still more peculiar is a case reported in the *Gaz. Méd. de Liège* of April 22 in which menstruation occurs the 28th of each month through the thumb. The woman, 37, had had double salpingectomy performed in 1890, which caused the cessation of the menses for four years, when suddenly her thumb began to bleed, and blood oozed from it continuously for five days, when the hemorrhage ceased, to recur again the next month and each month since, at the same time and place.

Moscow International Congress.—The Committee in charge of the Section of Military Medicine announce that the halls and rooms of the Moscow Clinic of Surgery are at the disposal of the members of the Congress who take part in the proceedings of the Section of Military Surgery, for free lodgings. The rooms have been vacated, repainted, disinfected, etc., and will accommodate seventy-five, with separate rooms for eighteen and the rest in halls with four to eight beds. Those desiring to take advantage of this invitation will please communicate without delay with Prof. Lewschine, Moscow, Volhonka, maison Mihalkoff.—*Progrès Méd.*, June 5.

Beer and Athletics in Life Insurance.—At the annual meeting of Medical Directors of Life Insurance Companies in the United States recently held in New York city Dr. Gordon W. Russell of Hartford, Conn., in a paper on the "Selection of Lives for Insurance," introduced the subject of beer drinking. He classed the users of this beverage as poor risks. In the course of the discussion it came out that the mortality is strikingly low among brewers in early years. Up to the age of 40, or thereabouts, brewers seem to be about as good risks as anyone else. After that age the mortality rises high and at 50 or 60 about three brewers may be expected to die where one other person dies. Under the subject of "Albuminuria," Dr. F. C. Young of the Mutual Benefit Life Insurance Company said that football, bicycling and other athletic exercises greatly impaired a person as a risk for a life insurance company. He said he had observed that after athletes had been engaged in their sports the presence of albumin was discovered in the system, and that albumin was found in the systems of athletes much more than in persons unaccustomed to violent exercise.

Improved Pessary.—Pinna-Pinta's pessary is described in the *Gaz. degli Osp. e delle Clin.*, of May 30, as consisting of two parts, an aluminum endo uterine canula and a rubber-covered vaginal part. A special sound accompanies it which can be passed through it into the uterus for irrigating and therapeutic purposes without disturbing the apparatus. It holds the uterus in a normal position when inclined to become displaced; it ensures drainage of the uterine cavity: it stimulates the circulation and exerts a favorable excitation on the uterine contractions, which is of great benefit in chronic uterine or peri-uterine inflammations and in aplasia and atrophy of the internal genital organs. It has always been well tolerated, some of his patients wearing it for months at a time without experiencing any inconvenience from its use. In every case treated, the sacrolumbar pains ceased, or the dysmenorrhea, leucorrhœa or whatever the symptoms that had indicated it, and all the objective symptoms also disappeared. He recommends it in high terms.

Intestinal Occlusion by Calculi formed of Salol.—A woman with gastro-intestinal disturbances, took 4 to 5 grams of salol a day in 50 centigram doses, for ten days, when she developed symptoms of complete intestinal occlusion, which resisted the most energetic treatment, including electricity, for thirty-six hours. In the evacuation then secured a dozen calculi were found, all formed of salol which had been taken in the form of a powder, and had evidently been dissolved in the intestines and recryst-

allized. The largest weighed 2 grams, with a total weight of 4 grams. "The case shows the possibility of intestinal lithiasis of therapeutic origin, and also adds another to the already numerous inconveniences of intestinal antiseptics."—*Bulletin de l'Académie de Médecine*, March 30.

No Consolidation. Bellevue Hospital Medical College and the Medical Department of the University of the City of New York will not amalgamate as was recently announced. Bellevue will build a new medical college at Second Avenue and Twenty-sixth Street, adjoining the Carnegie Laboratory. The estimated cost is \$100,000 and the building is to be completed by Jan. 1, 1898.

Gleanings. Camphor found effective in suppressing the lacteal secretion. Herrgott administers it in powders of 20 centigrams, three times a day, with remarkable success.—*Semaine Méd.*, June 2. Airol announced to be efficacious as an anti-diarrhetic, 11 cases cured. Doses from 20 to 80 centigrams in two to four powders an hour or so apart in one case. No unfavorable results were observed.—*Gaz. d. Osp. e d. Clin.*, May 30. A Belgian physician insists that the only effective prophylaxis of epidemics of measles is to close the schools at once when a single case is discovered and keep them closed for nine to twelve days, when all exposed will have had a chance to develop the disease. He adds that the germs in the building will die of themselves in that time.—*Sem. Méd.*, June 2. Radical operation of a 4-hour-old infant with hydrocephalus for a cerebral hernia into a tumor extending down the back as large as half the head. Prompt recovery.—*Wien. klin. Woch.*, May 27.

Societies.

THE MONMOUTH COUNTY (N. Y.) Anatomical and Pathological Society was organized in Long Branch June 16.—The Lucas County Medical Society held its last meeting for the summer at Toledo, Ohio, June 18.—The Academy of Medicine and Surgery, Richmond, Va., held a session June 22.—The surgeons of the Southern and Alabama Great Southern Railways met at Lookout Mountain June 29 and 30.—The Elkhart County Medical Society held a session at Elkhart, Ind., June 17.—The one hundred and thirty-first annual meeting of the Medical Society of New Jersey was held at Atlantic City, June 21 and 22.—The Delaware Medical Society held its annual session at Muncie, Ind., June 22.—The Franklin County Medical Society met at St. Thomas, Pa., June 22.

Osteopathy in Court.—A conviction which was had Jan. 27, 1897, of an osteopath for violation of the Ohio law, has been reversed by the court of common pleas of Summit County, as per report in the *Ohio Legal News* of June 19, 1897, the case being styled Eugene Eastman v. The State of Ohio. The accused was a graduate of the American School of Osteopathy of Kirksville, Mo., who had located at Akron, Ohio. For pay, he undertook to treat a case of paralysis, without prescribing, directing or recommending the use of any drug or medicine. This raised the question whether the act of kneading and rubbing the body with the naked hands, for compensation and for the treatment and cure of bodily disorders, is a criminal act under such a law regulating the practice of medicine as that of Ohio. It was contended, on behalf of the State, that the act within the term "or other agency," in the provision of the Ohio law that "any person shall be regarded as practicing medicine or surgery who shall, for a fee, prescribe, direct or recommend for the use of any person any drug or medicine or other agency for the treatment, cure or relief of any wound, fracture or bodily injury, infirmity or disease." But the court holds that the words "other agency," although comprehensive, must mean something in the same general sense that medicines or drugs is an agency, and that if it was the intention of the general assembly to prohibit the practice in the State of osteopathy, clairvoyance, mind healing, faith cure, hypnotism, massage and Christian science it should have been specifically mentioned and not left to mere inference from the general

words "other agency." Consequently, it holds that in the particular acts set forth there was no violation of the statute mentioned.

Washington.

A SENATE BILL POSTPONED.—The bill to regulate the sale of poisons in the District of Columbia, S. 470, originated by the Medical Society, was called up for passage on the 21st ult., but by request of Senator McMillan was recommitted for future consideration to the committee. It is hoped that an early and favorable action will be had on this bill.

MEDICAL AND SURGICAL SOCIETY.—At a meeting of the Society held on July 20, Dr. McKimmie read a paper on "Hypertrophy of the Lingual Tonsil and its Treatment." He referred to the location and anatomy of the gland and the relation of hypertrophy to throat symptoms, as shown by Lennox Brown in 1880 and since indorsed by recent prominent throat specialists. He gave the classification of diseases of the tonsil and its relation to the varix at the base of the tongue. He also referred to the relation of age and sex and general debility as predisposing causes. He also suggested a neurotic origin of the disease. He recommends treatment with nitrate of silver, one or two drams to the ounce, prefers the use of the cold snare to that of the guillotine or cautery. The paper was discussed by Drs. J. D. Morgan, Chas. W. Richardson, Fred. Sohon and others. Dr. J. F. Moran read a paper on "Cerebellar Tumors," and gave the history of a case where two exploratory operations had been performed for the relief of intracranial pressure. Previous treatment by potass. iodid. had failed. The operation gave temporary relief. He called special attention to the absence of distal localizing symptoms in the case and the improvement of locomotion and incoordination, notwithstanding the fact that half of the right lobe was destroyed and considerable inflammatory changes were present in the adjacent lobe. No history of syphilis could be established, though tuberculosis contaminated the maternal relatives. He referred to the symptoms of cerebral tumors and the treatment recommended by recent authors. Notes and specimen from the autopsy were presented. Discussion followed by Drs. Chas. W. Richardson, Allen, Bishop and W. P. Carr. Dr. E. Sotheron presented an axis traction obstetric forceps which he had devised, and detailed its special advantages.

THE COLUMBIAN MEDICAL SCHOOL HOSPITAL.—The Trustees of the Columbian University have given the Medical Department a large building, formerly the Preparatory School, for the purposes of a hospital. The building is being remodeled and provided with wards, private rooms and operating amphitheater. The hospital will be under the exclusive direction of the Medical Faculty, and will be ready for use by October 1. A large amount of money has already been subscribed to make the necessary changes and the improvements are in charge of a Committee of the Faculty, consisting of Drs. J. Ford Thompson, W. W. Johnston, A. E. de Schweinitz and D. K. Shute. The hospital building is located within fifty feet of the Medical School.

THE PUBLIC SERVICES.

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from June 10 to June 25, 1897.

Col. William H. Forwood, Asst. Surgeon-General U. S. A., is granted leave of absence for three months, to take effect about July 1, 1897, with permission to go beyond sea.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending June 19, 1897.

Surgeon E. Z. Derr, ordered to duty with new naval rendezvous, New York.

P. A. Surgeon J. F. Urle, detached from marine rendezvous, Boston, June 24, and ordered to the "Wabash" same day.

Surgeon F. B. Stephenson, detached from the "Wabash" June 24, and ordered to marine rendezvous, Boston, same day.

Asst. Surgeon W. B. Grove, ordered to the naval laboratory, New York, June 21.

P. A. Surgeon L. W. Sprattling, ordered to the naval hospital, Norfolk, July 1.

CHANGE OF ADDRESS.

Alderson, J. C., from 107 Throop St. to 426 Van Buren St., Chicago, Ill.; Adams, Samuel S., from Washington, D. C. to Mountain Lake Park, Md., for July, August and September.

Buckmaster, S. B., from Hudson to Janesville, Wis. After August 1 address will be Lake Geneva, Wis., where he assumes Superintendency of the Oakwood Sanitarium.

Calderon, E., from 607 to 526 Sutler St., San Francisco, Cal.; Clarke, B. F., from 634 to 1009 Sutler St. San Francisco, Cal.; Cook, J. F. D., from Doland to Clark, South Dakota.

Davis, J. S., from Charlottesville, Va. to Box 8, Osceola Springs, Miss.; Dougan, W. McKay, from White Rock, Nev. to Oteo, Oklahoma; De Jong, C., from Grand Rapids, Mich. to Edgerton, Minn.

Eagan, J. A., from Chicago, Ill. to Sec'y Illinois State Board of Health, Springfield, Ill.

Gibon, A. L., from New York, N. Y. to Sykesville, Md.; Gentsch, D. C., from Washington, D. C. to New Philadelphia, Ohio.

Holland, J. W., from Philadelphia, Pa. to Care of The Checkley, Prout's Neck, Me.

Judd, C. E., from Chicago, Ill. to 618 Kansas Av., Topeka, Kan. Lewis, Bransford, from 1006 Olive St. to the Century Building, St. Louis, Mo.

Morse, E. R., from 4356 to 4337 Berkeley Av., Chicago, Ill.; Martin, W. E., from 51 W. Fort to 40 Howard St., Detroit, Mich.

Newton, C. S., from Winfield to Altamont, Kan. Quigley, J. M., from 44-6th St., 213 Powell St. San Francisco, Cal.

Stoye, J. P., from Chicago to Mayville, Wis.; Scates, D. W., from Waxahatchie, Texas, to Martin, Tenn.

Tisdale, D. L., from Chicago, Ill. to Alameda, Cal.; Thomas, E. W., from 636 Sutler St. to 1148 Market St., San Francisco, Cal.

Warne, F. C., from 1105 75th St. to 939 72d Place, Chicago, Ill.

LETTERS RECEIVED.

Aaron, Charles D., Detroit, Mich. Boehringer, C. F. & Soehne, New York, N. Y.; Bulkley, L. Duncan, New York, N. Y.; Bausch & Lomb Opt. Co., Rochester, N. Y.; Burns, W. W., Polo, Ill.; Bell, A. N., Brooklyn, N. Y.; Boyd, E. T., Leadville, Colo.; Barton, James L., White, Tenn.

No. 2.

ORIGINAL ARTICLES.

ONE HUNDRED CASES OF TYPHOID FEVER.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY H. G. McCORMICK, M.D.

WILLIAMSPORT, PA.

Since the first day of September, 1893, I have treated 124 cases of typhoid fever. The first year I treated twenty-four cases; twenty-one recovered and three died. From Sept. 1, 1894, to March 1, 1897, I treated 100 cases of typhoid fever with one death. Why this great difference in mortality? This is the question I purpose answering for you today.

The first twenty-four cases were treated as the text-books and college professors teach that such cases should be treated. Baths were used where such treatment was practicable, and where I could persuade the patient that a cold bath was a pleasant pastime. The diet was carefully regulated and in the absence of my knowledge of a better drug, sulpho-carbolate of zinc was given. I believed then what was greatly taught on this subject, that typhoid fever was a self-limited disease and that I must carefully watch the symptoms, and when anything occurred that in any way jeopardized the life of the patient I must give something for its relief. But even after doing all this I found that I lost one patient out of every eight, though the text-books said this was not an undue proportion.

The first case I lost was a young, previously healthy man; on the sixteenth day he had a hemorrhage. I gave him a hypodermic injection of morphin and ordered acetate of lead by the mouth. The next day he had another hemorrhage, much larger than the first. I then called a consultation of the staff and they agreed that everything was being done for the man that could be done. His bowels were now bound up and he was very tympanitic. I continued the treatment as before, and on the twentieth day he had another hemorrhage and died on the twenty-first day from exhaustion.

My second death was similar to the first and the same general *approved* plan of treatment was followed. After the second hemorrhage she was very tympanitic and died of perforation, seventy-two hours after the second bleeding.

My third death was a child 13 years old who had become so weak and debilitated from a long siege of this disease that she turned over in bed and died from sheer exhaustion.

The average length of time these twenty-four cases ran until the temperature reached normal, was thirty-two and one-half days. In a discussion on the subject of typhoid fever, before our County Society, I made the statement that I purposed showing by a series of cases what I had endeavored to prove by theory, that there was not a single valid reason that, up

to that hour, had been offered which went to prove that typhoid fever was a self-limited disease, except the one single statement of the fact, that it had always been considered a self-limited disease and all the text-books had so taught.

At this time I abandoned all the old plans of treatment and entered upon an entirely new one, with the result that in thirty months I have treated 100 cases of typhoid fever and have lost but one case, and this was a man who had been admitted to the Williamsport Hospital on the fifteenth day of the disease and died on the nineteenth from perforation of the bowel, as was determined by a postmortem.

The average length of time these cases were sick until the temperature reached normal, was twenty-two days. Thirty-eight of these cases were seen on or before the seventh day, and the average time until the temperature reached normal was sixteen and one-half days. The longest any one case ran was twenty-two days and the shortest thirteen days. Of those seen after the seventh day, under the same plan of treatment, the average was twenty-six and three-seventh days. Of the one hundred cases nineteen had hemorrhage, some very severe; one bled six pints in six days; another seventy ounces in forty-eight hours. There were eleven with relapses. There was but one who was seen prior to the seventh day that had a relapse.

The treatment used was as follows: The diet was carefully looked after. That food was selected which could be most easily digested and assimilated, and no more was given than could be readily digested. Many physicians suppose if they give a certain quantity of milk each two or three hours that they are providing the necessary nourishment. This is a great error. There are cases that should be given little, if any milk, for some can not digest it, and when this is the case the patient is rendered much worse by its giving. The stools should be examined and if undigested milk is found, the diet should be changed, for I have seen a few cases, which were naturally mild, that were rendered severe by the continued use of milk diet. It is far better to give all these cases a mixed diet of milk with animal broths and buttermilk, than to rely wholly upon any one kind of diet, and the moment any one article is found to disagree with a patient it should be immediately abandoned.

The room should be clean and airy. The bed-clothing should be changed daily and the patient should have a tepid sponge bath twice each day. The mouth and teeth should be cleansed each day, and the patient should be kept as clean as can be made with soap and water.

Now for medicines. The bowels should be kept thoroughly opened, and as a rule nothing will do this better than calomel. This should be given every two hours until the bowels are thoroughly moved, and what I mean by this is that there should be from four

to eight passages in twenty-four hours. Salts may be substituted in order to secure desired number of movements, or when the longer continued use of the calomel is not deemed desirable. Sometimes I combine podophyllum with my calomel in order to make it more affective, but by all means the bowels were kept open, and in not a single instance was anything given to control the bowel movements. The colon was washed out twice each day in order to secure the proper cleanliness, and if the temperature was high this enema was ice water. If there was a weak pulse salt was added to the water in order to secure its absorption. In many of these cases the glands of the colon are involved; Dr. Osler says in one-third of all the cases. If this is true you are carrying your solution to the seat of disease. Water is given by the mouth as freely as the patient will take it, and they are encouraged to take water in large quantities.

We have now rendered the alimentary canal as nearly aseptic as it can be without medicines, and no undigested food has been allowed to accumulate to undergo decomposition to form poisons, which are readily absorbed by these inflamed glands. In addition to the above I give every two hours, in emulsion, two drops of guaiacol. I give it entirely for its antiseptic effect, and know of no better intestinal antiseptic, for I believe it is still guaiacol when it reaches the diseased parts. This was to a great extent proven in the case that died from perforation. An autopsy was made and it was found that the perforation had taken place three inches above the ileo-cecal valve. When the abdomen was opened the unmistakable odor of guaiacol was found to be present. The guaiacol that had been given this man was still guaiacol at the ileo-cecal valve and would not undergo any further change in passing through the colon.

There are some patients with irritable stomachs who are unable to take the guaiacol in this form. When this was proven I then gave them the next best intestinal antiseptic—carbonate of guaiacol—in two-grain doses every two hours. Stimulants were rarely given. If the heart was weak I gave one-thirtieth grain of strychnia nitrate, every three hours, or oftener if demanded. When hemorrhage occurred, 15 minims of ergotal was given hypodermically, and the colon was washed out with an ice-water enema of normal salt solution. This cleaned out the colon, stimulated contraction of the bowel, carried off the clots of blood—a fruitful soil for propagating the poison—and rendered the parts as nearly aseptic as possible.

If the prostration from the loss of blood was great the patient was at once transfused with a normal salt solution, at a temperature of 107 degrees, to the amount of a quart. This quickly strengthened the heart's action, filled the blood vessels with a fluid which went to nourish the body, and the patient rapidly rallied. In one case transfusion was performed four times; in another three times, and in quite a number of cases once.

In not a single case of hemorrhage was there any opium, or its alkaloid morphia given, and they all recovered without the use of acetate of lead.

This may appear like wandering a good distance from the tenets as taught by our teachers, but there has never been a greater error promulgated than the teaching of the giving of opium in hemorrhage in typhoid fever, and a large number of the mounds in our cemeteries can be charged up to this false doctrine. What reason do they offer for such practice? Simply that

it controls peristaltic action and renders the bowel for the time being, asleep. I grant all and more than they claim, but what is it doing when it is controlling this peristaltic action? It is also drying up the secretions from the whole alimentary canal, the food taken decomposes, forms a gas, tympanites follows, the bowel is put upon the stretch and hemorrhage of necessity is more likely to follow, the weakened bowel due to ulceration is more likely to be perforated, and you are adding to a mere complication one that will likely terminate in death.

If the temperature is inclined to remain above 103.5 degrees, I apply guaiacol, the amount used varying as to the age and susceptibility of the patient, etc. I have now applied guaiacol locally for the reduction of temperature, 1066 times and I have found it a prompt and efficient remedy. The dose should vary from 10 to 25 drops. There is an impression in the minds of many physicians that this is a very dangerous drug; it has not proven such in my cases. Care must be exercised in its use; this is not only true of guaiacol but it is true of all active medicines. That it will promptly reduce temperature can not longer be questioned, and that it does so without weakening the heart muscle, I have proven by many clinical cases, as shown in a previous article.

The use of the coal-tar products for the reduction of temperature in typhoid fever is a very dangerous class of remedies and I believe they should be universally condemned. I have seen at least two deaths that could be traced to their use.

Does not the treatment, as here outlined, appeal to your reason and common sense? Is it not a rational treatment to apply to the diseased parts, as taught us by the pathologist?

Has not the result as shown by my 100 cases, with one death, appealed to you as being a mortality rate that has not been equaled by any form of treatment, except that of the cold bath, and this only in the hands of its originator? Dr. Brand, after he had treated over 200 cases of typhoid fever with the cold bath, made the statement that when he heard of a death from typhoid fever in a young person, of previous good health, he believed there had been a homicide. This is strong language and should cause each one to consider, in their deaths from this disease, who is the guilty party. I believe there are entirely too many die from typhoid fever who, if they had been treated properly, would have gotten well. A physician said to me, "I gave a patient with typhoid fever guaiacol and he died;" this is probably true. It will not do to give your patient guaiacol and stop at that. There must be an intelligent management of the case and an intelligent use of the drug. There is as much skill required in the use of drugs as there is in the use of the pen, pencil or the knife. If a case of typhoid fever is properly treated, the dry tongue, sordes of the mouth, the tympanites and low muttering delirium, as described in the books, will rarely be seen.

As a result of my experience in the treatment of typhoid fever, I am thoroughly convinced that a statement which I made two years ago, that typhoid fever prior to the seventh day was capable, by proper treatment, of being very much shortened in its duration was true. I am further thoroughly convinced, that in cases seen and properly treated before the seventh day, a death will be a rare occurrence.

The whole question of the treatment of typhoid fever might be summed up as follows:

Keep the bowels thoroughly open.
 Keep the alimentary canal as aseptic as possible.
 Give good nourishing food—that which the patient will readily assimilate.
 Give plenty of water both by the mouth and rectum.
 Use the best intestinal antiseptic known.
 Never give opium.
 Never give phenacetin or acetanilid.
 Give strychnia as indicated.
 If this plan is followed you will rarely have a death from typhoid fever.
 1300 W. Fourth St.

DIET IN TYPHOID FEVER.

Read by title in the Section on Practice of Medicine at the Forty-eighth Annual Meeting of the American Medical Association at Philadelphia, Pa., June 1-4, 1897.

BY FREDERICK C. SHATTUCK, M.D.

JACKSON PROFESSOR OF CLINICAL MEDICINE IN HARVARD UNIVERSITY.
 BOSTON, MASS.

When typhoid fever kills it does so either by perforation or exhaustion, the proportion of the former being estimated at 5 to 10 per cent. The main factors in producing the exhaustion which causes the death of at least nine-tenths of the fatal cases are toxemia, continued fever, diarrhea and vomiting and intestinal hemorrhage. The heart is ordinarily the best index of the presence and degree of exhaustion, and the most frequent serious pulmonary complication, hypostasis, in its various forms, degrees and consequences is the direct outgrowth of the cardiac weakness. Moreover typhoid fever is not short and sharp like pneumonia, but of long course, and usually attended with decided, often with very great wasting of the muscular and fatty tissues.

Most of us are agreed that we are not as yet acquainted with any therapeutic measures which will either abort or very materially shorten the course of the disease. We are, I think, unanimous in believing that husbanding the strength from the start through skilful nursing, the judicious use of water externally and internally, and the supervision of a wise attendant on the watch for and prepared to meet such indications as may arise, materially modifies the course of the disease and lessens its mortality. If what I have assumed to be facts be really facts, the question of diet must be a very important one in the management of typhoid fever. It is through the food which is assimilated, not through that which is merely put into the stomach, that we seek to limit the tissue waste while the process is active, and also try to land the patient on the low shore of convalescence with as much of his property as may be; for the recovery of his property is a necessary preliminary to the attainment of the high table-land of full health.

Under the old doctrines as to inflammation fever was an unfailing indication for depletion; directly by venesection, pukes, sweats and purges; indirectly by starvation. Indiscriminate direct depletion is now a thing of the past, and since the time of Todd the fact has gradually been more and more clearly recognized that the febrile state is often an indication for more, rather than less, nourishment, with selection as to quality rather than diminution as to quantity. In the shorter essential fevers a few days' starvation can not do much harm, and may even be of great service with a certain class of patients. But suppurative fever, for instance, whether of tubercular or other origin, especially if chronic, we feed to the largest limit; and

we do this because we treat the condition and not the disease, individualizing our cases. Since our knowledge of gastric chemistry has been enriched by the adaptation of the soft catheter to another hollow viscus at the opposite extremity of the abdomen, a more complete explanation has been afforded for the fact which we knew by practical experience before, that gastric digestion is often weakened in the febrile state. But the same practical experience teaches us that it is not always so, or very materially so, and when theory and practice conflict the former must prevail. Have we not fully escaped from the domination of the old doctrine as to the lowering treatment of inflammation, or are there valid reasons why we should be less bold in feeding our typhoid patients than our chronic febrile consumptives? Three such reasons deserve special consideration. In the first place, typhoid is far more frequently a self-limited disease than is phthisis; but the fact of self-limitation does not seem to me to warrant us in underfeeding, for the less the patient loses the less does he require to regain. In the second place, typhoid has constant intestinal lesions which may bleed or perforate and which may be accompanied by a general catarrhal state of the intestinal tract. I may perhaps add here that diarrhea is not nearly as constant a symptom in typhoid fever as the books lead students to believe. In at least 50 per cent. of my hospital cases no diarrhea was present at any time. We must therefore have reference to the local intestinal lesions as well as to the general state. In a disease of such long course, it is impossible to prevent accidents by putting the bowels in splints, even if it were desirable to do so. More or less peristalsis must go on, and waste matter must pass over the ulcerated surfaces; and how deep or extensive the ulcerated surface may be in any particular case no symptom or group of symptoms enable us to measure. Hence, it seems rational, quite apart from the fever, to withhold from the diet any articles the residue of which is liable to irritate either the mucous membrane in general or the ulcerated portion in particular. This would seem a fair explanation for the popularity of milk as a diet for typhoid, containing as it does a large proportion of water and every principle necessary to nutrition so combined as to make relatively small demands on the digestion of most persons, and leaving a residue which, though notoriously large, is not mechanically irritating. The objection to milk is that it is repugnant to a few persons and becomes either repugnant or monotonous to a considerable number sooner or later. It is not necessary here to specify the many expedients which may and often must be resorted to to overcome this objection, and in some cases to render it digestible whether palatable or not. Milk is likely to maintain a very important, perhaps leading place in the diet of typhoid as well as of other diseases and conditions. For a number of years I adhered as strictly as possible to an exclusively milk diet in typhoid fever until at least a week had elapsed from the date of the first normal evening temperature. I closed my ears to the clamors of adults, and my eyes and heart to the tears of children, as I now believe unnecessarily. Thirdly, it was only comparatively recently the general opinion of the profession that relapse is or may be due to errors in diet. I well remember the time when a fresh access of fever led my teachers and me to carefully inquire into the kindness of officious friends. It was often proved that forbidden fruit actually or metaphorically had

been brought in by a visitor, and this was an entirely satisfactory explanation. When proof could not be had the fact of relapse was strong presumptive evidence of sin. We know better now, and while we recognize that errors in diet may produce fever, as may fatigue or excitement in convalescence from any severe disease, we do not believe that they can start up a fresh invasion of bacilli from within. One of the things which set me thinking on this question of the diet in typhoid was the favorable course run by several acute febrile cases for whom I ordered a full diet because they were weak; believing at the time of so doing that typhoid could be excluded, but being forced to the conclusion later that only typhoid fever could explain the whole course of the disease. These patients did perfectly well, were happier and convalesced more rapidly than my recognized typhoid cases fed exclusively on milk. For five years now, I have been enlarging the diet of my typhoid cases and have seen no reason to regret this course, but on the contrary found cause for satisfaction.

During the twelve years, 1886 to 1897 (both inclusive) 380 cases of typhoid fever have come under my personal care in the Massachusetts General Hospital. From 1886 to 1893, 233 cases were treated under a milk diet with a mortality of 10 per cent. From 1892 to 1897, 147 cases have been treated under a much more extended diet with a mortality of 8.1 per cent. I know well the liability to reach false conclusions in reasoning from too small figures in a disease like typhoid fever. And it is also true that water has been used more efficiently of late than in former years. But I can see nothing in my figures to contravene my observation that an enlarged diet has not been injurious. I would not be understood as advocating an indiscriminate diet. My plea is simply for treating the patient rather than the disease; for feeding him with reference to his digestive power rather than solely or mainly with reference to his fever; for the view that the danger of accidents from the local intestinal ulceration is not increased by allowing him to partake of articles which leave no irritating residue, and which cautious trial shows are digested without disturbance or discomfort. At one end of the scale are the cases with such irritability or weakness of the stomach as to lead to the unfortunate term gastric fever, or those with pronounced diarrhea and undigested food in the stools; at the other end are those more numerous cases with clean tongue and a desire for food. Between the two is every gradation. The life of the former may depend on the skill and ingenuity of the doctor, assisted by the intelligent devotion of the nurse. The comfort and the duration of disability of all others may be materially modified for good by careful study and wise individualization of our cases. A long list of permissible articles from which selection can be made for different cases, and for the same case at different times under varying circumstances can be given. That which I append makes no claim to completeness, but is meant merely to be suggestive and illustrative.

TYPHOID DIET.

1. Milk hot or cold, with or without salt, diluted with lime water, soda water, apollinaris, vichy; peptogenic and peptonized milk; cream and water (*i.e.*, less albumin), milk with white of egg, slip, buttermilk, koumyss, matzoon, milk whey, milk with tea, coffee, cocoa.

2. Soups: beef, veal, chicken, tomato, potato, oyster, mutton, pea, bean, squash; carefully strained and thickened with rice (powdered), arrowroot, flour, milk or cream, egg, barley.

3. Horlick's food, Mellins' food, malted milk, carni-peptone, bovine, somatose.

4. Beef juice.

5. Gruels: strained cornmeal, crackers, flour, barley-water, toast-water, albumin, water with lemon-juice.

6. Ice-cream.

7. Eggs, soft boiled or raw, egg-nog.

8. Finely minced lean meat, scraped beef. The soft part of raw oysters. Soft crackers with milk or broth, Soft puddings without raisins. Soft toast without crust. Blanc mange, wine jelly, apple sauce and macaroni.

CAN TYPHOID FEVER BE ABORTED—THE ANSWER.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, June 1-4, 1897.

BY J. E. WOODBRIDGE, M.D.

CLEVELAND, OHIO.

There are departments in medicine of which it may be truly said that "reasoning is deceptive;" in which actual experience gives the only light by which our footsteps may be guided; in which the clinical experience of a single observer, who has been wisely taught and has wisely followed the teaching, is of greater value as evidence of the justness of a conclusion, than is the subtlest reasoning of the most astute logician. This is eminently true of the subject which is presented for your consideration today.

The question which forms the title of this paper can be correctly and forcefully answered only by those who can speak from bedside experience.

The subject has already been fully and ably discussed, every imaginable argument has been adduced to establish a negative, but the force of most of these has already been broken by the silent footfalls of advancing science.

The effect of the antitoxins of diphtheria, the bubonic plague and other diseases, and the discovery of Laveran, that ague is a specific infection in which every drop of blood is invaded by a living organism, coupled with the well known fact that a single dose of one of the least harmful of drugs will not only abort an attack of malaria, but will effectually disinfect the blood circulating in every part of the body, from the tip of the finger to the ball of the toe, emphatically negatives all the arguments that have been advanced to prove that the course of the specific infections can not be interrupted, and especially that typhoid fever will run its course in defiance of all medication; yet these dogmatisms have been quoted, repeated, reiterated and applauded, as if they contained the very essence of all the wisdom of all the ages, past, present and future. They are not true, but the declaration that typhoid is a curable malady has been for years and is yet nearly always greeted with such "acrimonious and vituperative dissent" that it should not surprise us if the bravest men were to hesitate before reporting cases of "aborted typhoid fever," well knowing that such reports would expose them to the ridicule, invective and brutal sarcasms of those who, lacking their knowledge of the power of anti-septic medicine, receive with derision every allusion to the curative treatment of the specific infections.

No wonder then that physicians who cure these diseases are afraid to publish their reports; no wonder that some physicians who promised to send me the clinical histories of their cases have never done so; no wonder that some of my friends, who kindly sent valuable statistics, with permission to use their names in this report, afterward withdrew their consent. The wonder is, that under the circumstances any physician should have had the courage of his convictions and should have dared to allow me to use the data which are here presented. It was, therefore, with extreme diffidence that I wrote to a few physicians who had previously written to me for specific information about this method of managing typhoid fever, asking them for reports of their cases for publication.

But the medical profession it seems is equal to any emergency and there is no demand that can be made upon it in the name of suffering humanity, which it does not immediately supply, as the generous and noble responses that are embodied in this report clearly prove; and despite the fact that the ordinary difficulties which beset the gathering of statistics on any new method of treatment have been enormously augmented for the abortive treatment of typhoid fever by the sharp criticism to which it has been subjected, I present herewith the statistics of 6,911 cases of typhoid fever that have been treated by the method I have advised, with quotations from the reports of a few of those physicians who have not only had the intelligence to institute scientific treatment and with it to abort the disease, but have also had the heroism to brave the innuendoes and criticisms of the molders of medical thought, and have supplied the data which must unequivocally place this heretofore most terrible sickness among the curable diseases. In signing these reports they have braved dangers as real as those which confront the soldier on the battlefield, and in speaking out in advocacy of the abortive treatment of typhoid fever they have jeopardized their professional careers, but they have exhibited the true nobility of their characters.

At the last meeting of this ASSOCIATION, the method of managing typhoid fever, which is dealt with in these reports, being under discussion, certain arguments were advanced with the manifest object of detracting from the value of the treatment by showing that the typhoid fever of this country and during recent years, is not the same disease that prevailed here twenty or thirty years ago or that is today so much dreaded in foreign lands. These arguments must have sounded strange to the ears of scientists who regard the bacillus of Eberth as the cause of the disease and who would naturally expect a given cause to produce a given effect under like circumstances. These arguments, aside from being unscientific, are in conflict with well known facts. For example, from 1864 to 1869 there occurred in the Boston City Hospital 152 cases of undoubted typhoid fever, 21, or 13.81 per cent. of which died, while the duration of the illness of those that recovered was 24.25 days. In St. Bartholomew's Hospital, London, 1860 to 1864, there were 244 cases of typhoid fever treated, with 27 deaths, or 10.06 per cent., while in the same hospital during the five years preceding the opening of the discussion of this subject in this Society (1893), 406 cases were treated, with 54 deaths, a death rate of 13.2 per cent. In the Buffalo General Hospital during the years 1892-3-4 (the only report to which I have access at present), 271 cases were treated to a

finish with 47 deaths or 17.34 per cent. In the St. Louis City Hospital, during the years 1890 to 1893, there were treated 353 cases with 73 deaths, or a death rate of 20.68 per cent. During the years 1889 and 1890, there were treated in the Providence Hospital, Washington, 72 cases, of which 23 died, a death rate of 31.94 per cent. "Murchison places the death rate from this disease at 17.45 per cent., which is perhaps none too high for this city (Washington) during the time mentioned (July 1 to Oct. 31, 1895)." (Dr. Kober in Report of Health Office District of Columbia, 1-95.) It is well known that a few other hospitals have reported lower death rates in a few instances and it is frankly admitted that these numbers are too small to eliminate possible errors, or to constitute a safe basis upon which to found exact conclusions, but so too are those from which are obtained the marvelously low percentages so vociferously acclaimed by a few enthusiastic advocates of cold water. They are large enough, however, for the purpose for which they are introduced—not to antagonize any particular method of managing the disease, but to prove that typhoid fever in this closing decade of the nineteenth century has lost none of its old-time virulence and intractability; that it is still man's most insidious and relentless foe, running as tedious and obstinate a course to as certain death today as it did forty or fifty years ago.

The grave character of typhoid fever being proven we are confronted by several important questions: Can the disease be aborted? Can its course be interrupted? Can its death rate be lowered? Can its grave symptoms be ameliorated? Can relapses be prevented? Can complications be averted? In other words, is typhoid fever amenable to medical treatment? For answer I submit the following reports and in making the estimation of the value of the statistics, I beg you to remember that the physicians who have presented them were applying a method which was not only new to them, but which embodied practices that so far contravened all accepted theories, that many hesitated and did not dare, all at once, to throw away the old and fully adopt the new plans.

FRANCIS M. GREEN, M.D., Lexington, Ky., May, 1897:—I have treated in all thirty cases and without a single death. I aborted the disease in several cases, the temperature reaching normal by the seventh to ninth day. In the JOURNAL some time since I alluded to the ignorant and unjust criticism of the method. It is unfair in its enemies to cry out against our diagnosis without having first tried the treatment in cases which they themselves have pronounced typhoid fever. It is sufficient that the treatment will prove successful in a large majority of cases when commenced early.

WILLIAM M. WRIGHT, M.D., Huntington, Tenn., May, 1897:—I approach a case of typhoid fever now with more confidence than ever before, and I attribute it to your method of treatment. To say that I am highly pleased at being able to make favorable mention of your method to physicians with whom I come in contact but puts it lightly. I tell them it is now the *sine qua non*. I am an unqualified advocate of and enthusiastic believer in the virtue of this method.

WALTER N. SHERMAN, M.D., Merced, Cal., May, 1897:—I also use your tablets with splendid results in many other diseases in which I think intestinal antiseptics are indicated.

SAMUEL W. HOVER, M.D., Fayette, Ohio, May, 1897:—I am sorry I can not give you a fuller report of my cases, but if I had any number of cases of typhoid fever I should use your treatment on every one. My cases have all done so much better under your treatment that I have practically all the field in this neighborhood and for all ailments. My worst case was an old lady aged 71 years and she had a very bad attack with all characteristic symptoms of the disease. No one thought she could live. I broke the fever in nine days and she made a rapid recovery. Six cases.

CARL BONNING, M.D., Detroit, Mich. :—I treated only two

patients suffering from typhoid fever by your method. The first was an old lady nearly 60 years old, who was treated according to your method from the beginning. This was a mild case of true typhoid fever which ran its usual course of twenty-one days, with good recovery. The second case was a boy 14 years old, treated by your method from the first day. The symptoms became worse from day to day, temperature rising constantly and going up to 105 degrees F.; evacuations very frequent. On the ninth day a severe hemorrhage of the bowels set in, when I stopped your treatment at once, as I could not help but think that the treatment was the cause of his early and severe hemorrhage. The boy finally recovered under different treatment, though he was confined to his bed for six weeks more. Since then I have not given your treatment another trial.

HENRY CLAY DALTON, M.D., St. Louis, Mo., May, 1897:—I have treated eleven cases by the Woodbridge method, in fact all cases that I have had since I have commenced the treatment, because I certainly would not now treat that disease by any other method. All the patients recovered. None of the cases had any complications or sequela. With the exception of one case the tendency of the fever was to steadily abate. In the exception referred to the temperature became higher for two days after the commencement of the treatment, in fact the temperature increased two or three degrees. At the end of the second or third day it fell to about 102 degrees

have been using the Woodbridge treatment for a considerable length of time with very satisfactory results.

BENJAMIN MOSBY SMITH, M.D., Davis, W. Va.:—I have the first case to lose since I adopted your treatment two years ago. The great trouble is physicians do not use the treatment as they should or as directed. I am with you heart and soul and feel certain it is the only sure treatment we have now.

EDWIN O. BOARDMAN, M.D., Overton, Neb., May, 1897:—I have treated thirty-six cases by your method. The first ten cases were not so successfully treated as were the later ones, because of two facts: 1, the medicines were not properly prepared; 2, they were not properly given. Since then I have used the tablets prepared by P. D. & Co., without a single death, my two deaths occurring among the first ten. One of these was complicated with an old heart lesion—a woman 45 years old; the other a boy of 8, died of purpura hemorrhagica ten days after the subsidence of the fever.

FRANK C. MYERS, M.D., Kalamazoo, Mich., May, 1897:—I have been very much pleased with your treatment and have used it faithfully for two or three years, in fact I was the first

Dr. Wm. H. Arthur, Fort Myer, Va. Patient John L., Fort Myer, aged 15 years; admitted to hospital April 4, 1896; diagnosis, typhoid fever. Previous history: Patient treated for intermittent fever for three days. April 4 and 5 delirium continued, quinin stopped, resisted all treatment. April 6, modified Woodbridge treatment commenced. Patient slept all night. April 7, no delirium. April 8, guaiacol added. April 12, all treatment stopped, liquid diet. April 14, ordinary diet resumed. Modified Woodbridge treatment consisted in multiplying dosage and dividing intervals by four. Patient's sleep never disturbed, but treatment resumed immediately upon awakening. Guaiacol carbonate was not on hand at first. It was procured and added on April 8. Persistent delirium of a very obstinate and exhausting kind was unaffected by chloral. Disappeared as soon as evacuations of bowels became free and frequent.

and in less than a week was entirely gone. In none of my cases was there delirium or tympanites. Dr. Simon Pollak of this city, at my suggestion, treated his son after your method. He was delighted with the treatment. I feel that you have a grand treatment of the disease and that it is the duty of every physician to use it. Certainly up to the present time there is no remedy which approaches it in efficiency. My experience is somewhat limited, but in the cases in which I have used it patients have gotten along most comfortably and the disease has been cut short. Eleven cases: no deaths.

J. W. R., M.D., Missouri, May, 1897:—I think there is nothing like "Woodbridge treatment for typhoid fever." I have had the best results in every instance, with no deaths.

CHARLES S. JAMES, M.D., Centerville, Iowa, May, 1897:—I

Dr. D. F. Manning, Marshall, Mo. J. N., aged 45. Diagnosis, typhoid fever.

to use it in this city. I have read two or three papers in its favor at our Kalamazoo Academy of Medicine.

ROBERT J. HILL, M.D., St. Louis, Mo., May, 1897:—I have so thoroughly adopted your plan of treating typhoid fever and typhoid conditions that, judging from my past experiences, I have no more typhoid. I do not allow the disease to go so far but that when I meet a case which I think from the past history might run into it I immediately go for Woodbridge. I have no deaths and no protracted cases. I have placed my genuine cases at fifteen. I have no doubt the number would run much higher, but as I said before, all cases of a suspicious character are at once put on that treatment. I have seen much benefit from your plan in cases of septicemia and even in fermentative dyspepsia.

BYRON I. PRESTON, M.D., Rochester, N. Y., May, 1897:—I regret that my first cases were not properly recorded but they were apparently aborted—five of them inside of ten days

They all had nose bleed, ileac tenderness, tympanites, diarrhea and the usual temperature of typhoid fever at first.

GEORGE M. ATWOOD, M.D., Haverhill, Mass.:—I never saw patients with typhoid have so few unpleasant symptoms as these had after once getting down to business with the bowel.

WILLIAM A. JARNAGIN, M.D., Atlanta, Ga., May, 1897:—I am perfectly satisfied with the rationale of the Woodbridge plan. Unless my experience is very different from what it has been heretofore, I will adhere to the treatment in the future. I believe this treatment is the best—it certainly appeals to common sense.

JOSEPH A. DANIEL, M.D., Davenport, Iowa, May, 1897:—Should I be unfortunate enough to contract typhoid fever I should want to be treated by your method.

DONALD MACREA, M.D., Council Bluffs, Iowa, June, 1897: I learned the value of the Woodbridge treatment of typhoid fever soon after reading your first paper before the AMERICAN MEDICAL ASSOCIATION. Since then I have used it in all cases of typhoid, indeed in all cases of continued fever, both in hospital and private practice. I do not know how many cases I have used the treatment in nor have I any charts—I am not methodical enough for that—but I must have used it hundreds of times. I not only depend on the Woodbridge treatment myself, but I have spoken so strongly in its favor before medical societies, holding out such bright and sanguine hopes of recovery, that it is very generally used in these parts. I have never had a death since using the treatment. The duration of the disease does not seem to have been particularly shortened but the course is modified to such a degree that instead of

ment a fair trial and, reasoning from my own experience I think he will be more than pleased with the result.

T. M. L., M.D., Virginia, May, 1897:—I must say that I am thoroughly convinced of the efficiency of your treatment and expect to continue its use until I find some other that is better.

MATTHIAS BORTZ, M.D., Cleveland, Ohio, May, 1897:—I have been using your system, antiseptic and eliminative, for several years, during which time I have lost no patient.

HENRY W. LATHAM, Latham, Mo., May, 1897:—I have been using "Woodbridge treatment" almost exclusively during the past four years; the longer and the more faithfully I apply it, the better I like it. I would be glad, and I am sure that it would be a great blessing to humanity and an honor to yourself if you would compile your ideas and experiences of the nature and treatment of typhoid fever in book form. For the principle of intestinal antiseptics is neither understood nor appreciated by one hundredth part of the profession, and after an experience of twenty-five years I admit that I groped in the dark, with no definite idea of the treatment of that terrible fever, until I got it from your writings.

OLIVE E. WORCESTER, M.D., Conant, Fla., June, 1897:—I used the "Woodbridge treatment" of course, . . . excellent recovery.

ALFRED WOODHULL, M.D., Denver, Colo., May, 1897:—One

Dr. W. R. Kelly, Watonga, Oklahoma. Goldie S., aged 14, female, admitted Oct. 4, 1895; diagnosis, typhoid fever. October 4, began treatment on fourth day of disease. Temperature below normal October 12, up to 100 on 12th, normal on 14th. Gave sponge baths and phenacetin to control excessive temperature.

wearing anxiety and constantly doubtful prognosis, my visits seem to be almost unnecessary and the case smoothly runs along. The only objectionable feature in the treatment is that the patient becomes tired of the bed and of being half sick.

ISAAC A. MCSWAIN, M.D., Paris, Tenn., May, 1897:—The method suggested and urged by you has contributed greatly toward the limitation and alleviation of typhoid fever, and while I have seldom been able to use the exact formula of your prescriptions, yet your pointed arguments in favor of the antiseptic plan have been convincing and have caused great changes in the management of this dreaded disease. I have also used your No. 3 alone, and have been gratified with the results.

GEORGE W. LONG, M.D., Graham, N. C., May, 1897: I have also tried the method in several cases of malarial fever with very satisfactory results (following up, of course, with quinin, etc.). At first I was much prejudiced and very slow to make the venture. Since my limited experience I feel emboldened to try the treatment further.

HENRY G. CRUMP, M.D., Seddon, Ala., May, 1897:—I have given your treatment a test in some cases of typhoid fever, and as far as my experience goes I think it will do all you claim.

W. H. NIXON, M.D., Killeen, Texas, May, 1897.—My uniform success has turned me from a "doubting Thomas" to a true believer. Let the physician stop and think and give the treat-

Dr. Wm. A. Merriam, Struthers, Ohio. John McE. Struthers, Ohio, aged 14; admitted January 27, 1897. Reaction of serum on Eberth bacilli positive.

serious case came under my knowledge last year in which, partly by my suggestion, the treatment was attempted. The beneficial effects hoped for did not immediately follow and after a somewhat prolonged trial it was abandoned. The case ultimately recovered, although the illness was very grave and prolonged.

R. E. SEVIER, M.D., Liberty, Mo., May, 1897: Not one case in which I had a fair chance died.

D. Y. STEM, M.D., Slidel, Texas, May 1897:—I was gratified with the results obtained. All the literature that I had received to this date failed to outline your treatment as recommended in your recent work on typhoid fever; so, at first, I feared to give up all of the older methods and rely strictly on yours. Had I followed your instructions in full I believe I would have shortened the disease in all these cases. While your treatment is adverse to all taught in the standard works that have been examined by me, I feel now that it is the ideal treatment and that it will be a boon to suffering humanity. I wish to congratulate you on the marked success you have had in the treatment of typhoid fever and to praise the untiring energy you have manifested in trying to thwart a disease so much to be dreaded.

RICHARD S. MARTIN, M.D., Stuart, Va., May, 1897:—I shall continue to use it in all of my cases, as I am highly pleased with the results. I am confident that it is far superior to any other known treatment.

WILLIAM C. HUMPHRIES, M.D., Acworth, Ga., May, 1897:—I am a strong advocate of the "Woodbridge treatment" of typhoid fever. I am sure the mortality would be *nil* if the cases were seen in time and the treatment begun early and used persistently. I think it is intestinal antisepsis *par excellence*. I am a thorough convert to the method.

ARTHUR U. WILLIAMS, M.D., Hot Springs, Ark., May, 1897:—I have also used this treatment in diseases not recommended by you—malarial cases where the patient seemed to be drifting into malarial fever—general malaise, etc. Last fall my wife had all the premonitory symptoms of typhoid fever: nothing seemed to do her any good. I gave her your tablets and in a week she was on the way to recovery, and soon was all right. Many similar cases have occurred in my practice and I have been delighted with the results.

JOSEPH H. GREEN, M.D., Decatur, Ga., May, 1897:—I have been treating fevers in general by your method since last June. Several of the cases were seen for the first time in the second and third weeks of the disease, and while they ran on for two or three weeks longer, yet their symptoms were very much ameliorated and they were made comfortable and all terminated in a happy recovery.

Dr. John E. Wood, Maysville, Ohio. Patient, Walter Wood: admitted September 1, discharged September 14. Diagnosis, typhoid fever.

WILLIAM P. PIERCE, M.D., Hoopstovwn, Ill., May, 1897:—In the fall of 1895 I was called by the attending physician to see a young man, 20 years of age, dying of typhoid fever. I had been hearing for several days that his death was expected at any time and that the case was deemed hopeless. I found the patient unconscious, cyanotic, his heart beats 150, pulse at the wrist not to be detected, skin cold, and bathed in a clammy sweat, teeth loaded with sordes, low muttering delirium, restlessness and extreme jaotitation, stools passing unnoticed into the bed, bowels tympanitic. The patient could not swallow. The room was filled with a sickening, cadaverous odor. We put one tablet of Woodbridge No. 1 in his mouth every fifteen minutes. He was soon able to swallow and took the tablets every fifteen minutes all night. He continued to improve—the Woodbridge method was fully carried out with almost marvelous effect. The patient slowly but regularly convalesced and in two weeks was discharged.

RAY W. GREEN, M.D., Worcester, Mass., June, 1897:—My cases are hardly worth reporting as, in the majority of cases, the treatment was not begun early. While I have not seen any cases aborted by your treatment, I am confident that the course of the disease was modified favorably, and the convalescence rapid.

VILAS E. LAWRENCE, M.D., Ottawa, Kan., June, 1897:—The disease has lost much of its dread to me. My patients begin to improve in one or two days after beginning treatment and all the symptoms die away except the fever, which gradually disappears. Most of my patients wanted more milk than I thought best to allow them. I discovered that the secret lay in giving medicine energetically and keeping the bowels well open all the time.

F. MARION KENT, M.D., Spring Valley, June, 1897:—I first used your method of treatment in a number of cases three years ago. My results were much better than formerly, but I did not succeed in aborting but a few of the cases. One death occurred. Since then I have been using your treatment and have had very good results—no death in three years. My results in the first cases may have been due to impurity of drugs or improper administration of the same.

WILBERT B. CLARK, M.D., St. Louis, Mich., June, 1897:—One of my patients was in a family where there were two others sick with the same disease, and treated by other physicians, and both of these terminated fatally.

GRANVILLE MACGOWEN, M.D., Los Angeles, Cal., June, 1897:—I have treated a few cases by your method and have been pleased with the results. None of the cases died and none relapsed.

EPHRAIM J. MCCOLLUM, M.D., Tiffin, Ohio:—If any other doctor has had better success than I have reported, I should like to hear from him. I have been called into families where other physicians have suspected typhoid—that shows the faith of our community in the Woodbridge treatment and in those whom they know have been successful in the use of the same.

CLYDE W. CRUMLINE, M.D., Lone Pine, Pa., June, 1897:—I

Dr. John F. McGarvey, Loraine, Ohio. Patient, Walter Stang, aged 18 months. Admitted March 2. Recovered. Woodbridge treatment. This was a typical case and all his friends said he would die. I said he would live.

feel we owe a great debt of gratitude to you. My individual experience is limited, but I followed your directions faithfully. Not a dry tongue, no tympany, no "head symptoms," and in fact not a thing that I did not wish to see after the first twenty-four hours of treatment. There was no question about the correctness of diagnosis.

PERLEY P. COMEY, M.D., Clinton, Mass., May, 1897:—I have used your treatment in every case and feel perfectly satisfied with it. It is a sure thing and I advise it in all cases.

WILLIAM S. SMITH, M.D., St. Clair, Minn., June, 1897:—I do not hesitate to say that this treatment is by far the best yet devised for treating typhoid fever. In my hands it has yielded better results than the enthusiasts of other methods have claimed for their favorites.

EDWARD L. BAKER, M.D., Indianola, Iowa, May, 1897:—While I have not aborted cases, the comfort from the absence of delirium has been marked and recovery after intestinal hemorrhage has taken place before, such cases have died in my hands.

WALTER W. L. OVERFIELD, M.D., Forreston, Ill., May, 1897:—Prior to November, 1896, I treated my typhoid patients by

the older methods, but I am now convinced that the treatment advised by you is far superior to any heretofore in use.

T. W. S., M.D., Virginia, May, 1897:—Although I varied the method slightly, I consider it the only treatment to use.

LORENZO D. RAY, M.D., Blakesburg, Iowa, May, 1897: I remember one case, a very severe one, of a man who drank to excess. The symptoms were grave; the prognosis of consulting physicians was sure death. After consultation I began your treatment, improvement began inside of eighteen hours and his recovery was uneventful. He was married, 58 years of age a hard worker and a harder drinker. This treatment has worked exceedingly well for me in all cases especially of men who are inveterate drinkers.

MATTHEW K. ELMER, M.D., Bridgston, N. J., May, 1897:—In one case it cut the disease short, but in the others, while I thought it made the cases lighter, the cerebral symptoms less severe and the patients easier in every way, and they ran a very mild course, the duration of illness was about the same as usual. However, it is a great satisfaction to have these clear minds and mild symptoms.

JOSEPH O. YOST, M.D., Youngstown, Ohio, May, 1897:—Deaths? No, indeed! I would feel guilty of an unpardonable sin if I failed to use the "Woodbridge treatment" in typhoid fever or in fact in any intestinal trouble of bacterial origin.

WARREN C. EUSTIS, M.D., Owatonna, Minn., May, 1897:—I had one relapse but a return to your treatment prevented complications and in two weeks the patient was again convalescent.

LOWELL M. GATES, Scranton, Pa., May, 1897:—I have faith in the method but think it might be improved. I do not like to give medicine every fifteen minutes, so have given two every hour. If double the strength, it would not require so many tablets. The principle of intestinal antiseptics, combined with elimination of the septic material in the intestinal tract is doubtless the correct one in the treatment of typhoid fever. It has the advantage over the Brand method in being more reasonable. To treat by the Brand method alone is as unscientific as to treat the fever of an abscess by the same method without opening and washing out with an antiseptic solution.

JOSEPH E. BUNDY, M.D., Cissna Park, Ill., May, 1897:—We had an epidemic of rather a malignant type and I began treating typhoid in the usual way and lost two out of eight patients. Not satisfied with this I began with your antiseptic treatment and did not lose another case out of twenty. In these cases all of the symptoms were pronounced, and in those in which there was hemorrhage it was slight. I am satisfied that under your treatment most cases can be saved if seen in time.

ALOYSIUS G. BLINCOE, M.D., Bardstow, Ky., May, 1897:—I have never before seen eight successive cases of typhoid fever do so well.

C. W. FOSTER, M.D., Woodfords, Maine, May, 1897:—I have used your treatment with most satisfactory results, and shall use it again if I have occasion.

GEORGE W. HALL, M.D., Saint Louis, Mo., May, 1897:—We were much pleased with the effect of the remedies used. I believe that your treatment, modified to suit the requirements of individual cases, will be the treatment of the future in typhoid fever, and I feel that we owe you many thanks for directing the profession to the efficiency of "intestinal disinfection" in this disease. If we except the use of turpentine by Wood, and the use of nitrate of silver by Dr. J. K. Mitchell, to you belongs the honor of directing the attention of physicians to the intestinal canal as the place to which the main treatment should be directed.

C. RICHTER, M.D., Ashland, Wis.:—Most of my patients were in St. Joseph's Hospital, Ashland, Wis., and the charts are in the possession of the Sisters there. I have treated thirty cases and had two deaths. One of these had been treated by a druggist for two weeks while ambulatory drastic purgatives were given followed by salts; when the man fell into my hands he was in a precarious condition. The outraged intestinal mucous membranes responded by copious watery discharges, later by hemorrhages. There was an enormous tympanites and consequently and partly dependent on this, a weak heart's action. The Woodbridge treatment did not improve his condition and another hemorrhage ended the case fatally.

The second fatal case was of a nervous temperament. His wife and parents of a like disposition, proved a decided stumbling block to any rational treatment. Dr. G. W. Harrison, who treated the case, falling ill, I attended the gentleman. I remember that I predicted to Dr. Harrison a fatal termination of the case. His pulse was fast—120 to 125. His nervousness and restlessness were excessive, his general physique was anything but robust. I saw him about the second week of the disease. In his case I have the strongest reason to believe that the treatment was not properly carried out, from the mistaken kindness of wife and parents, who positively refused to awaken him to give the medicines. His life ebbed away by hemorrhages in the third week. Yet in his case, I noticed some of the symptoms—or rather the absence of the symptoms usually met with in typhoid fever under this treatment and of which in a general way I shall speak later. I consider both of these cases for obvious reasons as not properly to be classed under the head of those patients in whom I exhibited the Woodbridge treatment; however, I desire to be unbiased in the matter and consider it my duty to mention these cases and something of their history to you. Outside of these cases I have had no death while using the Woodbridge treatment in typhoid fever. My observations while treating typhoid fever patients with the Woodbridge treatment show that the disease has run a much shorter course than usual in typhoid fever. In several cases, fever stopped on the fifth and sixth day. Tympanites was entirely absent in all cases, after commencing. The stools, usually two in number during twenty four hours, while soft, were not diarrhetic nor very offensive. There never was a diarrhea with the characteristic pea-soup stools, but the

Dr. J. P. Matthews, Carlinville, Ill. Admitted August 11, 1895.

JAMES A. LIFFERTY, M.D., Concord, N. C.:—I am well pleased with the treatment.

MILTON C. CONNOR, M.D., Middletown, N. Y., May, 1897:—I have used the treatment, with my own modification, in every case that has come under my care for the last three years. Some cases relapsed from stopping the treatment too soon.

J. B. TAYLOR, M.D., Broadway, Ohio, May, 1897:—I believe the Woodbridge treatment is the best we have for typhoid fever. Hereafter I shall adhere strictly to your plan. All of my cases recovered, the average duration of illness being about seventeen days. I am perfectly satisfied that I was not energetic enough in the beginning. One point in particular I noticed, that while giving the treatment the tongue and teeth remained clean, the first being moist and the latter free from sordes: and there is also less distension of the bowels.

COLUMBUS N. UDELL, M.D., Blakesburg, Iowa, May, 1897:—This treatment is all right.

STEWART ROBINSON, M.D., Alleghany, Pa., May, 1897:—I had no relapse under this method—one case was tedious but finally made a complete recovery.

discharges were rather of a pultaceous nature. There was entire absence of distressing nervous symptoms—no severe headaches, no jactitation, no complications, no excessive thirst. In fact I base my recommendation of this treatment more upon its beneficial influence in abating these symptoms, than in particularly aborting or cutting short the attack, although it certainly has done so in several of my cases. My patients appear to me never to be very sick while under this treatment. The general clinical aspect of the disease was entirely changed and I say this after having seen and treated hundreds of cases of typhoid fever.

These are a few brief quotations from the reports of 193 physicians who have treated (since their previous report, or since they commenced the use of the treatment) 2,078 cases, with forty-five deaths. All of these reports have been received since I presented my paper to the Ohio State Medical Society on May 21, 1897, which gave the statistics of 5,449 cases and 105 deaths, all that had been reported to that date.

The statistics now show 7,827 cases treated with 150 deaths, a death rate of 1.91 per cent. This includes every death known to have occurred under the treatment, or any modification of it. Several deaths in which the treatment was known not to have been properly applied, a large number in which the treatment was not commenced until after the patient was moribund or practically so, and eleven in which the patient was so near the end when the treatment was commenced that death actually occurred within from eighteen to forty-eight hours, and a few cases in which the death was not due to typhoid fever or its sequelæ, are included. In only seven of the fatal cases do the reports show that proper treatment was instituted on or before the eighth day of the disease.

The average duration of illness in the 4,935 of the cases which recovered and in which it was given, was 12.7 days. Of the cases that recovered, 101 had intestinal hemorrhage. Ninety-five relapses are reported. Forty-seven were pregnant women, of whom two miscarried and died, six miscarried and recovered, and thirty-nine carried their children to full term, two giving birth to twins. In every instance in which the condition of the child is mentioned it is described as "fine," or "healthy," or "fine and healthy." Forty of the cases were complicated with pneumonia and recovered.

In 85 of the fatal cases the cause of death is given, 12 being due to intestinal hemorrhage, 14 to perforation, 10 to pneumonia. Six of the deaths are said to have been due to meningitis, 3 to consumption, 3 to Bright's disease, 2 to intussusception, etc. The stage of the disease at which the treatment was instituted is given in 69 of the fatal cases, in 10 of which it was from the first to the eighth day, in 10 from the eighth to the tenth day, in 14 from the tenth to the fourteenth day, in 16 from the fourteenth to the sixteenth day, and in 19 from the sixteenth day to the end of the third week. In 66 of the cases the stage of the disease at which the treatment was commenced is not stated.

These are the statistics and these brief quotations, together with the more than one hundred pages of closely typewritten excerpts from earlier reports presented to the Ohio State Medical Society, on May 21, constitute the verdict of the only jurors who are competent to render judgment, viz.: those who can speak from bedside experience. Among all these hundreds of reports, there appear but twelve adverse critics, not one of whom could possibly have been in possession of any accurate knowledge of the subject, not one of

whom had written to me for advice, nor called me in consultation, nor read the one published article in which I have given detailed directions for the management of typhoid fever. At least seven of the twelve, by their own admission, and one other certainly, did not use the treatment as advised, and the remaining five spoke from an experience limited to the treatment of fifteen cases, an average of three cases to each observer. This is an experience altogether too insignificant to justify an adverse criticism.

What are the salient features of this mass of reports of physicians who have broken away from the ideas of the past? These reports show that those who followed the directions given in my book, "Typhoid Fever and its Abortive Treatment," most closely, had the best results and have become the most enthusiastic advocates of the method and, vice versa, those who diverged most widely from the prescribed course met with failures. They show that many dangerous modifications have been made and that some of the deaths are due to these alterations. They show that rapid recoveries have followed its use when first applied at all the different stages of the disease, and even after all hope had been abandoned by the attending physicians who had used other methods, and in several instances after the supervention of alarming intestinal hemorrhage, they show rapid recoveries during the most careless and injudicious use of the most subversive counterfeits of the original prescriptions. They show the administration of such infinitesimally small doses as would make the most orthodox homeopath blush and of doses the size of which would make the rashest heroic of the past tremble.

Despite these encumbrances, the method of treatment has passed through the ordeal of its first years of trial by both its friends and its enemies, who have treated 7,827 cases with 150 deaths, or a death-rate of less than 2 per cent. and a duration of illness of a trifle over twelve days. Under its benign influence the severity of the disease is greatly ameliorated, the symptoms minimized, all grave complications averted and dangerous sequelæ prevented. The tongue is quickly rendered moist, tympanites promptly relieved, excrements lose their offensive odor, delirium is rare and the "typhoid state" unknown. The appetite soon returns and the patient expresses a desire to get up and eat solid food, which he may do if he has been properly treated from a sufficiently early stage so that ulceration of Peyer's glands has been prevented. Tedious convalescence is avoided, the patient generally passing rapidly from the fastigium of the disease to vigorous and robust health. These are results which have never before been obtained in hospital or private practice, in so large a number of cases, by so many physicians. They are results which were never before deemed possible. They have been obtained in most instances, without the use of the cold bath, medicinal antipyretics, or alcoholic stimulants, all of which are generally unnecessary. They prove by incontrovertible evidence that typhoid fever can be aborted. They teach that it is amenable to curative treatment in all of its stages and they go far toward proving that death or protracted illness are wholly unnecessary consequences of the disease.

In conclusion I wish to say that I am deeply grateful to the physicians who have so courteously and courteously responded to my letters of inquiry and in so doing have made it possible for me to submit this report.

TRICHINOSIS IN THE UNITED STATES: WITH THE REPORT OF A CASE.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association held at Philadelphia, June 1-4, 1897.

BY FREDERICK A. PACKARD, M.D.

PHILADELPHIA.

Feb. 5, 1897, an Italian was admitted to my ward at the Philadelphia Hospital, complaining greatly of pains in the thighs and legs. Owing partly to his natural mental obtuseness, partly to his nationality, the history that could be obtained even with the aid of an interpreter, was by no means satisfactory. On this account many points in his history are vague, while some of the facts in his case could not be determined.

He gave his age as 28 years, his occupation that of a farm hand. He could give us but little information in regard to the locality in which he had last worked, but said that it was in New Jersey. After three months of enforced idleness (from lack of work) he started to work on a farm on February 1. The work being too laborious for him he left the farm, although he seems not to have felt ill in any way. On the third of the month (two days before admission) he had a decided chill, with some vomiting but no diarrhea. On the day of admission the face had begun to swell. As to the dates recorded there may be some doubt, although repeated questioning only seemed to confirm the statements made above.

On examination it was found that he was a rather strongly built man. There was quite marked edema of the eyelids and the surrounding skin, especially above the brows. The swelling was quite sharply margined above and over the malar bone, the skin being quite red and rather shiny. The pupils were equal and natural. The pulse was of good force, full volume and rapid. The tongue was slightly coated and rather dry. Examination of the heart and lungs showed nothing abnormal. The abdomen was rather scaphoid, showed no tender area or gurgling and there was no eruption. The areas of hepatic and splenic dulness were normal.

The joints were free from swelling, redness or heat. There was no visible change in the painful parts but the least pressure upon the legs or thighs at once caused complaint of pain. This tenderness was diffuse, in that it did not correspond to nerve trunks, blood vessels or bone, but was decidedly more marked toward the ends than over the belly of the muscular masses. The temperature on admission was 101.4 degrees, the pulse 94, respirations 20.

Sodium salicylate, gr. x, every three hours, and also a sponge bath if the temperature reached 103 degrees was prescribed. The patient passed a sleepless night, and on the next day complained rather more bitterly of muscular pain in the thighs and legs and also in the arms. Examination of the urine showed that it was yellow in color, of acid reaction, specific gravity 1025 and contained no albumin, but in the sediment there were found a few granular casts and leucocytes. He complained much of thirst and dryness of the mouth.

A daily record of the events of the case would be rather devoid of interest and it will suffice if the main facts of the clinical course are noted. The pain in the muscles of the thighs and calves continued without intermission until March 2, almost a month from the time of onset, although it is questionable whether

they were very severe during the latter part of this time, inasmuch as they suddenly departed on that date, after a small incision of the calf. Insomnia was a marked feature for the first eleven days of his stay at the hospital. There was no vomiting after admission. The bowels moved three times on the day after admission, twice on the 9th and five times on the 10th of the month; but were simply brown, watery movements without distinctive character.

The edema of the face subsided after four or five days and the skin at once presented its normal appearance. There was no swelling, ecchymosis or redness of the conjunctiva at any time.

On February 9, the sixth day of his illness, the fourth day after admission, some small red spots were found on the abdomen, which were caused to disappear by pressure and were called "suspicious." These persisted but a day or two and were not succeeded by others. There was slight cough on and for a few days after February 16, with scanty, glairy white expectoration. This was examined on the day of appearance and a few tubercle bacilli were found. As the diagnosis of trichinosis had been made with quite positive certainty before that date and as there were no physical signs of lung involvement, subsequent careful examinations were made, always without result, and it was concluded that the presence of bacilli in the first examination must have been due to accidental contamination.

The urine was scanty, at times only measuring from twelve to nineteen ounces in twenty-four hours; the specific gravity was invariably high, ranging from 1024 to 1027. No albumin was ever found, but in two examinations there were found granular casts; on one occasion on ordinary sedimentation without the aid of the centrifuge. No estimations of urea, uric acid, etc., were made. Profuse sweating was present on four days (from the tenth to the fourteenth day of his illness).

The temperature, as will be seen by the accompanying chart, pursued a remitting course from the time of admission until March 9. For the first two days it progressively increased until it reached 104.4 degrees, then suddenly fell to 100.6 degrees, only to soon rise to over 103 degrees. On the ninth of the month (the sixth of the disease) he had but little fever for the greater part of the day, then the temperature quickly ascended to 103.8 degrees, to fall irregularly almost to the normal point on the next afternoon. On February 11 it suddenly descended to 96.6 degrees with no apparent cause other than profuse sweating, and from that date became extremely irregular until February 16. From that time onward it pursued an erratic course of slight elevation above the normal until it finally settled to the normal on March 9.

The pulse was accelerated during the whole time of fever but was not out of proportion to the elevation of temperature. At the latter part of the febrile period it became rather soft and compressible. The respirations were abnormally numerous from the day of his admission until several days after his temperature had remained at the normal point. As will be pointed out later, this was one of the most potent factors in arriving at the diagnosis. On February 23 the feet and legs were found to be very edematous, white in color and pitting deeply on pressure. This persisted until his discharge from the hospital on March 25.

The blood was examined March 10. The result showing 4,230,000 red cells per c.mm., hemoglobin 74 per cent., 8,000 leucocytes per c.mm. After reading T. R. Brown's "Studies on Trichinosis," in the *Johns Hopkins Hospital Bulletin* for April, 1897, I much regretted that repeated examinations with differential estimation of the leucocytes were not made. The estimation of the relative proportion of eosinophiles would have been especially interesting in view of Brown's finding a percentage of these corpuscles as high as 68.2 per cent., with corresponding decrease in the polymorphonuclear neutrophils to 6.6 per cent. Brown's discovery of great leucocytosis (30,000 per c.mm.) was certainly not present in our solitary examination on the thirty-fifth day of the disease.¹

Dr. C. A. Oliver kindly made an examination of the ocular conditions and furnished me with the following report: "Vision and accommodative power normal. Pupils 3.5 mm.; irides equally and freely movable to the light, convergence and accommodation, marked hyperphoria for near and far, eye ground normal with the exception of a fine striated hemorrhage partially overlying the inferior temporal vein just beyond its primary bifurcation in the left eye. Field of vision normal. *Summary:* No gross ocular changes except a slight disturbance in extra-ocular muscle equilibrium in the vertical meridian, and a fine isolated venous extravasation in the superficial layers of the left retina." The voice was at no time husky or altered beyond the changes produced by the dryness of the mouth. Laryngoscopic examination was negative. Hearing was at no time impaired.

On February 25 I lectured on this case in the clinic, giving the following reasons for my diagnosis: There were but six possible diagnoses: typhoid fever, rheumatism, influenza, non-discoverable tuberculosis, myositis from cause other than the trichina spiralis and trichinosis. Typhoid fever could be excluded by the atypical temperature curve, by the facial expression, the appearance of the tongue, the absence

of tympanites, the lack of splenic enlargement, the character of the stools and the absence of the ordinary prodromal symptoms of that disease. The few "suspicious" spots on the abdomen were not atypical of typhoid and were not succeeded by other skin lesions. No form of rheumatism would give us such symptoms as we had in this case, except the so-called "muscular rheumatism," which is usually accompanied by but slight elevation of temperature, is seldom distributed in the manner here present, is seldom accompanied by pain of such acute character and would in no way account for any of the symptoms here present except the muscular pains. Influenza could with rather more difficulty be excluded, but was ruled out by the long continuance of the pain and temperature and by the extreme muscular tenderness present, while the occurrence of many of the symptoms could hardly be accounted for by even this protean malady. Non-discoverable tuberculosis should only be diagnosticated after careful exclusion of every other possible cause for the symptoms, and in this case there was no good reason for suspecting its presence, while it would only account for the temperature elevation and would not explain the peculiar pains. No cause for a non-trichinous myositis could be found. In favor of trichinosis were the muscular pain and tenderness, chiefly near the tendinous insertions of the muscles, the history of vomiting at the outset, the atypical and irregular temperature curve, the insomnia, the thirst, the sweating, the rapidity of respiration, but above all by the early swelling of the upper face and the late edema of the feet. Two points militated against the diagnosis—the absence of early diarrhea, the vague history of the eating of raw pork and the absence of other known causes of infection. The absence of diarrhea showed but little, inasmuch as it is by no means constantly present in trichinosis. Careful inquiry showed the occasional eating of bologna sausage as the only probable source of infection, while the fact that the patient immediately left the place where he probably contracted the disease and his ignorance as to his fellow laborers rendered futile any attempt to discover the existence of other

¹ Cabot (A Guide to the Clinical Examination of the Blood, 1897, p. 192) says that a case has lately been observed in Dr. Osler's clinic at Johns Hopkins Hospital with a leucocytosis of 25,000, and 61 per cent. of eosinophiles. It is possibly the case reported by Brown and referred to above.

cases. The two points that made me feel most certain of my diagnosis were the occurrence of frontal edema and the otherwise unaccountable rapidity of respiration, the latter being readily explained by the predilection of trichinae for the diaphragm.

On March 2 the patient consented to the removal of a piece of muscle from the left gastrocnemius. A small piece was excised and showed a very large number of living, non-encapsulated embryonal trichinae scattered among the muscle fibers. The operation greatly relieved his pain, so that there was no difficulty in gaining his consent to a second exploration in the gastrocnemius of the right leg on March 17. This specimen showed a great number of embryos with beginning capsule formation.

Some of this muscle fiber was fed to two white rats for experimental purposes, and it was my desire to present to this meeting some results of feeding experiments, but unfortunately I have not been enabled to complete my study of this portion of the subject in time to give my conclusions at present. Through the kindness of Dr. D. E. Salmon of the Bureau of Animal Industry I obtained a large supply of trichinous meat, which I have fed to white rats and guinea pigs in order to determine some of the still undecided questions in regard to the path of migration of the embryos and to the finer changes in the infected muscle fibers, but the investigation has required more time than I have been able to devote to it and I shall have to report my results in a later communication.

This is the fourth case in which I have made the diagnosis of trichinosis during life, but the first in which I have been able to persuade the patient to allow me to make the one crucial test in sporadic cases—the excision and examination of a piece of muscle. That many cases of infection by trichinosis must occur annually in this country can, I think, not be doubted. I regret that it was not in my power to further follow up the source of infection of my patient. When last seen my patient was steadily gaining flesh and had returned to work.

In the Twentieth Annual Report of the State Board of Health of Massachusetts, published in 1889, there

is an interesting paper by Prof. E. L. Mark, of Harvard University, upon "Trichina in Swine." Between the years 1883 and 1888 he examined 3,064 hogs raised near Boston. Of these 394 or 12.86 per cent. were trichinous. Of 3,298 hogs raised in Massachusetts, 436 or 13.22 per cent. showed trichinae on examination. Of the 234 examined hogs slaughtered for State institutions, 42 or 17.95 per cent. were trichinous. The pork intended for export or interstate trade (see 8th and 9th Annual Report of the Bureau of Animal Industry, 1891) is inspected, and if found free from trichina by the inspectors of the Department of Agriculture, is labeled as inspected and passed. For the year ending June 30, 1882, 1,267,329 hogs were examined. Of these, 25,899 were trichinous, 2.043 per cent. As the trade in pork within the States does not receive official inspection it may be that the figures given by Prof. Mark for Massachusetts are not very much, if at all, above the average of other States. If so, there must be frequent infections. Reports of individual cases, such as is the present contribution, are of but little value as compared with the accounts of groups of cases, yet I can not think that the disease is frequently diagnosed when so little mention of it is found in the journals. Possibly the observers of the disease have not thought the subject sufficiently interesting to make it worth their while to publish their isolated cases. I hope that their opinion is not correct.

In order to obtain some idea of the prevalence of trichinosis in the United States and Canada I have tabulated the cases reported in the various journals, in so far as they are accessible to me. A tabulated list of these I have appended to this paper. The results may be summarized as follows:

Between the years 1864 and the present time there have been reported in the United States and Canada 357 cases of trichinosis. Of these, 243 recovered, 80 died, while in 17 the result is not stated. The mortality, therefore, of the 323 cases where the result is definitely stated, was 24.76+ per cent. The total above given is probably far too small, inasmuch as a large number of the reporters state that many cases

ANALYSIS OF CASES OF TRICHINOSIS OCCURRING IN THE UNITED STATES AND CANADA.

No. Year.	Reporter.	State.	Place of Publication.	Total.	Recovered.	Died.	Remarks.

occurred where medical aid was not sought. By the second table it will be seen that cases of the disease have occurred in seventeen States, in the District of Columbia and in Canada. The State from which the the largest number of cases has been reported is New York, which also heads the list in regard to the number of reports. On the other hand the largest definitely estimated epidemic occurred in Massachusetts. The greatest number of cases reported in one year occurred in 1892, when there is seen to have been more than fifty-one cases. The reason for this can not be given and there is no evidence of any growing frequency of the disease before or after that year. There occurred in that year three outbreaks of considerable size, two in Massachusetts (15 and 21+) and one in Mississippi (19).

Occurrence by States.	Total.	Number of reports.	Largest number at one time.

In conclusion, I report this isolated case in order to again draw attention to a disease that I believe may be of greater present importance than is usually thought, and also to draw particular attention to a symptom that did much to guide me to a correct diagnosis—the great rapidity of respiration without other evident cause. I mention this symptom especially for the reason that, while many state that symptom was present in their cases, I do not believe that sufficient importance has been attached to rapid respiration as a prominent symptom of this affection. Finally I would urge the importance of certainly excluding trichinosis before making the much abused diagnosis of muscular rheumatism.

A REPORT OF TWO CASES OF MYXEDEMA WITH REMARKS ON AN ANOMALOUS TYPE.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association held at Philadelphia, Pa., June 1-4, 1897.

BY J. M. ANDERS, M.D., LL.D.

PHILADELPHIA, PA.

Myxedema is a general disorder of metabolism, dependent upon diminished or lost thyroid function. Among various morbid processes affecting the gland and which have been observed to give rise to myxedema are the following: atrophy, atrophy associated with calcareous degeneration, atrophy with enlargement of

the pituitary body, actinomycosis, syphilitic degeneration of the organ, and the presence of neoplasms. It is to be recollected, however, that disease of the thyroid is not followed by cachexia strumipriva, provided even a small portion of the gland remains functional. The truth of this dictum was shown by the postmortem findings in the case contributed by Sieveking,¹ in which sarcoma had invaded the thyroid. This fact is also fully confirmed by the results of experimental extirpation of the thyroid in animals; total removal of the gland is regularly followed by myxedema (except functional accessory thyroids be present), while if even one-tenth of it is allowed to remain, the animal escapes the disease.

Of intense interest are recorded cases in which myxedema is either associated with or occurs in persons who have previously suffered from exophthalmic goiter. Baldwin² reports four cases belonging to this category. The first occurred in a boy of ten, four years after Graves' disease; the second affected a girl of fourteen, two years after the exophthalmic goiter was cured; the third, a girl of fifteen first showed signs of myxedema five years after improvement from Grave's disease; and the fourth, a woman of forty-four, four years later.³ It is an almost universally accepted belief that exophthalmic goiter is dependent upon excessive thyroid secretion the direct antithesis of myxedema. Like cachexia strumipriva, exophthalmic goiter is held by the weight of authority to be caused primarily by thyroid changes that bring about "thyroidation." Accepting this view it is quite conceivable that morbid processes first causing over-stimulation of the gland, may, in their future progress, lead to abnormally feeble or an entire absence of glandular secretion, and thus the former condition may predispose to the latter. The tendency to myxedema may be observed in several members of the same family, but I believe this to be rare.

The complex symptom-group of typical cases of myxedema is at present writing well known, and the literature bearing on this aspect of the subject is so extensive as to be much beyond the compass of this article. The following cases are reported: 1. For the reason that one of them manifested certain features of unusual significance. 2. To confirm the well-deserved professional favor gained by thyroid extract in the therapy of this disease. 3. To discuss a few of the main questions which have been raised in connection with the subject of treatment; and lastly, to direct attention to an anomalous or a rudimentary type that yields easily to sheep's thyroid.

Case 1.—M. R., age 50, female, fell ill about fifteen years ago, showing symptoms that were of slow and gradual development, becoming eventually typical of this affection. When I first saw the patient, the neck and supraclavicular regions were observed to be bloated; also the face, giving rise to a peculiar physiognomy. The features were bulky and expressionless, the face broadened, and the lineaments were practically obliterated; the lips were greatly thickened and the tongue markedly swollen. The general bulk of the body was obviously increased. The pressing finger showed an absence of pitting, even over the face, where stiff edema was most marked. A circumscribed red patch was noticeable on the cheek. The skin, particularly the backs of the hands, was dry, rough, somewhat scaly and inelastic; the nails were quite brittle, the hair was coarse and constantly shed.

The mental symptoms were not striking, except that thought and speech were slow, and the tone of the voice, was characteristically leathery. Hallucinations and impairment of memory were not observed. Occipital headaches and neuralgic pains

³ Gould's Year-book of Medicine and Surgery, 1896.

were frequently complained of, as was also muscular weakness. The temperature was slightly subnormal (98 degrees), but cold hands and feet were not experienced.

There was slight though decisive albuminuria, and this symptom I learned had been present for four or five years at least, with hyaline and granular tube-casts at intervals.

On account of the presence of persistent albuminuria, her former physicians, two in number, had diagnosed chronic nephritis. Temporary albuminuria with casts, is frequently met with in this disease, but the persistent characteristic features of chronic Bright's are not seen. After treatment with extract of thyroid for six weeks, the urine presented no abnormalities: neither has albumin or casts reappeared since then (as shown by repeated testing). Believing herself to be a sufferer from renal affection, and being possessed of superior intelligence, I was unable for a long time to induce the patient to make a trial of thyroid extract.

The interesting features were limited to the urinary phenomena. The relation of mere albuminuria or actual nephritis to myxedema is not definitely known. On the other hand, it should be pointed out that the symptoms of Bright's have been observed to appear after the accomplishment of a cure by thyroid feeding, in cases in which no urinary phenomena had been present during the course of myxedema.

Case 2.—Mrs. Rebecca Coates, aged 50, a patient under the care of Dr. A. E. Roussel at the dispensary services of the Howard Hospital.⁴ Mother died of phthisis, father killed in an accident. Patient has been in the best of health until three years ago, when menstruation ceased. Has had several attacks of rheumatism, and recently, the body in general has been getting more and more bulky. The face at present is puffy and edematous-looking, but does not pit on pressure. The skin is rough and dry and the lips blue. The hair is dry and falling out. The nails are clubbed and brittle. Her expression is heavy and stupid; the speech is slow and hesitating and the voice rough. The memory is impaired and she frequently suffers from headaches. Mental aberrations occur frequently, she talks incoherently and believes she sees objects. There is a certain stiffness and clumsiness in the gait. The respiration is slow. Her temperature is 98 degrees and she complains of feeling cold. She is easily fatigued, complains of a bitter taste in the mouth, has a poor appetite, and her bowels are irregular. The urine is normal (specific gravity 1020, no sugar, albumin nor casts present).

Treatment was commenced on March 20: the patient was asked to lead a quiet life and was put on the extract of thyroid, grs. iii, three times a day. On March 23 the patient returned and stated that since taking the remedy, she suffered greatly from pain in the stomach and bowels, and at night from aggravated nervous symptoms, such as mental wandering and the apparent sight of different objects. The dose of the remedy was then reduced to 1 gr., three times a day, and on March 27 the patient came back complaining that the medicine still disagreed with her and produced profuse sweats.

On April 1, the desiccated thyroid powder was ordered, grs. 3, three times a day. On April 6, the dose, which had been well-borne in the meanwhile, was increased to grs. 5, thrice daily. On April 10, she presented herself again and reported that she had been troubled with copious sweats, and had noticed that her weight (found to be 168 pounds at this time), was decreasing. On April 13, the thyroid gland powder was increased to 7 grs., three times a day, and on April 17, she complained of severe pains in the limb particularly the legs, and a burning sensation in the stomach. After the use of small doses of hydrochloric acid, internally and of chloroform liniment, locally for the leg pains, relief came. The patient did not return for eleven days (May 1), or about six weeks from the date of the commencement of the treatment. At this time the bloating of the hands and face had largely disappeared; the voice was less harsh and leathery in tone, and her weight 160 pounds. On April 18 she presented herself again apparently in excellent health, and expressing herself as being free from gastric or other symptoms. Her weight was now 143 pounds, a loss of 25 pounds while under treatment with thyroid gland powder.

As the result of wide experience, to which a mite has been contributed by many different clinicians, the specific virtues of sheep's thyroid in the treatment of pure myxedema have been conclusively established. It is also the unanimous opinion of writers, that certain precautions must be taken during the administration of this remedy. The commencing dose must be small, since many individuals are remarkably susceptible to the action of this agent. Thus in case No. 1, not more than one grain daily of the thyroid gland powder could be tolerated at first. The dose was very gradually increased, until at the end of the fourth week, five grains daily were well borne, and the myxedematous condition rapidly disappeared under this small dose. This patient took three doses of 3 grains each on the same day, and after the last, symptoms of hyperthyroidation developed. There were intense headache and syncope, with a feeling of powerlessness in the legs. Rest in bed for a short period, and the use of cardiac tonics soon caused these symptoms to disappear. Subsequently, I combined with each dose of thyroid extract, gr. 1-36 of strychnin sulph., and after that no toxic effects were observed. There can be no question but that the evidences of cardiac failure constitute a really serious defect, and perhaps, the only one in the thyroid treatment. Murray⁵, who first used thyroid extract in the treatment of myxedema, lost two of his early cases from cardiac failure, brought on by over-exertion. This observer strongly recommends rest in bed for a time after treatment has been instituted, with a view to avoiding cardiac and arterial strain. This may be necessary in long-standing cases, and in those in which "cardiac or vascular degeneration" are present. Ordinarily, the administration of strychnin will be found to avert any dangerous degree of cardiac failure, and this should not be omitted until a cure is effected. Only the gentlest exercise is permissible during the same period.

Case No. 2 manifested toxic symptoms (gastro-intestinal pains, profound sweats, etc.,) from the administration of small doses (gr. 1, t. i. d.) of the glycerin extract of thyroid. It is worthy of repetition that the desiccated thyroid gland could be taken by this patient in doses three times as large as the glycerin extract, and without unpleasant or toxic effects.

Not all of the symptoms that follow the administration of thyroid are due to over-dosing. As pointed out by Murray, an increase in the pulse-rate amounting to ten or twenty beats per minute simply indicates that the dose is quite large enough. In case No. 1, a most intense itching over different parts of the skin-surface occurred at intervals, and caused intolerable distress; a diminution in the size of the dose did not seem to influence the course of this symptom. The phenomena to be watched for and to be regarded as adequate reasons for stopping the remedy, are numerous, and are not sufficiently emphasized in our textbooks. They are tachycardia (over 100 beats per minute), elevation of the temperature (amounting to one or more degrees), syncope, vertigo, suffusion of the face, profound prostration, intense headache, profuse sweats and gastro-intestinal disturbance. Granting that exophthalmic goiter is attributable to hyperthyroidation, if during the administration of thyroid glands symptoms of this disease, such as slight tachycardia, fine tremor, exophthalmos, heat and sweat, insomnia, restlessness, polyuria, glycosuria, or albuminuria and the like appear, the dose should be

⁴ The notes of this case have been kindly prepared by Dr. Mishkin.

⁵ British Medical Journal, April 13, 1891.

reduced, but the remedy need not be discontinued. It is well understood, that after total disappearance of the myxedematous infiltration, the treatment may have to be continued off and on, if not continually: this is due to the fact that the thyroid is no longer functional, being as a rule atrophied.

Examples of what may be regarded as an anomalous type, that do not seem to progress to the fully developed disease with its characteristic clinical picture, are, I am certain, not infrequent. They are not to be regarded as instances of cretinism, since they develop after the age of 15 years, and few of the characteristic symptoms of myxedema are present. The face is rather flat, the skin somewhat swollen, dry, firm and inelastic. The features also lack mobility, but are not so coarse or bulky as in true myxedema. The physiognomy is dull, uninteresting and phlegmatic. There is a slight increase in the general bulk of the body, but the lips, nose and tongue are chiefly implicated. The lower jaw may be prognathic. The gait is somewhat uncertain, owing to trivial disturbance of coördination. There is some alteration of the voice with a tendency to occasional nasal explosions during speech. Thought is somewhat slow and the memory lags. Other mental phenomena are irritability of temper and an unnatural degree of suspiciousness though not so pronounced as in typical cases. Such patients are often apathetic or even melancholic and if constipation or gastric disturbance be present, a supposed chronic dyspepsia is liable to be mistaken for this complaint. There is also danger of confounding these cases with neurasthenia. Even in the presence of the above symptom-group it is not possible to make an absolute diagnosis, but the therapeutic test (improvement under thyroid feeding), if properly made, clears the doubt with reasonable certainty. I have recently observed the disappearance of a grouping of symptoms such as I have described in two cases as the result of the administration of sheep's thyroid. One of these patients had been treated for nervous dyspepsia and constipation for a long period of time.

THE TREATMENT OF EXOPHTHALMIC GOITER AND OTHER VASOMOTOR ATAXIAS WITH PREPARATIONS OF THE THYMUS GLAND AND OF THE ADRENALS.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY SOLOMON SOLIS-COHEN, M.D.

PHILADELPHIA, PA.

I desire to make a brief report of a number of cases of exophthalmic goiter, and of conditions more or less closely resembling exophthalmic goiter, treated by means of extract of the thymus gland and of the suprarenal capsule. It is not my purpose in this paper to discuss at length the vexed questions of the etiology and pathology of Graves' disease, and of those conditions to which I have in a previous paper given the name of vasomotor ataxia. Nevertheless, some slight allusion to these subjects is necessary to make myself fully understood. I hold that there are almost innumerable varieties of disturbances of the cardio-vascular balance, ranging from the merest departure from the normal, to the most pronounced case of Graves' disease on the one hand, and of Raynaud's disease upon the other. The principal clinical

phenomena of these conditions are disturbances of the heart's action, and central or peripheral phenomena indicative of abnormal contraction or dilatation of the vessels. The essential element is incoördination or ataxia of the circulatory mechanism, and among more or less prominent secondary symptoms are murmurs in the heart and vessels; blood losses which may range from severe pulmonary, uterine or renal hemorrhages, to slight epistaxis, hematemesis or hemoptysis, or perhaps merely petechiæ upon the skin, or the presence of blood cells revealed only to microscopic search in the urine; headache or vertigo; syncope with flushed or with pale face; local heat and redness of ears or face, usually unilateral; numbness and tingling of the extremities; discoloration of the hands and feet; subjective pulsations and "flashes" of heat and cold; excessive sweating, polyuria, and the like. These phenomena in their milder or in their severer forms are more common in women and are often associated with disturbances of menstruation; the familiar symptoms of the "change of life" belong in this category.

Among other associations having an etiologic suggestiveness are abnormality of the thyroid gland, gastric and intestinal disturbances, gout and lithemia, rheumatism and rheumatoid arthritis, hay fever, neurasthenia, hysteria and cutaneous pigmentation. The phenomena may be intermittent and capable of artificial reproduction, and we thus find as their principal exciting causes, toxins (both autogenetic and heterogenetic), temperature changes, and emotional disturbances. In most cases, of whatever origin, a distinct temperature relation can be made out, the patient feeling better or worse in summer or winter, respectively.

As a whole the phenomena are merely exaggerations, in duration and degree, of the effects of the same kinds of exciting influences upon normal individuals, or to put it another way, the same phenomena which in the cases under consideration are interpreted as evidences of disease, may occur transiently in normal individuals under similar exciting causes of greater magnitude. Thus severe cold may cause in a healthy person phenomena much like those which, excited by a minor cause, we call Raynaud's disease; and intense heat, anger, fright, sexual excitement, produce many of the phenomena we find among the symptoms of Graves' disease. Familiar illustrations of the minor varieties are the attacks of urticaria, which in some individuals result from the ingestion of foods that most persons can take with impunity, and the eruptions and edemas that mark so-called idiosyncrasies to drugs. Here, too, we find an interesting connection with angio-neurotic edema, which in some of my cases can be produced at will, in certain localities, by moderate trauma, for example as a slap on the lips; and in this as in other phases of the general subject the influence of family and of heredity is marked. In some cases the phenomena of irregular and excessive dilatation, in others those of irregular and excessive contraction of vessels predominate; in all some phenomena of both kinds are found; in all there are paroxysmal exacerbations; in some normality apparently prevailed during the interval. Whether the group of affections thus included would or would not form in rigorous nosologic classification and order, whatever the exact mechanism of the symptoms or the immediate exciting influence, the fundamental cause is apparently a

constitutional vice of nutrition, an instability in the nervous centers governing the cardio-vascular balance; and we are led to direct our therapeutic measures accordingly.

Confining our attention now to those cases which present phenomena chiefly referable to vascular dilatation, we find that the most severe of these have for their usual concomitants, enlargement of the thyroid gland and protrusion of the eye-balls. In nearly every case tremor is associated with the tachycardia, exophthalmus and goiter, which Graves and Basedow described as the triad, characterizing the affection to which their names have been given; and in all of the cases which I have studied since 1892, I have found dermatographism, factitious urticaria, and the peculiar crescentic markings upon the nails, to which I called attention in my first paper on this subject.

The statistics of treatment in exophthalmic goiter are confusing to the student. Some cases recover without treatment, some fail to recover under any treatment, and many cases of recovery or great improvement are reported from the most varied forms of treatment. In order to be made valuable the recorded statistics need close analysis as to many facts, some of which are not commonly observed. We should include not only heredity, age, sex and apparent exciting causes, but the physical and mental temperament of the individual, and such other relations of morbidity and susceptibility to therapeutic measures, as may be needed to give a complete picture. Let statistics be what they may, few among those who have had large experience with Graves' disease will be content to trust to spontaneous recovery, or will fail to draw a conclusion of cause and effect between the treatment instituted and the results following.

It has been my fortune to have had a comparatively large number of cases of exophthalmic goiter under observation, and I have seen recovery and partial recovery from various methods of treatment, which have, however, agreed in that they were devoted to the removal of excretion and intestinal antisepsis, of toxins that might be circulating in the blood; to the soothing of the excited nervous system by rest; and to the restoration of cardio-vascular tone by appropriate medication or other remedial influence, *i. e.*, galvanism or the application of cold.

In common with many other observers, I was led to the use of thyroid extract experimentally, when that substance was first introduced into practical medicine by British observers, and contrary to the experience of most others, and to my own experience in other cases, one of my patients so improved that he refused to remain longer in the hospital. He was under treatment from January to March, 1893.

Dr. David Owen of Manchester, published the report of a case in which wonderful improvement followed the supposed ingestion of thyroid gland; but further investigation showed that the butcher had been supplying his patient not with thyroid gland but with thymus. In my case the preparation was furnished by Messrs Parke, Davis & Co., while they were still experimenting as to methods, and before they had placed it on the market, and they assured me that no such mistake had occurred. Paton's partial recovery, therefore, remains unexplained.

I should also mention in this connection, the good effect of thyroid extract in a case of marked vaso-

motor ataxia, characterized by right or left hemiparesis, with temporary numbness and paresis of the opposite arm, and great pallor of the face, occurring at first spontaneously, but now only after certain indiscretions in meat or drink, in a man whose mother had had exophthalmic goiter. The continuous administration of a small dose of thyroid extract will ensure complete absence of attacks; a large dose will cause headache and vertigo, with opposite symptoms, namely flushing and warmth of the face; while nitroglycerin or amyl nitrite is required in the paroxysm. As a rule thyroid extract benefits that group of patients who feel best during the summer, and injures those whose worst symptoms occur in warm weather.

From Owen's experience with thymus; from almost universal experience that thyroid is harmful to patients with Graves' disease, exaggerating the symptoms; from the fact that tachycardia and vascular unbalance, even to fatal issue, may be produced from incautious use of thyroid in myxedema; from the frequent persistence of the thymus in akromegaly, indicating some yet unexplained reciprocal relation between this gland and the thyroid, I was led to the deliberate administration of thymus to patients with exophthalmic goiter and minor degrees of vasomotor ataxia.

I have so treated twelve cases of pronounced Graves' disease. I present a few cases in which the improvement has been remarkably great. In Mrs. B. (May 5, 1896) the goiter has almost entirely disappeared, the exophthalmus is scarcely perceptible, the heart is quiet, concomitant rheumatoid arthritis has much improved, pain being almost gone, and the nervousness and trembling, which was her principal complaint, is entirely gone. (See case of Mrs. McD.)

In Mrs. McE. (Aug. 7, 1895) the goiter has been reduced about two-thirds, the Addisonian color has been much lightened, the nervousness and sleeplessness has disappeared. In a third case, Miss L., a patient referred by my friend and colleague Dr. S. D. Risley, the improvement is equally great but less striking; inasmuch as the goiter never was very large nor the exophthalmus prominent. Tachycardia and nervousness have disappeared and general nutrition has been greatly benefited. In a fourth case, Mrs. McD., quite severe, which I saw in consultation with Dr. Albert M. Eaton of this city, there were many interesting diagnostic and etiologic points. After an operation for ovarian cyst, followed by sepsis, the patient complained of severe cardiac pain and dyspnea, and there was observed excessive rapidity of pulse. At the time I saw her she had been confined to her bed for some months; goiter and exophthalmus were evident. Thymus extract was presented and the patient was so far reduced after treatment that she was able to follow her accustomed duties. A relapse suddenly followed and it was found that the druggist had given thyroid instead of thymus. I may add that Mrs. E. experienced a similar relapse from the same cause, the goiter enlarging and becoming quite hard and tense like a cyst.

Upon return to thymus there was renewed improvement. Although the dose given has been throughout too small, the patient refusing to take the quantity prescribed, Dr. Eaton tells me that the goiter is almost gone, the dyspnea entirely gone, the heart quiet and regular except on unusual exertion, and the patient able to go shopping.

In two other cases of genuine Graves' disease, and in some twenty or thirty cases of minor varieties of vasomotor ataxia, of the relaxing variety. I have seen equally good results. Dr. Hector Mackenzie recently reported twenty cases of exophthalmic goiter treated with thymus without benefit.

More recently, the physiologic experiments showing that in the adrenal secretion there exists a natural raiser of blood pressure, probably active by constriction of the vessels; together with the fact that Addisonian pigmentation occurs in some cases of Graves' disease; and that exceptional cases are met with in which exophthalmic goiter and Addison's disease are alternate diagnoses, suggested the use of adrenal extract in the treatment of this affection. Since I instituted it, at the Philadelphia Polyclinic, I have seen publications of similar observations elsewhere. Two patients disappeared from observation before any conclusion could be drawn, except that they could take remedy without ill effect. I therefore reverted to an old patient who would remain under observation. I refer to Mrs. B, whom I have already shown as an example of the good results of thymus treatment. She had been absent from the clinic for six months, during which time she had been without medicine. She returned complaining of a recent return of nervousness and of pain in the finger joints. We placed her under treatment with adrenal extract, which she is still taking, and, she thinks, with equally good effect in maintaining and even increasing her improvement. The case lacks conclusiveness because of the great gain previously made under thymus treatment.

In the case of Mrs. McD. before reported, suprarenal dosing failed to give good results, but increased the headache and apparently caused increased excretion of uric acid (brick dust sediment appearing), bloody sputum and vertigo. I present two other patients, Mr. S. and Mrs. M., both of which have been treated only with suprarenal extract. They were never marked cases as to goiter or exophthalmus. Mrs. M. (Jan. 8, 1897), had a decided tremor which has been much reduced, while the cardio-vascular and neurotic phenomena have greatly improved in both.

Miss K. is a marked case. Her improvement is chiefly as to nervous and vascular phenomena and general nutrition. The pulse is quieter, the breathlessness relieved. She says that the goiter is smaller and we are all sure that the exophthalmus is much less, but unfortunately accurate measurement was not made when she first appeared.

Mr. H. is a patient presented for the sake of fairness; he appeared at the clinic the same day as Mrs. K., and was just as marked a case. We presented adrenals and he disappeared until this week; has much improved, but has been for the most part without treatment.

Miss F. is presented to show the effect of a different remedy—picrotoxin. Her improvement is equally great.

From the clinical observations, including sphygmographic tracings made on the various cases I have thus far studied, I conclude that thymus extract will in many cases of exophthalmic goiter, improve nutrition, mitigate nervous disturbances, reduce exophthalmus, greatly reduce goiter, and moderately quiet the heart and restore vascular tone, completely accomplishing this in milder cases; while adrenal extract

seems to have greater influence upon the circulation and less effect upon the thyroid and ocular symptoms. We are making studies upon the blood and secretions, which are not sufficiently advanced for publication. I do not believe that either of these remedies or any other remedy removes the fundamental, constitutional, idiosyncratic instability of the toxic mechanism of the circulation; but I do believe that they are competent in the one case—thymus—chiefly by an anti-toxic action, to counteract the exciting influences, and in the other case—adrenal—chiefly by opposing action upon the circulation to neutralize the effect of those influences. Probably both share both these actions in some degree, and I should expect the best results to follow their combined administration.

THE IMPORTANCE OF THE HABIT OF PROGNOSIS IN THE DEVELOPMENT OF THE INDIVIDUAL PHYSICIAN.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-3, 1897.

BY LOUIS FAUGÈRES, BISHOP, A.M., M.D.

Late House Physician St. Luke's Hospital; Chairman of the Section on General Medicine of the New York Academy of Medicine; Secretary of the Section on State Medicine of the American Medical Association; Member of the Neurological Society, etc.
NEW YORK CITY.

It is the duty of a physician to himself and to his patients, not only to be well informed, but it is also to look out for new methods that tend to the best possible training for his work. Habits, good and bad, are the relentless masters of our lives and actions. Powerful as they are for evil they are equally potent for good if seized upon, developed and directed. Habits of mind and thought are just as much habits as those pertaining to the physical nature.

Now there is a particular attitude in approaching a medical case that would seem, more than almost any other, to lead to sound judgments and judicious management, the attitude that takes account of not only present conditions, but discounts them by the probable future. It not only considers what the course of disease will be, if treated, but its course if untreated or treated in a different way. This we may call the habit of prognosis, and upon it must be based all thoroughly judicious and honest therapeutics.

Medicine is a science and at the same time an art. Indeed it is a combination of many sciences and many arts. Thus there is the science of pathology, the science of chemistry, the art of treatment, the art of feeding, the science of diagnosis and the art of prognosis. The power of prognosis is at the same time an acquirement and a gift. Like all other faculties it is improved by exercise and increased by cultivation. Its basis, though largely personal experience, is equally found in a knowledge of medical literature. Thus the experience of a long lifetime may not afford as good a basis for prognosis in a particular case as an hour intelligently spent in a medical library. The faculty is best cultivated by the exercise of the habit of forming, with care and study, the most definite possible prognosis in every case that comes under observation, and then faithfully promulgating it to those who have a right to such an opinion. The first step in prognosis is accurate diagnosis, not the mere naming of disease so that it may fall within the list of diseases such as are found in the index of a text-book of medicine, but the placing of a case in a particular group of a particular variety of the disease. Then, by recalling from per-

sonal experience and searching literature, as many parallel cases as possible are summoned as witnesses; then the mathematical theory of chances and probabilities is brought to bear and the conclusion is reached. It seems strange, at first sight, that in art so varied as medicine, mathematics should have any possible bearing, and yet in the almost parallel science of life insurance, mathematics has found one of its most useful applications. The life insurance company can not say with certainty that a certain man of 40 years of age will live so many years, but it can say with very close certainty of a particular group of ten thousand men, that so many will be alive and so many will be dead in ten years. It is the same way with the prognosis of particular classes of disease. If we can assemble, from personal experience and experience as recorded in literature, a group of one hundred of whom ninety have survived a year, we can give a prognosis in the particular case, all attending circumstances being carefully considered, that the chances of survival for a year are nine out of the ten; in the same way is the prognosis of the time of recovery in particular cases. If we have summoned to our aid, truthfully, a group of parallel cases, and have intelligently discounted particular surrounding circumstances, we can give a prognosis as to the time of recovery which will be correct six times out of seven; seven times out of eight; eight times out of nine, or nine times out of ten, according to the breadth of our knowledge, and the accuracy of our observation.

The value of the constant habit of prognosis can not but be very great to the individual physician. It will give him encouragement and hope in many a desperate case, and save him from undue disappointment when the inevitable laws of nature have run their relentless course. He who has mastered the art of prognosis stands, as it were, on the summit of a mountain where he can see beyond his fellows who have not climbed up the steep and laborious path. Observe the calm philosophy of this man, who with his eye ever on the future, neither urges rash measures nor advocates undue delay, and who is not carried away by the promises of false prophets. He is not deceived by the bright coloring given to the landscape, by the passing meteor, into the belief that the force of all nature has been permanently changed.

The ideal opportunity for the study of therapeutics would be by the treatment of exactly parallel cases by several methods, and their comparison at the same time with cases untreated and pursuing the natural course of the disease. These conditions are only found in rare instances and in large hospitals. Usually, if cases are treated by various methods, it is at different times and the mind pictures of older cases are dim and indistinct. The untreated case is hardly to be found. It is in supplying the place of untreated cases that the development of the habit of prognosis finds its most important place. By careful analysis of the case in hand, by summoning to one's use the records of previous cases accurately observed, by discounting the treatment of one by the treatment of another, and observing the course and outcome under various conditions, one may construct an ideal case similar to the one in hand, but with its history continued into the future. This ideal case supplies a prognosis by which to be guided in the selection of therapeutic measures, the judgment of their efficacy and the expectation as to cure.

Prognosis is often enough modified by the wealth

or poverty of the patient, by his character, by his hopefulness or depression, and by a thousand other things that arise in the individual case, but the discussion of more exact methods of prognosis must find a place elsewhere. What would be emphasized is this, that every physician should form the habit of constructing a well-founded judgment as to the future course of any case of which he seriously undertakes the care. With this judgment he should constantly compare the course of this case while under treatment, and honestly acknowledge the futility of useless therapeutics as well as the modifying influence of really valuable measures.

The remark is often made that prognosis is not worth while, that it does not influence the outcome of the case, that a wrong prognosis is apt to bring disrepute, and that it is better to treat the case from day to day, and leave the result with Providence. This is the reasoning of those who take a superficial, and as it were, a symptomatic view of disease; is the reasoning begotten of intellectual laziness, timidity, and self-conceit. How much more moral courage does the physician exhibit, who throwing his whole intellectual acumen into a case, carefully studies all the circumstances, carefully summons to his aid his own experience, and that of others, and then having given the results of his very best work, is willing to stake his reputation on the result. Even from a lower standpoint, that of professional reputation and success, this in the long run pays best. The greatest physicians in all times have made errors, but the consultants, the men whose counsel is sought in time of great danger, have been men of strong characteristics, who were able and willing to form an opinion and to stand faithfully by that opinion when formed. The mistakes of such men are apt to be condoned while their successes become a glory to their profession, which obscure practitioners are proud to promulgate.

REPORT ON THE TREATMENT OF PULMONARY TUBERCULOSIS.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4.

BY DELANCEY ROCHESTER, M.D.

ADJUNCT PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE
MEDICAL DEPARTMENT, UNIVERSITY OF BUFFALO.

BUFFALO, N. Y.

This report covers in most of the cases a period of about eight months, in some of the cases a period of nearly two years.

The various remedies, upon the use of which the report is made, are Edson's aseptolin, Paquin's tubercle antitoxin and Vaughan's nuclein. In all cases where the stomach does not rebel, cod liver oil was also used. Alcoholic stimulants have not been used, except as temporarily called for. Locally, inhalations, sprays and insufflations consisting of iodoform in ether and in powder, menthol in alboline, essence of peppermint and a mixture of acetanilid, carbolic acid and glycerite of tar according to the formula of Dr. R. P. Lincoln of New York City, have been used. In all cases reported the tubercle bacillus was found in the sputum.

Following is the detailed statement of cases treated by aseptolin (which is a solution containing 3 per cent. of absolute phenol and 0.01 per cent. of pilocarpin-phenyl-hydroxid). This is in no sense an antitoxin but is designed, according to Dr. Edson's

statement, "to greatly reinforce the natural antiseptic power of the blood."

Case 1.—D. N., male, age 47, nativity United States.

May 1, 1896. Previous history.—Has been running down for nearly a year: coughing and raising considerable; vomiting frequently; having irregular chills followed by high fever and night sweats; weight at this date 119 pounds. Tubercular infiltration of right upper lobe; aseptolin treatment begun.

May 21. Since the treatment began patient feels better, appetite has improved, no chills or vomiting, temperature has not gone above 100 F., no night sweats, weight 121 pounds. Pulmonary condition unchanged. Supply of aseptolin gave out and treatment was omitted until June 19 when general and local conditions were not different from previous record. Weight 124 pounds.

July 16. During last month there have occurred two hemoptyses and treatment was omitted for five to seven days each time. The upper lobe of right lung shows distinct sign of softening, and cough and expectoration have greatly increased in amount, but temperature has not gone above 98.5; there have been no chills, sweats or vomiting and the weight is 129 pounds.

August 13. No change in patient's condition except that he has lost appetite, feels weak and dispirited and physical examination reveals extension of the area of softening. Weight 131 pounds.

August 23. Profuse hemorrhage; weak and discouraged; weight 130½ pounds.

October 2. Since last record patient has had two more hemorrhages, not so severe, and more since September 4: feels a little stronger and in better spirits. Temperature has reached 100 several times. Pulmonary condition not materially changed. Weight 131 pounds.

October 20. During last three weeks patient has felt worse, there has been increase in cough and expectoration and there has been vomiting (caused generally by the iodoform spray). Physical examination reveals infiltration in left upper lobe and distinct cavity in right upper lobe. Weight 129 pounds.

December 1. Patient's general condition has improved somewhat, vomiting has stopped, cough is not so distressing, but temperature has ranged rather above 100, reaching 101 several times. Physical examination shows steady advance of the tubercular process in both lungs. Weight 129¼ pounds. Patient complained bitterly of the pain of the injections and treatment was stopped.

Case 2.—H. K., male, aged 37, nativity United States. Aseptolin.

July 15, 1896. Previous history.—For eighteen months there has been progressively increasing anemia, and malaise, marked anorexia, night sweats and occasional hemoptyses, considerable dyspnea, lack of sleep and depression of spirits. There was consolidation of upper left lobe and some infiltration throughout the rest of the left lung. The temperature frequently reached 101 and sometimes fell as low as 97. The respirations ranged in the neighborhood of 30 and the pulse from 80 to 100. The weight record of this case for the first three months was lost. Cough was very troublesome, almost continuous, and there was a large amount of sputum raised.

August 13. During the last month there has been great improvement in all respects: appetite better; sleeps well; cough and expectoration decreased; dyspnea continues; no night sweats since July 18. Temperature has not gone above 99.2.

September 12. Condition has remained about the same.

October 13. Improvement continues in all respects, except that cough and expectoration have increased and there is evidence, on physical examination, of infiltration at right apex in addition to that existing in left lung which has not changed. Weight 130 pounds.

November 10. Improvement continues. Weight 134½ pounds.

December 8. Improvement continues. Weight 138 pounds; cough and sputum diminishing.

January 12, 1897. Continued improvement in all respects. Weight 142 pounds. Aseptolin stopped on account of pain of injections.

February 2. Not quite so well. Weight 130½ pounds.

Case 3.—F. S., male, age 31, nativity United States. Aseptolin.

May 4, 1896. Previous history.—For six months gradual failure in strength and health, anorexia, anemia, marked cough, profuse expectoration, afternoon fever, profuse night sweats. Tubercular infiltration of upper and middle lobes of right lung. Weight 92 pounds. Aseptolin begun.

May 21. Appetite improved, temperature lower (100.8

highest), no night sweats. Cough still severe and sputum still profuse. Marked dyspnea. Weight 92 pounds. Aseptolin omitted until

June 19. During this month improvement continued and cough became less troublesome. Pulmonary condition not changed. Weight 98 pounds.

August 23. During last month there has been falling off of appetite and disappearance of previous sense of improvement. Cough and expectoration have again increased and the dyspnea is more marked. There has been an extension of the diseased process downward to the lower lobe of right lung. Weight 100 pounds.

September 2. Aseptolin omitted on account of soreness of abdomen. Temperature has again increased and patient feels weak and dispirited, suffers greatly from dyspnea and complains of pain in left chest. Weight 101 pounds.

October 2. Aseptolin resumed. Patient's general condition not materially changed except that soreness in abdominal walls is less. There is evidence of infiltration of entire right lung and of left apex. Weight 98 pounds.

November 8. Patient has gradually and steadily failed in all respects, general and local. There is infiltration of entire right lung and cavity in left upper lobe surrounded by zone of breaking down lung. Weight 91 pounds. Aseptolin stopped.

Case 4.—T. D., male, native of Ireland. Aseptolin.

May 2, 1896. Sickness dates back six years. During this time there have been periods of long quiescence with occasional outbursts of cough, fever, etc. These have gradually increased in frequency. Patient is anemic and has no appetite, feels very weak, suffers from great dyspnea. There is evidence of consolidation of upper left lobe, and scattered areas of broncho-pneumonia through rest of left lung and slight bronchitis in upper right. Coughs a great deal with not very much sputum. Temperature not above 100, pulse 100, respiration about 30, weight 130 pounds.

May 21. During the last three weeks temperature has not gone above 99, and night sweats have ceased. Otherwise, no change in patient's condition. Weight 128 pounds. Aseptolin omitted until

June 19. During last month no change in patient's condition. Weight 126½ pounds.

July 24. Some general improvement, sleeps well, appetite good, no sweats, cough and expectoration less. Dyspnea marked. Weight 126 pounds.

August 13. General condition not changed. Weight 122½ pounds.

October 13. During last two months there has been no material change in general condition, but the disease in lungs has progressed so that there is now cavity in upper left lobe and infiltration in lower left, with bronchitis in right lung. Weight 123 pounds. Aseptolin stopped on account of pain of injection.

December 8. No change in general condition nor in pulmonary condition. Weight 119 pounds.

Case 5.—H. G., male, age 54, nativity United States. Aseptolin.

May 3, 1896. Previous history.—For a year patient has had cough, with slight expectoration, frequent asthmatic attacks, very slight fever occasionally, no night sweats. Has poor appetite, is anemic, sleeps poorly, feels weak and debilitated. Has general bronchitis and emphysema and infiltration of right upper lobe and left apex. Temperature ranges from 96.5 to 98.5, pulse 60 to 90, and respiration 20 to 30. Weight 145 pounds. Aseptolin begun.

May 21. No change in condition except that he coughs and raises a great deal now. Weight 149 pounds. Aseptolin omitted until

June 19. No change. Weight 150 pounds.

July 24. During last month sleeps well; appetite not so good, does not feel as well.

August 23. No change except that cough and expectoration are increasing. Dyspnea somewhat relieved by quebracho. Weight 144½ pounds.

September 1. No change. Weight 146 pounds. Aseptolin stopped on account of soreness of abdomen.

October 6. During the last month patient has felt better, appetite improved, dyspnea not so marked, but cough and expectoration continue to increase. Weight 143½ pounds. Aseptolin resumed.

November 17. During last six weeks patient has become worse in all respects. The local conditions have not improved. The cough continues severe and the expectoration very profuse. Temperature has reached 100 on several occasions, and once fell to 96. Weight 138 pounds. Aseptolin stopped. On December 1 weight had fallen to 135½ pounds.

February 2. Patient has improved in all respects during last two months. Weight 139½ pounds.

Case 6.—J. M., male, age 50, English parentage. Aseptolin.

August 1. Previous history.—Has had cough and occasional diarrhea for one year. In December, 1895, had very severe cough. Since then has lost forty pounds in weight, coughs considerable, sputum thick and tenacious and considerable in quantity. Temperature does not go above 100. During last two weeks has suffered from night sweats. The left apex and the right upper lobe are infiltrated. Weight 150 pounds. Aseptolin begun.

August 23. Pulse stronger, no night sweats, but appetite is poor and he is kept awake by coughing. Has developed slight laryngitis. Weight 151½ pounds.

September 12. During last three weeks has had some diarrhea: laryngitis has improved. Developed albuminuria with markedly diminished urine. Aseptolin stopped. Weight 152 pounds.

October 9. After the first diminution in the amount of urine secreted, there came a marked increase in amount of urine, and although the albuminuria remained, the polyuria became extreme: during last two months of his life patient passed from 2000 to 5000 c.c. of urine in twenty-four hours, containing from 20 to 50 gm. of urea, though of low sp. gr., and containing albumin in abundance, and some casts. Weight 157 pounds. December 19, he died, having been comatose for twenty-four hours before death. During last two weeks of his life he had two attacks of severe gastritis and developed corneal ulcers in both eyes. His weight two weeks before death was 136½ pounds. No autopsy.

Case 7. R. B., male, age 35, nativity United States. Aseptolin.

August 12, 1896.—Previous history.—For six or seven months has suffered from cough and expectoration, chills, fever and night sweats. Loss of appetite, loss of weight, great weakness, marked dyspnea, respirations have ranged between 30 and 40, pulse 80 to 120 and temperature 97 to 102 degrees. There is infiltration of left apex, infiltration and softening in upper lobe of right lung with bronchitis in middle right lobe. Cough and expectoration slight. Weight 100 pounds. Aseptolin begun.

September 12. No material change except that night sweats have ceased and temperature is ranging nearly a degree lower at its maximum, cough and expectoration increasing.

October 13. During last month there has been a steady decline in all respects, except that the temperature has ranged lower and the night sweats have not returned. Patient has been troubled greatly with sleeplessness and nightmare. The diseased processes in the lungs have progressed quite rapidly and the cough and expectoration increased in a marked degree. Weight 91 pounds. October 16, patient died.

In addition to these seven tabulated cases, two other cases were treated with aseptolin although they were rapidly advancing in tubercular destruction of the lungs. In neither case was any benefit observed from the treatment, either locally or generally. The treatment was stopped after two months. Both cases died. Except in the cases that died the treatment was continued from four to six months. Of the nine cases treated, in seven the night sweats ceased entirely and the temperature range was lower during treatment than before the treatment was begun; in one (case No. 2), there was a gain in weight, and improvement in all general symptoms, appetite increased, sweats ceased, temperature fell to normal or half degree above, but the local conditions as revealed by physical examination did not change though the cough and expectoration were much lessened; in one other (case No. 1), there was gain in weight for four months, sweats ceased, appetite improved, temperature did not range above 100 degrees F. but the local changes in the lungs progressed, cough and expectoration increased, there were several hemorrhages and during last two months patient began to lose in weight, appetite failed and temperature began to range higher.

In all of the other cases there was progressive loss in weight, marked progress in the local disease, and no improvement in any symptoms except in the cessation of the night sweats and the somewhat lower range of temperature.

Of the nine cases treated four died, two from two to three months after treatment had been stopped, one during treatment and one, I think, because of the treatment. This case (No. 6), deserves especial mention. In this case as in all others, careful examination of the twenty-four hours' excretion of urine was made before treatment was begun. The kidneys were in normal condition. (The urine in all cases was examined every day.) Treatment in this case was begun August 1. On September 12 albuminuria and almost complete suppression of urine occurred. Treatment was immediately stopped. Patient had gained four and one-half pounds during first three weeks of treatment and lost two and one-half during last three weeks. During the month following the stopping of treatment he gained five pounds, although the albuminuria persisted and gradually increased. About October 1, three weeks after aseptolin had been stopped, in addition to the albuminuria he developed a marked polyuria which lasted until his death, which occurred December 19. The amount of urine voided daily during the last two months of his life was from 2000 to 5000 c.c., containing from 20 to 50 gm. of urea and a large amount of albumin and hyaline, granular and epithelial casts in abundance. During the last two weeks of life he was confined to bed, had three attacks of severe gastritis and developed corneal ulcers in both eyes. He died in a state of coma. Autopsy was not secured.

In no case can I report a cure. In judging of the value of aseptolin in these cases we must bear in mind the fact, that the treatment was begun in the early summer and continued through the summer and somewhat into autumn and early winter; that the improvement in those cases in which improvement was noted, took place during the summer, while the weather was such as permitted out-of-door life, but that when the weather grew more inclement and out-of-door life was interfered with, the improvement did not continue. The one thing that impressed me as of value in the use of aseptolin was that in all cases the night sweats were promptly stopped and did not recur. In most cases also, the range of temperature was lowered. As these same results can be obtained by other measures which do not carry with them the possibility of producing an albuminuria and even a nephritis and death, I question whether the use of so dangerous a remedy is justifiable.

The next series of cases I have to report is a series of cases treated with Paquin's tubercle antitoxin.

Case 1.—D. M. was Case 1 of aseptolin series. Aseptolin treatment had been stopped two weeks and patient gained in appetite, ability to sleep, and slightly in weight. Temperature ranged from 98 to 100.5 degrees, pulse 80 to 100, respiration 20 to 28. Weight 130½ pounds.

December 12, 1896. Tubercle antitoxin begun: there is infiltration in upper left, cavity in upper right.

January 4, 1897. Patient feels very badly, has steadily gone downward since treatment was begun, great pain was produced by the injection: they were followed by a marked dermatitis and by swelling of left axillary glands, headache, gastric pain, anorexia, diarrhea, pain and stiffness in limbs. Temperature ranged during this month from 97 to 102.5 degrees, pulse 80 to 110, respiration 22 to 28. Infiltration in upper left remained inactive but there was marked increase in softening about cavity in upper right. Cough and sputum greatly increased. Weight 129½ pounds. Treatment stopped.

January 27. Headache and ache in bones have disappeared, sleeps well and feels better. Weight 126½ pounds.

Case 2.—F. S. This case had also been an aseptolin (case No. 3), and had not improved since aseptolin stopped.

December 14, 1896, had held his own in weight in spite of three small hemorrhages. Temperature has varied between 98 and 100, pulse between 88 and 100, respiration 20 to 24, cough and

sputum have diminished, appetite is good, sleeps well, no night sweats, weight 91½ pounds. Infiltration of left apex and of right upper lobe with bronchitis in right middle lobe. Tubercle antitoxin begun.

January 1, 1897. During the last month patient has failed in all respects; shortly after serum treatment was begun, he began vomiting severely, and has had one severe hemorrhage. Cough and sputum have both increased. Injection set up dermatitis and caused swelling of axillary glands; the infiltration has proceeded downward from left apex into entire upper left lobe, softening has begun in upper right and infiltration has progressed into middle right. Temperature has ranged from 97 to 101.4 degrees; pulse 80 to 120, respiration 28 to 40, weight 88¾ pounds. Patient is distinctly worse in all respects. Treatment stopped.

Case 3.—T. D. This case also has been on aseptolin (case No. 4), and had not improved. Aseptolin stopped October 13. Since then patient has lost three pounds in weight but has held his own in other respects. Appetite is fair, sleeps well, feels pretty well, coughs and raises considerable. Temperature 98 to 100 degrees, pulse 70 to 100, respiration 20 to 30. There is infiltration in upper left and in middle right, and cavity in upper right. Tubercle antitoxin begun Dec. 14, 1896.

January 5, 1897. During last month patient has lost ground in all points: feels very badly, appetite gone, sleeps poorly, severe and continuous headache, dermatitis marked, cough and expectoration markedly increased; condition of the left lung remains the same, but there has been marked increase in the softening about cavity in right lung. Temperature 97 to 100 degrees, pulse 80 to 110, respiration 20 to 30. Treatment stopped.

February 2. Patient continued to lose weight for three weeks after treatment stopped. Since then has gained a little. Headache ceased; feels, sleeps and eats better. Cough not changed.

Case 4.—M. R., male, age 34, native of Ireland. Tubercle antitoxin. Jan. 8, 1897. Previous history.—Negative until in July 1896, when he began to have a slight cough, loss in weight and strength, and suffer from pain in side and chest. Is anemic and has had occasional night sweats. Temperature has ranged from 99 to 101 degrees, pulse 100 to 110, respiration 20 to 30. There is infiltration of left upper lobe as far down as the level of the second rib in front, and as far as the spine of the scapula behind. Considerable cough and expectoration. Weight 120 pounds. Antitoxin treatment begun.

February 2. Patient felt better for first two weeks, and gained two pounds in weight which he lost in the third week, but gained one back in next week. The pain in his chest disappeared in first two weeks, but returned with greater severity during last three weeks; he also developed pain in his left hip and his stomach. During last three weeks has vomited nearly every day, his appetite has failed and the cough and expectoration have increased. His temperature has ranged from 98 to 102 degrees, pulse 90 to 120, respiration 22 to 34; he has had three severe night sweats. Softening has developed in left upper lobe and there has been some extension of disease downward. There has been no dermatitis or swelling of lymph glands. Weight 121 pounds. Treatment stopped.

Case 5.—P. R., male age 54, native of Ireland. Tubercle antitoxin. Previous history: Pneumonia five years ago; cough for two years; hemorrhage one year ago. In September 1896, had another hemorrhage and began to run down in weight and strength. Entered hospital Oct. 14, 1896. Fair appetite, sleep poor, night sweats, occasional diarrhea. Temperature 97.5 to 98.8 degrees, pulse 90 to 100, respiration 24 to 32. Cough and expectoration considerable, sputum often blood tinged. Scattered areas of broncho-pneumonia in both lungs, together with considerable emphysema; cavity in upper right lobe. Weight 125 pounds.

December 12, 1896. Under hygienic measures, good diet and creasote, patient has gained nine pounds in weight, hemorrhages have ceased, night sweats less severe and less frequent. Temperature 98 to 98.5 degrees, pulse 90 to 100, respiration 24 to 30. Areas of broncho-pneumonia have materially diminished, otherwise pulmonary condition is the same. Weight 134 pounds. Tubercle antitoxin begun.

January 4, 1897. From the time injections were begun patient began to feel badly, aching and numbness in limbs and back, headache, bones ache with return of night sweats in great severity, cough and sputum increased greatly in amount and hemorrhages again began. Temperature 97 to 100 degrees, pulse 80 to 120, respiration 24 to 36. Areas of broncho-pneumonia again increased and there developed considerable softening about cavity. Weight 129 pounds. Treatment stopped.

From this time on patient continued to grow worse in all respects; hemorrhages continued, sweats, fever

and broncho-pneumonia increased and softening extended; patient finally died March 1, 1897.

I have three other cases treated with tubercle antitoxin to report. One Miss B., age 17, American of German descent. This case I first saw in September, 1896. She at that time was having high fever in the afternoon, night sweats, severe cough, considerable expectoration, poor appetite and occasional diarrhea. She was not weighed. I put her upon Vaughan's I per cent. solution of yeast nuclein. She did well upon it, appetite improving, cough diminishing and sweats becoming much less frequent and fever also subsiding to a marked degree. The local condition, which at first showed cavity in right upper lobe, infiltration in rest of right lung and in left upper lobe improved to a considerable degree, the lower lobe of right clearing up almost entirely, the cavity in upper right remaining, but apparently not extending, the infiltration in upper left remaining about the same.

In spite of this improvement I foolishly changed to the antitoxin in December, beginning the injections on December 10. The injections of tubercle antitoxin were very painful, a marked dermatitis occurred and swelling of the axillary lymph nodes. Her general health suffered greatly. The afternoon fever returned, the sweats again became marked, appetite diminished and after about three weeks' treatment the girl declined further treatment by injection of any kind, even declining to go back to the use of nuclein. The local condition took a new start in progress of disease, the cavity on the right side enlarged, the left upper lobe also began to break down and areas of broncho-pneumonia showed themselves in lower lobes of both lungs.

The cases so far reported were undoubtedly cases of mixed infection and it may well be said that good results from a specific antitoxin should not be looked for in such cases. The next two cases were apparently pure tuberculosis. The first, David D., a young man 20 years of age, tubercular family history in grandparent and aunt, consulted me first Dec. 13, 1896, on account of cough. Physical examination of the chest revealed nothing, but chest tending to pigeon shape and poor development. Examination of throat showed enlarged tonsils, especially the right one, and a reddening of the vocal bands with some edema of false cords. He was referred to a throat specialist who treated the laryngeal condition and a diseased nasal condition without much relief to cough. Patient also began to vomit considerably at this time after severe attacks of coughing. Almost no expectoration, the little that was brought up being mostly glairy mucus not containing tubercle bacilli. On December 31 I amputated the right tonsil. For nearly a week after this the cough was much better. It then began again. His voice became quite hoarse and at times he could only speak in a whisper. Examination of the larynx on Jan. 26, 1897, revealed tubercular infiltration of the larynx—ulceration of the free margin and superior surfaces of both vocal bands over the anterior halves of the membranous portions—swelling of the arytenoids prevents complete closure of glottis; about this same time physical examination revealed some infiltration of right apex but no softening. Not until a week later were tubercle bacilli found in the sputum, which remained very scanty. On January 26 began injection of Paquin's tubercle antitoxin, and gave them daily for thirty-two days, patient growing steadily worse and the injections producing such severe

pain, lasting for from four to eight hours, that the patient dreaded the coming of another day. The local condition of the lung did not improve, on the contrary, began to show distinct signs of breaking down. Patient gained three pounds for two weeks and then lost nearly three. On February 26 the injections were stopped, certainly having done no good and possibly having been productive of harm.

The last case of those treated with tubercule antitoxin was a man from whom a tubercular testicle had been removed two months before. This case presented no evidence of pulmonary tuberculosis, but presented enormously enlarged lymph nodes in the groins and extending into the pelvis and some distance into the abdominal cavity. He was put on the serum injections on Dec. 12, 1896. He suffered no inconvenience from them and gained in weight and strength. The injections were continued until April 22, 1897, when he left the hospital much improved in general health, apparently not injured by the injections, though at one time they had to be omitted on account of soreness produced, but were begun again in a week. There was, however no change observed in the size or contour of the glands already involved, but on the other hand there was no further extension and involvement of other glands or organs.

The conclusions to which I have come in regard to Paquin's tubercle antitoxin are that in cases of phthisis that are at all advanced it is of no value, and that in the one case of almost pure tuberculosis of larynx and upper lobe in which I used it, it was worse than useless, not having stayed the disease and having produced great physical suffering; that in the case of gland tuberculosis it has apparently done no harm and may yet be of value; that in all cases, with the exception of the last, the pain produced by the injection and the unpleasant after-results in the way of dermatitis and glandular swellings would almost, if indeed not entirely, prohibit its use.

The next series of cases to which I wish to call your attention gives brighter outlook as regards results from treatment.

In 1894 Dr. Victor C. Vaughan of Ann Arbor sent some of the early production of his yeast nuclein to Dr. Chas. G. Stockton of Buffalo, with whom I have the honor to be associated in one of our hospitals. Since that time Dr. Stockton and I have used nuclein on a number of cases of tuberculosis and other infectious diseases. I have yet failed to see a case in which it did not do good. I have seen many in which it has not effected a cure. I have seen some in which it has effected a cure. In all there has been at least temporary improvement.

Case 1. The case of Miss C. I have already mentioned as showing marked improvement under the 1 per cent. nuclein. She had advanced as far as 3 c.c. at a dose, when, to my great regret, I changed to the tubercle antitoxin and she afterward refused treatment.

Case 2.—Mrs. W. F. H., age 57; nativity, United States. Nuclein. Tubercular family history; has coughed more or less for twelve or fifteen years. First came under observation in June, 1894. Suffering with gastric distress after eating; this has troubled her for the last eight years. Case is emaciated and has marked enteroptosis. The study of stomach contents shows slight diminution of hydrochloric acid, impaired motion and impaired absorption, large amount of lactic acid. Infiltration with some softening of upper lobe of left lung. Considerable cough and expectoration in the morning, slight at other time of day. Temperature ranges from 97 to 100 degrees, pulse 100 to 120, respiration 24 to 30. She was on cod liver oil, creosote and inhalation of menthol until June 15, 1895. Her weight fell during this year from 111 to 98 pounds. The dis-

eased condition in the lungs also progressed so that when put upon nuclein,

June 11, 1895, her physical condition was poor, her appetite very small, sleep poor, gastric distress marked, occasional diarrhea, marked anemia and emaciation. There was infiltration of the upper right lobe and of the entire left lung with softening in the upper lobe. Weight 98 pounds.

August 2, 1895. She felt better and held her own in weight. A small cavity had developed in upper right lobe. The 1 per cent. nuclein was gradually increased in dose until by October, 1895, she was taking 6 c.c. hypodermically daily. She continued at that dose until May 1, 1897, then changed to 5 per cent. solution nuclein, beginning with 1.5 c.c. and gradually increasing dose until May 20, 1897, when she was taking 4 c.c. She continued that dose. During these two years she has changed very little in her physical condition, except that the gastric indigestion has been to a great extent overcome. The sleep has improved, the cough has remained about the same, the strength of patient has not increased, the night sweats very seldom occur. Her pulmonary condition has varied, occasionally a little outburst of broncho-pneumonia occurring, but on the whole there has been a slight improvement. Since the beginning of the 5 per cent. nuclein this improvement has become marked.

May 20, 1897, physical examination showed that the cavity in upper right had disappeared though there remained some condensation of tissue there. There was small cavity in upper left with some infiltration about it. The cough diminished, the sputum was about the same in amount but less purulent in character, still containing tubercle bacilli. Temperature 97 to 99 degrees, pulse 100, respiration 22 to 26.

Case 3.—Elizabeth McD., age 42, American. Nuclein. First came under observation Nov. 11, 1895. History of pneumonia two years before and pleurisy one year before; since then loss of weight and strength, with cough and considerable expectoration. The records of this case, except the first and last physical examinations, have been lost. The first one, which was made Nov. 11, 1895, when nuclein was begun, showed slight infiltration in upper left, broncho-pneumonia areas in lower right, cavity surrounded by area of softening in upper right. Nuclein, 1 per cent. solution, was begun at 1 c.c. and gradually increased to 4 c.c., in February, 1896. She remained at this dose until she passed from under observation on Aug. 15, 1896, when her general condition was markedly improved; she had gained several pounds in weight, her appetite was good and bowels regular, she slept well, she coughed only occasionally and the last two examinations of sputum (which was very slight in amount) failed to show the presence of tubercle bacilli; physical examination showed that the signs of cavity and softening had entirely disappeared, leaving only the evidence of slight condensation in right apex; the signs of disease in lower right and left lung had entirely disappeared. Pulse 74, temperature 98 degrees, respiration 18.

This case I consider has recovered, though there remains slight condensation in upper right.

Case 4.—John D., age 21, nativity United States. Nuclein. This case came under observation Nov. 14, 1895, with a history of frequently occurring "colds" during the previous two years, and of a severe one in October, 1895, which has remained. Patient is losing in weight, sleeps poorly, has occasional night sweats, becomes slightly cyanosed upon exertion. There is considerable cough and expectoration. There is infiltration in upper right, infiltration and slight softening in upper left, bronchitis in lower left. Temperature 98 to 105 degrees, pulse 85 to 120, respiration 20 to 34. Injections of 1 per cent. nuclein begun Nov. 14, 1895. Weight 105 pounds.

December 17, 1895. During last month patient has shown no change in his general condition, except a slight improvement in appetite; the temperature 98 to 102.5 degrees, pulse 72 to 110, respiration 20 to 30. Cough and expectoration slightly increased. Area of infiltration and softening in left slightly increased.

January 16, 1896. Nuclein 4 c.c. Slight general improvement during past month, appetite and sleep improved, no night sweats, cough and sputum not materially changed. Temperature 98 to 101 degrees, pulse 80 to 120, respiration 20 to 30. Bronchitis has disappeared from lower left. Area of infiltration in upper left has diminished, but there is distinct, though small, cavity in upper left, but evidences of further softening are lacking.

February 17. During last month there has been very marked improvement in general health. Temperature 97 to 99.5 degrees, pulse 76 to 110, respiration 20 to 26, cough and sputum diminished, no bronchitis, areas of infiltration in both lungs diminishing, cavity in left distinctly smaller, no softening about it.

March 17. Nuclein has reached 6 c.c. Patient's weight has increased to 122 pounds. Temperature 97 to 99 degrees, pulse 70 to 90, respiration 18 to 22.

April 17. Continued improvement in every respect. Good appetite, sleeps well, normal temperature, pulse and respiration. Improvement in left lung particularly marked. Infiltration in upper right still pronounced. Weight 130 pounds. Patient went to Colorado, but returned in late autumn feeling so well that he has neglected treatment all winter and spring.

May 20, 1897. Patient feeling very well, appetite good, no fever or sweats. Temperature 98 degrees, pulse 70 to 80, respiration 18. Evidences of disease have entirely disappeared from left lung, which seems in normal condition. Slight condensation of upper right with evidence of small cavity posteriorly at junction of suprascapular and interseapular regions. Cough much less, some days none, but sputum still contains the tubercle bacilli.

Case 5.—Christina S., age 17, German parentage. Nuclein. History of measles in early childhood, hip disease when 14 years of age, recurrence of disease at 16 years of age. For four months, during which she was under observation, before nuclein was begun, she felt badly, was losing in weight, appetite poor, bowels quite irregular, tending to constipation with occasional diarrhea.

Physical examination revealed bronchitis in right upper lobe. Infiltration and slight softening in left upper especially noticeable anteriorly in the infraclavicular and mammary regions, cough troublesome, expectoration about 150 c.c. in twenty-four hours. Pulse 80 to 110, temperature 97 to 102.5 degrees, respiration 25 to 35.

September 1, 1896. Nuclein begun. Weight 98 pounds.

September 13. During last two weeks there has been a slight change for better, both in the local signs and in the general symptoms. Pulse 70 to 96, temperature 97.5 to 98.5 degrees, respiration 24 to 26.

September 25. During the last ten days an acute pneumonic process has attacked upper left lobe, pulse reaching 120 in frequency, temperature 104 degrees, respiration 28 to 34.

After the subsidence of the pneumonia, the case made steady improvement in all respects; appetite good, bowels regular, color returning to face and patient enjoying a feeling of good health to which she had been a stranger for several years. Her pulse has ranged about 80, her temperature from 97 to 98.5 degrees, her respiration from 20 to 24.

May 10, 1897. Her right lung has cleared up entirely, the evidence of softening in the left lung has subsided and there remains only slight condensation in the upper lobe. The sputum has almost entirely gone, not more than 8 c.c. in twenty-four hours, containing only six or eight tubercle bacilli, in examination of eight slides, after precipitation of the sputum by means of the centrifuge. Patient has menstruated this week for the first time in a year.

Case 6.—David D., male, age 20, native of United States. Nuclein.

This case is the case of laryngeal and upper right lung tuberculosis that was given Paquin's antitoxin from January 29 to Feb. 26, 1897, and did so very poorly. Weight 123 pounds. Temperature 96 to 102.5 degrees, pulse 110 to 120, respiration 26 to 30. April 30 I began injections of 5 per cent. nuclein. At this time the patient's condition was one of anemia, anorexia, severe cough, frequent vomiting, poor sleep, great depression of spirits.

May 20, 1897. During last month there has been gradual improvement in all respects; sleeps better, does not vomit so frequently, appetite better, acknowledges (for the first time in four months) that he is feeling better. Larynx shows slight improvement, signs of softening in right lung are disappearing, though condensation remains. Sputum somewhat less in quantity and a little more easily raised. Pulse ranges from 100 to 110, temperature 96 to 100 degrees, respiration 24 to 28.

May 22, 1897. Today noticed the first unpleasant effect from injection of nuclein. Immediately after the injection, which had been gradually increased to 4 c.c., patient said he felt badly, there was great difficulty in breathing and a feeling of nausea followed by a tremendous determination of blood to head and shoulders, giving them a dusky red hue. This lasted about five minutes and then gradually subsided. About one hour later it was followed by a chill which terminated in vomiting, and then the patient felt better but weak. There was left on the shoulders and upper chest a slight purplish mottling. Injection was omitted the following day. For the next four days injections were given, and twice a slight recurrence of the feeling was produced; on the fifth day the attack was similar to but more severe than the first. During the period before the flushing, patient became pulseless, face became pinched and drawn and without color, breathing

shallow, infrequent and difficult. Death seemed imminent. The mottling which followed the flushing this time showed itself to be intradermal minute hemorrhages. Two days later I gave a smaller dose with a slight recurrence of the symptoms. The patient was evidently so terrified that the dread of the injection precluded the possible benefit and I have since begun giving the 5 per cent. solution by mouth, on an empty stomach, beginning with 2 c.c. and daily and gradually increasing to 4 c.c., t.i.d.

I should like to mention one other case that has been on treatment for two weeks only, but has made so great improvement as to surprise the patient, all her friends and myself:

Case 7. Martha McD., aged 24, native of United States, bookkeeper. Nuclein. Came under my observation May 11. Father died of heart disease; mother of "tumor"; one sister of consumption.

Patient had measles and whooping cough when 8 to 10 years of age. Began menstruating when 14 years of age. When 18 years old had severe cough lasting two months; has coughed occasionally since. Three weeks ago caught a severe cold by change of clothing. Cough has constantly increased since that time. She has a tubercular aspect and weighs 112 pounds; pulse 104, soft and quick; temperature 99 degrees, respiration 24; she sleeps well and her digestive apparatus is in good condition; heart and blood vessels are sound; blood shows slight anemia. Nose is normal, but there is muco-pus in naso-pharynx; larynx normal; particles of broncho-pneumonic infiltration throughout left lung, especially in upper lobe; sputum raised mostly in morning is muco-purulent in character, in chunks, contains tubercle bacilli, streptococci and diplococci lanceolati; amount raised in twenty-four hours 50 to 100 c.c. Treatment: Cod-liver oil and strychnin, t.i.d., and cough mixture of fl. ext. pruni virg., 1 c.c.; syr. scilla comp., 1 c.c.; syr. lactucarii, 2 c.c.; every two to four hours. Nuclein, 5 per cent. sol., hypodermically; began with 0.30 gm. and increased dose gradually until she is now taking 2 c.c. daily.

May 27. She is feeling well, coughs only in the morning and thinks most of expectoration comes from naso-pharynx. Amount in twenty-four hours 15 c.c., is very tenacious, contains a few diplococci and a few streptococci, no tubercle bacilli. There are, however, still a few râles over upper lobe of left lung.

She has held her own in weight for the last two weeks, whereas before that she had been steadily losing.

Other cases that I have put upon nuclein have not been under observation long enough to justify any report. The following conclusions, however, I think are justified. Nuclein does no harm if injections are not too rapidly increased; the injections are not painful; one case recovered although there was a cavity in the right lung when treatment with nuclein was begun. The chronic case that has been on treatment for two years, receiving a hypodermic dose every day, bears witness to the value of the remedy. Signs of cavity have disappeared from one lung and become much less marked and more limited in the other, the evidences of softening having also disappeared.

In one case beside the one that recovered, the bacilli have disappeared from sputum, which have become almost none. In another case I have no doubt that recovery might have been reported if the young man would stick to treatment, but he feels so well that he neglects himself, though the bacilli are still present and there remains signs of small cavity.

In closing this report I want to lay great stress upon the importance of properly conducted exercises in the treatment of pulmonary tuberculosis. Exercises designed to develop the chest muscles and increase the lung capacity; specific directions as to the character and amount of exercise and the time of day when the exercise should be taken are necessary. Whatever specific medication we may use, without exercise and fresh air our efforts will come to naught. The treatment of special symptoms deserves a few words:

Cough.—This symptom is generally best relieved by attention to the upper air passages, keeping them clean and free from secretion and by inhalations, mentha in some of its forms having been, in my experience, productive of the best results. The constant inhalation of essence of peppermint through a perforated zinc mask, as suggested by Carasso of Genoa, is especially valuable. When internal medication is needed to give further relief, the cough being irritating and the sputum difficult to raise, a combination of the fl. ext. pruni virg., syr. scillæ comp. aa 1 c.c., and syr. lactucarii q. s. ad 8 c.c. at a dose, given once in three to four hours has done best; chloroform water alone or combined with a little dilute hydrocyanic acid is very useful. Opium and its derivatives should be avoided entirely, excepting in advanced cases where they are the only remedies that give the patient any relief; of the various anodyne preparations, codeia and chlor-anodyne are the two that I have found most useful.

Dyspnea.—Not a very common symptom in phthisis, is sometimes very troublesome. For its relief, when not dependent upon the cardiac weakness, the fl. ext. quebracho I have found invaluable.

Pain in the chest is best relieved by strapping the chest or, if this fails, by hypodermic injection of morphin.

Hemoptysis.—Morphin hypodermically, rest in bed, dry cupping of chest, followed for several weeks by the internal use of the infusion of bugle-weed (*Lycopus Virginicus*).

Fever.—Best controlled by the nuclein administration. Sponging with alcohol and water is often of great value. Regular bathing should be a part of the routine treatment of every case.

Sweating.—This generally disappears during the treatment with nuclein. Sometimes, however, it requires special treatment. Atropin and aromatic sulphuric acid still remain at the head of the list of drugs useful in controlling this distressing symptom.

The *dyspeptic* symptoms require special study in each case and no general rule can be laid down for their treatment. Sometimes recourse to a diet of nothing but koumyss for two or three weeks will give the needed rest to the stomach and later allow a gradual return to a mixed diet. In all cases frequent examinations of the blood should be made in order to determine whether we are gaining on the anemia that is present to a greater or less degree in them all. Red bone marrow is the best agent to combat the anemia.

REMOTE EFFECTS OF BONE TRAUMA.

Read at the Third Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Ill., Sept. 23, 24 and 25, 1896.

BY D. S. FAIRCHILD, M.D.

SURGEON TO THE CHICAGO AND NORTHWESTERN RAILWAY.
CLINTON, IOWA.

Some experiences during the past few years has suggested the subject of this paper, and I have in consequence examined a considerable range of medical literature for the purpose of obtaining data upon which to base certain propositions. The result is somewhat disappointing for the reason that writers, even those standing highest as authorities, have written but little in reference to the remote consequences of bone injury, especially in relation to such cases as may become the subject of controversy. Exception must be made of the writings of those who before the discovery of the special cause of tuberculosis

regarded certain classes of joint disease and certain cases of osteomyelitis as the result of injury more or less remote, recognized or assumed.

The effects of injuries upon the future condition of bone tissue are so varying in their nature that it would be quite impossible to predicate the future possibilities in any case of trauma in an empiric manner based upon experience alone, but rather, in the first place, on well-known pathologic facts. The apparent relation of cause and effect in medicine are, as is well known, so often misleading that a most critical application of facts, derived from a close study of pathology, becomes necessary to protect the surgeon from falling into serious error. So many writers on medical, as well as on other subjects, have fallen into the habit of loose and indefinite statement, that it is not difficult to find that the highest authority may be used in the support of propositions, often no doubt, quite in discordance with the author's real views.

It is true that unusual difficulties lie in the way of certainty in medicine from the fact of the complex nature of the subject and of the unforeseen accidents which may arise to complicate the course of events, but much of this may be avoided by the employment of critical methods of study. The primary consideration in the study of the subject of this paper must be the influence of injuries in producing bone inflammation.

It is generally agreed that contusions of bone will produce swelling of the periosteum from extravasation and if the injury is sufficient or of such a character as to influence the bone an osteoplastic process will follow. It may generally be expected that resolution will take place in a short time, and that the periosteum and bone will be restored to to their former condition. If, however, this does not take place other results will follow, which it is the object of this paper to consider, and if we can reach an understanding of what may be expected from the standpoint of pathology and from the most reliable practical observations, we may be able to answer certain questions and come to conclusions which will be just and proper.

Leaving out of consideration for the present moment the results of infection, we will consider the effects of the osteoplastic process when resolution does not take place. I think it proper to stop long enough at this point to say that chronic irritation or inflammation of bone can not continue for an indefinite period of time without certain organic changes taking place. Assuming an injury to be the cause of an inflammation or an irritation of a more or less persistent character, we have as a result a proliferation of cells.

The density of bone tissue is such as to interfere with this multiplication of cells without the occurrence of a coincident absorption of bone substance, hence the bone changes in condition. The vascular structure of bone periosteum and medulla are involved, becoming more vascular and an exudation takes place underneath the periosteum into the medulla and into the enlarged Haversian canals, or in spongy bone into the trabecular structure. As the embryonic cells increase in number the osseous lamella becomes softened and absorbed and the lacunæ become larger, and these with the enlarged Haversian canals become filled with granulation tissue together with multinuclear cells, osteoclasts, which are believed to aid in the absorption of bone.

This form of inflammation of bone, known as rarefying osteitis, is attended with the formation of new bone beneath the periosteum and in the medulla, hence two processes are observed: 1, new embryonic cells and enlargement of lacunar spaces and Haversian canals; 2, the conversion of the new elements into bone.

Therefore the two processes of rarefying and formative osteitis occurring together give rise to conditions which will vary according to the predominance of the one or the other. If the irritation continues, resolution, of course, does not take place and disease becomes progressive, involving well determined pathologic changes, be they of the character of rarefying osteitis or osteo-sclerosis. If the disease is chronic or slow in development the rarefying process continues until an abnormal degree of sponginess is reached, whereby the bone becomes larger, lighter and lessened in its power of resistance and fracture easily occurs. Section of a bone which has undergone this change will show the numerous spaces, the enlarged Haversian canals and medulla or the more fragile condition of the trabecula. The extent of these abnormal appearances will be determined by the degree of inflammation present and the advancement it has made.

If, instead of the continuance of the rarefying process, the bone granulation tissue becomes organized and new bone is formed, the spaces become slowly filled, the medulla is encroached upon and the bone becomes changed in character; it becomes harder and denser. The continuance of the bone formation process indefinitely must result in an interference with the vascular supply by compression of the blood vessels and an ultimate interference with the nutrition of the bone, leading finally to necrosis of greater or lesser areas. If, however, the disease becomes arrested at a point short of a serious interference with nutrition, the condition of osteo-sclerosis may remain permanent. The lesson, then, to be derived from a consideration of the pathologic changes in chronic inflammation in bone, teaches that this condition can not continue indefinitely without giving rise to well marked internal and also external changes, which may be readily recognized if the bone is situated superficially so as to place it within easy reach. No doubt slight degrees of pathologic changes may take place without objective signs which can be discovered by ordinary surface examination.

It appears from a considerable personal observation among railway and mill employes that the organic changes in bone resulting from chronic inflammation rarely terminates in complete resolution, a degree of permanent thickening remains, which, however, gives rise to no troublesome symptoms or disability, unless the thickening is in the immediate neighborhood of a joint. There may be no constant relation between the severity of the subjective symptoms, the extent of pathologic changes and the objective signs, but it is fair to presume that if symptoms of disease persist without abatement, more or less active changes are really taking place with the results already indicated.

The foregoing relates to cases which escape the influence of microbic action, either septic or tubercular. In predicting the future results of bone inflammation we have always in mind the possibility of infection. In general terms it may be said that the more abundant the granulation tissue, the more active the suppurative process in the event of pus infection, a condition most often met with in inflammation of

spongy bone, or in the trabecular structure of long bones near the articular extremities. A traumatic osteomyelitis with pus infection, occurring early or late, means a pathologic condition, manifested by evidences of a positive character, showing very soon the serious nature of the lesion; the more or less rapid approach of pus to the surface, redness and inflammation of the soft parts and final discharge, and the formation of sinuses communicating with carious or necrotic bone. In the case of rarefying osteitis of denser bone, the granulation tissue filling the enlarged spaces may become infected and the lesser formation of pus, and the more localized process may give rise to a small abscess, chronic in character and occasion less marked symptoms, but in the search for the cause of the symptoms the objective evidence will be unmistakable.

Tubercular infection of the actively granulating tissue will be marked very soon by an accession in the symptoms and a more decided progress of the disease, the early formation of sinuses consequent on the development of tuberculous pus, and if double infection from the invasion of the true pus microbe happens, the added constitutional symptoms of sepsis will follow.

There can be no doubt according to the best authorities that an osteitis of traumatic origin, even if resolution has taken place, at least to the extent of subsidence of all active inflammatory processes, may become the focus of a tubercular development, by serving as a point of least resistance. But can we say that this local predisposition to tubercular infection is permanent, *i. e.*, that after all inflammation has subsided and the structural changes have been followed by a restoration in the nutritive balance, can we say that the thickened bone, or the bone that has been subject to an inflammation, is still exposed to the special danger of a tubercular disease. The best evidence is to the effect that when the nutrition of the bone has been restored the *locus minoris resistentiæ* ceases to exist. The time for infection is when the nutrition is impaired by the products of inflammation, or when the products are in that special condition which invites the cultivation of the bacillus tuberculosis. It may be difficult to determine when the bone has become restored to that condition of normal resistance, but to my mind the appearance of a tuberculous process long after all evidence, save the thickening, of the inflammation has disappeared, is not sufficient evidence of the causative relation of the inflammation itself.

It is generally admitted that an injury to a bone, particularly to the cancellous structure in which trabeculae are broken or in which a minute hemorrhage occurs may be the foundation of a tuberculous inflammation having its exact seat either in the new cells formed incident to repair, or in the hemorrhagic focus.

In the examination of a case of bone inflammation, even when resolution is apparently going on favorably, we can not avoid the apprehension that a tuberculous process may develop at any time, and in the light of this fact our opinion must be guarded, for the otherwise reasonable expectation of a recovery may not be realized. If it is true, as it is generally accepted, that an injured or chronically inflamed bone is subject to tubercular infection, for how long a time and under what circumstances may the above conditions serve as etiologic factors in the production of

the disease? Much loose generalizing has been indulged in on this point and efforts have been made to show that a slight injury to a bone may give rise to a *locus minoris resistentiæ* which will especially predispose to the disease for an indefinite time. That is, if a bone becomes injured and all symptoms of such injury subside, yet after months, or even years, tuberculous process develops. Therefore, it is said that the injury is the remote cause. It may also be assumed in a given case of injury that even if apparent recovery takes place the claimant is exposed for an indefinite period to the rise of a dangerous disease as the logical sequence of the injury.

I am not advised that any modern writer of eminence holds to this view, but it is a fact that opinions of this character are entertained by members of the profession. Senn regards bone tuberculosis as the result of trauma under any circumstances as rare, and Cheyne, while believing in the etiologic influence of injuries in producing bone tuberculosis, cites only a few cases in which there was satisfactory evidence to his mind of the causal relation, and in all these cases the tuberculosis followed immediately without any apparent recovery from the injury itself, and the same is true of all other cases recently recorded. Referring to a previous statement in this paper, I contend that the circumstances under which infection must occur, if at all, is when the local resistance in the bone is impaired by the injury; or in the presence of a minute hemorrhage; or in the presence of granulation tissue as the result of a mild inflammation or repair; and the limits of infection must not extend beyond the restoration of the injured bone to its normal condition and that the evidence of such restoration must be the disappearance of objective symptoms in bones subject to easy physical examination.

The origin of a true bone tumor from a metaplastic process is no longer entertained. The formation of an exostosis or a localized or diffused hypertrophy from the reparative process in a bone following an injury may occur, but the fact is so plainly indicated by the physical condition of the bone that it can not fail of recognition and the continuity of symptoms subjective and objective with the development of the bone enlargement will indicate the causative relation, however slow the process may be. In the process itself we recognize the histogenetic changes already considered, viz.: Hyperemia, exudation and proliferation of cells from the deeper layer of periosteum and the conversion of the osteoplastic elements into bone.

The development of sarcoma from bone trauma is altogether possible, especially in persons predisposed through heredity. This is occasionally seen to occur in the immature callus after fracture.

In irritation following trauma newly formed embryonic cells may form the matrix for a sarcomatous development through failure to undergo transformation into tissue of a higher or more resistant physiologic type. That hereditary predisposition is not absolutely necessary in the development of a sarcoma matrix, although it must be assumed in the present state of knowledge of the histogenesis of tumors that a preëxisting matrix of embryonic tissue was present to be lighted into activity under favorable conditions, was shown in a case which came under my care some eight years ago. A man received an injury to the middle of the right humerus, not sufficient to produce a fracture: this was followed by a moderate irritation in the bone accompanied by sufficient pain or uneasi-

ness to attract his attention when not otherwise engaged; in a few months he observed that the bone was increasing in size. The enlargement gradually increased during a period of two or three years, until it became difficult to pull over it a coat sleeve of ordinary size; finally the bone was fractured by ordinary muscular effort. The bone appeared to unite but the condition became so troublesome that he consulted me. The malignant nature of the disease was so apparent that I had no hesitation in declaring it to be a sarcoma of the bone, and advised amputation at the shoulder joint. The proposition was promptly accepted and the arm removed. A microscopic study showed the disease to be a sarcoma of the myeloid type; the growth beginning in the medulla and finally leading to the absorption of bone and extending to the contiguous soft parts. There has never been any return of the disease. The sequence of events satisfied me that trauma was an important factor in the etiology of the disease.

The practical propositions involved in this paper are based on inflammation or irritation in bone following injury and the sequel resulting therefrom.

1. Resolution, including a complete restoration of the bone to its normal condition, occurs in the vast majority of cases.

2. Resulting in rarefying osteitis. Condensing osteitis, or a combined rarefying and condensing osteitis, which may remain as a more or less permanent condition; if slight in degree giving rise to no well marked subjective or objective signs after the process becomes arrested.

3. If the process continues for a period beyond a few months, well marked and unmistakable changes in the physical condition and appearance of the bone will become manifest.

4. A persistent acute or chronic osteomyelitis will also give rise to unmistakable physical changes in the bone.

5. A persistent chronic osteo-periostitis will give rise to thickening of both periosteum and bone of a character that will be readily recognized if the bone is so situated as to admit of easy surface examination.

6. If the products of inflammation in cases of rarefying osteitis or in osteomyelitis become infected with pus-forming microbes, the suppurative process will become plainly evident, except in cases in which the process is very limited, giving rise to a small abscess in the bone which may be indicated only by subjective symptoms.

7. The injury and irritation following may establish a *locus minoris resistentiæ* which may become the seat of tubercular infection with certain definite results. The length of time after a trauma, during which this influence may exist, can not be definitely determined, but it may be assumed in the light of critical practical experience and pathologic research that the special predisposition will cease to exist as soon as the effused blood is absorbed, and the protoplasmic elements—the products of irritation or inflammation—have been resolved into new bone or have undergone degeneration and absorption, *i. e.*, as soon as the normal nutrition balance is restored. I do not believe there is any scientific evidence or any practical facts that will bear criticism, which will support the assumption that the *locus minoris resistentiæ* may continue for months or years after all signs of the injury and its immediate results have disappeared.

8. There is no evidence to show that a carcinoma or

sarcoma may develop as the result of an injury after the immature bone elements have become transformed into tissue of a normal resisting physiologic type.

DISCUSSION.

Dr. REED, Columbus—The subject of "Remote Effects of Bone Trauma" is of interest to every surgeon, and especially to the railroad surgeon; the repairing of bone, the possibility of disease and the changes that are wrought, are all points which may interest the surgeon and interest the company especially if the patient has occasion to call on the company for damages. The subject has been very ably handled by the Doctor; he has reviewed in brief and concise form cases relative to the repairing of bone, and the changes which take place in the anatomy, in an admirable way; at the same time there are some points which the Doctor did not touch upon, and which might be of interest to us in this connection. I have no doubt you have all had occasion to observe in your practice cases in which you had taken the best care, and in which you had put on the ordinary splint, kept the bone in proper position and to all appearances in apposition, kept him quiet the ordinary amount of time, the patient had got well; and yet after all this the patient after he was given his liberty would go out and come back to you probably in one or two years afterward with a deformed limb. Now the question comes up, Is that the fault of the surgeon or is the company in any way liable? I have in mind two cases of this kind in which the patients had a fracture of the femur, an ordinary fracture in one case and an oblique in the other; in each the patient was cared for by a competent surgeon, and was dismissed with little or no deformity, or very little shortening, and yet in each case after the patient had gone out about his business his limb became deformed. Now we have there a case of imperfect repair. We have no doubt had in the first place a perfect union, the intervening space filled, new bone tissue formed, that is, the bone cells had bridged across the chasm, but they were not properly supplied with lime salts so as to harden them, and the result is that instead of that new bone becoming solid it was still elastic, of a cartilaginous character and we, in one case, had the bone not becoming actually displaced but giving away and causing a bow leg. In the other case the union was solid and the weight of the man on the limb gradually forced the bones past each other, not because they were not united, but because there was not sufficient bone salt to make the new bone hard. Those are points I do not think the railway company or any other company are responsible for. I think we ought to discriminate between cases in which deformity followed a union and the case where the surgeon did not properly adjust the bones from the case where the man does not have sufficient vitality to repair the bone properly, or to furnish the lime salt after the new bone was formed. Again, in reference to sarcoma, the Doctor speaks of what I think it is well to remember, that in the case of sarcoma we can not have a sarcoma following traumatism—and I think Dr. Senn has gone into that in his last work very thoroughly—unless there is a pre-natal or post-natal embryonic cell condition; if there is a pre-natal or post natal disposition then a traumatic trouble may cause sarcoma, but this must exist prior to the injury and is liable to be the result of previous condition because we know sarcoma does occur without there being a traumatism at all.

In reference to tuberculosis, I recall a case that came to my notice in the hospital a year and a half ago, in which there was a marked case of tuberculosis; a gentleman had pulmonary tuberculosis, which was confirmed not only by expert diagnosticians, but by microscopic examination of expectoration, and in this case the person was emaciated and to all appearances he would die from tuberculosis before he had time to repair bone. It was a railroad accident and he was caught between the cars when the accident occurred, and there were seven distinct fractures distributed between ankles and knees. I observed in this case one fracture repaired at a time—one fracture and then on the same limb another fracture and so on; it went the round, finishing one limb before repairing the other; it was a beautiful case, and notwithstanding he was suffering from tuberculosis, coughing and expectorating profusely, the repair processes went right along just as promptly, so far as any one fracture was concerned, as if tuberculosis did not exist at all. Now the point is this: If tuberculosis is liable to come as the result of injury why would it not occur where the man was suffering from tuberculosis and the whole system run down from disease and in an ill condition to take on reparative processes at all, but we do not have it occurring in any other part of the system excepting the lung. I simply bring these cases up to emphasize what the Doctor has said in his paper, that I do not believe an injury, a traumatism, is conducive to the development of tuberculosis or sarcoma in and of itself, that it

requires a condition that is entirely separate from the traumatism to induce it.

Dr. E. M. DOOLEY, Buffalo—Dr. Reed's remarks in reference to remote effects of bone trauma in case of fractures recall to my mind an interesting case that occurred in Buffalo about three years ago in which the case was a fracture of the tibia about the middle, and a classmate of mine attended him. He had a perfect result and a rigid union and the patient was able to use his limb. But a year afterward at the seat of fracture the callus softened and he had in reality a case of nonunion. The case was interesting because the surgeon was sued for malpractice. Now it was a case of the fault of the patient and not the surgeon, yet, although the surgeon won his suit, it put him to a great deal of expense, both in time and money. And I think these remarks in reference to the possibility of fracture, after it has firmly united to all appearances, softening a year or year and a half later, worthy of emphasis.

Dr. C. K. COLE, Helena—*Appropos* of what has just been said, I wish to refer to a case which occurred about two years ago in the practice of one of my neighbors, and which illustrates one of the phases of the subject touched upon in this paper. A man while riding on horseback was rubbed against a tree and the humerus was broken near the head, which was dislocated. The accident occurred in a remote region and a doctor was not consulted until, I think, four days subsequent, when the man received proper attention. The head of the bone was reduced, the fracture was restored. The patient then and for some weeks following complained of pain, increasing constantly. He consulted a prominent surgeon in San Francisco, who, after making a cursory examination said some things to the patient which reflected upon the doctor who had charge of the case, and these reflections suggested to the patient a suit for malpractice. But before bringing the suit, Dr. Senn of this city was consulted, and Dr. Senn discovered—I think this was some four months after the accident—an osteo sarcoma. Amputation was resorted to, injections were practiced, and the patient remained in St. Joseph's Hospital for some weeks; he returned home and again came to Chicago and was again treated, in the meantime having instituted legal proceedings against the doctor; and he died here in Chicago from a bona fide sarcomatous growth. The reason for calling attention to this case is that it is pertinent to one phase of the subject discussed in the paper and that is a phase of the subject that is not well understood. The fact that a traumatism may precipitate this growth, as Dr. Reed has well said, so far as our knowledge goes there is a preexisting condition, but an injury of this kind does precipitate a growth of this character. The medico-legal aspect is interesting to us as railway surgeons, because unless this is well understood we, and the companies we represent, are liable to be sued for malpractice in cases in which we are not at fault.

THE PRESIDENT—I remember a case where a blow was received on the clavicle and on the skull, and sarcoma developed in both places, at the two contusions.

Dr. GALBRAITH, Omaha—I don't believe we will have a more important paper before this Association than the one just read. While we have so far confined ourselves entirely to pathology of bone trauma, bone inflammation and the products of bone inflammation, I think it would be well for us to give the treatment of these conditions, these lesions, some consideration, more especially as to that part of the bone which enters into the formation of the joints, inasmuch as the treatment in my belief, varies as regards the location of the bone, more especially does that apply to traumatic osteomyelitis. At various times I noted that the Doctor spoke of resolution following, as I understood, simple osteomyelitis. This may occur, but as regards the syphilitic, I do not think it possible; I believe osteomyelitis attacks this portion of the bone. More especially is this subject one, or should be one, of the most serious considerations that is presented to us of a surgical character, and my results in almost every case I can recall to mind now have been a necessitated amputation.

Dr. WARD, Conneaut—I happened to be unfortunate enough to witness a case in which a man 50 years of age had a very large osteo sarcoma develop after the fracture of a clavicle. From its magnitude, before attention was called to it, any operative procedure was interdicted, but, in connection with it there developed a very friable condition of the osseous structure generally, and from the simple act of turning in bed, or something of that kind, fractures of one or more of the limbs occurred, and death finally ended the scene. This man was supposed to be healthy and in good condition until he met with the accident leading to the fracture of the clavicle, but from that time on there was a general decline, with the development of the condition specified filling all the space. It was a very large growth and a degeneration of the bone structure generally.

There must have been a preëxisting constitutional condition, but undoubtedly, in that case the fracture was the exciting cause or the developing cause of the trouble that immediately followed.

Dr. REED—Permit me just to make one statement in rebuttal, as they would say in court, to the remark made by our distinguished President: he spoke of sarcoma following contusion on the head and on the clavicle. I simply want to say, not less than eight weeks ago, I made an exploratory incision into the abdomen for the purpose of diagnosis, and there I found a sarcoma of the liver and the left kidney, the lower portion of the right lobe of the liver and the right kidney, and both distinct, as far as any anatomic connection was concerned.

Dr. EGGLESTON, Seattle—A young man about 28 years of age, inmate of a penitentiary, while working in a brickyard received a blow on the right side of the skull from a piece of brick thrown by one of the other inmates, and a few months later a tumor developed at the point of injury, which was at first attempted to be removed by the surgeon of the penitentiary; he had to stop the operation on account of excessive hemorrhage; I believe that he attempted to do it under cocain without an anesthetic; a few months later he gave an anesthetic and removed the clot, scraping off the bits of bone: it healed nicely, but a few months later it developed again, and when it came back, a year ago last June, I observed there was a tumor on that side of the skull as large as a goose egg; I pronounced it a sarcoma. I happened to have at that time some of Dr. Colles' culture of the erysipelas and commenced the use of that by injecting it in the tumor and pushed it to the extent that I almost killed the patient, but it had no result on the growth. It went on and a few months later another tumor developed on the opposite side of the skull about the juncture of the parietal with the frontal bone, and in a short time he developed paralysis on the left side from pressure on the right side, and died. A postmortem was had: the tumor went down through the skull and pressed on the brain as large as a goose egg and there was a deposit of two or three pounds of the sarcomatous growth in the left cavity. A sarcoma resulted from contusion of the bone in this instance.

Dr. BALDWIN, Salt Lake City—A man running from a policeman jumped on a shed and broke his thigh. I happened to be one of two to dress the wound. After the first, there was union there but not a bony union. Afterward he fell into the hands of Dr. Cole and that portion was excised and the bone wired, but never got a union; the result was that they finally amputated it. I have in mind another case that possibly shows the result of very remote traumatism: A young boy about 13 years old was playing with a dynamite cap which exploded and struck him on the head and it was thought only the outer table of the skull was fractured. But it went on for something like four years, when I first saw him and he began to suffer with severe pain. I do not know how long, but two or three years after the injury; and it kept up so long that it was said that something was necessary to be done. At the same time, I think about the time the pain began, he began to have indigestion—he could not eat anything or keep anything on his stomach. Dr. Cole and myself trephined and removed a portion of the bone and afterward he was relieved of the pain and materially relieved of the indigestion or the stomach trouble. Now what connection that could have with the stomach I do not know, but certain it was he was relieved considerably.

Dr. FAIRCHILD—The object of this paper was to call the attention particularly to sequelæ which might appear as the remote effect after apparent repair had taken place. It sometimes happens we have a patient, which is exposed to difficulty in a bone like the tibia, for instance, to inflammation in that bone. On examination we find nothing whatever, no thickening of any kind in any direction, a inflammation persisting in a bone for a long period of time, say one or two years, without any marked signs being manifest. That was one of the propositions in the paper, whether we could have a bone inflammation continue without giving rise to that hobbled around on crutches and having litigations over it, and yet a physical examination showed no sign whatever of a physical character. Then further along after the injury we might expect tuberculous disease to develop. Now in a case of fracture I believe it is true that tuberculosis does not generally occur, because reaction is so active that tubercles are liable to develop, that it develops in slighter injuries. Now, in slighter injuries can we say a tubercular process is liable to develop in that bone. Suppose for instance a patient received an injury and it apparently healed, yet eight or ten months or an almost two years, say, lack

patient has a tubercular process develop. Now a suit is commenced, instituted on the ground of tuberculosis as the result of the injury, and yet there was no sepsis for many months. These were points on which I was anxious to get some information. Again, in case of injury to a bone which has healed, repair has taken place, and yet a year and a half after that a sarcoma develops at the seat of injury. Sometimes we are able to determine that all the nutritive balances have been established, the cells have reached maturity, perfect physiologic poise has been reached, and yet a sarcoma develops. Can we say it was the injury which caused that sarcoma, or that it resulted from the injury received months before? Those were the points I desired to bring up, and in looking up the authorities I have had difficulty to find any authority specific enough on this subject as to enable one to believe or to form an opinion as to a consensus of medical opinion. We hear in litigation, what changes will occur in bone tuberculosis, and I have attempted to say that when the nutritive balance was restored in the bone then the danger from tuberculosis was ended, and the question would be to determine when the nutritive balance was restored, whether the repair process has occurred and cells restored to maturity. We do not believe the cell that has reached a state of maturity will become degenerate, so that in bone when the bone has become restored to a normal condition tuberculosis does not occur as the result of injury. We pretend to say that in injury to the bone if the cells become restored to physical maturity, if sarcoma develops, it is not the result of the injury. It was not intended to discuss the question of reabsorption of the callus in case of fracture, although as the discussion has gone in that direction I will mention a case, a compound fracture of the bones of the forearm: the part healed without union; the bones were resected and wired, and union began. Then it was noticed after a while that an additional joint existed, that is the callus had become absorbed. A friend of mine in Washington was operated on in the same way, and I had a letter from the doctor in which he stated he had excellent results. I saw the case six months later and the additional joint was there. But this branch of the subject I did not take up, but simply the matter of the future possibilities in the examination of an individual case; and in examining a case in which there is a claim made, can we say this condition has any bearing upon the injury which the person alleges to have received?

SOCIETY PROCEEDINGS.

Medical Society of the State of Pennsylvania.

Minutes of the Forty-seventh Annual Session.

(Concluded from page 32.)

The next paper was by Dr. E. H. James of Harrisburg, on PLEURITIS.

Until recent years, the exposure to wet and cold was supposed to be the cause of pleurisy. Medical text-books of less than a quarter of a century ago spoke of it as occurring idiosyncratically, or to quote Flint, "in the large proportion of cases it is spontaneous, that is, it proceeds from some unknown cause." The discovery of the tubercle bacillus by Koch in 1881 revolutionized our knowledge of the subject. We know now that the majority of pleurisies are caused by tubercular infection. It has been found that the tubercle bacillus has the property of exciting a fibrinous or a suppurative inflammation not necessarily specific in character. The infection of pleurisy like that of phthisis is not a simple but a mixed one. Some of the microorganisms are more destructive in character than the tubercle bacilli.

A certain proportion of pleurisies are undoubtedly of rheumatic origin. The infectious matter which will excite a rheumatic polyarthritis in one individual may in another cause pleurisy or inflammation, in another serous membrane.

Treatment: In the acute stage, acetate of potassa, 15 grains, tr. aconite R. 2 drops; sulph. codeinæ gr. $\frac{1}{8}$; spirits of mindererus 2 drams. This mixture to be given every three hours. Dry heat externally. When of the rheumatic type add 10 grains of salicylate of sodium to the mixture given above. To get rid of an effusion of serum, withhold liquids as much as possible and give saline purgatives and diuretics: the blood being thus deprived of its watery elements will frequently take up that from the pleura. If it does not do so the aspirator should be used and from ten to twelve ounces of liquid withdrawn, the remainder will usually promptly disappear. The character of the fluid in the pleural sac may be easily determined by withdrawing some with a hypodermic syringe. When pus is

found neither the aspirator nor trocar and canula should be used, but a free incision should be made in the seventh or eighth intercostal space on a line with the posterior axillary fold; the pus and fibrinous clots can thus be thoroughly evacuated, after which a drainage tube guarded with a safety pin should be introduced and a dressing of sterile gauze and cotton applied. The tube may be shortened from time to time and when the discharge is thin or serous may be withdrawn. The initial operation as well as all subsequent dressings must be done with strict aseptic methods, the danger of acute infection is great. It is necessary to excise a portion of rib when drainage can not be properly secured by thoracotomy. This allows thorough exploration, pockets of pus can be broken up, drainage will be perfect. Irrigation of the pleural sac I believe is harmful, it irritates, delicate adhesions are broken up.

In the pre-antiseptic era according to statistics 87½ per cent. of empyemas died. Today we expect over 90 per cent. to recover. Of six cases of empyema which I treated recently all recovered. In one of these a portion of the seventh rib was excised, the others treated by thoracotomy and drainage.

A resolution was adopted by which each member was earnestly requested to write to his members of the Legislature urging the passage of the Act now before them relative to malpractice suits.

Dr. W. M. ROBERTSON of Warren presented a paper on

A COMMON CAUSE OF LOOSE BODIES IN THE KNEE JOINT.

An authority says that "In joints that have been free of disease loose bodies are invariably the result of a trauma." It is my intention to direct your minds to the more common lesion of the knee joint produced by trauma according to the teachings of Arbuthnot Lane of Guy's Hospital, London.

Injuries to the knee usually occur when it is flexed. As in all hinge joints the articular surfaces of the knee are best protected when in a position of extension. In flexion the articular surface of the tibia covered by the interarticular cartilages glides backward on the femur, exposing the articular surfaces of the condyles of the femur. During flexion the patella falls more and more into the intercondyloid notch of the femur and forms a great protection, but you will observe that the outer condyle is favored much more than the inner one. It is a great defense to the joint from injuries inflicted in front and distributes the weight when in the kneeling posture.

In falling forward the thighs are usually abducted in such manner that the exposed and unprotected articular surface of the inner condyle sustains the force of the fall and receives the trauma from which the loose bodies originate later on.

It has been supposed that these bodies came from the separation of portions of synovial fringes and injuries to the semi-lunar cartilages and without doubt such is the case many times, but in the majority of cases Arbuthnot Lane has demonstrated that the more common origin of loose bodies is the dry necrosis and separation of a portion of the articular fibro-cartilage of the inner condyle injured by direct violence, such as is sustained by a fall forward. In these cases the blow suffered by the articular surface is sufficient to devitalize the area.

The nutritive processes are stopped and after a time separation of the cartilage occurs and becomes the loose or floating body in the joint. This may produce the history of locking and pain, or it may give rise to simple chronic synovitis, which may in time present every appearance of rheumatoid arthritis or of tubercular disease.

A number of cases might be cited in which Mr. Lane exposed the inner condyle to view showing the area from which the cartilage had separated and then after careful search enough of cartilage found in the joint to exactly correspond to the space left after its separation.

The practical point is to recognize these cases and lose no time in operating. In a number of cases I saw Mr. Lane pare off the edge of partially dislocated semi-lunar cartilage of the knee.

Dr. EUGENE WANDIN, Pittsburg, read a paper on

PATHOLOGY OF INFLUENZA.

Laboratory observation has alone resulted in any service here. The organism of causation has been demonstrated by Pfeiffer and Canon. It is difficult of cultivation. This disease is of great importance. It increases largely the death rate from pneumonia. He sketched its complications at some length, demonstrated the gravity of the disease, even when uncomplicated. Unfortunately, the nomenclature is much confused. General symptoms of catarrh of the stomach and small intestine are frequent. After the thoracic condition is pronounced, attention is called to the distension of the abdomen. There is no pain, but a sense of fullness, diaphragm is displaced, the weakened heart much embarrassed: all this depends upon the

toxic influence of the sympathetic nerve supply. In the lungs the elastic tissue being highly organized, impairment of this tissue is followed by loss of proper action of the capillaries.

Dr. J. M. DOUTHETT of Pittsburg read a paper on

CLIMATE IN CONSUMPTION.

He alluded to the want of attention to the physiologic effect of climate. We need reliable statistics on the climate of these places so much lauded for consumptives. Each vaunts its own and attacks the others. Few can go away, not having the means to travel. The most desirable conditions are: As much altitude as the patient can stand; as little humidity as possible; moderate temperature devoid of cold. High altitude increases the red blood corpuscles, with an increase of the hemoglobin, increase of lung expansion. In elevated arid regions, decay is slow, and indeed under favorable conditions does not occur, because of dryness, air purity, freedom from organic dust and germs, large amount of ozone present, etc. A dry climate is very important; next an even temperature. On the whole, the central plateau of Mexico presents the best climate for the tuberculous, combining desired altitude, low humidity, even in the winter months, and in the mountains one may have very pleasant summer weather. Hotel accommodations are very poor, the chance for employment is moderately good if one knows the Spanish language. El Paso and Las Cruces are the best all-round places in the United States. In western Texas are numerous places where one might obtain employment at a ranch or in the mines. Colorado has too severe winters, summer is the best time there. For those who have heart complications, Florida and Southern California are the best. A residence of several years is needed for a cure, hence it is necessary to find employment so as to get interested in the place. Sanatoriums are of advantage to a certain class; all should be encouraged to obtain out-door employment, to get the benefit of the sun and fresh air.

Dr. EVAN O'NEILL KANE of Kane read a paper on

WHY THE TOBACCO HABIT IS PECULIARLY REPREHENSIBLE IN AND DETRIMENTAL TO PHYSICIANS.

His purpose was to draw the attention of the profession to the injury which they do both to themselves and to their patients by this indulgence. In order to prove the truth of this statement, it is pointed out that no delicate patient can tolerate the odor of tobacco which the attending physician frequently intrudes upon them. Stress is laid upon the fact that all special senses are to a more or less serious extent dulled by using tobacco, the power to diagnose disease being thus greatly curtailed. Having passed briefly in review the manner in which each of the special senses suffers, the paper closes with the claim that even the will power becomes weakened in those who are addicted to the tobacco habit.

Singular to say, this paper was received with a round of applause from all present, as also were the remarks of Dr. A. B. Brumbaugh of Huntingdon, who fully accorded with Dr. Kane and arraigned the members for the indulgence so freely on the occasion of the reception the evening before, where every lady was compelled to pass through a crowd of smokers in order to reach the parlor where the reception was being held.

THE FAUCIAL TONSIL AS AN AGENT IN SYSTEMIC INFECTION

was discussed by Dr. G. B. SWEENEY of Pittsburg. The faucial tonsil occupies a humble position. As an agent for the secretion of fluid to aid deglutition, it is no more active than the surrounding mucous membrane. It is only when it becomes the seat of disease that it demands attention. While in a state of inflammation it frequently affects the entire economy. It is a most readily accessible point of attack in infections; however mild the process, the tonsil becomes a hot-bed for infection, and readily distributes morbid products to adjacent and remote organs. Interfering when enlarged with respiration, it produces the "mouth breathers." Hence improperly filtered, moistened and warmed air is hastily conveyed to the lungs, oxygenation is prevented; we see then the dull, listless eye, impaired mentality, the pallid complexion, contracted chest, anemic and wasted muscular organism. The tonsil is a vulnerable point of attack for diphtheria, and often a culture medium for propagation of germs which would otherwise perish. We are now able to establish almost beyond doubt the infectious nature of rheumatism. We can not fail to observe the analogy in the systemic symptoms of follicular tonsillitis and acute rheumatism. Though we have not yet been able to isolate a germ for rheumatism, yet in this disease we find in the blood streptococci which characterize follicular tonsillitis, and are found in the tonsil when affected by that disease. Tuberculosis shows us the glandular system largely affected. Here we may regard the tonsil as mainly if not wholly the source of infection. So with typhoid and malarial fevers due

to a specific bacillus, and as drinking water plays a conspicuous part in the causation, we may infer that these bacilli are thus aided in obtaining access to the whole economy. We claim that the tonsil being an open gateway for the reception of all forms of disease germs, it is plausible that it is liable to infection equal with Payer's patches, etc.

Dr. LOUIS LAUTENBACH of Philadelphia read a paper on
THE NECESSITY FOR ACTIVE, NOT PASSIVE, TREATMENT IN EAR DISEASES.

It is my purpose to advise a more intimate study of ear conditions, and to present advanced methods of treatment. I am thoroughly convinced that by paying close attention to the ear chronic cases can often be materially improved and relieved, but especially do I advocate that upon the first evidence of any ear trouble it should be thoroughly examined, and if the physician feels himself incompetent to take charge of the case he should refer it to some one whom he knows will do justice to it. The policy of doing nothing at all, of letting diseased nature have its own way, is, to say the least, dangerous. What I protest against most strongly is the neglect of the family physician to give proper weight to the symptoms of ear disease in their incipiency, when a thorough treatment or two would dissipate the pathologic condition.

The importance the nose and throat bear to the ears has been recognized and has given rise to a false idea that ear diseases created by nose and throat trouble is curable through the nose and throat alone without local ear treatment: that the removal of the cause of the disease cures the disease itself. The removal of the cause is a necessity, surely, but attention to the changed ear condition is equally important.

To keep open the Eustachian tube, but especially to prevent any ossicular stiffening, membrane thickenings or adhesions I early use massage with the Siegle speculum or a phono or pneumo or mixed masseur of my own devising. I use the phono and mixed massage, as I find even early in cases of ear involvement there is often a tendency to a dulling of the sensitiveness of the auditory nerve from disuse.

By my masseurs I can produce any amount of suction force on the membrane I wish, with or without sound waves, giving any number of suction I may deem advantageous, and can let the machine act upon the drumhead any period from a few minutes to several hours, if necessary. For this purpose I use machines actuated by electricity in which the suction is produced by a diaphragm operated by an electro-magnet: again a stronger one in which a suction pump is worked by an electro-magnet, and another in which a double suction pump is worked by a motor, this latter machine I am at present operating in connection with an ordinary Gramophone with an extra loud transmitter. These machines applied sufficiently early will frequently prevent the serious effects so often observed of rigid ossicles and thickened attached membranes and non-responsive ear nerves.

In cases of acute, active, painful middle-ear inflammation, I not only rely on dry heat, but am constantly using hot flaxseed poultices, and I must confess that I get remarkable results when they are used very hot and often. They will relieve pain and infiltration at times marvelously. Contrasting the results of the two methods, the passive serves to remove the exciting cause of the ear disease, depending upon the reparative powers of nature to restore the ear to normal. The other method endeavors to combat the pathologic ear processes and encourage nature to resume her normal sway. It endeavors to retain the full function of the conducting apparatus as well as of the ear nerves, and in every way possible strives to minimize the danger of any permanent disease of the ear or impairment of hearing.

There is another case of ear patients which has been almost totally neglected so far as direct ear treatment is concerned. I refer to the deaf mutes. I have succeeded in restoring one to such an extent that she can attend the ordinary public school course in Philadelphia, and another girl, 7 $\frac{1}{2}$ years, from Shenandoah, now under treatment by me, has within the past few weeks given marked proofs of hearing, while at the same time she has learned to speak several words fairly plainly. Her facial expression and manner has become transformed from that akin to an idiot to a degree of intelligence. This has been accomplished, too, after she had been discharged from a deaf and dumb institution for the training of lip speech, on the ground, as I understand, that the child's brain was weak and inclined to be idiotic, and it would be useless to attempt to teach her. So far, in nearly all the deaf mutes placed under my charge, I have been able to develop some hearing, provided the caretakers followed my instruction. I consider the ear masseurs the important element in the treatment. It was with the conviction that my massage apparatus had helped me in my ear work that I presented the machines to the medical public

some three years ago, and with the knowledge of the successful results obtained I have continued their use, modifying them as experience suggested, and I again present them here at this meeting as a method which opens up an entirely new field of ear treatment, with new possibilities not only for preventing the bad effects of ear inflammations, but for modifying and overcoming the results of such cases as have been neglected or have developed into chronic ear thickenings, membrane retractions, ossicular unions and sluggish nerves.

Dr. W. T. ENGLISH of Pittsburg read a paper on

THE ELEMENT OF FEAR IN HEMOPTYSIS.

He assumed that the extent of the fear and the neurotic perturbation are out of all proportion to the amount of blood expectorated and can not be interpreted except through the language of the emotions. After citing a number of cases exemplifying the fear element in hemoptysis he argues that the special study and treatment of this element is essential to success in the treatment of hemoptysis generally. To quiet the fear and the resultant neurotic tumult is as essential to the welfare of the patient as to cause a cessation of the blood spitting.

In hemorrhages of this character quiet is of first importance. This quiet can not be secured simply through enforced inactivity. We need calm which will diffuse itself with sure celerity through the nerve centers and plexuses, that will reach with its message of peace the remotest fiber of the nervous organism and restore the coordinations that have been lost through the element of fear as exemplified in hemoptysis. This rest is available through the hypodermic use of a decisive dose of atropia. Until this tranquility is secured all treatment will be experimental. It quiets the tumultuous demeanor of the central cardiac organ and restores its wonted rhythm. The unstable behavior of the peripheral vessels in the general circulation, as also in the pulmonary area, is replaced by a placidity that is at once restful and restorative. This quiescence is distributed equably and with promptitude and it is in this special direction that the efficiency of the atropia lies. It quickly and surely puts to rest the emotional elements that otherwise might continue indefinitely.

Moreover, the fact that atropia is rapidly diffused and quickly eliminated adds to its value in these cases. It becomes the duty of the physician to adjust the treatment to the element of fear as well as to the hemorrhage. If the hemorrhage is abundant the dosage should be large enough to paralyze the peripheral vasomotor nerves and thereby lessen blood pressure, causing a general determination of blood to the surface and thus relieving the vessels from which dangerous hemorrhages emanate. If the hemorrhage be small and the emotional manifestations, as exemplified through the element of fear be great, the dosage should be proportionate to the fear element and therefore must be generous. If there is a medium exhibition of both elements the treatment should prevail as in excessive hemorrhages. When the hemorrhage and emotion are at variance in any degree, that element which has the ascendancy indicates the treatment as to the urgency, dosage and frequency of repetition. Fear must be judged of by its type, its intensity and its persistence, as also its immediate and remote influences, with the same caution as the hemoptysis.

Dr. I. C. GABLE of York read a paper entitled

APPENDICITIS WITH CASES.

The profession are more divided as to this operation perhaps than any other. When mild it may subside with no marked symptoms. The ulcerative form is seldom if ever from a primary catarrhal condition. Ulceration is due to fecal concretions and rarely to foreign bodies. The infective form may result from either. Recurrent and relapsing are not interchangeable terms. Recurrent are those which repeat at considerable intervals; relapsing when the attacks are so close as to be almost continuous. In the first it would appear that there had been a recovery from the peritonitis while the appendicitis had continued. In relapsing there is no complete recovery. In mild types, starvation in its therapeutic sense, with such other as indicated. Delay is justifiable to avoid operation in absence of acute symptoms. He gave the details of some cases operated upon with success, others where operation was declined.

The officers for the ensuing year are: President, Dr. W. Murray Weidman, Reading; secretary, Dr. C. L. Stevens, Athens. The society adjourned to meet at Lancaster the third Tuesday in May, 1898, where the 50th anniversary will be celebrated, that being the place where the society was organized in 1848. About 300 members were in attendance. The afternoon of Thursday was occupied by an excursion on the Monongahela River by steamboat, and a visit to the Carnegie Plate Armor works.

Association of American Medical Colleges.

Pursuant to a call issued April 27, the Association of American Medical Colleges met in the Hotel Walton, Philadelphia, May 31, at 10 A.M.

Dr. J. M. Bodine, president, in the chair. Thirty four colleges were registered. On motion of Dr. Larrabee, the Association resolved to adjourn to meet at the College of Physicians at 4:30 P.M., Tuesday, and thus secure the attendance of delegates known to be on the "Journal train." On motion of Dr. H. O. Walker a committee of three was appointed to consider the report of the Committee on the Codification of the Constitution. The Chair appointed Dr. J. W. Holland of Philadelphia, Dr. C. W. Kelly of Louisville and Dr. John Heffron of Syracuse on this committee. After some informal discussion the Association adjourned.

On Tuesday afternoon the Association met in the lower lecture room of the College of Physicians. Twenty-three colleges were represented, with the President, J. M. Bodine, in the chair. The minutes of the Atlanta meeting were read and approved.

The President's Address was then read and, on motion of John B. Roberts, ordered printed.

The Committee on Amendments to the Constitution then reported by its Chairman, Dr. J. W. Holland. After receiving the report each article of the constitution was taken up separately and then adopted as a whole as given in JOURNAL, Vol. 28, pp. 796-7, corrected as follows:

ARTICLE II, SEC. 2. The college applying "shall be elected to membership if it receives the favorable recommendation of the Judicial Council and the favorable ballot of a majority of the colleges represented at the meeting."

ARTICLE III, SEC. 2. "In place of this examination, or any part of it, colleges, members of this Association, are at liberty to recognize the official *certificates of reputable* literary and scientific colleges, academies, high schools and normal schools, and also the medical student's certificate issued by any State examining board covering the work of the foregoing entrance examination."

ARTICLE III, SEC. 6. "(b) To graduates and students of colleges of *homeopathic or eclectic* medicine, as many years as they attended those colleges, provided they have met the previous requirements of the Association and that they pass an examination in *materia medica* and therapeutics. (c) To graduates of reputable colleges of *dentistry, pharmacy and veterinary* medicine, one year time."

ARTICLE V, SEC. 2. . . . "The seven members constituting the *Judicial Council* shall serve three years each. Vacancies by expiration of term shall be filled at the annual election of officers. Vacancies by death or resignation shall be temporarily filled by the surviving members of the *Judicial Council*."

The By-laws were unamended.

After some discussion, on motion of Dr. John B. Roberts, it was declared the sense of the Association that this constitution was in force for this time forward.

The Secretary's report was then read and approved.

Dr. J. P. Lord moved that suitable resolutions on the death of Dr. Perry Millard be prepared and spread on the records of the Association. The President appointed a committee for that purpose consisting of Dr. J. P. Lord, Dr. C. W. Kelly and the Secretary. This committee afterward reported as follows:

WHEREAS, We are reminded by the absence today of one who had been among our most active members, Dr. Perry H. Millard; one who was untiring in his devotion to the interests of this Association and the cause which it represents. In his death the Association has sustained the loss of its best friend, most earnest and faithful worker and wise counselor: the profession a true friend and exemplar; and this Association deplors his untimely death; therefore

Resolved, That we make this sentiment of our regard for him a matter of record; that it be placed among the minutes of our proceedings and that a copy be furnished his family.

The report of the Committee on Course of Study was read by title and ordered printed.

The recommendations and report of the Judicial Council were then read and approved.

The Medical Department of the University of Niagara was elected to membership.

The following named officers were elected for the ensuing year:

President, Dr. J. W. Holland of Philadelphia.

Senior Vice-President, Dr. H. O. Walker of Detroit.

Junior Vice-President, Dr. Thomas Opie of Baltimore.

Secretary and Treasurer, Dr. Bayard Holmes of Chicago.

Vacancies in the Judicial Council were filled by reelection. (Signed) BAYARD HOLMES, Secretary.

JUDGMENT AGAINST THE MEDICAL COLLEGE OF OHIO RESUBMITTED TO THE COUNCIL TO FIX PENALTY.

WHEREAS, By the unanimous decision of the Judicial Council of the Association of American Medical Colleges it was heretofore adjudged on May 31, 1897, that, "After due examination of all the evidence before us, and the statement of Prof. James G. Hyndman, secretary of the faculty accused, we find as follows: That the John E. Yarling specified in the charges was actually graduated at the said Medical College of Ohio as a Doctor of Medicine on April 9, 1897, and that the said Yarling matriculated for the first time in the Illinois Medical College in April, 1895, all of which is in violation of Section 5 of Article III of the Constitution of the Association of American Medical Colleges."

Now, therefore, as it appears from the action of the Association of American Medical Colleges held at Philadelphia on June 1, 1897, that the Judicial Council must fix penalties in the determination of all such matters as involve a violation of the constitutional requirements of the College Association, the Judicial Council decrees that: The provisions of Section 5 of Article III of the Constitution embody fundamental principles which must be held sacred and inviolate, and that the said Medical College of Ohio has forfeited its membership in the Association of American Medical Colleges.

The language of the Constitution is mandatory; Section 5 of Article III reads as follows: "Candidates for the degree of Doctor of Medicine shall have attended three courses of graded instruction of not less than six months each, in three separate years," prior to 1899. The Council has heretofore held that "no student can be admitted to a second course of instruction within twelve months from the date of the beginning of the first course," by any college holding membership in this Association, and that "no amount of previous study can be accepted in lieu of any part of any one of the three courses of graded instruction provided for in Section 5 of Article III of the Constitution." (Signed)

DUDLEY S. REYNOLDS.

STARLING LOVING.

JAMES H. ETHERIDGE.

I certify that this is an exact copy of the original, signed by six members of the Council. L. B. BALDWIN, Clerk.

Fifteenth German Congress of Internal Medicine.

Berlin, June 9-12, 1897.

In his opening address von Leyden called attention incidentally to the danger that general therapeutics may be neglected in the modern development of specialism, and Virchow observed that for fifty years he had fought specialism, but had gradually become convinced of its utility, while still recognizing its menace to general science. This peril must be borne constantly in mind and no fundamental divisions allowed in spite of the numerous ramifications. He added that pathologic anatomy is the one thing common to all special branches, and yet the pathologists are on the point of organizing a special congress!

The first subject, "Chronic Articular Rheumatism," was presented by Professors Bäumler and Ott. After urging a more exact definition and limitation of the word rheumatism, the former reviewed the bacteriologic investigations: Schüler's bacillus (1892), and the small dumb-bell bacillus found by Bannatyne and Wohlmann in twenty-four out of twenty-five cases (1894), confirmed by Blaxall as a small, short, pole-staining bacillus found in the synovial fluid in eighteen cases of polyarthritis, and absent in other forms of articular affections. He succeeded in cultivating it on the usual media, except gelatin. but did not find it pathogenic in experiments on animals. Bäumler urged further research in this line. The preponderance of female subjects suggests the possibility that the genital mucosa is the route traveled by the exciting agent. He warned against the abuse of morphia, stating that the syringe should never be given over to the patient. He added that the term, *arthritis pauperum*, is incorrect; the well-to-do are

affected as often as the poor. Potassium iodid was recommended by Krönig, v. Noorden and others. Davidsohn recommended "fango," Battaglia mud. V. Noorden has been testing the lemon cure in this disease, and finds that it does no harm, and even produces a transient subjective improvement, but has no effect on the metabolism. He advises antiobesity treatment, as it often leads to increased mobility of the articulations. Schüller uses an emulsion of iodoform and guaiacol injected locally. Sixteen out of twenty-nine cases thus treated were completely cured. The injections are painful, and must be repeated in large joints three to seven times. Complete cure sometimes follows one injection in the case of small articulations. An operation is more rapid in its effects. He has operated sixteen times, eleven on the knee, with complete restoration of mobility. No relapses. Improvement perceptible in a fortnight.

Professor Ott in his address signaled the importance of trauma, dampness and lack of light and air in the production of the disease: recommended woolen clothing and especial attention to the diet, with meat for a foundation, combined with eggs, fish, vegetables, butter and cheese, especially milk. Water the best beverage; alcohol and carbohydrates much restricted; moral depression avoided; a journey to be advised in some cases. Treatment should be prompt and meet every stage of the disease, which should be carefully watched over even long after convalescence. Each acute symptom must be hastened past with every possible means: Fever by repose in bed and restricted diet; local pains and swellings with Priesnitz compresses, liniments or salves with opiates or injections of morphin. Absorption is accelerated by painting the surface with tincture of iodine. Puncture is also useful in severe swellings, and elastic bandages. He adds that the success of the salicylic preparations in acute articular rheumatism is only equalled by their ineffectiveness in arthritis deformans, not only at first, but in the exacerbations. Some find salol beneficial, others antipyrin, acetanilid, phenacetin, phenocoll and malakin. When there is more or less swelling of the joints, without much loss of mobility or dislocation of the ends, external treatment is indicated that will favor absorption, such as tincture of iodine and ichthyol, which sometimes score a success. When all the symptoms of acute or subacute inflammation have subsided, baths should be recommended. They should be suspended whenever inflammatory symptoms reappear, until they pass away again. In all baths the main point is heat. This can be wonderfully attained by the new partial steam and hot air baths (Tallermann's 104-119 degrees C.); mud baths produce a mechanical stimulation of the surface in addition to the heat, and partial mud baths for weak patients have been found useful applied as hot mud compresses, with occasionally surprising success. The simple hot springs, such as at Teplitz, Gastein, Warmbrunn, etc., are especially adapted to patients with much nervous excitability. The success of sulphur baths is probably due to the heat. He also recommends the hyriatic processes, which combine hot and cold baths, as an advisable supplement to a course of hot baths, to tone up the system debilitated by the effects of the heat. They also render it less liable to relapses. In the raw seasons it is better to resort at once to a hyriatic course. He also advocated massage as an important aid in the treatment, but if the capsule is already contracted, massage can not restore it. Active and passive movements should also be undertaken to prevent stiffness; especially useful in this respect is the Zander apparatus. The climate for persons affected with polyarthritis deformans should be warm, even, dry and sheltered from the wind, with hot springs convenient. These conditions are fulfilled at Battaglia in northern Italy for the spring and fall, Ischia, where there are natural hot springs and also natural hot sand baths, and Algiers. Medication should aim to strengthen and tone up the system: Iron, quinin and cod liver oil. The iron is best administered as syrup ferri iodat., which is especially effective in younger patients. Singer has cured one typical case of acute rheumatism with intravenous injections of sublimate.

Program of the Berlin Leptra Congress.

October 11-16, 1897.

GERMAN EMBASSY, WASHINGTON, D. C., May 21, 1897.

Dr. Albert S. Ashmead:—Referring to my letter of March 22 last, I have the honor to enclose a program of the International Conference of Leprologists, to be held in Berlin, Germany, from October 11 to 16 next. You will oblige me by stating its receipt. Yours very truly,

BARON THIELMANN, Ambassador of Germany.

IMPORTANT LEPTRA CONFERENCE WHICH WILL MEET IN BERLIN, OCTOBER, 1897.

More and more of late the interests of scientific circles have been directed to the question of the spreading of leprosy. The public attention also has occupied itself actively with this subject. Therefore it seems to us, that now the favorable moment has come to lead the work by unanimous consent into the right grooves. We shall stand for this, that the disease, which everywhere is in a slow but constant condition of expansion, be stopped by suitable measures. We are of the general opinion that anything good in this field can only be obtained by a strict program, whose object and means would be as comprehensible as possible. In this sense we have the honor to make an invitation to a discussion on the lepra question to be held at Berlin the month of October, 1897. Further details will be communicated hereafter. The preparative works have been undertaken by the undersigned.

E. EHLERS, Copenhagen.
G. ARMAUER HANSEN, Berlin.
R. KOCH, Berlin.
O. LASSAR, Berlin.

PROGRAM.

The beginning of the sittings is proposed to be for the time from Monday, October 11, to about Saturday, October 16. The deliberations will take place in the meeting hall of the Imperial Board of Health, 19-20 Klopstock Strasse, Berlin, N.W., which the Imperial government has placed at our disposition for that object. The time of the plenary sitting is from 11 A.M. to 2 P.M., in order to leave the members of the conference time for other consultations and possible sittings of commissions. An exhibition of all the objects interesting for the investigation of leprosy will be connected with this meeting. The object of the conference is, in the first place, a scientific discussion of the lepra questions as well as of the methods recommended for the limitation and suppression of the disease within the limits of possibility. The result of the debates shall be formulated in such a manner that on the foundation offered by them further steps may be taken eventually for legislation, administration and by international arrangements. The scientific material in hand will be analyzed and sifted by the conference in such a manner that the governments of all the states interested may be enabled to take appropriate measures. An international scientific understanding is therefore the real task of the lepra conference and state medical tendency, the larger point of view.

In order to accomplish these objects as much as possible all lepra authors, known as such, are invited to attend. As a large number of these gentlemen have already promised to come the success of the enterprise is assured. The manner of the work is in common about as follows: The questions are previously prepared by reporters and as far as the object requires or permits it provided with discussable theses. These elaborations, written in German, English or French languages, which most of the participants are likely to understand, are printed as soon as they have been delivered to Prof. O. Lassar, 19 Karlstrasse, Berlin, N.W., and continuously sent to all the gentlemen who have promised to attend. In this manner everyone is enabled to choose for himself a position for the discussions and to advocate or combat resolutions. The printed works are not used for lectures. Thus all the time and labor will be spared for the meeting without putting any constraint to the expressions of opinions and literary activity of the reporters. The reports sent are in conjunction with the record of the meeting to form a permanent literary monument of the congressional work. The printing of them is, therefore, for the present considered as a confidential manuscript and not otherwise published. Tables and diagrams will be reproduced, as far as it is possible.

As themes we can at once mention the following, barring possible changes, for which the gentlemen whose names are also mentioned have offered themselves. As a matter of course, every correction or addition which the expected participants, learned societies, or state governments will be received with pleasure and is even requested. The committee is ready to meet, as much as possible, any further proposition of this kind. It also will be thankful for everything done personally or materially in the interest of the Leprosy Congress.

THEMES.

1. The place of leprosy among the infectious diseases; Dr. R. Koch.
2. Pathologic anatomy of leprosy, Dr. Rudolf Virchow, Berlin.
3. Histology of leprosy, Dr. P. G. Unna, Hamburg.
4. How far are we justified in considering the lepra-bacillus as the cause of the disease? Dr. A. Neisser, Breslau.

5. The attempts at culture of the lepra-bacillus, Dr. B. Campana, Rome.
6. Etiologic rôle: *a*, of heredity: *b*, of transmissibility, Dr. E. Besnier, Paris.
7. Alimentation and leprosy, Dr. J. Hutchinson, London.
8. The question of inoculability, Dr. H. Köbner, Berlin.
9. Does leprosy go directly from man to man, or does it go indirectly? Dr. Lie, Bergen.
10. The patent consequences of the emigration and immigration for the leprosy question, Dr. E. Arning, Hamburg.
11. Leprosy returning from the colonies into the great cities of Europe, Dr. Hallopeau, Paris.
12. General view of the condition of therapy, Dr. O. Lassar, Berlin.
13. Leprosy of the eye, Dr. Borthen, Drontheim.
14. Visceral leprosy, Dr. Doutrelepont, Bonn.
15. Anesthetic forms, Dr. Looft, Bergen.
16. Relations between syringomyelia, Morvan's disease, Aïn-hum and lepra, Dr. Zambuco Pacha.
17. Optional or obligatory isolation, Dr. Armauer Hansen, Bergen.
18. The best arrangement of leprosy, Dr. O. Petersen, St. Petersburg.
19. Foundation of lepra societies, Dr. Kirchner, Berlin.
20. Nomenclature, Dr. Dehio, Dorpat.
21. Historicals of leprosy, Dr. E. Lesser, Berlin.
22. Geography of leprosy: 1. general consideration, Dr. Kübler, Berlin; 2. Norway, Dr. Hansen; 3. Sweden, Dr. Sederholm; 4. Denmark and Iceland, Dr. Ehlers; 4. Russia, Dr. Pospeloff, Moscow, and Finland, Dr. Fagerlund of Helsingfors; 6. Turkey, Dr. von Dühring, Constantinople; 7. Greece, Dr. Rosolimos, Athens; 8. Bulgaria, Dr. Bogumil Berin, Sofia; 9. Roumania, Dr. Kalindero, Bucharest; 10. Hungary, Dr. Schwinmer; 11. Austria, Dr. Kaposi; 12. Germany, Dr. Blaschko, Berlin; 13. Italy, Dr. Pellezzari, Florence; 14. Spain, Dr. Zuriaga, Valencia; 15. Portugal, Dr. Seferino Falcao, Lisbon; 16. France and colonies, Dr. Feulard, Paris; 17. England and colonies, Dr. Phineas Abraham, London; 15. Holland and colonies, Dr. Broes Van Dort, Rotterdam; 19. Belgium and Congo, Dr. Bayet, Brussels; 20. Canada, Dr. A. C. Smith; 21. United States, Dr. White, Boston; 22. Central America, vacant; 23. West Indies, Dr. Numa Rat, St. Kitts; 24. Ecuador, vacant; 25. Colombia, Dr. Carrasquillo, Bogota; 26. Chili, Dr. Valdes Morel, Santiago; 27. Argentina, Dr. Sommer, Buenos Ayres; 28. Brazil, Dr. Silva Arango, Rio Janeiro; 29. Madeira, Dr. Goldschmidt, Paris; 30. South Africa, Dr. Impey, Cape Town; 31. Dutch Africa, Dr. Schön, Berlin; 32. Egypt, Dr. Engel Bey, Cairo; 33. China, Dr. Kerr, Canton; 34. Japan, Dr. Kitasato, Tokio; 35. Oceanica, Dr. Mouritz, Hawaii.

The Exhibition which is connected with the Lepra Conference will be held in the rooms of the Imperial Board of Health. It embraces exclusively scientific objects and is divided into the following sections: Anatomy and morphology, micrology, photography, cartography, bibliography. We pray that this Exhibition may receive abundant contributions. In the enclosed formulary please find the provisional indications of the sendings expected. Government Councilor, Dr. Köbner, member of the Imperial Board of Health, has undertaken the direction of the Exhibition.

Formulary.—The undersigned offers for the Exhibition of the Leprosy Conference for the group: 1. *Anatomy and Morphology*. 2. *Micrology*. 3. *Photography*. 4. *Cartography*. 5. *Bibliography*. The desired space is . . . square meter table surface, . . . square meter wall surface. The objects are sent by post, by freight, and will arrive at the latest September 15.

Signed,

PRACTICAL NOTES.

Paralysis of the Forearm from Bicycling.—Dr. Destot has published in the *Gazette des Hôpitaux* an account of his own experiences. An abstract of the paper appears in a recently published number of the *Neurologisches Centralblatt*. After a long ride he experienced paresthesia in the fourth and fifth fingers, with impaired sensibility and paresis in the interossei, lumbricales, and the adductor pollicis. The paresis was followed by distinct atrophy in the affected muscles. He considers the affection to be the result of pressure upon the branches of the ulnar nerve, aggravated, doubtless, by the vibration occasioned by bad roads. He also considers that predisposing factors existed in the softness of the skin of the hand and in the exhaus-

tion of the muscles and the consequent loss of protection to the nerves lying in or under them.

Arsenious Acid Again brought out as a Cancer Cure. The *Semaine Méd.* of May 1 contains photographs of three persons radically cured of cancer of the nose, one a woman of 84, with views of microscopic sections of the neoplasms, showing their character. The only treatment was painting the surface with a solution of arsenious acid 1 gram, to 75 grams each of ethyl alcohol and aq. dest. (reducing this amount to 40 grams each, as the eschar grows thicker). A little fresh blood is drawn to the surface, which is then painted with the solution, and left exposed to the air if possible. An extensive cancer requires daily painting for two to three months before the cure is complete. Cerny and Trunczek conclude their report with the statement that they have not succeeded in curing carcinoma of the mamma with this treatment, but that all surface cancers are relieved and rendered almost entirely odorless with it. It is perfectly harmless, as has been shown by cases of cancer in the buccal cavity treated for months without any evidences of arsenic intoxication, and it is indicated in every cancer of the skin without ganglionic indurations.

Uncontrollable Vomiting in Pregnancy, Continuing after the Death of the Fetus.—Fabre notes a case of uncontrollable vomiting in a primipara, 18 years of age, who had previously suffered from anemia and hysteria. The vomiting began at the fifth month of pregnancy and had continued up to eight and a half months, with increasing weakness. The fetal heart was not to be heard, yet the vomiting continued and medicinal means were of no avail. It was therefore decided to induce premature labor, and Krause's method (introduction of a bougie into the uterus) was employed. On the day before this was done the patient was so weak as to require injections of caffein and ether and 200 g. of artificial serum into the subcutaneous tissue of the abdomen. Twelve hours after the introduction of the bougie into the uterus a dead female fetus was delivered by means of forceps. The vomiting still continued and the patient died twelve hours later. The only lesions found at the necropsy were those of recent gastritis. The case is interesting, for the death of the fetus was not followed by a cessation of the vomiting, a circumstance probably due to the fact that here pregnancy was not the sole factor, but had superadded to it the pathologic state of the stomach.—*British Medical Journal*.

Ligature of Carotid Arteries for the Control of Hemorrhage due to Pharyngeal Abscess.—At a recent meeting of the Royal and Medical Chirurgical Society Clutton (*Brit. Med. Jour.*, May 29, 1897, p. 1349) reported the case of a victualer, 28 years old, with a history of having bled rather profusely the day before from an abscess in the pharynx above the right tonsil. After the lapse of a few days the soft palate was divided for the purpose of a complete examination of the abscess. A hole was found passing through the wall of the pharynx into the tissues of the neck. This opening was enlarged and the cavity plugged with cyanid gauze, as it was thought from the character of the hemorrhage that the bleeding might be from the internal jugular vein. During the night following this operation, the man bled so furiously that no doubt could be entertained as to the hemorrhage being from a large artery, probably the internal carotid. On the following day the bifurcation of the common carotid on the right side was exposed and an animal ligature applied by means of a stay knot to the common carotid and its two branches. A saline infusion of two pints was given whilst the wound was being closed with sutures. The wound in the neck healed by first intention, and the abscess cavity in the pharynx was found by digital examination to have closed some time later. There was no further hemorrhage after ligature of the carotid arteries.

The Treatment of Wounds of the Air-passages.—Platt (*British Medical Journal*, May 8, 1897, p. 1149) reports ten cases of sui-

cidal wounds of the throat in which the air-passages were injured and appends the following summary: 1. Suicidal wounds of the throat should be treated by primary suture in all cases in which the general condition of the patient permits. 2. Antiseptic precautions are most important. 3. If necessary, chloroform should be administered, and is perfectly safe. 4. Divided muscles should be sutured, and in bringing together the edges of the skin the inversion caused by the platysma muscle should be corrected. 5. The wound in the air-passage should be completely closed. 6. In many cases it is quite safe to dispense with the use of a tracheotomy tube. If a tube be deemed necessary, it should not be introduced through the suicidal wound in the air passage, but through a fresh vertical cut at a lower level. 7. Silk is the best material for suturing the larynx or trachea. 8. During the after-treatment it is unnecessary, except in certain special cases, to feed by a tube or by the rectum. 9. If the foregoing methods of treatment be adopted, not only will a large proportion of even dangerous and extensive wounds of the air-passages recover, but the period of recovery will be greatly shortened, the patient will not be exposed to the same risks of secondary inflammatory complications, and he will be much less liable to the occurrence of permanent stenosis of the trachea or the formation of an arial fistula.

Successful Removal of Brain Tumor with Permanent Recovery.—Ziehl and Roth (*Deutsche medicinische Wochenschrift*, May 6, 1897, p. 297) have reported the case of a man, 60 years old, who, in the midst of perfect health, was suddenly seized with a peculiar rigidity of the thumb and index finger of the right hand, followed by loss of consciousness for several minutes, but without twitching or convulsion. With the return of consciousness vomiting took place. The gait was somewhat staggering, but there was no paralysis. On the following day the patient had returned to his usual health. Rather more than six weeks later the man was seized with transient tonic followed by clonic spasm of the right hand, without loss of consciousness. After another interval of about the same duration he was awakened at night by severe headache and found himself paralyzed on the right side. In the course of two weeks the palsy of the lower extremities had receded to such a degree that the man could walk, while that of the upper extremities subsided rather more slowly. From time to time, however, the right upper extremity was the seat of clonic spasm, always beginning in the thumb and index finger. At times the entire right side of the body was involved. These attacks were followed by headache, which was absent in the intervals. A small area of tenderness was detected in the right parietal region, which subsequently became edematous. No ophthalmoscopic changes were found. It was learned that the patient had had a chancre at the age of 23 years, but secondary symptoms had not been observed. Two or three years before coming under observation he had fallen and struck his head. The use of potassium iodid was unattended with relief, while mercurial inunctions were followed by amelioration of the headache following the attacks of loss of consciousness, although without effect upon the attacks themselves. Memory beginning to fail and the general condition to suffer, trephining was decided upon. Accordingly the motor area for the right thumb and index finger was exposed. The bone was found hard and dense and covered on its surface by hyperostoses and osteophytes. The dura was covered with a brownish-red mass resembling granulation tissue, a portion of which was adherent to the overlying and eroded bone. The adventitious material was removed, together with the involved bone, and the wound was tamponed and closed. Histologically the material was found to be constituted of round cells. The surgical progress of the case was uncomplicated, but the convulsive attacks recurred, and finally the condition of the patient became so aggravated that a second operation was undertaken at the site of the first, the dura being now opened and a collection of material similar to that found originally removed. This, on microscopic examination, proved to be an angio sarcoma. The operation was followed by right hemiplegia and paraphasia, and impaired sensibility in the right arm. Later, however, progressive improvement set in, with almost complete restoration of function, and this condition was still present more than two years after the second operation.

Two Cases of Brain Cyst, with Operation, and Recovery in One.—

At a recent meeting of the Boston Society for Medical Improvement two interesting cases of brain-cyst were reported, in both of which operation was undertaken, resulting in the one in recovery and being followed in the other by death. The first was reported by Cabot (*Boston Med. and Surg. Jour.*, June 5, 1897, p. 533) and occurred in a man, 23 years old, who at the age of 11 was struck on the top of the head by a heavy stick. At the age of 21 he first noticed occasional numbness at the middle of the right thigh upon its anterior aspect, associated with tickling, and recurring every three or four weeks. After rather more than a year these manifestations appeared almost daily and were soon attended with contractions of the anterior muscles of the thigh and twitching in the abdominal region. The leg became rigid and rotated back and forth involuntarily. In a short while a severe attack occurred, followed by a general convulsion and loss of consciousness. As in the other seizures, the movements in this began in the right thigh. The attack was followed by vomiting. Bromids only partially controlled the paroxysms; amyl nitrite was somewhat more successful. The attacks now began to be followed by a feeling of paralysis and numbness in the right leg and later also in the arm and face. Aphasia succeeded upon one attack. Surgical interference having been decided upon, a square opening was made in the skull over the motor area of the left hemisphere, and after an interval of five days the wound was reopened and the bulging and feebly pulsating brain exposed. The cortex presented a yellowish appearance toward the upper part of the opening. In this situation puncture was made with a trocar, and was followed by a spurt of brownish serum. A small opening was made into a cyst cavity about the size of a pullet's egg and possessing a smooth yellowish brown wall and extending deeply into the brain toward its center. On account of the size of the cyst and its probable simple non-malignant character it was decided to treat it by drainage, in the hope of thus obliterating its cavity. Several large strands of loosely woven silk were accordingly introduced and brought out through an opening in the middle of the dural and cutaneous flaps. The patient made a good recovery from the operation and was free from symptoms for two months, when the aura began to return, and soon the motor-symptom manifestations also, together with headache. Hearing and vision on the right side also became impaired. It seemed probable from the symptoms that the cyst in the brain was refilling, and, accordingly, some fifteen months after the primary operation, the wound was reopened. At once brownish serum made its escape through a yellowish area marking the site of the cyst. The walls of the cyst were now removed as thoroughly as possible and drainage was established temporarily by gauze, but later by glass. Considerable fluid escaped for ten days: the drainage-tube was kept in place for forty four days. For a time there were no further symptoms except on mental application, but subsequently even this became possible without serious discomfort. Some degree of paresis and sensory impairment persisted in the right lower extremity.

The second of the cases was reported by Elliott (*Ibidem*, p. 536) and occurred in a colored man, 59 years old, with a history of syphilis, who presented progressively increasing weakness in the right upper extremity, with convulsive movements. After exposure of the motor area of the left hemisphere and evacuation of a few drops of clear, rather viscid, brownish fluid by means of an aspirator, a knife was introduced by the side of the needle, giving exit to more fluid. Examination with a finger disclosed a cavity about the size of an English walnut, whose walls were lined with gelatinous-looking granulations. A drainage-tube was introduced into the wound and improvement followed. After nearly two months an attempt was made to obliterate the cyst by dissecting away the sloughing tissue and granulations lining its walls and packing the wound with gauze. In the course of fifteen days the sloughs had all come away and the cavity was lined with pale granulations. The patient remained under immediate observation only a short time longer, insisting upon returning to his home, where he died after an interval of three months. It is thought that the condition may have been a cystic glioma, although the surrounding brain appeared healthy.

THE

Journal of the American Medical Association

PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
 Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
 No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, JULY 10, 1897.

THE INDIVIDUAL AND PHYLOGENIC GOOD
OF PLAY.

An eminent actor, Mr. GEORGE GROSSMITH of London, narrating on the stage his impressions of the United States, remarked how seriously the average American takes his amusement, all the popular plays, music and songs being of a sad and melancholy nature. Not only must we plead guilty to this stricture of the genial and good-natured actor, coming as it does from a layman, but from the view-point of the medical man we must further admit that the physician of the present day does not need to be a profound student of the stigmata of degeneration to have noticed that the tendency to play is lacking in idiots of all classes, and that this defect is directly proportional to the degree of mental weakness. Since recent pathology has done much to throw light upon certain physiologic questions, the foregoing remarks would seem to furnish material for an obvious inference.

Besides the many homely adages of condensed wisdom bearing upon the importance of play and recreation, we know that the activity expended in the form of play is a normal and necessary manifestation that greatly concerns not only the development of the young but the preservation of the adult.

As the zoölogical scale is ascended, we find the play instinct in various animals. The ludicrous performances of spiders is more suggestive of incitation than of any other imaginable purpose, says ROMA-

NES, while DARWIN writes with fulness and particularity upon the love antics of birds; and others since his time have commented upon the play impulse in discussing the theory of natural and of sexual selection, which he says acts throughout all the higher dominion of the animal kingdom. From childhood days we recall to mind the skip and play of young lambs that our primers used to tell about, as well as the rompish sports and certain festal pleasures occurring in the hey-day of life, and making red-letter days in our career, all of which go to show the existence of an impelling force inciting to the performance of actions not the result of reflection and manifesting themselves in the form of sport, frolic, gambol, recreation, pastime or amusement.

This deep-rooted instinct observed in primitive tribes, though differing somewhat in details of manifestation, is in fact only a differentiated form of the same tendency existing in civilized communities. For instance, the group of games to which our backgammon belongs is ancient and widely spread over the world, as the ancient Mexican game of *patolli*, which appears to be of Asiatic origin. Similar instances of mimetism and the like have been observed among the Eskimo of Behring Strait and the Chuckchis of Arctic Siberia, the latter of whom play football, a fact of interest in connection with the remark of the Duke of Wellington, who said that Waterloo was won on the ball grounds of England. The Chuckchis being the only tribe of Northern Siberia that has not yielded to Russia, the existence of football among them may be looked upon as suggestive of the incitation that prompts the manly pastimes of a vigorous race.

While additional instances may be cited, it seems unnecessary to say more in order to justify the position that the play impulse, deeply implanted in the race, is one of the motor activities evolved from the central nervous system, and that many of its manifestations are not only essential parts of life, but things that have a conservational tendency and make life worth living. Military and naval statistics may also be cited to show the disappearance of certain epidemic affections after rigid discipline had been relaxed and liberty to indulge in proper sport was allowed. Moreover, the recreative effect of change by breaking up monotony in the treatment of many nervous diseases, is so well known to physicians that some of them go so far as to recommend an occasional spree for the benefit of health, and HUFELAND even says that it prolongs life. A study of the relative longevity of English and American statesmen shows the average usefulness and longevity of public men in England to exceed that of the American by ten years. Most public men in England are among the best and keenest sportsmen: but with us it is quite different. Even General GRANT could not swim and did not care

to shoot or hunt, and the same may be said of nearly all the statesmen of the National Capitol. Imagine the effect on his constituents of one of our hayseed senators in a pink coat riding to the hounds, arrayed in a bicycle suit, or frequenting the golf links with the British ambassador.

Notwithstanding these well-recognized facts of sport and play, the deep interest that should be felt in the people's amusement still awaits a champion; and a philosophic study looking to the furtherance of the great cause of innocent recreation most fit for health, is yet a virgin science badly in need of an exponent. Moreover, we find among the various instances of fanatic folly many cranks and sham-pious who denounce anything like the manifestation of play or amusement as a wicked thing, because in their prudish and evil-thinking minds there still lingers the puritanic spirit which calls anything sinful that makes people feel happy. The time has come, however, when biologists and physicians may treat this apparently trivial and hitherto neglected subject with ordinary seriousness, and place the same on record.

Without enumerating the sports that improve the body and break up the vices of the mind, it may be said that just as long as mankind is endowed with the faculty of emotional expression, so will its demonstration in various forms continue to manifest itself. As a rule people must and will divert and amuse themselves, and nobody can prevent them. But in these days of excessive drive and over-pressure, when undue waste of vital energy shows itself to the clinical observation of the physician in the way of various nervous and brain diseases, the question of averting or mitigating such mischief comes to us as a serious problem.

The obvious solution lies in the encouragement of all innocent recreations as a compensating factor in the phenomena of life. Clearly, our people do not play enough. If we want to keep up the spirit of a race in which runs the blood of Robin Hood and the old Viking kings, the palestric element must enter into its pastimes. If we would hold the trident of Neptune and have a long run on the world's political stage, "the man behind the gun," as well as the political ruler, will be none the worse for having been trained in the manly school of rude play and rompish sport.

Therefore, we should do all we can to further the great cause of innocent sport and recreation that bring together men and women during leisure hours at such places as the tennis court, the hunt, the meet, the golf links. In the light of more humanistic ideals of the present day, we do not admit the ethical cogency that such amusements are wrong because they are worldly. We should strive to meet people with a simple word or two expounding "the gospel of relax-

ation," with a view to make life better and make human actions abler when prompted by the two great motor forces of life which incite in our subliminal self the source and spring of all human actions, namely, the preservation of the individual, and the continuance of the species.

THE MEDICAL MAN AND HIS MORALS.

The question has been raised, is the profession of medicine of such a nature as to ennoble those who follow it? Would the man who comes under its influence be the same as if he had not had this experience? It is not easy to determine this matter for each individual case, but if we consider medical men in their relation to the members of other professions, and the duties and obligations society thrusts upon them, as compared with what it expects of other men, we will find that certain facts are patent to show that there is a different standard of morals for the medical profession. And this standard if followed must influence the medical man for good.

But more than this, the every-day life of a healer of the sick is of such a peculiar character that it can not but exert a power for good on those who practice it.

Let us examine these premises more carefully. Society expects the minister of divinity to be as near perfect as it is possible for him to be; it expects him to be free from petty vices, to be honest, to be dignified; it in return respects him, accords him precedence in all its assemblies and public gatherings. The "cloth" will silence levity, will gain admittance without question, will be credited without doubt. Society places such men above others in the moral scale.

In a similar way, but to a less extent, the physician has the respect of society. In continental Europe the healer of the body has as dear a place in the minds of his patients as the healer of the soul has in the minds of his flock. No one can read the strong picture of the Scotch country physician drawn by IAN MACLAREN in "Beside the Bonnie Briar Bush" without instinctively feeling that it is a true one, and that the devotion of country people was real and not unusual. A life so spent, relieving suffering must surely react strongly on the mind and make it purer, nobler and higher than it otherwise would be. Society, as we said before, demands a certain seriousness of the physician; it demands wisdom, courage and quickness of perception, but more than this, it demands soberness. The man who is jolly, who is light-hearted, who is a clown, soon finds that such a temperament is not wanted in the sick room. It serves now and then, as when it whiles away the tedious hours of a primipara's labor, but the grave face, the thoughtful look, the gentle soothing and consoling tone is the most appropriate. Hence, as a class medical men *are* serious and sober.

The medical man again must be ever ready and on

the alert; he can not give up his nights to carousing, even though his patients see him not; the morning comes and with it stern responsibilities, eyes must be clear and hands steady.

Society likewise asks that its medical men have a certain mannerliness about them; they must not be fops, or dudes, but they must be dressed in a becoming fashion, they must be cleanly in appearance and habit. Lastly, society wants the physician to be above material greed. In some countries it is improper for a medical man to sue for the collection of a bill. Fees are considered as marks of gratitude and not as a compensation for services.

Even in our own country among many of the foreigners it is customary for the patient to slide the fee into the physician's palm as if it were a present, and it would be thought very unbecoming in the physician were he to "look the gift in the mouth," or complain as to the amount.

Society does not ask the butcher or baker to supply meat or bread for nothing, or even on credit, but what reproaches it would cast upon the doctor who would refuse to visit a sick patient because he had no means or because the patient had not paid his bill. In our commercial days and in the cities the doctor is becoming more like the business man, but somehow the public will not consider him in that light, and dislikes him if he practices business methods.

The doctor is asked to give his services freely to every charity "under the sun" and to feel himself honored in being accorded the privilege of so doing. But the teacher, the lawyer and the musician are paid for their services; yes, and the chaplain too.

So much for the demands of society compelling physicians by an unwritten law to behave differently from other beings. Now as to the medical Code and its demands. Every organization of men, from that of the association of robbers to that of the church, has its peculiar code of ethics, which serves to influence every member for the good of all. These codes are oftentimes more powerful in governing the conduct of men than the law of State or the opinion of society. In no organization does the code mean as much as in medical organizations. From the time of HIPPOCRATES down to the present day fraternal feeling among medical men has been a common virtue. The oath of brotherhood is taken in all lodges, in workmen's associations, even in the society of thieves and pirates, but in medical societies it has a deeper significance. It strives here to abolish the law of competition. The ignorance and mistakes of a weaker brother, which in the natural evolution of things would destroy him, are through the Code of Ethics covered up by the stronger and abler brother. Where a word might destroy the confidence that it has taken years to gain, that word is seldom forthcoming. When the patient is impatient and endeavors to

displace his medical attendant in an abrupt manner he is usually prevented from doing so by another physician, and the Code forbids the latter to in any way throw distrust upon the work of the former.

Again, the Code establishes a fraternal feeling by making it almost obligatory for one physician to treat the members of the family of another physician. Almost obligatory we say, though never considered in the light of an obligation but rather in the nature of a duty.

The Code sets the pace and though many feel themselves not bound by its articles, all strive to live up to its spirit. It serves to take the "fight" out of the medical man, to wipe out of him all traces of the competitive brute. The law of trade is "strive to conquer others, succeed by downing others, build up on the ruins of others." The law of the medical Code is "one for all and all for one. Succeed only with others, strive to aid others." Avoid competition, avoid contention.

Remember this is not a church commandment that is only believed in by the Sunday-school boys and girls, but a living commandment that is practiced every day all over the world wherever physicians are organized.

Such men who refuse to abide by this Code and grossly abuse it speedily find themselves ostracized and the profession refuses to recognize them as reputable physicians, even though the world accounts them a comfortable living and a certain confidence. The medical Code therefore would have a tendency to make men nobler who come under its influence and to make them better. Thirdly, the daily life of the doctor, what does it mean? Does it signify anything to come in contact hourly with the ills of all classes of the community? Not only the physical ills, but all the moral ills, all the mental suffering of hundreds of families. Can any one remain unmoved by the spectacle that any ordinary physician encounters daily? The young girl of promise about to graduate, stricken with phthisis; the only child of devoted parents dead after weeks of suffering; the breadwinner sick in his room with typhoid, his little ones and patient wife wanting the necessaries of life; the debauched husband killing his feeble helpmate by obliging her to be the mother of many children, or infecting her with virus picked up in the brothel; the woman pregnant for the first time, the months of anxious preparation, the final suffering, the happiness on the faces of all when in the midst of extreme agony the child is born. Such are the daily scenes of the active family physician, and it is inconceivable to us how they can fail to affect any man no matter how morally obtuse he may be, and affect him for good. The confidences of women, of men, of young people, are his; the life of the community—the inner secret life is as open to him as the sky and yet so sacred is this trust that seldom

do his most intimate companions know these secrets from his lips. In fact, a famous physician was but recently fined a large sum of money for divulging a secret he obtained in professional confidence, although he abused this confidence in order to prevent his own daughter from being made unhappy. Entrusted more often with important secrets than either the lawyer or priest, yet so great a reliance is placed in the morality of the doctor, that he is changed as the grocer is changed, often for the slightest reasons, and without fear that these secrets because of revenge will be divulged. The physician must never complain of his own troubles, he must give strength and consolation to the suffering, but he must not look for it from his friends. And yet when one sees how others bear their troubles and how great is the load that others have to carry, our own ills seem little indeed, and we learn to *bear* them without complaint.

Thus the daily life that a physician is obliged to endure, in close contact with disease, misfortune, misery, death, poverty and vice, we believe tends to ennoble him, to purify and strengthen him, to make him forbearing and forgiving, loving and patient.

Can any one visit daily a poor little sick child with the purpose of relieving its suffering, without learning to love it? And when at last it is well and gains each day in health and the worn-out mother pours blessings over your head and hails you as a veritable savior, can any one at such a time be cruel or mean? We doubt it.

Every one who studies medicine does not remain in the profession. A great number each year leave, and we contend that a few years' practice will drive out those who are evilly inclined, either making of them quacks and ostracized charlatans, vendors of nostrums or disreputable abortionists whom no respectable community recognizes, or it sends them over into other professions and trades.

All physicians are not angels. But what we mean is that having a certain moral foundation to start with, a man must become stronger and better as he is subjected to the experiences of a medical life. It is true that the profession of medicine offers certain temptations to do wrong which other occupations do not, and sometimes the physician makes ill use of the trust imposed upon him, but this is comparatively seldom, and when one considers the power a medical man has to do wrong and how many chances are open to him to commit crime, it is a wonder so few of the profession do become convicted criminals. It is asserted in some quarters that as the struggle for existence grows more severe more of the medical fraternity will be compelled to do wrong, will in other words degenerate, will perjure themselves for expert fees, will perform abortion, play the rôle of charlatan, etc.

This remains to be seen. Strong social forces are at work to oppose the competitive spirit and the situ-

ation may change before many moons, the struggle being lessened or done away with entirely.

Some may say that the physician is no better at heart than other people, it is only the fear of the law, the fear of being ostracized by his brethren and the fear of pecuniary loss which keeps him in the beaten path, and that when he can violate the Code without being discovered he does so; that he is hypocritical and apt to pretend knowledge of things he is ignorant of and that he ascribes to his own powers effects which are in all probability the results of natural causes.

Such criticisms are to some extent true, but they fail to affect the general statement; they rather strengthen it because what is thus condemned in the physician is permitted to the merchant and tradesman. Whether men abstain from evil from fear or because they love the right, the abstinence in itself produces changes which are lasting. And physicians, because they are compelled to lead such lives, must in time become changed so that what was once compulsion becomes natural and automatic.

THE CRITERIA OF SENILITY.

It is not infrequently the duty of physicians to decide upon the disqualifications from age, but he would be a rash medical authority who would formulate a general rule as to the exact period in life when all men should give up active pursuits and be considered as unfit for the ordinary duties of business or professional life. It is true that senile changes occur in perhaps a majority of those that reach any advanced age that disqualify them to a greater or less extent, but there is no uniformity as to this and it is impossible to lay down any law that is universally applicable. MOLTKE at past the age of 70 was the organizer of the most successful great campaigns of modern times, and GLADSTONE at a still greater age is influential and active to a degree surpassing most younger men. These are prominent instances, but they are typical of many less prominent ones, and it would be hard to say that there is any essential reason why a man may not be as good for counsel and as mentally active at 70 as he is at 50. Many men are not, it is true, and it would be an excellent thing if most men could retire at that age to a well-earned leisure and ease. This is not the case, however, with very many, and there are others still whose retirement would be a public loss.

While our profession has never fixed the period when senility can be said to disable, legislative and judicial authorities have been more willing to attempt it, and it has been legally decided in at least one State of our Union that after the not very excessive age of 66 a man is entitled to at least the privileges and exemptions that old age should be allowed, no matter what may be the bodily vigor or the capacity

for mental work. It is a natural and proper thing that a certain age should exempt from active military service, though it is notorious that the fixed age of retirement of army officers seldom is willingly accepted by the individuals, who generally, and often correctly, believe themselves still capable of good service. There are other reasons, however, than their disability for this limit and it is likely to stand, especially as the government can still claim their services in emergency. There are other departments of the public service where there is no apparent age limit, and where senility, understanding by this the mental failure of old age, can be most serious in its consequences. It is a curious fact, moreover, that judges who give the decisions as to the age limit, themselves, habitually pass beyond the limit they set, while still in active life. Our supreme courts are largely made up of old men, and it seems to be one of the facts of human experience that courts that possess the highest reputation and authority are chiefly found among those that are thus composed. Some time ago there were published in a leading English periodical some criticisms of the British higher courts of justice based on the ages of the judges who, it was claimed, showed senile infirmities that ought to disqualify them for their positions. English conservatism, or perhaps we should say English common sense, has not been affected by these criticisms and the British bench still contains its octogenarians. In this country, too, we have aged judges as well as aged physicians still in active exercise of their professional functions, but it is only on the higher judicial bench that this is frequent enough to almost be the rule, and there is here a possible danger that is worth considering, even if it be but slight. A business man or a physician is, as it were, constantly on trial, but a judge is the arbiter himself and his duties are not such as would be so seriously embarrassed by a physical incapacity that would disable one in another life pursuit. He is therefore protected to some extent against the disabilities of age, while some of its infirmities may be already upon him. Are aged judges always the best court of last resort in questions where senile incompetency is involved, even when especially qualified to interpret the law on other points? This is a question that may sometimes arise, and, it is possible, injustice has been done in some instances by the unconscious prejudice of old men against what they may feel to be a reflection against themselves. This is only an example of the medico-legal suggestions that arise in the consideration of this subject.

What is wanted is, as MINOT has said, a more complete study and review of the facts of senility and its effects, and some authoritative expression of the latest and fullest acquisitions of medical science in regard to it. It is not necessary to have a fixed period when

a man can be said to be aged; some men are older mentally and otherwise at 50 or 60 than are others at 80. What we need is a better and fuller knowledge of all the general laws governing senile changes to and in the judgment of any individual case, a better body of scientific doctrine to govern the making and the application of general and special rules. This is one of the desiderata of modern medicine, and is equally needed for the guidance of courts and legislators, as well as for the better instruction of the public, who are at present inclined to exaggerate the disadvantages of age, often to the great hardship of the individual.

CORRESPONDENCE.

The Reorganization of the Public Hospitals in New York in 1895 and the Present Attitude of the Profession on the Subject.

NEW YORK, July 1, 1897.

To the Editor:—Two years ago the profession of this country was somewhat startled by the announcement that twenty-eight or more physicians who were serving gratuitously in the hospitals in the Department of Charities of New York were about to be set adrift without cause or pretext, except that the medical colleges clamored for their places. Surprise was heightened when it was made known that in spite of the protests of the veteran members here threatened with dismissal, and the repeated appeals of the local medical societies, the medical colleges defiantly proceeded to nominate physicians for places not yet vacated.

This procedure stirred the general profession into prompt and vigorous action, as it certainly seemed to involve the violation of one of the basic principles of the Code of Ethics of the AMERICAN MEDICAL ASSOCIATION.

The County Medical Association of New York—that medical organization which has remained loyal to the AMERICAN MEDICAL ASSOCIATION—immediately appointed a committee on "The Relation of Physicians to Public Hospitals," which at once cited every member connected with any teaching corporation to appear before it and explain or justify their action. At the same time a circular notice was served on them, requesting that "they take no action in the nomination of candidates for positions not yet vacated until those about to be removed have had charges preferred against them, or have had an opportunity to be heard in their own defense." But this notice was in every instance ignored, when the work of retaliation was begun; the fiercest blows being first directed against the medical school which occupied the public grounds covered by Bellevue Hospital.

Here the avenging hand of retaliation was first felt, and the city authorities were forced to serve notice on Bellevue Medical College to move off public grounds, when the faculty moved across the way and for a week or two joined forces with the University Medical School. Next this Committee appeared before the Commissioners of Charities and demanded one half of all the medical-staff appointments in the hospitals of New York for members of the profession at large, such appointments to be submitted by the medical societies. This proposition was received as acceptable and it was promised to be put into effect.

Matters finally came to a climax at the June meeting of the New York County Medical Association, when the following resolutions were presented by the Committee on Hospitals and adopted by the Association:

"1. *Be it resolved*, That after a thorough and impartial investigation by the Committee on Hospitals and Dispensaries of the New York County Medical Association, it now be declared the sense and belief of this Association that the reorganization of the medical service in the public hospitals in New York in 1895, as far as it concerned members of the medical profession, involved a violation of the Code of Ethics of the AMERICAN MEDICAL ASSOCIATION, was vicious in principle and unjust in its effects.

"2. *Be it resolved*, That this Association deprecates and condemns the present system on which the medical management of the Department of Charities is conducted and with the advent of Greater New York unconditionally pledges itself to leave nothing undone to effect its early repeal."

Immediately on the passage of these resolutions all formal charges against members, it appears, were withdrawn.

At the time of this reorganization upheaval in New York the JOURNAL took the ground that it was a humiliating spectacle to witness the wholesale removal of medical men without any adequate justification or pretense.

It is now to be hoped that the voice of the profession has been heard in unmistakable terms, and that means may be devised by which an honorable and equitable adjustment may be arranged and the profession once more united.

JUSTITIA.

A Literary Endorser.

SPRINGFIELD, ILL., June 21, 1897.

To the Editor:—Allow me to call your attention to the following facts and enlist your coöperation in assisting this gentleman in a way that it seems to me he richly deserves from our profession.

One of the most glaring frauds of this decade has been an appliance known as "Electropoise," advertised in *Harper's Monthly* and other leading publications. The sale of this appliance has been fostered by the certificate given its promoters by one W. H. DePuy, assistant editor for some time of the New York *Christian Advocate*, whose official position on one of the leading religious papers of the country added some weight to his statements.

Recently I received an advertisement of "The University of Literature," edited by W. H. DePuy, A.M., D.D., LL.D., who I find is the clerical endorser of Electropoise. I wish you would call the attention of the 125,000 medical men in this country to the facts in this case, so that they may treat the compilations of the Rev. DePuy with the scant courtesy which they deserve. I send you copies of the advertisement of the Electropoise and University of Literature herewith.

Yours very truly, GEO. N. KREIDER, M.D.

PUBLIC HEALTH.

Rates of Mortality in 1896 in Thirty-two Large Cities.—From the last registrar-general's report (London) and from other official sources the following death rates for 1896 have been compiled. The cities are listed in the order of their reported low rates of mortality: Frankfort-on-Main, 15.6; La Hague, 16.3; Stockholm, 16.8; Copenhagen, 16.8; Edinburgh, 16.9; Cincinnati, 16.9; Genoa, 17; St. Louis, 17.3; Amsterdam, 17.4; Hamburg, 17.5; Berlin, 17.9; Brussels, 18.2; London, 18.6; Rotterdam, 18.6; Nice, 18.6; Paris, 19; Rome, 19.1; Turin, 19; Philadelphia, 19.8; Dresden, 19.9; Brooklyn, 20; Glasgow, 20.4; New York, 21.4; Vienna, 22.3; Boston, 22.5; Munich, 23.2; Venice, 25; Breslau, 25.1; Buda-Pesth, 25.4; St. Petersburg, 30.9; Calcutta, 33; Bombay, 41.5; Alexandria, 42.4; Cairo, 55.2.

Inroads of the Bacilli. The report of the city bacteriologist of Syracuse, N. Y., shows that during the year 1896, 600 cases of suspected diphtheria were examined. Of these, 223 proved to be true diphtheria. In 411 cases given a secondary examination to see that the throats were free from the disease, as

shown by the culture test, fifteen days were found to be the average time of persistence of the diphtheria bacillus in the throat. The greatest number of cases occurred in October. Of the 223 cases, 102 were those of children 5 years old and younger, and only 17 persons were over 20 years of age. In 150 cases the tonsils alone were involved. In 187 cases the diphtheria bacilli were found alone and in 36 cases mixed with some form of cocci. In 26 of the 36 cases that resulted fatally, antitoxin was not used, while the remaining 10 cases were moribund when first seen. Examinations for tuberculosis numbered 223, and of these cases 113 were found to have tubercle bacilli present.

Judgment of Board of Examiners Conclusive.—Another victory for the cause of higher requirements has been won. It is in the decision of the case of Van Vleck v. Board of Dental Examiners, which the supreme court of California handed down March 29, 1897. A writ of mandamus had been granted, to compel the board to issue to the petitioner a certificate entitling him to practice dentistry. But the supreme court holds that there was no cause of action stated, and reverses the judgment granting the writ. Its decision turned on the construction to be given to the California statute, approved March 12, 1885, entitled "An act to insure the better education of practitioners of dental surgery, and to regulate the practice of dentistry in the State of California." It provides a board composed of expert practitioners, with power to examine and license those who have not graduated elsewhere, and to investigate and pass upon the reputability of schools and colleges issuing certificates or diplomas, and the right of the holders of such diplomas to their possession. The powers thus conferred, the supreme court says, are broad and comprehensive and, in some respects at least, must in their nature be final. The judgment of the board, for instance, as to the qualification of an applicant for license by examination, which is largely if not wholly discretionary, it holds, must of necessity be conclusive. And the requirement to "indorse, as satisfactory, diplomas from any reputable dental college, when satisfied of the character of such institution, upon the holder furnishing evidence satisfactory to the board of his or her right to the same," it maintains, implies quite as necessarily the exercise of judgment and discretion as in the examination of an applicant as to his fitness; and that the board's action thereunder is final, and not subject to the mandatory control of the courts. On the other hand, if the statute had required that the applicant make a prescribed showing in a particular manner, and that thereupon the board should indorse his certificate, the court says that it might with some reason be said that the act was more ministerial than judicial, and that, upon the prescribed showing being made, the board could not refuse to act. The allegations that the American College of Dental Surgery "was a reputable college, and there existed and was at the command of defendants sufficient evidence of such fact," and that the petitioner furnished "evidence satisfactory to defendants that he was the person named in said diploma," the court further holds, were not the legal equivalent of an allegation that the defendant board had so found, and hence furnished no basis for the issuance of a writ of mandamus.

Health Regulations in the Adirondacks.—*To the Editor*:—Our Board of Health recently adopted the following ordinance concerning the sale of milk and cream in this village:

AN ORDINANCE CONCERNING THE SALE OF MILK IN THE VILLAGE OF SARANAC LAKE.

SECTION 1. No milk or cream shall be received, kept, offered for sale or delivered in the Village of Saranac Lake after the 20th day of June, 1897, without a permit in writing from the Board of Health, and subject to the conditions thereof.

SEC. 2. Every person applying for a permit to receive, keep, offer for sale, or delivery of milk or cream, must register his or her name and residence in a book kept for that purpose in

the office of the Board of Health, file a certificate with said Board from a qualified veterinary surgeon, or such other person as the Board of Health may designate, certifying that he has inspected all of the milch cattle of the applicant from which such milk has been drawn: that they have been found sound and healthy, and that the dairy and other appurtenances necessary to the business are kept in a cleanly and proper manner. Any failure to comply with and maintain the conditions herein set forth shall be a sufficient ground for the immediate cancellation of such permit.

SEC. 3. Any person violating any of the provisions of this ordinance shall suffer and pay a penalty of \$25 for each and every offense.

Adopted April 10, and amended May 15, 1897.

E. S. McCLELLAN, M.D.,
W. F. ROBERTS,
H. L. LOBDELL, } Board of Health.

Attest:

F. P. CALKINS, Secretary.

In view of the requirements of this ordinance, the dairymen supplying the village with milk, through the assistance of the Board of Health, procured the services of Dr. Cooper Curtis, a veterinary surgeon of national reputation, to inspect and test their cattle. A physical examination was made and the tuberculin test applied to the cattle of all the herds, aggregating 220 head. Every animal was found free from tuberculosis and otherwise in a sound and healthy condition. This remarkable immunity from tuberculosis is perhaps in some measure due to the hardy character of our native cattle, as rarely any importations from foreign herds occur. Scattered throughout this section there are always a considerable number of consumptives, many of whom ramble over the pasture fields and expectorate on the grass, and some fears were entertained by the laity lest the cattle might be infected by swallowing infected sputum; but experience seems to demonstrate that tubercle bacilli do not germinate in the vigorous stomachs of our native cattle. Very truly yours,

E. S. McCLELLAN, M.D.

Saranac Lake, N. Y., July 5, 1897.

Liability of City for Health Officer Burning Property. The evidence in *City of Dallas v. Allen* showed that the city authorized its health officer, during an epidemic of smallpox in that city, to burn property which in his judgment was infected with the disease, when in his judgment it was necessary to do so to prevent its spread. In the execution of this authority he caused a house to be burned with its contents. This suit by the owner of certain of the contents, against the city, the health officer and the sureties on his official bond followed. The district court directed the jury to find against the city and in favor of the other defendants. April 14, 1897, the court of civil appeals reversed that judgment and remanded the cause. It says that the chief question was as to the right of the city to destroy property in the exercise of the power conferred on it by its charter, to all acts and make all regulations which may be necessary for the promotion of health or the suppression of disease. It thinks that the governing rule is found in a decision of the supreme court of Texas relative to the destruction of a house by the fire department, where it held that property can be so disposed of without the city or its agents becoming liable; that such a taking does not violate the constitutional pledge that private property shall not be taken, damaged or destroyed for or applied to public without adequate compensation being made, unless by consent of the owner. But the court of civil appeals thinks that a necessity for the demolition of the building for the purpose of checking the progress of the fire would have to be shown by the city, and the destruction of a house in an isolated place that could constitute no agency in communicating the threatened danger, would not be justified. And it holds that to the same extent that a city can destroy the property of a citizen in checking a fire it can do it in stamping out an epidemic, with exemption from liability. There being in this case evidence both to the effect

that the articles in question could and could not have been rendered innocuous by a simple process of disinfection, the issue of fact thus raised, it holds, should have been left to the jury to decide. Furthermore, the city having directed or authorized the destruction of the property, if it was wrongfully destroyed, the court holds that the city could not escape liability.

ASSOCIATION NEWS.

Amendment to Constitution.—The following amendment to Article IV of the Constitution and By-Laws was offered by Dr. Wm. LeMoyné Wills, of Los Angeles, Cal., in the general session on Friday, June 4, 1897, but was received too late to be incorporated with the printed minutes of the general sessions:

ART. 4. Officers. The officers of this ASSOCIATION shall be a president, four vice-presidents, one secretary, one assistant secretary, a treasurer and librarian. They shall be nominated by a special committee of one member from each State represented at the meeting and shall be elected by vote on a general ticket. Each officer shall hold his appointment for one year and until another is elected to succeed him.

Resolutions Against the Antivivisection Bill.—The Permanent Secretary has sent the following circular to the Senators and Members of the House of Representatives:

PHILADELPHIA, PA., June 29, 1897.

HON. —, U. S. Senate, Washington, D. C.

Dear Sir:—The following resolution was unanimously adopted at the annual meeting of the AMERICAN MEDICAL ASSOCIATION in Philadelphia, June 2, 1897:

WHEREAS, Senate Bill 1063 (formerly Senate Bill 1552) has been reported favorably to the United States Senate; and

WHEREAS, We believe that its passage would seriously interfere with the progress of practical medicine, and therefore be a public calamity; therefore, be it

Resolved, That the AMERICAN MEDICAL ASSOCIATION, with a full knowledge of the contents of Senate Bill 1063, most earnestly protests against its enactment.

The day following the adoption of the above resolution, the ASSOCIATION, in general session, after listening to the address on surgery by W. W. Keen, M.D., directed, with the greatest unanimity and enthusiasm, that the following extract from his address be added to the above resolution, to be forwarded to the Senate, and later directed that a copy of the entire address should be forwarded to each member of the Senate and House of Representatives:

Animal experimentation has had also a very large share in the development of modern surgery. The whole question of the introduction of animal ligatures was begun in America by Physick, who used buckskin, and his follower Dorsey, who used kid and cut both ends short, Hartshorne, who used parchment, and Bellenger and Eve the tendon of the deer, and has been solved principally by experiment upon animals in order to determine accurately the behavior of such ligatures in the tissues. Only professional readers can appreciate what a boon to humanity this single achievement has been. Modern cerebral surgery also owes its exactness and success almost wholly to cerebral localization and antiseptic, both of which were first studied upon animals and later by the application of the knowledge so gained to man. Bacteriology would not now exist as a science, nor would accurate modern surgery and a large part of modern medicine be possible, had experiments upon animals been prohibited, as some zoophilous women who love dogs better than men and women, and even little children, desire.

The foregoing resolutions of the AMERICAN MEDICAL ASSOCIATION were adopted by unanimous vote at its annual meeting, when the registration of delegates present was almost two thousand. The total membership of the ASSOCIATION is over eight thousand, from every State and Territory of the United States (except Wyoming) representing over one thousand State and county medical societies.

Commending these resolutions to your favorable consideration and enclosing a reprint of the bill in question, I remain,

Very respectfully, (Signed) WM. B. ATKINSON, M.D.,

Permanent Secretary.

SOCIETY NEWS.

The International Medical Congress.—A letter received from the Secretary-General of the twelfth International Medical Congress conveys the following information which is additional to that which has been published in the medical journals. As it is too late to send tickets to the American congressists, they are requested to send to the Secretary-General at Moscow their addresses in London or Berlin, or Vienna, or Paris, or to avail themselves of the National Committees in those cities. in order to receive their tickets and free passes over Russian railroads in those places. The free passes are valid from July 13 to September 13 over the following routes: Eydtkunen to Moscow, back: Moscow to St. Petersburg, or Moscow to Graniza, or Moscow to Odessa or vice versa: Graniza, Warsaw, Moscow and return by Moscow, St. Petersburg (or Odessa, or Eydtkunen, or Ungheui, or Alendrowo) or vice versa. Different lines going and returning may be chosen, and stop over is permitted. Eydtkunen to St. Petersburg is excluded from the free list. A. JACOBI, Chair. Amer. Nat'l. Com.

NECROLOGY.

BENJAMIN H. THROOP, M.D., of Scranton, Pa., who died June 26, was a man of mark and influence not only in Scranton, but throughout Pennsylvania, and the long biographies of him in his home newspapers contain some interesting facts. Though he was the first settler and the first house-builder in Scranton, he was born in Oxford, Chenango County, N. Y., November 9, 1811. His family came there in 1800. They were of the Puritan revolutionary stock, both his father and grandfather having belonged to the Fourth Connecticut Volunteers under Washington. Dr. Throop studied medicine in Fairfield Medical College, Western New York, graduating in 1832. He first settled in Honesdale, Pa. After short but successful periods of practice there and in Oswego, N. Y., he settled in the town of Providence, in the Lackawanna Valley of Pennsylvania, in 1840, but in 1847 moved to what is now the town of Scranton. He procured the completion of the Delaware, Lackawanna and Western Railroad and the extension of the Delaware and Hudson Railroad to Scranton. He obtained the first charters for gas and water, and for a hospital in the town. He laid out the suburbs now known as Hyde Park, Providence, Dunmore, Priceburg and the town of Throop. He secured the creation of the Luzerne County out of Lackawanna County. He was the first postmaster at Scranton, founder of the Lackawanna Hospital, trustee of the Danville Insane Asylum, president of the Illuminating Heat and Power Company and the chief medical adviser for many years of the railroad companies running into the city, which now numbers over one hundred and twenty thousand people. He was the first surgeon from his county in the war for the Union, taking charge of the Eighth Regiment of Pennsylvania Volunteers, and afterward of the One Hundred and Thirty-second Regiment of that State, and he established a system of Hospitals at Chambersburg and at Harper's Ferry, as well as a system of medical relief in the field, which became general throughout the Northern armies. There were no public interests in which he did not take an active part, and, while he retired from the practice of his profession many years ago, his energy in affairs was unabated to the end. About three years ago he celebrated his golden wedding.

WILLIAM C. WEY, M.D., Albany, 1849, for many years Health Officer of Elmira, N. Y., died of apoplexy June 30. He was President in 1871 of the New York State Medical Society and was also President of the Board of Managers of the New York State Reformatory.

JOHN FREELINGHUYSEN TALMAGE, M.D., New York University 1859, of Brooklyn, N. Y., died in Rye, N. Y., June 30, while on a visit to his daughter, the wife of Congressman J. Murray Mitchell. He was 61 years old.

JAMES CAVANAUGH, M.D., Easton, Pa., June 28, aged 67 years.—John Norwood, M.D., Columbus, Ga., June 28, aged 60 years.—Albert S. Rogers, M.D., Pavilion, N. Y., June 30.

MISCELLANY.

A Deserved Compliment.—Prof. Virchow is to be elected a Foreign Associate of the French Academy of Sciences.

Decrease of the Birthrate at Home.—A recent table makes the birth-rate of the United States in 1890 only 26.68 per thousand whereas in 1880 it was 30.95.

Plague Commissioner Rand not Dead.—So far the reports from Bombay of June 24, indicate that Commissioner Rand, wounded by a native while leaving the Governor's reception, was still living although in a precarious condition.

Etiology of Yellow Fever.—At the request of Dr. Freire the Government of Brazil has appointed a committee of seven prominent physicians to investigate his claims in regard to the micrococcus xanthogenicus.

Duty in Selecting Surgeons.—The supreme court of Iowa holds, in the case of Maine v. Chicago, Burlington & Quincy Railroad Company, April 8, 1897, that it was the duty of the company, under its contract with the relief department which it organized whereby it was required to furnish an injured employe surgical aid and attention, to exercise due care and diligence to select surgeons who were reasonably competent to treat him, and, if it did so, it was not liable for the negligence of the surgeons in treating and caring for his injuries. An allegation that a surgeon "either lacked the requisite skill or failed to exercise the same," the court says, does not show that he was in fact unskilful, nor that the railroad company was negligent in employing him.

Discharge from Insane Asylum after Escape.—The California statute concerning the management of the insane asylum at Napa provides that the resident physician shall be the executive officer of the institution, and shall discharge such patients as, "in his opinion, have permanently recovered their reason." Under this provision, where the physician had come to the conclusion that a patient was restored to reason, and had intended to order his discharge if his condition did not change in a few days, the supreme court of that State holds, in *people v. Geiger*, April 7, 1897, that the fact that the patient had in the meantime escaped, and was not present when his discharge as "recovered" was entered of record by the physician, was no ground for impeaching the physician's act.

The Sensational "Affaire" Thomson at Paris, mentioned in these columns at the time, resulted in the condemnation to five years imprisonment of the two physicians involved. Whether legally liable or not, Dr. B. was certainly indiscreet in curing the uterus of a woman without ascertaining whether she was pregnant or not, and with such a lack of skill as to extract loops of the intestines through the cervix, not to mention the impropriety of performing such an operation (for which there was not the slightest excuse of urgency) on his dining table, with the assistance of his cook and coachman. He was on the staff of the *Revue Medicale*, and this magazine denounces Brouardel's expert testimony in the bitterest terms. Nothing seems to have been proved against Lajarrige except that he had directed Miss Thomson to Boisieux.

Not Hospital "Treatment."—One of the questions in an application for life insurance is as to whether the applicant had ever been under treatment in any hospital, asylum or other institution. This was answered, "No," in the case of *Chinery v. United States Industrial Insurance Company*. But there was evidence that some twenty-five years previously something had blown into the applicant's eye, that she went to a hospital, by appointment, to have it removed, and returned the same evening. This, the appellate division of the supreme court of New York holds, April 6, 1897, was not being "under treatment in any hospital" within the meaning of the policy. It adds that it had nothing to do with the general health of

the assured, and if it had been known to the company, could not possibly have been considered by it as a reason for refusing to issue a policy of insurance.

H. D. Didama, M.D.—A dinner was given in honor of Henry D. Didama, M.D., on the occasion of his fiftieth anniversary as a practitioner of medicine, by the faculty and the Alumni Association of the College of Medicine, Syracuse (N.Y.) University, on Wednesday evening, June 9. Dr. Nathan Jacobson acted as toastmaster. Eulogistic speeches were made by Dr. E. D. Ferguson, Dr. A. Vanderveer, Dr. Matthew D. Mann, Dr. Wm. S. Ely, Dr. Robert L. Morgan, Dr. Brace W. Loomis, Dr. Henry O. Marcy, Dr. John Van Duyn. Speeches were made by Chancellor James R. Day, Dean James B. Brooks, Rev. George B. Spalding, Hon. Frank Hiscock, Hon. Carroll E. Smith. The occasion was one long to be remembered by Syracuseans, and Dr. Didama's colleagues in the ASSOCIATION throughout the country join in congratulations.

Domestic Remedies in the Retrospect.—The *N. Y. Evening Post* of July 3 in a running summary of "The American Frugal Housewife" printed in 1835, refers to several expedients for home treatment. The usual precaution "before sending for the doctor" appears to have been omitted. To prevent lock-jaw, lye, a rind of pork, strong soft soap, spirits of turpentine, and pulverized chalk are recommended; for throat distemper, the old name for diphtheria, a poultice of roasted apple mixed with an ounce of tobacco, the whole wet with spirits of wine and spread on a linen rag to be bound about the throat, is a panacea; to stop the blood from a wound apply scrapings of sole leather: a spoonful of ashes stirred in cider is suggested to relieve nausea in cholera morbus. A salve to reduce inflammation in wounds is made from lard melted and cooled five times in succession, then simmered with sliced onions, and once more cooled: low-blackberry tea is prescribed for calomel sore mouth.

Colleges.

THE annual commencement of the Yale Medical School was held June 30. About thirty new doctors received degrees.—Merced University has conferred the degree of LL.D. on W. A. Adams, M.D., Chief Surgeon of the Fort Worth (Texas) and Denver City Railway Company.—The Maine Medical School, Bowdoin College, at Brunswick on June 23, presented thirty-four diplomas.

Societies.

THE ninth June meeting of the Dubuque (Iowa) Medical Society was held June 30. The Eastern Iowa District Medical Society met at Washington, Iowa, June 24. The new officers chosen are Dr. W. B. La Force of Ottumwa, president; Dr. Grimes of Wapello, vice-president; Dr. M. C. Carpenter of Fairfield, secretary and treasurer.

Hospitals.

A NEW free hospital was opened by the Christian Hospital Association, Los Angeles, Cal., July 1.—The Salem (Mass.) Hospital is the recipient of \$10,000 for the establishment of a home for convalescents, a memorial to William G. Webb, who at the time of his death (May 17, 1896) was president of the hospital corporation.—An annex to St. Vincent's Hospital, New York City, has been opened at Far Rockaway, about three minutes' walk from the station. Ocean breezes, ample rooms, well shaded grounds and trained nurses are mentioned as the attractions.—The Ladies' Deborah Nursery and Child's Protectory, New York city, has passed into the hands of a permanent receiver.

THE proposed new hospital of Harlem, New York city, is likely to meet with much opposition by the owners of the site. It was to have been located on the east side of Lenox Avenue between 135th and 136th Streets, but the Equitable Life Insurance Society demur because the necessary condemnation proceedings will give them only the mark price instead of the prospective value. The old Harlem Hospital has outgrown its capacity and a new institution in the upper section of the city

proper is an absolute necessity. The Commissioners of Charities, who have taken in consultation the proper medical authorities, have authorized an expenditure of \$300,000 upon the building alone and the cost of the land as calculated should not have been more than \$200,000 at the extreme limit.

Washington.

THE CHINESE APOTHECARY.—A local Chinaman has made application for a license to sell medicine to his countrymen in the District.

MANDAMUS FOR THE BOARD OF MEDICAL SUPERVISORS.—The Board of Medical Supervisors for the District, in the opinion of Dr. Alderman, have been too slow in issuing a license for him to practice medicine and surgery in the District, therefore he applied to the courts to secure his rights, as he understands them. Judge Bradley issued a pre-emptory writ of mandamus, requiring the Board of Examiners to show cause, etc.

HOSPITAL FOR THE INSANE.—President McKinley has appointed Ex Surgeons General Francis M. Gunnell of the navy and John Moore of the army as members of the Board of Visitors to the Government Hospital (St. Elizabeth's) for the Insane.

THE CONTAGIOUS HOSPITAL SITE.—The Commissioners of the District have reported adversely the recommendation of Senator McMillan to locate the contagious hospital, recently appropriated for, in the grounds of the Washington Asylum. They base their adverse report on the bad hygienic conditions adjacent to the Asylum grounds. The eastern branch of the river, which passes directly back of it, is a cesspool and hotbed for disease breeding, it being practically an open sewer, receiving the sewage from a large portion of the District, where it is subsequently washed over the flats. This pestilential condition has more than once been reported by the surgeons in charge of the U. S. Naval Hospital and Marine Barracks and the surgeons in charge of the Government Asylum for the Insane, as being directly causative of a great deal of otherwise preventable disease in these institutions. The Medical Society and the Washington Board of Trade, through their health committees, have frequently pointed out the dangers of this locality. It is probable that the contagious diseases will eventually be treated in isolated buildings, to be erected in the grounds of two of the general public hospitals of the District.

Cincinnati.

DR. GILBERT I. CULLEN is announced as associate editor of the *Medical Fortnightly* of St. Louis.

DR. O. V. LIMERICK, who was jointly indicted with ex-Health Officer Dr. J. W. Prendergast on the charge of attempted blackmail of the Fraser Tablet Co., has been granted a new trial by the circuit court.

DR. ROBERT SUTTLER has placed an order with Mundheuk, the sculptor, for a bust of the late Dr. E. Williams, who was the founder of the Ophthalmic Institute of Cincinnati.

THE TUBERCULOUS PATIENTS and convalescing children of the Cincinnati Hospital have been removed to the branch hospital, which is located twelve miles from the city and in every way adapted for the care and treatment of these patients.

THE ANNUAL MEETING of the City Hospital medical staff resulted in the election of Dr. N. P. Dandridge president and Dr. J. C. Oliver secretary.

DR. JOHN K. WOODS of Van Wert, Ohio, has been appointed chiefurgeon of the Ohio division of the Jackson and Mackinaw Railway.

THE HEALTH DEPARTMENT has issued an order to the effect that hereafter all cattle added to the dairies supplying milk to the city must be tested with tuberculin, and those found diseased will be condemned.

AT THE MEETING of the Academy of Medicine last week, Dr. James T. Whittaker read a paper entitled "Six Years with Tuberculin." He claimed that this remedy had proven to be the most valuable diagnostic agent and single remedy we have. The period of childhood was given as being the time of most frequent infection, and that of puberty of most frequent manifestations. Children who suffer with frequent or more or less continuous malaise, who feel more than others the confinement of the school room, who are said to be predisposed to phthisis, should be tested for some depot of tuberculosis. Children who live in an atmosphere of infection are almost necessarily subjects. Among the earliest signs mentioned usually are a peculiar odor of the breath, a red line on the gums, clubbed fingers, and local signs, as affection of the

bones, joints, skin, testes, Fallopian tubes, adenitis. Scrofula is external tuberculosis. There is a pre-tubercular albuminuria, which is recognized by delicate tests, as by that of Spiegler. Cardiac palpitation and early dyspnea belong to the same toxemia. This albuminuria is not a nephritis, but is a toxic alteration of the albumin whereby it becomes more dialyzable. The Diazo reaction is less common and less reliable. The search for the bacillus in the blood in hectic fever and the other blood tests are really quite superfluous. Cough is most suspicious when it occurs in the morning and evening. Local depots excite no cough and there is no cough in acute miliary tuberculosis. The great contribution of modern times came with the discovery of the tubercle bacillus in the sputum. The use of the centrifuge, after fluidification of the sputum with soda or potash, shortens the examination and increases the value of the test. The pseudo-bacillus, the bacillus of leprosy, of syphilis, and of anemia were next differentiated. The discovery of elastic tissues was passed by because by this time there are physical signs. The importance of hemoptysis was remarked. It is not too sweeping an assertion to say that hemoptysis in perfect health means tuberculosis. Next followed the demonstration by inoculation of the guinea pig, which is certain but too slow to be of diagnostic value. In this way the clear effusions of pleurisy are determined to be tubercular in nearly three-fourths of the cases. The value of tuberculin in the diagnosis of the disease in cattle is universally accepted. According to the report of Salmon, thus far we have yet to meet the first case which reacted and did not show tuberculosis upon postmortem examination. The value of tuberculin was slow of recognition in man because of various objections, one, that reaction may set in in the absence of tuberculosis. These cases are now explained by the existence of concealed latent depots. The objection of Klemperer to the effect that reaction will occur with every deposit, even in latent cases, is really only confirmation of the value of the test. The most serious objection, that of Virchow, that tuberculin awakens tuberculosis from latent sources and disseminates the disease, an objection which was caught up and echoed on all sides, has been found to rest on erroneous premises. All the individuals who have had the most to do with the use of the remedy disclaim any danger of this kind. Thus Peuzoldt, Wassermann, Prior, Springthorp and Klein all speak of the absolute safety of the remedy in proper use. The speaker had himself used tuberculin every day in hospital and private practice for six years, in now nearly one thousand cases, and had never seen any kind of evil result. Most of his use of the agent had been, of course, in the small therapeutic dose. But in the larger quantity necessary to secure the test reaction he had come to consider it the best possible and a perfectly safe means of diagnosis. Koch declared that his own individual experience in the early diagnosis of tuberculosis in man in more than one thousand cases shows its perfect safety and puts the diagnostic value of tuberculin in recognition of the disease in man on the same plane as in animals. The action of the remedy is ill understood, notwithstanding all the work that has been expended upon it. Introduced under the skin, it produces a general leucocytosis and fever, but tolerance is soon begotten to the use of the agent, so that individuals who react to a few milligrammes become finally insensitive to one hundred times this quantity. The knowledge of the existence of this tolerance to a poison was known in antiquity, and the principle is utilized in increasing the antitoxic properties of blood serum. The old tuberculin neutralized only the toxins of the tubercle bacillus, but in this method superficial processes are detached and discharged while reabsorption takes place in the interior of organs. Unfortunately, the effect is in no case final, because of the fact that the remedy has immunizing properties only against the toxins. With the new tuberculin there is higher promise because it immunizes against the tubercle bacilli themselves. "I have used the new tuberculin for about six weeks in twenty selected cases. The time is too soon to say anything more than that the dose is well borne by these patients, the signs of improvement are more continuous and the patients, most of them individuals under treatment with the old tuberculin, are better suited with the new."

THE PUBLIC SERVICES.

NOTICE.—An Army Medical Board will be in session at Washington City, D. C., during October, 1897, for the examination of candidates for appointment to the Medical Corps of the United States Army, to fill existing vacancies.

Persons desiring to present themselves for examination by the Board will make application to the Secretary of War, before September 1, 1897, for the necessary invitation, giving the date and place of birth, the place and State of permanent residence, the fact of American citizenship, the name of the medical college from which they were gradu-

ated, and a record of service in hospital, if any, from the authorities thereof. The application should be accompanied by certificates based on personal acquaintance, from at least two reputable persons, as to his citizenship, character and habits. The candidate must be between 22 and 29 years of age, and a graduate from a Regular Medical College, as evidence of which, his Diploma must be submitted to the Board.

Successful candidates at the coming examination will be given a course of instruction at the next session of the Army Medical School, beginning November 1, 1897.

Further information regarding the examinations may be obtained by addressing the Surgeon-General, U. S. Army, Washington, D. C.

GEORGE M. STERNBERG,
Surgeon-General, U. S. Army.

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from June 5 to 11, 1897.

Capt. Robert R. Ball, Asst. Surgeon, leave of absence granted is extended two months.

Capt. Charles M. Gandy, Asst. Surgeon, now on duty at Washington Bks., D. C., will report in person, on July 1, 1897, to the governor of the Soldiers' Home near Washington, D. C., for temporary duty during the absence on leave of Col. William H. Forwood, Asst. Surgeon-General, and upon the return of that officer will rejoin his proper station.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the two weeks ending July 3, 1897.

P. A. Surgeon G. B. Wilson, detached from the "Yantic," ordered home and granted two months' leave.

Asst. Surgeon J. F. Leys, detached from the "Vermont" July 6 and ordered to the "Helena" July 7.

Asst. Surgeon C. E. Riggs, ordered to the "Vermont" July 6.

PAMPHLETS RECEIVED.

Columbian University Announcement for 1897-1898, Washington, D. C. Experiment with the Serum Reaction as a Test for Typhoid Infection in Water. By Wyatt Johnston, M.D. Reprint from the New York Medical Journal for June 5, 1897.

Howard University Medical Department Announcement for 1897-1898, Washington, D. C.

Ichthyol as a Therapeutic Agent in the Treatment of Diseases of the Uterine Annexa. By Robert Bell, M.D. Reprinted from the Edinburgh Medical Journal for April, 1896.

ORIGINAL ARTICLES.

SERO-DIAGNOSIS IN TYPHOID FEVER.

Presented in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association held at Philadelphia, Pa., June 1-4, 1897.

BY WYATT JOHNSTON, M.D.

MONTREAL, QUE.

By his admirable summary, covering so thoroughly the general subject, Professor Welch has made much simpler the work of those who are to speak upon special divisions of the subject. In speaking of practical results I shall confine myself chiefly to my personal experience because it is with regard to that that I can speak most positively and which I feel most certain about. But I think where the results of one observer differ from those of another in this test one should be very careful in comparing the two, because very slight differences in technique, or interpretation of the phenomena observed will give a very different percentage in results.

My own experience consists so far in the examinations of somewhat over 600 bloods, of which more than half were from cases of typhoid fever. In these examinations and in my work I have been assisted very much by Dr. MacTaggart, of Montreal, resident pathologist of the General Hospital. Before covering the ground which Professor Welch has indicated as being a suitable field for discussion I might point out one or two directions in which the study of this reaction may be profitable aside from the question of the diagnosis of typhoid fever. There are other diseases which will give the reaction, cholera for instance, and, it is said, Malta fever and the bubonic plague. But both of these are rare diseases with which we have little to do. It seems to me that some other common diseases may give a diagnosis in this manner. With reference to typhoid, other applications of the test, such as the identification of doubtful cultures isolated from suspected water or suspected stools, might receive more study than they have. It would be foreign to the discussion to go into this subject, but some of the results of the preliminary studies which I have made in this direction have been extremely interesting, and very encouraging as showing a possible future for applying the test for the identification of the typhoid bacilli in suspected water, etc. We tried to utilize the clumping as a means of isolating the typhoid bacilli from mixed liquid cultures, and when one acts with media artificially infected with typhoid and colon bacilli the results are quite striking. One can produce clumping in the mixed bouillon of typhoid bacilli and colon bacilli, and one can filter this very much clumped culture through a filter of sand so that the typhoid will remain in the sand while the colon runs through the sediment. This can be seen very nicely by using this differential test on the sand and filter. The typhoid very largely

remains in the sand, and the filtrate consists largely of colon bacilli. I have endeavored to apply this more in routine laboratory work, but have not yet succeeded in getting a definite practical method for routine use. This isolation might be of more value if combined with some other method.

Another experiment was to inoculate with a culture, and test for typhoid in the animals after about one week. In some cases I was able to obtain the reaction where the quantity of the typhoid material originally introduced was very small, represented by one part of bouillon culture to four millions of water, containing eleven thousand bacteria to the cubic centimeter. These experiments, however, I do not think are by any means as severe a test as one would find in natural unintentional infection of water, for where you artificially put in typhoid it is relatively easy to get at it again. I mention this simply as a field of possible utility.

With reference to the application of the method to the diagnosis of disease by using pure cultures, the field of application seems to have been transformed by advanced steps. Prior to Widal's discovery the impression was general, and I shared it, that this was an exceedingly complicated subject and very difficult to take up. The methods of Pfeiffer certainly did not sound easy. Widal, I think, has introduced marvelous clearness into the method. The whole thing became clear and comprehensible to the ordinary mortal, and has been largely carried out since. It was thought to be a bedside or clinical reaction, but subsequent events have shown that while it may answer well as a clinical test, perhaps the best results can be obtained in laboratories, and sending of material taken for diagnostic purposes to the laboratories to be examined there, is the best procedure.

With reference to the general application of the method, my own small share in the matter has been in the direction of trying to apply the principle of what I may call wholesale-public-health diagnosis, as introduced by Professor Biggs and Dr. Park. The object was to reduce to the minimum the trouble of the technique which one would expect of a person who had charge of a case, and transfer that, as much as possible, to the laboratory: so I made use of the fact which Widal had established, that drying of the blood did not interfere with the reaction, and applied it to the use of dried blood for the test. Whether this is the simplest way for transmitting material for examination depends largely upon the conditions of the case. As bacteriologist of the Province of Quebec, which comprises about two-hundred square miles, much of it sparsely settled, I think the method has distinct advantages. We have seen cases from Murray Bay, where the doctors are prompt in sending cultures. They send them on paper. We find that a great assistance in our work. I do not say that it is the method which should be used in hospital practice or

city practice where the facilities for transmission are greater. It is a very simple thing to send the dried blood by post, and in our work we use the postal facilities very largely. So that, as to the method to be employed, I think Professor Welch has stated the matter extremely well, that it should be as simple as possible, but we must have an accurate technique. The attention to the technique has been, I think, very largely in the direction of quantitative estimation. The dried blood method at first did not seem to offer a promising field for quantitative estimation, and I remember feeling rather discouraged because other people were getting quantitative results and I could not. However, by the use of the hemometer, testing the hemoglobin by the ordinary coloring method in the solution of dried blood, one would get results corresponding very closely to what he would get in a control drop of blood which was not allowed to dry. Of course the longer the drying was continued the less accurate the results were. But I found that by this dilution I was not able to diagnosticate cases which I could diagnosticate without the accurate estimation of the dilution. A little practice will enable one to get a distinct reaction with a high degree of dilution. I do not say that it gives as good scientific results, but after using both methods I found that I could get just as good results without the dilution as with high dilution. But instead of the dilution, we used a special kind of culture, and I found there was a difference in this respect between serum and a solution of the entire blood. I think that is a point of some importance, so that what I say of blood solution may not hold true of serum. Blood solution appears to be more liable to give clumping, a false clumping, than serum. This is especially the case with typhoid cultures where the movement is very active, and for this reason in using dried blood it is better to get cultures where the motility is gentle. There is not much motility where we use old cultures. We found that out by accident. At first we used old cultures and got good results. It was only when we changed cultures that we got bad results, and on returning to the old method we found out what was the cause of success.

The question of the alkalinity of the culture is, I think, one of considerable importance, and one to which little reference has been made. The alkalinity has a marked effect on the clumping. A slightly acid medium may give no clumping, but by rendering it slightly alkaline clumping will again take place. The bouillon in which the culture is made seems to exercise some influence. Recently we found an excessive amount of spontaneous clumping taking place in our cultures and we were able to trace it apparently to the fact that the laboratory bouillon was made more alkaline than formerly; it was strongly alkaline instead of slightly alkaline. A culture which gives a very heavy growth, which does not work well with a bouillon of twenty-four hours, does not work well with the dried blood method, although it may with the serum. And if there is any deposit with the dried blood method in twenty-four hours, it does not work well so that one can tell, if he is using the culture every day, whether it is in good condition or not. It is important to get the bouillon in a proper state of alkalinity, and my object has been to get cultures into such condition that with this method they will not react to other bloods and will act decidedly to typhoid bloods. Although no positively accurate method may be

obtained, yet one may get a method which is qualitative and reliable for the greater percentage of cases.

With reference to quantitative estimation, I think the variations produced by the condition of the culture and the alkalinity of the medium may have an influence in determining the quantitative result. There must be a fixed basis for the quantitative result and if this is going to react differently with different cultures there will be a shifting base.

With reference to the *B. coli* reaction, referred to by Dr. Welch, I find that also of considerable use in diagnosis in doubtful cases, where there are symptoms like typhoid but no reaction, or where there was a doubtful reaction blood. Such bloods I found generally to give a very decided reaction with the colon bacillus. This I interpreted to be due to *B. coli* inflammation, and it seems likely the colon bacillus in these cases is capable of producing a distinct infection which will give rise to symptoms very much like typhoid.

Definition of the reaction perhaps deserves more attention than it has received. What one man would call a reaction perhaps another man would say was not quite complete, so that uniformity of terms would be desirable. I believe that the coincident occurrence of the gradual cessation of motion and clumping is the characteristic feature; but if motion goes on and the clumping is not ultimately typical, that looks very much like pseudo-reaction. If there is clumping with incomplete loss of motion, it is perhaps to be regarded with suspicion; and I think in doubtful cases should not be considered so seriously as to upset the whole theory, borne out by such an enormous number of cases, as to the specific value of the reaction. Perhaps the selection of cases is something which deserves consideration, for one's results depend very largely upon whether he takes typical cases or doubtful cases; and I think a corroborative examination by means of bacteriologic tests in doubtful cases would give valuable additional evidence. Personally, I have never yet got a typical reaction in a case in which there was not strong ground for believing it was typhoid fever. I have had one case of typhoid fever in which the reaction was absent as far as I could make out, both by the dried blood method and the serum method, but that case was seen only in the later stage. It ended in recovery. Therefore we are not certain as to the nature of the disease. But possibly the reaction may be absent. It is not infrequently delayed into the late stage so that repeated examinations are necessary, and one can utilize for statistics only cases in which there have been abundant chances for observation and re-examination. I think these questions will be decided by the clinicians, not by the laboratory men, because so much depends upon the diagnosis of the case being accurately made.

DISCUSSION.

Dr. N. S. DAVIS, JR., Chicago—This question of serum test has been one of great interest to me the last year, and fortunately soon after Widal's paper first became generally known I succeeded in interesting our resident physician, Dr. Miller, in making the examination in all typhoid fever cases which entered the hospital the last winter. He has carefully carried out the various methods, and the conclusions he has reached correspond very closely with those given by Dr. Cabot in his general summary. For example, he found in about 90 per cent. of the cases of genuine typhoid fever a positive reaction; in 6 per cent., of the cases he has found a partial reaction, not a perfectly positive one; in 3 per cent. there was no reaction whatever.

I remember one case under my observation a few weeks in which the febrile symptoms were so mild that we would scarcely

have regarded it as a case of typhoid fever. There occurred, however, after the patient had been in the hospital four or five days characteristic typhoid stools. The reaction had been obtained in a very pronounced manner immediately upon the patient entering the hospital, which was on the third or fourth day of his illness. The course of the disease in that case was short, lasting only about two weeks. In other instances the reaction was not obtained until late in the disease. Of the cases examined not of typhoid fever, Dr. Miller found the reaction in 2.5 per cent. In part of these cases there was a history of prior typhoid fever, but not in all of them. It is evident, therefore, that while this reaction is very frequently present in typhoid fever, it is not an absolutely constant occurrence.

I feel inclined to criticise the tendency to call the reaction the typhoid fever test. Would it not be better to call it a symptom of typhoid fever? We have other symptoms of typhoid fever upon which we have relied in times past very largely in making the differential diagnosis where diagnosis was difficult, for example the occurrence of rose spots. Yet we know that rose spots occur occasionally in other diseases than typhoid fever. We know they do not occur in all cases of typhoid fever. Yet when we find rose spots in connection with other symptoms we make our diagnosis. We rely upon the *tout ensemble* rather than upon the individual symptoms. Therefore, would it not be better to regard the serum reaction as a symptom of typhoid fever rather than as a test, and take it only in connection with other symptoms, and not look upon it so exclusively, as some seem inclined to do, as a test pure and simple for typhoid fever?

Dr. H. A. WEST, Galveston, Texas—I wish to make one remark with regard to the importance of this test in sections of the country from which I come. It appears to me that it may be the possible means of settling some vexed questions in my section of the country with regard to the diagnosis of fevers. While in my own mind I have been satisfied as to the extensive prevalence of typhoid fever throughout Texas, and believe that the continued fevers which fail to yield to the salts of cinchona are typhoid fever, yet there is a division of opinion and the question is far from being settled. There is a class of practitioners who do not regard this continued fever as typhoid. They do not see the eruption; they do not find the ordinary classical symptoms of typhoid fever; they call it slow fever, catarrhal fever, simple continued fever, thermic fever, etc. There is another class of practitioners who call them cases of continued malarial fever. While they acknowledge the fact that they last three or four weeks, sometimes six or eight weeks, in spite of daily doses of 20 to 40 grains of quinin given during that period, still it is claimed that they are cases of malarial fever. The question came up at the State Association, and I regard it as one of the most important questions before the South or the country at large. From what I have heard this evening, I do think this method may be the means of settling that vexed question. I propose to carry it out to the extent of my ability, but I may say that the cases which I see in Galveston are classical typhoid fever with eruption, and running the course which typhoid fever runs the world over.

Dr. J. B. HERRICK, Chicago—I will mention some of the results obtained in about one hundred cases by Dr. George H. Weaver in the laboratory of Rush Medical College. In general his results have been confirmatory of those we have listened to today, but in two cases, shown postmortem to be typhoid, the blood examination during life and after death was negative. Now it may be a peculiar coincidence that in these cases there was also tuberculosis. One patient, an adult negro, under my own observation, died of typhoid fever as nearly as we can judge, in the fourth week, and postmortem we found typical healing typhoid but also a tubercular gland opening into a vein serving to explain distinct tubercular foci. In the second case, not under my own observation, a somewhat similar finding was made. This, I say, may be a coincidence, but it opens up the question whether this serum reaction will be modified by mixed or secondary infection. I believe other observers have reported on a few cases of mixed infection where the reaction has been positive.

RELAPSES IN TYPHOID FEVER.

Presented in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY WILLIAM OSLER, M.D.

BALTIMORE, MD.

One of the most distressing incidents which we may meet in typhoid fever is the occurrence of a relapse after we have guided the case safely to convalescence. The temperature has become normal, the

patient is happy and hungry, the relatives contented, the doctor congratulates himself that he has cured a case of typhoid fever, and then comes the relapse and the tempest of the soul, so to speak. In the first place it is always a source of congratulation to the doctor that he is not personally responsible for the relapse. The condition under which relapse occurs is not, I think, in the large majority of cases within the control of the physician. Errors in diet are in some instances held responsible for it, but only in a very limited number of cases can the diet be held to be definitely responsible.

It is important in the first place to define accurately what a relapse is. I think the term should be limited exclusively to reinfection after a distinct and definite period of apyrexia. It is quite true that that definition does not include a certain number of cases which have been termed the intercurrent relapse, and we have a certain number of cases in which the temperature falls not quite to normal, say to 100 degrees F. or the morning temperature to 99.5 degrees, while for three or four days there is a distinct lull and then a recurrence of the symptoms. One is often in doubt whether such a case should be positively called a relapse or not; but such cases should be grouped as intercurrent relapses and not as true relapses. The occurrence of a relapse is an indication that immunity in typhoid fever is slowly acquired, and not fully acquired when apyrexia is reached.

The sources of the reinfection are as yet unknown, just as are the conditions under which relapse develops; but of the possible sources of reinfection we may mention the lingering of the typhoid bacilli in the mucous membrane and in the adenoid tissues of the intestines. We have been told today by Dr. Richardson, that even after a considerable period of apyrexia typhoid bacilli have been found in the stools. Then it is possible that the source is in the mesenteric glands and the spleen—in the latter region we know that typhoid bacilli remain for a very considerable length of time after convalescence. Chiari recently made an interesting suggestion that the typhoid bacilli remain in the gall bladder, persisting after a long period of time, not only for weeks but even for months, and that the organisms in the gall bladder may be the source of reinfection. He has found typhoid bacilli in the gall bladder in nineteen out of twenty-three cases, a much larger percentage than has been met with by other observers. But the persistence of the typhoid bacilli in the bile passages is well recognized, and he suggests that the taking of an extra amount of food and gastric disturbance may be associated with the passage of a large number of these bacilli from the gall bladder into the intestines.

The evidence of relapse is very different in different series of cases. Up to Aug. 5, 1896, 500 cases of typhoid fever were treated in the wards of Johns Hopkins Hospital and forty cases had relapsed, or 8 per cent. That is the same percentage as is given by Liebermeister in about the same number of cases. It is a very much larger percentage than that given by Murchison in a larger series of cases—in two or three thousand cases there were only 3 per cent. of relapses. Other percentages run up as high as 20, but older observations, and even more recent ones, show that the percentage of relapses varies very much indeed. The relapses may not be single but double, now and then triple, and a few cases have been reported in which four or five relapses occurred. We have only

had a few cases in which two relapses occurred, none in which there were three.

As illustrating the extraordinary length to which a case of typhoid may drag itself with only two relapses, I may mention a case which was admitted in October, 1893. The patient was a doctor, admitted to a private ward with well characterized typhoid fever. The temperature became normal on the forty-first day. There was then complete apyrexia for twenty-three days and the patient had arranged with relatives to be taken home. But fever developed and persisted forty-one days, the temperature reaching from 104 to 105 degrees F. Then there was a period of complete apyrexia for forty-two days, six full weeks without fever. Then there was fever for fourteen days, without rose spots, it is true, but with furred tongue and moderately high fever and with some abdominal distension. So that altogether the original attack with the two relapses covered a period of very nearly six months.

The mode of onset of the relapse is interesting. It is not always, as stated in most works, exactly like the original attack—a stepping up of the temperature each day. It may, in fact, begin abruptly, as in the case which I have just mentioned. The onset of the first relapse was with a series of chills, and a maximum temperature of 105.5 degrees was reached within twenty-four hours of the beginning of the fever. Those cases are not very uncommon. In other instances the relapse is the exact counterpart of the primary attack, the temperature rising gradually, a degree or a degree and a half daily.

Another question has been raised to which I would like to refer, namely, whether the Brand treatment has anything to do with the increased number of relapses. Our percentage is, as you have noticed, not very high, and I do not think one can state that hydrotherapy has any influence in promoting relapses. There are many series of cases with a larger proportion of relapses in which hydrotherapy had not been carried out. Indeed, in certain series in which the relapses have been up to 15 or 20 per cent., the ordinary expectant method of treatment, or perhaps more correctly, the various medicinal plans of treatment have been carried out.

FURTHER REPORT OF CASES TREATED WITH ANTI-TUBERCLE SERUM.

Read in the Section on Practice of Medicine at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY PAUL PAQUIN, M.D.
ST. LOUIS, MO.

In presenting this report to the AMERICAN MEDICAL ASSOCIATION I am not mindless of the many objections which have been presented against sero-therapy in this disease, and of the numerous criticisms which have been passed upon it, and of the feeling of apprehension and doubt which still pervades the minds of many of the profession. I am fully aware that experimental tuberculosis in small animals has failed to accomplish to the degree expected, the kind of so-called cure, hoped for. Nevertheless, I again take the liberty of presenting a report of cases treated with serum, with the results obtained since the last months of 1894 to this date. Naturally, I must leave out a large number of cases of which the reports are incomplete, or otherwise unsatisfactory for the reason,

on the one hand, that some physicians did not keep the proper records, and on the other, there was in certain cases some doubt of the nature of the disease and of the results obtained. The cases reported here are such as I know had tuberculosis, and, I feel convinced, have experienced the results I shall mention.

In January, 1895, I presented to the St. Louis Medical Society a report of the results obtained in twenty-two St. Louis City Hospital patients, who had been treated exclusively with serum for three months. The good results in certain classes of patients were so uniform that the presentation of the matter was warranted at the time. The experiments were interrupted there by change of administration and the patients scattering I was able to keep track of only three of those improved, all of whom are still living and back at work apparently well, although I do not yet use the designation cured.

A second report of entirely new cases was made to the St. Louis Medical Society in March, 1896, and included the recovery of two *acute* cases of pulmonary tuberculosis, who had been in the care of three leading physicians of Missouri, who had given as their opinion that there was no hope. It also included the recovery of fourteen cases of chronic pulmonary tuberculosis. In that report I made the following statement: "That of 100 cases treated in a period of eighteen months, the following results obtained: In the first and second stage, as understood in general practice, 14 recovered; in the second stage, improved or checked or still improving at the time, 26; among these 26, 12 seemed to have really recovered, although the time had not been long enough to warrant positive assurance; there had disappeared from observation, in all stages, 35; died during treatment, begun at the third and fourth stages, including 10 moribunds who insisted on trying the treatment, 25. In the same year, Dr. Hayden of Evansville, Ind., reported 4 cases of tuberculosis; all improved and 2 apparently recovered. Besides these, Drs. L. L. Shropshire, San Antonio, Texas; Dr. William Miller, Boerne, Texas; Dr. Hoell Tyler, Mentone, Cal.; Dr. H. S. Lewis, New Orleans, La.; Dr. E. L. Mitchell, Carbondale, Ill.; Dr. J. M. Allen, Liberty, Mo.; Dr. A. G. Deardorff, San Francisco, Cal.; Dr. J. L. Wiggins, E. St. Louis, Ill.; Dr. J. L. Dunwoody, Cripple Creek, Colo.; Dr. W. H. Prioleau, Summerville, S. C., reported the recovery of ever twenty-five cases and marked improvement in over one hundred, while at least seventy-five physicians have reported improvements, of various degrees, in over one hundred cases impossible to record, most of them hopeless from the beginning.

In September, 1896, I presented a report to the Virginia State Medical Society, of a total of 226 cases of tuberculosis. I quote from this paper:

Class.	Pulmonary Tuberculosis.	No. of Cases.
1.	Destructive broncho-pneumonia with cavities	37
2.	Destructive broncho-pneumonia without recognizable cavities	66
3.	With diffuse febrile pneumonia with or without a destructive process	19
1.	With diffuse non-febrile broncho-pneumonia with or without destructive cavities	19
5.	With circumscribed febrile broncho-pneumonia	35
6.	With circumscribed apyretic broncho-pneumonia	13
	Diagnosis not reported clear enough for classification	32
	Hip-joint tuberculosis	2
	Laryngeal tuberculosis	2
	Ovarian tuberculosis	1
		226

In every one of these cases the diagnosis had been verified microscopically. During the treatment of these 226 cases the following conditions obtained:

Effect of serum on fever: 60 subsided, 56 reduced, 26 stationary, 84 not recorded.
 Effect of serum on night sweats: 60 subsided, 17 unchanged, 140 not recorded.
 Result of serum on weight: 125 increased, 15 unchanged, 27 decreased, 59 not recorded.
 Result of serum on strength: 154 increased, 9 unchanged, 24 decreased, 39 not recorded.
 Result of serum on appetite: 114 increased, 15 unchanged, 31 decreased, 66 not recorded.
 Result of serum on local signs: 40 disappeared, 58 mitigated, 28 unchanged, 100 not recorded.
 Result of serum on tub. bacilli: 40 disappeared, 103 reduced, 7 altered, 76 not recorded.
 Result of serum on general well being, exclusive of the 40 recoveries: 145 improved; 9 unchanged, 32 not recorded.

Of these, have recovered	57
Apparent recoveries with lesions in statu quo	3
Improved capable to perform again usual duties	76
Improved to a lesser degree	80
Deaths reported (probably some not known)	36
Cases disappeared from observation	11

293

Number of recoveries that seemed complete and permanent	40
Number of apparent recoveries with existing lesions (cavities) in statu quo	3
Number of improved capable of performing usual duties	41
Number of improved to a lesser degree	69
Number of deaths reported	32
Number of cases disappeared from observation or under various treatments	41
	226

As to the pulmonary cases, the extent, stage and importance of the conditions at the beginning of were as follows:

In Class I there were 20 cases in advanced stage; 3 in early stage	
" 2 " " 33 " " 6 " "	
" 3 " " 12 " " 0 " "	
" 4 " " 9 " " 0 " "	
" 5 " " 12 " " 3 " "	
" 6 " " 7 " " 1 " "	
	13
	93

Not classified accurately enough for satisfactory description of the stage 120

I beg to say today that those cases reported as having recovered, dating back from one to three years, are still living and apparently well. None of these cases recorded as having improved greatly have succumbed yet, but some of those reported as having up to that time remained unchanged or mitigated or slightly improved, have since died. I have been unable to get an absolute record as to the number of these, although we are using a method of tabulation and clinical report chart which we send out to physicians using the serum. It seems that not one of the cases reported by doctors as having recovered, or in which the disease seemed to have been arrested permanently, have had a relapse, so far, although most of them remain in an unfavorable climate where the disease originated, as in St. Louis, for instance.

I beg now to present a report of 67 cases, which were not included in the foregoing, and which have been treated in the last year, and purposely recorded since the last meeting of the AMERICAN MEDICAL ASSOCIATION, concerning which I have direct information.

Total number of cases 67.
 Effect on fever: 17 subsided, 22 reduced, 5 increased, 23 not recorded.
 Effect on night sweats: 26 subsided, 4 unchanged, 27 diminished, 10 not recorded.
 Effect on weight: 40 increased, 11 unchanged, 4 decreased, 12 not recorded.
 Effect on strength: 34 increased, 10 unchanged, 4 decreased, 19 not recorded.
 Effect on appetite: 34 increased, 10 unchanged, 4 decreased, 19 not recorded.
 Effect on local signs: 17 disappeared, 22 mitigated, 27 not recorded.
 Effect on tubercle bacilli, 17 disappeared, 35 reduced, 15 not recorded.
 Number of recoveries that seem complete at present 17
 Number of improvements to a considerable degree 35
 Improvements to a lesser degree 11
 Deaths 4
 Thus the grand total of cases recorded above properly enough for reliable report is, not including the various doctors' reports herein mentioned 293

This report does not include the numerous cases in which serum was tried in moribunds or in more favorable cases for too short a time. Nor does it include a number of cases improved in the last few months by using serum by rectal injection.

In concluding this report, I wish to say that too much is expected of sero-therapy in tuberculosis, or of any treatment for that matter. It can never be possible to arrest consumption when the tissues are so destroyed and their generative energies so enfeebled that they are beyond the power of stimulation. It is only in the early stages that one may expect the best results (and in the early stages it is a most efficacious remedy). One great trouble we have to deal with is mixed infection and this can be reached only by the use of antitoxins prepared specially for the germs producing the complications, assisted occasionally by other measures. Tubercle antitoxin can not act directly against microbic complications. Furthermore it should not be forgotten that the destructive process of tuberculosis is so great, so comprehensive, that no means of wise special or general treatment should be spared to assist sero-therapy or any other special treatment in the work of repair. Most of them were cases of an experimental character. The cases which I have submitted here have been treated almost exclusively by the use of serum.

I am fully convinced that no one is warranted today in proclaiming the absolute and exclusive curative properties of an exclusive specific alone in tuberculosis of all kinds. Every case must be treated on its merits, considering in each the symptoms, lesions, predispositions, inherited conditions and the various susceptibilities present. Sero-therapy is nature's remedy and offers the greatest assurance of benefit in the subjugation of the specific cause or causes, but in most cases, as just stated, it should be supported in its splendid work by such hygienic, dietetic and medicinal measures as are considered wise for each individual case.

THE CAUSE AND MECHANICAL TREATMENT OF SUBLUXATION OF THE KNEE-JOINT.

Read at the Third Annual Meeting of the American Academy of Railway Surgeons held at Chicago, Sept. 23, 24 and 25, 1896.

BY S. L. McCURDY, M.D.

SURGEON TO THE PENNSYLVANIA CENTRAL RAILWAY.
 PITTSBURG, PA.

In order that the treatment of subluxation of the knee-joint may be properly carried out its cause must be thoroughly understood.

Subluxation of this joint is an under-dislocation of the head of the tibia back of, or posterior to, the condyles of the femur. Such a deformity does not exist as a result of chronic disease when the femur is kept parallel with the tibia, during tubercular, synovial, traumatic, gonorrhoeal and other inflammatory diseases in and about the knee-joint. It can only result from direct violence and from faulty position during the course of treatment.

The series of experiments has been carried out to determine the relative power of the flexor and extensor muscles of the leg, as well as to determine at what

angle, in flexion, the flexor muscles equal the extensors in power. We must remember that extension of the leg is limited to a parallelism with the thigh, and that flexion is only limited by the resistance of the calf with the thigh muscles, or through an arc of 90 degrees. In extension the flexors and extensors are antagonists, and oppose each other with equal advantage, so far as the position of the bones themselves are concerned, because they both have direct action. The advantage, however, is in favor of the extensors, because they are always more powerful. When the leg is flexed the extensors lose their power of direct action and act over a pulley. This pulley is formed by the action of the quadriceps extensor femoris, patella and ligamentum patellæ over the condyles of the femur. As the leg is flexed the extensors lose power and the flexors gain. In order to determine the power of these sets of muscles and to more particularly determine at what angle of flexion the flexors equal the extensors, experiments have been carried out.

Without giving in detail the various experiments which were made upon different individuals, it was found that the extensor muscles upon an average had a resistance of thirty-two pounds, and the flexors twenty-four pounds and that at an angle of about 35 degrees the resistance of the extensors was reduced to twenty-four pounds. This shows that the extensors and flexors have equal power when the leg is flexed to an angle of 35 degrees. A slight variation from the above is found in different individuals.

The experiments were carried out by the use of a goniometer, a pair of spring scales, and four hooks on the jam of a door, one on either side opposite the knee and the other two below these near the floor. To test the extensors, a tape is secured to the hook in front of the knee and thrown around the knee above the joint. The scale is hooked to the hook back of the foot, and another tape is thrown over the ankle and the free ends passed through the ring of the scale. With the leg in extreme extension the tapes are drawn through the ring of the scales. The scales will first register the extreme power of the extensors, but as it is drawn back to about 10 degrees it requires less force to make flexion, hence, a reduction on the scale dial.

To test the flexors, the scales are placed in front of the foot and the knee secured from the hook immediately back of it.

It is quite customary to treat the diseased conditions of the knee-joint in flexion, the degree of flexion being determined by the attending surgeon. Some reasons given for this are that it places the leg in a better position for use during after years, or it is more comfortable to the patient, etc. All of the reasons given are fallacious and founded upon anything but sound reasoning.

In the case of traumatic and other forms of synovitis it is probably true that a greater area of synovial surface is included between the heads of the bone and semilunar cartilage. Such a reduction in actual surface pressed upon could not diminish the pressure, but would place the leg in a less secure position and thus increase muscular spasm and as a result increase intra-articular pressure.

It must be remembered that all muscles which pass over, or the tendons of which pass over or control the action of a joint in inflammation, are in a state of spasmodic contraction. This increased action on the

part of the muscles is an effort on the part of nature to protect the sensitive joint. The deformity which follows is in the direction of the most powerful muscles, or sets of muscles.

In hip-joint disease it is flexion, adduction, or abduction. In tarsal disease it is valgus, varus, flexion, extension, etc. In knee-joint disease it may remain normal, as it generally does in diseases of the shoulder or wrist, so long as the leg is kept in a position favoring this. Just as soon, however, as the flexors have a greater power than the extensors we have an increase of flexion.

As a result of my experiments an approximate estimate of the muscular power showed that the flexion at an angle of 45 to 50 degrees, the flexors had absolute control of the leg. This will admit of two things, an increase of flexion and a tendency of the head of the tibia to glide further back under the condyles. This is not only correct theoretically, but it is borne out clinically and has no doubt been observed by many of my hearers.

I have thus dwelt at length on the cause of the condition under consideration in order that the treatment might be preventive rather than that we be called upon to correct the deformity after its existence.

The treatment of subluxations may be summed up briefly as follows:

It must first be determined whether true or false ankylosis exists, whether the dislocation is partial or complete. In true ankylosis a complete section of the bone must be made either by the use of chisels or saw, and if the relationship of the bones can not be restored without it, a wedge-shaped section should be made, the bones brought together and or otherwise secured.

In cases of ligamentous or false ankylosis with a partial subluxation, *brisement forcé* with tenotomies of the hamstring tendons is generally sufficient. The most difficult cases to manage are those where the adhesions are more or less firm and a complete luxation of the bones exists.

Tenotomies of the tendons will free the lower portion of the head of the tibia, but great force does not as a rule restore the joint surfaces to a normal relationship. It is quite possible, after tenotomy, to bring the leg parallel with the thigh, but it will be found that the leg is upon a lower plane than the thigh. This is due to the fact that the head of the tibia does not slip down and forward upon the condyles, but instead the relationship of these bones are not disturbed.

Immediate reduction of subluxation of the knee-joint is prevented: 1. By the adherent patella and synovial membrane to the condyles. 2. By the impinging of the anterior portion of the head of the tibia against the condyles. In cases where the hamstrings are not cut this burrowing in of the bones upon each other is much greater, and an immediate reduction is less likely to be effected. Gradual and continuous leverage offer the best means for correcting the deformity mechanically. In this degree of deformity a rapid cure can not be promised, except by a radical operation.

A complete correction mechanically must not be attempted at the time of the practice of *brisement forcé*, but instead the leg should be carried forward to an angle that would permit a gradual correction of the subluxation. If plaster of Paris is used as a support, it should be reapplied every ten to fourteen days.

DISCUSSION.

Dr. MAYO—Dr. Gillette of St. Paul, in a number of cases, has broken up the adhesions by means of great force, using some form of mechanical apparatus in one sitting and without tenotomy. I have myself been afraid to apply this extreme degree of force, and, if the deformity is sufficiently great, much prefer to make an osteotomy of the femur after the method of Macewen: this, it appears to me, gives the best results with the least loss of time and danger. The mechanical apparatus of the doctor I believe would succeed better in the hands of the inventor than with the rest of us. In my experience I have seldom been able to succeed with another man's splint as well as does the inventor himself, and as a rule do better with the plaster of Paris cast.

Dr. HAWES—I wish to take exception to one statement in the paper; no mention is made of complete reduction of the subluxation at one sitting. I think the best result I ever had was where it was necessary for me to use force; I actually tore the skin in the popliteal parts. The splint I have been accustomed to use has two bars on the outside and one inside, extending from the inside of the thigh to the heel and outside to the heel and carrying the bandage around it all, behind the tibia. It seems to me I ought to get better results than I would with this splint.

THE DIAGNOSIS OF MALARIA.

BY ARTHUR R. EDWARDS, A.M., M.D.

Professor of Therapeutics, Northwestern University Medical School; Professor of Practice and Clinical Medicine, Northwestern University Woman's Medical School; Attending Physician to Cook County Hospital and St. Luke's Hospital; Pathologist to Wesley Hospital, Chicago.

The diagnosis of malaria, like its pathogenesis, has a scientific life of scarcely two decades. The subject has been roughly handled since an acquaintance with its microscopic diagnostic methods has reached the general profession from the laboratories of scientific biologists and clinicians. As in all newly developed methods, medical and otherwise, there is a tendency to swing from one extreme to the other. Great skepticism greeted Laveran's initial reports that certain parasitic elements existing in the blood of malarial patients and hitherto confused with pigment-bearing leucocytes, were the cause of malaria. The general skepticism of Laveran's colleagues is now superseded by equally universal credulity. While previously no parasites were admitted, now they are even confused with the constituents of the normal blood. Five years ago the existence of malaria in Chicago was denied, while today many vague diseases, especially obscure or obstinate fevers, are diagnosticated malaria.

1. DIAGNOSIS OF THE EXISTENCE OF MALARIA.

(a.) *Positive blood findings*, i. e., the detection of the plasmodium of malaria, establishes the fact of malaria, since malaria is always caused by the parasite, and again the organism is almost always found in malaria and in malaria only. A few microscopic examinations will convince the greatest skeptic. It must not be forgotten that, in certain instances, two diseases may occur simultaneously. We have seen malaria in conjunction with various ancient heart lesions, ulcerative endocarditis, pulmonary tuberculosis, chronic nephritis, although never with typhoid fever. These coincidences are, however, infrequent, and the presence of malaria plasmodium makes possible positive differentiation from other diseases, e. g., the frequent error of overlooking or misinterpreting an incipient pulmonary tuberculosis attended with

chills. Atypical fevers, associated with chills and sweating, which have few or dubious local findings and are therefore difficult of diagnosis, can at least be differentiated from malaria; for example, analagous typhoid, septico-pyemia occulta, generalized military tuberculosis, febrile gastritis, cholecystitis suppurativa, central pneumonia, deep-seated sarcomatosis, ulcerative endocarditis, etc.

(b.) *Negative blood findings*, in suspected malaria, are not definitive from one examination. Not infrequently is more than one microscopic search necessary for the positive exclusion of malaria. While suggestive, then, a single negative finding is far from conclusive. The parasites may be indistinguishable in the first few days of the disease. In certain forms they swarm in internal organs, avoiding the peripheral circulation; and lastly, in chronic and recurrent types they are found with great difficulty. Sometimes visceral (splenic) puncture is needed for their detection.

(c.) *Fallacies*.—Certain deformities in the red blood corpuscles are often mistaken for plasmodia, e. g., crenations, poikilocytosis and vacuole formation. Not only can the more intimate structure of the red blood discs retract, simulating plasmodia, but the exterior of the hemacyte is far more plastic than is commonly acknowledged, even to the extent of protruding pronounced pseudopodia-like processes. These are but too frequently mistaken for parasites, being found in very many instances of apparently otherwise normal blood. Vacuole formations are characterized by their sharp contour and high luster.

Melaniferous leucocytes are readily distinguishable from the plasmodia by their large nuclei and by their ameboid movement, always absent in adult parasites of equal size. Unstained spores may be confused with the blood plaques, which are, however, structureless and contain no pigment. An Austrian pediatricist lost a docentship for reporting as malaria cases whose blood preparations afterward proved to contain only blood plates and no plasmodia. Coagulation products have been confused with flagella. Many of the small dots seen in malaria which resemble micrococci and were mistaken for such by the earlier Italian observers are similar to those found in most anemias and described by Ehrlich as degenerative changes.

II. DIAGNOSTIC TECHNIQUE.

Complex methods of staining and counterstaining the parasite have been in vogue, but the simplest and most accurate is the direct examination of the freshly-drawn unstained blood, a method we have used with entire satisfaction for several years. In this procedure injury to the corpuscles and staining of the blood plaques are obviated.

The lobe of the ear is cleansed, pricked and a quite small drop is gently expressed. A clean cover glass is held in a pair of forceps to avoid the heat and moisture of the hand, and is carefully brought in contact with the top of the drop. The heat and moisture of the hand or rudely placing the cover against the drop favor imperfect spreading from precipitate drying of parts of the blood. Rubbing the slide well facilitates equable spreading of the blood. Examination is best made with an oil one-twelfth inch immersion lens, although Laveran used lenses of lower magnification. Permanent preparations are procured by allowing the covers to dry, to remain half hour in equal parts of absolute alcohol and ether and by painting with filtered eosin and methylene blue. The use of stains is not usually

advisable, since they obscure the otherwise more brilliant microscopic findings, they act as protoplasmic poisons, abolishing both the ameboid movement of the parasite and the highly characteristic vibrations of its pigment, and finally, they stain the blood plates and coagulation products, thereby confusing the findings, particularly for the unwary clinician.

III. THE DIAGNOSIS OF THE TYPE OF MALARIA.

It is impossible to enter here into the detailed differential morphology of the malarial parasites. Blood examination, however, demonstrates not merely the fact of malaria but also its types, since the various clinical forms of the disease correspond to zoologically distinct, immutable species of parasite. Determination of species embraces more than purely biologic interest; it declares also the prognosis as in the pernicious forms and designates the treatment, as arsenic in the tropical types. Councilman stated several years ago that in intermittent fever the parasite was seen within the red blood corpuscle, while in remittent fever or in malarial cachexia it was frequently seen without the same or in elongated forms and crescents. Crescents augur relapse. The presence of segmentation forms predict an imminent or incipient paroxysm. The alleged detection of plasmodium is often doubted by us, since it is not uncommon to hear practitioners state that they have found Laveran's organisms an error at least in species determination.

In general terms, the number of parasites found in the blood corresponds to the severity of the attack, although Antolisci, and others with him, believe the large spore-producing bodies remain largely in internal bodies.

Relative exceptions to this rule exist.

(a.) *Diagnosis of type from motility.*—In the ordinary tertian parasite there is lively ameboid movement in the young and middle-aged forms. In the quartan form there is slight movement in the young parasite. In the estivo-autumnal type it is variable, often very active.

(b.) *Diagnosis from pigment.*—In tertian malaria the pigment is pale and yellowish brown, is fine, and in the young forms is most active, or "swarming"; it accumulates toward the periphery of the parasite, as the pseudopodia protrude, but in the older forms it becomes central. The pigment is inversely proportional in amount to the ameboid movement, *i. e.*, the more pigment the less the ameboid movement.

In the quartan the pigment is coarse, being somewhat larger than in the tertian, irregular, with but little if any movement.

In the estivo-autumnal form the pigment is active, although some describe it as slight, at first fine, later coarse, even rodlike.

(c.) *Diagnosis from size.*—The tertian is as large as the red blood disc, even larger; the quartan not larger than the red corpuscle, while the tropical forms are much smaller, from 1.5 to $\frac{2}{3}$ the size of the hemacyte.

(d.) *Protoplasm of the parasite.*—In the tertian it is pale and indistinct; in the quartan sharply outlined, and of a characteristically high index of refraction; in the autumnal type it is ringlike, very small, hyaline and difficult to detect.

(e.) *Morphologic alteration in the red blood cells.*—In the tertian the red blood cells hypertrophy and are rapidly and completely decolorized. In the quartan they are but little decolorized, may be darker than nor-

mal and are not essentially altered in size, although the corpuscles may become slightly smaller than normal. In the more pernicious types they are shrunken, become either darker, of "brassy" color, or completely decolorized, "shadowlike."

(f.) *Diagnosis from sporulation form.*—In the tertian the spores are more or less irregularly grouped, individually small, round, whose nucleolus is seldom seen in unstained specimens, numbering 15 to 20 or somewhat less. The segmenting forms are about the size of a red disc, and are of irregular form. The segmenting bodies are found in the peripheral blood rarely, or in small numbers only, except at the time of a paroxysm.

In quartan malaria the spores exist in the marga-rite form, spores being individually long, with distinct nucleolus, 6 to 12 in number. The segmenting forms are smaller than a red blood corpuscle, of a rosette form, are found in equal numbers in the peripheral and visceral circulations, and may be detected in the apyretic interval as well as in the paroxysms. In the estivo-autumnal types the spores are irregularly formed or stellate, six to eight in number, possibly more, and segmentation occurs chiefly in internal organs.

(g.) *Diagnosis from crescents and flagella.*—The crescents are found only in the estivo-autumnal forms, and represent a very resistant form of the organism. They may exist for months at a time without fever or other symptoms. They may be converted into round bodies, from which flagellation is frequently observed. We have never seen crescents apart from extreme anemia. Persisting as they do we can scarcely consider them solely as degeneration forms; they impress us rather as resting stages.

Flagella may be found in any type, though not frequently in quartan fevers. They may be seen when quinin has been previously given, and have been considered by some as degenerative forms. They are but rarely seen in freshly shed blood, but we have seldom missed them when examining a specimen for a long period, *e. g.*, in clinic demonstrations.

IV. THE DIAGNOSIS OF INDIVIDUAL MALARIAL SYMPTOMS.

The diagnosis of individual or isolated cases is most intimately linked with the diagnosis by blood examination. Certain malarial symptoms are not only immediate sequences of the malarial infection, but are also most beautifully explained by the life cycle, life activity and metabolism of the organism.

The melanemia corresponds with the structural disintegration of the hemoglobin of the red blood cells and its diffusion through the blood plasma. The anemia is secondary to reduction of the hemoglobin and diminution of the number of red blood corpuscles; in other words, to morphologic hemodyscrasia. No leucocytosis is seen, save a transient apparent increase at the beginning of the paroxysm. The hemoglobin and red discs are destroyed in equal degree. The anemia is rapidly produced; in fact, corpuscular deglobulization is more rapid than in any other acute affection, and can be utilized to differentiate from pneumonia or typhoid fever.

Each paroxysm being the ripening of a new generation of parasites, the fever corresponds to their sporulation and a saturation of the blood with toxins liberated from the red blood cells. It is a chemic hemodyscrasia or, as Mannaberg aptly puts it, a "protozoan

sepsis," analogous to that discharge into the blood stream of infective material observed in septico-pyemia.

We fully comprehend any clinical form of fever, when we realize that the fever is a toxic manifestation and that as often as the parasites segment, fever occurs. Hence two generations of tertian parasites cause quotidian fever, also caused by three generations of quartan parasites of unequal age. Quotidian continued fever accompanied by splenic tumor, the diazoreaction, and even roseolæ or slow pulse, may cause difficulty in diagnosis from typhoid fever, especially as typhoid may be attended with chills and sweats. The blood examination speedily differentiates and Widal's serum test for typhoid is of great aid. The splenic tumor and bone pains are explained by the phagocytic process in their substance, the hemoglobinuria, diarrhea, retinal and other hemorrhages by the toxemia, the cerebral symptoms, as coma, convulsions or bulbar symptoms, by aggregations of the parasite in the cerebral vessels with thrombosis.

Some special mention of the diagnosis of the estivo-autumnal form is timely since the disease may be imported from the South, and require prompt recognition. Personally we have seen two fatal and a third comatose case, the same number reported from Osler's clinic. The disease is acyclical, arrhythmic in sporulation; while quotidian in type, the paroxysms are of long duration, lasting nineteen to twenty-four hours and frequently overlapping each other with irregular or continuous fever as a sequence. Often chills and chilly sensations are lacking, the rise of fever is gradual instead of sudden and the febrile solution is also gradual. There is greater tendency to retardation or anticipation of the paroxysm than in quartan or tertian types. Profound anemia and cachexia are common, fever may be lacking, relapses are imminent, as long as crescents are found, indeed after they have disappeared and finally spontaneous recovery is infrequent.

V. THE DIAGNOSIS E JUVANTIBUS.

The therapeutic diagnosis, despite the fact that quinin is a specific remedy, is subject to certain errors. First, many fugitive febrile diseases disappear under the use of quinin, which run their short course with equal celerity under other treatment or with no treatment at all. Hence not all is malaria which quinin seems to cure. A blood diagnosis must precede and succeed the therapeutic test.

Second, malaria manifests a certain tendency toward spontaneous recovery. The disease untreated follows a cycle: 1, a gradual increase in the intensity of the paroxysm; 2, a period of oscillation; 3, spontaneous recovery; 4, a relapse in one or two weeks. Then the same rhythm of symptoms is followed. Not infrequently in hospital practice when we give a placebo that we may study the plasmodium, the disease disappears without therapeutic interference. Hygiene, change of habitation, rest in bed and lack of reinfection favor self-limitation. While the fever is a symptom of malarial infection, it is per se a conservative process, killing the parasites. Indeed if all parasites are of the same age, a catastrophe ensues, and the disease is instantaneously cured by the fever. Many of the germs remain sterile. Spontaneous recovery is most common in tertian types and least frequent in the estivo-autumnal variety. The process of phagocytosis, while not yet completely understood, un-

doubtedly plays an important rôle in spontaneous recovery. The multinuclear neutrophile leucocytes have the greatest phagocytic action and the process is almost always noticed when the flagellate forms abound. Phagocytosis is most marked during the paroxysm and lasts eight to twelve hours. It is consummated by the macrophages of the spleen, liver and bones and to a lesser extent by the endothelial cells in various organs. *e. g.*, the cerebral vessels and by the leucocytes. The slow current of the hepatic vessels, and their large caliber aid the process.

The use of quinin.—The drug does not greatly impress the endoglobular parasite, shielded as it is within the protoplasm of its host, the red blood cells. Coming in access with the free spores in the plasma, it speedily destroys them, and the disease may be extinguished at one dose, as it were, if the parasites are of but one generation. Highly specific in the tertian and quartan types, it is resisted more effectual by the estivo-autumnal form. Most authors state that the specific action of quinin is manifest even in this form, unless the case is far advanced before treatment is begun. We have seen the estivo-autumnal resist sixty grains of quinin per diem for two weeks, and then to react but slightly to the drug.

Regarding our endogenous malaria, the benignant tertian variety, the therapeutic diagnosis can be quickly made. Twenty to thirty grains should at once destroy at least the fever type and, repeated, should in two days cure the disease. If the disease lingers, but two alternatives exist: 1. The quinin is not absorbed, due to faulty administration, in the form of pills, etc., or 2. The disease is not malaria. When we hear that a Chicago malaria resists quinin, we know that another disease causes symptoms which simulate malaria, providing of course the administration technique is irreproachable. Not to encroach upon the treatment of malaria, we assert that at least our northern malaria reacts at once to quinin therapy and that, conversely, failure in treatment positively disproves a diagnosis of malaria.

MANAGEMENT AND TREATMENT OF CROUPOUS PNEUMONIA.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, at Philadelphia, Pa., June 1-4, 1897.

BY D. S. CAMPBELL, M.D.

PROFESSOR OF CLINICAL MEDICINE DETROIT COLLEGE OF MEDICINE AND ATTENDING PHYSICIAN HARPER HOSPITAL, DETROIT, MICH.

In croupous pneumonia we have, I believe, a special and independent affection. Its frequent occurrence, especially during our winter and spring months, affords abundant opportunity for observing it in all its phases. And though these seasons have an undoubted influence upon its prevalence, yet from the tables of mortality we find it also occurs in the milder seasons and in every degree of latitude, wherever rapid changes of temperature with stormy winds take place, particularly with moisture. But in a climate similar to ours this is usually the exception. For it rarely makes its appearance before the colder seasons approach. But while we are conscious of the undoubted fact that these cold, moist seasons have a great bearing toward developing and spreading this affection, there are other important influences at work, which play a part in the inherent qualities of increasing its development, and these are chiefly intemper-

ance of every kind, and poverty, especially if the individuals live in large and crowded cities, in dwellings having poor ventilation; also occupations involving exposure or over exertion, or indeed any other potent factor which might depress the vital forces of the system, as from fevers, etc. These are agencies which might be made subordinate to our surrounding conditions. Be that as it may, we find pneumonia attacking the rich and the poor alike, under every condition, favorable or otherwise, and both alike suffer indiscriminately from its toxic effect.

Now as to the nature and pathology of croupous pneumonia, it is pretty well understood to be more than a local affection or simple inflammation of the lungs. One's system may be greatly borne down by its ravages, accompanied with high fever, rapid pulse with nervous depression several days before any of the general physical signs of congestion and consolidation are manifest. In fact some may pass through an actual attack before the lesion is recognized; then danger is usually past. Besides, the smallness of the area of the lung involved, very frequently does not correspond to the ratio of the fever and the general depressing constitutional symptoms which attend it. Again, after the complaint has assumed or rather has become a local inflammatory affection, where we may have excessive cell formation, with fatty degeneration and liquefaction of the inflammatory products, with all the general physical signs and indications of purulent infiltration attending it, the constitutional effect of the disease, which usually consists of high fever, rapid or depressed pulse, great physical prostration and delirium, with other nervous symptoms, is very frequently, if not entirely, absent.

Realizing then that we have more than a local affection to contend against, a disease which I consider truly specific, infectious and constitutional in character, and which is usually of comparative short duration, and is generally ushered in with a severe chill, or followed very soon afterward with high fever, and, if complicated with either heart or renal trouble, with delirium and a general train of nervous symptoms, it clearly follows that the treatment should be directed, in the main, toward hastening the natural progress of the affection to a speedy close, so as to limit as far as possible its toxic effect on the great nerve centers, on which the strength and volubility of the heart depends to maintain life, using measures which have no depressing effect whatsoever, either on the nervous system directly or on the heart itself, thus assisting in controlling the excessive temperature, which really registers from the beginning to the close the actual termination of this fatal malady. This, in my mind, and I believe in the minds of many others of experience and observation, forms the basis of the present rational treatment of croupous pneumonia, whether complicated or not.

From this process of reasoning we are justified in assuming that there are two distinct pathologic conditions to be considered in the treatment of croupous pneumonia: 1, local disturbance, involving more or less lung tissue, with perhaps considerable structural changes, without much fever or general physical depression; 2, when the system is laboring under great nervous and perhaps physical depression, with high fever, without much local disturbance.

Now as regards the first pathologic condition, it may be laid down as a clinical fact, and this based on nearly 80 per cent. of cases, that the moment the

morbific cause runs its natural course or subsides entirely, the laws governing the vital forces become active in repairing and restoring the diseased parts to their normal condition without any material assistance. But of course it is always necessary to carefully watch the local morbid lesion, to note whether the exudation thrown out by the inflammatory act is remaining unabsorbed or the inflammation itself is becoming chronic or abscesses are forming or gangrene taking place. These and other complications are very exceptional. Interference then in such cases is not indicated or warranted, unless it be careful nursing, because the tendency is toward their own cure. For if we construe aright the morbid phenomena attending them, we will find they consist chiefly of a certain modified temperature and disturbance of the functions of the lungs by an inflammatory act, in which the former, owing naturally to its short duration and moderate amount of fever, is not sufficient of itself to cause alarm. And when it subsides the latter or local morbid process becomes completely insignificant, if not complicated.

The cases then which really demand the greatest attention, and in which material assistance becomes invaluable, are the remaining 20 per cent., the ones which are attacked very severely in the outset with prolonged rigors, and accompanied very soon with excessive fever and rapid pulse, in fact cases in which even from the beginning of the rigor great constitutional disturbance with a tendency to heart insufficiency, especially of the right side, are really anticipated.

Now then what should be the most rational form of treatment from the outset to the decline of this specific constitutional disease, judging it from its infectious nature? Can any constant or uniform method of treatment be adopted as being perfectly applicable in combating its specific properties, by mitigating its toxic influences on the great nerve centers and heart?

We thoroughly understand the chief danger arising from a severe malignant attack of croupous pneumonia. The excessive fever, labored respiration, coupled with nervous exhaustion; also the local inflammatory process, with its deposit of fibrous exudation interfering with the functional properties of the diseased section, rendering it almost impervious to the circulation, thereby increasing the impelling force of the right side of the heart, which is constantly endeavoring to limit as far as possible pulmonary retardation of the blood, are pathologic conditions always favorable to heart insufficiency, the danger to be avoided if possible. So in answer to the first question the expectant treatment presents itself, as it corresponds to the modern view of the pathology of this specific affection, by removing deranging influences without using active therapeutic agents, unless the case absolutely demands it. And as to the second, no constant or uniform method can be adopted as sufficiently adequate in rendering material aid in cutting short the natural course of the disease, aborting its constitutional effects, unless it is by mechanical reduction of temperature, from which the expectant plan also claims some credit. But I am fully persuaded after careful observation—though this latter expedient has been extolled by eminent authorities—that such can not be accomplished. For the disease intends to and will run its natural course, no matter what one may do to arrest it, similarly to any other specific constitutional affection, as typhoid

for instance. We can, however, control or reduce excessive heat by cold applications, and ease up, as often as it is applied, the one organ above all others that the system is most dependent on at this time, viz., the heart; but that only sustains and holds in reserve as it were vital energy which would otherwise be lost, should the struggle be continued unabated.

The treatment then in the management of croupous pneumonia, is best carried out in the large majority of cases, by the expectant plan already alluded to. And though the term expectant is somewhat misleading, in medical language it suggests the various means at our command, other than that of actual depletion or agents that consume the vital forces, viz., free blood-letting and the use of the general depressing drugs, as that of tartar emetic, veratrum viride, heavy doses of aconite, belladonna, etc. Hence, by adopting this system of treatment, apart greatly from the antiphlogistic plan, in the treatment of croupous pneumonia, it enlarges our views immensely, therapeutically and mechanically, allowing us to take advantage of every available means which our judgment suggests to alleviate and modify the course of the disease.

Since the heart is the chief organ upon which the burden of labor is thrown in pneumonia, it is necessary, owing to its increased functional duties, to sustain it from exhaustion, by every means possible. Now how is this best accomplished? First, let us look into the prime factor or cause of this increased exertion on the heart before the deposit of exudate in the lung exerts pressure on the blood vessels within the diseased area. From the very commencement of this affection the fever is a most constant symptom of the elevation of temperature, and it is not only constant, direct and persistent, but also appears to have a complete mastery over every physical exertion it makes. So to this excessive elevation of temperature it becomes entirely subordinate or dependent. This can be shown from the mere fact, that after the fever subsides partially or wholly, when the heart is already exhausted, feeble, but willing to pump, though the local disturbance in the lungs remain about the same, it gradually assumes its old wonted form, and excites within itself a healthy tone toward a normal action. Again, while the fever is still in the ascendancy, after the exudate has been freely thrown out, and exerting pressure upon a considerable portion of the healthy lung tissue beyond the diseased section, which not only produces retardation of the blood and increases the muscular capacity of the right heart, preventing by that means the free escape of carbonic gas and other detritus which form very rapidly during fever, the very poisonous elements the system is most desirous of getting rid of, it throws additional labor on the left heart, and arrests, in a certain modified degree, the functional capacity of the respiratory muscles, and all due to the excessive fever, the chief resultant of this specific pulmonic trouble. The chief point of attack then, from the very beginning to the end of the constitutional effects of pneumonia, is the fever. But the management in the reduction requires the most careful and constant attention. To be over active and meddling is most injurious, and should be decidedly deprecated, while with prudence and judicious interference, it is not only possible to avert death, but even hasten recovery by sustaining the functions of the heart.

In respect to the reduction of excessive pulmonic

fever, various notions and theories have been advanced regarding the best remedies at our disposal to accomplish it; but the one above all others, in my mind at least, is cold applications. And though it has long been extolled and practiced, especially by a few eminent German authors like that of Juergensen and Liebermeister, it has in great degree been held in bad repute and looked upon, in this specific disease, by the vast majority of physicians, especially in this country and England, as not only an extremely radical measure, but a foolhardy and dangerous one to follow. For my part, the experience which I have had has enabled me to save a number of lives by it, when their hearts were almost paralyzed from sheer exhaustion. Now the part which cold, judiciously applied, plays in the role of an anti-pyretic, is simply the gradual subtraction of excessive heat from the body while under the influence of pyrexia. It undoubtedly acts also, by this means, as a stimulant to the nervous system; for in all febrile conditions, destruction of the tissues takes place rapidly and they are changed into various substances of lower chemical composition. Thus through its stimulus on the great nerve centers, cold tends to eliminate these newly formed substances by the natural excretory organs, and in that way arrests its poisonous effects on the nervous system, the heart governor.

This can be clearly illustrated from the report of the following case, which recently came under my notice:

Mr. M.—, banker, aged 50, habits and general health good, was suddenly taken with several severe rigors followed soon afterward with a high fever, and though I saw him a few hours after the last chill, found him restless and delirious, with temperature of 105.5 degrees, pulse 130 and bounding. On examination I found at base of right lung slight modified dullness, with few crepitant rales. Respiration hurried, but the characteristic irritant cough usually accompanied with tenacious rusty sputum, was still absent. He was given a full dose of calomel (15 grs.) after which cold wet compresses were applied. The action of the calomel was prompt and efficient, by disgorging the portal circulation, which necessarily relieved the blood stasis existing in the effected pulmonary tissues. Indeed, calomel, owing to its prompt action on the intestinal tract, is one of the best therapeutic agents at our command, in any of the acute infectious diseases. But I believe it is chiefly owing to its antiseptic properties in destroying the diplococci of Fraenkel, in the mouth and fauces, and the removal of the ptomaines from the gastro-intestinal tract, that we owe so much to it. The result of the application of the cold wet compresses was highly satisfactory. They were applied assiduously every hour until fever was reduced 3.5 degrees. This took place after the eighth application, when they were discontinued. But whenever the temperature rose to 103 degrees they were resumed as before, and always with prompt reaction. The heart's action, after the reduction of temperature, was greatly modified, pulse fell to 100, but strong, full and regular. The delirium and restlessness, which he greatly suffered from in the onset of the disease, passed away and remained absent after the first reduction of temperature. No medicines were administered during the active stage of the disease, but when crisis ensued, which occurred on the seventh day after the initial chill, strychnia was used hypodermically (one-fortieth gr. every four hours with diluted whisky by mouth). They were discontinued after a few days for tonics and expectorants, until patient recovered. The effects of the cold wet compresses on the patient were, a clearing up of the mind, fuller and deeper inspirations, calmer countenance denoting diminished irritation of the nerve centers, sleep became more restful, and the skin and kidneys acted freer.

No doubt the constant application of the cold compresses on the surface of the body while the fever was in the ascendancy, invigorated the nerve centers through the indirect stimulating influence they had upon the peripheral fibers of the skin—the latter always presenting a ruddy hue and being active in

perspiration. Then the reduction of temperature lessened the amount of tissue destruction, and the vital organs, especially that of the heart and kidneys, received a rehabilitating influence from the toned-up nerve centers, which in turn resisted the toxic elements coursing through the circulation.

In the other malignant cases of croupous pneumonia, which happened to come under my immediate notice during the last three years (thirty-eight in all), and treated similarly to the one already mentioned, the temperature vacillated between 103.5 degrees and 106 degrees. In each case the organ of circulation labored hard and showed signs of exhaustion; but under this local anti-pyretic stimulant, behaved well. The cold wet packing in a sheet, and sponging the surface of the body with cold water, were the modes of application employed. This was practiced, on an average of every three hours, until the constitutional effects of the disease showed signs of waning. It usually reduced the temperature from 1.5 to 3.5 degrees, without producing the slightest discomfort—in fact the patients appeared to enjoy it. The usual temperature of the compresses was 60 degrees F.; and though pneumonia patients are as a rule very susceptible to the influence of cold application, the reduction of temperature being frequently marked after the third or fourth application, in some cases its action is not so prompt, requiring diligent and persistent effort in applying cold compresses, perhaps for hours before reduction of fever is noticed. But whenever the cooling process begins, the fever gradually continues to fall and appears to be under easier control, thereafter, than in the susceptible ones. The reason of this, no doubt, is owing chiefly to the more direct poisonous effect of the toxic elements on the sympathetic system or to its chief cervical ganglion; or perhaps to this heat-producing center being more impressionable or under more direct influence of the nervous system. But in either case, whenever the activity of the toxic agents are under control, their elimination is only a question of time when the danger mark is passed. I may be allowed to reiterate that I did not resort to the use of any direct or indirect anti-pyretic medicine internally, save the use of stimulants when cases demanded them. But while cough was severe and annoying, and pleuritic pains present interfering with respiration, I used morphia, hypodermically, in moderate doses from one-twelfth to one-fourth gr., every four to eight hours, until relief was obtained, when they were suspended. I also employed strychnia in the same manner, from one one-hundredth to one-thirtieth gr., and occasionally nitroglycerin in one one-hundredth gr. doses, when I considered the heart and circulation needed them. I used in a few instances, with good effect, hydrate of chloral in moderate doses, diluted freely with syrup and water, when patients were greatly harassed from want of sleep and rest. This drug, though considered an intense depressant upon the nerve centers at the base of the brain when given in full doses, causing more or less weakness of the heart's action, is quite different when administered in small doses. It acts more as a stimulant to these centers, and as a powerful and certain hypnotic to the cerebrum. I occasionally employed, when patients were suffering severely from either occipital or frontal headache, a combination of bicarb. soda, grains 2; acetanilid, 2; phenacetin, grains 3; codeia, grain one-sixth; one given every three hours until the desired effect was obtained, when they were immediately sus-

ended. I consider the combination a useful adjunct, especially in some instances, in combating symptomatic cephalalgia, due to its sedative or quieting influence, without producing any depressing effects on the nervous system or heart. Also I invariably administered, as early as possible, a free dose of calomel, either alone or in combination with some mild cathartic, to start up the hepatic and intestinal secretions: repeated only when necessary. Indeed it is very important for several reasons that the functions of the stomach and bowels should be maintained, especially during the active stage of the disease. The lymphatic system is usually very active, during this time, in excreting from the blood all poisonous matters, and conveying them to the chief emunctory organs, viz.: the kidneys, cutaneous sweat glands, lungs, liver and the intestinal mucous membrane. But none of these excretory organs can be acted upon as readily as the latter during the pyrexial period, in excreting and eliminating the waste products of disintegrated tissues and other effete matters containing ptomains. If these secretions remained too long in the intestinal tract, they would naturally incapacitate the chief functional property of the stomach and bowels, that of proper digestion and assimilation, whose active duties we rely upon for nourishing support. I do not believe in too active catharsis, for it is too depleting, and tends to weaken the general system; only sufficient to cause two or three bowel movements daily. The sick room in each case was kept as well ventilated as possible, and at about 70 degrees. As far as possible, absolute quiet was maintained, with good attention to the regulation of the stomach and bowels, and the giving of good wholesome, plain nutritious diet in liquid form during the pyrexial period, and resorting usually about the period of crisis, to the use of alcoholic stimulants. I abstained from the use of all depressing drugs and cough mixtures, for from past experience I had found that they produced more or less gastric irritation, with intestinal disturbance. The hypodermic injections of the morphia salts appeared to better alleviate the pain and harsh cough.

Such, in a brief way, is the manner in which these cases were managed, suffering as they were from a malignant type of croupous pneumonia, and all but two made good recoveries without serious complications, a maximum saving of 94+ per cent., while under the old routine expectant régime I was exceedingly fortunate in saving 60 per cent. Indeed, by this plan of treatment I was able to reduce the excessive fever sufficiently to enable the heart to have some repose, which enabled it to withstand the severe muscular strain during the period of crisis. Yet I believe had I practiced the German or Continental method in the obstinate or erratic cases, that of placing them in baths and keeping them there from fifteen to thirty minutes, beginning first with a temperature of 90 degrees, gradually reduced to 68 degrees, there would have been more rapid and complete reduction of temperature and it would have remained absent longer than by the method employed.

I believe it impossible to reduce to any degree of satisfaction the excessive fever in this disease by any other process without producing a tendency to heart insufficiency. The several derivatives of cool-tar products are all valuable, and perhaps in some instances reliable internal antipyretics, but they have a tendency to produce heart weakness when given in large doses, and as a consequence limit the eliminating process of

the excretory organs. Salol and quinin are two very valuable remedial agents in abating pyrexia, but they too are not sufficiently potent to cause much reduction of temperature without exaggerating nervous symptoms and arresting the secretions. They are more adapted, along with the muriate, carbonate and iodid of ammonia, after the crisis has taken place and the disease become purely local, as stimulating alterative tonics; and as for any of the depressants I leave it for you to decide concerning their antipyretic virtues in cutting short or abating a true case of croupous pneumonia. For myself I have no faith in them whatever, because they are heart depressants, and when any drug assumes that particular therapeutic phenomenon, not only deficient elimination of the substances generated in excess by such excessive heat in both the tissues and blood occurs, but their retention or suspension in the system have a very deleterious or poisonous effect on the nerve centers and ganglia, and should the accumulation of urea, uric acid, carbonic acid and other detritus remain too long in the system paralysis of the vital organs would inevitably ensue and death result. Yet even several of our most prominent medical writers and observers, and indeed a very large proportion of general practitioners of apparent large experience, still cling to the old antiphlogistic plan of treatment, believing that not only better results can be obtained from its practice, but that by a sudden sharp reaction of the general circulatory organ, either by large doses of any of the selected depressants frequently repeated, or perhaps by blood-letting in plethoric cases, with the constant application of hot poultices, and perhaps sinapisms, they can abort or at least limit the inflammatory lesion of the lung to a very circumscribed area, from which little danger can be expected. This I believe is owing to their positive convictions, based on what I should term old pathologic fallacies, having for their ground work or argument that croupous pneumonia is purely a local manifestation and not the resulting pathologic lesion. If we look over the statistics, dwelling upon results obtained by the use of cold applications, coupled with the employment of some active alcoholic stimulant, as that of whisky or brandy, when actually needed, in comparison with the regular or uniform methods, viz.: By general internal medication in conjunction with hot applications externally, etc., whether in hospital or general practice we will be forced to admit, though we have to refer and rely upon Jurgensen's reports compiled more than twenty years ago (for we ourselves have no such compilations of documentary materials to draw from of any account), that it had a greater saving of life by over 10 per cent. in its malignant form. Even as early as 1866 to 1876 the mortality decreased at the Basel clinic, and according to Liebermeister, in a given number of cases nearly 10 per cent. from the usual routine treatment practiced the ten years previous, a showing which is not only correct, but astounding, when considered how imperfect their practical knowledge must have been in carrying out the principles of treatment their minds suggested at so early a day, and in the face of public opinion or censure. Yet in the face of this it is equally amazing why the very laity in all our land should not only indulge in suggesting what the treatment in this subtle specific affection should be, especially when disease assumes a serious aspect, but persist in having us practice the old-time antiphlogistic plan, or the general routine treatment with

hot applications, etc., when in their hearts they are forced to acknowledge they can not discriminate between the depressing effects of the one and the exhilarating virtues of the other. How this belief has become so thoroughly instilled in the minds of so many apparently intelligent persons is a mystery to me, unless it is from our own lack of self-independence and fear of public censure. But such is the fact, for I have experienced it to my full satisfaction in several instances.

Now in regard to the proper administration of diet. The food should be nutritious and easy of assimilation. Beef tea, beef, mutton or chicken broths, with eggs and milk are the most valuable articles and should be given at regular intervals and in definite quantities, four to six ounces every two hours, and if required, peptonized. And as to the use or employment of stimulants, their chief indications are the occurrence of delirium, a very rapid, weak or dicrotic pulse, especially when associated with adynamia or collapse with low nervous symptoms. They should also be given to patients who are old and feeble, who expectorate with difficulty on account of the excessive viscosity of the sputa. Blisters, hot fomentations, with or without anodynes and sinapisms are only useful for the relief of pain in the advanced stage of the disease. Dr. Beale claims that when the kidneys are in good repair large doses of either brandy or whisky may be given with good results; that owing to its direct action on the nerves of the stomach, it immediately stimulates the heart's action and thus promotes the capillary circulation. Also after the absorption into the blood it alters the consistence and chemic properties of fluids and solids and cuts short the life of rapidly-growing bioplasm, or causes it to live more slowly, and owing to its contractile influence it renders the walls of the vessels less permeable to fluids and checks the disintegrations of blood corpuscles. His opinions are well founded, but the employment of alcoholic stimulants should be used only when the case actually demands it, and that is usually about the period of crisis.

There are other symptoms pertaining to this affection which need considerable attention, but I am unable to dwell upon them now. They are all referable to the digestive organs and often cause great annoyance. Thirst perhaps stands most prominent. Cooling drinks agreeable to the patient's taste should be given freely throughout the pyrexial period.

Such then, in a brief way, is the treatment I advocate in the management of a malignant case of croupous pneumonia. I rely upon cold applications in the subtraction of excessive heat and the use of only such remedies as are adjuncts in alleviating annoying symptoms above all other measures so far advanced. Also I would advocate its use in the catarrhal forms as well and the regular cold bath in obstinate cases, as already stated, as a mode of application in preference to the other methods. I am sure it is the most valuable and reliable form of treatment at our command in combatting excessive temperatures in this disease, either in the home or at the hospital. All we want is courage and self-reliance, and good competent nurses, and unless the disease assumes a terribly malignant form, will yield to its stimulating influence and run its natural course without producing much damage to the patient.

DISCUSSION.

Dr. H. A. WEST of Galveston, Texas—The author empha-

sizes unnecessarily the purely mechanical effects of pneumonia, and leaves out of view the action of the toxins; he also emphasizes the elevated temperature unnecessarily. We do not know to what extent the high temperature may be a conservative process, and while the action of the cold bath may be beneficial, its action is probably to be explained by other facts than its mere influence upon the temperature, just as in typhoid fever its effect is upon the nervous system, stimulating the circulation, respiration and skin. So we should take into consideration the necessity for counteracting the effects of the toxins of the disease. Many patients with pneumonia are in a condition like that of a man who has been bitten by a rattlesnake, and the same indication exists to counteract the toxins by stimulation. I believe there are a number of cases which can not be saved without stimulation by alcohol and by strychnin. When we come across such cases the indication is to keep the patient alive, to keep the vital powers going until nature has time to produce an antitoxin. We can do that most successfully by use of alcohol and strychnin, both given with a free hand. Many other patients will get well without any treatment at all.

Dr. WAINWRIGHT, Kansas City, Mo.—I believe that pneumonia requires the most scientific treatment of any disease which medical men are called to see; that more lives can be saved by the study of pneumonia and the proper application of drugs than in the treatment of any other fever. The indications for treatment so far as the heart is concerned are not, in my opinion, laid down in text-book literature. The average practitioner, when called to the bedside of a patient suffering from pneumonia, is unable to tell when alcoholic stimulants, strychnin or any cardiac stimulant is indicated. Why? We are taught to watch the pulse and study the first sound of the heart. The part of the heart to study in pneumonia is the right side. We have not exactly the same pathologic conditions present here in the right side as in hypertrophy of the left ventricle without pneumonia. In pneumonia nature makes an effort to compensate, but she has not time. If the time were long enough hypertrophy would take place in the right side of the heart in pneumonia. Then the question arises whether we shall give stimulants. In some cases alcohol and strychnin are positively and decidedly indicated, yet they are in some cases responsible for the death of the patient by causing exhaustion of the heart. When we give alcoholic stimulants it is at the expense of stored up energies of the heart, and they ought not to be given until they are decidedly indicated. I claim that the indications for the use of alcohol and stimulants in pneumonia depend upon the state of the right side of the heart, which can be determined by careful study of the pulmonic element of the second sound. The right side fails first.

One other point relating to the pathologic condition which embarrasses the right side of the heart. In addition to the hepaticized lung, there is vicarious emphysema in the healthy lung. In emphysema of the lung the right side of the heart is always greatly embarrassed.

Dr. E. B. BORLAND of Pittsburg—We have in pneumonia, not only a weak or partially paralyzed heart, but also a markedly depressed condition of the vasomotor system all over the body. The cold-bath treatment is in vogue both as a local and as a general treatment. The local cold treatment in pneumonia seems to me too much like imitating nature's way of chilling the body, and it is not nearly as efficient as the general cold bath in stimulating the vasomotor control of the vessels of the body.

Dr. CAMPBELL—I did not have time to finish reading my paper. In reply to Dr. West I did dwell on the use of strychnin and alcohol when necessary. But what I wished to express fully was the influence of the nerve centers, the sympathetic system particularly, on the course of pneumonia. The toxins are absorbed and carried to the nerve centers of the cerebrum, and there cause paralysis, which affects the nerves, including the sympathetic ganglia, which Brown Sequard has shown to be related to the heat production of the body. Cold applications stimulate not only the vasomotor system but also the sympathetic system, getting rid of the toxins and the ptomaines through the sweat glands, the kidneys and the bowels.

HOT BATHS IN PNEUMONIA.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY JOSEPH EICHBERG, M.D.

CINCINNATI, OHIO.

The hot bath, as employed at the Cincinnati Hospital, is given in pneumonia at a temperature of about 100 degrees. In the cases which furnish the material for this report the temperature of the water has been at times 95, at others 102 degrees; in a few cases a temperature of 110 degrees has been advised. Judged by results, no very great difference could be observed dependent upon the slight elevation of temperature in the water employed. A tablespoonful of whisky is given before immersion. The tub is moved alongside the bed of the patient and immersion of the body is complete, the level of the water rising to the chin. The stay in the bath is prolonged to ten minutes, during which time the face is frequently sponged with cold water. On emerging from the bath the patient, without previous drying of the skin, is wrapped in a warm dry blanket, in which he remains for half an hour. The bed clothing is then changed, the skin rubbed vigorously until dry and the patient left for the next three hours, when the process is repeated.

When first entering upon this plan of treatment, I thought of it only as an antipyretic measure, and the bath was advised when the body heat rose to 103 or 103.5 degrees. It was soon observed, however, that the good effects of the bath were to be found not so much in its antipyretic action, as in its influence upon the general comfort and well-being of the patient. From that time on, the bath was ordered wholly irrespective of the high or low degree of fever, and was given regularly every three hours.

I shall have occasion presently to refer to some figures. It is but fair to repeat what experience in hospital life has taught many clinicians, that in no acute infectious process are figures so likely to prove deceptive as in the case of this disease. Hospital cases of pneumonia afford, in the first place, the very worst material upon which to base working conclusions as to the value of remedial measures. Weakened by intemperance, exposure, privation or previous disease, the pneumonic process overtakes these patients at the lowest ebb of resisting power and speedily terminates a checkered existence.

Aside from this potent factor, which influences so greatly the percentage of hospital mortality, there is something in the type of the disease which makes its percentage of fatalities very variable. There are times when the number of cases received in public institutions is considerable enough to warrant the title of its epidemic prevalence; yet the number of recoveries is so great that too much is allowed for the operation of some particular therapeutic measure. In another series of cases the same plan of treatment signally fails. The startling figures of Petrescu with the digitalis treatment, showing a mortality of only 2 per cent. in upward of seven hundred cases, can be explained only in this way, since later experience has unfortunately failed to confirm the vaunted universal efficiency of this drug.

Taking all these factors into account, I am strongly inclined to the belief that we have in the hot bath a powerful adjuvant in the management of this disease; nor would I ascribe to it any secondary rank, believing it to be of almost greater importance

than any single feature of the treatment. The most powerful argument is found in the request of many patients for its repetition. Strongly averse to its early employment, they soon experience so much comfort from its frequent application that in many instances patients have asked to be put in the bath before the time for its repetition had arrived.

This sense of greater comfort especially affects dyspnea, and thus strengthens the impression now gaining ground that dyspnea in pneumonia is not dependent on the extent of pneumonic consolidation nor in any sense proportioned to it, any more than is pulse rate or temperature. It seems difficult to combat this old and at one time widely promulgated doctrine. On the day following the crisis, when the clinical picture has undergone so great a transformation, the physical signs remain unchanged. The dyspnea of the preceding period has wholly disappeared, yet there is quite as much consolidated lung as there was the previous day; and a considerable period may yet intervene before the affected lobe is wholly rid of inflammatory products. The dyspnea is to be interpreted as part of the intoxication due to specific infection, and resulting from the action of the poison on the mechanism of respiration.

It is just in this connection that the association of the skin with the mechanism of respiration deserves especial mention. Ordinarily, cutaneous respiration in the human being is of little consequence as far as the actual exchange of gases is concerned. Scharling and Hannover estimated that the exhalation of carbonic acid gas from the skin bore to the total amount the proportion of 1 to 130; Gerlach gives it as 1 to 200. So small a fraction as this could hardly influence the general well being. Much more important are the well-known experiments of Soskolow, Lang, Berne, Loschkowitz and others in suppressing the function of the skin by covering it, in its entirety or in limited portions, with a coating of some impervious material. As is well known, death promptly ensued when one-fourth or more of the skin had been thus treated; and death was not, as had been first

believed, due to excessive cooling, seeing that the retention of the animals in warmed ovens only delayed, but did not avert, the fatal issue.

It could not be supposed that death was due to retention of excrementitious matter or auto-intoxication, for the blood of the animal that had thus succumbed was not toxic when injected into the circulation of another of the same species. The only probable inference was that death ensued as a result of the suppression of the respiratory stimuli emanating from the skin. The need for air, like the sense of hunger and thirst, is not a localized sensation, though referred to the larynx; all parts of the body participate in sending to the center the urgent message for more oxygen when the proportion falls below the minimum for actual consumption.

The temperature in some cases seems to be influenced but slightly by the bath, as far as immediate results are concerned, there being no strikingly rapid fall, though the general febrile course is certainly controlled in some measure; for there is almost always from the first day of the bath treatment a slight lowering of the daily average, which continues from day to day; so that the critical fall entails a drop of but two or three degrees, the temperature being nearly normal at the time of the crisis. At other times a striking improvement in the range of fever manifests itself; the accompanying chart may be fairly taken as a type of many that present an almost identical picture.

As an antipyretic, the hot bath is not less effective than many of the recognized aniline antipyretics. In my collection there is the history of one patient, a colored laborer aged 20, whose temperature on the second day rose to 105 degrees. He received 10 grains of phenacetin; one hour later another dose of 10 grains; the following hour a similar dose, the temperature still remaining at 105 degrees. When the infection is intense, no antipyretic measure is likely to be attended with very striking results. With the aid of the hot bath, many cases present a prompt decline. A laborer, aged 40, had an evening temperature of 104.6 degrees. The hot bath was given at 6, 9 and 12

P.M. The temperature steadily declined until noon the following day, when it was normal. It rose slowly to 101 degrees on the third day, but never exceeded this. The crisis occurred on the fifth day. In another patient after the sixth bath the fever declined from 104.2 to 99 degrees. Instances similar to these could be multiplied.

The effect on the respiration, while not so striking, is none the less certain. At times the change after the bath is so considerable that the diminished frequency must be regarded as conservative, enabling the patient to husband his strength. In the patient whose chart is shown the frequency of respiration before the bath was 35 per minute; after the second bath it dropped to 24 per minute. In other cases the difference was less, amounting to 4 to 6 per minute; even this improvement is not to be disregarded in a disease in which the resisting power of the individual turns the balance for or against recovery. In another patient one bath reduced the frequency of breathing from 42 to 30 per minute. Two recoveries are noteworthy; one where the respirations were 80 per minute, nother where for three days the rate was 60 per minute.

The greatest relief is experienced in the prompt suppression of certain nervous symptoms of rather frequent if not constant occurrence. Of these one of the most distressing is a sense of "indefinable unrest," a term employed by a colleague now passing through his convalescence from a pneumonia of the left lower lobe, and who, after his second bath, marveled at the placidity and comfort experienced. Similarly, great benefit is experienced in combating the insomnia which enters very regularly into the early history of the attack. Delirium subsided promptly in all cases except those complicated with alcoholism or meningitis.

It may have been mere coincidence, or it may have been due to the bath, that many of our patients seemed to void larger quantities of urine than did those in the ward where this treatment was not regularly employed. I am unwilling to express final judgment until our observations shall have been more fully verified. It is not unlikely, however, that the dilatation of the peripheral vessels following the bath may involve other small arteries in the systemic circulation and thus allow of more ready filtration through the kidney.

The pulse is modified by the systematic use of the hot bath rather in its quality, than notably in frequency. The hard, bounding, vibratile pulse of what our fathers called sthenic pneumonia, gives place to a pulse that is softer, more gradual, compressible, not lacking in force, while wholly without the thrill connected with the earlier periods. In this respect the hot bath can be confidently counted upon to modify the pulse in the same manner observed after the former regulation process of blood-letting. Indeed, the hot bath gives us the power of letting blood without losing it; by opening up the superficial arteries and capillaries, we obtain an action that equalizes the circulation in furnishing channels other than the congested pulmonary vessels, to which the afflux would otherwise take place. It may be that it is of no especial advantage to the patient to retain a blood undoubtedly charged with many toxic principles; but it is easier to save it than to reproduce it and, as already stated, the power of resistance counts for much during a process essentially short and self-limited.

In how far the local process itself is influenced it might seem venturesome to say. On several occasions, four that I now recall, the first examination had shown impending involvement of an entire lung; dulness on percussion, increased resistance and diminished or absent breath sounds being found over an entire side. After the use of the bath the limitation of the process to a single lobe has been clearly evident, the unaffected lobe clearing up very promptly. This may have been occasioned by the relief of a collateral congestion which would never have advanced to consolidation, or the bath may have actually limited the distribution of the disease by prompt diversion of blood to the surface.

Still more difficult is the determination of any increased elimination of toxic material through the skin, in consequence of the bath treatment. That such toxic products exist may be inferred from the leucocytosis accompanying the disease, from the increased toxicity of the urine at the time of the crisis, as shown by Roger and Gramme; from the frequency with which death occurs by the heart at a time when convalescence seems established and acute symptoms have subsided, and from the actual discovery of the pneumococcus in the blood. Thus Kohn examined the blood in thirty-two cases with negative results in twenty-eight; eighteen of them recovered. Of the remaining nine, seven showed the pneumococcus and died, the other two died from staphylococcus empyema. Admitting that such toxic principles probably exist, the patient's chances are only likely to be improved by stimulating the skin to further activity; the hot bath offers opportunity for doing this in the simplest manner.

Patients receiving the bath are allowed full, nourishing, concentrated diet. The bowels are moved regularly by enema. Medication has generally consisted of small doses of digitalis and strychnia. Expectorants were ordinarily not found to be necessary.

The hot bath may be given at any age. The oldest patient who recovered was 73 years old. It is universally indorsed for children, on the plea that the use of warm water prevents the nervous shock attendant on the employment of colder baths, such as are recommended for adults; but the adult patient with pneumonia also dreads his cold bath; and the necessary stimulation for the reflex respiratory act can be elicited equally well by bathing the face and head with cold water while the patient is immersed. The frequent repetition of the bath does away with the necessity for local dressings, while the interval of three hours has proven sufficient to allow for rest and sleep.

The number of baths to be administered will vary with the character and duration of the case. I can only repeat that the fever furnishes no indication for the use or repetition of the bath. The average may be given as five or six per day during the febrile period and one or two daily for several days thereafter. The largest number in my table, based upon carefully kept records of ninety cases, was given in the case of a butcher, aged 34, who had successive involvement of three lobes; each new attack supervened as the old approached the crisis, so that the acute period of his disease extended over twenty days. During this time he received 137 baths. The patient recovered. Another patient, a cigar-maker, aged 19, suffering from an old mitral regurgitation upon

which the pneumonia supervened, received seventy-four baths in eleven days and recovered. A third patient, a fireman, suffering from an old caseous phthisis of both apices in addition to his pneumonia, received thirty-three baths in six days and completely recovered from his pneumonia.

Recourse to the bath from the earliest period of the disease is to be strongly commended. Naturally the diagnosis must often be deferred for three or four days, owing to obscurity in physical signs. When, however, the nature of the disease is no longer doubtful, the bath treatment should be promptly instituted. Experience has shown that the patient is thus kept in better condition and the course of the process influenced more decidedly than if the bath is given at a later stage.

Of the ninety cases forming the basis of this report seventy-one recovered and nineteen died. Four of these were moribund on admission, and of the others there was the usual contingent of chronic nephritis, pericarditis and tubercular diseases; six died quite suddenly, two on the fourth and two on the seventh day, while the remaining two succumbed when all danger seemed past, one expiring during a meal, the other just after he had answered that he was much better.

I believe that wider experience with the hot bath will but add to the conviction of its general utility in the management of one of the most fatal of acute diseases. In private practice the mortality is not so appalling, but in hospital life no other acute process claims so many victims. Where the bath can not aid in cure, it rarely fails to assuage, and it is not the least of the physician's duties to bring comfort to the sick.

DISCUSSION.

Dr. WISNER of Baltimore—I would ask the author whether there was free diuresis after the bath, and what was the temperature. I have had a considerable experience with the tepid bath in the pneumonia of children among poor people, especially among people not given to cleanliness. Repeated tepid baths, three or four a day, were sufficient in many instances without any other medication to alleviate the symptoms and hasten the cure in the cases where there was no constitutional taint to make the disease a mixed one.

Dr. F. S. NEVELING of Clearfield, Pa. I rise to favor the warm bath. With regard to the lancet, while years ago it was used too freely, I think that of late years some do not use it enough. In some cases of pneumonia especially it will give the greatest relief. I have employed it, in certain cases, more than twenty years and have never regretted it, except in one instance. I do not bleed in every case, but when I find a very severe one in the early stage the withdrawal of some blood gives almost immediate relief. I have treated no fewer than two hundred cases of pneumonia and of that number have bled, I presume, 25 per cent. It is contrary to the treatment laid down in the books and I always hesitate to say anything about it, but I have been so successful with it and it gives so great relief that I think it should be resorted to not only in pneumonia but in some other diseases as well.

In reply to an interrogatory when he used bleeding, Dr. Neveling said: When the temperature is high, the patient very restless, the lungs engorged, the heart's action embarrassed. Bleeding seems to stimulate the heart, the patient soon falls into a peaceful slumber and then perspiration breaks out. I order warm baths every three hours after that. Later judicious stimulation may be of benefit. I know that if the patient should die I would be told that I had killed him, but I have never yet lost one that I have bled.

Dr. S. SOLIS COHEN—What has been the influence of the baths on the urine? What about the temperature of the bath?

Dr. EICHBERG—Very frequently, when the patient is taken out of the bath the amount of the urine is increased. He is wrapped in a hot blanket and left an hour without any drying, and is then dried only in case the skin is very active. As to bleeding, I felt sure that would arise in the discussion. One of the objects of the paper was to call attention to the fact that

the bath took the place of the bleeding. The temperature of the bath is higher for debilitated patients. With regard to the cold water treatment, there was a man who, on sending his boy out into the world, gave him this piece of advice: "My son, honesty is the best policy. I know, for I have tried both."

CURABILITY OF PULMONARY TUBERCULOSIS.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association held at Philadelphia, Pa., June 1-4, 1897.

BY E. B. BORLAND, M.D.

Clinical Lecturer, Diseases of the Chest, Medical Department of the Western University of Pennsylvania; Assistant Physician to the West Pennsylvania Hospital.
PITTSBURG, PA.

Evidence has been recently accumulating, which goes to show that tuberculosis is not only a universal but *the* universal disease. Postmortem examinations made in recent years, point to the probability that 25 per cent. is much too low an estimate of the total number of infections.

Schlenker made one hundred consecutive post-mortem examinations on children and adults for this special purpose. He examined every part of the body, especially the cervical and mesenteric glands and apices of the lungs, and found 65 per cent. tuberculous. Caseous and calcareous degenerations were considered tuberculous but simple fibroid adhesions were not so considered. In over 4,000 successive postmortem examinations made in Breslau in 1893, one-third of the bodies contained gross tuberculous lesions. If the microscope had been used, probably enough lesions could have been discovered to make 2,500 infections.

Turning to pulmonary tuberculosis, Babes found lesions of the bronchial gland in more than one-half of his postmortems on children. Biggs could demonstrate characteristic lesions in the lungs alone, in 60 per cent. of his postmortem examinations. Grawitz found primary tuberculous deposits in the lungs in 152 out of 221 cases, being nearly 70 per cent. of all infections. Loomis found the bronchial glands infective to rabbits in eight out of thirty bodies apparently free from tuberculosis during life. Long before Koch discovered the tubercle bacillus, Louis laid down the rule, that if tuberculosis was found in any other part of the body it would be found in the lungs.

From the above observations, it will be a moderate estimate to say that nearly 50 per cent. of the human race are infected at some period of life with tuberculosis, and further that two-thirds of all infections are pulmonary. The greater frequency of the pulmonary over all other tuberculous infections is directly due to the inhalation of fine particles of dried sputum, containing tubercle bacilli and the pus-producing germs.

Large as the death rate (14 per cent. of deaths from all causes), when the number of cases which remain latent through life, is taken into consideration, the tubercle bacillus does not seem to be a markedly virulent germ. It requires, besides its own existence, two additional essential factors, viz., debility and abrasions, before infection is possible. Without the addition of septic germs, pulmonary tuberculosis would not in all probability, be the fatal disease it is today. The vile habit which American people have (for Europeans consider it an evidence of ill breeding) of expectorating on floors and sidewalks, has much to do with the transmission of septic germs as well as tubercle bacilli, to the lungs. All advanced cases are associated with streptococci.

While the bacillus is the keynote to the identification of tuberculosis, it has probably less to do with the fatal termination than was formerly supposed. When the blood and juices of the body contain pus-producing germs in eight out of fourteen cases, the septic germs must be held responsible for at least one-half of the destructive process.

Nature can wall up tubercle bacilli with bodies of leucocytes and connective tissue cells, for life, but can not imprison septic germs for any great length of time. If, as it seems probable, tuberculous lungs die mainly of the engrafted septicemia, then tuberculosis without sepsis or where sepsis can be avoided, is a disease capable of permanent relief. It is well known that hectic fever of the ulcerative stage, is mainly due to streptococci and staphylococci. The large proportion of cases dying of septicemia, probably explains the failures of tuberculin and tubercle antitoxins. Original investigation is always to be commended so long as there is a ray of hope, but since not a single antitoxin has been discovered, for any chronic disease, the scientific physician will do well to use, to the full extent of his ability, the older light which still shines clearly.

Tuberculosis uncomplicated with sepsis, may be considered a curable disease, in the sense that it may be held in abeyance, that is to say, kept in a latent condition for a lifetime, providing the vital resistance of the individual is kept up to the normal standard. Nature has been known to completely eradicate it in a limited number of cases. The scientific physician will endeavor to imitate nature as far as he can interpret her methods.

Investigations in search of an antitoxin have demonstrated that there is no immunity against tuberculosis when the three essential factors of infection, viz., debility, abrasions and bacilli are present. If there was anything in the theory of immunity, a child born of an infected mother ought to be less liable to infection after birth, other things being equal, on account of its being almost constantly inoculated with toxins during intra-uterine life.

The question arises, can tuberculosis be cured in all to all intents and purposes in its latent stage? It has been demonstrated that two-thirds of all infections either disappear or remain quiescent during an average life. If nature can accomplish so much under the reign of mainly empirical medicine, what will she be able to do when the physician concentrates all his energy on building up and maintaining the vital resistance of cell life, and keeping septic germs, as well as tubercle bacilli, away from the latent infection.

If latent pulmonary tuberculosis is to be taken proper care of and its curability further increased, it must be discovered promptly. This is too infrequently done at the present day. The early suggestive general signs of chronic indigestion, flushed cheeks, enlarged lymphatic glands, anemia, scanty or suppressed menses in the female, dislike for meats (especially fats) and the special early signs of a small localized area (in one lung) of harsh respiration which persists, usually in smaller bronchial tubes, jerking inspiration and prolonged expiration, impairment of the percussion note, especially in the apices, and a chest expansion of less than three inches, are over-looked when they ought to be discovered and their importance carefully weighed in the mind of the physician.

The curability of disease is not necessarily connected with the exhibition of drugs. In fact nature

alone cures, while the scientific physician only aids her.

The hygiene of latent pulmonary tuberculosis must receive more attention if it is to be more curable. Moderately dry aseptic air containing as much ozone as possible is the matter of vital concern. Altitude itself has probably little influence. True, the lungs expand and unused air cells are ventilated at the expense of the life-giving element oxygen. The watchword should be, keep latent pulmonary tuberculosis as free from the death-dealing putrefactive germs as possible. Attention to the excretory organs, especially the skin, will materially aid in crushing out or keeping pulmonary tuberculosis latent. The skin throws off toxins promptly under circumstances when the other excretory organs are unequal to the task. Woolen clothing assists this excretory process; cotton checks it. Wool is a poor conductor of either heat or cold and is therefore always indicated. Nature clothes the lower animals with wool, while only foolish man insists on wearing woody fiber and as a result he suffers.

It is self-evident to any careful student of dietetics that the animal foods (except pork) require less digestive and assimilative force and elaboration, to build them up into physiologic tissue, than foods from the vegetable kingdom. Digestion may be regarded as the balance wheel and should be carefully guarded. Such agents as cod-liver oil, preparations of creosote, iron, phosphorus, strychnia or oil of cinnamon, may be employed when the vital resistance falls much below the normal standard.

Moderate pulmonary gymnastics have an important bearing on the individual's future prospects for life and health.

The author has nothing new to offer on the curability of the ulcerative stage, that is to say, the well developed mixed infection. Perhaps less than three per cent. throw off both infections and fully recover. In probably 20 per cent. the disease becomes quiescent, and remains for a number of years and is then lighted up again. The average life of the remaining 77 per cent. may be placed at two years.

Recent investigations in search of specific treatment have not discovered any factor of much value in the cure of the mixed infection. The posting and enforcing the placard "gentlemen will not, others who do not class themselves under this title, must not expectorate on floors and sidewalks," would do more to improve the prognosis of either stage of pulmonary tuberculosis than all the toxin or antitoxin treatments of the last decade, from Koch's original tuberculin down to his TA, TO and TR.

The belief that tuberculosis is inherited has done much to propagate the disease as well as to lessen its curability. Fortunately very few physicians now place much emphasis on heredity or question the contagious nature of the disease. Those who do, have not examined the almost incontrovertible proofs. Men who doubt the existence of a specific germ or question its power to do harm, are not only clogging the wheels of preventive medicine, but of curative measures as well.

Believing that pulmonary tuberculosis is a germ disease, frequently associated with the more virulent septic germs is a decided advantage in formulating a rational therapeutics. While no germicide has been discovered which will kill the germs without destroying the tissues in which they are planted, yet much

can be done toward neutralizing and eliminating toxins, and even inhibiting the growth and multiplication of the germs themselves.

Too many medical men, with almost unused measures of relief within their grasp, are today lying supinely on their backs, hugging the delusive phantom of an undiscovered specific treatment, while the great white plague, with its insatiable, relentless and ruthless ally, is still destroying thousands of valuable lives which ought to be saved.

ANTITOXIC SERUM FOR TUBERCULOSIS.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY E. A. DE SCHWEINITZ, Ph.D., M.D.

DIRECTOR, BIOCHEMICAL LABORATORY, BUREAU OF ANIMAL INDUSTRY, DEPARTMENT OF AGRICULTURE, WASHINGTON, D. C.

In speaking briefly of the preparation and use of antitoxic serums in my laboratory, it may be of interest to note a few points which indicated the advisability of the method I have used for treating animals to produce the desired serum.

The preliminary experiments, published in 1894¹ on the production of an immunity or resistance to tuberculosis by attenuated cultures, have been continued and are confirmatory of the first results, showing the production of great resistance and in some cases complete immunity. A detail of two sets of these experiments may be given as an instance of their general results.

TABLE 1.—Two sets of experiments showing the average of results in experiments in which the guinea pigs were vaccinated with attenuated germ and then inoculated with virulent germ.

The first effect of the injection of the attenuated germ was, in some instances, to cause a slight decrease in weight; sometimes a local swelling was noted at the point of injection, and occasionally an enlargement of the inguinal glands. This disappeared after

some weeks. This local swelling is probably due to the mechanical action of the bodies of the germs on account of their high fat content and possible presence of a minute amount of the acid causing necrosis. It does not always result from a subcutaneous inoculation and an apparent immunity to this action is acquired by repeated injections. This is well shown in horses and cows submitted to treatment with the attenuated germ. From six to eight weeks after the date of the injection of the germ guinea pigs seem to be entirely well, and are then inoculated with the virulent germ. As can be seen from the table, the checks died within six weeks from date of inoculation while the others, vaccinated remained well four months afterward. It has appeared, from the many experiments, that, if the inoculation with the virulent germ is made before complete recovery from the treatment with the attenuated germ the resistance is considerably less. The inoculation of the animals with the virulent germ and subsequently with a single injection of the attenuated germ showed that the latter produced a slight resistance but no very material retardation of the disease.

The production of this partial immunity or artificial resistance by means of the attenuated germ suggested already in 1894 the availability of this same material for the purpose of treating animals for the production of a serum which would have some effect in curing tuberculosis. It suggested the idea further that possibly cattle could be vaccinated with this attenuated germ and made immune to tuberculosis.

TABLE 2.—Serum from horse injected with attenuated culture used on tuberculous guinea pigs.

No.	Weight—ounces.	Date and amount of virulent culture.	Dates and amount of serum injected—ounces.						
			Nov. 6.	Nov. 17.	Nov. 25.	Dec. 3.	Dec. 8.	April 10.

*Plus 1 1/2 c.c. †Alive and well

Two cows and one heifer were selected for the work which was conducted for us by Dr. Schroeder in charge of the Experiment Station of the Bureau of Animal Industry. One of these animals was originally tuberculous, the other two healthy. The tuberculous animal received large doses of tuberculin until it had received altogether 19,407 c.c. (19 1/2 liters), and as much as 1,500 c.c. of tuberculin at a single dose, from November 1894 to April 20, 1897. The other animals received injections of the attenuated culture, the amount injected in fifteen months being 11,425 c.c. and 18,100 c.c. respectively, and by this I mean the liquid culture media *in toto*, including the germs, just as taken from the incubator without any further treatment. At first the injection produced a slight reaction and occasionally a local edema and abscess. After they had been continued for some time this effect diminished or disappeared. The serum of all of these animals was tested a number of times. Guinea-pigs were injected with the serum in quantities varying from 1.5 to 6 c.c. and subsequently inoculated, together with checks, with a germ sufficiently virulent to kill the checks within four to five weeks, or the pigs were inoculated with the virulent germ and treated by subsequent injection.

¹ Medical News, Dec. 8, 1894.

tions of the serum. Without giving the details of the experiments we may say that the serum from the cow treated with tuberculin would cause in the pigs a slight resistance to the germs, the serum of those treated with the attenuated germ produced more resistance on the part of the animals or prolonged their life to some extent but not sufficiently as compared with the quantity of material injected to make the use of cow serum appear practical. The cow serum, although sterile, frequently produced abscesses in guinea pigs. This serum we expect to test again shortly, when it should be stronger.

While these experiments were in progress two horses had been pressed into service. These were treated by injecting the attenuated cultures, culture fluid germ and all. The first injection of 5 c.c. caused a decided temperature reaction, local edema, stiffness, slight loss of appetite, and recovery after a few days. At first local abscesses were formed but healed fairly readily. After a time the abscess formation ceased. After eight months treatment the doses of the culture being gradually increased to 300 to 400 c.c., the total amount injected in fifteen months equaling 4,459 c.c.: the serum was used for testing. It separated out clear and well. Two sets of illustrations may be given to show its action on tuberculous animals. In one set the checks and two treated pigs died, the other two treated pigs are alive and in apparently perfect health, after a number of months. In another set the checks four in number died within four to five weeks, while the treated ones lived two or three weeks longer showing, on autopsy, much less disease in the lungs than did the checks. We endeavored, further, to isolate antitoxic substances from the serum by a slight modification of the Brieger-Boer method. We finally succeeded in obtaining a small quantity of a grayish powder, giving the biuret reaction, difficultly soluble in water, which was used for treating guinea pigs in the same way as the serum. The result was about the same as in the first instance. The pigs one-half pound in weight were inoculated with a virulent germ and treated by a single injection of 0.008 grams of this solid substance. They lived three to four weeks longer than the checks, the lungs again showing considerably less disease, while less necrosis was noted in the liver than in the checks.

The effect of the serum was also tried in preventing the rise of temperature in tuberculous guinea pigs and in saving them from a fatal dose of tuberculin. The injections of $\frac{1}{4}$ c.c. of diluted tuberculin and at the same time of $\frac{1}{2}$ c.c. of the serum, either caused a decided reduction of the temperature or prevented a characteristic tuberculin reaction in animals weighing 500 grams. This is the way (at present) of gauging the effect of the serum.

The result of all this work leads me to the conclusion that the injection of the live culture produces substances antitoxic to the disease in tuberculous animals, that the quantity of this substance can be increased gradually, that the treatment of tuberculosis is and will be for some time in the experimental stage. One point, however, must be remembered, viz., that while it may be difficult to cure the disease in a guinea pig where its course is very rapid, a virulent germ requiring only from four to five weeks to kill, it might be much easier to check the disease when more prolonged in action, as in the majority of cases in man. Again, in addition to some form of specific treatment for the disease, man usually has the advantage of be-

ing placed under the best possible surroundings as to diet, climate, etc., and every effort is made to aid the improvement of the patient, while with experimental animals the conditions are different. The results obtained undoubtedly lead to the conclusion that while the treatment with antitoxic serum is still in the experimental stage and should be as yet used only in sanitariums and under the best conditions, we are on the road to success and nearer our goal than ever before. In an experimental way, the antitoxic serum as prepared in my laboratory, has been used by Dr. Stubbart at the Loomis Sanitarium, and some by Dr. Trudeau at Saranac Lake, as well as by Dr. C. W. Richardson in this city. Dr. Richardson has reported beneficial results and improvement in his patients from the use of this material. Dr. Trudeau has found that the serum causes a remarkable reduction of temperature, and Dr. Stubbart records satisfactory results. Two of Dr. Stubbart's cases will serve to indicate its general effect.

Serum from U. S. Department of Agriculture, Bureau of Animal Industry, Biochemic Laboratory, used at Loomis Sanitarium, Liberty, N. Y. Age, 14 years; American; school boy. Treatment began Feb. 23, 1897. Feb. 23, weight, 90 lbs.; general condition good; consolidation slight; no cavities; no râles; very little cough and expectoration; no tubercle bacilli; temperature normal; serum injection, 10 minims. Feb. 27, weight 91 $\frac{1}{2}$ lbs. March 1 and 7, no tubercle bacilli; temperature normal. March 9, weight 94 $\frac{1}{2}$ lbs; cough and expectoration less. March 15, no tubercle bacilli; temperature normal. March 25, no cough or expectoration; no tubercle bacilli; temperature normal. March 29, weight 95 lbs. Result: Gained in weight and general condition until discharged.

Serum used at Loomis Sanitarium, Liberty, N. Y. Age 20 years, female, German, nurse. Treatment begun March 1, 1897. March 1, weight 119 lbs.; general condition good; consolidation, incipient stage, infiltration; no cavities; râles, sibilant and sonorous right lung apex to base, left lung at apex; cough bad at times, expectorates very little; temperature normal. March 13, no tubercle bacilli. March 23, no tubercle bacilli. March 29, weight 129 lbs., general condition good, no cavities; sonorous râles, second interspace, left side. April 1, no tubercle bacilli. April 7, weight 130 lbs.; râles only on deep inspiration, very nearly disappeared. April 13, no tubercle bacilli. Result: The patient's general condition was good when the series was started. Tubercle bacilli were present on admission in December, 1896, but had disappeared in February, 1897. There has been no unfavorable reaction from the use of serum; the râles and other physical signs have improved; she has gained in weight, coughs less and does not expectorate; she is able to take long walks and other exercise.

It may be noted that the serum used in these cases was from the same animal as the serum which cured the guinea pigs recorded above. While these results are exceedingly encouraging and there is a possibility of obtaining a serum for tuberculosis which if not specific may be very beneficial, I do not believe that investigators are warranted in recommending for general clinical use with lurid promises as to its wonderful results, a material which has not in each and every instance been tested upon experimental animals and had its efficiency actually proven.

Maragliano, Babes, Behring and Paquin are the other principal workers in the preparation of antitoxic serums. Maragliano (*Revue de la Tuberculose*, Juillet, 1896, p. 131) gives the method he has used for the production of antitoxic serum, and notes that there is present, in the cold filtered cultures of the tuberculosis germ, a substance which causes the reduction of temperature and another not destroyed by heat, which causes the rise of temperature. In all probability, without isolating the principle Maragliano was using solutions of the same substance we described in a paper before the

American Physicians, May 6, 1897. While this is not destroyed by heat, as he seems to think, it does undergo some change by probably combining with the albuminoid matter in the media and thus losing its distinct property as a temperature-reducing substance. The serum which he claims to obtain from his treatment of the animal has some effect in reducing the temperature and apparently improving the disease.

In the *Zeitschrift für Hygiene* (Bd. 23, Hft. 3), Babes, in reviewing a portion of the work on the treatment of tuberculosis with serum, comes to the conclusion that he is the first individual to have discovered any antitoxic properties in this serum, that there is an antitoxic substance present in treated animals, but that it has not yet been brought to a sufficient development to warrant general use.

Our experiments lead us to conclude, that while the injections with tuberculin produce in healthy animals, a serum containing antitoxic material the amount of this is small; and that the injection of the live culture is the proper treatment. We can not agree with the statements that horses are unsuitable for the work. Mules and donkeys may perhaps give quicker results but horses seem to be entirely satisfactory. At no time have we found that the horse serum produces toxic effects, although these have been noted from the cow serum. If the antitoxic serum treatment for tuberculosis could be freed for the present from its commercial aspect, and careful systematic experiments continuously conducted in numerous hospitals and sanitariums, this or a similar modified method of treatment could be looked to for good results. When tuberculosis can be uniformly cured in guinea pigs, as certainly as diphtheria, then does the commercial aspect become a fair and legitimate one. In the meantime the laboratory worker desires the intelligent coöperation of the clinician who will be desirous not only of curing his patient, but of advancing the theory as well as the application of those principles which, with the expenditure of many years time and often at great personal risk, have been made intelligible.

INTERRUPTED RESPIRATION: A STUDY OF CERTAIN PHYSICAL SIGNS OF DISEASES OF THE CHEST.

Read by title in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, at Philadelphia, Pa., June 1-4, 1897.

BY J. N. HALL, M.D.

PROFESSOR OF THERAPEUTICS AND CLINICAL MEDICINE, UNIVERSITY
OF COLORADO,
DENVER, COLO.

The very unsatisfactory condition of our knowledge, as presented in our text-books, regarding the causation and significance of those physical signs grouped under the general head of "interrupted respiration," has led me to study these signs with considerable care for some years, and I present today some of the results of this study.

It is apparent at the outset that, by different writers, several totally different signs are considered under the general terms, "interrupted, cogwheel and wavy respiration," including irregular inspiration from weakness of the respiratory muscles; irregular action on account of painful affections, as pleurisy, pleurodynia and intercostal neuralgia; cardio-respiratory murmur; irregular inspiration from excitement, affecting either the respiratory mechanism itself or the heart, producing a systolic interruption in the latter

case, covering the whole chest in certain cases; interruption from the presence of swelling of the mucous membrane of the bronchi; from the presence of gelatinous mucus in the smaller tubes; from outgrowths of tubercles into the caliber of the tubes; from compression of vessels of the lung by contracting pleurisy, or by fibroid or other contractile processes in the lung itself; from pleural adhesions, and possibly from other causes.

In order, then, to arrive at a proper conception of its real value, we must define more narrowly what we mean by interrupted respiration, for it is obvious that some of the phenomena we have spoken of have no pathologic significance. Let us investigate the different matters we have mentioned.

Flint, Powell and others speak of irregular rhythm heard over the entire chest in perfectly healthy persons of very nervous, excitable temperament, due to irregular or spasmodic action of the muscles of respiration, as in crying children or sobbing women. The mere mention of this form of irregularity will suffice, since it has no importance in diagnosis or pathology.

The disturbed rhythm caused by the painful affections just mentioned should be so obvious as to its causation as to present nothing of interest in this connection, for it has no known connection with any pathologic condition of the lung tissue proper.

The interrupted respiration from weakness of the respiratory muscles, mentioned by Liebermeister, is of importance only because such weakness would probably predispose to the development of tuberculosis, since decided inactivity of the lungs must follow as a result. I have not recognized this form of respiration.

Many writers have spoken of systolic interruption, ordinarily as occurring on the left side only, especially in front, and upon inspiration, the inference, avowed or not, being that it is due to the compression of air in the lung, and consequent displacement of that in the bronchial tubes, directly by the heart's action (the so-called cardio-respiratory murmur). The fact that such a condition exists upon auscultation over the entire chest during excitement, occasionally, would lead to a consideration of the possibility of its being due to an unusually forcible current of blood passing through normal arteries in the lung tissue, possibly thus changing its volume, by unusual filling of the vessels, so as to influence the air contained in the tubes. The possibility of such a phenomenon from aneurysm or dilated aorta, must also be borne in mind.

It is much more common, I think, to find systolic interruption of respiration in cases of fibroid phthisis, especially upon the left side, in which decided contraction of the affected lung has occurred. The description of a recent case of my own, in which this phenomenon was exceedingly well marked, will answer for that of the group in general:

W. P., male, 26 years of age, of good heredity, had pleurisy with effusion six years ago, and developed a slowly progressing phthisis. At the present time he has a decided retraction of the left apex, the shoulder being one and a half inches below the right, and the heart being so much drawn upward and to the left that its apex is found in the fourth space, slightly to the left of the nipple. Much of its anterior aspect has been uncovered by the retraction of the lung, giving rise to increase in its dulness. Over the left lung above the fourth interspace are found decided

dulness, loud bronchial respiration, bronchophony and occasional coarse moist and leathery râles, the latter with a creaking character. Interrupted respiration has existed in parts of the left lung for some years.

At present, most markedly over the left back, between the left scapula and the spine, where there is a fair resonance, and somewhat below this area, may be heard, when the patient takes a slow inspiration, a systolic interruption of inspiration so marked that the heart's action may be observed with as much ease, so far as the estimation of its frequency is concerned, as over the precordial area. During expiration the interruption is less marked, but still easily heard. The sound is exactly that obtained by pressing with the bell of the stethoscope over the subclavian artery in many tuberculous patients, excepting that it is fainter and less distinct. It certainly has to me every appearance of being caused by the forcing of blood through arteries narrowed in caliber by pressure from without. In this case such narrowing might have been caused either by old thickening of the pleura, or by fibroid contraction of the lung with resulting compression of its contained arteries, or by both processes acting in conjunction. It seems probable that the branches of the pulmonic artery are the ones involved, because of their much greater size.

If this phenomenon were due to displacement of air in the bronchial tubes (as mentioned by certain authors), by the expansile pulsation of the heart, it should be much more common than it is, and in this case should be found near the heart in front, as well as in the back. Under either hypothesis, however, we may account for the fact that such interruption is often found on the border of the contracted lung, where there is but slight if any dulness, for the sound might be as easily propagated in the tubes as in the blood vessels.

Sahli and others have thought that in certain cases interruption of respiration occurs from the presence of gelatinous mucus in the smaller tubes, yielding slowly to the in-coming current of air, a theory accounting more satisfactorily than any other, I believe, for those cases in which the interruptions are not synchronous with the cardiac pulsations, and in which the sign under discussion is confined to a region bordering upon a localized area of tuberculous infiltration, particularly in the apex of the lung. To my mind, the chief objection to the explanation lies in the fact that the sign is more constant in a given case than such an origin as that mentioned would lead us to anticipate.

Some cases are thought by Sahli to be explainable upon the ground of a swelling of the mucous membrane lining the tubes, yielding in a valvular manner to the advancing air current; but probably not to the expiratory wave, we should be obliged to infer, because of the comparative rarity of the phenomenon in expiration. It seems that some of the cases, presenting what to me sound like two or three distinct suction sounds during the course of inspiration, are best explained upon this hypothesis.

Musser mentions stoppage of the current of air by outgrowths of tubercle. While certainly possible at times, such an explanation could scarcely apply in any great number of cases, since the sign is too often seen in the chests of patients in whom, from the history and the physical examination, there can be no grounds for the belief in the existence of such tubercles.

Powell once saw the most marked interruption of respiration in a case in which autopsy showed a cavity with a small aneurysm near its margin. The signs of a cavity were also present. This is obviously an exceptional case.

There seems to be reason in the suggestion made by Walshe, that possibly interrupted respiration may occur "from textural disease in the lung itself, causing a want of uniformity in elastic and expansile power." In some cases, Walshe believed that pleural adhesions might act in similar manner to prevent the regular and uniform expansion of the adjacent lung tissue.

I can not understand how subpleural nodules could cause a friction sound so resembling the sign in question as to deceive the experienced ear, although Rühle apparently thought so. His theory of the compression of the bronchi by nodular growths, which might certainly interfere with the passing air current, seems tenable under certain circumstances, however, these acting in the same way that outgrowths of tubercular tissue or swelling of the mucous membrane may act.

I think we may reasonably conclude, then, that interrupted respiration may originate in so many different ways that but little importance should be attached to the sign excepting as a confirmatory one, especially in conjunction with more reliable ones, such as bronchial râles, dulness, bronchophony, bronchial respiration, and particularly broncho-vesicular respiration. The presence of the sign should always warn us to seek more carefully than otherwise for further signs of respiratory disease; while in certain cases, in which one could possibly decide with reasonable certainty that the interruption was due to some particular one of the several causes mentioned, he would be justified in basing his judgment of the case to a certain extent upon this factor.

IMPROVED METHOD OF COCAIN ANESTHESIA.

BY J. F. OAKS, M.D., Ph.C.
CHICAGO.

My apology for the following polemic on a brief article entitled an "Improved Method of Cocain Anesthesia for the Nasal Mucous Membrane," which appeared in the *JOURNAL* of May 22, p. 976, is the fact that the general use of so dangerous a drug as cocain demands our scrutiny of the various methods of its employment. In the article referred to Dr. Anderson gives his method of local anesthesia, which consists in a preliminary use of a one-tenth per cent. solution of cocain as a spray to the nasal mucosa, which after being repeated in thirty seconds is followed by the use of a 25 per cent. solution on a probe, armed with a whip of cotton.

The object of this kindly criticism of Dr. A.'s method is to check any tendency the article might create to the too bold and free use of that dangerous drug.

The "preliminary spray of a one-tenth per cent. solution" may appear to some to be unnecessary, yet it is believed by some authorities that the preliminary generalized use of cocain in the nasal cavities insures a better and more satisfactory anesthesia, where it is followed by the local application of a stronger solution, and that this result can be obtained with a less amount of the drug. It should not be forgotten, however, that a special spray apparatus or tip should be

used for cocain solutions. The Davidson sprays so commonly used throw too coarse a spray, and in the absence of any control of the compressed air supply the spray is distributed too freely and that beyond the nasal cavities into the post-nasal space, which is not only unnecessary and undesirable, but quite discomforting to the patient. After the "preliminary spray" Dr. A. uses a 25 per cent. solution "by rubbing the probe, on which is arranged a small amount of cotton, back and forth gently, but continuously, allowing the cocainized cotton to reach every desired part of the membrane," intimating in the same paragraph that "anesthesia will take place in from three to five minutes."

Many of us who have had some experience of a not very pleasant kind, even from the use of solutions much weaker than a 25 per cent. solution, would not be so likely to follow Dr. A.'s "method," but "there are others" who would be specialists, that might realize the danger too late, especially in the case of an individual with a peculiar idiosyncrasy. Therefore I must warn such against so free a use of so strong a solution of cocain in the nasal cavities.

In summing up the advantages of his method Dr. A. claims a saving of time, "not requiring more than three to five minutes, while the tampon method is fifteen to thirty minutes." The latter statement is contrary to the experience of most nose and throat specialists. Although time and space will not permit me to either defend or condemn the so-called "tampon method," suffice it to say that when correctly used (*i.e.* by placing in contact with the mucosa a thin layer of cotton fibers moistened with a 5 per cent. solution of cocain covering a little more than the operative area, thereby limiting absorption and controlling toxic effects) is all sufficient for cautery and the various intra-nasal operative procedures. Dr. A. asserts that by his method a small amount of cocain is used, yet it is to be supposed that the rubbing of the probe charged with cocainized cotton back and forth continuously for from three to five minutes would permit the absorption of a sufficient quantity of the drug to produce decided toxic effect in persons only moderately susceptible to it.

He also asserts that the equal distribution is more desirable than the localized effect, for cautery, etc., which is true only in part, as explained in the first part of this communication. He furthermore asserts that "the admixture with mucus does not dilute nor lessen the anesthetic effect." Granting this latter statement to be true, the argument would be in favor of the method he incorrectly calls the "tampon method."

The suggestion of Dr. A. "to arrange the patient in the prone position, as for general anesthesia," is entirely gratuitous, since it is neither necessary nor convenient, in view of the difficulty to obtain hemostasis in operative procedures within the nasal cavities. It is a fact that the free hemorrhage so usual in intra-nasal operations makes the upright position imperative.

In conclusion, I would reiterate the statement that a 5 per cent. solution of cocain will be found all sufficient to secure the desired anesthesia of the nasal mucosa. In endolaryngeal operations, however, and in the post-nasal vault the careful use of a 10 per cent. solution is more satisfactory. I consider a 25 per cent. solution either in the nose or larynx to be recommended in exceptional cases only.

126 State Street.

A CASE OF BENIGN CICATRICIAL STRICTURE OF THE ILEUM.

OPERATION, LATERAL ANASTOMOSIS, EXHIBITION OF SPECIMEN REMOVED FIVE YEARS AFTER.

Read at the meeting of the Chicago Pathological Society, April 12, 1897.

BY M. L. HARRIS, M.D.

Professor of Surgery, Chicago Polyclinic.

The patient from whom this specimen was obtained presented the following history: Mr. C., age 57, American, married. Family history good. His health previous to the present trouble had been good. I could obtain no history of a former intestinal trouble such as dysentery, severe diarrhea, typhoid fever or any illness likely to have been attended by the formation of an ulcer or ulcers in the intestinal tract. He could date his present trouble back about three years. It began very gradually with symptoms of indigestion or dyspepsia, and for a long time was supposed to be due to his drinking habit, as he was a man who indulged rather freely in intoxicants. The symptoms, however, continued to increase in severity, unrelieved by medication. The bowels became constipated, with periodic attacks of diarrhea. His appetite failed and he wasted greatly in strength and flesh.

When seen by me Dec. 10, 1891, he was in an extremely miserable condition. He had wasted to a mere skeleton, weighing but 85 pounds. He was unable to retain nourishment, as he vomited everything put into the stomach. The ejaeta were very offensive and semi-fecal in odor. Nothing had passed the bowels for several days.

An examination of the abdomen showed it to be somewhat distended. Large coils of small intestine were distinctly outlined through the abdominal wall and the peristaltic contraction was plainly visible. During these peristaltic waves, which were intermittent, the patient would experience severe griping pains. I have never seen coils of intestine so distinctly outlined and the peristaltic wave so plainly visible as in this case. Upon palpation an indistinct sense of resistance could be felt deep in the lower part of the abdomen, a little to the right of the mid-line. With the finger in the rectum this was more distinct, yet a tumor could nowhere be defined. The urine was normal except for the presence of a large amount of indican.

A diagnosis of chronic intestinal obstruction was easily made. Its location in the lower portion of the small intestine seemed likewise quite clear. Whether malignant or benign, however, was not so easily determined. His age and great emaciation spoke for malignancy. The length of time, fully three years, during which distinct symptoms had been present, the rarity of carcinoma in the small intestine and the absence of a tumor in an emaciated abdomen easily palpable, spoke more in favor of a benign stricture.

With this in view I determined to operate at once and form an anastomosis around the obstruction. The operation was performed Dec. 11, 1891. Upon opening the abdomen, the seat of obstruction was fortunately quickly reached and the loop drawn out. A linear mass of cicatricial tissue about 1.5 cm. in width, apparently involving most of the thickness of the gut wall, encircled the intestine, and by its contraction had almost completely obliterated the lumen of the canal. It did not extend at all on to the mesentery, which was perfectly free. It was evidently a simple, benign cicatricial stricture, and was located in the

lower part of the ileum. The intestine below the stricture was very small, flat and empty, while above it was remarkably dilated, looking like a distended colon, its wall, from hypertrophy, being as thick as that of the stomach. A lateral anastomosis was made between the loop above and the one below the stricture, about 30 cm. being excluded from the intestinal current. Senn's large size decalcified bone plates were used in the operation. The recovery from the operation was rapid and without incident. He regained his health at once and made the most remarkable gain in weight, from 85 to 190 pounds in eleven months.

He continued in good health for about four years, when the effects of chronic renal and cardiac disease, aggravated or perhaps superinduced by his habits, began to show themselves, and from this time on the usual course of these diseases was passed through—general anasarca, ascites with repeated tappings, etc., and finally death in December, 1896, exactly five years after the operation. At no time was there any trouble with his intestinal tract after the operation. The specimen still shows the thick cicatricial mass forming the stricture and allowing but a small probe to pass.

The loop of intestine which was excluded has shrunken or atrophied to but a few cm. in length. The anastomotic opening is of good size, having contracted but little, and permits a free unobstructed passage of the intestinal contents. The great dilatation of the bowel above the stricture has all disappeared, the gut being now of uniform size. This is, so far as I am aware, the oldest specimen—five years—of a lateral anastomosis on record.

The cause of the stricture was in all probability cicatricial contraction following an intestinal ulcer, but the history of the patient gave no clue to the primary trouble, and no examination of the body or intestines was permitted after death.

A CASE OF DEFECT IN THE VENTRICULAR SEPTUM AND STENOSIS OF THE PULMONARY CONUS IN A MAN THIRTY-TWO YEARS OLD, WITH DEMONSTRATION OF THE HEART.

Read at the Meeting of the Chicago Pathological Society, April 12, 1897.
BY JOSEPHINE E. YOUNG, M.D.
CHICAGO, ILL.

October 2, 1896, a patient, 32 years of age, entered Cook County hospital, Chicago, with evidences of an acute, febrile disease. He gave the following history: When 2 years old a consultation of physicians was held—the child always having been so delicate that it was necessary to carry him about on a pillow, at that time being very poorly nourished and developed, unable to walk, and having at frequent intervals attacks of marked cyanosis. The consultants told his mother that he could not live to maturity. At the age of 17, Prof. Lyman of Rush Medical College demonstrated the case in his clinic as one of cardiac disease. During his entire life, upon marked exertion or excitement, the patient had attacks of pronounced cyanosis.

Upon entrance to the hospital, physical examination revealed the following: General development and nourishment good, clubbed finger ends, color ruddy,

no evidence of cyanosis at this time. The pulse was full and regular, later becoming irregular and distinctly sublingual. *Heart:* percussion, relative dullness *right border* to the right of the right sternal line, *base* third rib, *left border* left mammillary line. There was increased dullness when the patient leaned forward. One month later the dullness extended two cm. to the left of the left mammillary line. Palpation: upon entrance there was distinct fremitus over the entire precordia. The apex beat was strong and regular. One month later there was marked arrhythmia. Auscultation: a very loud systolic murmur could be heard over the entire thorax, anteriorly and posteriorly, the maximum intensity being at the junction of the third rib with the left border of the sternum. The murmur was heard very distinctly along the entire left sternal border. There was no accentuation of the second pulmonic tone. Notwithstanding the fact that for eighteen days the temperature remained at or near 103; there was never any cyanosis. The urine was negative, both as to albumin and morphologic elements. Other findings bear no especial relation to the cardiac lesions, the diagnosis of the acute disease halting between acute endocarditis and typhoid fever. Dr. James B. Herrick at this time made a diagnosis of congenital heart disease.

The patient was discharged Nov. 24, 1896, after recovery from the acute attack. Dec. 12, 1896, he reentered the hospital with facial erysipelas.

The heart and lung findings were as before. In a few days, with a temperature of 104 degrees, cyanosis became a marked feature. The heart was very arrhythmic, the pulse correspondingly irregular and compressible. The spleen extended five cm. below the left costal arch, the liver one and one-half cm. below the right costal arch and in the mammillary line. Examination of the urine showed albumin in rather large amount and granular casts. The extremities were not edematous. Two days before death the dyspnea was extreme and respirations increased to fifty-two. The patient's critical condition and constant right decubitus prevented a thorough examination of the right lung, which later showed evidences of pneumonia. He was rational throughout.

Death occurred Jan. 12, 1897, after one month's illness, during which time the temperature was frequently 104 and 105 degrees.

The clinical diagnosis was facial erysipelas, acute splenitis, nephritis, pneumonia (?), general septic infection, and congenital heart disease. The autopsy was made by Dr. Ludwig Hektoen, Jan. 18, 1897.

Anatomic diagnosis: healed facial erysipelas, lobar pneumonia, embolic abscess in the left lung, acute splenic tumor, chronic and acute nephritis, chronic gastritis, pigmented Peyer's patches, hypertrophy of the heart, chronic and acute endocarditis of the tricuspid and pulmonary valves and the wall of the right ventricle, stenosis of the pulmonary conus and congenital defect of the ventricular septum.

The bacteriologic examination of the organs showed staphylococci pyogenes albus and citreus to be present everywhere.

The cardiac findings more particularly are the following: The hypertrophy is rather marked; the heart weighs 400 grams; the apex is composed equally of the right and left ventricles; the wall of the right auricle measures 4 mm. in the thickest part, that of the left auricle 3 mm.; the wall of the right ventricle averages 1 cm. in thickness, that of the left ven-

tricle $1\frac{1}{2}$ cm.; the circumference of the aorta at the valvulus is 5.7 cm., that of the pulmonary artery is 5.4 cm.; the ductus Botalli is closed; the arrangement of the pulmonary artery is normal, that of the aorta, which communicates only with the left ventricle, is normal also. Four cm. below the upper margin of the pulmonary semi-lunar valves there is a stenosis of the pulmonary conus, due to fibrous tissue. The lumen of the conus measures 1 cm. in its largest diameter; the foramen ovale is patent, admitting a lead pencil through its orifice; a sickle-shaped valve covers it. Directly below the semi-lunar valves of the aorta there is a defect in the ventricular septum which measures 2.6 cm. in the horizontal diameter, 2 cm. in the vertical diameter. This defect corresponds to the septum membranaceum, or undefended space, the last part of the ventricular septum to close, composed normally of a thin layer of fibrous tissue covered with endothelium. The pulmonary valves are thickened; the free margins of the posterior segment are covered by large polypoid vegetations. These spring also from the ventricular surfaces of the valves and from the wall of the pulmonary artery. The free margins of the tricuspid valves are thickened. Here then are distinct polypoid vegetations. The orifice admits four finger-tips easily; the right auricular appendix shows some irregular masses; the aorta valves are free from thickening; the aorta shows no atheroma; the mitral valve is normal, admitting four finger-tips snugly; the myocardium, except at the stenosis of the conus, is normal. Microscopically, the striæ and nuclei of the fibers are normal, but there is a general segmentation.

The clinical diagnosis of congenital heart disease was based upon the history, the cyanosis, hypertrophy of the right heart, position of the systolic murmur and thrill at the junction of the left third rib with the sternum, the intensity and widespread transmission of the thrill and the weak second pulmonic tone.

As to the formation of the lesions, Fraentzel, Bamberger and Oppolzer support the Hunter-Morgagni theory, a myo- or endo- carditis occurring before the eighth week of fetal life is the cause of the stenosis of the pulmonary artery or its conus. This greatly increases blood pressure by preventing the proper escape of the blood from the right ventricle, the blood necessarily forcing its way into the left ventricle through the undeveloped septum. If the opening in the septum is sufficiently large blood pressure in the right heart is compensated for—there may be no opening (in the septum) of the foramen ovale. If not large enough there will be hypertrophy and dilatation of the right ventricle, stasis in the right auricle, with passage of blood through the foramen ovale, which remains patent.

The case is of interest not so much from its rarity as from the following points: The patient had reached the age of 32, was a strong, well-developed man doing the ordinarily heavy work of a laborer, had passed through an acute febrile attack of eighteen days' duration without any evidence of cyanosis, had resisted for a month profound erysipelatous and septic infection and had entirely escaped pulmonary tuberculosis, a condition frequent in these cases, owing to the diminished supply of blood sent to the lungs.

A Progressive Potentate.—The young Emperor of China, with a lost faith in the traditional remedies of his people, has dispatched to the medical centers of Europe a large number of students. London, Paris, Berlin and Vienna have already received a respectable installment.

ADAPTATION AND INSERTION OF AN ARTIFICIAL EYE; ENUCLEATION, SYMPATHETIC PHENOMENA, ETC.

BY WILLIAM B. MEANY, M.D.

MEMBER OF THE AMERICAN MEDICAL ASSOCIATION, ETC.
SAINT LOUIS, MO.

The exercise of a little care with "troublesome" cases in the taking of a cast—either with dentist wax or with superfine dental plaster-of-paris—of the tissue walls of the orbital cavity resulting from the removal of an eyeball, and the artificial eye to be inserted fashioned on the lines of the "model," may overcome the difficulties complained of by advocates of dangerous substitute proceedings for the benign operation of enucleation.

An artificial eye should be fabricated to meet the requirements of the anatomic conformation of the orbital cavity, rather than the adaptation of the tissue walls to a misfit or bespoke eye—which has never been known to vary from its present shape for half a century or thereabouts.

By the adoption of this plan of procedure hazardous and unwarrantable "operations" that permit the retention of a portion of the structure of an eyeball that has become or is liable to take on disease at any moment, and thereby incite sympathetic phenomena, will be avoided; and the present unsatisfactory process of "grinding down" of the shop (stock) eye be dispensed with.

The insertion of an artificial eye is very simple and is soon learned by the patient. It must first be steadily pushed beneath the upper eyelid and held there while the lower lid is brought around its lower edges.

Its removal is readily facilitated by depressing the lower lid so as to expose the lower edge of the artificial eye, when it usually slips out by its own weight, and should be caught in a handkerchief or permitted to drop out upon a bed. An artificial eye should not be adapted or inserted until the cicatrix of the conjunctiva and other tissues of the orbit become firm, quiet and free from ulceration or inflammatory discharges. By selecting an artificial eye somewhat smaller than the remaining or sound eye, the distorted or over-exaggerated appearance is avoided. The eye should not be worn continuously—that is, never during bedtime.

ENUCLEATION.

This operation or excision of the eyeball is usually performed as follows: A fold of the conjunctiva on the inner or nasal side of the eye having been seized with the forceps is divided with a scissors at the corneo-scleral juncture along its entire circumference. The tendons of the muscles caught up with a strabismus hook and divided, the globe turned firmly outward and forward; the scissors (those curved on the flat being used), introduced either on the nasal or temporal side of the eye as the operator may elect, the blades of the scissor being separated so as to straddle the optic nerve, permitting of easy division. Care should be taken to excise the nerve some distance from its ocular attachment.

The globe being brought out of the orbit, the oblique nerves and vessels are divided. The cavity is then carefully syringed with a cold boric acid or a 1 to 10,000 sublimate lotion, or both; the slight hemorrhage that follows the operation is usually arrested by the "syringing" of the cold antiseptic solutions.

A suture uniting the superior and inferior margins of the conjunctiva introduced; a rondelle of antiseptic cotton wool previously moistened with distilled water is inserted between the lids and a compressive bandage applied, and permitted to remain for twenty-four or thirty-six hours.

The stitches uniting the superior and inferior margins of the conjunctiva are generally removed on the second day following the enucleation.

The following operation has been suggested a decade or more ago and appears to possess the important advantages derived from the operation of enucleation with none of the disadvantages of that of evisceration, as proposed by Mr. Mules, or other "operations" that do not materially differ from evisceration other than as to the method in removing a little more or less of nerve tissue, and the dangers arising from sympathetic trouble being almost *nil* when compared to the so-called surgical interferences that permit the retension of a portion of the structures of a globe that has already become or is liable to take on disease at any moment.

The operation is similar or in fact is practically identical with that of enucleation with the addition of a sterilized hollow glass sphere (to avoid the dangers of a sphere becoming fractured one made of silver or aluminum has been suggested as a likely substitute) is inserted into the cavity of Tenon's capsule and the conjunctiva stitched firmly over it; a temporary catgut drain will have to be used in conjunction with the operation.

When the eyeball is entirely removed as in this operation there is no likelihood of disease being propagated and thereby displacing the questionable practice commended by a writer in an article of a late date, of the "ingrafting" into the tissues of the orbital cavity portions of so dangerous a substance as the "deadly" sepsis-generating sponge, to act as a "support" for an artificial eye.

Advocates of "substitutes" for enucleation who, for reasons of their own, appear unable to obtain a proper support for an artificial eye following their enucleations, will find a useful and movable support, as the muscles of the eyeball are attached upon the sphere inclosed within it; as Tenon's capsule is attached to the conjunctiva in front, when this is sutured the capsule is rendered tense and becomes accurately adapted to the selected sphere. This operation, however presents some disadvantages.

The operation of enucleation is wonderfully benign and if carefully performed does not in the least interfere with the adjustment of an artificial eye, whose motility will be as perfect as if resting upon a shrunken globe, besides being free from the dangers of a shrunken remnant of a lost eye, acting in the same prejudicial manner as an injured or diseased eye before having parted with its contents or a portion of its structures. A most happy effect is gained by enucleation, in arresting and subduing the *irritation* which threatens to develop into *destructive* inflammation of the sound eye.

Enucleation at an early stage should be insisted upon where eyes have been crushed by blows, that are the *site* of neoplastic growths that may prove malignant; eyes that have been penetrated by foreign bodies which are not removable, which belong to patients who can not be trusted to take either proper care of themselves or to return if they are threatened with sympathetic *irritation*.

When the exciting eye is evidently rendered useless by the wound or from consequent inflammation, that is when its vision amounts to perception of light, and when there is no probability that sight will improve without incurring the risks of the sympathizing eye, the exciting eye should immediately be excised. If the sympathizing eye is only suffering from *irritation* and presents no symptoms of *inflammation* the removal of the exciting eye will be followed by immediate relief of the irritation and no symptoms of inflammation are likely to appear; hence the necessity of an early enucleation of useless eyeballs from persons in whom one sound eye remains as a prophylactic measure. Advocates of such "operations" as abscission, neurotomy, optico-ciliary neurotomy, exenteration or substitutes of a like character that permit the retension of a portion of a diseased globe, can hardly advance any claim to merit, save to afford *only* temporary relief from sensitive and painful eyeballs without offering the least safeguard to the prevention of sympathetic phenomena or destructive inflammation of the sound or remaining eye.

The operation of enucleation should alone be practiced, and the "substitute" procedures adopted and advocated every now and then by some youthful or experimental surgeon, inhibited by law.

3907 West Belle Place.

A NEW SPLINT FOR NASAL FRACTURES AND DEFORMITIES.

Read at the Third Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Sept. 23, 24 and 25, 1896.

BY JESSE HAWES, M. D.

DIVISION SURGEON ON THE UNION PACIFIC, DENVER AND GULF RAILWAY, GREELEY, COLO.

This splint is intended for cases of nasal fracture in which there is a drawing upward of the point of the nose or of the alæ. Permit me to describe it by the narration of a case in which necessity demanded it

C. W., boy aged 10 years, was brought to me, having been kicked by a horse several days before. The toe of the animal struck the nasal septum at its junction with the upper lip. The blow cut the septum loose from the lip. A wound extended through the septum from the point of union with the lip directly upward for three-fourths of an inch.

The detached edge of the septum was rolled up into the nose; both alæ were forced upward; the nasal bones were detached from the maxillary and driven upward, and small pieces of the maxillary were broken on each side of the nose. The contractions of the levators of the nose held the soft and hard tissues where they had been driven by the kick. The point of the nose was far above its normal position; the right ala was much higher than the left.

The first step toward repair must be to bring down and fasten the septum in its position, the next to replace the fractured bones, the last to bring down and retain in position the upturned nose. To fasten the septum by stitches was simple; the nasal bones were easily pressed into their normal position, but slipped outward as soon as manual pressure was removed. To bring down and *retain* the point of the nose in its proper place was impossible.

The best suggestion I could get from "the books" and experience was to draw the nose down by grasping its point, then to transfix the lower end of the

septum antero-posteriorly with a long, stout, steel needle, the point of which was driven down in the palatal process of the superior maxillary. (See illustrations in Roberts' Surgery.) While this partially held the point of the nose from being drawn upward, it did so very imperfectly; the upward dislocation of the alæ was corrected but very little. The quite recent editions of Bryant, Keene, Ashhurst, Stephen Smith, Wyeth, Roberts, Ashhurst's Cyclopaedia, Hamilton's Fractures, Holmes, Gross and Stimson offered no helpful suggestion.

After several days of chagrin over my inability to control the deformity, the very simple nasal appliance which I here present suggested itself.

It consists of a piece of No. 15 spring brass wire of suitable length, bent first into the form of a rectangular letter U, the arms of which are about an inch apart and long enough to extend from the center of the upper lip to the crown of the head or beyond that point; opposite the supra-orbital ridge a sharp angle is formed; this angle is to permit the splint to enter the orbital cavity just beneath the orbital ridge; this angle is a means of fixation of the splint against the supra-orbital ridge and is one of the most essential features of the appliance. The lower end of the splint—i. e., the transverse portion—is carried forward, away from the lip, the distance of a half inch.

A continued narration of the case will best illustrate the application of the appliance: Having formed the wire splint to fit the head, forehead and nose of my patient it was applied to these parts; a folded piece of lintine was placed between the wire and the orbital ridge to prevent painful pressure at that point; the splint was held firmly in contact with the head with a broad strap of rubber adhesive plaster carried across the forehead and completely around the head.

The nasal bones, which could only be held in position by continuous pressure, were easily retained by pads of lintine placed between the splint and the side of the nose. A large, strong silk suture was carried through the septum near the point of the nose, the nose was pulled down by tying the ligature to the transverse wire beneath. The mucous membrane and cartilage (but not the skin) of each of the alæ were pierced by similar ligatures, and when drawn down to their proper positions the ligatures were fastened to the wire beneath.

The result in my case was eminently satisfactory though not perfection and was far better with this

splint than it could have been by using any splint that has preceded it: indeed there is no appliance, so far as I can learn, that can perform the office of this.

I have recently added to the appliance a means of elevating depressed portions of the nose and permanently retaining them in position. It consists of a wire of spring brass, bent so as to elevate the depression to the normal position by pressing upward from the inside of the nose. The wire should be covered with soft-rubber tubing; the stiffness of the wire should ordinarily be less than that of the outside splint. Each intra-nasal wire can be firmly fixed to the lower angle of the splint by a simple mechanical arrangement. This permits the intra-nasal wire to be removed from the nose and from the splint when necessary to change its form or pressure. I have experimented with these intra-nasal attachments and believe that when properly fitted to the inner surface of the nose they will raise the depressed part and retain it in position more satisfactorily than any other device heretofore offered. The splints are manufactured by Chas. Truax & Co., 75 Wabash Avenue, Chicago.

Let me recapitulate the advantages of the appliance:

1. They are simple; the first described appliance can be made in a few minutes by any surgeon who has the wire and a pair of suitable forceps.
2. It is easily applied, remains permanently in position and permits the organ to be inspected during the progress of recovery.
3. It holds a compress firmly to the side of the nose when such are needed to correct deviations, an important matter in some cases.
4. It will draw down the point of the nose or the alæ and hold them firmly in their normal position. No other appliance for accomplishing this has heretofore been presented to our profession.
5. The intra-nasal wires, when used, remain where placed, a statement that is not true of the intra-nasal plugs ordinarily used, such as cloth-cotton, rubber tubes, etc.
6. I suggest the use of the intra-nasal splint in restoring the normal esthetic shape and overcoming the deformities of noses long previously fractured, after vicious adhesions and unions have been broken up.

DISCUSSION.

Dr. E. M. DOOLEY, Buffalo—I think, as I have served as a lay figure for the demonstration of this apparatus, it is my privilege to speak on this subject, and I would like to state for the benefit of those who have had no experience with the splint, that my experience was extremely pleasant: in other words, it was quite comfortable as long as I had it on—but whether the inside is as comfortable or not I have my doubts. But I think from my experience with broken noses, and owing to the locality in which I live I have had a great deal of experience with broken noses, and I have often been at a loss to have a splint that would do in any and all cases, and I feel very thankful to Dr. Hawes for exhibiting this splint, and I shall use it in the next case where I think it will be of service.

Dr. KIBLER, Cory, Pa.—Just one matter that occurred to me in connection with the splint, and that is—I am glad that Dr. Dooley testifies to the fact that the splint is a good one—could that part that enters the nose be made of hard rubber? It could be made more thoroughly aseptic and I believe give less danger to the mucous surfaces than you could have from the brass wire.

Dr. HAWES—It probably slipped your attention that that is covered with a soft rubber catheter.

Dr. LEMEN, Denver—As this originated in my neighborhood, Dr. Hawes being a neighbor of mine, and I was being occasionally asked to treat broken noses, he insisted that I use it, and I have used it in a number of cases and am very much pleased with its application: it holds the position of the bones per-

fectly. If the surgeon's apposition is properly attended to, the same is continued by the application of the splint.

Dr. COLE, Helena—It strikes me as being an extremely ingenious device. In the entire field of accidental surgery in minor matters there is nothing more troublesome, perhaps, than fracture of the nose with displacement, and to get a satisfactory result is sometimes exceedingly difficult, and if I understand rightly the application of this apparatus it should be a practical part of every surgeon's paraphernalia.

Dr. W. J. MAYO, Rochester, Minn.—I was very much interested in the splint of the Doctor, the external part I have never seen used in this connection. My brother, Dr. C. H. Mayo, has used a somewhat similar intra nasal splint in the elevation of depressed nasal fractures, and also a method of his own for the relief of sunken nose caused either by fracture or specific disease. In sunken nose he cuts obliquely through the septum and the depressed tissues behind and inside of the nose with a heavy chisel or cartilage knife, and elevating the septum introduces the splint, which allows sound union at a high level. In these cases the results have been excellent and continued so. The bevel of the cut surface enables the sliding upward of the depressed portion. The splint used by him consists of a similar piece of brass wire bent by a single turn into a coil, the two projecting ends being introduced into the nostrils, one along the floor, the other sprung up beneath the depression; the tension of the spring thus formed gives the necessary upward curve, one splint thus constructed and covered with iodoform gauze being introduced into each side and left for a number of days.

Dr. BRYANT, Omaha—I think this invention of Dr. Hawes for holding down the nose after an injury, not only the best splint I have seen, but the only one. I have never seen one for this particular purpose. The difficulty in a majority of the cases where injury to the nose has been received, is not to hold the nose down, but to raise it up—probably 90 per cent. or more would have a depressed nose, instead of an elevated nose; but this seems to be an all-round splint, not only to hold it down but to elevate it. If I were to criticise this I think it would be in the portion that enters the nostril, and that criticism is not anything of value, it simply would be this: In many cases, make it larger in order to keep it in, and that could be done by winding the copper with thread or string and then using soft rubber over that. I believe soft rubber is the best thing to prevent irritation of the mucous membrane, and I think this [indicating] might be uncomfortable after using it any length of time—that is, I think it would.

Dr. HAWES—In making some remarks upon the comments that have been made I come first to the comment that the inside appliance is uncomfortable. Any man that has ever had any experience knows that nothing is very comfortable in the nose; whenever you push up there a lot of cotton or cloth it is uncomfortable—but that has hardly ever been an objection during the years it has been practiced; it would be customary to use a wad of cotton, which is a thousand times more uncomfortable than the other, which is much more efficient. One of the other criticisms was on account of using a hard brass substance that was liable to corrode. That I reply to with the statement that in the paper it was stated it should be covered with a soft rubber catheter. I want to call attention to another fact, that I have presented to you two splints, the second is an outgrowth of the first; the second can be used for all purposes that the first was used for, the first can not be used for the purpose for which the second is. The first is intended to draw down the nose when it has been drawn upward; the second is intended to raise the nose from the inside, which is wholly outside of the field intended as the proper field of the first. Dr. Mayo speaks of a method which I was not aware of; I have never seen it mentioned in the books. It is very evidently an excellent method of raising these depressed noses. This one of mine, while I have never had an opportunity to raise depressed noses, I have no doubt will do exactly what the other one does. The person who is using the splint should have some knowledge of the anatomic form of the inside of the nose, and should then bend his wires so that they should fit that form in particular, and raise the nose to its normal and esthetic position. The comment of Dr. Bryant that it should be larger can be very easily attained by using a larger catheter instead of the little catheter—I peeled off and threw away the rubber that I had on the outside when I began to talk, to show you the wire. By using the larger catheter you can adapt it on the inside to a nose of any size that you desire. Another of our members inquires, Where can I get these splints? I have stated in the paper that all you have to do is to get a piece of wire and a pair of pincers. If you want something better you might go down to any of the instrument makers, or even to the common tinsmith, and by giving your

ideas, you might get it made in a very few minutes—if you go to the instrument maker it will cost you a dollar and a half; if you go to the tinsmith it will cost you ten cents. That is all.

THE PRESIDENT—Can the surgeon readily make that second splint?

Dr. HAWES—I made one; I am not a tinker or son of a tinker, but I made one in a bungling sort of way. This I took to the tinker and asked him to make it, and he made it rather better, shapelier far than I can; you would have to take that second one to the tinker or tinsmith or instrument maker. I do not think it is wholly perfect, but that it is an embryo of a valuable instrument, a valuable appliance.

Dr. REINERIKS, Sheboygan, Wis.—I would like to make a suggestion in regard to the enlargement of the intranasal portion. I think that can be done and made comfortable by winding around absorbent cotton and dipping that in melted paraffin which can be impregnated with an antiseptic solution; a backing of cotton cloth can be built up on the intranasal splint; the paraffin is hard enough to make sufficient pressure.

Dr. HARNDEN, Waverly, N.Y.—I think it would be in order that a vote of thanks of this Academy be extended to the Doctor for bringing to our attention the valuable instrument.

Motion seconded and unanimously carried.

REMARKS ON THE TREATMENT OF FRACTURES.

Made at the Third Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Ill., Sept. 23, 24, 25, 1896.

BY R. ORTEGA, M.D.

CHIEF SURGEON TO THE MEXICAN INTERNATIONAL RAILWAY.
CIUDAD PORFIRIO DIAZ, MEXICO.

I want to talk about a treatment or practice which gives the patient entire relief at once from pain and puts him in good condition for work as soon as the fracture is solid. As soon as a patient breaks a bone I make massage from the lower part of the fractured limb to the upper part; we commence to do the massage very gently just on the skin, with anything, oil, or soap and water, salve or vaselin to allow the hand to rub without hurting. Ten or fifteen minutes afterward we do the massage on the muscles, always from the end of the member up, never making pressure; in ten or fifteen minutes after the pain is gone and we can reduce the fracture without chloroform or pain. As soon as the fracture is reduced we roll it in a simple flannel bandage, from the end of the member upward; if it is in the arm we put the arm in a simple handkerchief from the neck; if it is in the upper arm, the weight of the arm is enough to keep the fracture in good position. And the next day we do the same treatment, a little massage and a little movement in all the joints of the broken limb. I have done this treatment for a year. I have had but few cases as my practice is very small. One boy about 18 years old, had a wheel from which he fell and broke his right arm in the middle with a compound fracture, the upper end of the humerus projecting through the skin. Dr. Lord reduced this fracture, put on a good dressing and an apparatus, and he called the next day to see the patient; the patient wanted to cross the river. I saw the boy with Dr. Lord; we took off the apparatus, the wound was in good condition, aseptic because the doctor had put a very nice and good dressing on. I told him I was going to take off the apparatus as soon as I brought the boy over the river. I did so and then applied a bandage, and made motion in the elbow and other joints and in fifteen days this boy was at work as before the injury. There was a compound fracture of the humerus and simple fracture of the ulna, and in fifteen days later the boy recovered and worked as before, all the bones completely healed. I had one day two cases: one a small

boy about 6 years old, broke the humerus of the right arm, not a compound fracture; I applied massage at once, and in ten days this little boy climbed trees and did almost everything. The same day in the shop, a workman broke his humerus in the middle, and the fracture was displaced, I did massage and put the fracture in position and rolled it in a bandage, and I left this arm without an operation; I did massage every day and about 20 days afterward this patient was in good condition. I do not remember the details of other cases, but I want to call your attention to this treatment. It gives a little more trouble to the doctor but that does not count; the patient does not suffer and is able to work very soon. My company does not give wages to people when they are sick and I think this treatment is very good because it does not keep patients two or three months without working; they can go to work in 15 or 20 days.

SURGERY ONE HUNDRED YEARS AGO.

AN HISTORICAL STUDY

BY DR. GEORGE FISCHER.

DEDICATED TO THE GERMAN SURGICAL ASSOCIATION.

TRANSLATED FOR THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION
BY CARL H. VON KLEIN, A.M., M.D.

VIII.—PROFESSORS OF SURGERY AND PRACTICAL SURGEONS
(WUNDAERZTE).

(Continued from page 29.)

In October, 1765, two Germans traveling for study reached Leyden together. With the greatest kindness, their celebrated countryman, Albinus (born in Frankfort on the Oder), whose anatomical works and drawings surpassed anything which had hitherto been done in descriptive anatomy, opened to them his invaluable storehouse of specimens. The two young men, who here formed a bond of friendship which lasted through their whole lives, became later the best teachers of surgery, A. G. Richter and *Carl Caspar von Siebold*. The latter, who was six years the elder, was born (1736-1807) in the little town of Nidecken, where his father was a surgeon, and at the age of 16 he entered the school in Cologne, in order to study philosophy. There he made such good progress that he was enabled to take part in public disputations. In 1755 he returned to his father, who gave him instruction in surgery. When the "Seven Years' War" broke out Caspar entered the French army, which marched against the Hanoverians in Jülich. For three years he remained in the French field hospitals, where he had opportunities to perform operations. While in winter quarters he attended the lectures which were given by some French surgeons, according to official requirement. In 1760 he was stationed in Würzburg, became acquainted with the professors there, gave up his appointment and became assistant to Stang (later his father-in-law), who had been chief surgeon in Julius Hospital since 1731. Here he also attended theoretic and practical lectures for three years and then took his doctor's examination. The conferring of the degree was postponed, as the bishop-prince gave him money out of the university funds to enable him to travel. Siebold went to Paris (1763), remained there eighteen months, attaching himself chiefly to Morand, in the Invaliden Hôtel. He heard Sabatier, de la Faye, Bordenave, A. Petit and Levret, industriously practiced lithotomy on cadavers under Moreau, and visited the Hôtel Dieu. In 1765 he visited Le Cat in Rouen, and resided with him a long

time in order to learn better methods in lithotomy. Then he went to London. There W. Hunter, Pringle and the operations of Pott, Bromfield and Hawkins engaged his attention for three months. From there he went to Leyden and visited Albin and Gaub. In 1766 he turned back to Würzburg, where three years later he received his degree. He assisted the professor of anatomy, surgery and obstetrics, Hüber, and the chief surgeon Stang, who now retired. After their death he filled the two offices of city and country obstetrician (1779). He refused a call to Berlin as professor of surgery, and surgeon in the Charité. The battle of Würzburg, in which Archduke Charles forced the retreat of the French, brought many wounded Austrians into Julius Hospital, and these were cared for by Siebold and his sons. As a recognition of his untiring activity, Emperor Francis II raised him and his descendants to the nobility of the Holy Roman Empire (1801). Soon after the bishop-prince advanced him from private-surgeon to private-physician, and the court-councillor promoted him from professor to privy-councillor. Siebold's activity in the various faculties was very extensive, yet he managed affairs with great energy. In the winter he lectured on anatomy, conducted the experiments in preparations, at first without a prosector by his side, lectured on operations and gave a course in operations. In the summer he lectured on bones and bandages. After New Year's he gave instruction to the midwives and frequently gave private lectures on the theory of obstetrics and diseases of the eye. He was also engaged in making a collection of surgical specimens and conducted the surgical clinic in Julius Hospital every day. For his relief he gave up obstetrics (1790) and had his son, J. Barthel, appointed extraordinary professor of anatomy and surgery (1797), who had had the special instruction of treating the patients in Julius Hospital with his father. When, in 1802, the government of the bishop-prince was abolished and the Bavarian kingdom set up in its place, a reorganization of the university, henceforward called Julius-Maximilian University, was effected, and the chair of anatomy was separated from that of surgery. Carl Caspar and J. Barthel were appointed professors of surgery, and the former acted as director of the anatomico-surgical institute.

With C. C. von Siebold there began for Würzburg a new and brilliant epoch, such as the university had never before experienced, inasmuch that at the end of the century Würzburg was considered one of the first universities in Catholic Germany. Aside from the successes which Siebold achieved in behalf of his little fatherland through the founding of the surgical clinic, the improvement of obstetrics, through his active part in the organization of Julius-Maximilian University, and through the elevation of the surgical profession in the eyes of physicians and of the public, it was especially upon his eminent qualities as a teacher that his reputation in Germany rested. After Göttingen came Würzburg, which had the advantage of possessing over the first mentioned and over other universities, a very large and beautiful hospital—the principal school for surgeons. Siebold attracted a great number of students, among them many foreigners, and he distinguished himself before his colleagues through the fact that he trained up a large number of academic teachers from his body of assistants. Among these, besides his sons, were Professors Weidmann and Fibig in Mainz. Rösch in

Bamberg, Brünnigshausen and Hesselbach in Würzburg, Markard, Adelman and others. Many of his countrymen considered Siebold as one of the greatest surgeons of his time, and his copper-plate portrait bore the inscription "Chirurgus inter Germanos princeps." Sometimes the reputation of an eminent man is depreciated by envy, but in this case it was exaggerated by enthusiasm. Only the crucible of time brings out the true merits, and history has moderated that judgment. Doubtless Siebold was one of the best surgeons of his time, but he had no very great scientific importance; surgery was not advanced by him. He was a good operator and was honest enough to regret that he had never become skilled in cutting with his left hand, and he advised his pupils to early learn to cut and saw with the left hand, in the dissecting room. For the first time in Germany (1778) he performed the synchondrotomy with success, for which the *Académie de Chirurgie* in Paris made him one of its members. He also several times ventured upon the extirpation of the *scirrhus parotis*, yet he adhered to the principle of Celsus against too great a readiness to operate: Never lay a hand on one whom thou canst not save, then thou wilt not be thought the murderer of those whom thou couldst not save.

We can get a clearer picture of Siebold's intellectual bent if we allow him to speak for himself. After he had reviewed, in the preface to his surgical day-book, the difficulties with which he at first had to contend in Würzburg in order to elevate surgery and the profession of the surgeon, he says: "Often my labors were not entirely unrewarded, but I have found the greatest reward within myself, and in the abiding consciousness that I have neither utilized nor called forth all that might be achieved in the realm of the profession, in its extreme limits. . . . As chief surgeon of Julius Hospital I was in a position to practice the profession to my heart's desire, and to put its principles into the completest execution. I always consider the hours which I devote to visits in this place as the best and most pleasant of the whole day. . . . Almost from the first hour of the practice of my chosen profession I have taken the opportunity daily to write down faithfully and circumstantially all or nearly all the cases which have come before me, together with their progress and result, because I would be so completely absorbed in many cases that conversation with colleagues of sterling worth was impossible to me. Literary work was not at that time a part of my intentions, and indeed could hardly have been so, as I was expected to remedy ills with the knife and not with the pen. This note book I kept up every day, and I do not know whether one of my natural functions or the keeping of this so-called day-book is now the more natural to me. I noticed at the same time a subtle influence upon my own development, and encouraged my young colleagues to undertake a like system with their cases, for the sake of their own progress and for the refining of their powers of observation, which demand training just as much as any other of the faculties. . . . Many observations I turned to good account in disputations . . . but in the eyes of my friends I was no writer. At times I indulged in enthusiasm; I had illusions, and saw in the most vivid colors huge volumes before me, with which I should shine in the world of letters; many a time I wrote half the night (for the days left me no time). . . . Sometimes all desire for the life

of a writer forsook me; at times the greatest indifference overcame me; such was my fate for twelve years, in which sometimes I would be a writer, again I would not. A few friends, indeed, addressed themselves to my conscience, and said that the "not yet writer" committed a sin of omission which I (they flattered me!) with my scholarly career took to heart. . . . My friends were not entirely wrong; I will resolve to seat myself and sharpen my pen for a literary life. I resolved, yet long remained undecided, for all kinds of difficulties confronted me; the greatest was my ever-increasing practice. Then I found that it is not so easy to establish one's self as a writer; it is one thing to settle a matter with the knife and quite another to do so with the pen. . . . I finally resolved to all earnestness. . . . In my fifty-fifth year I entered upon my literary career. But once more (rief ich ihm unter der Haushüre), supposing the effort should not meet with applause or should fail. My friends vouchsafed me scarcely a glance, I was obliged to pluck him by the coat and extort an answer from him. 'How can you have any doubt of it?' said he, 'your business is truth, and it is the business of humanity.' . . . My readers will see that to me, or rather to my temperament, which I can not change, it is a hard matter to become an author, a career upon which many cheerfully venture before they know anything whereon they can write, and carry a pencil in their trousers pocket, and suppose themselves to be writers before they even have at hand material enough for a single letter. . . . I began to break off many pleasures, to sacrifice myself, and gradually to become accustomed to sitting, in the face of former habits of long duration. Now the time for action had come. . . . But from all this my readers will see that I was not born a writer. . . . I have often observed in young surgeons, and, if I may be permitted to say so, also in older ones, that the most ordinary things, or rather their proper handling, seemed the greatest rarity. Accordingly I consider the most valuable those of my notes of which the intelligent reader can make the most use. It is not my purpose to dispense so-called observations rariores, yet I will let such go with the rest; let anyone use them who can. I have employed the chronological order, and a kind of disorderly order, which also appears in other writings of the kind which have passed unscathed through the hands of good critics. . . . I lead my friends through a blossoming meadow; let every one pluck and read and carry away what pleases him, and leave the tree and shrub standing; that which appears to him unfruitful perhaps he may take to his colleague. . . . Pardon me, worthy masters, that I can not appear in your uniform; I have the misfortune to be a man who finds himself continually on the road in behalf of his science and of mankind, and one who can not possibly find time to change his traveling clothes in order to present himself in a literary garb. . . . My intention is to use and not to publish. . . . Elegance of diction is no part of my business, and still less is literary adornment, yet I have not been careless in seeking for the greatest possible accuracy of expression. Should many an inaccuracy have crept in, I request that the honorable police court of the language, charged with the keeping of the purity of the German tongue, do not exceed the bounds of its jurisdiction, and for the sake of a small twig uproot the whole tree. What would be said of such a forester? . . . I believe I have observed a certain kind of punctuality in the

applying of the bandages and the use of the instrument, even in cases of minor surgery, so-called against my comprehension and wish. for I consider such just as little beneath the dignity of a surgeon as the greatest and most celebrated operation, because in all cases a man can be a great or a small surgeon. Truth, I repeat, is the stamp which I wish above everything to incorporate in my observations; I have accordingly not only related my successful cases, but even my mistakes, and have acknowledged myself as the author of a mistake when I either misunderstood the language of nature or anticipated it in too hasty a manner, and all with the best intentions! I have also striven, as appears to me to be the duty of an honorable man, to present all sides, even at the expense of my own vanity. . . . I make the honest confession to my readers that I have felt just as much delight when I could endorse an old method for the benefit of the profession as when I saw something new gained for it. I have, therefore, never affected a love for innovation. I have cheerfully been the last to take up a new theory, and have accordingly gained thereby. . . . So I confess that in the confirmation of an old principle throughout a number of uniform experiences I count it as much to my credit as in the discovery of a new and unheard of case, which is often the result of accident, and in need of further confirmation. Yet my readers will find, least of all, that I condemn what is new, for I believe myself to have kept up with the spirit of the times. Only in difficult operations do I follow the old methods to which I have been most accustomed from the time of my first instruction. For instance, I have never attempted a lithotomy in any other way than according to the method of my teacher and guide, Le Cat. . . . I have preferred a safe cure, approved after long trial, to any unsafe attempt, even if its color of novelty was ever so alluring. . . . I will now see how it is to be an author. If I meet with misfortune my friends who persuaded me to this step will have to answer for it. Literary vanity and fondness for writing were never, I repeat, the happiness of my life. But if success comes, and this effort results prosperously, then a continuation will soon follow. . . . But nothing can come of it if my critics go too far."

A number of Latin dissertations preceded his masterwork, "The Surgical Daybook," (1792). In this there are a hundred case reports, which cover a period of one year, and are given in chronological order; brief, clear and sharply outlined pictures, unfortunately without the diagnosis in every case. They show an experienced practitioner, but very little science. Siebold wrote on lithotomy (1778), on the cutting of the os pubis (1778), castration (1802) and several lesser articles for academies and periodicals.

Carl Caspar was the father of an illustrious family in medicine. Four sons devoted themselves to it; the eldest, George Christopher (died 1798) received from his father the professorship of obstetrics in Würzburg; the second son, Damian, was a medical counsellor; the youngest, Adam Elias (died 1828), after his brother's death became professor of obstetrics and teacher of midwives. He founded the lying-in hospital in Würzburg and also in Berlin, whither he was called. The third son, *John Barthol von Siebold* (1774-1814) after his studies in Würzburg and Jena, became assistant to his father, as has been mentioned before. He gave anatomic demonstrations, lectured on osteology and bandaging, and in every semester

taught theoretic surgery. He prided himself on being the first of the Würzburg professors to lecture on pathologic anatomy. He was appointed ordinary professor of surgery, and, upon the death of his father, took the position of chief-surgeon in Julius Hospital. The hospital fever, which during the war proved fatal to so many physicians (eighteen in the Grand-Duchy of Würzburg alone), caused his death. Barthol's scientific accomplishment, like that of his father, is of minor importance, yet he possessed a talent for teaching and skill in operating, kept a day-book, and published annual reviews in the *Würzburger Gelehrte Anzeigen*. Some of his notes were scattered through the dissertations of his pupils, and in different journals. He established (1805) a new periodical, the *Chiron*, and took charge of a collection of rare surgical observations.

At the same time, in Würzburg lived *H. J. Brünninghausen*, one of the best pupils of C. C. von Siebold and A. G. Richter. He was general staff-surgeon of Würzburg, professor and chief district-surgeon: he gained much credit for his treatment of fractures of the lower limbs (1789) and of the collar-bone (1791), invented a machine for club foot and an artificial foot for use after the amputation of the lower limb. The Würzburg collection was greatly enriched through him. At the same time Würzburg possessed *Friedrich C. Hesselbach* (1759-1816), an able demonstrator who turned his attention especially to surgical anatomy. Untiringly active in his lectures and in the conduct of pathologic dissections, he amplified the anatomic cabinet in such measure, that under his direction it came to possess 680 dried specimens, and 501 in alcohol. In consideration of this service, the faculty made him a Doctor. It is to him that we owe the first distinction between the two forms of inguinal rupture, which he accurately described together with thigh-rupture (1806), and a statement of the various positions of the Art. epigastrica in internal and external rupture (1815). He also distinguished the anterior inguinal ring from the posterior, and showed that both were ends of the inguinal canal. The value of these researches is only appreciated when one considers that in Heister's time, the difference between inguinal and crural rupture was not at all understood, and that even A. G. Richter had no conception of the anatomy of the inguinal canal.

Surgery in Berlin, in the second half of the century, was chiefly represented by the military physicians Bilguer, Schmucker, Theden and Mursinna, to whom, as the best physicians of their time, we will later devote a special chapter. *J. Frederick Henckel* (1712-1779) lived in Berlin, first as military, later as civil surgeon. Born in Prussian Holland, he studied surgery, first with his father, then with surgeons in Königsberg and Danzig. In 1731 he went to Berlin to visit the colleges and the Charité under Eller, when he engaged to serve three years in the Kleist Infantry Regiment, as company surgeon. He became surgeon to the Potsdam Grenadiers; then was advanced to pensionary surgeon, and in 1739, King Frederick William I sent him to Paris for two years, where he studied under le Dran, Ferrein, St. Yves, and became acquainted with La Peyronie, Petit and Winslow. As regimental surgeon of the prince's regiment he treated the king during his last illness, was with him at his death and present at the embalming. When Henckel returned from the first Silesian war, he held private lectures and demonstrations for stud-

ents in the Royal theater, and gave courses in bandaging, which subjected him to much ill will and envy. Sentf and Neubauer were at the same time exposed to similar annoyance. Receiving his doctor's degree in Frankfort (1744) he entered the second Silesian war, took part in the battles of Striegau and Sorr, and then forsook the military service in order to devote himself to study. In 1750 he became a member of the Paris Académie de Chirurgie and was appointed professor of surgery and midwifery at the Collegium Chirurgicum and surgeon-in-chief in the Charité. Henckel was very industrious. He encouraged the publication of practical experiences, insisted upon autopsy, inspected surgical preparations himself, and showed so much enthusiasm that he offered from his own pocket, ten Friedrichs d'or to the scholar who should write the best *chirurgia medica*, Henckel himself being the judge. Unfortunately, he was hampered by the want of a good education, as is shown by his dispute with A. G. Richter, and his abuse of other critics. He opened his literary career with a collection of medical and surgical treatises (8 St. 1747-63). His most important work is, "Directions for better surgical bandaging" (with fourteen tables and 102 copper plates, 1756), which ran through many editions, and was indeed, for half a century, the most popular work of its kind in Germany, in so much that seventy-three years after its appearance, it was re-edited by Dieffenbach. Henckel decided, when the suggestion had been made to him after he had lectured on bandaging for twelve years, to re-edit Bass's work on bandaging. According to his own confession he essentially followed this, and indeed, like Heister, frequently copied it word for word. It is seldom that the development of a science can be followed so clearly as that of bandaging. Dieffenbach revised Henckel, Henckel based his work on Bass, and Bass on Verduc, who wrote in the year 1703, covering a period of twenty-six years. Henckel's works, indeed, suffered from a superfluity of obsolete bandages, but what he wrote was clear, brief and practical. His treatise on fractures and dislocations (1759) is worthless. His treatises on surgical operations (8 St. 1770-76) were cursory and without importance, written without order or consistency, and were completely exploded by Richter's critique. In his later medical and surgical sketches (two collections, 1769-72) there were good notes from the Charité and also in his last work, the medical and surgical notes (1779) which were for the most part read in the Royal Academy of Sciences and Fine Arts in Berlin. Henckel was also an active writer on obstetrics and was the first German to perform the Cæsarian section in the *linea alba* (1769), which operation was, moreover, successful.

Among other Berlin civil surgeons, Professor A. Frederick Pallas (1731-1812), son of Simon Pallas, made himself known through his "Surgery" (1764); for the most part he was faithful to the doctrines of his time, but was so superficial that, for example, he devoted only thirty pages, in the tenth part of his book, to the discussion of wounds. His colleague, J. G. Zenker (1759-1807), was professor of surgery in Collegium Medicum Chirurgicum and was famous as a good teacher and operator. He wrote little; his most important production dealt with the injection of equal parts of water and wine in cases of hydrocele (*Theden's Neuen Bemerkungen*, 3 Th., 1795).

Surgery was taught at the Universities of Jena and Halle by a very active man and industrious writer,

J. Christian von Loder (1753-1832). Born in Riga, he studied in Göttingen and was there made doctor by his future father-in-law, A. G. Richter, as "a young scholar of no ordinary promise." In the following year (1778) he became ordinary professor of anatomy and surgery and director for the lying-in-hospital in Jena, where we have already had occasion to visit him in his medico-surgical institute. He taught here for twenty-five years. He gave up his position as body physician and privy councillor in Saxe-Weimar, and went to Halle (1803-1810) and from there to Moscow, as professor of anatomy and surgery, where he was ennobled. In the war of 1812 he conducted several large field hospitals built by him and took an active part in the establishment of the great military hospital at Moscow, of which he was for three years the head. In 1819 a new anatomic amphitheater was built there according to his plans. He died two years after the outbreak of Asiatic cholera in Moscow in the midst of his activity. Loder was more of an anatomist than a surgeon. As such he recognized, as did his father-in-law, that the true value of a surgeon lay, not alone in skill in operating, but above all in the knowledge of so-called medical surgery, by which a man learns to avoid operations. Among his works should be mentioned in this place his medico-surgical notes made in the hospital in Jena (I. 1794), in which he, among other things, appeared as a spirited champion of the Alanson method of amputation. Soon after Richter had called him to act as co-editor of the *Chirurgische Bibliothek* he began to publish (1797) his own journal of surgery, obstetrics and medical jurisprudence. The "Elements of Surgery" (1799), so popular at that time for use in lectures, must not be left unmentioned. An early death claimed a very hopeful student of Loder, namely J. V. H. Köhler. He had accompanied his teacher in scientific journeys through France, England and Holland, and was assistant superintendent of the lying-in house and the hospital in Jena. When he died, in his 22d year, he was court surgeon and privat docent (1796), and had already published a good introductory work on bandaging and described a part of Loder's physiologic and pathologic specimens.

Two students of Richter—Just. Arnemann (1763-1806) and Wardenburg—lived with him in Göttingen. The former came from Lüneburg and at first studied philosophy then later medicine in Göttingen. That university appointed him a professor in 1787 and he went on a two years' journey to Berlin, Vienna, Pavia, Paris and London. The Society of Sciences in Manchester and Joseph's Academy in Vienna, both made him an honorary member. After fifteen years' residence Arnemann left Göttingen, whether on account of Himly who had just been called, or Langenbeck who had just settled there, is unknown. He moved to Hamburg, where he soon took up his residence. Arnemann was full of zeal for his science. Aside from an essay on fatty oils, which won a second prize during his student days, he conducted very successfully an experiment in regenerating living animals. In his first book, devoted to the regeneration of the nerves (1786), after many experiments on dogs, rabbits and goats, he believed he had proven beyond doubt the impossibility of regeneration and held the former demonstrations as untrustworthy and incomplete. The nerve sheaths were said to extend on both sides over the marrow extravasation and when a

firm junction was formed, which he found only in the nerves of the forelegs, in the cruralis and tibialis, the adjacent cellular tissue contributed most largely thereto. In the second volume followed experiments with the brain and spinal column. Arnemann's relation to Richter appears to have been unfriendly from the beginning; this is shown by the fact that besides founding a clinic of his own in Göttingen, when a very young professor he ventured to publish a *Bibliothek für Chirurgie und Praktische Medizin* (Library of surgery and practical medicine) in 1790, at a time when Richter's *Bibliothek* was most popular. He did not once mention Richter's work and thought that in spite of all the journals a new periodical would not be entirely superfluous, because all the others, as everyone complained, were considered either much too lengthy or too brief for practitioners. It was also a fact that the student never contended against his teacher, but almost never quoted him or praised his work. His *Bibliothek* was discontinued after three numbers. Soon afterward a new experiment was made with the *Magazine for Surgical Science* (1797). Not satisfied, the undismayed editor founded for a second time a *Bibliothek* for medicine, surgery and obstetrics (1799) which was chiefly to give general critical reviews from the mass of special periodicals. It lived but two years, while the *Magazine* held out until Arnemann's departure from Göttingen. We have besides, from his pen, a discussion of surgical instruments; a practical treatise on medicine, a treatise on surgical remedies, a hand book of practical medicine and finally a system of surgery (2 Bde., 1798-1801). Like Richter, Arnemann also protested against every one-sided system of medicine; the best operations always seemed to him a reproach to the science. As progress in surgery stands in inverse proportion to the necessity for operations, so the unusualness of an observation is inversely as its value.

His colleague, *G. Wardenburg* (176?-1804), born in Varel, studied in Göttingen, then became Richter's assistant, and went for a year and a half to Paris, where he made friends with Bichat. Appointed professor extraordinary in 1800, he remained in Göttingen only three years, leaving there to become body-physician to Prince Sanguszko in Volhynien. His translation (1799) of the surgical inaccuracies of Desault, published by Bichat, made the principles of the great French surgeon generally known in Germany; that is his service. His letters ("Letters of a Physician written in Paris, and with the French Army, from May 1796 to November 1797;" 2 Bde., Göttingen, 1799) are very interesting, giving a glimpse of French surgery. *Christian Frederick Michaelis* (1754-1814) was born in Göttingen. He studied under Richter and afterward in Strassburg, Paris and London. When the hostilities broke out in North America he became general staff physician in the Hessian corps stationed there in 1779. After the war (1783) he received the professorship of medicine in the Colleg. Carol. in Cassel, and three years later accepted the same position in Marburg. His doctor's dissertation (de angina polyposa sive membranacea, 1778) was the first detailed work in Germany which recommended tracheotomy in croup. He gives an especially interesting account of J. Hunter's experiments during his own stay in London in regeneration of nerves, and asserts that not only severed nerves but even large pieces cut from a nerve could, after a few weeks, be made to grow together through simple cel-

lular tissue or real nerve substance, and the grafted piece would again exhibit motion and feeling. ("Richter's Bibl. und Brief an Peter Camper.") Arnemann disagreed with this view. Michaelis reported the methods of treatment of various physicians and surgeons in London and New York ("Richter's Bibl.") as Pott's results in spondylarthrocace, the use of opium in mortification, the treatment of croup among the Americans, gunshot wounds, observations during his stay with J. Hunter and the effect of common salt in internal hemorrhage. (Before 1766 Dr. Schiel had brought to Philadelphia this discovery of an Irish woman; since then common salt had become a general remedy in America for hemorrhage.) Michaelis investigated the difference between suppuration and matter allied to it, described instruments for compression of the art. pudenda comm., for injection in the tuba Eustachii, to check hemorrhages of the art. epigastrica, tourniquet for art. subclavia, etc. ("Progr. de instr. quib. chir. Marburg," 1801.)

There is great temptation to linger over the works of C. J. M. Langenbeck in Göttingen and B. N. G. Schreger in Erlangen, following after A. G. Richter, the most illustrious of German surgeons, but, lest we overstep too far the limits of our work, we must pass them both, since their activity fall entirely within the century.

The other professors of surgery in Germany were quite unimportant. Rougemont in Bonn, through his *Bibliothèque de Chirurgie du Nord*, made the French acquainted with the best German works. The Erlangen anatomist, *Iscnyflamm*, wrote on diseases of the bones; *Weidmann* in Mainz on necrosis and declared that necrosis is an exostosis, which should be treated not with corrosive but with mollifying remedies; he also opposed the abuse of cutting off gangrenous bones with hot iron, which was then practiced. *Metzger* of Königsberg had for twelve years collected material for his handbook of surgery, but its excessive brevity and superficiality rendered it worthless; his system of medical jurisprudence received greater applause. In Brunswick *Sommer* instituted collections of the choicest and newest works for surgeons, in which he included the best writings of foreigners, translated into German; his great industry resulted in twenty-seven volumes within sixteen years. Emmerich's Academy in Erfurt had a demonstrator, *Löber*, whose elements of the science of surgery was even at that time abandoned as one of the most transient of compilations and completely useless.

Kurt Sprengel, who was professor in Halle from 1789, deserves especial credit for his historical studies. A man of the widest learning, a general historian in the best sense of the term, who was equally proficient in the ancient and the modern languages, he wrote a history of surgery and operations (1805) which, in spite of many one-sided presentations, has not yet been superseded.

Ernest Platner, principally known as an anthropologist and a champion of Stahl's system, and whose opinions on medical jurisprudence were of great value, wrote appendices to his father's "Surgery" (1776), based on a masterly knowledge of literature and so excellently gotten up that one must regret that Platner could not have chosen the career of a practical surgeon. When he said that a practical surgeon would consider one single cure of more value than

this whole book, by reason of his literary studies—a view which he would endorse if he were a practitioner—he only reflected the low state of the culture of his countrymen, and the often falsely understood judgment of his best contemporaries. He translated le Dran's and Morand's surgical writings.

The number of *practitioners* who distinguished themselves in surgery, whether physicians or surgeons by profession, is exceedingly small; and yet what little good was accomplished in German surgery a hundred years ago is due to some of them. Among the results are the tenotomy of Thilenius; Brückner's mechanical compression in case of aneurysm; Vogel's resections and Eckoldt's esophagotomy. That was real progress, of which many German professors of surgery could not boast at all; and if those achievements did not receive due honor at that time it was chiefly because of the meager education of the people. The name of the modest city and district physician of Lauterbach, *Moritz Gerhard Thilenius* (1745–1809), will never be forgotten in German surgery. Although a physician, yet it was he who for the first time, on March 26, 1784, in a case of club foot, had the surgeon Lorenz cut through the skin and the tendon of Achilles, thereby accomplishing a cure. The case made no stir at that time. Richter himself included it in his *Bibliothek*, with other notes of the author concerning a comb (Med. u. chir. Bemerkungen," 1789). *August Brückner*, who was a court physician, died in Gotha (1791) in his twenty-eighth year, had a similar experience. He was the first to accomplish a cure of a true case of aneurysm (art. poplitea) by indirect compression; besides this, he invented a ring tourniquet, and was fully aware that this treatment was the principal remedy (Loder's *Journal*, 1797, I, 248). This observation was also forgotten and modern surgery has yet made little use of the opinions and work of Brückner. He was one of the first in Germany to devote himself to the treatment of club foot. *J. A. Ehrlich* (born 1760) was eminent in Leipzig as an intelligent surgeon with thorough knowledge and operative skill; he was sent upon journeys by the magistrate of that city and later took part in the war and published his surgical notes (2 Th., 1795–1815). In an interesting manner he relates what he had seen in London with Hunter, Earle, Cline, Wathen, Abernethy and others. With him in Leipzig lived *J. G. Eckoldt* (1774–1828), whose name is known to this day through an instrument invented by him for the extraction of foreign bodies from the esophagus, and also through his method of esophagotomy ("Concerning the Extraction of Foreign Bodies from the Esophagus and Windpipe," 1799). *A. Frederick Vogel* (1746–1785) in Lübeck was a good surgeon who, from Richter's school, went upon a three years' journey through Germany, France and England at the expense of the senate and then published his surgical observations (1778–80), which were written with great clearness. He earnestly defended the ligature for the stoppage of blood-flow, therein opposing Agaricus, and was one of the first German surgeons who made resections. The Saxon surgeon, *L. E. Schneider*, in Mitweyda, wrote twelve volumes ("Surgical History, with Theoretical and Practical Comments," 1762–88), containing quite interesting cases, with useless comments and in frightful German. *J. Christian Jäger* lived in Frankfort-on-the-Main, as jury surgeon, after he had completed his studies in various barber shops, and had been

employed in Bremen and Hamburg; he left to posterity five volumes of practical surgical precautions (1788–97). Like him *G. H. Fielitz* was the son of a surgeon who, after attending the surgical school in Dresden, had been established since 1773 as city surgeon, in Lukau in Niederlausitz, and contributed various notes to Richter's *Bibliothek*. He paid great attention to all kinds of plans for furnishing the state better surgeons and midwives. *J. Frederick Böltcher*, a practical physician in Berlin, wrote the first complete work since Petit's time on bone diseases, and also a work on selection of surgical bandages (1795), in which only the most necessary were recommended. *Hofer* in Dillingen produced a similar work ("Bandagenlehre," 1790). The Saxon mining surgeon, *J. G. Bernstein*, was also an industrious writer known through a very popular, alphabetically arranged, handbook for surgeons (4 Bd. 1790), a history of surgery and works on luxations, fractures and bandaging. There are a few other physicians and surgeons whom we will meet later in special surgical diseases: *Hagedorn* in Dessau, *Ficker* in Paderhorn, the dentist *Serre* in Vienna, later in Berlin, *Lange* in Lüneburg, *Greding* in Waldheim, and others.

Among oculists in the second half of the last century, we have already mentioned A. G. Richter as the founder of ophthalmology. In this department of science, as in surgery, he gathered the seed in foreign lands and planted it in German soil. Until then the principles of Boerhaave had prevailed but they were now broadened in all directions: indeed, for a quarter of a century, Richter gave to ophthalmology its specially characteristic type. *Joseph Barth* (1745–1818), who has the honor of having introduced ophthalmology into Austria, trained himself independently of Richter; since that time this science has been fostered with great care in the Vienna school. Barth was born in La Valletta in Malta, and studied surgery there and afterward in Rome, and was introduced to Störk and Leber in Vienna. Ophthalmology could hardly be said to exist in Austria at that time. Rich men suffering from cataract went to Paris to be operated on, or sent there for an operator. Barth devoted his leisure hours to this science and in the sojourn in Vienna of the celebrated French oculist Wenzel, who, upon van Swieten's invitation gave private lectures there, he found an opportunity to make himself thoroughly acquainted with the technique of operations on the eye. His first experiments as a practicing oculist, were attended with so happy results that in 1773, in recognition of his special skill in treating diseases of the eye, and in higher anatomy, Maria Theresa appointed him public teacher of ophthalmology with a salary of 800 guilders. He took the place of professor of anatomy and assumed the duty, connected with this office, of caring for the anatomic specimens presented by van Swieten. In 1774 he became ordinary professor of anatomy and ophthalmology, with a salary of 1,500 guilders, which was soon increased to 2,000 guilders. He established a private sanitarium for his ophthalmic patients. When the General Hospital was founded he was given two wards, in which during May and June he operated upon poor patients with cataract who, through an advertisement in the Vienna newspaper, were invited to Vienna from all the provinces of the empire. Emperor Joseph, whom he successfully treated in a dangerous disease of the eyes, was personally attached to him and appointed him imperial

court oculist. In 1786 he accepted the chair of physiology. His anatomic work expanded in a brilliant manner when he received the means to build in the new university an anatomic amphitheater for three hundred students; the state bought his specimens for 2,000 ducats. His activity as a practical oculist was just as marked. From far and near patients streamed into Vienna to be cured by him—the only one. His private sanitarium had long been inadequate, and the collegium, made vacant by the suppression of the Jesuits (1773), and the Spanish hospital were opened to him. In 1787 over three hundred cataract patients were operated upon.

In order to preserve his experience to the State for future times, the sick Emperor, four weeks before his death, ordered that for a salary of 1,000 guilders, Barth should instruct the two demonstrators, Ehrenritter and Adam Schmidt, in ophthalmology, for which A. G. Richter's works were taken as a basis. But he could not have possession of the money until both men should prove their skill through six successful cataract operations, a test which was brilliantly established the following year. When Joseph II. died, Barth's love for public activity weakened, with a stain upon it; in 1791 he had himself pensioned. He now gave himself up to the study of antiques, and was recognized by the greatest artists of his time as a genuine connoisseur. His collection of intaglios was unique of its kind. The malignity of public attacks upon him made him exceedingly diffident and unapproachable. Except a small treatise on cataract operations without assistance (1797), and a work on muscles, he wrote nothing. His pupil, *A. Schmidt* (1759–1809), became professor of ophthalmology and teacher of anatomy and surgery in Joseph's Academy. After the "Bibliothek," published by him and Hunczovsky, was discontinued, he and Himly, in Göttingen, founded the ophthalmological Bibliothek (3 Bde. 1802–7). His name is immortalized in music, because for a long time he treated Beethoven for deafness, who out of gratitude dedicated a great Trio to him (op. 38, 1801), and expressed the desire in his holy will and testament that after his death Schmidt would describe his sickness. A second student of Barth lived with Schmidt in Vienna, Professor *G. J. Beer* (1763–1821), who as professor, author and practitioner, contributed very considerably to the advancement of ophthalmology. Students flocked to him from all countries and there were at that time few oculists who did not have him to thank for their training. Professor *Lobstein* in Strasburg and Professor *Jung* in Marburg, are well-known; and also *Siegerist* in Gratz, *Willburg* in Gemündt, and *Hellmann*, city surgeon in Magdeburg. The last mentioned was a skilful oculist of no mean reputation: he performed fifty operations for cataract within seven years (32 successful, 10 partially so, and 8 unsuccessful. "Gray Cataract and its Extraction," 1774). While Richter was a professor in Göttingen, *Hellmann* was called to Hanover, where he operated in the presence of Zimmermann.

(To be continued.)

SOCIETY PROCEEDINGS.

New Jersey State Medical Society.

Proceedings of the one hundred and thirty-first annual meeting held in Atlantic City, June 22, 1897.

PRESIDENT T. J. SMITH, M.D., Bridgeton, called the session

to order at noon. It was opened with prayer by Rev. W. M. WHITE.

The Address of Welcome was made by Mayor F. P. STORY, and after some routine business, the report of Committee on Legislative Action on Bovine Tuberculosis was read by the Chairman, Dr. J. W. STICKLER. "The number of cases of bovine tuberculosis examined since the last report is about 1,200: Tested with tuberculin, 214; condemned by the test and physical examination, 159; total sum paid for condemned animals, \$3,849.74: an average of \$23.57 per head, including registered." The above is quoted from the Commissioner's report. Considering the great prevalence of tuberculosis in cattle in our State, especially in the southern section, in Morris and Essex Counties, from 6 to 10 per cent., I am told by competent authority—the Commission is not accomplishing as much as the emergency demands. Again, the State Board of Health reports 3,758 deaths from consumption during the last year, which is 417 more than the average for the past eighteen years. In other words consumption causes about one-eighth of all deaths in New Jersey. It is in view of these facts that the New Jersey State Society wishes thorough work to be done by the Commission already formed, or by a commission which we as a special committee of the State Medical Society would like to form. One obstacle to the proper performance of the work of the Commission is the very small appropriation made by the legislature. It is to be hoped, however, that in time, when the great importance of the work shall be recognized, all hindrances will be removed and the State amply protected.

After a recess, Dr. Wm. H. ISZARD of Camden reported on

APHORISMS IN MEDICO LEGAL TESTIMONY.

He said that an expert in medicine depended mainly upon skill and experience. An expert witness is one whose opinion in medical points is valuable for his accurate knowledge of the subject under consideration. An expert in law is one who is experienced, skilful or having peculiar knowledge of the certain subject or in certain matters. In other words, a scientific witness. Testimony is used more frequently in the Bible by writers than either in medicine or law. It is defined as evidence of a witness under oath or affirmation. All medical testimony is expert testimony in a qualified sense. Expert testimony is that which is usually denominated by the term corroborative testimony. Many lawyers object to expert testimony because so-called experts differ in opinion and statements and will endeavor to break the testimony of good medical men because of this fact. It must be admitted that such witnesses do often differ, and we find them backing their opinion in heated discussion as to the cause of disease. Thus in typhoid fever and insanity legal proceedings are instituted against a city or corporation, for providing unhealthy water: death has occurred from typhoid fever in a family. Men are found who testify that the water does contain specific germs, and thus impress the jury that the water is full of them. In the same court, the other side, by scientific testimony, prove the contrary, viz., that the germs found were the effect not the cause of the disease. Both are equally honest and sincere, hence it is no wonder that lawyers who are not schooled in medical science (and few are) should attempt to prejudice the jury against the reliability of medical testimony. *Insanity*: Hamilton says, especially on the question of insanity, whether civil or criminal cases, we are to determine the influences that may destroy responsibility of an individual, and should always bear in mind that the offices of the physician are only those in which he is warranted in forming an opinion relative to the enfeeblement of the mind through disease. The question of law should not concern him and the courts do not permit him to express more than what he knows. He should always remember the dignity of his calling, never lose his temper, no matter what or how much he may be galled by the impertinences of counsel, who are not always gentlemen. He should never be hurried, give hurried answers, but should demand time and not allow himself to be choked off or interrupted. He should never show eagerness to testify or too much enthusiasm in the cause of the side on which he is called. Testimony should be given in a cool impartial manner. He should be on the alert and avoid being trapped by his opponent. A favorite plan with lawyers is to put a hypothetical question and demand an answer to isolated parts, possibly to get a truthful negative answer to many real elements of insanity: thus, when a man is slovenly or careless in his habits, is this a sign of insanity? An infallible sign? The reply is "No." Yet this and other indications may be an important element of mental disease. Therefore the physician should be on guard and refuse to answer, save in a qualified manner. Remember all dodges will be resorted to. Thus the physician is asked whether he has

read certain works, he replies in the negative. Yet these works never existed. Avoid being drawn into a discussion on various other subjects which are foreign to the case. Refuse to answer any abstract questions not strictly medical. Do not pose as an expert in other fields. It is not wise to pose as a radical and one of more than ordinary ability. Do not tincture an answer with anything extraneous: the witness declares himself an agnostic, he injures the case and renders himself ridiculous. One is not warranted in ventilating, before a jury, any views that he can not maintain. A flippant witness is sure to injure his case, by trying to cause a laugh or by repartee. An old lawyer bides his time and turns his remark against him and creates an opinion not complimentary to him in the minds of the jury. In other words, thoughtless answers destroy the weight of all the sound testimony given before. Keep all the facts before you. Never attempt to give information except what is absolutely demanded. Never explain or enlarge upon something of which you know practically nothing. You may be able to theorize, but before a court you must know practically what you are saying. Called as an expert, theory amounts to nothing. You can not swear by theory. The stenographer notes the testimony, every word is recorded. It is not very complimentary when the stenographer reads his notes to the witness to have it shown that his evidence is absolutely contradictory. Learn the lesson then, be on guard. If doubt crosses your mind let the answer or evidence always be, as far as permitted by the court, given in a qualified sense. There is a growing sentiment in favor of judicially appointed medical and chemist experts. Judge Garrison of our supreme court believes there is a need of medical experts employed by the court so as to do away with the apparent discrepancies between medical experts due to answers on hypothetical questions by counsel. A bill has been introduced into the Minnesota Legislature and one in New York, bearing on this subject. The central idea is that the expert witness should be judicially selected and properly qualified and not depend upon their remuneration from one side or the other. This would be a great improvement on the present system, where medical men hire themselves to testify in criminal cases to suit counsel rather than the unfolding of the truth.

Dr. CHARLES YOUNG, Newark, reported upon

SURGERY.

He gave a brief review of the progress made during the last year. He mentioned the results obtained by Murphy in end-to-end union of blood vessels. These were united by continuous suture; in one case, after five weeks, where suppuration had occurred and hemorrhage from the sloughing point, he had to ligate the artery above and below, and resect the damaged vessel: recovery occurred without disturbance of the circulation of the limb. In another case the vessel much torn by a pistol ball, the artery was secured by a clamp and the vein sutured with excellent results; no blood escaped, and the circulation went on. He quoted a new mode of ligation so as to remove the ligature without cutting. The operator places under each tie-loop silk to be used as tractor. The first loop is designated by one simple knot: next with two knots; next with three knots; and so on. When it is desired to withdraw the ligature, that with the largest number of knots is seized and drawn upon a see-saw motion, till at last it slips away, the loop is withdrawn, and the process repeated with the loop having the next number of knots till the last and the whole is easily removed. The device is simple and far more efficient than any other known plan. Especially is it serviceable in deep-seated ligatures for stumps or pedicles and after removal of abdominal tumors. Intravenous saline injections, in cases of extreme shock, had been found of great value. They give a respite from death, during which the organization may recover from the shock, or throw off septic trouble. Local anesthesia in Schleich's method was advocated for preparatory operations; the cocain solution was thrown into subcutaneous cellular tissue. Caution, however, is of great importance as when the tourniquet is removed, the cocain may suddenly be carried into the circulation and to the heart, with serious results. Loosen the tourniquet slowly, say for three or four seconds, then tighten and gradually permit the blood to resume its course. The treatment of tetanus with biniodid of mercury baths and antitoxin, had resulted in recovery. The bath should be 1 to 5000, and followed by no salivation, but great amelioration of all the symptoms. Serum therapy is still *sub judice*. Results vary. Its main utility is as a prophylactic. *Hernia cerebri*: One hundred and nine cases had been reported. The causes were various, and there was great need of prevention of sepsis. Gunshot wounds of the head and trephining had occupied much attention in surgery. The operation is indicated when there is considerable arterial hemorrhage and symptoms

of lateral paralysis or spasms. Later, when fever comes on and paralysis, or the presence of the ball is known, the operation may be employed. Wounds of the air passages demand great care as to antiseptics. Chloroform may be used if necessary. We should close the wound in the air passage completely: if the wound be large, in the trachea or larynx, a tube is demanded. Silk makes the best suture for the larynx or trachea; all the sutures must be introduced before any are tied: then the posterior one tied first. Divided muscles must be sutured and when bringing the skin together correct any inversion. Drainage is generally necessary. Wounds of the heart and pericardium have been treated by exposing the site of injury by freely dividing and laying back the walls of the thorax above, so as to obtain free access to the wound of these organs. Then the large vessels above and below the wound are closed by gut, the walls replaced in position, and in certain cases good recovery occurred. Wounds of the liver demand prompt exploration. Employ laparotomy to know what the injury is and to repair it. Use blunt needles for sutures through the hepatic tissue. Tie sutures tightly but slowly. In rupture of this organ, an unusual quantity of blood has been seen to flow into the abdomen. Here flushing was carried on till the part was cleared of the blood, and fragments of liver were seen floating in it. Suture being impossible, the hemostatic effects of hot water were relied on; all foreign matter was removed by irrigation, drainage by glass tubes was employed and good recovery followed. In several cases of gastric ulcer, excellent results were obtained by laparotomy and suturing. Perforating typhoid ulcer may be thus relieved. Of all diagnostic signs of ulcer, the most reliance can be placed upon an attack of severe continued abdominal pain with nausea and vomiting and increase of the white blood corpuscles. There are no contraindications to the operation. Lateral anastomosis by Senn's operation was mentioned as having been performed on dogs, producing complete end-to-end union. The indication in operation for appendicitis was considered. Continued frequent progressive acceleration of the pulse, in the absence of other dangerous symptoms. Local pain was valuable when sudden and with a chill. Increase of the temperature is third in importance. A gradual subsidence of these symptoms is a legitimate reason to postpone the operation. He spoke of intestinal anastomoses, etc., and then of fractures treated with the ambulatory plan. The plaster appliance enabled the patient to walk about on the sole of the apparatus. It promotes the formation of callus and even enables one to attend to business. This plan is still being improved upon. Massage and mobilization of the part are liable to cause danger as producing scanty callus. Many very interesting cases were quoted from various authors.

Dr. HENRY MITCHELL, Secretary of the State Board of Health, reported upon

STATE MEDICINE AND HYGIENE.

He said scientific investigation has been industriously pursued during the past year. We have acquired a store of new facts. Bacteriology yields many treasures to the student. Protective inoculation is destined to be successfully applied in many ways if not to all diseases. Immunity as obtained by Koch against rinderpest and diphtheria has stimulated work in this manner. Vaccine bacteriology has been worked at by several and Klein and Coplin describe small bacilli in vaccine and variolous lymph, which they think is the true bacillus of smallpox. The typhoid bacillus has not yet been found to induce the disease experimentally, but the diagnosis of this disease by observing the reaction of the addition of serum from a typhoid case to the blood, has attracted much attention, a reliable method of diagnosis although thus far not much certainty has been obtained for want of more experimentation.

The investigation in England, by the local government board, on oysters and infection from sewage, shows that the typhoid bacillus and that of cholera may live in salt water for two or three weeks and thus the oyster may be a source of contagious disease. Oysters and other shell fish from polluted beds may convey both typhoid fever and cholera. Sanitary supervision of the oyster industry is demanded and the sale of that which is doubtful should be prohibited. Formaldehyde as a disinfectant, has caused a revival of interest, among sanitarians, concerning methods of purifying premises when infected with disease. Test culture has rendered it possible for health officers to prove their work, and show the efficiency of the cleansing. Steam as a disinfectant can perhaps never be supplanted when properly applied as a germicide, but it is not always practicable. As a germicide a solution of formaldehyde is excellent: not being poisonous, capable of destroying the bacilli with great certainty it is warmly welcomed, and its use is extending with remarkable rapidity. A novel device for purifying sewage has

been introduced by M. D. Cameron, Exeter, Eng., the septic tank system. Raw sewage flows into the tank, from which all light and air are excluded to favor the development of putrefactive organisms which are believed to be the cause of rapid changes in the sewage. Fermentation follows, and causes the suspended organic matter to be thrown into the solution; the overflow is odorless and comparatively clear. The effluent is still further treated by passing it through coke breeze filters, when it is discharged as a clear sparkling fluid, without smell.

The mortality among infants, during the summer of 1896, was unusually small in the cities of New Jersey, and the commonly accepted explanation is that many mothers and nurses have learned the value of pasteurization of the milk: hence we have reason to expect that infant mortality will be further decreased in the future. Applied hygiene has made gratifying progress in schools. Boston has for several years had daily medical inspections by the sanitary authorities, to check the spread of disease, especially diphtheria. The result has been so satisfactory that the measure has been adopted by the city as a regular system for promotion and protection of public health. New York City has recently adopted the same plan. All show the great value of this branch of the service. The medical inspectors of the schools report many cases of disease kept out of school. There is need of coöperation of the Boards of Education and the Health Inspectors, then, without waiting for the passage of a law such inspections can be thorough in all New Jersey. Closing of schools is undesirable and should only be resorted to prevent the spread of infectious disease.

The Sanitary Convention of Venice, in February and March 1897, to prevent cholera from India and other eastern countries, marks a progressive step. Since 1851, the first sanitary convention, there has been a gradual yielding to the view of inspection, isolation of the sick and disinfection, as a substitution for the long and vexatious quarantine. Commercial interests always dominated in maritime quarantine and the necessity for relief to trade led to attempts in Europe to prevent the spread of infectious disease, so as to avoid this delay. In the twelfth century, the republic of Venice, after being devastated by repeated epidemics organized a system of inspection and detention of vessels from infected ports of Asia, and established a *lazaretto* to which all passengers, crew and cargo were committed. Thus began by slow degrees the maritime quarantine which has prevailed for five hundred years in the western hemisphere. The national tendency is to modify the harassing features, as advancing knowledge of disease will permit. The port of New York has kept pace with the best service abroad, and the facilities for disinfecting passengers and baggage is unsurpassed.

Measles has demanded considerable attention from health officers, because of varying views. Hitherto it has been allowed to go without isolation, hence we have reaped with exasperating regularity an epidemic every three or four years. This could be wholly prevented by isolation of the early cases. The difficulty is almost insurmountable. It is exceedingly infectious in the pre-eruptive stage, and thus persons not immune are exposed. In the prevention of tuberculosis great activity is shown everywhere. The New York Board of Health has been led to place it among the list of noticeable diseases. In our State no measures like this have yet been possible; but the people will soon demand progress in this as well as other matters: in fact we may say the demand is even in advance of the sanitary authorities. The relation between the health boards and the people is in strong contrast with the conditions existing several years ago. We believe that official inactivity is due to the inadequate supply of trained employes. Instruction is provided for every other profession, but none for sanitary officers, either by the State or private plans. Hence Boards of Health are compelled to entrust the enforcement of health laws to the unskilful. The Medical Society of New Jersey has led for one hundred and thirty years in many good works. Why not give us reform in the selection and education of health inspectors? Last year we took action which resulted in placing on a permanent basis the State Bacteriological Laboratory, and without doubt the same influence could, if exerted, establish in the State, a system for training health officers. This would give us a class of men capable of intelligently applying the arts of hygiene now being promulgated with almost daily additions.

In the evening the President delivered the annual address, his subject being "The Problem of Dependency." The address was devoted to an appeal in behalf of the insane, and the feeble-minded and the society was so impressed by his arguments that a committee was appointed to consider the subject, and granted power to act, with the view of obtaining an act of the legislature which will aid in the care of these unfortunates.

Dr. L. FAUGERES BISHOP of New York, then read a paper on

SOME IMPORTANT POINTS TO BE CONSIDERED IN THE TREATMENT OF ACUTE LOBAR PNEUMONIA.

He thinks we are still seeking the best method of treatment, but that there is a tendency to overfeed. It is questionable whether in the acute stages of this disease with the undoubted accompanying congestion of the abdominal organ, whether harm is not often done by stuffing the stomach with milk, to the production of large quantities of gas and upward pressure on the diaphragm. Now and then a feeble voice is raised against overfeeding, but we have learned too well the lesson of support. The lesson of feeding in other febrile diseases causes us not to consider the shortness of the attack of pneumonia. There are undoubted benefits in restricting the diet in so acute a disease. Overfeeding means a consumption of physiologic force in the digestion and assimilation of food; it means the diversion of so much energy from the repair forces of the body to the digestive forces; it means the throwing into the circulation of a quantity of crude food that must be taken care of; it means the presence in the intestinal tract of the waste matter of the food that must be gotten rid of. The patient dying in acute pneumonia does not die from a lack of more remote reserve force, such as might be produced by a system of stuffed feeding, but rather from the failure of the development, when needed, of the latent force already existing. If by a system of overfeeding, such as would produce this more remote force, part of our stock of immediately available energy is used up, more injury than good is done. It is just as if the captain of a ship with an important and pressing commission should stop to replenish coal supply on the wharf when he should be on his journey, burning the supply in his well filled bunkers. Diet should be bland and moderate in quantity. It would seem that only a misconception of the conditions of pneumonia lead to stuffing in a disease in which it is more important to discount future events. An acute delirium in an alcoholic patient, when fully developed, frequently means death. The feeble power of drugs to control this delirium short of paralyzing the patient with dangerous doses, is too well known. If at the outset of pneumonia in an alcoholic patient, we foresee that the day of delirium is bound to come, we can, by the free use of safe sedatives avoid, or at least limit, the delirium of the latter days. If such a patient, from the beginning of the disease, is brought under the influence of bromid in efficient quantities, the use of the more powerful sedatives at a later period may be avoided. After delirium is once thoroughly established bromid is a drug too mild to be useful. It should be begun at the outset, given freely so that the patient gets half an ounce to an ounce in twenty-four hours. Lives have thus been saved. The next point in this disease is the value of hydrotherapy. The great problem is the maintenance of the circulation in spite of the obstruction in the consolidated lung. We must regard the circulation as a whole, not concentrating attention upon the heart or the lung or the system, always remembering that what benefits a part benefits the whole. The stimulation of the heart and the use of vaso dilators to relieve the burden have been briefly considered. Hydrotherapy is not frequently enough employed in combatting the symptoms, prostration and blood stasis. The difficulties and prejudices to be overcome before it can be generally adopted in pneumonia are so great that it is with difficulty one undertakes to break the ground. It has been so much the property of men who have prostituted medical science to personal profit, that much of value has been lost to conservative practitioners. No one who has witnessed the splendid results of systematic cold bathing in typhoid would ever be willing to be cut off from this resource in a severe case. So in pneumonia, hydrotherapy properly adapted to the condition of the patient would reduce mortality as much as in typhoid. Its value extends far beyond the limits of mere reduction of temperature. The effect is a general tonic to the nervous system. To accomplish these results the temperature and duration of the bath must be properly adapted to the case and conditions present, but there is one element in this application that is of so much importance that we are almost tempted to alter our terms and speak of the treatment as "tub-rubbing" instead of tub-bathing. While in the bath the patient must be rubbed properly on every part of the body by a number of trained attendants. Without the rubbing, the bathing in an acute disease is a fearfully dangerous procedure. The direct care of the heart is equal in importance to the attention to the delirium and the destructive forces of the high temperature. Every one who has watched a patient with pneumonia, from the onset to the termination, has felt that the heart was the organ upon which the brunt of the battle had fallen. No question is of equal importance or greater difficulty than that of heart stimulation.

We approach this problem with humility because there are so many points where definite facts are not known. The mechanism of the heart and circulation are admirably adapted to fulfil their functions. The heart has its wonderful nerve supply, both from the central nervous system and also from the ganglia within itself. The blood vessels are governed by the vasomotor system acting as a system of regulators. In health the slightest mental or physical exertion is followed by increased effort of the heart and respiration. When disease or obstruction to the circulation or breathing occurs, the heart responds by increased labor to overcome the obstruction, and the lungs work even to a greater degree. Hence the question of stimulation resolves into an inquiry as to whether we can with advantage supplement the natural stimulus. We may have unsafe stimulation and exhaust the natural resources. We can not control the action of the heart and conserve its forces to calm the stimulation of an excited nervous system and thus reserve the force required to tide over a critical period. Nutrition of the heart is also of great importance. Hence we may conserve the forces early by controlling delirium by using a proper antipyretic, but at the same time tonic bathing and such drugs as will relax general circulation and diminish hyperactivity of the heart. The aconite group affords very valuable properties. Faith in the value of hydrotherapy is more the growth of time and thought. Its literature is meager. To carry out this method requires courage, skill and apparatus. Until an antitoxin is discovered, the treatment of pneumonia must be expectant in its analysis; protect the patient from harm, and support him to resist the disease. Judgment is the great need.

Dr. EVANS of Morris Plains Insane Asylum exhibited a variety of articles taken from the stomach of a patient who, after swallowing this vast load of stones, spoons, etc., died of starvation.

The Society reassembled on Wednesday morning, and Dr. R. NEWTON COLES of Montclair read

A CRITICISM OF MODIFIED MILK AND PRESENT DAIRY METHODS.

The Doctor said that when we consider the fact that the present science of lactology, if he might coin the word, is only about twelve years old, the progress that it has made is a matter for congratulation and a promise of much better things. He greeted with approval Professor Corsi's prediction that "within ten years the discoveries in bacteriology will produce a complete revolution in almost every branch of the dairy industry."

His subject offered so many and such varied phases for discussion that he was obliged to confine his remarks to the dietetic value of milk from the clinician's standpoint. Systemic writers all agreed that cow's milk must be more or less modified before it can be used for infant food. He objected to the stand taken by some writers, that the milk of cows can be so satisfactorily modified as to make it undesirable to experiment with the milk of asses, goats or mares, and alluded to the fact that the Kurds drink mare's milk made into koumiss and that phthisis is never known among these people. He also spoke of the experiments made in Paris in 1883, in which sickly children nursed asses directly and 70 per cent. of them survived, whereas of these cases heretofore all had died.

The ass is a docile, hardy and long lived creature, and less liable to tuberculosis and similar diseases than the cow. Schwartz, who prefers goat's milk for infants' and invalids' food, was quoted, and the establishment of dairies that would furnish asses' and goats' milk as required for use was advocated. The doctor said that it is an exceedingly encouraging sign of the times that the dairymen themselves have set to work to improve their own dairy products. He believes that there is very much yet to be done, and spoke at considerable length of the poison known as tyrotoxin, which is probably the chief cause of cholera infantum. The presence of this poison in milk is not perceptible to any of our senses. Hence its great danger. Fortunately, it will not be found in properly aerated and cooled milk. The antitoxic property of fresh milk then engaged attention, with a number of interesting observations which prove that all fresh milk has certain germicidal properties. This shows that the general assertion that milk is a perfect culture medium has several limitations. It is evidently very desirable to retain this antitoxic quality in the milk as long as possible, as it is doubtless one of the reasons that nurslings are less susceptible to infection than older children. The study of this newly opened field offers great promise to investigators. Next he considered the reaction of the milk and showed the great advantages likely to follow if dairy milk could be kept alkaline for considerable periods without the use of chemicals. He quoted Rotch, who says that ten pounds of Austrian sugar beets fed to milch cattle every day

will keep the milk alkaline, and also that cattle pastured on limestone lands, or the blue-grass regions of Kentucky, will give milk that will remain alkaline for a long time.

A number of facts are given to show the exquisite sensitiveness of milk to any change in the animal's diet, surroundings, care or treatment, and particularly in the way the process of milking is carried out. As to the bacteriology of milk, the limits of this paper prevented its consideration. Two years ago over two hundred varieties of bacteria had been demonstrated in milk, and each species produced its own form of fermentation. This phase of the subject opened another important and as yet only partially explored field. The writer then quoted from Mr. Ernest Hart's recent address on the "Conveyance of Contagion by Milk" and alluded to our ignorance of some of the most important facts connected with this means of infection. He also showed that the most carefully handled and Pasteurized milk might entirely disagree with infants and quoted cases to prove his point, dwelling particularly upon the bad effects of agitation and movement of milk and also upon certain occult but as yet irremediable changes which occur in milk, merely from lapse of time, which impair its dietetic value. He dwelt upon some important facts which investigation had brought out in reference to the spread of tuberculosis among dairy cattle. Professor Bang, Dr. Theobald Smith and Dr. E. A. de Schweinitz have done much to show that tuberculosis rarely appears in small herds of cattle, and also by sterilizing the milk fed to the calves of tuberculous cows and by a strict isolation these calves will grow up non-tuberculous. The danger of tuberculous infection in neat cattle increases in geometric progression with the number of cattle kept together and the number of hours during the twenty-four in which the cattle are housed. There seems to be no reason why Alvord's excellent suggestion, not to milk cows in the stables but in an airy, light and disinfected place kept free from excrement, flies and dust, should not be generally adopted by our dairymen. The Doctor concluded his paper with the following: "Fortunately the day of rationalism in medicine has begun to dawn and the clouds of superstition and ignorance are fleeing away. Whatever unsanitary evils can be prevented by scientific knowledge and hygiene we are today struggling to get rid of. We rely less upon drugs than did our ancestors, but more upon common sense as exemplified in sanitary science. In the words of the honored secretary of the Society: 'It is only by removing or obviating the causes of disease in general that medicine will make any real advance.'"

(To be continued.)

Chicago Pathological Society.

Regular Meeting April 12, 1897.

The President, Dr. JAMES B. HERRICK, in the chair.

Dr. EMIL RIES read a paper on "Papilloma and Carcinoma of the Fallopian Tube." (See JOURNAL, Vol. 28, p. 962.)

Dr. H. A. BRENNER reported a case of "Measles Complicated by Diphtheritic Conjunctivitis." (See JOURNAL, Vol. 28, p. 1221.)

Dr. M. L. HARRIS read a paper on a case of "Benign Cicatricial Stricture of the Ileum. Operation, Lateral Anastomosis. Exhibition of Specimen removed five years after." (See JOURNAL p. 117.)

Dr. J. E. YOUNG presented a specimen of "Defect in the Ventricular Septum." (See JOURNAL p. 118.)

Dr. EMANUEL J. SENN read a paper entitled "Inflammation of Joints in Gonorrhoeal Patients."

SELECTIONS.

The Administrative Treatment of Undefined Cases Certified as Scarlet Fever.—Drs. Frederick Dittmar and Brownlee, both of them formerly or at present attached to the Glasgow Health Office, report on the above subject as follows: "In this communication we intend giving an account of the management of the undefined cases admitted to the Glasgow Fever Hospital, Kennedy Street, from November, 1895, to November, 1896. Prior to the former date there was an arrangement for the special observation of cases of this nature. The hospital, which is exclusively employed for the treatment of scarlet fever, consists of fourteen wards built on the pavilion system, and has accommodation for about 320 patients. The pavilion chosen for the purpose of isolation consists of three divisions separated one from another by brick partitions which extend from floor

to ceiling, while each division has a separate communication with the outside. Two of them have a capacity of 16,500 cubic feet each, and the third of 8,000 cubic feet. The last has also separate latrine accommodation and bathroom.

"The patients sent to the pavilion were of three classes: 1, cases in which the appearances on admission did not justify a positive diagnosis of scarlet fever; 2, cases where the symptoms and appearances suggested some other disease, *e.g.*, tonsillitis or non-specific erythema; and 3, cases of undoubted illness where the symptoms were obscure, but suggestive of some other infectious disease, *e.g.*, enteric fever. Cases in which some other infectious disease was frankly present were immediately transferred to the Belvidere Fever Hospital without admission to the wards.

"The two larger divisions were used for the first two classes, and the smallest division for the third class of cases. The whole pavilion was under the supervision of a very careful and experienced charge nurse whose powers of observation could be relied on, while each division had its special staff of day and night nurses. During their residence in the ward the patients were carefully observed for signs of scarlet fever, the urine being examined twice daily for albumin and evidence of desquamation carefully looked for. As soon as desquamation became definite or scarlet fever complications showed themselves the patient was transferred to a scarlet fever ward, where he completed the statutory period of eight weeks in hospital. Cases which did not turn out to be scarlet fever were kept in the isolation ward for a period varying with the nature of the case, but as a rule were not dismissed under four weeks, which we considered long enough for any such definite evidence as desquamation or nephritis to develop. None of the cases dismissed from the isolation ward were sent back to hospital with evidences of scarlet fever. The main objection which we have heard raised against the kind of arrangement adopted by us is that now and again patients who ultimately prove to have scarlet fever are mixed with those who do not, and thus may infect the others. Our experience seems to show that this fear is more or less baseless, as no case of scarlet fever occurred in the isolation ward. We tried to minimize the risk of infection by putting the patients at as great a distance from one another as possible and allowing at least 4,000 cubic feet of air space to each. We also cautioned the nurses to take special care when attending a patient the subject of any inflammatory secretion by which infection might be carried.

"The number of cases observed by us amounted in all to 45, and they fall into the following groups, of the more important of which we give typical examples. Of the 45 cases observed, 11 (24.4 per cent.) ultimately proved to be cases of scarlet fever, 6 (13.3 per cent.) belonged to the class of doubtful scarlet fever, and 28 (62.2 per cent.) were not scarlet fever. The last class was made up as follows: Tonsillitis, 11 cases; non-specific eruptions, 4 cases; dermatitis, 2 cases; cellulitis, 2 cases; measles (?), 2 cases; r othein (?), 1 case; bronchopneumonia (one complicated with marasmus), 2 cases; gangrenous ulceration of throat, 1 case; general tuberculosis (?), 1 case; and not classed, 2 cases.

"The cases which proved to be scarlet fever may be dismissed with the remark that the certifying practitioner, having seen the case earlier, had probably more definite and specific signs on which to found his diagnosis. We would call attention to a patient in which no desquamation was observed, though the child suffered from well-marked scarlatinal sequelae, *viz.*, enlarged cervical glands, rheumatic pains in the joints and albuminuria.

"Of the cases of doubtful scarlet fever there was a fairly typical example. A brother admitted at the same time probably had scarlet fever. He also was considered doubtful at first, but was after a time transferred to a scarlet fever ward on account of desquamation on the legs. He was dismissed

from the latter after five weeks' residence without having contracted scarlet fever.

"As regards cases of tonsillitis no great difficulty is experienced when they occur singly in a family none of the other members of which are suffering from scarlet fever; but when they arise in a family in which one or more of the members are suffering from scarlet fever they are a cause of great anxiety to the physician in attendance. Attacks of this nature are considered by many authorities to be specific and infectious, and yet they do not seem to confer immunity on the person attacked. We have a good example of this in the family the case of one member of which is reported *in extenso*. On the same day a younger brother was admitted. A day or two later an elder brother and a sister were also sent to the hospital. The history in each case was similar, and on admission there was nothing observed but a tonsillitis. The sister and two younger brothers were transferred to the isolation ward on Dec. 7, 1895, and were dismissed well on Jan. 1, 1896, nothing having occurred to warrant the diagnosis of scarlet fever. The third brother was left in scarlet fever ward, and after twenty-six days developed a typical attack of scarlet fever. Similar cases with a like sequel have been observed by ourselves and are doubtless familiar to anyone who has had charge of scarlet fever wards for some time. We have classified such cases under the heading of tonsillitis, though one might be justified in considering them as cases of aborted scarlet fever. The class of non-specific eruption includes, beside the case of which a synopsis is given above, one case of urticaria and two where an erythema of an indefinite character was present, but where neither the history nor the cause of the case led to any reasonable suspicion of scarlet fever.

"Of the unclassified cases, one patient was hysteric and the other was sent in from a public institution along with another child who was suffering from scarlet fever. She, however, neither had that disease on admission nor did she contract it."—London *Lancet*, April 3.

Analysis of Two Hundred Gallstone Operations.—Dr. Kehr of Halberstadt, has in six years performed 209 laparotomies for the relief of cholelithiasis. The mortality in this series was seventeen cases, or 8 per cent. Where the stone was in the gall bladder, and was removed either by cystotomy or cystectomy, the mortality was practically 0 per cent. The highest fatality occurred in those cases associated with some grave complication, as carcinoma of the liver or pancreas, etc. The most remarkable results were obtained in the operations on common duct, where there were only two fatal cases in thirty operations, or 6.6 per cent. This is in marked contrast to the results heretofore obtained. Kehr collected eighty-two cases from the literature, in which twenty-six died, giving a mortality of 31 per cent. These results should interest physicians, because, while medicine may be said to have not advanced the treatment of gallstones a step in five years, during the same period operative treatment has made great strides in the hands of the surgeon. From 1890 to 1896 Kehr performed his 200 laparotomies on this behalf. These were performed on 174 patients, some having been operated on more than once. Of these, 23 were males and 151 females. Of the latter, 133 were married, 117 of whom had borne children, and 18 were single. The operations are divided into five groups: 1. Those in which the gallstone was situated either in the gall bladder or cystic duct. Under this group there were 127 operations, with only 1 death. The fatal cases occurred in a man, 64 years of age, who had emphysema and arterio-sclerosis. 2. In twenty-one cases a cystectomy was performed, owing to obliteration of the cystic duct or to fibrous contraction of the gall bladder, rendering the latter functionless. The gall bladder was accordingly excised. Only one case died. 3. In thirty cases the stone was situated in the common duct, and was so large that it could not be forced either into the duodenum through the papilla or through the cystic duct back into the gall bladder. In these cases a choledochotomy was performed, the stone being removed through an incision into the common duct. Of this group only two cases terminated fatally. 4. Under this

group were included seventeen cases, in which, instead of the suspected gallstone, either some other disease-process (as ulcer of the stomach, echinococcus of the liver, or wandering kidney) was found, or the gall bladder, being free from stones, was, however, adherent to the omentum, stomach, intestine or abdominal wall. Two of these cases died. These cases demonstrated to Kehr, first, that in some instances an exploratory incision is necessary to make a diagnosis; and, secondly, that adhesions between the gall bladder and adjacent structures may produce colicky pain indistinguishable from that produced by a gallstone. 5. The last group included cases in which, in association with gallstones, there existed various complications, as carcinoma of the liver, stomach, common duct, or head of the pancreas, suppurative cholangitis, syphilis of the liver, or liver cirrhosis. This group comprised nineteen cases, ten of which terminated fatally, while nine obtained relief from their symptoms for periods of from one and one-half to ten months.—*Arch. für klinische Chirurgie*.

Variation in the Size of Drops of Even the Same Liquid.—The great variation in size of the drop furnished by different liquids is well understood, but the large divergence in the size of drops yielded by the same fluid, even under ordinary conditions, is not so fully appreciated. Pharmaceutical literature acknowledges the unreliability of the drop as a method of measurement, yet with singular unanimity gives approximating numbers of drops to the fluid dram for similar liquids. This would leave one unfamiliar with the facts to infer that the number of drops to the fluid dram of any given fluid is fairly constant, which is far from being the case, unless much more than usual attention is paid to the proper conditions to secure what might be called the recognized drop of any given liquid. The use of the drop as a means of measurement is on a par with that of the pinch and handful, and all three are quite unsuitable for potent drugs.

The number of drops of water to the fluid dram is usually given by various authorities as about sixty, and similar figures are accorded to such watered preparations as Fowler's solution and dilute hydrocyanic acid. Our attention was first strongly called to the great ease with which the size of drops can be varied under ordinary circumstances, by being consulted by a prominent physician, in regard to the number of fluid drams of dilute hydrocyanic acid to be used in a prescription, where he wished to secure a certain number of drops in each fluid dram of the finished product. Upon inquiring of him the size of the drop desired, it developed that the physician thought that a drop of dilute hydrocyanic acid always represented a minim. In reply to this, forty drops were dropped from the one ounce glass-stoppered bottle holding the dilute acid, into a small narrow-lipped, thin-edged graduate and they were found to measure one fluid dram. The graduate was then elevated and turned until drops began to fall directly from the lip, without the intervention of a guiding-rod, stopper, or any other aid whatever, and one hundred drops were secured from the original forty. In one case the drops were 50 per cent. larger than he expected, and in the other they were only six tenths of the size anticipated. The larger drops were two and a half times the size of the smaller ones; yet either method of dropping would not be considered unusual.

To show how widely drops of the same liquid will vary in size when obtained under different conditions experiments were made with water, which is much used as a menstruum, and fairly represents several powerful preparations. A fluid dram was dropped under the varying circumstances noted below with a yield in drops as stated:

From the bottom of a ten ounce evaporating dish, the number of drops was 18.

From a two pint funnel, choked with cork for dropping, square, thick end, 24.

From the bottom of a five ounce beaker, 25.

From a six ounce funnel, choked with cork for dropping, square, thick end, 28.

From a large glass stopper, two inches in diameter, 30.

From a five ounce lipped beaker, with guiding-rod, $\frac{3}{8}$ inch in diameter, 31.

From a $\frac{3}{8}$ inch guiding-rod, taking supply from two ounce dropping funnel, 32.

From a four ounce glass stopped bottle (half full), stopper kept partly in neck, 33.

From a two ounce lipped graduate, offhand, without guiding-rod, 45.

From a one dram lipped graduate, offhand, without guiding-rod, 47.

From a two ounce funnel, choked with cork for dropping, slanting end, 52.

From 3 16 inch diameter guiding-rod, taking the supply from two ounce dropping funnel, 62.

From a 3-16 inch diameter guiding-rod, taking the supply from one dram graduate, 96.

From a $\frac{1}{8}$ inch diameter guiding-rod, taking the supply from two ounce dropping funnel, 96.

From a five ounce lipped beaker, offhand, without guiding-rod, 100.

From a five ounce lipped beaker, with guiding-rod, 3 16 inch diameter, 120.

From a pointed guiding-rod, 1-24 inch diameter at point, from two ounce dropping funnel, 160.

From a pointed guiding-rod, 1-40 inch diameter at point, from two ounce dropping funnel, 600.

The drops which were obtained with the very small guiding-rods and from the bottoms of the vessels were abnormal and are only given to illustrate what is possible under certain conditions. The list, however, shows quite plainly how easy it is to obtain drops of water under ordinary circumstances, varying from 33 to 120 to the fluid dram.

There are several factors which cause the drops of the same liquid to vary in size, among which are the adhesion of the fluid mass to the solid which it bathes, the cohesion of the molecules of the liquid to each other, the gravity of the fluid, the temperature, the rapidity of dropping, and the area and shape from which the drop falls. The adhesion of a liquid is greater for some kinds of solids than for others. If a liquid does not wet a substance, it is because its adhesion for such a material is overcome by the cohesion of the liquid. Films of grease covering a dropping surface, in part or completely, have a decided influence in altering the size of the drop. A fluid dropping from such a non-wetted surface has principally the adhesion to overcome, as it is weaker than the cohesion which holds the liquid particles together. When the solid is wetted, cohesion is stronger than adhesion and it is the cohesion which has to be overcome before the drop can fall.

The gravity of any mobile body determines in a considerable degree, its ability to cling to different surfaces and results from certain surfaces for one liquid are not necessarily proportionately correspondent for a fluid of different gravity.

Differences of temperature cause variations in the viscosity of fluids and in this way influence the size of the drop. In liquids which readily become viscid, at not unusual degrees of cold, this factor is most marked. In liquids like water, whose mobility is but little effected by ordinary changes of temperature, the size of the drop shows but slight variation from this cause. As an illustration, water from a two ounce dropping funnel gave 44 drops to the fluid dram at 0° C., 47 drops to the fluid dram at 22° C., and 47 drops to the fluid dram at 100° C. These identical results were obtained in each of three trials at the three different temperatures.

Rapid dropping furnishes smaller drops than when the dropping is done slowly. This is due to the momentum of the liquid, which as the velocity of its flow is increased, enables it to more readily overcome causes which tend to produce a larger drop.

The area and shape of the surface from which the liquid drops, probably causes the most important differences in the size of drops from any one liquid. The larger the surface to which the fluid can cling and from which the drop mass can secure material at the period of its segregation, the greater the drop will be. Small guiding rods give smaller drops than larger ones, and guiding-rods of similar size with conical ends yield smaller drops than those whose ends are globular. Rounded or globular surfaces are well adapted to illustrate the great influence which is exercised upon the size of drops by the area of the surface from which the drop actually falls. Plane surfaces are not suitable, as it is almost impossible to prevent the dropping from occurring at the edges. In the case of water, above illustrated, the size of the drop steadily increased from the rounded surface 1-40 inch in diameter up to the one ten inches in diameter. At certain diameters for different liquids, a point is no doubt reached, where, from conditions being carried to extremes, a drop is obtained of equal size to that which is possible from the under side of a perfectly level plane surface of unlimited extent.

Where wild guessing is not permissible, fluids should not be dropped, but should be measured. The minim or 1-10 c.c. should be used for describing small quantities of liquids, and in cases where it is absolutely necessary to use drops, but little dependence should be put in their estimated sizes, but an actual trial should be made of the material in the way it is intended to be dropped, that one may know what part of a fluid dram this particular kind of a drop actually represents.

(Geo. F. Payne, M.D., in *Druggists' Circular*.)

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, JULY 17, 1897.

MEMBERSHIP IN THE ASSOCIATION.

That the ASSOCIATION is growing in membership at an unprecedented rate is perhaps not known to all the members. We therefore take great pleasure in informing them that 763 names were added to the membership list at the Philadelphia meeting.

The books show an increase from June 1, 1896, to July 1, 1897, of 1,500 names. For the same period, our books show an increase of an even 500 on the subscription list.

These are gratifying evidences not only of the sincere desire of the medical profession to organize under the ASSOCIATION banner, but that its JOURNAL is fairly satisfactory. It will be the aim of the present management to make the JOURNAL more and more useful to our colleagues with each succeeding issue.

This is an appropriate occasion to invite members to do their part toward increasing the membership. Help us pass the ten thousand mark before the close of this year. Every one can help. Blank applications for membership can always be had by writing to this office for them. "Be not weary in well doing."

THE ROLE OF THE SPLEEN IN INFECTIOUS
DISEASES.

Other than that the spleen plays some part in the destruction of old blood-corpuscles and the generation of new, little is known concerning the function of this organ. That it is somehow affected in the course of

many of the infectious diseases is apparently shown by the frequency with which it undergoes enlargement of size in conjunction therewith. Various hypotheses have been propounded as to the nature and the purpose of the alterations that take place, but none has thus far withstood the tests of experimental inquiry. It is therefore a source of satisfaction to note that the subject has recently been taken up and given consideration on a generous scale by BLUMREICH and JACOBY (*Berliner klinische Wochenschrift*, May 24, 1897, p. 444) at the Second Medical Clinic of the University of Berlin. These observers made a careful and scientific study of the influence exerted upon the susceptibility of guinea pigs to infection by bacteria and their toxins respectively by reason of the presence or absence of the spleen. After a little skill had been acquired in the technic of the extirpation the animals operated on speedily recovered and gained in weight.

Diphtheria bacilli and active diphtheria toxin were first experimented with. Twenty-four animals were taken and the spleens removed from twelve. Of each group six animals were now inoculated with the bacilli and six with the toxin. Those of each kind treated with the toxin presented like symptoms, all dying at about the same period; while of those inoculated with the bacteria the six from which the spleens had been removed resisted fatal doses longer than the control animals, the latter dying on an average after 34½ hours, the former after 47 hours.

Fourteen normal animals and twelve from which the spleens had been removed and all inoculated with virulent anthrax bacilli died at about the same time; only one animal deprived of its spleen recovered. These observations with regard to anthrax bacilli are practically in accord with those of others, apparent variations being due to differences in degree rather than in kind. Between animals with and those without spleens treated with pyocyanus toxin there was little or no difference, although of fifteen from which the spleens had been removed two died (one through an accident) and thirteen recovered, while of twelve normal animals treated similarly eight died and a ninth was made very sick.

Again of eighteen animals without spleens treated with cholera bacilli four died and fourteen survived, while of fifteen normal animals similarly treated thirteen died and two were made very sick.

It would thus appear that guinea pigs deprived of their spleens possess an increased resistance to infection by the bacilli of diphtheria, pyocyanus and cholera, but not to their toxins. To determine if this peculiarity is dependent upon the removal of the spleen from the body or merely from the circulation the spleen was ligated in nineteen animals. The operation was borne badly, fifteen animals dying in a short while and only four being available for further

experiment. In these the results were found to be just the same as when the spleen had been removed from the body. The conclusion would thus seem justified that it is really the removal of the spleen from the circulation that is responsible for the increased resistance of guinea pigs to bacterial infection.

To determine if the blood of animals deprived of their spleens is endowed with the property of diminishing the virulence of bacteria in greater degree than the blood of normal animals virulent cultures of the bacillus pyocyaneus were brought in contact for several hours with defibrinated blood obtained from normal animals, as well as from others deprived of their spleens, and the mixtures injected into other animals. The results were constant that the animals treated with mixtures of bacteria and the blood of normal animals died earlier than those treated with mixtures of the bacilli and the blood of animals deprived of their spleens. The conclusion seems therefore justified that the blood of animals deprived of their spleens possesses a greater bactericidal activity than that of normal animals. Bacterial toxins on the other hand behaved in the same way with the blood of both sets of animals; that is their activity was in no wise enfeebled.

In order to determine if experimental infection could be neutralized by hyperleukocytosis and if this result were to be attributed to the bactericidal action of such blood from the presence of the increased number of colorless corpuscles, the blood of sixteen animals was taken and counted before and at various times after extirpation of the spleen. In fourteen considerable increase in the number of leukocytes followed; in two there was a diminution, but in one of these suppuration took place and in the other death resulted on the fifth day from pneumonia. To demonstrate that the hyperleukocytosis was not dependent upon the operation rather than upon the removal of the spleen it was shown that the blood-state did not occur when the remainder of the operation was performed while the spleen was left intact. It was further found also that the hyperleukocytosis resulted when the spleen was merely ligated and thus excluded from the circulation only.

The evidence would thus go to show that removal of the spleen is followed by hyperleukocytosis, increased bactericidal activity of the blood and increased resistance of the body to certain forms of bacterial infection. There is thus afforded an explanation why animals deprived of their spleens are more resistant to bacterial infection than to intoxication with bacterial products and also why in diphtheria, in which the toxic factor preponderates, destruction of the bacteria is of so little direct importance, and why the infection of cholera is so readily overcome. It must, however, be remembered that the protective influence of the leukocytes is limited both in degree and in time.

Perhaps in this fact is to be found the explanation of the aberrant results obtained with anthrax bacilli.

Now it may be suggested that if immunity to infection on the part of animals deprived of their spleens is due to hyperleukocytosis, opposite results should be secured if bacterial inoculation preceded removal of the spleen. The correctness of such an assumption was demonstrated by inoculating fourteen animals with bacilli pyocyanei and several hours later removing the spleens from eight. Of the latter six died, while of the six control-animals only two died. It may be, that other changes, chemic or morphologic, in addition to hyperleukocytosis, may have some share in the effects produced. Future investigation will have to determine whether the changes effected follow only removal of the spleen or other lymphoid structures or may develop in the sequence of removal of any other important organ. It has already been shown that injections of extracts of spleen, thymus and bone-marrow (lymphoid organs) induce hyperleukocytosis, while extracts of other organs do not. It yet remains for the clinician to determine whether in diseases attended with enlargement of the spleen and hyperleukocytosis, or hypoleukocytosis, these respective conditions bear a constant definite relation to one another and whether the enlargement of the spleen, like the number of leukocytes, is of favorable or unfavorable prognostic significance.

THE NERVOUS ACCIDENTS OF BICYCLING.

The bicycle has become so an important element in modern life that it is certainly worthy of an occasional mention by the medical press. The subject has not been exhausted in its hygienic and medical relations and new points arise from time to time for consideration. A few weeks ago the nervous disorders induced by bicycling were discussed, not exhaustively it is true, by certain English physicians and it was pointed out that excess in this as in other reasonably good things had its more or less damaging influences. Other than medical writers have discussed also the iniquities of this modern indulgence, the bicycle hump and the bicycle face are matters of common jest, not on the principle of ridiculing a false alarm, but as an evidence of the popular taste for the ridiculous even in self-inflicted misfortunes. Still the bicycle becomes daily more popular and its influence on our civilization will be seriously discussed by future historians and students as much as will its physical effects by physicians.

Much of what has been said against the bicycle, without doubt, falls into that class of hygienic criticism that, if sufficiently influential and accepted, would make life miserable by depriving it of all its pleasure. Still there is something to be said to its disadvantage now and then and this is accentuated by the almost universal use of the wheel by persons of all ages and

classes at the present time. Extreme youth and advanced age have each their special drawbacks; in the one there is the possibility of overtaking and possibly of deforming an only partially developed organism, and in the other the general danger of overstrain of an enfeebled one together with the special hazard of aggravating certain senile weaknesses. For the great mass of mankind of either sex the dangers could hardly be said to counterbalance the advantages if it were not for the tendencies to the excessive use and the abuse of what ought to be a pleasant and profitable exercise. The pleasure of rapid movement and the emulation and competition, the sporting instinct that exists in almost every one, all have their part, and the results are often disastrous. To say nothing of the frequent surgical accidents, the bad effects of vesical and prostatic irritation, the heart strain, and other disadvantages that have been frequently pointed out and are incontestable, there are yet other possibilities of evil. Drs. SEMPLE and TAYLOR have reported myelitis as a direct consequence of excessive use of the wheel, and another English physician, speaking from personal experience as an observer of road races and other bicycling sporting events, gives quite a formidable list of the nervous accidents he has seen follow in the participators. Most of them it may be presumed were only temporary, but some may not have been, and temporary or not, none of them were desirable symptoms. It would be interesting to know the extent of the nervous symptoms that actually do occur in scorchers and bicycle racers; as yet we have only a few observations on record, but these are suggestive and lead us to suspect that there are many yet to be reported. The use of the bicycle is rapidly extending and it is only a few years since it became so general; any remote nervous effects of its misuse have therefore hardly had time to develop. With its extended use there have been some improvements in a hygienic point of view; the pneumatic tire, reducing the jar, is one; the improved saddles are another; but modern high gearing and the tendency to sacrifice everything to lightness and speed are perhaps advances in another direction. In any event it will be long before all the medical aspects of the subject are fully discussed; they are all the while developing. But there is certainly room at the present time for a complete investigation of the effects of the altogether too common misuse in many ways of the bicycle upon the nerves and central nervous system.

THE BACTERIOLOGY OF MUMPS.

It does not seem unreasonable to believe that the entire group of so-called self-limited diseases, including among others the exanthemata, pneumonia, acute rheumatism and chorea are dependent upon bacterial invasion. The dependence of many of these upon

specific bacteria has already been demonstrated and it is not improbable that the near future will bring similar demonstration for the remainder. The list of the former is steadily growing, while that of the latter is correspondingly diminishing. Among the latest of the disorders which have been shown definitely to owe their origin to microörganismal activity is mumps.

PASTEUR noted in the blood of patients suffering from this disease bacilli $1\ \mu$ thick and $2\ \mu$ long. CAPITAN and CHARRIN, and also OLLIVIER, observed in the blood and in the urine of such patients small rods in addition to cocci. BOINET found in the blood cocci arranged in part in pairs and in part in chains. LAVERAN and CATRIN, and later MECRAY and WALSH, found partly in exudates and partly in the blood diplococci capable of cultivation on artificial media. At a recent meeting of the Berlin Society for Internal Medicine MICHAELIS (*Deutsche medicinische Wochenschrift*, May 13, 1897, Suppl. 1, p. 93) detailed the results of a number of bacteriologic examinations made by himself and BEIN in cases of mumps observed at the clinic of Professor LEYDEN, who had some time before noticed peculiar diplococci in the sputum of a child suffering from this disease. These bacteria lay principally within pus cells. In all of seven cases of epidemic mumps recently studied the same organism was found both on microscopic examination and on culture, and not only in the secretion of the parotid gland as obtained from STENON'S duct, but in two cases also in pure culture in the pus from an abscess and in one of two cases examined in blood obtained by venesection.

In spite of this small number of observations the belief is expressed that in view of the constancy of the results the conclusion is justified that the microorganism found may be considered to bear etiologic relations to the disease. The individual microörganisms are $1\ \mu$ in size and resemble the biscuit-shaped meningococci and gonococci, although smaller than these. They lie frequently within the cells, sometimes to the number of eight or ten or more, and are also partly distributed throughout the pus or in long chains or strings. They stain readily with the usual anilin dyes, especially with LOEFFLER'S methylene-blue, and they can be decolorized by the method of GRAM. They grow upon the usual culture media, though slowly. Upon agar they develop tiny transparent, dewdrop-like points that do not coalesce. Upon peptone-bouillon they form a white, rather granular than flocculent, deposit, the bouillon itself remaining clear. The growth is more rapid on strongly alkaline than on feebly alkaline media. The bacteria grow also upon ascites-fluid and upon milk, the latter coagulating in the course of forty-eight hours. They are capable of slight movement. Inoculation experiments were unsuccessful, except in the case of a white mouse which died after thirty-six hours. Inocula-

tions of cultures were made into the parotid glands of white mice and rabbits, cats and dogs and into the testicles of guinea pigs. Control observations failed to disclose the presence of the same organism in the saliva and the parotid secretion of healthy persons.

AN INCREDIBLE SCANDAL.

In addition to the great amount of amusement and edification derived from the works of CHARLES DICKENS, it is a well known fact that several of his writings called attention so emphatically to various existing abuses that these errors in administration, or in habit, were speedily corrected. It is stated that HOOD'S "Song of the Shirt" did more toward relieving the condition of a certain class of sewing women than many years of charitable endeavor extended in other directions. It seems to us that Italy needs a CHARLES DICKENS or a THOMAS HOOD to call attention generally to the very extraordinary condition of affairs which a correspondent of the London *Lancet* asserts exists in the Foundling Hospital at Naples. This correspondent asserts that this particular institution is no worse than many other institutions of its kind established "in the great centers of population where the large celibate communities of both sexes accommodated in religious houses are the cause of illegitimacy on an enormous scale, the hapless offshoots of which find their way as foundlings into the city hospitals, where, if they are not killed outright, they can hardly be meant to live." It is stated that in the last two statistical years the foundlings admitted into this particular hospital of Naples amounted to 856, and their deaths at the close of these two years amounted to 853. It seems hardly credible that such a mortality could exist in any institution in the civilized world, and continue at such a shocking rate for a period of two years before any attention was paid to it. The fact that only three children out of 856 survived, finally caused the authorities to make a rigorous investigation of the management of the asylum, with results which are almost equally extraordinary with the death rate which we have spoken of. Not only were the dormitories filthy beyond description, but absolutely no provision had been made for the separation of children affected with contagious or infectious diseases from those who, while they were not affected by such disease, were in a hopeless condition of feebleness and neglect; that one wet-nurse was supposed to supply no less than four children each day, that there was no hot water in the building, that the baby linen was filthy and deficient and was very rarely washed. Milk obtained from cows and goats was never sterilized nor were the feeding bottles ever disinfected. In the case of a few children who, during the course of years, had survived this method of treatment, charges of insubordination were preferred against them as soon as they reached the age of seven and they were sent to

Houses of Correction, thereby giving room for other foundlings, and at the same time compelling these young children to associate with thieves and other criminals. We would not have believed a year ago that any such condition of affairs could be found in existence in any country of the world, and we do not believe that any approach to it is to be found in the management of asylums of any kind by English-speaking communities; but this story, which reads like an account of hospital management in the twelfth century, is so extraordinary that we have thought it of sufficient interest to make an editorial note of it.

Let us have a Department of Public Health!

MEDICAL UNITY IN NEW YORK.

The medical profession in New York City has determined to make a united effort to correct the medical charity abuses, and for that purpose a joint committee composed of two representatives of each of the following societies have met and organized, viz.: The New York County Medical Association, the New York County Medical Society, the New York Medical League and the Society for the Advancement of Medical Practice. The committee will sit through the summer, prepare plans and data, appeal to all the medical societies of the State for sympathy and aid, and have ready for presentation to the Legislature when it convenes next winter a bill meeting with the approval of the entire medical profession. We are pleased to see such harmony exist, and believe that by the united efforts of the various medical bodies throughout the State, the crying abuses can and must be corrected. The bill offered last year obtained the unanimous support of Senate and Assembly and only failed becoming a law by the neglect of the Executive giving it sanction. Our best wishes are for the success of our brothers in New York, and we are sure that the whole profession in the Republic gives them its moral support.

CORRESPONDENCE.

The Treatment of Typhoid Fever.

CLEVELAND, July 8, 1897.

To the Editor:—The current issue of the *JOURNAL* contains a politely worded attack on the "Woodbridge Treatment" for typhoid fever, by John N. Upshur, M.D.

As Dr. Upshur confesses that he has no practical, and as the many inaccuracies in his allusions show that he has no theoretical, knowledge on the subject, his article ought perhaps to be passed unnoticed, but his high and numerous titles, and his assumption of a knowledge which he does not possess, justifies the application of the principle that "ignorance of the law gives no exemption from its penalties." I therefore ask you to accord me a little space in your already over-crowded columns to answer him, not on my own account, because these last years have rendered me callous to such mild sarcasms as flow so smoothly from the Doctor's facile pen; not because he has criticized the "Woodbridge method"—others have done as much—but because he has made an unjustifiable and unprofessional attack on many hundreds of members of the AMER-

ICAN MEDICAL ASSOCIATION, as able, honest and honorable as himself, and whose only fault is that they have aborted typhoid fever and for the benefit of humanity have said so and have reported their cases.

It is not necessary, perhaps hardly proper, to call attention to the fallacies in the Doctor's paper, yet one can not help mentioning a few of them, *e. g.*, "The diet should be liquid. . . Milk is the best of all foods." Milk is a liquid outside of the body, but is it a liquid food in the stomach? "When the case has terminated the room should be thoroughly disinfected for at least two weeks before it is occupied and the furniture washed with a solution of bichlorid 1 to 1000." This is fairly good advice for two or three decades back, but insufficient and laborious. We live in an enlightened age now: we simply close up the room and send a stream of formaldehyde gas through the key hole and the next night use the room with safety as a surgical ward. "Such preparations as phenacetin, etc., may be used in small doses, but I deprecate most decidedly the use of the coal-tar derivatives at any stage of the disease." Does Dr. Upshur not know that phenacetin is one of the coal-tar derivatives? "Numerous drugs have been used with the object of abridging typhoid fever, but all clinical experience shows the effort to have been fruitless." "We have no evidence of proof given, except the bold assertions of success by himself and others, and the testimonials are not worth any more than the testimonials given by hundreds to the so-called cancer cures and kidney cures et id omne genus." In one sentence Dr. Upshur shows his respect for clinical experience, coupling it, however, with a gross misrepresentation. In the other he designates the reports of cases of those who have succeeded with the abortive treatment and the opinions they have expressed regarding it—the highest expression of clinical experience—as testimonials and attaches the same value to those of the deluded victims of quacksalvers as to the clinical reports of educated physicians: and because these physicians cure so large a percentage of their cases and in so short a time that Dr. Upshur regards their results as marvelous, he condemns them as impossible and raises the hackneyed question of "errors of diagnosis." In comparing the clinical reports on the abortive treatment of typhoid fever to the "testimonials," generally of impecunious patients given to shameless quacks or patent medicine venders, is a gross insult to hundreds of the ablest and most honorable physicians in all parts of the United States and through them to the entire medical profession, and scarcely less insulting is his theory that all of the wonderful results of the method which he condemns are due to errors "of diagnosis." To accept this theory it would be necessary to believe that physicians who have been at the head of some of the largest hospitals in the United States—that hundreds of physicians who have won high repute and large practice, and many of them high official positions such as high rank on the Medical Staffs of the United States Army in Marine Hospital Service, etc., and have reported 7,857 cases of typhoid fever treated by the method I have advised, are incapable of making a correct diagnosis in one of the commonest and in its typical form, one of the easiest diseases to diagnose which they encounter; to believe that the physicians who adopt this method of managing the disease frequently in the midst of epidemics suddenly cease to meet with it: to believe that the hospitals in which the treatment is used acquire a like immunity, and that while in the same locality and during the same epidemics, physicians were treating typhoid with the ordinary death rate and duration of illness—these hospitals were receiving and these physicians were treating these 7,857 cases of a disease which was being mistaken for and presenting pathognomonic symptoms of typhoid fever with a death rate of 1.90 per cent. and an average duration of illness of 12.7 days of those that recovered: that the patient whose temperature dropped rapidly to 99 degrees and afterward died of intussusception, the necro-

scopy revealing extensive ulceration of Peyer's glands, was an "error of diagnosis;" the patient in whom the treatment was instituted and the temperature dropped from 104.8 to 99.7 on the fourth day and to normal on the tenth, the pulse in the meantime dropping from 96 to 76, the treatment having been previously discontinued, a relapse and death followed and the necropsy showed ulceration of Peyer's glands and intestinal perforation—an "error of diagnosis;" Diazo reaction positive—Widal's test of reaction of serum on Eberth's bacilli characteristic of typhoid fever—disease aborted—"errors of diagnosis." Is Dr. Upshur himself credulous enough to believe all these absurdities?

Aside from the small doses of phenacetin, the use of which is always reprehensible, the recommendations in this remarkable paper are in consonance with the procedures in vogue during most of the passing century; indeed the one remedy from the use of which the Doctor says he has seen marvelous benefit, was recommended and used during the last century in "typhus mitior"—not necessarily a condemnation. It is fair, therefore, to presume that his death rate (a subject upon which he is discreetly silent) is the ordinary 15 to 20 per cent., and his average duration of illness from four to six weeks. He is then to be commended for his unwillingness to "subject his patients to such experimentation" (as the Woodbridge treatment)!

Finally, Dr. Upshur is to be congratulated on his desire for "convincing proof of the brilliant results claimed," a wish which I promise to gratify if he will come to me, and I pledge myself that he shall be able "to approach the treatment of *his* cases of typhoid fever with the assurance of its harmless nature and certainty of cure." I am, my dear editor,

Your most obedient servant,

JOHN ELIOT WOODBRIDGE, M.D.

"Life Insurance Fees for Medical Touts."

HARTFORD, CONN., July 8, 1897.

To the Editor:—Your edition of July 3 contains an editorial entitled "Life Insurance Fees for Medical Touts," which is in its initial statements so obviously unfair to the great majority of life insurance companies, as well as to the medical profession at large, that I beg leave to offer a remonstrance. You begin by saying, "for at least a half a century the American medical profession has been conscious of the great injustice done in the matter of fees for life insurance examinations." Now, I have been a practicing physician and life insurance medical examiner for thirty-one years, and for nearly half that time also the medical director of a large life insurance company. As the examiner of several companies I received, during the early part of my career, \$3, and for the latter years \$5, for each examination made, and when microscopic examination was called for I was paid from \$3 to \$5 additional. During all this time I have never heard any objection made by physicians, nor have I felt myself that these fees were unjust. In the days before uranalysis was so universally required, \$3 was regarded as good compensation for the twenty-minute or half-hour examination made. Some years later a fee of \$5 was allowed in cities and when chemic uranalysis became a general requirement the fee was advanced to \$5 in most instances, both in the city and country alike, with an addition for using the microscope. The company with which I am connected (the Connecticut Mutual Life Insurance Company of Hartford) has several thousand examiners, and I do not recall a single instance in which there has been an expression of dissatisfaction with the fees we pay; nor could such a claim be put forward with any degree of fairness. The time and professional ability requisite for this work is as well paid for as in any other branch of medical service. Still more conclusive evidence is found in the fact that fee tables adopted by our medical societies in no

instance, so far as my knowledge goes, calls for or suggests even a fee in excess of the amounts named above. Surely this would appear to be a strange way of manifesting to the world a life-long consciousness of great injustice.

Again, you say, "of late this feeling has been intensified by the wanton reduction of fees to medical examiners, while at the same time the salaries of presidents were increased by thousands." It is true, I believe, that one or two companies have reduced somewhat their fees, or made a graded scale of fees, within the past year or two, but no such action has been taken by the great majority of companies. Of course I am speaking of the old line life insurance companies and do not refer to assessment or society insurance at all. The Connecticut Mutual Life Insurance Company and the great majority of similar companies still pay a \$5 fee, which has been and is accepted by our examiners as adequate and just. There can be no question, however, that an abundant corps of competent medical examiners can be found in all parts of the United States who are not only willing but anxious to make life insurance examinations for the old fee of \$3, including chemic analysis of the urine, and our industrial companies inform me that they find little difficulty in securing competent service at a much lower cost to them. This illustrates the willingness of a large part of the practitioners in this country to perform such service for a fee much less than that generally paid by life insurance companies.

Continuing, you say, "while life insurance companies do not appreciate physicians highly in their proper functions as medical men, etc." Once more I must take exception to your statement. Nowhere is the service of a skilful and conscientious physician valued more highly than in an insurance office. The whole institution of life insurance rests upon the medical estimate of the individual applicant. The amount of money annually expended by life companies to secure competent examiners and to weed out those who are unreliable is very large, and is made necessary by the recognition on the company's part that the very best medical advice must be secured if a safe and stable business is to be transacted. In view of the great number of applicants for the position of examiner, and the high appreciation by the company of what is requisite in an examiner, any physician is surely to consider himself complimented when he is requested to occupy the position.

Criticise, if you please, business methods like those you mention in your editorial, but do not make it appear that the profession is being imposed upon or that life insurance companies are unmindful of the high service performed by their examiners, for this is surely unfair to both parties alike.

Regarding the employment of physicians as agents I care to say nothing beyond this: Should it come to our knowledge that one of our medical examiners was receiving fees from any of our agents for services as solicitor, I should consider the cancellation of his certificate as medical examiner an imperative duty. Very respectfully yours,

GEORGE R. SHEPHERD, M.D., Medical Director.

Color and Finish of Paper for Bookmaking.

SAN JOSE, CAL., July 8, 1897.

To the Editor:—Since I penned a few thoughts in the April 24 issue of the JOURNAL, on the subject of glossy paper for periodical and bookmaking purposes, I have been thinking more on the subject, and the more I think the more I am convinced that the matter needs thorough agitation all round. If one will call to mind the large number of periodicals and books now printed on paper of high glossy finish he will conclude that this style of paper is becoming a "fad."

A journal published in St. Louis entitled *The American Medical Journalist*, notices my former article and makes the following comments: "Dr. Simonton of San José, Cal., objects

to the high finish of the paper upon which the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION is being printed, and claims that the 'gloss,' as he terms it, is injurious to the eye, and suggests that the paper should have a dead white finish. The paper used upon the JOURNAL is what is known as an S. and S.C. (Sized and Super-Calendered) book, and is the best quality for periodicals of that character, giving life to the letter-press and affording an opportunity to use half-tone engravings without inserting special sheets for the purpose. If the quality of the paper is reduced, it would be at the expense of the appearance, and illustrations would necessarily have to be printed on separate sheets."

Well may the publishers of the *American Medical Journalist* come to the rescue in defence of glossy paper for periodicals, since the paper on which that particular journal is printed is of such smooth finish that a fly should not venture to light upon it without its life was insured. The paper of this journal is certainly "calendered" in the highest degree of the art.

The editor says that this highly calendered paper "gives life to the letter-press and affords an opportunity to use half-tone engravings without inserting special sheets." I submit that the issue of his journal (June, 1897) in which the words of the last quotation are printed, presents positive evidence that such high finished paper does not receive the ink readily and uniformly from the type. On the contrary, the letter-press is bad.

It stands to reason that paper of highly glossy finish can not take the impression from the type so readily and perfectly as paper of a softer finish.

And it is the half-toned engraving that is leading to this highly calendered paper "fad"; is it?

Must human eyes be sacrificed in order that it may be convenient for the printer to insert half-tone engravings on any page of periodical or book? Give us "quarter-tone" engravings or none at all, rather than to put unnecessary demands on human vision, in this high civilization, which is trying to the utmost the useful organs of sight.

Should the printers of periodicals and books consult their own convenience rather than the convenience, comfort and welfare of those who use and furnish market for their product?

Take up one of these "highly polished" journals and hold it before even a diffused light from a window, so that the rays of reflection reach the eye and it will be found almost if not quite impossible to read the print. Before the direct light of a lamp the difficulty is increased. And at any angle the light reaching the eye from the glossy surface is much greater than from one that is dead white.

For comparison take up the *Forum*, which is printed on paper of proper texture and color. Place this magazine in same positions as you have the "polished" journal and observe the difference and comfort to the eye.

I observe that the imprint of letters on the pages of the *Forum* is perfect, being a positive refutation of the statement that paper of high gloss gives the best letter-press.

A very large number of periodicals and books are now being printed on highly calendered paper and I suppose for the reasons that engravings make a better impression on same, but for reasons which I have set forth the practice should be condemned on all occasions.

All periodicals and books should be printed on a dead surfaced, slightly cream-tinted paper.

A. C. SIMONTON, M.D.

Sterilization of Catgut.

PHILADELPHIA, PA., July 5, 1897.

To the Editor:—Some time about the first of this year an article was published on the sterilization of catgut by treating it with formalin. I am not sure that it was published in your JOURNAL—will you kindly look it up and let me know if I can secure a copy of the magazine containing it, provided you published it?

GASTON TORRANCE, M.D.

Polyclinic Hospital.

ANSWER: See JOURNAL of Dec. 12, 1896, p. 1219.

Fracture of Skull, Rupture of Meningeal Artery. Ligation of Common Carotid, Recovery.

ATHENS, ILL., July 10, 1897.

To the Editor:—Believing the following case would be of interest to the readers of the JOURNAL, I will report it as briefly as possible:

On Wednesday, April 15, 1897, I was called to see T. J. S., carpenter by occupation, age 28, American, and found him lying on the bed profoundly unconscious, pulse 40, breathing stertorous, right pupil dilated, and obtained the following history: Some four hours previously while engaged in building a barn a piece of timber, oak 2 x 8 inches, 11 feet in length, fell from upper part of barn frame while being placed in position by an assistant and dropped a distance of eight or ten feet, striking S. on the top of the head, felling him to the ground, but did not produce immediate unconsciousness. At time of accident he wore a very thick cap on his head, which probably explained absence of external evidence of injury, as close examination of head failed to reveal anything more than a small discolored spot at the point of injury. After receiving the injury he mounted his horse and rode to his home distant about two miles and gave his wife an intelligent account of the accident and requested that the family physician be called. Unconsciousness developed slowly and at expiration of four hours after injury had become profound. I diagnosed fracture of skull with compression of brain and asked for surgical consultation.

Dr. J. A. Prince of Springfield, Ill., saw the case with me and concurred in the opinion expressed, and operation was decided upon, which was performed a few hours later, the patient not showing the slightest evidence of improvement in any way, having lost control of sphincter muscles and having involuntary passages from bowels and bladder.

Incision was made through soft tissues of the scalp down to the skull at the point of injury, and fracture of right parietal bone near superior border was found extending downward and forward considerable distance but no depression of bone. On removal of section of bone with trephine a very firm blood clot presented in the opening, which was enlarged with bone cutting forceps, and clot removed, after which hemorrhage from the middle meningeal artery was very profuse. Packing the opening with gauze, firm pressure and compression failed to control the bleeding. To accomplish this purpose we decided, after giving other methods a fair trial to ligate the right common carotid artery, which was performed in the usual way, the vessel being tied with a double silk ligature, the result was all that could be desired and the operation was concluded in the usual manner and patient put to bed. In a few hours consciousness returned, the pupillary inequality disappeared and the patient made an uneventful recovery, and at this time, now almost three months after operation, expresses himself as being as well in every way as he ever was in his life; he is going about as usual and expects to resume work at his trade at once.

A. L. BRITTIN, M.D.

An Open Letter.

IOWA CITY, IOWA, July 5, 1897.

To the Medical Profession, Members of the Legislature and Citizens of Iowa:

You are doubtless aware that the Board of Regents of the University of the State of Iowa have appropriated nearly \$150,000 for the construction and equipment of an hospital to be an adjunct to the Medical Department of the University.

This hospital has been planned to possess the greatest amount of facility for medical and surgical work possible in the present state of science; and, under proper restrictions, it might become a source of great benefit to the needy and indigent requiring medical or surgical treatment.

But the best information accessible indicates that the use and control of the hospital is to be *restricted* to members of the Faculty of the Medical Department of the State University, and that the practical working of the hospital is to be largely under the control of non-resident members of the faculty.

We are also informed that while it is the intention of those in authority to admit the poor, if funds for their board be guaranteed by friends, or by the county from which they come, the well-to-do are to be received and afforded advantages superior to those that can be given by local physicians and surgeons, or by local hospitals or sanitariums, provided they pay their board and reasonable charges to the physician or surgeon in charge.

Thus the State, in behalf of a few individuals connected with the Faculty of the Medical Department of the University, enters into competition with every general practitioner, and every hospital and sanitarium in the State: also offering to furnish a set of operating rooms, and all special appliances, to the members of the staff without expense to them: thereby giving them great advantages in competition with the large body of the medical profession, who have no such extraneous aid.

We call your attention to this matter in the hope that you may aid in obtaining from the legislature such enactments as will secure the enforcement of the following rules; without which, in our belief, the hospital should receive no help from the State or the medical profession:

1. That no patient shall be admitted to the hospital or receive treatment therein who is able to pay, or possesses sufficient means to pay for his or her treatment at home, or in a private institution.

2. That no physician or surgeon, a member of such hospital staff, shall receive any compensation for service in such hospital, or receive any pay or gratuity from any patient admitted to such hospital.

It is our belief that the adoption of such rules would in no way lessen the opportunity for good of a State hospital, and could in no way interfere with the *legitimate* work of the members of its staff.

Respectfully submitted,

ELMER F. CLAPP, M.D., Iowa City, Iowa.

C. M. HOBBS, M.D., Iowa City, Iowa.

A Query.

FORT YATES, N. DAK., July 7, 1897.

To the Editor:—Would you kindly give the formula and method of using Schleich's fluid for anesthesia, and as full particulars as possible of Maragliano's serum, in your next issue?

Yours very faithfully,

JAMES W. BAIRD, M.D.

ANSWER:—See THE JOURNAL, Dec. 29, 1894, p. 965, for Dr. Würdemann's article on Schleich's method, and THE JOURNAL, Nov. 21, 1896, p. 1105, for an abstract of an article on Maragliano's serum.

BOOK NOTICES.

Manuali Hoepli. Soccorsi d'Urgenza. Pel DOTTOR CARLO CALLIANO. Milano: Ulrico Hoepli. 1897. (Aid in Emergencies.) 4ta edizione.

La Morte Vera e la Morte Apparente. Con Appendice "La Legislatura Mortuaria." Pel DOTTOR FELICE DELL'ACQUA. (Real and Apparent Death, with Appendix, Mortuary Legislation.) Milano: Ulrico Hoepli. 1897.

The first of these two little volumes of the extensive and comprehensive Hoepli series, is a work that has received the approval of the Italian sanitary authorities and has passed through four editions, which facts ought to be an index to its worth. On examination the favorable presumption is con-

firmed: it is a very complete and thorough manual, covering rather a wider field than some of the other numerous publications on the subject, and seemingly very well suited to be utilized as a text-book for ambulance attendants, nurses and others who have to do with the class of cases of which it treats. Its compass will be better understood if it is stated that it gives the elementary facts of anatomy and physiology, the resources available for the immediate treatment of nearly or quite all accidents, poisoning and sudden ailments, the signs of death and the care of the dead, disinfection and asepsis, invalid diet, etc. It concludes with a very satisfactory index, and a number of plates illustrating anatomy, stoppage of hemorrhage, bandaging, transportation of the sick or wounded, etc. If it were only in English it would have our warmest recommendation to American readers.

The second volume gives apparently a very fair statement of the facts as to recognition of real and apparent death, with the Italian law of 1891 in regard to burial and mortuary dispositions generally.

Life of Thomas Wakley, Founder of the first edition of the *Lancet*, Member of Parliament for Finsbury and Coroner for West Middlesex. By S. SQUIRE SPRIGGE, with two portraits. Pages 509. London, New York and Bombay: Longmans, Green & Co. 1897.

We have here the biography of one of the most interesting members the medical profession has produced in Great Britain during the present century. If we consider his pugnacity we must admire the results which he accomplished by it. If we consider him an uncomfortable person to be in controversy with, we must at the same time admit his energy, his faithfulness in the pursuit of right, his great industry, and withal his ready grasp of the spirit of the times.

Wakley was a born reformer. Reformers although followed by many are usually loved by few, for they must run counter to the prejudices of the times, the sentiments of individuals and the customs of the country.

One marvels how it is possible for one individual to have accomplished so much work and at the same time it must be admitted, that done by Wakley was done well. As the editor of a great newspaper he was incomparable, as Member of Parliament for Finsbury, he was always ready with some interrogatory to embarrass the party in power and to advance the liberal cause and interest of his constituents. As coroner for Middlesex his career was marked by ability, industry, patience, courtesy, integrity and uncommon learning. These three occupations he carried on at one and the same time.

The career of Wakley is of great interest to every medical man and we commend the perusal of this biography especially to the young medical student, who views with concern the long and rocky road between himself and the goal of his ambition. As for Wakley himself, notwithstanding his success in the House of Parliament and the reforms which he successfully instituted as coroner for Middlesex his best monument is that wonderful medical newspaper which we welcome under the name of the London *Lancet*.

Medical and Surgical Report of the Presbyterian Hospital in the City of New York. Vol. 2, January 1897. Edited by ANDREW J. MCCOSH, M.D., and WALTER JAMES, M.D.

This volume contains besides the list of officers, managers, medical board, house staff, house officers the papers on various subjects by the staff of the hospital.

In medicine we have W. Gilman Thompson, Tilden Brown, W. P. Northrup, J. T. Thornley, Francis Kinnicott, and in surgery we have papers by Charles K. Briddon, Forbes Hauks, E. Elliott, and A. J. McCosh.

The volume opens with a well considered paper on cholelithiasis and surgery of the bile ducts by Dr. Briddon. Four cases are reported with analysis.

Gilman Thompson reports on cold tub bathing for typhoid

fever and concludes that the cold tub bathing does not ordinarily shorten the duration of the fever. That it does not prevent an occurrence of at least as many relapses that may take place without it. It does not prevent the occurrence of many of the complicated cases to the disease, most of which however are less severe than those that are often presented without it. It does not in any manner preclude simultaneous use of the internal antiseptic or any other recognized methods of treatment.

It is a rational plan of treatment directed toward the support of the nervous system by the double stimulus and as such it is practically useful in preventing those symptoms which result from the overwhelming of the nervous system by the toxin of the disease.

When patients come under the tubbing treatment within the first week of illness it offers the almost certain prospect of the disease running a mild course and it reduces a mortality of many of the severer cases by approximately one-half. These conclusions were based on the study of 284 cases received in six years of treatment, with the total mortality under all forms of treatment of 14.79 per cent.

The paper on renal tuberculosis by Tilden Brown is a careful study.

Transactions of the Southern Surgical and Gynecological Association. Vol. IX. Ninth session, held at Nashville, Tenn., Nov. 10, 11 and 12, 1895. Published by the Association. 1897.

This session was held under the presidency of Dr. E. S. Lewis, and was marked by harmony in its methods and enthusiasm in the professional work before it. Forty members were present.

The volume presents the same handsome appearance as its predecessors and it is on the same high plane. It contains the minutes of the session and all the papers read, with the discussions thereon.

The next meeting of the Association will be held in St. Louis, under the presidency of Dr. George Ben. Johnson of Richmond.

NEW INSTRUMENTS.

A SET OF NEW CURETTES FOR OPERATING IN THE NASO-PHARYNGEAL VAULT.

BY HENRY W. WANDLESS, M.D.

CONSULTING OCUList AND AuRIST, PARKLAND CITY HOSPITAL; CHIEF SURGEON DALLAS CHARITABLE EYE, EAR, NOSE AND THROAT INFIRMARY. DALLAS, TEXAS.

The cuts given herewith represent a set of curettes which I have devised for operating in the vault of the pharynx. They are specially designed for the removal of adenoids from the vault, granulations, and for curetting the mucous membrane in order to stimulate it to healthy functional activity. These curettes are made in pairs of which there are two. Each pair is composed of two sizes for large and small vaults and is designed for special conditions and localities which are described with each. It has been found that these curettes meet practically all the requirements in operating upon adenoids within the vault, except tumors that are too large to pass within the ring of the curette. Fig. 1 represents the first pair, which is adapted to the posterior walls of the vault only. It does not reach the roof of the vault, because the blade is not set on an angle for the roof. It is intended for this curette to have as near the same curve of the vault as possible, and when it sweeps over the walls it always conforms to the shape of the vault. When introduced the tumors pass within the ring of the curette and are cut off as the curette is made to sweep over the posterior walls. When the tumors have become hard as they often do, especially from age, considerable force is necessary to sever them from their attachment; and in such cases this is the only instrument with which I have had satisfactory success. This curette is not adapted for the removal of tumors

in the roof of the vault, because it is impossible to get a curette to conform to the curves of both the roof and the posterior walls. For that purpose I have designed a second pair shown in Fig. 2. This curette may be used for general use, and all adenoids may be removed with it except those that have become hard. It will be observed that the cutting edge of this instrument is set at an angle of about 45 degrees from the handle and when introduced its edge strikes the mucous membrane on its posterior walls at about the same angle; but if the curette is pushed far up and the ring brought well forward against the post-nasal septum at the same time lowering the handle, the blade rests flat against the roof and as the sweep is made over the vault the curette engages the tumors within its rings and brings them away.

Figure 1.

Any instrument which is not so adapted fails in its purpose to remove the tumors from the roof and simply scrapes those from the posterior walls. It is well to add here that the tumors in the roof around the post-nasal nares do considerably more damage than those on the posterior walls, and it is therefore much more important to remove them. Tumors within the posterior nares can not be reached with these curettes and are best removed with a Bosworth snare. I claim considerable excellence for these curettes, not because they bear my name but because of my practical experience in operating with them, which has been very satisfactory.

Figure 2.

For removing granulations from the vault and stimulating the mucous membrane, I only use the second pair, Fig 2. The granulations come away readily with moderate force and without much injury to the membrane.

For stimulating the membrane in cases of chronic nasopharyngeal catarrh I have used this curette with very happy results.

The curettes are made by Chas. Truax, Green & Co., Chicago, Ill.

TENSION ADHESIVE STRAPS.

BY E. H. KING, M.D., MUSCATINE, IOWA.

The greatest objection to the use of adhesive straps over wounds arises mainly from a collection of crusts or dried secretion under them, and from the difficulty of inspecting and

changing the underlying dressings. This difficulty can be easily remedied by taking common dress hooks, A, bend the circular parts of the shank at a right angle, B, and fix them on the end of an inch strap of Meads, a similar

adhesive plaster, C. The straps with the hooked ends may be placed one inch or more from the border of the wound, D, on either side and tension made with small rubber bands over any desired dressing, which will thus be comfortably retained in place. By unhooking the bands, the dressing may be removed without disturbing the straps, wound or patient. These hooks thus made were originated by me. I have used them over twenty years with satisfaction. There is no patent on them and the profession is welcome to the idea.

A VAGINAL SPECULUM.

BY G. R. FOX, M.D., PLAQUEMINE, LA.

I present herewith a photograph of a vaginal speculum which I have recently invented. The instrument is similar to Graves' in the mechanism for the vertical expansion of the blades, but has the following improved features. Instead of the screw used in most similar instruments to keep the distal ends of the blades expanded, I have adopted a ratchet and pawl mechanism, which permits the operator to expose the cervix uteri very quickly, and adjust the instrument with one hand, and to release the blades as quickly when he desires to remove the instrument.

Another improvement is a funnel shaped opening at the rear portion of the lower blade leading into a hollow shank on same, to which a piece of rubber tubing is affixed, thus providing a ready outlet for fluids while using the speculum.

The instrument is aseptible, and the lower blade can be detached and used as a Sims speculum.

Automatic Adjusting Thermometer.—The strain and inconvenience of the ordinary thermometer in severe prostration is avoided by the contrivance of Prof. Cornet, which holds the thermometer automatically in the armpit, by means of a broad spring which passes over the shoulder. The thermometer is curved to fit and can be read without removing.—*Deutsche med. Woch.*, June 3.

ASSOCIATION NEWS.

Competition for the Senn Medal.—Pursuant to a resolution adopted by the Section of Surgery and Anatomy of the AMERICAN MEDICAL ASSOCIATION, June 4, 1897, I have been appointed by the Chairman, Dr. Reginald H. Sayre, as Chairman of the Committee charged with the awarding of the Senn Medal for 1898. The other members of the Committee are Drs. H. O. Walker of Detroit, Mich., and S. H. Weeks of Portland, Me.

1. A gold medal of suitable design is to be conferred upon the member of the AMERICAN MEDICAL ASSOCIATION who shall present the best essay upon some surgical subject.

2. This medal will be known as the Nicholas Senn Prize Medal.

3. The award shall be made under the following conditions: a. The name of the author of each competing essay shall be enclosed in a sealed envelope bearing a suitable motto or device, the essay itself bearing the same motto or device. The title of the successful essay and the motto or device to be read at the meeting at which the award is made, and the corresponding envelope to be then and there opened and the name of the successful author announced. b. All successful essays become the property of the ASSOCIATION. c. The medal shall be conferred and honorable mention made of the two other essays considered worthy of this distinction, at a general meeting of the ASSOCIATION. d. The competition is to be confined to those who at the time of entering the competition, as well as at the time of conferring the medal, shall be members of the AMERICAN MEDICAL ASSOCIATION. e. The competition for the medal will be closed three months before the next annual meeting of the AMERICAN MEDICAL ASSOCIATION, and no essays will be received after March 1, 1898.

Competitors will address their essays to the undersigned.

J. McFADDEN GASTON, M. D., Chairman.

11¹/₂ Edgewood Ave., Atlanta, Ga.

SOCIETY NEWS.

Twelfth International Medical Congress.—The President and Secretary have issued the following circular under date of June 13 (old style) presidents of important medical societies:

Dear Sir:—His Majesty the Emperor of Russia has given authority to hold at Moscow, on the 19th to the 26th of August, 1897, the Twelfth International Medical Congress, and has deigned to take it under his august protection. Desiring to assure to this great reunion, learned men of the highest character, and that the international character of the meeting shall be marked, the Executive Committee has addressed itself to the most important scientific societies of the world and begs that they will send representatives to the said Congress. The Committee hopes that the honorable society of which you are the president will not refuse to contribute to the *éclat* of the next scientific *fête* of Moscow, by sending delegates, to whom it will be happy to accord the highest consideration. Accept, dear Sir, assurances of the highest consideration.

J. F. KLEIN, President.

S. S. KORSKOW, for the Secretary General.

The following have had credentials issued for Moscow by the AMERICAN MEDICAL ASSOCIATION:

Drs. L. Ashton, Dallas, Tex.; Frank Billings, Chicago; W. G. A. Bonwill, Philadelphia; D. R. Brower, Chicago; Augustus P. Clarke, Cambridge, Mass.; Judson Daland, Philadelphia; Charles Denison, Denver, Colo.; Henry B. Favill, Chicago; Thos. H. Fenton, Philadelphia; Geo. Ryerson Fowler, Brooklyn, N. Y.; Wm. H. Forwood, U. S. A.; Jacob Frank, Chicago; Henry Gradle, Chicago; Alex. J. Campbell, Syracuse, N. Y.; J. R. Hildreth, Cambridge, Mass.; Chas. H. Hughes, St. Louis, Mo.; Florence W. Hunt, Chicago; H. L. E. Johnston, Washington, D. C.; Wm. D. Kelly, St. Paul, Minn.; J. O. Knipe, Norristown, Pa.; O. Litzemberger, Converse, Ind.; T. Mortimer Lloyd, Brooklyn, N. Y.; Thos. McDavitt, St. Paul, Minn.; Harold N. Moyer, Chicago; J. O. Malsbury, Peru, Ind.; F. S. Milbury, Brooklyn, N. Y.; Thos. H. Manley, New York; Abner M. Miller, Bird in Hand, Pa.; John H. Packard, Philadelphia, Pa.; Theophilus Parvin, Philadelphia, Pa.; Geo. M.

Preston, Lynchburg, Va.; Nicholas Senn, Chicago; Catherine Slater, Chicago; Edmund H. Stevens, Cambridge, Mass.; Eugene S. Talbot, Chicago; Fred C. Valentine, New York; J. Henry Woods, Brookline, Mass.

The following party sailed from New York, Saturday, July 3, 1897, by the North German Lloyd Express Steamship *Werra*:

Dr. Catherine Slater, Aurora, Ill.; Miss M. Costigan, Chicago, Ill.; Miss Isabel McIsaacs, Chicago, Ill.; Dr. Harriet E. Garrison, Dixon, Ill.; Dr. I. N. Wear, Fargo, N. Dak.; Dr. A. E. Abrams, Hartford, Conn.; Mrs. Abrams, Hartford, Conn.; Mr. D. A. Bishop, Jersey City, N. J.; Mrs. Bishop, Jersey City, N. J.; Miss Bishop, Jersey City, N. J.; Dr. W. H. A. Bonwill, Philadelphia, Pa.; Miss E. Lincoln, Providence, R. I.; Miss Anne L. Gorman, Providence, R. I.; Mrs. Lillian Condell, St. Louis, Mo.; Miss Grace Reynolds, Sugar Hill, Ill.; Dr. B. T. Whitmore, Chicago, Ill.; Dr. Jas. G. Hyndman, Cincinnati, Ohio; Mrs. Hyndman, Cincinnati, Ohio; Dr. F. B. Galbraith, Pontiac, Mich.; Mr. Galbraith, Jr., Pontiac, Mich.; Dr. W. F. Southard, San Francisco, Cal.; Dr. W. F. Forwood, Washington, D. C.; Mr. N. B. Scott, Wheeling, W. Va.; Mrs. Scott, Wheeling, W. Va.; Mr. Jos. Stone Perry, Worcester, Mass.; Mrs. Perry, Worcester, Mass.; Miss Josephine Perry, Worcester, Mass.

The following comprise the Athens and Constantinople section on the same vessel:

Dr. J. H. Woods, Brookline, Mass.; Dr. George Ryerson Fowler, Brooklyn, N. Y.; Mrs. Fowler, Brooklyn, N. Y.; Dr. T. N. Lloyd, Brooklyn, N. Y.; Dr. Daniel R. Brower, Chicago, Ill.; Dr. D. R. Brower, Jr., Chicago, Ill.; Dr. Nicholas Senn, Chicago, Ill.; Dr. W. N. Senn, Chicago, Ill.; Dr. Eugene S. Talbot, Chicago, Ill.; Dr. Lucy Waite, Chicago, Ill.; Dr. Casey A. Wood, Chicago, Ill.; Mrs. Wood, Chicago, Ill.; Dr. Edward K. Root, Hartford, Conn.; together with Mrs. Fowler, Brooklyn, N. Y., and Mrs. Wood, Hartford, Conn.

LARYNGOLOGICAL SECTION INTERNATIONAL CONGRESS.

At a special meeting of the Oto-Rhino-Laryngological Society of Moscow, held June 21, 1897, it was decided that a "bureau" should be instituted for the convenience of members of the Twelfth Section of the Twelfth International Medical Congress (Otological and Rhino-Laryngological Section). The object of this bureau will be to give all information needed, not only as to matters concerning the Congress, but as to all other matters where our visitors may require assistance or information. This reference-bureau will be open from 7 to 9 P. M., from the 13th to the 19th day of August, in the Doctors' Club (Bolshay Dmitroffka), and during the meetings in the room of the Section XII b. (Laryngo-Rhinology). I. N. SCOTT, President.

ARRANGEMENTS FOR THE CONGRESS.

Transportation free of charge in first-class carriages from the Russian frontier to Moscow. Half-rate tickets will be issued to members of the Congress by the French, Italian, Spanish, Swedish and Norwegian, and Oriental railways, but not by the German roads. Reductions in fare are offered by many European steamships, but not by the transatlantic companies.

Foreigners must be provided with passports, properly *viséd* by a Russian Consul in the country to which they belong. The passports will be inspected at the frontier. Committees of Russian delegates will be present at the frontier stations to supply information and assistance, and there will also be committees at the Moscow railway stations, as well as offices, where information with regard to lodgings, etc., may be obtained. If physicians take their wives, or other members of their family, they will have to pay full railroad fares for them, but a committee of women, presided over by Mme. Sklifossovsky, will look after the ladies that go to the Congress and see that they have a good time. Rooms can be had at from \$1 to \$3 a day, with morning and evening coffee, and dinners in good Moscow restaurants cost from 40 cents to \$2. A buffet will be opened in the building where the Congress meets, in which meals may be had at very low prices.

Physicians intending to be present must apply to the treasurer, Prof. N. Filatow, Moscow, for tickets of membership, inclosing 10 rubles or \$4. The tickets will serve to identify

them and will entitle them to take part in all the meetings and excursions and also to all the publications of the Congress. Scientific men, veterinary surgeons, pharmacists and dentists may also obtain tickets, as extraordinary members, but no mere students of medicine can attend in any save their private capacity.

The Congress, which is held under the patronage of the Czar and the Grand Duke Sergius, opens August 19 (August 7 according to the Russian calendar) and closes August 26 (14). Railroad tickets are good from July 1 to October 10, and thirty-five pounds of baggage may be carried free. Several excursions are being arranged for the benefit of members of the Congress, to the monastery of St. Sergius, to Nijni Novgorod, to the Crimea and to the Caucasus. Communications should be sent to the General Secretary, Clinic for Nervous Diseases, Moscow.

American Association of Obstetricians and Gynecologists.—The American Association of Obstetricians and Gynecologists will hold its tenth annual meeting at the Cataract House, Niagara Falls, Tuesday, Wednesday, Thursday and Friday, Aug. 17, 18, 19 and 20, 1897, under the presidency of Dr. James F. W. Ross of Toronto. The railways have granted reduced fares on the certificate plan to all who attend the meeting; the Cataract House has made a reduction from its regular tariff of charges; the place of meeting is a famous one; the season of the year auspicious, and everything seems to conspire to justify a prediction that this will be a large and interesting meeting of this famous Association. The date of the meeting has been fixed in mid-August, apart from college sessions, during the vacation season and at a place where many people like to spend a part of their outing. The climate of Niagara is always desirable during the heated term, the spray from the cataract giving it a healthy moisture and coolness that is at once invigorating and charming. To visit Niagara under the auspices of this Association will afford the tourists exceptional opportunities for the enjoyment of a rare and radiant scenery that is the most sublime in the world. One session will be devoted to the exhibition of specimens and giving their history. The scientific work of the Association will begin on Tuesday morning at 10 o'clock and end Friday at 1 o'clock, and it is expected to so arrange the program as to afford the members opportunity to visit the places of interest each day on the adjournment of the afternoon session. It is expected that the inducements to attend this meeting are such that Fellows will not only come themselves but bring their families and invite their friends as well to visit the wondrous cataract.

PUBLIC HEALTH.

Medical inspection of Chicago Schools.—Incited thereto by the publication of the results of the first year's medical inspection of schools—first undertaken in this country by the Boston Board of Health under the supervision of Dr. S. H. Durgin, the able and energetic executive of that board—an appeal was made to the Chicago City Council in the spring of 1896 for an appropriation to defray the expenses of a similar inspection of the public and parochial schools of the city. "Financial stress" dictated the refusal of the appeal: but the Assistant Commissioner, Dr. F. W. Reilly, was so much impressed with Dr. Durgin's showing that eight of the ten medical inspectors of the department were relieved from all other duty at the end of August, 1896, and assigned to this special work for the ensuing school year—Sept. 3, 1896, to June 30, 1897. Dr. Reilly thus sums up the work accomplished with this small force:

The public and parochial school attendance during the period aggregated upward of 272,000—about 208,000 enrolled in public schools and nearly 65,000 in parochial schools. These occupied

572 separate buildings—234 city public schools, 131 branch and rented public schools and 207 parochial schools. Regular systematic inspections of each school building were obviously out of the question with the force at hand, and the work of the inspectors was therefore based upon physicians' notifications of cases of contagious and infective diseases occurring in their practice. Day by day each medical inspector was notified of the existence and the locality of every such reported case in his district, whereupon he proceeded at once to ascertain if the patient had been in attendance at any school; if not, his duties terminated with seeing that the case was properly isolated and the necessary precautions against spread of the contagion or infection on the premises and in the neighborhood were duly observed. If, on the other hand, the patient had been attending school the school was at once visited and taken charge of by the inspector so far as relates to carrying out and enforcing precautionary measures against further spread of the disease, to the remedy of insanitary conditions on the school premises, etc. In cases of diphtheria and scarlatina the throats of the children in the same room as the patient were examined after the method of Dr. Durgin; the teacher was instructed to watch for certain symptoms and to report their appearance to the inspector, and other appropriate actions were taken and surveillance maintained as long as deemed necessary.

During February, March and April the work was interfered with by various emergencies—for example, in February every available attaché of the department was engaged in looking up, reporting and relieving cases of distress and destitution among the unemployed and in the administration of the Mayor's relief fund. Nevertheless, a total of 1,181 visits were made to the schools during the school year; 4,023 cases of contagious and infective diseases were located and taken charge of for preventive purposes; insanitary conditions in 63 public schools were reported to the Board of Education and similar conditions were remedied in 53 homes of patients.

An important feature of the work was the examination, as to vaccinal status, of the pupils of schools visited. Nine hundred and fourteen such school examinations were made, covering a total of 90,220 scholars, 81,810 in public and 27,410 in parochial schools. Through these examinations 47,310 vaccination or revaccinations were secured, 37,470 of public scholars and 9,840 of parochial scholars.

Of the diseases reported diphtheria was the most prevalent: 744 individual reports of cases among school children, leading to the disclosure of 2,619 cases at homes. There were 231 school cases of scarlet fever and 745 home cases. Forty-six reported cases of measles led to the discovery of an epidemic prevalence of this disease in several sections of the city during November 1896 and again in May and June 1897. In October an epidemic of impetigo contagiosa spread through seven schools of the north division of the city, but was arrested in a few weeks, after excluding 107 cases from the schools and instituting proper preventive measures. Two schools were found afflicted with pediculosis to such an extent as to demand radical treatment. One case of tuberculosis was found at school in such an advanced stage as to justify exclusion from school attendance; this patient died before the close of the school year.

Stomatitis was found so prevalent in many schools that, upon the advice of the Medical Inspectors, the teachers instructed pupils to bring individual drinking cups from their homes and forbade the common practice of putting the lips directly to the water faucets for drinking.

The commonest sanitary defects of school building reported are uncleanness; dirty floors, passages and stairways; damp and filthy basements; foul water-closets located near furnaces, so that poisoned air is driven through the building, in which cases teachers suffer from headache, "sore throat," etc. Among other insanitary conditions noted are defective plumbing, stagnant pools on adjoining lots, dirty alleys, overflowing garbage boxes and general lack of sanitary policing. In few of the older school buildings is there any provision for drying the feet and clothing in wet or stormy weather. So far as practicable the School Board caused many of these defects to be remedied.

The present Commissioner of Health, Dr. Arthur R. Reynolds is so thoroughly convinced of the value of this work that he purposes making another appeal to the council for an adequate force of inspectors. New York has recently appointed 150 physicians for this service while Boston, with a population of less than half a million, employs 50 with an average of four schools and 1,400 pupils to each.

Smallpox at New Orleans in 1896.—Dr. W. H. Woods, the chief sanitary inspector of that city, has made the following com-

ments on the progress and management of the recent epidemic of variola. It can hardly be a matter of surprise that the disease operated so unfavorably upon the general mortality rate of the city, if the laws of New Orleans will only admit of an easy-going plan of prophylaxis as appears to have been at the command of Inspector Woods. His report says: "In February, 1895, a man came here from Arkansas and afterward developed a well marked case of variola. At that time the disease existed all over the Eastern Arkansas and Western Tennessee counties. Otherwise than in a very general manner we could not further or more definitely trace the origin of the disease. From this case others in due season developed. In February, 1; in March, 4; in April, 3, and in May it reached the alarming proportion of 58 cases; in June there were 36 cases. After the first case in February the authorities vaccinated all parties living in the infected localities—that is, *all who would accept vaccination*. The clothing, bedding and wearing apparel, except those worn by the patients when sick, and the bed upon which he slept, were subjected to boiling water for thirty minutes and afterward left over night in a bichlorid solution of 1 in 1,000. Those articles and fabrics coming in direct contact with the patient were destroyed by fire. All carpets and matting in the patient's room were also destroyed by burning. The walls, floors, all furniture and fixtures, the galleries and even walks, yards and outhouses were sprayed or otherwise washed down with a bichlorid solution of 1 in 1,000. The interior of the house after thoroughly closing the openings and chinking all cracks, was subjected to sulphur fumes for nine hours, with from five to seven pounds of sulphur candles to 1,000 cubic feet of air space. With these rigid measures observed in every instance of the disease the outbreak was in a manner controlled during the summer months of 1895, but with the advent of winter the disease seemed to take a fresh start, having been reintroduced from time to time from the country parishes where it existed to quite an extent. In the fall of 1895 a very rigid vaccination campaign was inaugurated by the board of health, and the work was not stopped until the entire city had been canvassed by a large and efficient corps of physicians, who systematically, by districts, went from house to house urging free vaccination. During this campaign 53,437 people were vaccinated and revaccinated. After this systematic vaccination campaign was over and the influx of darkies from the country parishes had ceased the disease steadily decreased. In March, 1896, or about twelve months after the inception of the epidemic, we had the greatest number of cases of any month during its prevalence, reaching a total of 334 cases. Since the introduction of the disease in February, 1895, we have had 1,126 cases with 291 deaths, making a mortality rate of 25.84 per cent. among those attacked."

Tuberculosis in Dairy Cattle in Ireland.—Dr. Kirkpatrick, an inspector of the Privy Council of Ireland, has investigated the condition of dairy cattle that are kept at Dublin and vicinity, and reports as follows: "It appears from the departmental records that the postmortem examination of the lungs of cattle slaughtered by direction of the Veterinary Department between the years 1888-1893 in the North and South Dublin Unions as having been in contact with cattle affected with pleuro-pneumonia, or otherwise exposed to the infection of that disease, showed that the proportion of cases in which the lungs were affected with tuberculosis was almost 5 per cent. The majority of cattle slaughtered were dairy cows." It is evident from this statement that if only 4 out of 1,500 cows are now affected with tuberculosis there must be a most marked improvement in the health of cattle in this district. Indeed, such a marked change in so short a time is sufficiently remarkable to call for some explanation. So far from an explanation of this improvement being forthcoming it is a matter of common knowledge

that little or nothing is being or has been done to improve the state of the dairy yards, the insanitary condition of which has been so often pointed out. Taking these facts into consideration and remembering that the extraordinary prevalence of tuberculosis among dairy cattle in general has been amply proved by numerous statistics, we shall, I think, be justified in doubting these results so long as the methods by which they were obtained are open to suspicion. Professor McFadyean, when summing up the results of his experiments for the recent Royal Commission, states: "The conclusion that appears warranted is that ordinary clinical examination is almost valueless for the detection of tuberculosis in its early stages." Over and over again in his published works this great authority on veterinary pathology has stated that ordinary clinical examination even in the hands of the most skilled and experienced veterinary surgeons is incapable of pointing out all the animals affected with tuberculosis. Unless some more accurate means of diagnosis is used than ordinary clinical examination affords, veterinary surgeons merely leave themselves open to the charge of incompetence by certifying animals to be free from tuberculosis. It would appear that Koch's tuberculin, in the hands of skilled surgeons, is the most accurate method of diagnosing tuberculosis of cattle, and where it can not be used most veterinary surgeons decline to express a decided opinion. We can not, then, accept any statement as to the number of tuberculous cattle in our dairy yards which is not based on examination with tuberculin or the result of post-mortem examination.—*London Lancet*, May 8.

Health in Michigan.—Consumption was reported present in the month of June, 1897, at 189 places; measles at 160; diphtheria at 73; scarlet fever at 51; typhoid fever at 28, and whooping cough at 21 places. In May consumption was reported at 180 places; diphtheria at 50; scarlet fever at 36; typhoid fever at 32; whooping cough at 17, and measles at the same number of places.

MISCELLANY.

Hardly Credible.—A bedside dispute over a patient has led to a duel in Germany. The conflict took place on the outskirts of Bonn, one of the combatants receiving a mortal wound in the chest. Hogarth has immortalized a somewhat similar quarrel between Dr. Pill and Dr. Potion, but the nurse improved the situation by rifling the moribund's trunk.

A New Medical Journal.—*The Medical Register*, Richmond, Va., Vol. 1, No. 2, is noted among our exchanges. This publication will appear monthly under the auspices of the Faculty and Alumni of the Medical College of Virginia. Subscription price \$1.00.

Not a Privileged Communication. Information communicated to an attending physician by the mother of a bastard child as to who was the father thereof, the supreme court of Michigan holds, in the case of *People v. Cole*, May 25, 1897, is not a confidential communication within the purview of the statute of that State which prohibits a disclosure of any information by any attending physician, "which information was necessary to enable him to prescribe for such patient as a physician, or to do any act for him as a surgeon," the information in question not being necessary to enable the physician to prescribe for the mother.

The Patriarchal Medical Student.—Probably the oldest medical student in the country is James Scott, who is taking an undergraduate course at the Maine Medical School, Brunswick. Mr. Scott of Crow Harbor, Guysboro, N. S., has entered upon a three-years course at the school, and when he receives his degree of M.D., will have passed his sixtieth mile stone. He is a native of Dumfriesshire, Scotland, and went to Nova

Scotia at the age of 18 years. He has been a Baptist minister at Crow Harbor and other places in Nova Scotia for many years. Within the last four or five years he had been studying and practicing medicine in a desultory way, especially in cases of accidents, and he finally made up his mind to acquire a thorough medical education. He has a wife, three daughters and a son at Crow Harbor. *Journal of Medicine and Science*, April.

An Undignified Circular.—We have received the following from the Birmingham Medical College, Alabama. Dr. Geo. A. Hogan is the Professor of Chemistry and Toxicology. It bears its own comment:

Dear Sir:—Please send me on the enclosed postal card the names and addresses of any medical student or students you may know, or young men who expect to study medicine.

Our announcement is herewith enclosed and gives information about the College and Faculty.

For every student you may influence to attend our school the Faculty will give you \$10. The said student or students to pay full tuition fees.

Hoping to hear from you soon, I am

Very sincerely, GEO. A. HOGAN, Sec'y.

The New "Revue Philanthropique," Paris, has been founded to describe and report the results of benevolent organizations, etc., and can not fail to stimulate many new efforts. We note in it that the Countess de Castellane has given a million francs to erect a permanent building in Paris for charity bazars; that the subscriptions received by the Layette Society are devoted to paying working women out of employment, who sew for the Society, which distributed last year 400 complete outfits for infants: the Maison Maternelle receives children whose parents are temporarily in distress, and has thus taken charge of 1,698 children in the six years since its foundation, with an average stay of 67 days. But the most important among the numerous charities in Paris it describes is a new semi official organization, known as the "patrouage" of the hospitals, which is to assure the bread-winner taken to the hospital that his family will be taken care of during his absence and that he will be assisted during his convalescence. The effect of this announcement is said to have a wonderfully beneficial influence upon the recovery of the patient. Paul Strauss, editor of the *Revue* and member of the City Council, is the originator of the scheme.

Diluted Fluid Extracts are not Tinctures. Tinctures are very frequently made from the fluid extracts, and some manufacturers issue formulæ for making them in this way. There is no proper nor admissible way of making official tinctures other than by the pharmacopeal processes, and diluted fluid extracts are not tinctures and can not properly nor safely be labeled nor dispensed as such, however common the objectionable practice may become. A number of the more important tinctures of the pharmacopeia, properly made from good materials is made up and listed by one or more manufacturing pharmacists. The list of one of them has a column showing the strength of each tincture given. This column can hardly fail to be a cogent argument against this class and in favor of the more uniform fluid extracts. In this column the strengths vary all the way from two-thirds of a gram to one two-hundred and seventy-fourth of a gram to the cubic centimeter. Several, however, are from one-sixth to one-twelfth of a gram to the cubic centimeter, and therefore the fluid extracts of the same drugs, which are uniform in strength, are from six to twelve times stronger than the tinctures: while although the latter cost from one-third to one-half of what the fluid extracts do, they occupy six to twelve times the space, and weigh six to twelve times as much. And the dose, usually a disagreeable one, is six to twelve times as large, and this latter at a time when it is claimed that homeopathy gains so much in popularity as to displace the regular physician by the smallness of doses.—*Annual List of Dr. E. R. Squibb.*

Dr. Laveran Resigns from the French Army.—The surgical staff of the French Army has been greatly weakened by the more and more frequent resignations, owing to the dissatisfaction of the surgeons. Dr. Laveran, formerly a professor at the School of Military Hygiene and the discoverer of the hæmatozoön of malaria, is among those who have found it difficult to remain in the corps by reason of the uncavalier treatment accorded to him by the War Ministry. The professors are nominated for ten years only, and at the expiration of M. Laveran's term his post was changed and he was sent by the War Minister to a provincial garrison town as a simple army surgeon, no regard being paid to his position as a member of the Academy or to his great scientific reputation. He remained for some time at this station with a rank far below that to which his length of service entitled him, coming to Paris and continuing his researches at the Academy. In consequence of the delays and worries which the war department made him undergo, putting actual obstacles in the way of his scientific work, he preferred to send in his resignation and to quit the army medical department, of which he had been a prominent figure, at the age of 56 years. In a similar case in this country, an assistant secretary, greatly puffed up during his brief term of office, when appealed to for protection from the spite of the malicious and mendacious beaureacrat who issued the order, and asked to consider the long and exceptional public service of the transferred officer, with an attempt at humor that made him so full of it that it exuded from every pore, replied, "He is a good man, but there are others;" at which the able correspondent joined in the hilarity, and the incident was telegraphed to the home paper, as one of the greatest of the evidences of statesmanship which the temporary great man produced. It is pleasant to add that when Mr. Gage took hold of the Department the temporary great man lost his office and his greatness together. We have forgotten his name!

Promises to Cure by Supernatural Power.—The conviction of a "Professor" of obtaining money under false pretenses was affirmed by the court of appeals of Maryland, March 31, 1897, in the case of *Jules v. State*. The charge against him was summed up as equivalent to the declaration: "I now have or am possessed of extraordinary and supernatural powers to cure you. I can and I will cure you." Paraphrased, it was, that he said: "I have the power. I have it now. I will exert that power in the future to cure you." This, it was contended, amounted only to a future promise, or a promise to cure in the future, which lacked, for the purpose of the prosecution, the essential element of a false representation of an existing fact. But the court holds that there was here a false representation as well as a promise—a false representation of an existing fact, and a promise to cure in the future. The alleged existing fact was that he then and there had the supernatural and extraordinary power to cure in the manner he claimed. The testimony of the prosecuting witness in this case was, in part, as follows: "The professor offered me paper, and told me to write my name and age upon it, and not to let him see what I wrote. I wrote my name and age, and he walked up and down the room, and looked out of the window, and took the paper, and folded it up, and placed it against his forehead, and then told me what I had written on the paper. He said: 'You suffer from stomach trouble, and I can and will cure you within six weeks, or return your money.' There was also a charm to be worn, which 'was essential to the treatment.' This evidence, the court holds was admissible to support the charge that the defendant pretended to have extraordinary and supernatural powers to cure, and as tending to prove that the assurance by the defendant of his power to cure was a false representation. It could hardly be contended, suggested the court, that a physician with ordinary powers, and using ordinary means to cure, would adopt the mode of treatment here testified to. And, it may be added, as might have been expected, the patient was not benefited, and, after securing the prosecutor's money, the defendant left the city.

Russian Medical Institutions.—Dr. S. M. Malischew of Rostaw, writes to the *Deutsche Med. Woch.*, No. 14, to correct several inaccurate statements in various articles that have appeared recently on this subject. He explains the official medical service as follows: Russia is divided into 97 governments. Two-thirds of these are governed each by an official appointed by the State, and the other third by a local institution known as the Semstwo, which has charge of the affairs of the government, including the medical and sanitary. The Semstwo of the Moscow government was the first established (1864), and possesses an ideal medico-sanitary organization, from which the rest were modeled. It has a population of a milliou and a half, and yet the medical service is so arranged that it is within the reach of all, effective and fruitful of results. This is accomplished by dividing the government into 118 medical districts. The physician in chief of each district resides in the hospital erected in the center of the district, and takes charge of the sick in the country around for a distance of twelve wersts. (One werst 1,066,781 meters.) The hospital has usually a capacity of twelve to fifteen beds, dispensary, etc., with a pavilion apart for maternity cases and another on the other side for contagious diseases. In ten of the districts there is also a building for chronic patients. All these hospitals and the medical assistance, dressings, etc., are free. Vaccination and sanitary oversight of the schools are also in the hands of the head physician, who has an assistant where needed. The sanitary conditions of the government are in charge of a corps of eight or nine special physicians, some of whom cooperate in recording the medical statistics of the government. The physician receives his residence free, heated and lighted, and also free transportation and 100 to 150 roubles a month. (The rouble about 55 cents.) The administration of the affairs of the medical department is in the hands of what is called the Health Council, composed of all the district physicians, and five or six members of the Semstwo. This cooperation of medical men and the officials best acquainted with the economic and financial conditions, etc., of the government, results in fruitful action. There is besides all this a vaccine institute, a colony for the insane near Moscow with 1700 acres of land, and a medico-statistic bureau in Moscow. Every two or three years all the physicians in the government meet in a general congress, the transactions of which are published. The expense of all these institutions amounts to almost a million roubles, part of which is contributed by manufacturing firms and landed proprietors. The state is planning to introduce the Semstwo into other governments as soon as possible, but has slightly restricted its independence of action since 1890.

Washington.

HEALTH OF THE DISTRICT.—The mortality for the past week was 128, of which 60 were white and 68 colored. The prominent causes of death were, diarrheal diseases 29; brain disorders, 17; lung diseases 19, of which 15 were from consumption. There were 3 fatal cases of diphtheria and 3 from whooping-cough, and 2 from typhoid fever. No new cases of scarlet fever were reported.

THE NEW SUPERINTENDENT OF CHARITIES.—Mr. Herbert W. Lewis has been appointed Superintendent of Charities to succeed Colonel Tracey, deceased.

MEDICAL SOCIETY.—At the stated meeting of the Medical Society held on the 5th inst., the semi-annual business of the Society was transacted. The treasurer, Dr. Franzoni, made his report. A number of applications for membership were received. The hot weather had a reducing effect upon the attendance of the Society, only seven out of three hundred and seventy-seven members being present.

TO LOCATE THE ISOLATING HOSPITALS.—The Commissioners have addressed circular letters to the different hospitals, setting forth the terms upon which they will agree to the location of the isolating wards. Thirty thousand dollars has been appropriated and is now available for that purpose. The diseases which will be treated in these wards are scarlet fever, measles, erysipelas and other contagious diseases of less gravity.

CENTRAL DISPENSARY AND EMERGENCY HOSPITAL. At the the July meeting of the Board of Directors of the Hospital,

the attending staff made the following report: Number of new cases treated, 1,329; number old cases, 2,540; total number of cases treated, 3,869; number of deaths, 7; number of post-mortems, 4; number of operations, 226; number of ambulance calls, 30.

THE PUBLIC SERVICE.

Army Changes. Official-List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from July 3 to 9, 1897.

Capt. William F. Lippitt, Jr., Asst. Surgeon (Ft. Leavenworth, Kan.), leave of absence granted to take effect about July 24, 1897, is changed to take effect when his services can be spared by his post commander, and is extended one month.

Capt. Henry P. Birmingham, Asst. Surgeon, on being relieved from duty at Ft. Trumbull, Conn., by Major Woodruff, will proceed to Chicago, Ill., and report for duty as attending surgeon and examiner of recruits, relieving Capt. Norton Strong, Asst. Surgeon. Capt. Strong, on being thus relieved, is ordered to Ft. Myer, Va., for duty, relieving Capt. William H. Arthur, Asst. Surgeon.

Major Louis M. Maus, Surgeon, is relieved from temporary duty in the office of the Surgeon-General of the Army, and will on Aug. 2, 1897, report for duty at Ft. Hamilton, N. Y., relieving Major Paul R. Brown, Surgeon. Major Brown, on being thus relieved, is ordered to Ft. Keogh, Mont., for duty, relieving Major Ezra Woodruff, Surgeon. Major Woodruff, on being thus relieved, is ordered to Ft. Trumbull, Conn., for duty, relieving Capt. Henry P. Birmingham, Asst. Surgeon.

A board of officers to consist of: Col. William H. Forwood, Asst. Surgeon-General; Major George W. Adair, Surgeon; Major Walter Reed, Surgeon; Major James C. Merrill, Surgeon; Capt. Leonard Wood, Asst. Surgeon, is constituted to meet at the Army Medical Museum Building, Washington, D. C., on Monday, Sept. 27, 1897, at 10 o'clock A.M., for the examination of candidates for admission to the Medical Corps of the Army.

CHANGE OF ADDRESS.

Anderton, W. B., from New York to East Quogue, L. I., N. Y.

Bonner, M. H., from Nashville to Murphreesboro, Tenn.

Battell, J. Geo., from Grand and Western Aves. to 790 N. Leavitt St., Chicago.

Clark, J. F., from Angola to 120 W. Lincoln Av., Goshen, Ind.

Cresswell, Willis W., from Minneapolis to Dundas, Minn.

Calwell, W. S., from Edinburgh, Scotland, to care of Union Bank of London, London, England.

Ebert, R. G., from Philadelphia, Pa., to care of Dr. W. H. Saylor, Hamilton Bldg., Portland, Ore.

Eads, S. O., from Somerset, Ky., to Arthur, Ill.

Fellman, G. H., from Oak Park, Ill., to 289 Pavonia Av., Jersey City, N. J.

Houston, Jas., from New York, N. Y., to Swartz Creek, Mich.

Kolmer, J., from 203 N. Illinois to 19 W. Ohio St., Indianapolis, Ind.

Johnson, L. D., from 819 W. Harrison St. to cor. Lake St. and California Av., Chicago.

Linjer, O. E., from Starbuck to St. James, Minn.

Makuen, G. H., from Philadelphia to Cresson Springs, Pa.

Rathbone, F. W., from Albuquerque, N. M., to Tonganoxie, Kan.

Sleicher, J. M., from Chicago, Ill., to 102 Main St., Watertown, N. Y.

Scofield, W. K., from Philadelphia, Pa., to 62 South View Av., Stamford, Conn.

Stone, R. F., from 250 N. Illinois to 14 W. Ohio St., Indianapolis, Ind.

Stewart, D. D., from 2602 N. 5th to 108 S. 17th St., Philadelphia, Pa.

Ward, Milo B., from Topeka, Kan., to Rialto Bldg., Kansas City, Mo.

Wolff, A. S., from Brownsville to Isabel, Texas.

LETTERS RECEIVED.

Arnold, Edmund S. F., Newport, R. I.; Atkinson, W. B., Philadelphia, Pa.; Arlington Chemical Co., The Yonkers, N. Y.

Baldwin, Helen, New York, N. Y.; Burgoyne, J. A., Columbus, Ohio; Barker, Lewellyn F., Baltimore, Md.; Beades, C. H., Sadlersville, Tenn.; Burwell, W. M., Chincoteague Island, Va.

ORIGINAL ARTICLES.

CHEYNE-STOKES RESPIRATION PHENOMENA.

Presented in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, at Philadelphia, Pa., June 1-4, 1897.

BY N. S. DAVIS, JR., M.D.

CHICAGO, ILL.

Mr. —, merchant, 73 years old, of good habits and good family history, came under my care in September last. His health had not been robust for many months. In midsummer his legs became edematous and he then first consulted a physician. He was found to have dilatation of the heart, a slight aortic murmur, atheroma to a moderate extent of the peripheral arteries and interstitial nephritis. His symptoms underwent no material change up to September, when I first saw him. As time went on he grew feebler, thinner and mentally depressed. He had little appetite for food or drink. He was often sleepless. About the middle of October he was too feeble to walk, and rarely slept more than an hour at a time. At night he was tormented by hallucinations which were very persistent. At this time Cheyne-Stokes respiration first manifested itself. The rhythmically increasing and diminishing respiratory movements with short pauses were very noticeable. The periods of apnea were short and the periods of dyspnea were not severe. The pulse was quite regular and was kept at about 85 by strophanthus. The pupils showed no change in size and there was no hebetude during apnea.

Cheyne-Stokes respiration was not constant at this time. It lasted for several days, and disappeared only to reappear from time to time for a few hours or days. Occasionally apnea was almost wanting, and even at the height of dyspnea the respiratory movements were not labored.

In November he improved; respiration became normal, sleeplessness was less troublesome and hallucinations were more infrequent and less persistent. Early in December he grew worse, Cheyne-Stokes respiration reappeared in an aggravated form and persisted for almost a month until he died. Dyspnea was more intense than during the first attack of Cheyne-Stokes respiration and the pauses were longer. His pulse quickened during apnea, and as respiratory movements grew shallower his eyes converged slightly, his lids closed and he seemed to be in deep sleep. If at this time his lids were lifted the pupils were uniformly found to be closely contracted. Conversation with him was slow, for he would cease speaking and apparently become unconscious during the period of apnea. With the first few shallow breaths his lids would open and his eyes would roll slightly as they are apt to do when one is suddenly roused from deep sleep. He would, so soon as respiration was

fairly established, resume a conversation without interruption of argument or break in the continuity of events that he might be describing. During apnea the power of speech was lost and mentality seemed suspended. If spoken to when thus apparently dozing he was not conscious of the question. Conversation with him was tedious, for these pauses occurred once in every eighty to ninety seconds and lasted about twenty-five seconds. The dyspnea was very wearisome to him. He was never cyanotic.

I have described this case as it illustrates Cheyne-Stokes respiration in its mildest form, and in that form in which all the accompanying rhythmic phenomena of pulse, eye and mind are present. In 1818, Cheyne (Dublin Hosp. Rep., 1818, vol. ii) first called attention to rhythmically ascending and descending periods of respirations separated from one another by short pauses.

Cheyne-Stokes respiration should be clearly distinguished from irregular breathing accompanied by pauses. In the latter form of respiration pauses occur, followed by several long gasping breaths which may gradually grow less violent and rapid or irregularly become so and cease with the beginning of another pause. Cheyne-Stokes respiration is characterized by a pause of from ten to forty seconds followed by from ten to twenty respirations which grow gradually quicker and deeper until they are dyspneic in character, both because of their violence and rapidity. During the succeeding ten to twenty respirations the movements grow progressively less violent and rapid until they cease and apnea begins. Usually the ascending and descending series of movements number about the same, but they are not always equal. The descending series are often less regular than the ascending. In the mildest cases apnea may be wanting, the ascending series of respirations may follow the descending without interruption. If, during the respiratory pause, voluntary efforts are made to breathe the whole chest is lifted by the unusual muscles of respiration, but the diaphragm and intercostals do not move.

Cyanosis is very rarely observable, although the pauses are frequent and many of the respiratory movements are shallow. Patients often complain of the wearisomeness of respiration, but not of hunger for air. In 1859, Reid (Dublin Hosp. Gaz., vi, 308) pointed out the commonly observable changes which occur in the pulse during Cheyne-Stokes breathing.

In most cases during apnea the pulse rate is quicker than during dyspnea; it will beat once or twice oftener in the quarter minute. Not infrequently the pulse is paradoxical. It is apt to be large and soft during dyspnea and small during the respiratory pause. Biot uniformly observed less arterial tension during apnea than dyspnea (*Rev. Mensuelle de Méd. et Chir.*, 1878, ii, 975). While these are the usual changes in the pulse, if any occur, it has been found

in rarer instances to be slow during apnea instead of quick, and once Heskyl (see Gibson, *Edin. Med. Jour.*, xxxiv) observed almost a complete disappearance of pulse beating during each respiratory pause.

In 1866, Leyden (*Arch. f. Path., Anat. und Phys. und f. Klin. Med.*, xxxvi) first called attention to the rhythmic changes that occur in the pupils during the phases of Cheyne-Stokes respiration. In very many cases, though by no means in all, the pupils become closely contracted during the pause and do not respond to the stimulus of light, although during dyspnea they are normal in size and respond readily to light. Contraction of the pupils usually takes place slowly and progressively, but in a few instances it has been observed to occur in slight successive spasms. Biot thinks these changes are due to variations in blood pressure, which are so often noticeable in the different phases of Cheyne-Stokes respiration. Recent observations, however, make it probable that they are not to be explained in this way, but are due to the direct influence of the nervous system upon the eye. Often, just as the pupils begin to contract, a slight convergence of the eyeballs occurs and still oftener the lids close during the period of apnea and the patient appears to be in deep sleep.

Not only do rhythmic changes occur in respiration, pulse and pupils but in a proportion of cases, as in the one that I have just described, mental processes seem to be suspended during apnea, although so soon as respiratory movements begin the mind awakes and seems normally clear. In many cases of Cheyne-Stokes respiration patients are deeply comatose and no mental variations are observable. Even in these cases, however, the pulse and eye phenomena are often seen.

In 1876, Ross (*Canada Med. and Surg. Journal*, v, 544) described a case in which general muscular rigidity occurred during each respiratory pause. Several similar cases have been described since. This is, however, not a frequent concomitant of Cheyne-Stokes respiration, and can not be regarded as one of the phenomena usually accompanying it.

In individual cases we find various combinations of these modifications of pulse, pupil and mental state. They by no means all occur coincidentally. The pulse and respiratory changes are the commonest, and next in frequency the eye and respiratory changes. Gibson (*Edin. Med. Jour.*, xxxiv) has described one case, which is interesting and important, as it throws light upon the nature of these phenomena. It was a case of meningitis, in which at regular intervals there occurred contraction and dilatation of the pupils, and coincident periods of somnolence and waking, but respiration remained normal. This case can not be called one of Cheyne-Stokes respiration, but it illustrates the fact that certain portions of the brain may be involved and produce certain of the rhythmic changes characteristic of Cheyne-Stokes phenomena, although the medulla is not affected. The reverse of this condition, which produces Cheyne-Stokes respiration, is much the commonest.

The phenomena of periodic respiration are very variable in their duration, sometimes lasting only a few minutes or hours, at other times persisting for many days or even for many weeks. An anonymous contributor to the *Lancet* (1890, i, 776) says that his father, who is advanced in years, has exhibited characteristic Cheyne-Stokes phenomena continuously for many years, although otherwise apparently well.

The dyspnea varies greatly in severity. For instance, in one case which was under my care this winter, the respiratory movements were so moderate that they caused the patient little annoyance, and he scarcely ever complained of difficult breathing. Usually, however, it is sufficiently severe to weary the patients very much, and every now and again it is intense. When respiration is wearisome and difficult it seems to demand relief by treatment. Text-books upon therapeutics and upon medicine give practically no information as to the mode of action or the utility of drugs for the relief of these peculiar symptoms. As one case after another came under treatment, I tried successively the nitrites and soporifics, thinking that they might relieve the dyspnea as they so often do that of asthma, but I soon found that their effects were uncertain, that apparently they afford relief in one case and none in another. I then tried respiratory stimulants and oxygen inhalations, but with similar results. As during the last year there came under my observation in quick succession a series of these cases, I was prompted to review the literature of the subject with care, hoping that I might there find more information in regard to the nature of the phenomena and its mode of treatment than is to be obtained from our usual books of reference. I have found the literature of the subject very large, but unfortunately, it contains almost no exact information of a therapeutic character. It is chiefly controversial in regard to the nature of Cheyne-Stokes phenomena.

When we approach the treatment of this affection we naturally ask ourselves, under what conditions does it arise and what is its nature? Cheyne-Stokes respiration has been observed as a complication of the most varied maladies, and has been provoked experimentally in very many ways. Edes (*Boston Medical and Surgical Journal*, 1879, ci, 734) and Cheyne have both pointed to certain families in whom there was apparently an inherited tendency to this peculiar form of respiration. It is rarely associated with such infectious diseases as typhoid fever, smallpox, diphtheria, cholera and whooping cough. It occurs much more frequently in cerebral affections such as meningitis, apoplexy, cerebral embolism and thrombosis, sun-stroke, insanity, hysteria, hemorrhage into the cerebellum and medulla, or aneurysm in the latter. Complicating hemophilia, hemorrhage after operations and deep anemia from other causes has been observed. It is frequently associated with certain circulatory affections, oftenest with fatty degeneration of the heart, valvular disease, pericarditis, aortic aneurysm and general arterial atheroma. At times, it also complicates respiratory affections such as bronchitis, pneumonia and tubercular disease of the lungs. It has been observed as a sequel to tracheotomy. In these affections, however, unconsciousness or semi-unconsciousness exists before Cheyne-Stokes respiration develops. It is also rarely observable in severe catarrhal affections of the gastro-intestinal tract. It occurs oftenest of all associated with chronic renal disorders, when it is usually regarded as a manifestation of uremia. It has been observed in healthy individuals who were sleeping deeply from the effect of prolonged or excessive exertion. It has also been seen when narcosis produced by morphin, chloral and the bromids was deep. In some animals it seems to be the normal mode of respiration during hibernation. It has been produced experimentally in frogs by subjecting them to very considerable changes of

temperature, or by holding them under water for an unusually long time. It has been provoked by bleeding and by the complete removal of the heart. In higher animals it has been caused by alternate compression and relaxation of carotid and vertebral arteries; by section of the medulla with or without section of the vagi; by pressure upon the medulla; and by various injuries to the brain and the medulla. It has been produced quite uniformly by section of the latter at the level of the *ala cinerea*. Of all these conditions under which Cheyne-Stokes respiration arises it occurs oftenest in uremia, next in meningitis and other cerebral diseases, next in cardiac, and least in other affections. In all cases there is malnutrition of the brain due either to toxic agents in the blood, to an imperfect blood supply or to other causes.

It must be admitted that the exact nature of Cheyne-Stokes respiration is unknown. Very many theoretical explanations of it have been given. No explanation worthy of the name of theory was propounded until 1869, when Traube (*Berliner Klin. Woch.*, vi, 1869, 277) offered the explanation that in all cases less oxygen was carried to the medulla than was natural, that therefore it was less sensitive than it should be. Accordingly more carbonic acid gas was needed to rouse it to activity than under normal conditions. He believed the stimulus of an excess of carbonic acid gas in the tissues was transmitted to the brain by the pneumogastric and other sensory nerves. An unusual accumulation of carbonic acid gas in the system took place during apnea. It stimulated the respiratory center and thus excited dyspnea, but it was soon wearied and apnea reappeared. This theory is no longer tenable, for it has been demonstrated experimentally that Cheyne-Stokes respiration will continue even though the pneumogastrics and all sensory nerves that might transmit impulses to the brain are cut. In 1874, Filehne (*Berlin. Klin. Woch.*, xi, 1874, 152) propounded another theory, which I need not describe for it too has been thoroughly disproven. He believed that rhythmic changes in blood supply to the brain were essential for the production of the phenomena. But it has been shown that Cheyne-Stokes respiration will continue even when the aorta is ligated and a varying blood supply is impossible. In 1877, Hein (*Wiener Med. Woch.*, xxvii, 317) announced his belief that whenever Cheyne-Stokes respiration was produced, vitality generally was lessened and the irritability of the medulla especially so; at the beginning of the pause in respiration, the blood was well oxygenated, but during the pause it gradually became venous; at the beginning of the pause when tissue change was taking place vigorously the respiratory center became more irritable, and as the demand for more oxygen gradually increased it was aroused to activity and produced the succeeding dyspnea, during which the blood was again well oxygenated. This theory, as that of Filehne, is refuted by the experiments which show that variations in blood supply or tissue oxygenation has nothing to do with the phenomena. Moreover, if artificial respiration is maintained during a few of the respiratory pauses, it will not prevent their regular recurrence afterward. In 1879, Luciani (*Lo Sperimentale*, xxxiii anno. Tome xliii, 341) and Rosenbach (*Zeit. f. klin. Med.*, Band I. 583) independently propounded theories which are somewhat similar, and which today seem to be most tenable. They both believe that the respiratory center is automatic,

although normally controlled by reflex motives, or by demands due to the condition of nutrition in various tissues or to mental states. Rosenbach believes that when Cheyne-Stokes respiration exists the whole brain is affected, although the medulla is especially so. The normal irritability of the central nervous system is lessened so that it feels influences from without less and its automatic power is more manifest. Its normal periodic exhaustibility is increased; at times even to paralysis. The experimental proof which has been produced, that periodic respiration is not due to irritation of sensory nerves, or variations in blood supply or oxygenation of the nerve centers, is good evidence that the respiratory center is automatic.

That Rosenbach is right in thinking that the whole brain is involved seems probable, because of the complex phenomena which are associated with the characteristic respiratory movements. Ordinarily the medulla is first affected and produces periodic respiration; later other centers are involved and produce the pupillary, pulse and mental changes. The case described by Gibson, and already referred to, in which only the pupillary and mental phenomena of Cheyne-Stokes respiration were present, shows that at times the higher nerve centers may alone be involved or sometimes may be first involved.

Unquestionably, the best treatment is that which is applied to maladies causing Cheyne-Stokes respiration; for instance, the general treatment for uremia when it is the cause of the respiratory phenomena. Improved cerebral nutrition and increased sensitiveness to reflex and external influences might be expected to directly aid the respiratory trouble. Therefore, as good nutrition as possible should be maintained, by carefully regulating diet and correcting digestive disorders in chronic cases of Cheyne-Stokes respiration. Inhalation of oxygen gas has not unfrequently been prescribed, in order to improve cerebral nutrition and make tissue change generally more perfect. Different observers give conflicting evidence as to its utility. In several cases it has seemed to me useless. In the case which I described at the beginning of this paper it was administered very faithfully during the first period of Cheyne-Stokes respiration, and during the first part of the succeeding three weeks when respiration was normal. About a week after the inhalation of oxygen was discontinued Cheyne-Stokes respiration reappeared. Oxygen was again used, but not as persistently, for it seemed to have no effect upon the respiratory phenomena or other symptoms. By these methods the attempt has been made to improve nutrition; and simultaneously strychnia has been given to increase the sensitiveness of the respiratory center. In the literature of the subject there is no evidence that strychnia has done good. Indeed, most authors frankly say that it is useless. In uremia it is contraindicated, for it might hasten the onset of convulsions. There is one instance on record in which it apparently provoked Cheyne-Stokes respiration. This was in the accidental poisoning of a pet dog. The animal was thrown into convulsions by strychnia, but its owner so supported it that the convulsive movements could not be easily re-excited by external influences. Periods of calm were thus produced between the gradually lessening convulsions, in which characteristic Cheyne-Stokes respiration occurred. (Tukey, *Edin. Med. Jour.*, xxxiv, 1117, 1888-9.)

Venesection has done good in a few instances. By it impurities can be removed from the blood, and an overloaded heart and engorged cerebral vessels can be relieved. It has been resorted to chiefly in cardiac and cerebral affections.

Various soporifics have been tried. As, however, normal sleep occurring in the course of Cheyne-Stokes respiration does not always modify the respiratory phenomena, so soporifics can not be expected to uniformly give relief. In some cases, it is true, sleep lessens the dyspnea. In such, morphin and chloral are most sure to give relief. Knaggs (*Lancet*, 1890, i, 744), reports one case that was greatly helped by paraldehyde. Sulphonal and urethan have been tried unsuccessfully. Hyoscin and atropin (Stadelmann, *Zeit. f. Klin. Med.*, 1894, 267) seem to aggravate the phenomena. The nitrites have been used by many observers, who undoubtedly hoped for as prompt relief of this nervous disturbance of respiration as is so usually obtained in asthma when these drugs are administered. Unfortunately they do not produce any more uniform results than the soporifics. In several of my own cases nitroglycerin has afforded decided, although not complete, relief, but in other cases it has been useless. In several I was unable to use it in efficient doses, because of the discomfort which it produced by dilating cerebral arterioles.

Cheyne-Stokes respiration can not be regarded as always indicative of grave disease, for it occasionally occurs in health when sleep is unusually deep. If it is produced by drug narcosis it is significant of serious poisoning. In renal, in cerebral and cardiac affections, it is always to be regarded as a grave complication, and as usually indicating approaching dissolution. It is least significant of gravity when it is most chronic. It is very frequently completely recovered from. This is oftenest true when it occurs in connection with infectious and cardiac diseases.

MULTIPLE NEURITIS FOLLOWING INFLUENZA.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association held at Philadelphia, June 1-4, 1897.

BY HERMAN B. ALLYN, M.D.

INSTRUCTOR IN PHYSICAL DIAGNOSIS IN THE UNIVERSITY OF PENNSYLVANIA; VISITING PHYSICIAN TO ST. JOSEPH'S HOSPITAL; MEDICAL REGISTRAR TO THE PHILADELPHIA HOSPITAL, PHILADELPHIA.

Multiple neuritis as a cause of pain, paralysis and wasting was for years overlooked. Graves suggested that many cases of paralysis attributed to disease of the brain or spinal cord might be due to disease of the peripheral nerves. James Jackson described alcoholic paralysis in 1822, and in 1864 Duménil first attributed it to multiple neuritis. It is from Duménil's time that the modern study of multiple neuritis dates. He was followed at a considerable interval of time by Joffroy (1879), Leyden (1880) and Grainger Stewart (1881). Since Stewart's paper the disease has been generally recognized and by degrees an extensive literature has accumulated. The danger now is, not that multiple neuritis will be overlooked but that affections really due to disease of the central and peripheral nervous systems shall be regarded as due exclusively to lesion of the nerves. Several writers have already recorded cases showing the existence of peripheral and central disease; Mills,¹ for

instance, says he has seen the apparent concurrence of multiple neuritis and poliomyelitis.

The causes of multiple neuritis now recognized are numerous. Ross and Bury, in their admirable monograph,² classify multiple neuritis under the following forms: 1. Idiopathic. 2. Toxic. 3. Dyscrasic. 4. Sensory, vasomotor and trophic. 5. Irritative. The toxic form includes neuritis due to alcohol, CO₂, carbon bisulphid, dinitro-benzin and anilin; the poisons of the infectious diseases, diphtheria, typhoid fever, etc.; the metallic poisons, lead, arsenic, mercury, etc.; and the poisons of rheumatism, gout, chorea, the puerperal state and diabetes. This classification is open to some objections but is in the main satisfactory. It brings out the fact that the great majority of the cases are clearly of toxic origin, and it shows what a great variety of diseases may develop the poisons capable of causing neuritis.

Just here it may be well to state that the term neuritis is used for convenience. It is not intended to imply that the pathologic process is really inflammatory, though it may be in some cases. To avoid a false impression, Sharkey has proposed the name "peripheral nerve intoxication," while others speak of "peripheral nerve degeneration."

Since the epidemic of influenza in 1889, cases of neuritis occurring in association with influenza have been reported. The number is now considerable. A much smaller number of cases of multiple neuritis has been recorded. Some of the more recent writers on multiple neuritis, however, do not mention influenza as a cause. Probably one reason is the difficulty in the diagnosis of influenza in some cases. In my experience it is the milder type of influenza which is more likely to be followed by neuritis; and it is in precisely these cases that it is impossible to be certain of the diagnosis. We lack the important tests which we possess in a culture from the throat in diphtheria, and an examination of the blood and urine in typhoid fever. Nevertheless, I am confident that we can attain a reasonable degree of probability in the diagnosis, and I feel equally confident that the poison of influenza is a frequent cause of neuritis and occasionally of multiple neuritis.

Ross and Bury declare that affections of the peripheral nerves were exceedingly common during the last two epidemics of influenza (1889-90, 1890-91). Isolated neuritis of almost every peripheral nerve in the limbs and of almost every cranial nerve, has been recorded; while multiple neuritis, though less common, was occasionally observed.

Putnam,³ on the other hand, has expressed surprise at the infrequency of nervous disorders following influenza.

In the statistics from the collective investigation of the Berlin Medical Society,⁴ it appears that nervous complications and sequelæ occurred in 1,442 cases, or 45.7 per cent. Neuritis, including multiple neuritis, is mentioned in 22 cases and neuralgia in 915. It seems to me that the difference between neuralgia and neuritis—meaning by the latter term intoxication and degeneration—is one of degree of irritation. Probably, therefore, some of the 915 cases reported as neuralgia would have been reported by others as neuritis.

⁴ Die Influenza-epidemie, 1889-90, im Auftrage des Vereins für Innere Med. in Berlin. Herausgegeben von E. Leyden und S. Guttmann, Wiesbaden. J. F. Bergmann, 1892.

So far as my personal experience goes, I have seen more cases of neuritis in the past year than in the preceding five years.

Case 1.—A brakeman, age 35, married, with two healthy children, and personally free from alcoholism and syphilis, was taken sick about April 20, 1895, with headache, coryza and sore throat. The catarrhal symptoms were mild. The children had had influenza a short time previously. I saw the patient first on April 23, 1895. The temperature was then only slightly above normal. The catarrhal symptoms persisted but were completely overshadowed by intense headache and somewhat less severe pain in the back and limbs. The temperature in a few days came down to normal, and throughout the remainder of his illness was always found subnormal whenever it was taken. The headache proved extremely obstinate persisting for six weeks or two months. Phenacetin and antipyrin only mitigated the pain. The headache was more intense at times but did not wholly cease. In a short time pains appeared in the right intercostal spaces, then in the left side and in both thighs and legs. Less severe pains developed in the shoulders and arms. These pains were at times extremely severe, especially the pain in the left side. It resembled the pain of pleurisy in being aggravated by breathing and motion, but the physical signs of pleurisy were absent. The pains in general were aggravated by motion, and were associated with muscular soreness and with tenderness over the nerve trunks. They were paroxysmal in character but not regularly so. During the first two months the headache was the most constant source of suffering; next in constancy and at times worse in intensity was the pain in the left side and arm. The patient was confined to bed. The appetite was almost completely lost and insomnia was as obstinate and almost as distressing as the pain. He lost flesh steadily but not rapidly. Toward the latter part of May and in June he improved considerably. He was able to move around his room with the help of a cane. Most of the pains had subsided, but pain persisted in the left sciatic and lumbar region. The sciatic was tender to pressure. The appetite improved slowly but fitfully. For a week or two he was able to eat scarcely anything because food caused intense pain, sometimes with vomiting; but more frequently food was hurriedly expelled from the bowel almost as soon as it had been swallowed.

On June 19 he developed pain and oppression over the heart and collapse, with cool moist skin and an extremely weak and irregular pulse. He rallied slowly from this attack, but had several recurrences in milder form.

On July 2 he was taken to a summer resort, where he improved wonderfully, especially in appetite and ability to sleep. For almost the first time since his illness began he could relish food and eat it without discomfort. The return of sleep was especially gratifying. He gained flesh rapidly and recovered considerable power in the left leg, though it was still stiff and painful.

After his return to the city there was partial relapse. The appetite was not so good and there was more pain. There was nothing left of his neuritis except the sciatica. He refused to go to bed and be treated properly, and by degrees became despondent. Very hot weather agreed with him. He wished it were 120 degrees F. continually.

By Dec. 6, 1895, his condition had not changed much. The left leg was wasted, knee-jerk totally absent on left side and diminished on the right. Most of the pain was referred to the left leg below the knee and to the left lumbo-sacral region. He still, at times, had pain elsewhere, with headache and insomnia. The sphincters were never involved.

On Jan. 13, 1896, he was much freer from pain. He had not been out of the house since November and had only twice been down stairs. The left foot was in the position of talipes varus. The foot could be straightened but did not remain straight and the patient walked on the side of the foot. Manipulation of the toes and foot caused pain in the leg. Anesthesia of the leg was first complained of. In other respects he had gained, eating and sleeping well and gaining in flesh. But he was unwisely advised by another physician, that the leg was hopelessly paralyzed and that the best thing to do was to wear a brace for it. The result was an aggravation of the paresis and the development of psychic paralysis. This condition was first recognized by Dr. J. H. Lloyd in the latter part of July, 1896. There was at this time very pronounced analgesia and anesthesia segmental in type, but the muscles could be made to react to the galvanic current. The patient was persuaded to abandon the brace, and by degrees has recovered nearly full power in the leg, with full sensation. He resumed his work as brakeman in April, 1897.

It is probable that in this case there was, in addition to peripheral neuritis, a mild poliomyelitis. The course of the disease could have been much shortened had the patient's means permitted him to have the proper care. He was also at times uncontrollable, wandering about to various doctors and healers and taking patent medicines.

In this case the neuritis involved sensory and motor nerves of the cerebro-spinal system, and also the vagus. In all probability the attacks of faintness and collapse, which occurred on a number of occasions, are to be best explained by supposing an involvement of the nerves in the heart substance; and the anorexia, vomiting and diarrhea by a similar involvement of the visceral ends of the vagus or possibly of the abdominal sympathetic. Dr. Seymour J. Sharkey, in his suggestive paper on peripheral neuritis,⁵ says that the vagus is not infrequently involved, and that it gives rise to marked and even fatal cardiac disturbance. A few observations have shown that the terminal distributions of the nerves of the heart are liable to alterations which probably play an important part in some cases of serious cardiac disease. He suggests also that the sympathetic nerves may be involved, and that such involvement may account for visceral neuralgias and disturbances of secretion and metabolism.

A case of neuritis of the viscera, reported by John Ferguson⁶ in 1890, anticipates these suggestions by Dr. Sharkey. The patient was a woman aged 40 years. A short time after the attack of influenza passed off she began to complain of paroxysms of pain of the most agonizing character. These attacks might occur at any hour in the day, but they were generally most likely and most severe toward morning. Despite all efforts to relieve her she grew worse and died after a period of great suffering lasting ten weeks. The postmortem examination of nerves and ganglia throughout the abdomen showed them to be in a highly inflamed condition. Under the microscope, marked degeneration of nerve tissue was shown.

In one of Sansom's cases there were shooting pains in the epigastrium; but the case, although of alarming intensity, ended in recovery. In Case 4 of my series the visceral symptoms were pronounced.

Case 2.—Woman, aged 40 years. On February 17, six days after a mild attack of influenza characterized by sore throat, headache, and pains in the back and limbs, she was seized with excruciating pain in the right side of the fauces. The throat was red, edematous and swollen, the tonsils only slightly enlarged. There was no suggestion of membrane. Other members of the family were convalescing from influenza. The throat trouble was probably an angioneurotic edema. Pain was much aggravated by swallowing, but under treatment had very much lessened by morning—so much so, indeed, that the patient seemed nearly well. She remained in the house until February 25, and then went for a short walk. She felt weak on her return but was obliged to go out the next day to call on one of the family who had been ill with influenza. On February 27 she felt threatened with a return of the pain in her throat, but it never became severe: that night and the next morning she had most excruciating pain in the back from the waist to the shoulders. The sensation was as though the flesh was tearing from the bones. There were no shooting pains in any direction, but there were pains in hips and legs, and the sciatics were tender to pressure. The muscles were sore to the touch. The pain in the throat subsided abruptly when the pain in the back began. The pain in the back lasted some hours, then moderated, but did not subside entirely: it increased again in the afternoon. A hypodermic injection of morphin (gr. $\frac{1}{4}$) and atropin (gr. 1-150) gave prompt relief and

⁵ Sharkey, S. J.: Brit. Med. Jour., Feb. 22, 1896, p. 456.

⁶ Ferguson, John: Alienist and Neurologist, 1890, 584.

secured a comfortable night. In the next few days numbness and soreness appeared in the arms. Closure of the hands caused pain; while she was able to walk, standing developed numbness in the legs and feet. There was no fever. Examination of the lungs, heart and abdomen was negative. The only spot of tenderness was about the third dorsal spine.

In the first week of March there was a gradual increase in the pains in the arms, appearance of pain in the left intercostal along the eighth rib, in the axilla, and a persistence of the paroxysms of pain in the back. These came on pretty regularly at first about midday, and gradually increased in intensity until 7 or 8 p.m. Under a hypodermic injection they subsided until midnight or the early morning hours, and then recurred, to again subside. For days the hours between 9 a.m. and 12 m. were almost entirely free from pain. When the paroxysms of pain in the back appeared there was an aggravation of the pain wherever it before existed. On March 7, some muscular twitchings appeared in the arms and legs. The pain appeared in the lumbar region and became less severe in the dorsal. The patient was made extremely nervous by flushings, which occurred frequently during the day and night and always aggravated the pain. They were followed by cool perspirations. There was no increase of dorsal pain by ice or hot water; no girdle sensation. By March 10, the superficial cervical nerves were involved. The neck muscles, especially on the left side, were tender. The face was painful to the touch at all times. Gradually the tender areas extended, and the sensitiveness became so delicate that tapping or a sudden touch almost made her scream. There was the same tenderness of the hands and fingers, especially on the left side. Pressure on any nerve trunk or motor point, Erb's, ulnar, median, sciatic or perineal, caused acute pain. The soreness and aching in arms and legs were constant, irrespective of a paroxysm of pain. Morphine, hypodermically, relieved the pain in the back, but had no effect on that in the arms. In the face the point of greatest tenderness appeared to be just under the left malar bone. It was painful to open the mouth. Food sometimes stuck in the throat and had to be coughed up.

During the following week the patient was very miserable; she had more or less pain all the time, and usually two or three times in the twenty-four hours there was a sharp exacerbation requiring a hypodermic injection of morphine. On several occasions she was nauseated and vomited. She complained that as soon as she fell asleep she was aroused by a violent jerking of the leg muscles. The dorsal position with the head elevated is the only one possible. If the patient lie on her side the flushes of heat become suffocating and unbearable. On several occasions there was disagreeable faintness on awakening in the morning. In the week from March 20 to 27, there was improvement in the amount of pain, and in the behavior of the stomach. The arms were firmly bandaged with flannel and became more comfortable. They are still constantly painful with diurnal exacerbations on which quinine never had any influence. Numbness is complained of in the hands and feet, and burning of the palms and soles of the feet. Nerve trunks are still very tender. The neuritis extended to the nape of the neck, involving the posterior auricular, the occipital and the temporal branches. This region, especially about the face and brow, had been very tender, but now became painful, and in a few days was the seat of greater pain than either back or arms. Nevertheless the pain was not as intense as formerly, and gr. $\frac{1}{8}$ of morphine and 1-300 of atropine, two or three times a day, was sufficient to make it bearable. The headache now became the most distressing pain. There was at times considerable depression of spirits and a feeling of general wretchedness. The pulse, which had gradually increased in frequency from 60 at the beginning of the illness to 100, now began to beat more slowly. Respiration had never been disturbed. The temperature had varied from a little below to a little above normal.

During the first week of April the pain lessened. There was still intense hyperalgesia of the fingers and face. The smoothest surface, as of a silver spoon, felt rough and granular. There was more freedom of motion both of arms and legs, so that the patient could turn from side to side. She was, however, unable to lie long on one side because the hip underneath her became so sore. Later the ears became so tender that the pressure of the softest pillow became unbearable for a longer time than an hour. For this reason the patient roused every hour during the night, turned over and again went to sleep. Morphine was no longer required, codeine, gr. $\frac{1}{2}$, two or three times a day, was sufficient, and by degrees this was lessened. In the beginning of her illness she had required the codeine and other anodynes by the mouth in addition to the morphine hypodermically.

On April 16, the flannel bandages were removed from the arms, and a long sleeved undershirt substituted. By April 22, she was able to sit up in a chair for about twenty minutes. The fingers were less numb, but still very sensitive. Both arms and legs were noticeably wasted, especially the left. The grasp of the left hand was reduced to the very faintest pressure. The knee-jerks were diminished but not absent. During the next few weeks there were days when the headache became temporarily worse, but improvement in strength and flesh was steady and satisfactory. Some numbness with hyperalgesia, persisted in hands and feet. There was complete loss of power to distinguish form, substance, size and weight by touch. The patient could not distinguish a watch from a handkerchief by touch.

In the first week of May she became able to walk a little. Station was disturbed. There was no incoordination of the arms. When seen May 16, the patient was able to walk about and had been downstairs. There was no disturbance of station when standing with the feet close together and the eyes closed. She had also regained power to distinguish objects by touch. The only pain that persisted was to the left of the vertex. Numbness in a diminished degree still persists in the toes and left thumb. She can now wear a loose shoe, whereas hitherto anything but a very large slipper caused unbearable pressure on the toes. The gait is that of a feeble person.

[July 12.—The patient has gained in strength and can walk fairly well. There is still numbness and disturbed sensation in the feet, especially the toes, so that in the dark she can not be sure where the feet are placed in walking. There is morning headache, confined to the left temple.]

In this case the sensory and vasomotor symptoms were more prominent than the motor. Both the spontaneous pain in the muscle masses and the hyperalgesia of the skin were remarkable for their intensity and persistence. I have never seen greater suffering from the same cause. The patient has naturally more than the average amount of self-control and is capable of bearing a great deal of pain without complaint; but the pain was absolutely unendurable. When it was moderately severe a combination of neuralgic remedies by the mouth lessened the pain sufficiently to make it bearable; but when it became very severe nothing sufficed but a hypodermic injection of morphine and atropine. These injections were required for several weeks with, however, gradually lessening frequency and dose. As a rule, they speedily brought about a state of comfort, both mental and physical; yet a complete relief from all painful sensations was not secured; for example, when the pain in the back was the most intense, a hypodermic injection appeared to stop it entirely; and while the pain in the arms was greatly lessened a dull aching persisted, as did the hyperalgesia of the skin. This hyperalgesia of the skin was noteworthy. The patient declared that the fingers felt as though the nerves were on the outside of the skin. Associated with it was numbness, especially in the left thumb. Although the fingers were so markedly hyperalgesic, there was loss of the power of distinguishing objects by shape and texture. In Senator's⁷ case there was also difficulty in distinguishing objects by touch. Moreover, there was also loss of the weight sense. The patient could not tell her watch from her handkerchief, and when partly recovered let objects fall from her hand because she did not know how tight to hold them.

Finally, the vasomotor symptoms are interesting. The flushings which were present had occurred for several months before her illness and were part of the menopause; but during the first month of her illness they recurred much more frequently and for a time were harder to bear than the pain. As the wave of heat would sweep over her the face would flush, the patient would feel suffocated, and there would be a

⁷ Senator: International Clinics, 1895, iii, 139.

great aggravation of whatever pain at the time might be present. The flushing lasted but a few minutes, being followed by perspiration, which was profuse in the beginning of her illness.

Taken all in all the case seems to me remarkable, alike for the wide distribution of the sensory symptoms, their manifold character, and their severity. So far as mere intensity is concerned, the case is not unusual. Pain has been present in all my cases, and at times was perhaps, as intense as in Case 2; but in none of them did it last as long with full intensity or have so wide a range.

In all of Sansom's⁸ five cases pain was the most prominent symptom. In one, a man aged 41 years, there were fearful nocturnal exacerbations in which the patient shrieked with pain.

The vasomotor symptoms were distressing, as already mentioned, but the sweating was probably not as great as in the case reported by Brosset.⁹ The patient was a woman aged 34 years. About ten days after the onset of influenza she felt some pricking in the left hand. Both palmar and dorsal surfaces of the hand sweat profusely. There were also profuse general perspirations, and later the same phenomena in the right hand. The disease was progressive. In the course of eleven months all four extremities had become involved. Pain still persisted even in the arms, and there was considerable wasting. Profuse, exhausting nocturnal perspirations were a marked feature in Case 6 of my series. Such muscular twitchings as was present in Case 2, is not uncommon. It appears to be an exaggeration of that which is at times noticed when a person is about dropping off to sleep.

In a curious case reported by Testi¹⁰ there were convulsive attacks and spasmodic contractions of various muscles. The muscular cramps recurred at first from eight to ten times a day. Pressure along the vertebral column did not cause pain, but provoked spastic contractions of the arms. There was, however, a painful spot at about the third dorsal vertebra. The nerve trunks in both arms were tender. The touch sense was diminished. There was hyperesthesia, some vasomotor disturbances and reaction of degeneration in the muscles.

Revelliod has reported a case of paraplegia following influenza. The patient was 16 years old. The disease took the form of spasmodic tabes. The gait was of spinal trepidation with condensed sub-sultus propagated to the whole body as soon as the foot touched the ground. The patient recovered. Revelliod also says that he has noted three cases of tetany of the upper limbs.

Case 3.—I saw some years ago a boy 3 years old who was thought to be paralyzed in both lower limbs. The condition had followed influenza, and had persisted for some weeks before I saw him. The boy was able to sit up in bed, but when moved he cried out with pain, and at night occasionally screamed with pain. He could not be made stand on his feet, although before his illness he could run about freely. His refusal to stand was ascertained to be not so much from inability, although the legs were somewhat wasted and the muscles flabby, as from the extreme pain which the effort caused. At first an outcry of pain was induced even when I lifted the leg. Associated with the pain, and probably caused by it, were persistent insomnia and very poor appetite. There was no

evidence of rickets, syphilis or rheumatism. Under suitable treatment for the neuritis there was rapid improvement and the boy could soon use his limbs.

Case 4.—I saw several years ago a healthy, robust young Irishman, aged about 28 years, free from alcoholism and syphilis, who had, following influenza of moderate severity, pains throughout the body and extreme weakness. The temperature was normal or subnormal. Subsequently the pains became localized, especially in the head and abdomen. The most distressing symptoms were retching and vomiting and insomnia. The man's condition was most deplorable. Repeated examinations failed to disclose any organic disease in chest or abdomen. Owing to inability to retain nourishment, to the pain and to insomnia, the loss of flesh progressed steadily for several weeks. Subsequently by slow degrees the pain lessened and he became able to take nourishment, but weakness persisted for months.

I believe that in this case the explanation of the symptoms is to be found in a multiple neuritis affecting the pneumogastric and abdominal sympathetic. It is analogous to Ferguson's case, but with a happier issue. Bidon has reported some cases in which the pneumogastric was believed to be involved.

Motor symptoms.—While in my own cases the sensory symptoms were very pronounced and gave character to the cases, there have been cases reported in which motor symptoms predominated and one, Buzzard's¹¹ case, which was almost exclusively motor. The patient was a man 46 years old. Shortly after an attack of the character of influenza, he suffered from pains in the legs and some numbness of the feet. He soon began to totter in walking, and in a few months was unable to support himself. His upper limbs also became weak, but he had never any pains, twitching or tremor. Alcoholism and syphilis as causes could be excluded. Thirteen months after the illness, when he was examined by Dr. Buzzard, there was a condition of almost universal paralysis. The lower limbs were absolutely paralyzed and the only movement retained in the upper limbs was the slightest possible power to lift the shoulders. The muscles were much atrophied and there was no reaction to the strongest faradic current. For a few days after his admission to the hospital the condition was critical, owing to his difficulty in breathing; but a very slow improvement soon began, and in a year's time he could move the arms quite well.

Remak's¹² case is invaluable for the clear history of influenza and for the careful examination of the nerves. The patient was taken sick about Christmas, 1889, with influenza. He had considerable fever and a severe bronchitis. There were several other cases of influenza in the same house sick at the same time. Striking symptoms from the beginning in this case were the severe pains in the back and in the extremities. These persisted until the paralytic symptoms appeared, about January 8. The pains then subsided and the nerve territories in which severe r.d. had not occurred began gradually to improve. There was absolute paralysis with severe reaction of degeneration in the region of both radial nerves, with the exception of the supinator longus; a middle form of paralysis with degenerative reaction, with much diminished nerve excitability and absent knee-jerk in the territory of both crurals, probably also of psoas, in the region of the ulnars and medians. The upper arm muscles showed partial r.d. The cerebral nerves were not involved, the pupillary reaction was intact. Pains in the arms and thighs persisted, and the nerve trunks were tender to pressure.

Remak regards the case as one of amyotrophic degenerative polyneuritis, or multiple degenerative neuritis.

In the development of these cases there may be other factors besides the poison of influenza. There is in some persons a disposition to nerve complications, as is shown in the cases of recurrent palsies. Thus, in Lehmann's¹³ case, a girl 10 years old had complete motor palsy of the lower extremities four days after an attack of influenza. Sensation was unchanged. The sphincters of bladder and bowel were not involved. This same girl had previously had a similar but more severe paralytic seizure. She was not much improved when dismissed from treatment.

Moreover, Putnam¹⁴ refers to five cases of polyneuritis in which lead or arsenic or both were present in the urine. He remarks that in two of these cases the catarrhal attack which preceded may well have been influenza. In the other three cases no such history was obtained, but influenza can not be excluded. I have myself seen one case of multiple neuritis in which the poison of influenza seems to have been associated with rheumatism in the development of neuritis.

Case 5.—A woman 40 years old was admitted to St. Joseph's Hospital May 8, 1897. She had a tubercular family history and a personal history of undoubted rheumatism. Two months before her admission to the hospital she had an attack of influenza with marked catarrhal symptoms, which confined her to bed for two weeks. This was followed by neuritic pains which appeared first in one of the right lower intercostal spaces. The pain was so severe she could scarcely breathe. The pain subsequently appeared in the left foot and then the right leg. At the time of her admission to the hospital both legs were involved. There was said to have been, at times, considerable swelling of the limbs, but the chief complaint after admission was of pain in the left shoulder, arm and left leg. She had suffered with insomnia for almost a week. The pain was found to be associated with marked soreness of the muscles and tenderness of the nerve trunks. In this case the pain yielded readily to remedies found useful in influenzal neuritis.

Case 6.—A woman 27 years old was admitted to St. Joseph's Hospital April 17, 1897. Two weeks before her admission she was suddenly taken sick with a severe chill, vertigo, tinnitus and severe occipital headache. She had severe left intercostal neuritis, a scapulo humeral neuritis and a slight degree of superficial cervical neuritis. There was slight bronchitis, considerable pallor, extreme weakness and profuse nocturnal perspiration. Examination of organs was negative except as to the existence of the bronchitis mentioned. The patient recovered and was discharged. It is possible that syphilis is a factor in this case, as the patient had had three miscarriages, the last one a year ago. There was no history of alcoholism or rheumatism.

The association of disease of the cord with multiple peripheral neuritis has been referred to. It seems to have been present in one of Westphalen's¹⁵ cases (man aged 29). This patient is said to have recovered from his neuritis in four weeks; but the knee-jerks were still absent three months afterward.

In one of Putnam's¹⁶ cases a man of middle life never recovered his strength after severe and typical influenza. After the subsidence of the early symptoms he began to suffer with severe epigastric pain of the character of the girdle sensation, which followed him for a year. He dragged himself about and tried to work, but the weakness of the leg gradually passed over into a condition of incoördination so great that he could walk but a few steps alone. There was not much paresthesia but a high degree of impairment of sensibility in feet and legs, passing gradually to the

upper part of the thigh. The knee-jerks were absent. The hands were somewhat ataxic and there was a slight lack of control over the bladder. There were no pupillary symptoms.

Dr. S. Shimamura¹⁷ has reported a case of myelitis from ascending neuritis. The patient was a woman aged 29. Death resulted.

Leyden has reported a case of influenzal polyneuritis with disease of the cord, which is of special interest because an autopsy was secured. The patient was a woman aged 27. She had paresthesia in arms and numbness in finger tips, chill, fever, frequent vomiting, steadily diminishing loss of power in arms. In about a week these symptoms were suddenly followed by paralysis of the extremities and loss of voice. There were marked sweatings, acute pains in hands and feet, absent knee-jerks and muscle jerks, paralysis of bladder and intestines. There were partial reactions of degeneration. Diaphragm became paralyzed. Delirium, cyanosis, collapse and death resulted. Immediately after the autopsy Goldschneider found a pronounced intense neuritic atrophy of the perineal and some twigs of the right radial nerves, and of the trunk of the recurrent. The cord showed much enlarged medullary longitudinal nerve fibers with considerably thickened and seemingly swollen axis-cylinders.

Thue's¹⁸ case seems to be an instance of multiple neuritis of the cranial nerves as well as of the spinal. The patient exhibited paresis of all the limbs, double facial paralysis, with complete reaction of degeneration, diplopia, anomalies of taste and slight anesthesia. These symptoms gradually developed during convalescence from influenza. The diagnosis was polyneuritis of the sixth and seventh cranial nerves, possibly also of the glossopharyngeal and hypoglossal as well as of the extremities.

Bruns has reported two cases which ended fatally. In the first, a general palsy, resembling Landry's paralysis, progressed from below upward and ended fatally. In the second, a man with tedious intestinal catarrh developed paralysis, first in the tongue and throat. He died on the seventh day. I have been unable to find the original report of these cases. They are referred to in Robert Gross's thesis.

Eisenlohr reported to the Hamburger Aerztliche Verein two cases. In the first, a boy 5 years old, shortly after a mild attack of influenza, exhibited paresis of the lower limbs, of the throat muscles and of the soft palate; then followed symptoms of weakness of the upper extremities. In the second case, a woman 44 years old, suffered eight days after moderate influenza with a general muscular paralysis, with abolition of reflexes, intense hyperesthesia of the skin, dyspnea and acceleration of the pulse. The mind was not affected. Death occurred on the second day.

Reformatsky has reported to The Neurological Society of Kazan a singular outbreak (epidemic he calls it) of neuritis. Eight members of one family all fell ill at nearly one time. At the onset they complained of weakness, headache, chills, coryza and gastro-intestinal catarrh. A short time after the onset there developed numbness of the limbs, weakness and emaciation. The knee-jerks were abolished, the muscles atrophied and pressure along the course of the nerve trunks was very painful. Other symptoms were paresis and disturbance of sensation in the

limbs. He says there was, therefore, a peripheral polyneuritis, occurring in several members of one family, consecutive to an infectious disease, probably la grippe.

Trophic symptoms.—These have not been marked in any of my cases. In one case the fingers became glazed and the arms and scalp scaly. In the case reported by Mills,¹⁹ a woman of middle life had a sharp attack of influenza five weeks before she came under his observation. On her recovery she was extremely weak in the legs and was scarcely able to drag herself around. In a few days her feet and legs began to swell and to be painful, and soon became of enormous size and exquisitely tender. The swelling was firm, not pitting on pressure; myxedemoid in character. There was great tenderness on squeezing the feet and ankles or handling the nerves and muscles.

The only case at all analogous to this one is that mentioned by Tessier.²⁰ A woman, 49 years old, developed cutaneous sclerema following well-marked influenza.

In looking up the literature of multiple neuritis following influenza I have found thirty cases reported. This number does not include the case of Havage, because the patient being an inn-keeper and 40 years old is open to the suspicion of having alcoholic paralysis. The case of Henoch (girl 10 years old, complete paralysis of all the muscles of the left arm) is rejected because it seems to me best not to include under multiple neuritis cases in which only nerve trunks in close association are involved. For the same reason the six cases of scapulo-humeral neuritis reported by Joffroy²¹ are not included. Finally the eight cases of Reformatsky are rejected chiefly because the brief reference to them at second hand in a French journal does not enable one to judge of their nature. If to the thirty cases collected from the literature the six cases observed by the writer are added we have a total of thirty-six cases. The great majority of these are instances of peripheral neuritis; in a few the cranial nerves also are involved and in a few also, as already mentioned, the spinal cord was at the same time affected.

The disease seems to be an intoxication of the nerve trunks. This intoxication may be sufficient to produce rapid destruction of the nerve fibers or only enough to cause more or less pain—an irritative instead of a paralytic toxemia. The salicylates are useful in these cases, probably because they seem to have the power of promoting the elimination of certain toxic agents.

CONCLUSIONS.

1. Influenza, like other infectious diseases, may be followed by neuritis and multiple neuritis.

2. One sex does not seem to be more liable to multiple neuritis than the other.

3. It occurs most frequently between the twenty-fifth and forty-fifth years; and appears during convalescence in a few days or two or three weeks after the influenza has subsided.

4. It may present sensory, motor, vasomotor or trophic symptoms or all combined, but sensory and vasomotor symptoms are more prominent than in diphtheritic and some other causes of multiple neuritis.

5. The great majority of the cases recover, both as regards restoration of function and power as well as

regards life. Five of the thirty-six cases collected in this paper died. In one of Bruns' cases the symptoms resembled Landry's paralysis, in the other there was paralysis of the tongue and throat. In Eisenlohr's fatal cases there was general motor paralysis with intense hyperesthesia of the skin. In Ferguson's case the neuritis was visceral and in Leyden's fatal case there was coincident disease of the cord.

6. Recovery does not usually take place under four weeks and may be delayed for months.

7. Treatment should consist first of absolute rest in bed. Anodynes must be given in sufficient dose to relieve pain, when that is a prominent symptom. Morphine hypodermically may be necessary, but may be often substituted with advantage by codein. The antipyretic anodynes are insufficient in any safe dose if the patient has pains for many days. The salicylate of cinchonidin is distinctly valuable, especially when the pain is not of the greatest intensity. At a later stage potassium iodid and the bichlorid of mercury in small doses are helpful. When the pain is in an extremity firm pressure with a flannel bandage gives great comfort. Blisters over the painful nerve trunks when they are superficial are also valuable in relieving pain.

Close watch must be kept on the action of the heart and the character of the breathing. Most of the fatal cases die through paralysis of the diaphragm. The closest attention must be given throughout the course of the case to the nutrition of the patient and to the condition of the skin, especially over portions of the body where pressure occurs.

As far as possible the stomach should be reserved for food. Medicine in these cases acts better when given hypodermically, and the stomach is not so likely to be deranged. This caution applies especially to the giving of anodynes.

8. Finally, while I think diphtheria as a cause can be excluded in the cases which I have seen, both from the absence of any clinical evidence of it in the patient or his surroundings and from the fact that diphtheritic neuritis is almost purely motor, yet I can not exclude the poison concerned in the production of follicular tonsillitis—infectious tonsillitis, for sometimes this is associated with influenza, and it may produce as much headache, backache and prostration as usually characterize the onset of influenza itself.

THE ORIGIN OF CORPORA AMYLACEA IN THE PROSTATE GLAND.

BY JOSEPH RILUS EASTMAN, B.Sc., M.D.
 INDIANAPOLIS, IND.

The formations designated by Seigert as corpora colloidea, and commonly known as corpora amyloidea, have been observed in various organs. Morgagni saw them first in the prostate gland in 1723. Virchow found them later in the brain, spinal cord, at the neck of the bladder, and in the so-called female prostate (delicate tubular glands surrounding the female urethra). Friedrich found them in the lung; Lubarsch in a tumor of the supra-renal capsule, and Hildebrand in a malignant growth from the sternum.

Widely varying hypotheses concerning the histogenesis of these bodies have been proposed by those whose attention they have attracted, the same after painstaking investigations, but none has led to an agreement as to the meaning of the observations made.

Morgagni compared the concretions macroscopically with snuff particles, and regarded them as a pathologic product of precipitation in prostate secretion. Virchow remarked the gray-blue nuance of color upon application of iodine, the characteristic reaction of amyloids and called the little formations corpora amyloidea; likewise Haller and Purkinje.

Friedrich examined the corpora amyloidea in the respiratory organs and considered them the product of hemorrhage or exudation into the lung tissue, and composed of some carbohydrate which is developed by chemie metamorphosis of the protein of extravasated blood.

Paulitzki treated concretions in the prostate with saliva and found that a few of these, which had previously given the blue reaction with iodine, after the application of saliva, responded with a brown tint. In these he found sugar by Trommer's test. Other concretions gave a brown reaction with iodine, without previous treatment with saliva, and some the blue of amyloids with a brown peripheral zone. These phenomena led him to the assumption that two substances, cellulose and amyloids are concerned in the formation. Jurgens (1875) showed that corpora amyloidea stained with methyl violet, become red, as does amyloid.

Zahn (1878) noticed in corpora amyloidea of the lung, besides a concentric arrangement of layers, a regular and symmetric radial marking. He found variously formed corpora, round, oval and triangular with rounded corners. The black nucleus, which is so often observed, he took to be a foreign body. He found also bodies in the form of drops which resembled degenerated epithelium. In these no radial marking was detectable. Zahn gave it as his opinion that the corpora are either a product of extravasated blood (Friedrich) or of degenerated epithelium (Langhans). According to Favre, a pupil of Zahn, the corpora amyloidea may nearly always be found in the adult, are formed by the degeneration of mucous membrane epithelium, and are increased in certain constitutional diseases.

Ceci, who studied the corpora amyloidea of the nervous system, found that osmic acid stains these intensely brown, while genuine amyloid gives no reaction with this acid.

Stilling speaks of a peculiar metamorphosis of the protoplasm of dying cells. He considers the hyaline masses so formed beginning corpora, and says the formation is favored by conditions which give rise to stagnation of the gland secretion: 1. Hyaline degeneration of muscular fibers. 2. Myxangioiditis (of Recklinghausen). Stilling's corpora were concentrically laminated but not striped radially.

Posner, in an elaborate article (1883), proved that the prostatic concretions are not made up of vegetable starch and further attempted to show that their micro-chemie properties do not justify their classification under the head of amyloid matter. He assumed that the prostatic epithelium contains some substance upon the presence or absence of which the specific reaction in the corpora amyloidea depends. This specific material he believed to be lecithin. After he had removed the lecithin with boiling ether, the concretions, although they retained their contour, gave no reaction upon the application of iodine. In short he classified the corpus amyloideum as a calculus.

Seigert (1893) busied himself with the study of the concretions of the lungs. He says that in these the single layers, seen in cross section, do not blend into each other as in the prostatic concretions, nor has he ever seen a blue peripheral ring.

After treatment with hydrochloric acid, he found in the centrum of corpora a defect corresponding in form to a cell, and in all concretions in which blue nuclei were not actually present, their absence was accounted for by this phenomenon. The sections being boiled in concentrated hydrochloric acid lost their structure, only the elastic fibers of the lung tissues remaining intact. As a peculiarity, Seigert mentions that he found such concretions in the branches of a capillary. He also observed a transition from degenerated epithelium into hyaline masses. (The latter with neither specific color reaction nor radial striation, but possessing strong resistance against chemie reagents and showing a tendency to calcification.) He decalcified the concretions with phloroglycerin. In the prostatic gland structure itself, Seigert found cystic dilatation of the canals and partial degeneration of the smooth muscle fibers about the ducts, and further the myxangioiditis hyalinoso of the ducts, described by Stilling.

Seigert attributes two principal qualities to the corpora amyloidea: 1. Strong light-reflecting power. 2. Great resistance against the strongest chemie reagents.

The origin of the corpora of the prostate he refers to a union of cell products with gland secretions and tissue juices.

In reference to the origin of the corpora in the lungs he confirms the theory of Zahn, namely, that of the blending of hyaline drops, the product of degenerated epithelium about any possible nucleus. A direct transition from cellular elements to corpora amyloidea he deems improbable, assuming preferably that insoluble elements of the alveolar contents are precipitated about some substance which serves as a nucleus and from this moment take on a radial striation and show the characteristic iodine reaction.

In the prostate, Seigert observes that "substances are set free by degeneration of gland epithelium

which, in union with alveolar contents, changed in character by stagnation, compose the formations in question." The same show from the first the characteristic iodine reaction.

Formations characterized by the above qualities, together with those of another variety, marked by irregularity of form, great tendency to calcification and indifference toward iodine are grouped by Seigert under the generic name corpora colloidea. These he divides into corpora versicolorata and corpora flava as follows:

1. Corpora versicolorata (corpora Virchowii, discovered by Virchow), have the following properties:

a. They are stained by chlorine, iodine and bromine, and show the amyloid reaction with various aniline stains.

b. They are of chalky consistence.

c. Their form is spheroidal, oval or angular; they show concentric lamination and are in many cases striated radially.

d. They originate from degenerate cells.

2. Corpora flava (described by Morgagni), have these properties:

a. They are not stained by iodine, chlorine or bromine.

b. They are of waxy consistence.

c. They vary greatly in form.

d. Concentric lamination is often absent.

e. They are never radially striated.

f. They calcify very often.

Hildebrand (1895) found in a large endosteal, round and giant-celled sarcoma of the sternum, small, round, glistening bodies of different sizes, which were more or less concentrically laminated and radially striated. Their color reactions corresponded with those of the corpora amylacea or of amyloid. He saw other analogous but irregularly formed flakes, with radial striations and giving the same reactions.

Here and there in the blood vessels were broad homogeneous bands of similar appearance and reaction, but without striation. Hildebrand concluded that starch was not a component of these corpora, for having been treated with the saliva they were stained, not blue, but brownish red, upon the addition of iodine. They were not soluble in water and no cross was visible by polarized light. Since he found no reaction which could serve to distinguish them from amyloid, Hildebrand believed these bodies to be made up of some amyloid substance. He believed the flakes to be changed sarcoma cells, assuming that the protoplasm of the cells had undergone some metamorphosis and that the nuclei had become disintegrated. "One cell had formed a centrum for other soft or fluid cells, which blended together and formed a ring about the first cell. Others being precipitated formed a second ring about the first ring and so further." Hildebrand explained thusly the concentric lamination, and set up the hypothesis that the difference in colorability of the different layers with iodine indicates a difference in the time of origin or age of the layers.

The writer examined twenty-four prostates. The persons to whom these had belonged ranged in age between 14 months and 74 years. Four glands were from persons of between 7 and 26 years, the others from men who had passed the fortieth year. Concretions were found in all the glands examined excepting two, which were from a 14 month old child and a 7 year old boy. In the prostate of a boy 15 years of age concretions were found.

Upon macroscopic examination, brownish bodies more or less spheroidal in shape, were seen upon the external surface of many prostates and scattered through all parts of the interior of all glands examined (except the two mentioned), being more abundant in that part which lies behind the urethra. Their consistence was about that of chalk.

Microscopically the corpora were seen situated in the gland alveolæ and ducts. The smallest were not larger than an epithelial cell. The largest were as large as a millet seed. A great number of the bodies were round in contour. Angular formations were also not infrequent. Among these many were tetrahedral some hexagonal and some polyangular. Those of the last sort were irregular with uneven edges. Oval and irregularly elongated forms were also observed.

Upon treating the surface of the gland with iodine, reddish brown points appeared, but no reaction which could be designated as that of any of the starches. However, upon addition of sulphuric acid to the iodine characteristic changes appeared.

The sections for microscopic examination were placed for five minutes in 10 per cent. sulphuric acid, then treated with iodine.¹ The use of Ehrlich's iodine mucilage solution was unnecessary, since the corpora proved, contrary to general acceptance, to be insoluble in water.

Sections cut with the double razor and freezing microtome showed exactly the same reactions as the paraffin and celloidin preparations, hardened twenty-four hours in absolute alcohol, differing only in intensity. Sections stained by the above treatment with sulphuric acid and iodine, had in general a yellowish green nuance.

Some corpora were weakly but homogeneously stained, appearing as round spots a trifle darker in shade than the surrounding tissue, and occasionally marked by faint concentric striation. Others again had taken on the typical starch-iodine nuance, were concentrically marked, and faintly showed the beginning differentiation of a nucleus. Other corpora contained a kernel of grayish-blue or purple tint and of about half the size of the containing corpus. Some bodies contained grayish-blue concentric rings, or a blue nucleus, or both together.

Bluish-red corpora, of which a narrow peripheral zone had remained unstained, had clear unstained centra, containing crystal formations.

Large, irregularly formed bodies with bluish color and distinct striation, embraced, each, several smaller corpora, which were likewise concentrically striated, and ranging between a light blue and dark greenish-brown in tint. The single layers of the enclosed corpora were often embedded in a light green hyaline substance, in which were scattered many still more minute corpora, with more or less distinct concentric striation, and bluish in color.

In a round concretion was seen a three-cornered blue centrum, the corners of which reached to the periphery of the round corpus. Again, corpora were found in the triangular cross section of which a round centrum lay, its periphery touching the limbs of the triangle.

Elongated pointed bodies contained a polygonal bluish striated nucleus, and oval concretions contained concentrically laminated wedge-shaped nuclei.

¹ Virchow treated the sections first with iodine, then with undiluted sulphuric acid. Boettcher applied the iodine first and then dilute sulphuric acid.

One irregularly shaped corpus was seen, in the middle of which was an opening. Upon this body, extending over its edge, lay another smaller blue body, which had exactly the same contour and size as the opening in the larger body and seemed to have fallen out of the latter.

Very elongated formations contained an elongated blue nucleus. Besides these bodies, formless masses without striation, but bluish in color, as well as diffuse masses with bluish centra were not uncommon.

Two types of concentric lamination could be distinguished. In one the layers were narrow and sharp and distinct from each other; in the other type they were broad and without sharp contour. Those of the latter sort gave varicolored reactions with iodine, while those of the first took up the yellowish-green color of the iodine only. Occasionally both varieties of lamination were present in one and the same corpus. In those corpora with sharp concentric striation, the contour was generally not circular but polyhedral, the layers becoming gradually more circular from the centrum toward the periphery.

Radial striation was only rarely seen. These striæ, when present, were either straight, punctated or broad irregular lines. They were sharper in outline than the broad concentric laminae, but less distinct in contour than the narrow, crystal-clear concentric lines of those bodies which do not react with iodine.

Epithelial origin.—In the lumina of gland tubules containing concentric bodies, it was observed that the epithelium had raised itself from the wall, cup-like, forming an acinus, the cavity of which was filled with disintegrated epithelium.

In an alveolus the epithelium had split off in about one-third of its circumference, and had embraced half of the periphery of a contained corpus amyloaceum. Immediately around about the body to which this split-off epithelium had attached itself, was another layer of epithelium-like formations. The embraced body itself was brown in color and contained a mass of bluish corpuscles.

In many alveoli the walls had become entirely naked of epithelium. In such about a concentric body in which were enclosed smaller concentric bluish bodies, a distinct ring of epithelial cells was to be seen. In one alveolus a coat of epithelium had loosened itself from the wall, enveloping a number of large laminated bodies. In another a concentrically striated body was surrounded without distinct order by a mass of epithelium-like elements. In the same field, a great number of small laminated, but unstained bodies lay in contact with the wall of a duct, the epithelium of this wall having swung itself in graceful arches about the conglomerate. All of the pictures just described were examined by Prof. O. Isreal of the Pathological Institute of the Charité in Berlin, and characterized by him as deciding ones.

Many concentrically arranged corpora, containing each a small bluish corpuscle, were surrounded by several rings of epithelium, in the outer of which tolerably intact nuclei were recognizable.

Some alveoli were filled with masses which had the characteristic swollen nuclei and flaky protoplasm-of degenerated epithelium.

The following special stains have been applied to the corpora amyloacea:

Ehrlich, iodine-mucilage.

Langhans, tincture of iodine.

O. Isreal, iodine-hydrochloric acid

Benda, iron-hematoxylin.

Lubarsch, *a*, iodine-hematoxylin; *b*, gentiana violet modification of Weigert's fibrin method.

For the definition of the cells and nuclei, in their different stages, as well as for elective staining of the laminae, Lubarsch's iodine-hematoxylin, a stain originally intended for glycogen, has proved to be most useful. The formula is as follows:

Delafalds, (very old) hematoxylin solution, 10 c.cm.

Grams, iodine-iodine-potassium solution, c.cm.

Aqua distillata, 5 c.cm.

The whole is to be filtered and protected from sunlight. The sections remain in the solution five minutes and are then rinsed two or three times with absolute alcohol, dried thoroughly with silk paper, covered with xylol and mounted in Canada balsam.

In sections prepared by this method the nuclei were stained red; the protoplasm, reddish or brownish red. In the corpus itself various shades appeared conspicuously, reddish-brown, brownish yellow and greenish-blue. In the center of the corpus, where the iodine starch reaction is to be expected, a more or less distinct blue came into evidence. The blue tint was more pronounced after the sections had been treated on the slide with a few drops of Gram's solution.

The Lubarsch stain defines the concentric lamination sharply, the two varieties of corpora, the one with broad laminae, the other with narrow ones, being easily distinguishable.

Often the layers were arranged about an elongated central axis layer, and gradually toward the periphery assumed a spherical shape like the layers of an onion. In these cases the single contours had a peculiar shreddy appearance and the corpora themselves were blue, brown and yellow in color.

In a few concretions broad blue rings alternated with sharp, concentrically laminated brown, or with light, hyaline unlaminated rings.

A radial striation was occasionally observed in corpora of the sharply laminated variety.

Swollen nuclei, arranged in concentric rings, presented themselves upon every field. The concentric arrangement was, however, in the more central layers more distinct, the rings standing in sharper relief than near the periphery, the blue reaction increasing in intensity from the periphery toward the centrum.

Not rarely, rings of nicely outlined columnar epithelial cells with red stained nuclei, embraced a mass of epithelium, the latter also containing red nuclei. Again smaller bunches of concentric bodies were contained within a ring of well formed epithelial cells. Such a ring with distinct cells and intensively red nuclei, and which contained a number of concentric bodies, had fallen during preparation across the section of the septum between two gland luminae so that a part was contained in each gland. This ring, upon being teased and pulled about with a needle, preserved its relation to the enclosed bodies, so as to awaken the suspicion that they were held together by some mucilaginous material.

A very significant picture was that of a distinctly laminated bluish corpus, surrounded by a ring of cells containing swollen nuclei, which tightly embraced the outermost layer of the striated body. In another case the epithelial wall of an alveolus has loosened itself, forming rings which contained flaky disintegrated debris. About the middle of the alveolus lay some small concentric bodies.

With the Lubarsch stain, as with the iodine method, gland luminae were found which were entirely filled with the bodies mentioned, the larger bodies embracing smaller ones, the smaller ones embracing still smaller, etc. No new features were detected by the use of other methods of staining.

Concerning the prostates of youthful persons which were examined the following data were obtained: No concretions of any sort were found in the gland of the 14 months old child. In that of the 7 year old boy, yellow hyaline masses were discovered. In the prostate of a 15 year old boy, however, in ducts, the wall epithelium of which was well preserved, perfectly round bodies, yellow in color and without peculiar structure, were present. Blue bodies, with or without ring-formed differentiation of color, and cloudy masses, containing weakly stained blue corpora, were also found in this prostate. In the prostate of the youth of 17 years there were observed small yellow and smaller bluish corpora with faint striation, also small uncolored corpora. Here and there, in masses of jelly-like material, were rings of nuclei. About some of these nuclei were remains of the cell wall.

In view of observations the following question concerning the origin of prostatic concretions presents itself, do the formations originate from cells, or are they formed from fluid material? Virchow believed the latter to be correct. He assumed that the prostate secretes a fluid in which precipitates are thrown down, forming concretions. Stilling, on the other hand, believed the corpora to be formed from cells. To use his own language, "there begins inside of the cell a degeneration which leads to destruction of the cell form and to disintegration of the originally hyaline but later amyloid mass." Posner refers the origin of the formations to both sources. According to his opinion they originate either by a simple coagulation of the contents of the glands, or in certain cellular changes, as first proposed by Stilling. Hildebrand believed in a cellular origin of certain corpora, which he found in a neoplasm.

The writer is of opinion that the concretions with broad concentric lamination are formed by direct metamorphosis of gland epithelium, and moreover that this metamorphosis has the character of amyloid degeneration.

The development of the concretions is not hard to follow in the above descriptions of microscopic pictures. With the sulphuric acid iodine stain, the relation of gland epithelium to the corpora was made apparent. Wall epithelium was seen bulging forward building acini. Epithelium had loosened itself more or less from the wall of the gland, partly embracing a concentric body. Occasionally it had entirely loosened itself from the wall and had formed a sac about a concretion.

A complete transition from epithelium to corpus amylaceum could be followed by Lubarsch's method of staining. In such cases the gland epithelium marked by red nuclei was arranged concentrically on the periphery. The cell walls were definitely outlined and the nuclei were in sharp relief. Toward the center signs of degeneration and the concentric lamination became more distinct. The cells everywhere showed the tendency to arrange themselves into rings, and the rings the tendency to embrace degenerated epithelium or tiny laminated bodies.

Why those who have worked upon the subject of the origin of corpora amylacea have been unable to

furnish direct proof for any theory of origin is not clear, unless it be for the reason that no prostate containing transitional forms came under their observation. The writer, in the first twenty-three glands examined, encountered no indications whatever of epithelial origin.²

Assuming that the corpora amylacea are developed by degeneration of epithelium, it remains to inquire into the nature of a process of degeneration which begins in intact epithelium on the gland wall, and passing through stages in which the nuclei are first swollen and slightly stainable, and in which later the cell structure is entirely lost, ends with the flaky masses, the peculiarly reacting substance described above.

The dirty blue reaction which appears upon treatment with iodine and sulphuric acid, might lead to the suspicion that glycogen is present in these degenerated masses. But the same reaction occurs after treatment of the corpora with saliva, and the glycogen gives no iodine reaction if previously treated with saliva. I used in the case of one prostate, which contained corpora large enough to be seen with the naked eye, the process which is generally employed to detect glycogen in the liver. I chopped the gland into minute particles, boiled it in three times its bulk of water, filtered, and treated the filtrate, according to the customary method, with iodine quicksilver solution. Had glycogen been present I should have precipitated a white powder reacting red with iodine. Upon the addition of iodine the result was negative.

If in a few instances (as Seigert proposed for all), the degeneration is of a hyaline character, such instances must be considered exceptional, for although the colorless, light-refracting flakes of hyaline material are very similar to the corpora amylacea in appearance, the former do not react with iodine: moreover the constant appearance of the iodine sulphuric acid and methyl-violet reactions speaks in certain terms for amyloid degeneration.

Posner concluded that the concretions are not of amyloid character since they show the blue reaction upon the simple addition of iodine alone. This I have never observed. In my examination the reaction appeared only upon application of iodine and sulphuric acid. Posner further pointed out that osmic acid stains the corpora a deep brown, amyloid matter remaining unchanged by it. I believe this color-ability with osmic acid to be due to other substances than amyloid, which are simultaneously present in the corpora. I would also explain by the same token, the presence of unstained rings between those stained with iodine. The epithelium loosening itself as a sphere from the wall could easily incorporate any prostatic juice (Schreiner's base) or hyaline matter contained within the alveolus. As evidence in point I refer to the above described picture, in which several corpora were united with each other, and with an epithelial ring about them, by some mucilaginous material, so that the complex could be pushed about without disturbance of the topographic relations of one part to another. The presence of unstainable matter between the essential rings of the concretions may be explained by these phenomena. The reaction mentioned, as well as others which testify against amyloid degeneration, are therefore to be

² Professor Hildebrand personally informed me that he had noticed a concentric arrangement of cells (sarcoma cells) about concretions discovered in a giant- and spindle-celled sarcoma.

referred to unessential substances which are accidentally enclosed in the corpora amylacea.

Since then a positive amyloid reaction appears almost constantly, and since no proofs that the degeneration is of other than amyloid character are at hand, I believe I may conclude with Hildebrand, that the presence of amyloid matter in the concretions may be fairly assumed.

The origin of the corpora from rings of epithelium explains clearly enough their concentric arrangement. This explanation applies, however, to those concretions only, showing broad laminæ and giving the iodine reaction.

The origin of those corpora which have sharply marked concentric lines and which do not react with iodine and sulphuric acid, can not be explained in this way. These bodies have exactly the same appearance as the unstainable yellow rings in the otherwise stained concretions which are described above. They have the usual color of the prostatic contents. These are the bodies which, according to Seigert, are the product of hyaline degeneration of epithelium. The innermost layer of these corpora were very often of triangular form. Round about this layer were angular layers; the angles becoming more obtuse, and the number of the same increasing toward the periphery, the shape became gradually circular. It was remarked that the sides of the triangular layer were made up of spindle-shaped, colorless formations.

As is well known, such spindle-shaped formations are abundant in the prostatic juice. Occurring in the prostate they are called Boettcher's crystals. They are identical with those formations which in the lungs and central nervous system are known as Charcot-Leyden crystals.

THE NATURE AND VARIETIES OF ANEMIA.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY ALFRED STENGEL, M.D.

Assistant Director Pepper Laboratory of Clinical Medicine; Assistant Physician to the Hospital and Instructor in Clinical Medicine, University of Pennsylvania.

PHILADELPHIA, PA.

It would be hopeless to attempt to review, even imperfectly, all of the questions of importance connected with the subject of anemia in the time at my disposal; but I believe it wisest to consider a few of the problems relating to the general conception of the nature of this disease or group of diseases, and to dis-

cuss briefly the varieties generally admitted to our nosology.

It is difficult to define anemia in a way satisfactory to the modern pathologic requirements. The older authors simplified the matter in conformity with the scope of their pathology, by defining it as bloodlessness, and by associating the clinical appearance of pallor with the disease anemia. Later, after the chemical studies of Andral and Gaveret, Becquerel and Rodier and Schmidt, names which must forever occupy a conspicuous place in the history of hematology, clearer conceptions of the exact nature of the disease seemed within reach, though time and repeated studies along the lines established by these pioneers have failed to realize the hope entertained in the beginning. The general revolution in pathology, stimulated by the genius of Rokitansky and especially by Virchow; and the special studies of the blood by Virchow, Bennett, Cohnheim and Neumann gave the study of the blood a different direction, bringing morphology into greater prominence and leading to various theories regarding the formation of the blood and the nature of anemia. Meantime methods of enumerating the cellular constituents and determining the amount of hemoglobin were introduced and perfected, and the morphological studies were brought to their present state through the labors of Bizozzoro and Hayem, and particularly of Ehrlich. During the past ten or fifteen years the influence of the last-named authority has been universally felt, and his opinions, based upon more accurate methods established by himself and his pupils, have everywhere dominated. So powerful has been this mastery that in certain quarters morphology alone has been considered the test by which anemic conditions should be judged of, and by which contending theories regarding the essential nature of anemia should be harmonized or rejected. Every active movement in science or politics or art carries its adherents beyond the proper limits and so it has been in hematology. Powerful for good, as has been the teaching of Ehrlich in renewing interest in the study of the blood and in the direct results, it merits the reproach of narrowing for a time the horizon of hematology in limiting attention to the corpuscles and indirectly discouraging chemical and physiologic studies of a broader kind. The return movement has happily set in, with what useful result remains to be determined.

A primal consideration in the study of the blood is the proper conception of its relations to the general organism and its limitations as a distinct issue. Virchow described it as a liquid tissue having close analogies with the solids. Standing alone this dictum must lead to erroneous notions regarding anemia. In every sense the blood is a dependent fluid, drawing no doubt from all the structures of the body in varying degree some part of the elements that make for preservation of its integrity. In how far the so-called blood-making organs are operative in predominance over the other structures, can not as yet be shown. Reasoning from the basis of morphology the spleen, the marrow and the lymphatic tissues are preëminently essential structures, and with a view of the analogies furnished by recent studies of the internal secretions as a whole, it would seem likely that these structures have other, and perhaps more important, functions than the mere manufacture of corpuscles. The therapeutic use of organic extracts, and particularly of those derived from bone-marrow, tempts me to a slight

diversion. Individual experience varies widely with regard to the efficiency of these and my own has been unsatisfactory. If, however, further trials should lead to uniform and positive results, we must regard this as a proof of secretory function rather than of the usefulness of marrow as a hematinic food. The amount of iron contained is no greater than that in other foods, and the form of its combination does not differ essentially from that in other animal diet. For the present, however, the relations of the bone-marrow in the direction of internal secretion are undetermined, and can not be utilized for the purpose of substantiation or disproof of any theory.

The individual life of the red blood corpuscle is a limited one, though we can not as yet assign a definite duration. Its birth and its ultimate dissolution are obscure. Certain it is, however, that both processes are dependent largely or wholly on the integrity of the other tissues and organs, and the opposing views of Virchow, Neumann and others, and of Biesiadecki and Löwit regarding the secondary or primary nature of leukemia (in the sense that this disease is in essence a disease primarily of the blood-forming organs, or on the other hand of the blood itself), might almost be decided in favor of the former on this consideration alone. Morphologic studies, as those of Biesiadecki in particular, led to the conception that leukemia is an essential disorder of the blood, characterized by a retardation of the evolution of the leucocytes, and the study of morphology alone would warrant further adherence to this view. The wider pathologic studies of Flemming, Neumann and Virchow and particularly the chemical experiments of Horbacewski and others, abundantly demonstrated the narrowness of the older conception and substantiate for this disease, what may be asserted of anemias in general, that it is altogether secondary to primary organic disorders.

Let me take another point of view and consider for a moment the subject of post-hemorrhagic anemia. This is the purest and most direct variety of which we have knowledge. Animals will tolerate great loss of blood and may thus be made intensely anemic. The effect of the hemorrhage is not a mere reduction of the quantity of the blood but a rapid deterioration of quality in certain directions. This is well known and is easily demonstrated in man as well as in experimental work. The primary result of the hemorrhage is a reduction in the quantity of the blood. Physiologists have shown that serious results in the way of ischemia, or local anemia, are prevented by the coincident and proportionate vasomotor contraction, the blood pressure remaining approximately normal. Later the blood becomes more fluid and the number of corpuscles together with the proportion of the hemoglobin falls. Liquid is in some way absorbed by the blood, and the ready explanation that the vessels are filled by the juices of the various tissues is at hand. There is not, however, a mere dilution with water as chemical analyses readily demonstrate. For example I would quote the following experiment:

A small dog weighing sixteen kilos, was bled from the jugular vein one-third of his total blood (estimating the total quantity at one-thirteenth of the body weight) being removed. Before the experiment the following values were determined: Red blood corpuscles, 6,900,000; white blood corpuscles, 42,000; specific gravity of blood, 1.059; specific gravity of serum, 1.022.8; dry residue of blood, 23.2 per cent.; dry residue of serum, 7.4 per cent. Ten minutes after the bleeding small quantities were taken for examination and the following results obtained: Red

blood corpuscles, 6,610,000; white blood corpuscles, 19,600; specific gravity of blood, 1.055.9; specific gravity of serum, 1.022.6; dry residue of blood, 21.6 per cent.; dry residue of serum, 6.9 per cent.

It will be noted that there was no immediate change in the quality of the blood; at least no striking change. Seven hours after the bleeding the following figures were obtained: Red blood corpuscles, 2,615,000; white blood corpuscles, 20,600.

Chemical analyses were not made at this time, but were determined at the next examination, forty-eight hours after the original bleeding. The animal was again etherized and blood removed from the femoral vein: Red blood corpuscles, 3,100,000; white blood corpuscles, 26,000; specific gravity of blood, 1.046.7; specific gravity of serum, 1.022.1; dry residue of blood, 10.47 per cent.; dry residue of serum, 7.4.

From the similarity in the blood count at this and the previous examination, I assume that the specific gravity and the residue of the blood and serum would have been found practically the same at the previous examination. It is evident then that the mass of the blood is soon diluted after hemorrhage and the diluted fluid is approximately the same in density and probably in character as the original plasma. This is shown by the preservation of the normal conditions of the serum while the total blood has undergone diminution in weight and in solid residue.

The manner in which this change occurs is of very great physiologic interest and bears important relations to the etiology of anemia. Either there is a direct transfer of the liquids of the body to the vascular system through the walls of the vessels, and a depletion therefore of the general system in favor of the blood, or there are active secretory processes affecting the vessels, according to the theory of Heidenhain. It will be recalled that this observer found certain substances capable of stimulating active flow of lymph, the latter also being more concentrated than usual and the increased flow continuing for a considerable period. There is no increase of the arterial pressure. His own theory regarding the action of such substances is that there is a specific stimulation of the endothelial cells of the capillaries of a secretory kind. While physiologists in general have not supported Heidenhain uniformly, certain of his experiments raise questions that have not as yet been satisfactorily explained by any other hypothesis. For example, the presence of sugar or salts in the lymph of the thoracic duct in greater quantities than in the blood, is a fact that can not readily be explained on the theory of simple osmosis. For the present we can not do more than refer to this interesting physiologic question, and cite it as having a bearing upon the general subject of the relations of the blood to organic metabolism, and the probable activity as secretory structures of tissues hitherto unassociated with such function.

In studying the relations of the corpuscles and plasma, the specific gravity of the blood and serum and the solid residues of these in cases of anemia, either primary or secondary, there is a striking resemblance to the conditions observed after hemorrhage. The specific gravity of the blood falls in proportion to the reduction of coloring matter; the quantity of serum rises while its specific gravity and its solid residue alters little in comparison with the change in the blood as a whole. There is undoubtedly a transfer of fluid from the tissues to the blood stream. Older observers sought to explain the changes in density and constitution of the blood upon the assumption that water is added to the blood and albuminous elements abstracted, and this view has even recently

found expression. The disproof is not far to seek. The studies of Grawitz have shown, as have recent experiments of my colleague Dr. Taylor, that though the proportion of albumin in aliquot parts of serum is reduced in severe anemias, the total quantity (taking into consideration the increased bulk of serum in the blood) is not reduced below the normal: indeed it sometimes increases.

Let me next refer to the character of the red corpuscles in anemia. I need not detail the various changes of form and general structure, but will only refer to the differences in size, in shape, and to the alterations in internal structure (vacuolation and pseudo-vacuolation, altered color-reactions and the like). These are conditions well known in anemia and more or less proportionate to its degree. They find their counterpart, however, in the artificial anemia following hemorrhage, and here again in proportion to the grade of anemia. Imperfect hemogenesis (the term being restricted to the making of red blood corpuscles) and active hemolysis in this or that locality, have been too readily assumed in explanation of these conditions according to the individual views of various authors; and the possibility of these changes being dependent upon primary change in the general construction of the blood itself, has been too often disregarded. It is true that recent studies of the effects of the various hemolytic agents have tended to alter the direction of opinion, and I may cite the experiments of Silbermann, Heintz and Hunter, from many contributed in recent years. The thought, however, that in the spontaneous anemias, changes of the fluid of the blood account for alterations in the corpuscles, has not frequently found expression. Maragliano and Castellino and Gilbert, have made the more important of the scanty observations in this direction, studying the behavior of corpuscles when exposed to the action of serum of anemic diseases. These studies, though open to criticism for their crudeness, in a measure contribute support to the belief that the serum is largely responsible for many of the changes observed in the corpuscles. In my own experiments I have found the serum of cases of pernicious anemia, chlorosis and leukemia powerfully destructive to normal corpuscles; but I have as yet had no opportunity of investigating the serum after serious hemorrhages.

The number and bulk of the red corpuscles in anemia offer interesting problems for solution; but first I wish to refer, for a moment, to the relation of pallor to anemia. The appearance of the patient has always furnished the test by which the probable presence of anemia has been obtained, and formerly was the only test. It must be remembered, however, that pallid features do not of necessity proclaim an actual state of anemia. Some individuals are naturally pale as others are florid, and the condition of the blood is not of necessity altered from the normal in either case. Clinical studies of chlorosis and other anemic diseases further give evidence of the fact that, pallor of the skin or of the mucous membranes is not a reliable guide to the condition of the blood. It is well to bear in mind in this connection, that the pseudo-anemic condition may be rather suddenly developed and may persist for a greater or less length of time. Interesting cases of this description have been reported; among others one that I now recall in which a young woman, who had fullen and suffered great fright as well as some concussion, became excessively pale, suggesting the existence of severe anemia; but on examination of the

blood a normal condition was found. Of the same sort is the pallor developed in visitors to tropical countries. These cases of spurious anemia are doubtless dependent upon vasomotor changes rather than changes in the blood itself. They are of interest in connection with my present subject only from the fact that they evidence the general relations of the vasomotor system to the distribution of blood.

Actual changes in the blood may occur in consequence of circulatory disturbances in persons residing at a considerable elevation, in those suffering with failure of the cardiac compensation and in consequence of peripheral congestion. Beginning with the last, I have frequently demonstrated the greater corpuscular richness of the blood of dependent parts over that of the finger held in the air. The difference has been variously estimated by investigators at from 10 to 15 per cent. In my own experiments the average has been about 8 per cent. In cardiac diseases there may be similar concentration of the blood and excess of corpuscles in the given quantity. In high altitude this is so regularly the case that this condition may be taken as one of the possible alterations effected by elevation that influence general organic process. We may deduce from these facts the general conclusion that alterations in the number of corpuscles are of less importance than has often been maintained; and that the changes in the blood, in the direction of concentration, are probably the result of the disposition and distribution of the serum. I am aware that there are facts favoring the view that actual increased formation of corpuscles occurs in residents of high altitudes, but taken in connection with the rapidly induced changes in the number of corpuscles in congestion and similar conditions, the conclusion seems not unwarranted that the altered distribution of serum is the more important factor.

I can not now go into the matter of altered chemical relations of the blood in anemia; into the change of proportion of the different albuminous constituents and of the inorganic elements, of the presence of compounds usually found in but small proportions or not at all; but can only cite these in evidence of the view that serum changes are of great if not commanding importance.

The estimations of the isotonic coefficients of the corpuscles and of the serum are of interest, though they have not as yet furnished definite results. There is a tendency, it may be asserted, toward decreased resistive power of the corpuscles in the anemias and perhaps a greater alteration of the hypertonic strength of the serum, the result of which is a lessened state of stability of the blood mass as a whole in anemia.

I have thus hastily sketched a few of the facts regarding anemia that are still most obscure, with the purpose of emphasizing this one point, viz.: that it would be an error to consider the blood from the standpoint of the corpuscular elements alone. Perhaps it needed no extended argument to make this fact apparent, but in actual practical study the profession has been so prone to regard the corpuscular elements as the criterion by which to estimate anemia, that an elaborate consideration (not to speak of the sketchy discussion I have undertaken), would be justified. I am convinced that the more important factor in anemia is the altered character of the fluid, and that studies to be profitable must be directed hereafter to the determination of the relations of this to the general organic life; and that less attention may well be

directed to the formation, number, or even the general characteristics of the corpuscles, though I would not for a moment underrate the value of these observations. We see, in every anemia, results of changes in the constitution of the fluid of the blood, and we see but few effects of altered corpuscular elements. The older authors believed that the reduced number of corpuscles and the reduced quantity of hemoglobin must interfere greatly with respiratory exchange of gases; but the accurate physiologic studies of recent years have shown that this is not the case. Indeed, there is if anything an increased respiratory exchange in anemia. Toxic elements undoubtedly occur in the plasma in these diseases though their nature is obscure. On this assumption we must explain the occurrence of degenerative changes in the solid tissues, notably in the heart, met with in pernicious anemia, and to a less extent in other anemic affections.

In considering the possibility of a comprehensive definition of anemia in the light of these considerations it is well to observe in the first place that no single constituent occupies a principal place.* It is true that all the anemias of which we have knowledge are diseases in which there is reduction either in the number of corpuscles in the proportion of hemoglobin or both; but it does not follow that these are the essential conditions. Indeed, it is likely that these are but the more evident expressions of the altered general condition of the blood, other changes being obscure. A recent writer (Frederick Taylor) in discussing anemia in its various bearings explicitly states that the number and condition of the leucocytes may be disregarded and I cite this merely in evidence of the too narrow view commonly taken of the disease. I believe anemia to be a condition of deterioration of the blood with altered relations of the fluid and solid parts. In some cases the number of corpuscles may be approximately normal, the quantity of solid residue, however, being reduced. The change in such cases may affect the plasma primarily or the chemic construction of the individual corpuscle. The definition does not include purely quantitative anemia and for the definite reason that I believe the condition of the blood is invariably altered in cases in which there is quantitative reduction. I can not now discuss the possibility of the existence of a continuous insufficiency of the quantity of the blood, but only state my belief in its occurrence.

The classification of anemias is extremely difficult. For clinical purposes we may still retain the terms primary and secondary, with the restriction, however, that these terms are used in a sense different from that originally intended. By the primary or essential anemia we may designate the group of diseases in which the more striking symptoms are those affecting the blood itself, or the blood-making organs with the blood. By a secondary anemia we would designate cases in which the condition of the blood is of less prominence than the primary disease which has brought with it a deterioration of the blood. Viewed from the standpoint of our modern pathology there is little doubt that that pernicious anemia, for example, is frequently a secondary anemia, using this term in its older sense: that is to say, pernicious anemia results from blood destruction dependent on organic disease or intoxication from some part of the organism and is not a disease dependent primarily upon disorder of the hemopoietic organs. It is true, however, that the primitive cause is always less conspicuous in this disease than in anemia itself, whereas in the secondary anemias,

in the clinical sense, the original disease is always prominent.

Chlorosis.—Chlorosis is undoubtedly a hemogenic disease, dependent on some defect in the general organism, affecting the blood-making power. It is well to recognize in the beginning that this disease can not be distinguished by the character of the blood alone. It is true that severe cases present a picture of the blood rarely seen in any other condition, but the absolute diagnosis can not thus be made. The strict morphologist and those who rely greatly upon clinical examination of the blood often state the contrary, but without sufficient authority. The chloro-anemia of tuberculosis and syphilis and gastro-intestinal disease in some cases produces exactly or almost exactly the condition of the blood observed in chlorosis. This leads me to question the existence of chlorosis in the male. There is no *a priori* reason for disbelieving the occurrence of this disease in the male, but all clinicians are careful in their statements regarding this possibility and many frankly state that the disease occurs only in girls and women. In examining the reports of those who claim its existence in the male sex I have been struck by the imperfect manner in which the diagnosis has been established. A recent report offers no convincing evidence of any kind and seems to be based entirely upon the existence of a moderate oligochromemia. Certain competent authors however have claimed to have seen genuine cases in males, and I believe that one instance has come under my own observation. In this case the most searching examination failed to disclose any primary disease. The patient was pallid with a peculiar yellowish cast; there was no emaciation and the tissues were rather flabby. The patient was effeminate, poorly developed and hysteric. Palpitation and dyspnea occurred and there were murmurs over the heart. The number of corpuscles was almost normal, the hemoglobin was reduced to about 40 per cent.; constipation was marked. I can not now enter into a discussion of theories regarding the nature of the disease. The opening sentence of this section states my belief regarding the nature of the disease. I must, however, make allusion to one consideration, viz., as to the advisability of increasing the scope of the term chlorosis so as to include all anemic conditions in which there is excessive oligochromemia. My experience makes the decision easy. Clinical observation leaves no doubt as to the existence of a distinct morbid entity, that we term chlorosis. Reduction of hemoglobin without commensurate reduction of the corpuscles may be important in this affection, but it does not alone constitute the disease. What other alterations the blood may present of an essential kind has not as yet been determined. Undoubtedly, however, there is more than a mere change in the character of the red cells.

Pernicious anemia. The discussion of pernicious anemia need not detain us long. The evidences in favor of an hemolytic origin of this disease are well nigh absolute. I wish to consider only one question, viz., the scope of the term pernicious anemia and its limitations. Certain authors, notably Eichhorst, designate two varieties: the primary and the secondary, the latter term including the cases in which definite lesions, probably of etiologic significance, are found. For my own part I can see no justification of this course beyond the deference it implies toward traditional teaching. The first observers regarded pernicious anemia as essential or idiopathic, admitting

no other variety. It is, however, undoubtedly true that many cases occur in which the clinical features are the same, the course and prognosis identical, but in which lesions presumably connected with the development of the disease are discovered. In these cases the evidences of hemolysis may be pronounced and the connection between the organic lesions and the anemia seems direct. On the other hand, the cases in which no such lesions are discovered may present evidences of hemolysis as clearly as those with lesions and as the course of the disease is alike I would put all cases in the same group. The diagnosis of the disease therefore rests upon the condition of the blood and the general course of the affection, rather than upon any evidence or lack of evidence of apparent cause. Besides the classical cases of pernicious anemia I have observed one or two in which the appearances were somewhat different and which I believe may be of slightly different kind in nature. One of these cases affected a man past middle life who began to grow anemic without apparent cause and continued to grow more and more pallid until his death. The color of the skin was almost an alabaster white, there was decided emaciation, rarely if ever any fever, the urine was pale, non-albuminous and watery; the blood presented marked but not excessive oligocythemia (2,000,000 to 2,500,000), the hemoglobin was rather more decidedly reduced (30 to 35 per cent.). The corpuscles were altered in form and there were a few nucleated forms. The patient was exceedingly weak and in spite of active medication died after an illness of several months. A complete autopsy, including every structure of the body, was performed and no lesions were found excepting fatty degeneration of the heart, liver and kidneys, and edema of the lungs. There was no excess of iron pigment in the liver or spleen; the bone marrow was normal. I cite this case merely as an instance of obscure pernicious anemia, difficult to classify and perhaps representing a form of progressive fatal anemia of a kind different from ordinary pernicious anemia. The condition of the heart did not at any time cause prominent symptoms. I believe it was secondary.

Leukemia.—I shall say but a word or two regarding this. Its close relations with Hodgkin's disease is evidenced by the occasional transformation of the latter into the former. Some have held that Hodgkin's disease represents an aleukemic stage of leukemia. This may be true of some instances and I am confident the one disease may lead directly to the other; it does not follow, however, that such a tendency exists in all cases. Regarding the nature of these diseases I can not but consider them as closely associated with sarcoma.

Infantile pseudo-leukemia.—Von Jaksch described a form of disease, in 1889, under this heading and held it to be a distinct variety. Similar conditions had been previously more or less satisfactorily described by the Italians. A careful review of the literature of this disease shows that it possesses no distinctive features to warrant its classification as a distinct entity. A large number of the cases are undoubtedly closely associated with rickets; in others syphilis may be the important factor. The pathologic lesions are those of chronic hyperplastic disease of the spleen and liver and do not warrant the assumption that there is a separate pathology. The marked leukocytosis is striking but does not constitute a feature of sufficient stability to separate these cases from other varieties of splenic enlargement.

Splenic anemia.—This term has been variously used. There are undoubtedly cases of Hodgkin's disease in which the spleen enlarges markedly while the lymphatic glands remain comparatively little affected. Moreover there are cases of secondary splenic hypertrophy in the course of chronic malaria, rickets, syphilis and other diseases in which the anemia is pronounced and the original etiologic factor is difficult to determine. Cases that have come to autopsy, or in which the character of the spleen could be determined at operation for splenectomy, showed that the condition of the organ is for the most part that of chronic connective tissue hyperplasia with some true splenic hypertrophy. It is true there are some cases recorded in which the appearances were those met with in Hodgkin's disease and leukemia, but such have been very unusual. These observations warrant our disregarding entirely the term splenic anemia. I do not know of the existence of a separate disease that we may dignify with this title, or with such names as "primary splenomegaly" or "idiopathic enlargement of the spleen." The conditions of the blood as the characteristics of the spleen do not differ from those met with in well-marked secondary anemia or splenic enlargements.

ON THE STUDY OF THE BLOOD.

Presented in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, at Philadelphia, Pa., June 1-4, 1897.

BY A. E. TAYLOR, M.D.

ASSOCIATE IN CLINICAL MEDICINE, PEPPER LABORATORY OF CLINICAL MEDICINE, UNIVERSITY OF PENNSYLVANIA.
PHILADELPHIA, PA.

The present tendency in the study of the blood is one directed by almost boundless enthusiasm. The diagnostic success of blood examinations for the protozoa of malaria, the differentiation of diseases with leucocytosis from those without it, the separation of the essential anemia, the serum diagnosis of typhoid fever and the frequent positive results of blood cultures, have been of such striking practical and pathologic importance that confidence in the results of blood study is wide-spread and profound. Now, therefore, is the proper time for care and caution. It is clear that many of our present methods are inadequate and that their results are being accepted for more than their real value. For the further successful study of the blood not only must it be studied in its widest biologic relations, but the methods and technique must be greatly enlarged and made more accurate and likewise more simple. At the beginning I wish to recall your closer attention to venepuncture as a most suitable method of obtaining blood for study. The blood drawn from the puncture in the finger or ear can be used only for the count, the hemoglobin estimation, and for morphologic study; for other methods where more blood is required venous blood must be used. To do venepuncture a bandage is applied above the elbow or ankle, the skin antiseptically cleansed, a spot over a good-sized vein anesthetized with ethyl chlorid and a large aseptic hypodermic needle, such as is commonly used in surgical work, inserted into the vein. It is very easy to insert such a needle into the distended vein, the patient feels no pain, the operation can be so conducted that the patient sees no blood, and after the withdrawal of the needle only a pin-point mark remains, which causes no inconvenience. From such a puncture several fluid

ounces of blood can be drawn for purposes of chemic, pathologic or bacteriologic study.

For the counting of the blood cells our present methods are fairly accurate, little improvement can be expected in the methods of counting, and many disturbing factors in such estimations may be eliminated by care in the use of the instruments and by counting many cells as a basis for calculation. For careful results one should count over 2,000 red cells and over 200 leucocytes in ordinary work. The hematokrit may be used to save the tedious care of counting, but I am convinced that the labor and time are saved at the expense of accuracy; highly as I value the employment of centrifugation in physiologic work, nevertheless I have not found it adapted to accurate estimations of the volume of blood corpuscles, nor are calculations from volume to numbers accurate. For dilution, saline solutions of isotonic concentration are available; among the best are a 5 per cent. solution of magnesium sulphate, or a 0.9 per cent. solution of sodium chlorid, to each of which a little glycerin may be advantageously added, and they may be colored with methyl violet if the white cells are to be counted with the red. For counting leucocytes, however, it is much better to use a larger pipette which will admit of a lower dilution, and to dilute the blood with a solution of methyl violet in a 1 per cent. solution of commercial acetic acid. The counting of plaques is at present entirely unreliable; the addition of peptone to the diluting fluid does not prevent their agglutination. For morphologic study, the blood smeared upon cover glasses may be fixed in alcohol and ether, alcoholic or aqueous solutions of corrosive sublimate or picric acid, in formalin, by heat either through the flame or on the copper plate or in the oven, in Fleming's solution or Altmann's fluid, or in many other ways. For general work, simple staining with hematoxylin and eosin is probably the best. Methylene blue and eosin, methylene blue and orange G., aurantia, tropoalin, the fuchsins, and the dark stains as nigrosin and indulin, are often of use for different purposes. For leucocytic conditions the Ehrlich triple stain of methyl green, acid fuchsin and orange G., is very valuable, especially for the staining of neutrophilic granulations. For basic granules thionin, neutral red and dahlia are the most serviceable. At this point I may refer to the perinuclear granules which Neusser has described as associated with the so-called uric acid diathesis. These occur in all leucocytes, especially in the large mononuclear forms, and are well stained by an Ehrlich triple stain very strong in methyl green. The general experience is that these formations are of no diagnostic value, nor have they any relations to clinical lithemia, nor to the alloxuric bodies, as has been shown by Fitcher. In the study of stained preparations care must be exercised in the differentiation of real alterations from artefacts in the widest sense. The history of the studies in the red cells shows this: the work of Foa and Maragliano was technically so faulty that many of the appearances described by them were pure artefacts, some of which can be reproduced at will. This is especially true of polychromatophilia, and all color alterations must be interpreted with great care. Structural alterations are of much more value, and good work upon blood cells along legitimate biologic lines has only commenced. Cell degenerations and the conditions which produce them are very important, quite as much so as the number of cells. The resistance of the red cells may

be estimated by the use of graduated strengths of saline solutions; whether or not this method possesses diagnostic value has not been conclusively determined. Our plaque technique is so faulty that we know almost nothing about them either in health or disease: they may be stained with iron-hematoxylin. The best results in blood histology have been achieved in the studies of leucocytes and in leukemia. For the further study of the pathology of blood diseases I believe that but little can be hoped for from morphologic study of the circulating blood; it must come from chemic, metabolic and organic studies.

A most urgent need is a perfected method which may supplant the hemoglobinometer. These instruments, so simple and easy of application, are woefully inaccurate; their range of error is fully 10 per cent. An especially poor feature of the Fleischl instrument is that the aperture for the light transmitted through the stained glass wedge is so wide as to cover 20 per cent. in the reading scale: this can be obviated by the use of a narrow slit, but even then the denominated range of error applies. Hoppe-Seyler's method of applying hemoglobin solutions, or the quantitative spectral methods, are very accurate, but almost beyond the range of clinical use. It is now an established fact that even in the most severe chronic anemias the blood still contains and carries to the tissues an amount of oxygen entirely normal and adequate to the metabolism of the tissues; that furthermore, in the chronic anemias suboxidation is not present, but rather superoxidation; these facts, however, do not diminish the value of accurate hemoglobin estimations. It seems clear that the oxygen-carrying power of normal blood is vastly in excess of the oxygen needs of the tissues; a small part of the normal amount of hemoglobin is able to carry the amount of oxygen needed by the body. The evil effects of anemias are therefore obviously not due to disturbed oxygenation; it is clear either that the hemoglobin has other functions than the transportation of oxygen, or that the loss of hemoglobin vitiates other properties of the red cells, or that there are ill effects in anemia entirely independent of the red cells and the hemoglobin, such as metabolic disturbances or intoxications; and it is probably the last group which includes the chief dangers of anemia. The diminution in hemoglobin and of the erythrocytes is of value not for itself, but as an index of the severity of the anemia and a sign from which we may in a general way infer the severity of the causal and associated conditions. To illustrate how comparatively harmless is simple diminution of hemoglobin, I need only to recall the fact that the nutritional and metabolic processes in chlorotic subjects have nearly always been found normal. The estimation of the specific gravity of the blood may be used instead of the estimation of hemoglobin, and in a general way there is a fairly constant relation between the quantity of hemoglobin and the specific gravity. Unfortunately, here again the determination is difficult. The Hammerschlag method, as commonly employed, for numerous physical and chemic reasons is very erroneous in its results; good results can be obtained with it, but require such experience and elaboration of technique as to make the method unavailable for ordinary clinical use. The accurate method is by carefully weighing in a picrometer; this, however, requires such delicate balances that its employment is largely restricted to institutions. The alterations in the dried residue may likewise be used instead of the

hemoglobin estimation; in such a procedure it is obviously assumed that the non-hemoglobinous residue is constant, which is of course erroneous.

The degree of the alkalinity of the plasma and of the cells is undoubtedly of great physiologic and pathologic importance. I believe the statement is fully justified, that all the alkalinity methods based upon the use of capillary blood, and the published results achieved with them, are almost entirely worthless. The chemic reactions of the blood consist of a number of metabolic relations, and the more clearly the importance of these is realized the more apparent it becomes that no one estimation can furnish all the desired information. All such estimations should be done upon blood drawn by venepuncture or venesection. v. Limbeck's method for the estimation of the total reaction utilizes as an indicator the coagulation of the albumin in the blood. About 10 c.c. of blood are mixed with an equal volume of a one-tenth normal acid solution and water added up to a half liter and heated to 90 degrees C. Owing to the acid reaction of the mixture the albumins are not coagulated at this temperature. The hot mixture is then titrated with one-tenth normal soda solution, and as soon as the reaction has been brought back to just the acid side of the neutral point the albumin coagulates and precipitates with the hemoglobin. The difference between the amount of acid and alkaline solution employed represents the alkalinity of the quantity of blood employed. Perhaps a better method is that of Berend, the principle of which is that a quantity of blood is mixed with a larger quantity (five vol.) of a neutral isotonic solution, the cells precipitated by centrifugation, the clear diluted plasma then drawn off and its alkalinity estimated by regular chemic titration, while the reaction of the cells is estimated in porcelain with lakmoid and one-tenth normal acid and alkaline solutions. These are the only two methods of estimating the total reaction which at all conform to chemic requirements, but, as stated, the total reaction does not settle the alkalinity question. In order to clearly understand the state of affairs we would also need to estimate the CO₂ and also the basic capacity. There is much work for the future along these lines.

I believe that the chemic study of the blood will henceforth prove more profitable than microscopic study. The spectroscope and polariscope will doubtless earn for themselves a valuable place in the study of the blood, a place corresponding to their importance in physiologic study, in the differentiation of pigments on the one hand, and on the other hand in the study of the azotized and carbonaceous metabolic substances. Their employment in blood toxicology is already on a firm footing. The direct chemic estimations and study of the total residue and the separated residues of the corpuscles and plasma; of the inorganic bases and acids, especially sodium, ammonium, potassium, iron and calcium and the chlorids, phosphates and organic acids; the ratio of the several plasma proteids and the quantity of non-proteid nitrogenous bodies; the variations in the caloric substances, especially the sugars, glycogen and the allied substances—these, together with the study of many unclassified substances directly or indirectly associated with healthy or diseased states, furnish a most wide field for the future cultivation of biologic and pathologic knowledge. Gasometric study is likewise in place and of value.

It is only since last year that we have had a reliable

method of estimating the fibrin, that of Kossler and Pfeiffer. The principle of this method is that the blood is rendered non-coagulable by the addition of sodium oxalate, the cells precipitated by centrifugation and the nitrogen of a specimen of the plasma estimated by the Kjeldahl method; the rest of the plasma is then made to coagulate by the addition of calcium chlorid, and then the nitrogen of the serum estimated. The difference between the two estimations corrected to equal volumes represents the nitrogen in the fibrin. To estimate coagulation, Wright's method of filling capillary tubes and blowing out the blood at regular intervals until clotting occurs is the best, but has a wide range of error.

Hematology is not a specialty, but simply a branch of general pathology, like urology, and ought not to be separated from morphologic and chemic pathology and clinical medicine. The disturbances in the nutrition and metabolism are intimately associated with the condition of the blood, and only rarely can the one be studied without the other. This applies especially to the anemias, but further research will surely demonstrate the same relations in all diseases, and the sooner the intimate relationship between hematology and the diseases of metabolism is recognized and utilized, the clearer will be our conceptions of both. Hematology, like every branch of our science, must be both practical and theoretic; not only must it aid in the diagnosis and treatment of disease, but it must aid in the advancement of biologic knowledge.

DISCUSSION.

Dr. JUDSON DALAND, Philadelphia.—Taking blood from the vein offers an improvement in the technique of blood examination. The capillary blood is undoubtedly different from the venous, and the great advantage which the hypodermic needle possesses is that we can obtain blood directly from the vein in sufficient quantity and purely aseptic. I was very much impressed with the statement Dr. Taylor made with reference to the inaccuracy apparently present in the use of the hemoglobinometer. All have met with difficulty in precisely estimating the hemoglobin in the ordinary way. In pernicious anemia particularly, the error seemed increased, and under those circumstances I have thought the error was diminished by the employment of two or more pipettes. I still hope that the method of determining the percentage of hemoglobin will be perfected. The cytometer, which is one of the best instruments we have for enumerating the number of blood cells, also has sources of errors. It has been my custom to count sixty-four sections and make two preparations. But under these circumstances I have seen considerable errors, so that we all feel that this instrument is not as accurate as it might be, though perhaps the best one for counting the number of blood cells. We had a good deal of difficulty in using the hematocrite before the technique was decided on. When the blood was diluted with 2.5 per cent. of bichromate of potash the percentage of error was considerable; but since we have found that we can withdraw the blood directly into the pipette and rotate instantly before coagulation can take place, the range of error has been greatly reduced. As to the comparative accuracy of the hematocytometer and of the hematocrite, I am of the opinion that the latter gives results which are as accurate as those obtained by the Thoma-Zeiss instrument.

Dr. TAYLOR—I am in accord with Dr. Daland, that clinically the hematocrite is as accurate as the hematometer, although physiologically it is inaccurate.

Efficacy of Kefir in Infantile Diarrhea.—S. G. Mikhalev reports that one or two bottles of old kefir administered after the first violence of the attack has passed over, arrest rapidly the diarrhea of infants. When this is accomplished, he changes to medium kefir. He has had great success in the cases thus treated at the Ekaterinodar Hospital.—*Semaine Méd.*, June 10.

THE OCULAR MANIFESTATIONS OF ANEMIA.

Read in the Section on Practice of Medicine, at the Forty eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY WM. CAMPBELL POSEY, M.D.

PHILADELPHIA, PA.

The clinician judges the state of the vascular system of his patient by noting the condition of the peripheral capillaries as it is manifested in the color of the lips and nails and the general appearance of the skin. He determines the force and power of the circulation by the pulse, and by the cardiac impulse. The ophthalmologist, however, by means of his wonderful mirror looks into the eye and obtains a highly magnified and unrestricted image of the perfect cycle of the supply of an organ with arterial and the escape of its venous blood, and is enabled to estimate the quality and the amount of blood by direct observation.

He can further study the action of the heart by means of the retinal pulse. It would seem *a priori* that it would be an easy and rapid matter, therefore, for the ophthalmologist to diagnose pathologic conditions of the blood, and one would think that it would only require an examination of the fundus of the eye to determine the existence of such disorders. As a matter of fact this is often true, for there are as a rule changes in the eye grounds which are quite characteristic of the different conditions which cause them, and their discovery by the ophthalmologist has frequently been the index for the recognition of the general disease. In many of the cases, however, where the disorder of the blood is but of slight degree there are no lesions which can be regarded as indicative of a vascular origin. This may be due to the fact that ophthalmologists are as yet unable to properly recognize and explain many of the finer changes which occur in the fundi, for the physiologic limits are so broad, and the changes wrought by the different states of ametropia are so varied that one hesitates to impute slight changes to any definite cause. While it is true, that the information gained by the use of the ophthalmoscope is often negative, and while, owing to the introduction of modern methods of blood-counting there may be but little need of the ophthalmoscope in properly diagnosing diseases of the blood, nevertheless, the opportunity of actually viewing the circulation should never be lost sight of, for an ophthalmoscopic examination will frequently aid in the elucidation of difficult cases, and will often throw light upon the different types of vascular disorders.

Simple anemia—chlorosis.—Although there are many general subjective symptoms of chlorosis it is seldom that we find structural changes in the fundi just as it is rare to see extensive histologic changes throughout the system, the direct result of this disease, so that the observations which have been recorded have been for the greater part variations in the retinal vessels. These were found to occur in the vast majority of the cases. Thus, Rahlman found an arterial pulse in two-thirds of his cases. In but 15 to 23 per cent. were there no changes in the fundi; in 20 per cent. there was retinal anemia, while in 57 to 67 per cent. there was distinct retinal hydremia. This is quite in harmony with the appearance of the conjunctiva, for it has been often noted that in place of the waxy bloodless appearance one expects to find in chronic anemia, there is frequently a pinkish yellow

color of that membrane which is due to a slight congestion or dilatation of its vessels.

Schmall, who based his results on the observation of ninety-four cases, of which fifty-five were chlorotic, thirty-eight from severe loss of blood, fevers, malignant neoplasm, etc., differed from Rahlman quite a little in his observations.

Saundby and Eales, who examined fifty cases of chlorosis, did not observe arterial pulsation in one instance, nor did they find that venous pulsation was more frequent than common. They did note, however, that the veins were usually nearly of the same size and color as the arteries, although they were sometimes broad and tortuous. They found in all cases a noticeable pallor of the disc and fundus, in some cases of extreme degree, and in quite a large proportion there were marked evidences of neuroretinitis, though none of these were of so high degree as have been reported by Gowers, Bitsch, Williams, Mackenzie, Nason and Diebella. In several of these cases, the changes in the fundi were so marked that they were mistaken for the retinitis of albuminuria and of brain tumor.

The easy tiring of the accommodation often seen in anemia is attributed by Berger to the insufficient nourishment of the ciliary muscle, and Noyes has found paralysis as well as paresis of that muscle to result from anemia.

The author has noticed that anemia is a frequent cause of many intractable cases of muscular asthenopia, particularly of that class designated as exophoria, where there is usually not only a weakness of the rectus interni but of the associated ciliary muscles as well. As further indicative of the same action Jacobson has seen a clonic spasm of the lids in anemic children, which was associated with a senile condition of the surrounding muscles, and resembled the clinical picture of chorea minor.

From the cases of chlorosis which the author has had an opportunity of examining, it would appear that ocular manifestations are far more frequent than is usually supposed, for in nearly every case where the per cent. of hemoglobin had been much reduced, he was able to note changes in the fundi.

On account of the close capillary system of the head of the optic nerve, any marked departure from the normal tint of the blood would be apt to make itself manifest there, and as a matter of fact the most constant change which was observed in the fundus was a dull lusterless, grayish white nerve. At times the nerve appeared a little fluffy, especially to the nasal side, and its edges slightly obscured, but of nineteen cases of marked chlorosis examined by the author he did not find marked swelling of the disc or true neuritis in any one case. The nearest approach to this was in a case reported by Dr. Oliver at the Ophthalmic Section of American Physicians in May, and which the author had an opportunity of seeing in Dr. Oliver's service at the Wills Eye Hospital. Here there was quite marked neuroretinitis. The disc was somewhat pallid and there was extreme tortuosity of the retinal vessels, especially of the veins. Next in frequency to the changes in the nerve head the author found a broadening and slight pallor of the retinal veins. Venous pulse occurred spontaneously, in nine of his cases.

Peruicous anemia.—Clinicians have recognized the presence of retinal hemorrhage in this disease pretty generally since Biermer first called attention

to it in 1871. In thirty cases examined by Horner there were large hemorrhages and dilated veins in nearly every case. Quincke noticed the same changes in seventeen instances and although many believe (Osler and Natanson) that the presence of retinal hemorrhage is a feature of the disease, later observations have shown that they are not nearly so uniformly present as these figures would indicate. As a rule they occur in advanced cases, although they may be absent even when the anemia is extreme, their presence, therefore, can not be recognized as diagnostic of the disease, although as Stengel says, the occurrence of hemorrhages in a long continued anemia, without adequate cause would be somewhat significant. They are usually flame shaped, although they may be round, and seen in contrast with the surrounding fundus, they appear redder than usual. They have at times whitish centers, which is an appearance peculiar to this disease and leukemia.

A far more constant symptom than the presence of retinal hemorrhage is the altered color of the fundus reflex, which becomes of a light yellowish pink or rose tint due to the alteration in the quality of the blood itself. A further change is the appearance of the retinal vessels, which is practically that which was described in connection with chlorosis. As in chlorosis also the inflammation of the retina is usually not severe, generally manifesting itself in a slight swelling of the retina which obscures the edges of the nerve. At times there may be a bluish white film over the fundus. As in chlorosis, although retinitis is rare, changes in the nerve are very frequent. Of Horner's thirty cases the discs were quite white in every instance; and in those observed by Norris in addition to a diffuse retinitis they appeared white with a faint greenish tinge. At times yellowish white plaques may be seen in the macular region giving the fundus the resemblance of retinitis albuminurica, and at times the symptoms may be severe from the beginning, as in a case cited by Sargent where there was an intense neuro-retinitis which led to retinal detachment and blindness.

In regard to the diagnostic value of the retinal changes in pernicious anemia, it would seem that the retinal lesions of pernicious anemia correspond to those observed throughout the entire body and are usually in keeping with the course of the general disease; thus Ulrich could find no hemorrhages in the early stages of a case of pernicious anemia which finally caused death, although late in the disease the typical picture of the retinitis of pernicious anemia with slight hemorrhage presented itself. This agrees further with the observations of Mackenzie that the retinal hemorrhage in pernicious anemia is a consequence of the degree of blood poverty, and also with those of Natanson, who thinks that these changes always point to grave lesions in the composition of the blood.

Of great interest from an ophthalmologic standpoint, as bearing on the causation of insufficiency of the ocular muscles, is an observation by Fraenkel. In examining the body of a case of progressive pernicious anemia, which died in the third month of the disease, this author found that while the other muscles of the body were well preserved, those of the eye were pale and flabby and much degenerated. During life there was no evidence of extra-ocular palsy, or even insufficiency, but the author suggests that in more chronic cases, it is possible that a careful prismatic

examination would reveal certain weaknesses in the extra-ocular muscle balance.

Leukemia.—As in pernicious anemia, the ocular changes in this affection are quite common, indeed they may first call attention to the existence of the disease. In acute cases, hemorrhages into the conjunctiva and eyelids may be the first symptom (Knies), while the ophthalmoscopic findings are so extensive that they point at once to some grave disease in the vascular system.

Contrary to what one would expect, it frequently happens that there is no change in the color of the fundus reflex. In severe forms of leukemia, an orange yellow color of the fundus may be visible; but this is not the rule, for in the majority of cases there is either a pale grayish pink color of the fundus (Loring) or no departure at all from the normal red reflex (Hirschberg). In addition to the difference in the frequency in which there is a marked pallor of the fundus, the retinitis of leukemia offers another point of dissimilarity between it and the retinitis of pernicious anemia, and that is, the greater tendency of the latter disease to retinal hemorrhage, for it even occurs in leukemia in cases where the percentage of red blood corpuscles is greater than in anemia (Gowers).

The retinitis of leukemia may manifest itself either as a hemorrhagic retinitis, which is the more frequent, or by whitish patches. The hemorrhages are usually more or less round, and are scattered through the periphery: at times they have a whitish center as in pernicious anemia. Extravasations occasionally occur, and are usually more marked in the periphery or in the macula. They are irregular in outline, and are often so large that they have been mistaken for lymphoid growths in the retina. Hemorrhages into the vitreous have been reported.

The veins are frequently enormously distended and tortuous, while the arteries are but little if at all changed in their appearance. The blood columns are usually of a rose tint, especially in the veins. The disc is often strikingly dull and lusterless, having a dirty white appearance. Neuritis is rare, although there may at times be marked papillitis as in a case cited by Oeller. Rarely, leukemic neoplasms may involve the orbit and cause proptosis (Birk, Chauvel and Osterwald). The choroid is at times infiltrated with leucocytes, when the vessels are much dilated and the coats enormously thickened. The lachrymal glands may be similarly involved. The ocular manifestations are seen almost exclusively in the splenic variety of the disease, and occur in at least one-third of the cases (Panaz and Leber).

As the lesions involve the periphery it frequently happens that central vision is not at all affected, whereas, in other cases an early involvement of the macula may lead to such impairment of sight that consultation of an oculist will be necessitated even before the general symptoms have been sufficiently marked to have demanded medical treatment. It sometimes happens, therefore, that the eye specialist is the first to diagnose the existence of the disease.

Purpura.—Hemorrhages into the retina in purpura are not uncommon, but as they are rarely of large size, and vision is but little disturbed by them, they frequently escape the attention of clinicians. The sight, however, may be much impaired, and Ruc ascribes the blindness seen in the cases which were recorded by Riedlinus and Du Toit to retinal hemorrhages. He further gives the notes of a case where there was

massive hemorrhages into the retina involving the macula of one eye. Mackenzie, Gowers and Goodhart have cited similar cases.

Hemophilia.—As yet no cases have been recorded where there were hemorrhages into the interior of the eye, as a result of this disease. Disturbances of vision, however, have been cited after profuse hemorrhages elsewhere, which were probably referable to optic atrophy, as in Grossman's case where double atrophy ensued after violent epistaxis. Priestley Smith has seen an interesting case of profuse hemorrhage from the orbit, following an injury to that cavity.

Scurvy.—In this disease the eyes are so deeply sunken, and are surrounded by such dark rings, that they give an appearance almost characteristic of this disease. As in purpura, hemorrhages into the retina are not infrequent, and become yellower as the disease progresses. As a result of the impoverished supply of nutriment to the retina, hemeralopia and nyctalopia are occasional symptoms.

In the rare but interesting manifestations of the disease in infancy Stengel says that edema of the lids has by some clinicians been considered characteristic of the disease.

Hemorrhages into the lids and orbit are also quite common and are at times very striking. Holmes Spicer has reported three cases, where, as a result of profuse bleeding into the orbits, there was great swelling of the lids, and protrusion of the globes.

Secondary anemias.—Simple loss or diminution in the quantity of the blood is very rarely followed by ocular changes, the additional predisposing factor of impoverished blood being seemingly required to bring about lesions within the eye. In the hope of arriving at some accurate figures, regarding the frequency with which changes occur in the eye in the secondary anemias, the author has made a study of a score of cases. As most of those observed by him were adults, and had been exposed to many causes which might have originated ocular lesions, which it was impossible to exclude from those due to the anemia, his results were in the main unsatisfactory.

In many cases of anemia resulting from heart and stomach diseases, however, pallor of the discs, narrowing of the vessels and lighter blood columns occurred with such regularity that it suggested that the anemia, which the blood count showed to be marked in each case, was the casual factor. In the majority of the cases, despite extreme pallor of the skin, and a marked reduction in the blood count (the reduction in red blood corpuscles being as low as 1,000,000 at times) the fundus was perfectly healthy and quite normal in appearance.

Far different is it in the anemia which occurs, after hemorrhages, especially if they be often repeated; for in this class of cases ocular changes are not uncommon, but are only seen here in individuals who are not in a healthy condition, so that in addition to the loss of blood there must be some other predisposing factor. Thus, vision is rarely if ever affected after hemorrhage the result of traumatism, but occurs at times after venesection.

As a rule the loss of vision does not manifest itself until some hours after the hemorrhage; it may, however, be immediate. Jaeger says that soon after loss of blood, vision becomes temporarily hazy, this being followed by partial clearing, which is dependent upon improved nutrition of the patient. If the hemorrhage be repeated the amblyopia augments with each loss of

blood, until vision is destroyed. In this manner repeated hemorrhage predisposes toward ocular changes, even more than copious bleeding; they may, however, be originated by small and apparently insignificant hemorrhages. Fries found that partial or complete recovery of vision occurs in about half the cases. In the remaining cases, blindness was complete. The prognosis is very bad for sight, especially after hematemesis, complete recovery of vision never having been observed after this form of hemorrhage.

If seen soon after the hemorrhage has occurred, an ophthalmic examination will reveal a diffuse retinitis and a marked pallor of the optic nerve head, the retinal vessels being reduced in size. Other retinal lesions are rare. Knapp has seen but one case, in which curious angioid streaks developed in the retina from previous hemorrhage. Other authors have noted instances where the neuro-retinitis was quite intense. The pathology of the ocular condition is still in doubt.

REPORT OF A CASE OF ACUTE LEUKEMIA WITH STREPTOCOCCUS INFECTION.

Presented in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association held at Philadelphia, June 1-4, 1897.

BY JAMES B. HERRICK, A.B., M.D.

CHICAGO, ILL.

In presenting the following brief history no attempt is made to review the entire subject of acute leukemia, nor to draw from this imperfectly studied case—under observation for little more than two days and with no autopsy—any general conclusions concerning the etiology or essential nature of this extremely interesting and relatively rare affection. But as the clinical picture was that of acute leukemia, and further, as there was a septicemia proven clinically and by bacteriologic examination, I have deemed the case worthy of record because the blood findings are somewhat at variance with those of most observers who have reported upon secondary or mixed infection in acute leukemia.

History.—Wm. P. was born in Minnesota twenty-seven years ago. Has lived in Texas and the South for twelve years; in Chicago for the past seven years. As a child, he had pneumonia and typhoid fever. While in the South he had malaria and was jaundiced. He admits having had gonorrhoea and chancroids, but denies syphilis. He has been for some years a bartender and has indulged freely in alcoholics. The family history, so far as known, reveals no hereditary taint.

Up to Christmas, 1896, he had been in his usual good health. During Christmas week and including New Year's day he was enjoying a holiday spree. About January 4 he had what he thought was an ordinary sore throat, the throat seeming quite swollen inside. He remained in the house for a few days and the soreness nearly disappeared, but a week later there was a recurrence of the sore throat, and this time the patient noticed that the glands on both sides of the neck were swollen. He had a little fever each day and felt weak and quite ill. A later exacerbation of the sore throat with fresh enlargement of the glands again kept the patient in bed for a week. Since this time he has gradually been losing ground. The extreme pallor was first noticed by the sufferer about February 1. He has lost eighteen pounds in weight.

Examination the day following entrance to the Cook County Hospital, Feb. 28, 1897, showed him to be a man of average size, well developed, intelligent and with unclouded mind. There was an extreme degree of pallor of the skin and all the visible mucous membranes. The tongue was moist but heavily coated; the breath was very offensive. The gums were bluish, swollen and bled readily. A ragged, foul ulcer was seen on the inner side of the cheek opposite an upper molar. The glands beneath the angles of the jaw were enlarged, some to the size of a pigeon's egg. On the left side there was evidently much periadenitis, there being a brawny, tender, slightly ede-

matous mass beneath the jaw, in which mass the glands could with difficulty be differentiated. So suggestive of pus was this swelling, that a physician outside had made an exploratory aspiration with a needle, but with negative result. There was also enlargement of the post-cervical, axillary and inguinal glands, some being as large as walnuts. The spleen was distinctly palpable, one finger's breadth below the costal margin. The only place where tenderness could be elicited by pressure over the bones was over the upper sternum. The lungs were negative; the heart, with dullness extending from the right border of the sternum to the left nipple line, was believed to be dilated; the murmur best heard over the pulmonary valve and with systole was thought to be hemic. The abdomen, aside from the splenic enlargement and an increase in the liver dullness (flatness from sixth interspace to two centimeters beyond costal arch), gave negative findings. There were numerous retinal hemorrhages with apparently some swelling of the retina. But one blood count was made. This showed a reduction of the red corpuscles below 1,000,000, the white 60,000. Of the stained preparations I shall speak later. The temperature ranged from 100 to 104 degrees, the pulse from 114 to 140. The respirations averaged 22. Death occurred eighty-eight hours after admission.

No autopsy was permitted. Immediately after death there were removed from the heart, presumably the right ventricle, puncture being made in the fourth interspace close to the left sternal border, several centimeters of blood under strict asepsis. This was employed for bacteriologic examination.

The blood.—The blood taken during life was pale in color. The fresh specimen showed the color in individual red globules to be well preserved. There was but slight poikilocytosis. White corpuscles were seen at a glance to be unusually numerous, and one could also state positively, even from the examination of the fresh specimen, that the smaller forms were relatively and absolutely increased in number. The specimens fixed by heat, and by alcohol and ether, and stained by methyl-blue and eosin, hematoxylin and eosin and by the triple stain, all agreed in the following particulars:

1. *Red cells.*—Form and size but slightly altered from normal; take stains properly; nucleated reds numerous. In counting 1,000 leucocytes, thirty-five nucleated reds were found. There were about 1,800 nucleated reds to the cubic millimeter. Of these a few were of a size sufficient to be called megaloblasts. From the average of the count of several fields the proportion of whites to reds was 1 to 11, about the same as obtained in the count with the hemocytometer. In this count the blood drawn from the heart was not employed, as intracardiac coagulation might have altered the relation between white and red. No malarial organisms were found.

2. *White corpuscles.*—Great preponderance of the mononuclear forms. Most of these correspond in every particular to the common small lymphocyte. Many other larger forms are seen, some with narrower and some with broader rim of protoplasm. Indentation of the nucleus, as in transitional forms, not uncommon. Even in some small mononuclear forms, that resemble in every other particular small lymphocytes, there may be found a nuclear indentation. It was impossible, accurately, to draw a dividing line between the smaller forms and the larger ones. All gradations between the two were found. Leucocytes with polymorphous nucleus and neutrophilic granules were few. Many fields were searched before finding one. Eosinophiles are extremely rare. There is an average of nearly seven leucocytes to a field (Leitz 1-12, Oc. 1).

The differential count of 1,000 leucocytes was as follows:

Small lymphocytes	868
Large mononuclear forms	98
Large mononuclears with wide rim of protoplasm	23
Mononuclear forms of all kinds	989
Polymorphonuclear forms (neutrophiles)	9
Eosinophiles	2
Total	1,000

The day before death blood was obtained from the sterilized finger, and from bouillon, blood serum and agar media a culture of the streptococcus pyogenes was obtained by Mr. C. F. W. Ready of the County Hospital laboratory. The blood obtained postmortem from the heart was examined in the laboratory of Rush Medical College. Cover slips, culture tests and inoculations in rabbits gave the reaction of a virulent streptococcus pyogenes. Blood from the rabbits

inoculated was taken at the end of twenty-four, forty-eight, seventy-two and ninety-six hours. A distinct increase in the white corpuscles could be plainly seen. This increase was, however, almost entirely in the polymorphonuclear cells—leucocytosis.

In studying these stained blood specimens several interesting forms were observed. Nucleated reds with irregular or fragmental nuclei were seen. A few corpuscles with two distinct nuclei were found. Some of the nucleated corpuscles were of a size warranting their being called megaloblasts.

What appeared to be degenerate leucocytes were not infrequently met with. These were often large oval or ovoid masses, faintly staining with the basic dye, containing no visible granules, no rim of protoplasm, and with non-stained spaces resembling vacuoles. These reminded one of the forms described and pictured by Gumprecht.¹

This case is typical of acute leukemia in its onset with sore throat, reported by many observers as an early symptom; malaise, early involvement of glands about the jaw, later enlargement of other glands, hemorrhagic tendency particularly marked in the nose and gums, splenic tumor, anemia, blood count showing great preponderance of mononuclear forms, in this case over 98 per cent. Sepsis was suspected clinically, by the course of the temperature, the general appearance of the patient, the peri-glandular edema and swelling. This was proven by bacteriologic examination of the blood to be an infection with a virulent

streptococcus pyogenes, presumably a secondary infection and not the one causing the condition of leukemia. This I assume to be the case, though one is justified in raising the question as does Hintze,² whether the whole disease was not a streptococcus infection with leukemia-like manifestations. The points in which the case presents peculiarities are:

1. The persistence of the lymphocythemia after the infection. While there are no previous data by which we may judge whether or not there had been a reduction in the absolute number of mononuclear forms after the infection with the streptococcus, it is certain that a count of 60,000 leucocytes, a relation to reds of 1 to 11 is contrary to the common finding in cases of acute leukemia with secondary infection.

2. There was no polymorphonuclear increase. One neutrophile to sixteen fields (Leitz 1-12, Oc. 1) shows not alone a relative, but an absolute, diminution in the number of these cells.

3. While we have no means of knowing how many nucleated reds had been present in the blood before the secondary infection, we can assert that they were fully as numerous after the infection as is common in acute leukemia.

In this connection I would state that in the only other case of acute leukemia I ever saw (a patient of

¹ Deutsches Archiv für klin. Med., Bd. 57, S. 323.
² Deutsches Archiv für klin. Med., Bd. 53, S. 377.

Dr. H. Milton Ferguson; a man with typical history as to onset, fever, spleen, glands, hemorrhage, lymphemia, etc.), the nucleated reds were a striking feature in the blood findings, fully as numerous, I should say, as in cases of the splenic variety that I have examined.

In these respects, *i. e.*, the persistence of the leucocytes and of the nucleated reds, the blood count differs from that of most other observers. Richter³ saw an intercurrent acute inflammatory rheumatism fail to make an impression on the blood count. And Müller⁴ saw under the influence of a sepsis, the blood count, in a case of lymphatic leukemia, rise from 180,000 to 400,000. While no differential count was made, he thinks the increase was in the polymorphonuclear forms rather than the mononuclear.

ON THE RELATION OF TUBERCULOSIS OF THE KNEE TO INJURIES OF SAID JOINT.

Read at the Third Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Sept. 23, 24 and 25, 1896.

BY H. REINEKING, M.D.

SURGEON TO THE CHICAGO AND NORTHWESTERN RAILWAY,
SHEBOYGAN, WIS.

The observation that injury of a bone or joint is frequently followed, after a variable interval, by chronic inflammation at the seat of injury, such chronic inflammation assuming the nature of a white swelling, or of destructive suppuration, or of caries, has long been familiar to the medical profession.

When, thanks to the labors of Volkmann, Koenig, Koch and others, the true nature of these chronic processes was incontrovertibly shown to be tubercular, the question of their relation to the trauma to which they were attributed, became one of great interest to the surgeon and pathologist as well as from a medico-legal point of view.

Tuberculosis being a specific bacterial disease, always depending for its causation on the presence of a well defined and constant bacillus, what part, if any, does injury of a bone or joint play in the subsequent development of tuberculosis at the site of such injury?

Since in the discussion of this subject, what applies to one joint is generally true of other joints and bones, I shall for the sake of convenience use the terms *bone* and *joint*, instead of speaking specifically of the knee-joint, though the latter, on account of its large size, extensive area of cartilage and synovial membrane, its exposure to frequent injury, the frequency of the occurrence of tubercular processes in it, and the ease with which its interior can be exposed and examined, is more than any other joint adapted for the study of the questions under discussion.

The accession of a tubercular arthritis or osteitis following closely, or after a few weeks, upon an injury of these structures, occurs with such sufficient frequency, that few clinicians at the present time deny the connection of the trauma, as one of the factors at least, with the production or localization of the local tuberculosis.

The importance of the trauma has no doubt been overestimated, especially before the etiology and pathology of tuberculosis were thoroughly understood. The tendency to attribute to two successive occurrences the relationship of cause and effect, has here, as in many other instances, greatly retarded a correct

interpretation of the phenomena under consideration.

That injury is not an *essential* or necessary factor in the causation of bone and joint tuberculosis, is shown by numerous cases in which the most careful investigation fails to disclose any history of preceding trauma. It follows that, even where the latter has occurred, the causative relation between it and the tuberculosis following can not be absolutely proven and may always remain a matter of some doubt.

Admitting, however, that such causative relation exists, how can we account for it, and what significance can reasonably be attributed to it?

Looking at the matter in the light of modern pathology, we can not admit that a trauma or any of its consequences can produce or furnish the essential factor of the disease, the tubercle bacillus. The trauma can at most serve as a means of introducing the bacillus into the system, or determining its point of attack if already there present. In other words, in order that the trauma may enter into the causation of the local disease the bacillus must either be present in the system at the time the injury is sustained, or be introduced at the time of the injury, or subsequently, before the effects of the trauma have disappeared. If previously present, the trauma may act as an *exciting cause* for the *local* tuberculosis by creating an area of lessened resistance for the attack and localization of the bacillus. If on the other hand the bacillus should gain access to the system *after* the occurrence of the injury and before the abnormal local and general conditions created by the latter have subsided, the trauma may assume the rôle of *predisposing cause*, by furnishing a favorable soil for the bacillus and enabling it to gain a foothold. I say local and general conditions, because tuberculosis being a communicable disease, there can be no doubt but that its invasion is favored by lessened vital resistance, both local and general, and by enforced confinement and other unfavorable conditions brought about by an injury.

Both clinical experience and pathologic investigation go to prove that the majority of cases in which tuberculosis of a bone or joint develops at the site of an injury, belong to a class in which the disease had been established in other parts of the body before the injury was sustained, in which the latter must therefore be regarded as merely an exciting or localizing factor. The bone or joint tuberculosis in these cases is metastatic or secondary, the infecting material being derived from some older tubercular focus located either in the lymphatic glands, lungs, alimentary canal, urinary or sexual tract, or the skin. Such old foci were found by Orth in 79 per cent. of fatal cases from Koenig's clinic. Making some allowance for cases in which they may have been overlooked or have healed by cicatrization, the percentage may be safely assumed to be still higher. While the mere presence of these foci does not prove them to have been the source of infection for the bone and joint disease, their presence is at least very significant. Unfortunately such old tubercular centers, if small, and especially if latent, will often escape detection during life by even the most careful examination.

Direct tubercular infection of bone or joint through an open wound is so exceedingly rare, that only a single case, and this not without some features which render it doubtful, reported by Mittendorpff, has found its way into literature.

This leaves a small contingent of cases in which to all appearances at least, the local tuberculosis must be

³ Discussion of Fraenkel's article in *Dent. Med. Woch.*, 1895, Nos. 43 and 45.

⁴ *Dent. Archiv f. Klin. Med.*, Bd. 50, S. 78.

regarded as primary, in which, in other words, the tubercle bacillus having gained access to the system by way of the air passages or alimentary canal, becomes located and develops in the injured bone or joint without having first caused a lesion in any other part of the system. Analogous processes no doubt occur in cases of osteomyelitis, periostitis and other infectious diseases following injuries not accompanied by wounds of the skin.

Whatever may be the sequence of events leading to the development of bone or joint tuberculosis, accumulated clinical experience has established the fact, that injury is very rarely followed by the disease except in individuals who either have previously carried the disease in other parts of the body, whose family history shows evidence of a tubercular taint, or who are burdened with that peculiar predisposition or tendency to tuberculosis known as scrofula. While the correctness of this statement may not seem to be borne out but rather disproven by many cases when they first come to the surgeon's notice, its truth will be confirmed if the patient and his family can be kept under observation for a few years. About six years ago I treated a boy 8 years old, for tuberculosis of the tarsal bones, attributed to a slight injury. At that time there was not the slightest evidence of hereditary taint, but since then the boy's father and father's brother have died of pulmonary tuberculosis, and a daughter of the father's sister is now in an advanced stage of the disease.

Clinical observation has established the further fact, that the kind of injuries most frequently followed by tuberculosis, are those of a milder type, such as moderate blows, sprains or bruises; while fractures, dislocations and severe crushing injuries are very rarely so followed. The conditions produced by a mild trauma seem to furnish a favorable soil for the tubercle bacillus, while the more intense reaction following severe injuries seem to antagonize it. Koenig has, however, seen tuberculosis develop at the seat of recent fractures; according to this authority, severe trauma is more frequently followed by tuberculosis of bone than of joints.

Applying the foregoing considerations to the study of tubercular processes in and about the knee-joint, in what manner, and to what extent, can injury influence their occurrence?

The cancelled structure of the adjoining epiphyses of the tibia and femur furnish a favorable locality for the arrest of infectious material carried along in the circulation, and is frequently the seat of tubercular foci which have a tendency to communicate by extension with, or rupture into, the knee-joint. We can readily see how an injury would favor this occurrence, either directly by the force of the trauma, or indirectly by the abnormal conditions brought about.

Traumatic synovitis with hemarthrosis, or with serous effusion and precipitation of fibrin, conditions very commonly found after injuries of the knee, seems to furnish a very favorable soil for the tubercle bacillus. The large area of serous membrane and the size and distensibility of the joint predispose to large effusions, with consequent slow absorption, thus increasing the danger of infection. It is also evident that neglect of proper treatment of the morbid conditions produced by the trauma will enhance this danger.

The importance of old tubercular foci in the causation of tuberculosis of the knee is indicated by the fact that their presence was demonstrated by Orth in

over 88 per cent. of fatal cases from Koenig's clinic.

In conclusion I may state then, that according to the present state of our knowledge, the proper significance to be attributed to trauma as related to local tuberculosis is, that it prepares suitable soil and conditions for the arrest and development of the tubercle bacillus, and that such localization may take place in consequence of a trauma, where otherwise it would not have occurred. While local tuberculosis very frequently occurs without the intervention of a trauma, and as the question of its accession depends largely on previously existing conditions and hereditary influences, and the causative relation between an injury and a subsequently developing tuberculosis can not, in a given case, be with *certainty* maintained, yet it would probably be impossible to eliminate this element in case of alleged damages by reason of tubercular disease following upon, and at the site of an injury and setting in before the evidences of such injury have disappeared. In other cases the connection is so problematic that it should not be considered as a ground for damages.

DISCUSSION.

PROFESSOR RIDLON—I came to learn and be instructed rather than to speak, but I am interested in this subject of tuberculosis of the joint, and the few words I may say would be entirely from a clinical standpoint. I have seen a fairly good number of tuberculous joints in my experience in orthopedic surgery; it seems to me that tuberculosis of the joint rarely if ever follows a serious injury unless the case is treated too much; it frequently follows slight injuries. In fractures and dislocation I have not seen tuberculosis; if unrestrained passive motion were employed by the surgeon I believe the joint would, without any question, from either fracture or dislocation, become tuberculous. But in sprains and contusions where the conditions are so slight that the physician is probably not consulted, or perhaps does not consider it important enough to treat, cases which are used while there is a little tenderness, a little stiffness, if they continue to be used and if the swelling and slight tenderness and slight stiffness remain long enough, these joints will ultimately become tuberculous. I think it depends on the individual in whom they are situated, but they do become tuberculous sooner or later if they are allowed to go on in their slightly inflamed condition. The point then that I would like to make in this relation is this: In severe injury do not use passive motion unless you are willing to take the risk of developing tuberculosis; unless you are willing to be responsible for tuberculosis of that joint; in slight injuries, in most cases at any rate, endeavor to impress upon the sufferer the very great importance of his condition and the necessity of submitting to treatment until all symptoms of inflammation have subsided. Those are the main things that strike me in this connection as an orthopedic man. I only see those cases, gentlemen, that you do not cure. I do not see the many that you do cure.

CYSTS OF THE VERMIFORM APPENDIX.

BY E. E. MONTGOMERY, M.D.

PHILADELPHIA, PA.

Cysts of the vermiform appendix have until recently received but little attention. These cysts are without doubt inflammatory in origin. The inflammation results in destruction of a portion of the mucous lining and obliteration of the corresponding canal. The secretion of undestroyed portion of membrane forms a cyst.

These cysts are usually of small size, although Virchow has reported one which attained to the size of the fist. Van Hook reports thirty-two cases. The writer removed one from a pregnant woman, in which there was marked hyperesthesia over the right inguinal and lumbar regions, more marked, indeed, than seemed justified by the local lesion. The patient miscarried the day following. Microscopic examination disclosed

staphylococci in the contents of the cyst. It has always been with me a question as to how much the symptoms were due to the appendiceal lesion, and how much to the occurrence of an attack of grippe. Generally cysts give rise to no symptoms. The case which I now report was operated upon for a number of uterine growths which were producing so much discomfort as to demand operative interference. The growths were of the extra-mural variety, one projecting beneath the peritoneum, another downward into and filling up the pelvis. This tumor had to be passed over to reach the cervix which was situated over an inch above the symphysis. The patient, though 52 years of age, still continued to menstruate, and of late much more profusely. Pan-hysterectomy was done.

While making the peritoneal toilet, after removal of the growth, a mass fell into the pelvis. Examination disclosed that it was a tumor of the appendix. It was drawn out and the bowel incised at its upper margin, permitting the removal of the cyst without opening the intestinal canal. The muscular wall and peritoneum was closed by a continuous catgut suture.

The patient recovered uneventfully. The cyst when fresh, was five and one-half inches long, four and three-quarter inches in its largest circumference. It has not been opened. Its contents are apparently thin and watery.

SURGERY ONE HUNDRED YEARS AGO.

AN HISTORICAL STUDY

BY DR. GEORGE FISCHER.

DEDICATED TO THE GERMAN SURGICAL ASSOCIATION.

TRANSLATED FOR THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION
BY CARL H. VON KLEIN, A.M., M.D.

IX.—THE ACADEMIE ROYALE DE CHIRURGIE AT PARIS.
PIERRE JOSEPH DESAULT.

Surgeons at the time of Louis XIV.; Wrangle between the medical faculty and barber-surgeons (Wundärzte); Foundation of the Académie de Chirurgie; Memoirs, prize subjects, members thereof; Its influence; Education of French surgeons; Reforms of the French Revolution; J. L. Petit, le Dran, Morand, Garengot, Quesnay, Arnaud de Ronsil, de la Faye, le Cat, le Vacher, Verdier; Louis, A. Petit, Sue, Hevin, le Blanc, Pouteau, David, Goulard, Frère Côme, Levret; Desault; Sabatier, Chopart, Lassus, Deschamps, Pelletan; French medicine: Bichat, Pinel, Corvisart.

In the beginning of the reign of the *l'état c'est moi* king, Descartes, the founder of the new philosophy, died (1650). Three years earlier Pecquet had discovered the lacteals, which next to Harvey's discovery of the circulation of the blood exercised the greatest influence upon the reform of medical science. Then, when in 1657 the illustrious anatomist Riolan, one of Harvey's strongest opponents, was carried to the grave, anatomic investigations came to a standstill in France. While English medicine made considerable progress under Sydenham and Glisson, there was not a single man in France to be compared to them. Medical practice in Paris fell far behind that in the capitals of Germany, Italy and England, and the ignorance of country physicians in France was extraordinary. Only with this in mind does the sneer of Molière in his comedies become clear, and the satyric expressions of J. J. Rousseau, when he considers medicine an art which is far more injurious to humanity than all diseases. Therefore a physician should never be called except when life is evidently in danger, since one has a hundred times as much to fear from his mistakes as to hope from his skill. It was the service of Colbert to urge upon his king, who was not educated in science

and "was afraid of ghosts," the position of a Macenas to the arts and sciences. Writers and scholars were lavishly paid. In 1665 the Académie des Sciences was founded, as well as that of inscriptions and medals and that of painting and architecture. But the achievements of the French in natural science were very meager; there were no original investigators, no important discoveries, no new ideas. They paid no attention to the work of the English, they even neglected that done under Louis XIV., until at the end of the seventeenth century there was hardly an educated Frenchman who understood the language of his neighbors. This was changed only in the next century when Voltaire called attention to English science. He, who overturned the authority of the old classical scholars, made Newton's philosophy popular in France, recommended the writings of Locke and was one of the first to study Shakespeare.

The French called the time of Ambroise Paré the golden age of surgery, and the glorious days of Louis XIV. the iron age. Under these kings surgery slowly began to develop. Neglected by Cardinal Richelieu during the reign of Louis XIII. its old glory faded and it was left more and more in the hands of artizans. Among the scientific surgeons, *Nicolas Habicot* opened the century with great promise. He especially cultivated tracheotomy; he performed it at first in a wound of the larynx and in a shot-wound in the windpipe, and he inserted a lead pipe when suffocation was imminent (1594). He also performed this operation on a boy who had swallowed several gold pieces, which stuck fast in the esophagus, and he saved both the life and the money of the boy. In recommending tracheotomy he said, among other things, "If we open the bladder to let out urine, how much more should we open the larynx to let in air." *Corillard* followed him with good observations on rupture and lithotomy. This operation was chiefly performed by the lithotomists *Francois Colot* and *Tolet*. The latter recommended in anuresis the introduction of a pointed hollow probe through the perineum into the bladder. The perpetual wars increased the regard for surgery and offered opportunity for training. In the unceasing effort to make Paris the center of the sciences, large hospitals and anatomic rooms were built, which soon became the center of gravity for native and foreign surgeons. Since 1684 lectures on anatomy and surgery had been held, by order, in the *Jardin du roi*, which even the princes attended. *Duverney*, who was really a zoologist, lectured on surgery; he wrote an anatomy of the organs of hearing and a work on diseases of the bones. His lectures appear to have been much used later in the systematic manuals of surgery. The first of these manuals was written by the younger *Verduc* (1693), who first described a tracheotomy on account of foreign bodies in the windpipe, and a laceration of the veins of the shoulder in dislocation of the humerus. Then followed *Leclerc* (1695) with a "Chirurgie Complète," in which there is a good description of tracheotomy, whereby the tube is fastened by means of bands around the neck. He first used the name *tourniquet*, which was invented in 1674 by *Morel*, a surgeon in the *Charité*, who also made a ligature forceps with slides. *De la Vauguyon* copied his predecessors. To the seventeenth century also belonged the observations of *De la Motte* (Traité 1722), among them a work on new growth of the bone after the removal of four inches of tibia, retaining the periosteum. *Haller* said of the vain man: "Laudes

suas non negligit, non perinde famæ collegarum studiosus." Like Duverney, *Pierre Dionis* became teacher of surgery in the royal garden. He published, in 1707, after forty-six years' practice, a course in operations which superseded all earlier works, and an anatomy which was translated even into the Chinese language. Next came the investigators, among whom *Saviard*, in the Hôtel Dieu, with his "Nouvel recueil," 1702, furnished the richest casuistry, with many reports on dissections. He first described the reposition en bloc, and operated in traumatic aneurysms, wherein a direct digital compression was by him first applied for hemorrhage; he also declaimed loudly against the celebrated lithotomist, Frère Jacques. *Belloste* urged the prima intentio in the treatment of wounds, and the anatomist *Poupart* immortalized himself by the ligament named after him (1695). *Littre*, a physician in Chatelet, described appendiceal hernia, suggested an artificial anus in the inguinal region, first used the term lipoma, furnished an accurate description of the urethra and wrote of tubal pregnancy, constriction of the esophagus, etc. Mauriceau was conspicuous among obstetricians.

Although those surgeons raised the status of their science, yet the *strife* between the medical faculty, the surgeons (Collège de St. Côme) and the barbers, continued. These last dared not treat any difficult surgical cases. It was to their honor that, with their yellow barber cups (white was wigmaker's color, which hung as a shield before the door) and their cosmetic art very popular at court, they made much more money and obtained more influence than the leading surgeons de robe longue. This excited the jealousy of the surgeons so much that they began secretly to shave beards. The barbers were greatly annoyed at this; parliament came to their aid and forbade either to dabble in the vocation of the other (1641). The surgeons now for the first time felt the great disadvantages of their separation from the barber trade, and to their shame, simply out of avarice, had themselves admitted to the barbers' academy (1660). Surgery could not have been subjected to a greater humiliation. Various circumstances combined, however, to mitigate these melancholy conditions. The newly founded Académie des Sciences consoled the surgeons by accepting them as members (Pourfour du Petit, Littre u. a.); the military surgeons enjoyed an increasing regard, the body-surgeons again freed themselves from their humiliating connection with the barbers (1699). Yet their oppressive dependence upon the medical faculty continued; this also was to be broken.

In the beginning of the eighteenth century the star of French surgery was in ascendent. An extraordinary surgical genius was born—Jean Louis Petit, who exercised upon French surgery the greatest influence since the time of A. Paré and, as he called himself, the first barber to the king. By reason of his eminent mental gifts, his classical works, his wide reputation as teacher and practical surgeon gradually extending over all Europe, he made it impossible longer to speak of surgery as under the patronage of the medical faculty. Hand in hand with him went the body-surgeons of Louis XIV. and Louis XV., Maréchal and La Peyronie, who with great zeal, inspired the French surgeons, and exerted their whole influence at court for the improvement of the external condition of the surgeons. Yet it was clear that the most illustrious members of the Collège de St.

Côme accomplished decidedly more than the professors of surgery. The beginning of improvement was the appointment of five royal teachers, among them J. L. Petit, for theoretical and practical surgery in the Collège de St. Côme, which appointment was due to the efforts of *La Peyronie* (1724). La Peyronie, an admirable intellectual man and a favorite of Louis XV., was ennobled and made maître d'hôtel to the queen, chamberlain and, after Maréchal's death, first body-surgeon, and knew how to skilfully turn the intrigues at the court of Versailles to the advantage of surgery. Indefatigably active, and encouraged by Maréchal, he attained the end for which men had striven in vain for four hundred years. He gave freedom to French surgery through the founding of the *Académie royale de Chirurgie*, in the year 1731. This was a hard blow to the medical faculty; the académie was entirely independent of them and on the same footing. The maîtres en chirurgie no longer took an oath before the dean, the faculty were not invited to the examinations of surgeons, cadavers were turned over to the academy for dissection without the permission of the faculty having been first obtained, etc. The medical faculty made a strong opposition. As complaints at court were of no avail, they endeavored to stir up public opinion by numberless polemics. But all in vain, the shackles were broken, and the surgeon was the political equal of the physician. The society organized itself under the direction of J. L. Petit, and began with a roll of seventy members. The plan was, that surgical notes be contributed and when these had been verified, they were to be published. Louis XV. would have given them the title of an academy if they had wished it. When in 1743, the king received from the hand of President La Peyronie the first volume of the "Memoirs," he declared surgery to be "a scientific profession, worthy of all honor." He confirmed the freedom of the academy, offered prizes for the best work, and ordered that no one should in future become maître en chirurgie, who had not first received the degree of maître ès arts, besides further showing evidence of scientific training by a knowledge of the Latin language and of philosophy. A new storm in the faculty, with the most preposterous and constantly repeated objections! They asserted that it was a reproach to scholarly training, that most of the discoveries were made by uneducated barbers, that the great Petit understood no Latin at all, and that the learned secretaries of the academy, Quesnay and Hevin, had no practice. The faculty submitted opinions from their colleagues in Göttingen and Halle, who naturally favored the desired subordination of the surgeons. What did they do next to injure the academy? They endowed a surgical chair of their own and had surgical papers read frequently! It was a fight for life and death. La Peyronie's generosity went so far that he gave his estate of Marigny to the academy in order that out of the revenues he might increase the salaries of the professors, maintain a permanent secretary, buy books and provide prizes and medals. He had a gold medal worth 500 livres struck, to be given annually as a prize, and he bestowed upon the surgeons of his native city, Montpellier, 100,000 livres for the building of a scientific institute. His successor in the president's chair, La Martinière, showed no less zeal in maintaining to their extremest limit the rights of the academy; the same may be said of A. Louis, who vigorously contended against an essay of Professor Com-

balusier ("La subordination des chirurgiens aux médecins"). The struggle continued with the greatest bitterness until, in the year 1751, Louis XV. put an end to it by a new regulation. He again confirmed the rights of the academy, declared the surgeons entirely independent of the faculty and only required them to submit each year to the Dean a list of their members. We may reproach Louis XV. with the fact that many writers were persecuted under his régime: Voltaire was forbidden to publish in French the works of Newton; but the deepest gratitude of surgeons is due to the king for the establishment of the academy, to which as a last memorial he presented a large and beautiful building.

The academy began its work with animation, and although in their conventions they often all talked at once, so that the voice of one drowned that of another, yet they introduced themselves very favorably in their first volume of "Memoirs." To this Quesnay wrote a beautiful preface, placing observations at the bedside on an equal footing with experimental physics, and physiology as the basis of surgery, and showing that operative skill was not the sole mark of a good surgeon, and that whoever slavishly followed the rules of operating was a melancholy and mechanical artisan. "Never could surgeons who confined themselves to one class of operations, as the lithotomists, become perfect in it, because they would not dare to undertake any modification; and in that way progress in other classes of operations was retarded. So a hundred years have passed since Paré's ligature discovery, and yet surgeons are afraid to bind the blood vessels, although otherwise they do not hesitate to subject their patients to the severest pain." The memoirs contained a mass of new work, a part of which was very clear and was of lasting value to surgery. J. L. Petit wrote in the first volume on injuries to the head, tumors of the gall bladder, malformations of the anus, rectal fistula; and in the same volume Quesnay treated injuries to the head and trepanning; Hevin, foreign bodies in the esophagus; La Peyronie, spermatorrhea and gangrenous hernia; and Foubert lithotomy. Louis wrote on amputations, lachrymal fistula (II), harelip and tracheotomy (IV), and fungus of the dura mater, trepanning, extirpation of the bulb, salivary fistula (V); Boucher on gunshot wounds and limb fractures (II); Verdier on hernia of the bladder (II); Lafitte on nephrotomy (II); Daviel on extraction of cataract (II); La Faye on harelip (I), and exarticulation of the humeri (II); La Martinière on gunshot wounds and trepanning of the sternum (IV); David on operations in empyema (IV); Bordenave and Jourdain on diseases of the antrum Highmori (IV, V); Sabatier on fractures of the collum femoris (IV), and on artificial anus (V); Brasdor on fracture of the clavicle and amputation at the joints (V); Verduin and Garengéot on amputations (II, IV); Moreau on luxatio femoris (III); and Morand on tapping of the breast (II).

Every year prize essays were written, and during the first year most of these were on general surgical questions. These, together with the numerous discussions on the treatment of wounds, exercised a great influence on European surgery. The academy did not practice the strictest severity in the judgment of the prize essays, lest they discourage the writers, and they rewarded many a motive which did not entirely meet their requirements. But soon they became more exacting. When in 1757 the exarticulation of the femur was allotted as a subject to be written on, Morand

declared that of the twelve papers submitted, not one was worthy of the prize, so that the subject was again allotted for 1759, for a double prize. In the fifties, Le Cat was almost always a victor, although often twenty other surgeons ranked with him: he won the prize for an essay on the use of pledgets and other means of dilatation; on the distinction of those diseases which require a frequent and those which require an infrequent change of bandages, and on the question whether cancer of the breast should be extirpated. Later, Peter Camper of Holland was awarded several prizes. In the eighties the academy preferred surgical instruments as the subjects of the prize essays (Teissier on probes, Percy on scissors and on the extraction of foreign bodies from gunshot wounds): unfortunately, by this means the bent of the French for operations was encouraged, and surgical pathology, which so much needed research, was relegated to the background. In those days, Percy so often won the prize that the academy asked him not to compete any more, lest the others be discouraged.

Let us take the year 1775, in which to become acquainted with the *members of the academy*. De la Martinière "leader of surgery in the kingdom" was president: Andouille, vice-president; de la Faye, director; Bordenave, vice-director; Louis, secretary; Sabatier, corresponding secretary; Goursaud, treasurer; Quesnay, secrétaire vétérinaire. Among the thirty regular habitués were Hevin, Lafitte, Sue, Fabre, Brasdor, Ferrand; among the seven conseillers vétérinaires were Guerin, Bagieu, Moreau, Levret. Then there were nineteen assistants and seventeen foreign members: among the latter, as the only Germans, were Henckel in Berlin, Böhmer in Halle, and Von Haller, Acrel, Moscati, Sharp, Camper, and various unknown surgeons who, at all times, were loaded with honors, though they had not the least merit as scientists. Before the revolution there was considerable complaint concerning the pressure of court influences, on the academy, through the chief body surgeon, by reason of which it was placed in a position of dependence, and personal influence was of the utmost importance for admission to it. Other eminent members of earlier and later times were Morand, Ravaton, le Dran, le Cat, David, Garengéot, Janin, Pouteau, Desault, Chopart and others. So far as the public was concerned, the history of the academy really closed with Louis. After Quesnay had published the first volume of memoirs, Morand succeeded him as secretary; but a number of quarrels in which he became involved, delayed further publication. Louis undertook the management and attended to the publication of the second volume. He wrote the eulogies of the deceased members (among them a warm encomium of A. von Haller), whereby he subjected himself to much unpleasantness. In 1793, one year after his death, the academy was abolished by the Revolution.

Without doubt it had contributed very much to the advancement of French surgery. Not only through the promulgation of the best achievements, but also through the fact, that it was the rallying place for French surgeons, such as was lacking in all other countries, and stimulated their ambition to win its applause through discoveries and useful observations.

The academy soon became so powerful, that for a hundred years, it dominated the surgery of all Europe, and was part of the universal supremacy of France. Whoever could invoke its authority in any case, added overwhelming weight to his opinion, and thereby ob-

tained the stamp almost of infallibility. One of the happiest tendencies was, that French surgeons mindful of the teaching of Fallopius "per anatomiam solus aditus ad chirurgiam" began to cultivate anatomy to a large extent, but with a high degree of uncleanliness. Surgical anatomy was a daily study and was facilitated by the state, with its abundance of cadavers. (At the beginning of this century Lisfranc made use of about a thousand cadavers annually in his operating exercises; his two months' course cost only 25 francs.) The career of a surgeon always began with anatomical work, and no one was esteemed as a surgeon who had not previously distinguished himself as an anatomist. In this way they acquired the greatest assurance and ventured on the most difficult operations. The real researches, which the academy stimulated, pressed book-learning into the back-ground; the diseases were worked up in monographs and indications were more sharply defined. Certain surgeons took certain questions as the chief subjects of their researches, this one employing himself almost exclusively with fractures, that one with hernia, diseases of the eyes, etc. In spite of this progress, it can not be denied that, with the glory of the academy, they sought to gild many abuses which had crept in, especially in the teaching of students. On the other hand, many improvements were delayed by it. With Louis it became old and decrepid; tracheotomy and artery ligation were dropped and no resection of joints or plastic operations were undertaken. It lacked the sense of greatness which was represented for us in Haller, and for England in Monro and Hunter.

The growing prestige of their science and the example of their celebrated countryman, had a favorable reaction on the rank and file of French surgeons, in so much that they distinguish themselves above their German colleagues. In the first place they were well organized. The chief surgeon of the king had supervision over the surgery and surgeons of the entire kingdom. Whoever wished to practice must be a Master; for the rest surgery was a free profession and the surgeons enjoyed all the rights and all the advantages which pertained to the free vocations. At the beginning of the year, every guild submitted to the chief surgeon of the king a list of its old and of its newly acquired members. If there was a hospital in a city, two Masters were selected from the guild, every two months, to take charge of it without compensation. A Master was selected each year to teach anatomy and surgery publicly and gratuitously. For twenty-two years no one was made a Master; a Master could never keep more than one apprentice. This regulation was made so that an apprentice could not undertake a serious operation except in the presence of his Master. While the majority of German surgeons came from the lower classes of society crude in their views and without education—in France, young men of the best families devoted themselves to surgery, and by their manner of living elevated the profession. The Germans, by reason of meager preparation, were incapable of scientific study, had no ambition and did not interest themselves either in theoretical or literary researches, for which the French had a taste. On the other hand, certain traits of character of the French nation, exercised an important, and not always favorable, influence on their surgery. From their animation of spirit, there often came a one-sidedness and incompleteness of observation. A method would be quickly discarded and on another occasion just as

readily taken up again; they went quickly from one extreme to the other. In addition there was their false patriotism, which was nothing else than a blind contempt for all foreign nations. The Frenchman was accustomed to being imitated abroad, and believed that he alone was able to advance science. With this consciousness he regarded surgery as his personal property, assuming that his anatomy and surgery were the best in Europe, without having the slightest acquaintance with the writings of foreigners. This vanity went so far that a critic asserted of Sabatier's "Médecine Opératoire" and the translation of Bell's "System of Surgery," that whoever possessed these two books held in his hands the surgery of Europe. Foreign works, and above all German works, were read by very few, and were seldom translated into French. The surgeon Louis translated van Swieten's "Commentaries of Boerhaave; A. G. Richter's "Elements," his treatise on hernia, Bilguer's work on amputations, his "Guide to Surgery in Field Hospitals," and a few others, found favor in the eyes of the great nation.

By reason of a certain practical sense which one must grant to the French in all the sciences and arts, it was very natural that their study, from the beginning should deal especially with the mechanical part of the profession. In this way they often went astray and cultivated operative surgery at the expense of surgical pathology. The frequent prize essays on instruments, which the academy called forth, combined with their ambition to perpetuate themselves in their annals, excited unduly the quest for new instruments and new methods of operating and bandaging. Instead of first proving the inutility of older methods and following with a critique of the new invention, the chief ambition of the Frenchman was to attach his name to some small mechanical improvement. "The scholars live only for the sake of perpetuating their own names, and often die without having done any real good to anybody. They chase after fame and trample on their true happiness" (Bichat). They wished to shine by a brilliant operation or a skilful bandage, and even strained after it, when the operation was unnecessary. Wardenburg was finally convinced that certainly ninety out of every one hundred Cæsarian sections were made out of self-interest. If a French professor, in his lectures, produced a badly constructed instrument, impelled by national prejudice, he exclaimed, "C'est une invention allemande." Even in the last decade of the century it was usual to say after an operation, "Elle a été exécutée avec le plus grand succès," even though the patient died under the operation or a few days later. The operation was at least *lege artis* and rashly undertaken: the death of the patient could not affect the celebrity of the new method. Under such circumstances, combined with the fact that they grossly neglected the after treatment and diet, many a skilfully performed operation resulted fatally and the mortality became very great. Even in the year 1783 Lombard was obliged to teach the French that in the treatment of injuries it was necessary to keep the patient's bowels loose; in the Paris hospitals one could see patients with head wounds who had not had a movement of the bowels for eight days. On the other hand, they often continued a strict diet so long that the patient died from weakness. The surgeons, like Frenchmen everywhere, could not dispense with elegance and external show. This extended to certain mannerisms, which were shown, for example, in the carrying of the

knife (the French surgeon carried his instruments in the pocket of an apron which he put on before beginning an operation), which indeed committed them to many ridiculous trifles. For instance, it was a customary movement for the speaker, in gesticulating, to hold the ends of the thumb and forefinger together and to extend the other fingers. Voltaire said that they carried the abuse of elocution so far that this art came to be an introductory manual to anatomy. Pouteau justly censured the long drawn out preparation for an operation because it filled the patient with terror and foreboding. Much was written by the surgeons; the number of *traités*, *présis*, *éléments*, *dictionnaires* and *periodicals* was legion. While the Germans wrote little besides manuals and handbooks, which did not advance the science, the French journals teemed with monographs. But in general the literature was superficial; it read: "In the memoirs is found the following note," but they refrained from more careful work. The royal censor passed upon the books for publication and frequently the corrector of the *hommes des lettres* did likewise, which resulted in an elegant style.

About the year 1750 a change in the French spirit took place in two directions. Then began the researches in political economy, finance and state questions (Turgot, Necker) and the attacks upon the constitution of the country; then Helvetius, the famous moral philosopher, and Condillac, the celebrated metaphysician, gave an immense stimulus to the study of nature. From this time forward every branch of natural science was advanced with extraordinary rapidity. Prevost stated the laws of light rays, Fournier the laws of radiation and Lavoisier was brilliant as a chemist, Cuvier gave to zoology its scientific character when he enunciated the principle (1795) that the classification of the animals must be made according to their internal structure and not according to external feature. He discarded the artificial system of Linné and pointed out by experiment a new and important method of research. Botany and mineralogy were elevated to sciences by the French shortly before the Revolution (Jussieu, "Genera Plant." 1789). During the last half of the century the French spirit hurled itself upon the external world with unparalleled fervor and did its part in bringing about the mighty movement, of which the Revolution was one single consequence. The scientific progress and the social upheaval both arose out of the desire for improvement, discontent with what had been hitherto accomplished, out of the same restless, searching, bold spirit (Buckle). How thoroughly the revolution in the natural sciences had permeated all grades of society we have already seen. It was also to result to the advantage of medical study.

(To be continued.)

SOCIETY PROCEEDINGS.

New Jersey State Medical Society.

Proceedings of the one hundred and thirty-first annual meeting held in Atlantic City, June 22, 1897.

(Concluded from page 132.)

Dr. TALBOT R. CHAMBERS of Jersey City read the report on PROGRESS IN OPHTHALMOLOGY AND OTOTOLOGY.

He says there has been great progress made in these subjects. Norris and Oliver have just issued a new system of diseases of the eye; the first volume only has appeared. Formalin solution is now used in mucopurulent conjunctivitis with excellent

results, 1 to 2000. The beneficial effects of subconjunctival injections are due to their stimulating effect upon the lymph circulation of the eye. One to 2000 bichlorid solutions set up an adhesive inflammation with obliteration of the subconjunctival space. Salt solutions injected have the same favorable effect without the ill results. An arrangement is proposed which gives an enlarged view of the field of operation. It is claimed that in pseudo-membranous conjunctivitis bacilli have been found which were not to be distinguished from Klebs-Löffler diphtheria bacilli. In mild burns immediately loosen them and pass ligatures to convert them into a small wound. The author mentioned cases where this had been done with good results. It has been found that the number of persons blind from blenorrea, in Germany, is 20 per cent.; in Holland, 13 per cent. Gonococci were found in more than one-half the cases. Credé's procedure is recommended. Pterygium is treated by touching the apex with a platinum probe heated to redness. Epilepsy in a woman had been unsuccessfully treated by bromid and animal extracts; she recovered after the latent esophoria and hypophoria were corrected by numerous tenotomies. Another case was cured by correction of eye strain. A piece of metal has been detected in the vitreous by the Roentgen ray. Prolapse of the iris has caused much discussion; the consensus of opinion is that it calls for immediate excision if detected at once; if a few days later, it may be treated tentatively. *Otology*: One writer says that tinnitus aurium has but little light thrown upon it, and two-thirds of all cases have a common origin, and cites a case of acute glaucoma of the tympanum causing, by pressure on the stapes and oval window, an acute tinnitus. When the pressure and pain had been relieved, the tinnitus remained. The author suggests the need of more symptoms to enable others to explain this condition. Some cases of tinnitus are difficult of explanation. Thus, it may be due to eczema of the auditory canal with healthy middle and internal ear. On account of so many findings continuous tinnitus and the belief, held by many, in the difficulty of relieving it, the author gave the following points bearing upon it: Tinnitus is only a symptom; in chronic internal ear disease a cure is well nigh hopeless. That progress has been made is seen by the number of reports of cases in cures of cranial abscesses and intra- and extra-dural tumors. The trephine, gouge, chisel and knife invade territories regarded formerly as impregnable. The mastoid is entered, clots are cleaned out; growths are removed; lives saved where surgical interference formerly was thought to mean death. Extensive thrombosis of sinus of the brain are reported: brain abscess is cured. Chloroform is preferable to ether in all operations about the head. The antrum of Highmore, superior maxillary fossa, the naso-pharynx, are all known as the seat of disease, hitherto failing of detection. In simple ear disease, and so-called scleroses dependent upon disturbances of the sound transmitter there is an interference with the mobility of the base of the stapes, and we may assume that the transmission of the lower sounds is normally performed by the chain of ossicles, which is not at all necessary for the highest sounds. In middle ear affections, air conduction for deep sounds is reduced, compared to bone conduction. In sclerosis the high sounds also suffer. Defects at the upper end of the scale are not of very great aid in diagnosis, but when joined to shortening of Schwabach's test a nervous affection can be supposed. If pneumococci are found in the middle ear or in the mastoid at operation, complications may be expected. In all cases look out for spinal symptoms. The most important point is slowing of the pulse: next are eye changes, as in severe otitis, etc. Cases have been cured, as reported, by an injection of hog pepsin or papayotin, in double deafness, about the stapedial articulation. It is held that the stapes, though fixed, still transmits molecular vibrations to the labyrinthian fluid, only the amplitude of the vibrations are diminished. Soap smeared over the mirror and wiped off when using the laryngoscope and otoscope prevents the breath from depositing its moisture, and the mirror remains bright. It is advised at the very outset of the exanthema that the nose and pharynx be frequently cleansed with warm alkaline solution and medicated sprays. Nasal douching has been followed by otitis media, hence they now use a douche perforated along its length. Where purulent discharge continues from the middle ear we may consider the possibility of latent mastoid disease and guard against it. Nothing is gained by removal of the stapes in affections of the labyrinth or round window, and the effect on tinnitus is doubtful. For suppurative chronic otitis media confined to the attic in which the malleus and incus only are carious, the removal of the ossicles alone will effect a cure. In fact, all carious bone must be removed, even if the petrous is affected. Goutiness is much related to ear diseases, and hence constitutional treatment is demanded. The Urbant-Schnitsch method has

developed hearing in three deaf and dumb children. Thorough cleansing with suction massage is demanded for otitis media purulent. The rigidity of the conducting apparatus causes the deafness, hence massage will improve the hearing. Now if the middle ear be thoroughly, persistently, patiently cleansed and studied, the cause may be discovered and relief obtained. In all cases of catarrhal trouble, constitutional treatment is indicated. Antinolin solutions and nosphen are excellent substitutes for iodoform. When discharge is present, the parts must be kept clean. Next disperse the rigidity of the foramen ovale and rotundum if possible. For the first the author has found the best means is syringing with carbolic solution, wiping out with cotton tipped probes loaded with hydrogen peroxid and drying, then following this a solution of antinolin (5 per cent.) on cotton tipped probes. The second indication is massage with rubber tipped probe against the bones wherever the procedure will be allowed, care being taken not to produce an inflammation which might get beyond control. The idea is to impart and start up vibrations in a labyrinthian fluid which has for a long time been quiescent. Then the Delstanche massage apparatus is brought into play, and the patient instructed to use it at home systematically, shortening the intervals as the improvement appears. This instrument is of great value. It must be compressed suddenly, and the spring be strong enough to produce a shock on its return. Old rusty joints will not budge with passive motion. Of course pain will require a stop, and that the pump be modified as demanded. In the meanwhile, the nose and pharynx and constitutional hygiene are to be looked after.

A communication from the Secretary of the AMERICAN MEDICAL ASSOCIATION relative to raising the sum of \$100,000 for the Rush monument and requesting the appointment of a special committee to take charge of this was read, and referred to a special committee to consider and report. The Antivivisection Bill now pending before Congress was mentioned as likely to pass and the matter was referred to the standing committee with power to see that every member of Congress, from the State, was properly informed of the feeling of this Society upon the matter.

Dr. W. EDGAR DARNELL of Atlantic City, read a paper on

FOUR TYPES OF INFANTILE DIARRHEA AND THE INDICATIONS FOR THEIR TREATMENT.

He explained how in infants unable to describe their symptoms much valuable information is obtained by careful observation. Mothers are rarely reliable. We must classify diarrheas. Hence we may classify them as "mucous," "serous," "pasty-white," and the "dyspeptic," subdivided into acid and alkaline. The mucous stool is usually small in amount, with whitish ropy mucus, of a gelatinous consistence, sometimes faintly streaked with blood, or stained with feces. Some attribute this to nervous disturbances. No doubt, the functions of secretion in the alimentary canal presided over by Meissner's plexus are without doubt often deranged by teething and other reflex influences. In children the secretive function is more active than in adults. Hence the outpouring of mucus. This mucous discharge may come from the whole tract. If possible we should locate it, to learn whether it represents gastritis, gastro enteritis, enteritis, entero colitis, or colitis. In true dysenteric states the colon being effected the stools are faintly streaked with blood, even hemorrhagic; tormina and tenesmus are present, rapidly exhausting the patient. The presence of ulceration is known by pus discharges with the blood, etc. Serous diarrhea has copious watery stools, that hardly stain the napkin. This is termed choliform diarrhea or cholera infantum. There is a profound collapse, often severe vomiting. It really is a shock. Some ascribe it to heat exhaustion, or heat stroke; again to toxemia from infected food. The vasomotor system is profoundly depressed. The outflow appears to be due to relaxation of the intestinal vessels, the tension is lost, the alimentary canal has millions of minute leaks through which the young life is draining away. Indication is for the bringing up of the nervous system and restoring the normal tone; check the leaking. The pasty-white or musty stool is often classified as cholera infantum, but is the opposite of that just described. Instead of leaking, every vessel seems to be locked up, and inactive. Secretion is at a minimum. The discharge on the napkin is so small as to be hardly visible, and appears like paste made of water and chalk, or is sometimes cheesy. The odor is musty. The usual history is that the child has had improper food. The general symptoms are not as severe as in the preceding form. Indications are to restore functional activity. The bile is nature's own agent to stimulate the intestinal secretions; flush the sewer, then with bile and the inactive glands will soon fall into line and do their part. In the fourth class, acute dyspepsia, the management is more a question of

artificial feeding than of medicine. The stools may be divided into two varieties: Those of a leaden color, acid reaction, with a sour disagreeable odor of fermentation; those of a grass green color, foul and offensive odor. The first is typical of bacteria of fermentation; the second of bacteria of decomposition, and the stools form a splendid culture tube for the growth of these organisms. Mixed in the discharges of both may be seen curds of undigested food. The disease is one of warm weather, bad hygienic surroundings, the warm temperature making the milk more congenial to the growth of bacteria. Indications are to unload the bowels and arrange diet. Proper hygiene is of great importance. Daily baths in tepid water, or even in high temperature more frequently, and plenty of fresh air; clothing, napkins, etc., frequently changed. Nursing bottles should be simple, thoroughly scalded each time of using, the abdomen covered with a light flannel binder to prevent susceptibility to draughts, otherwise the child clothed loosely, not warmly. In the mucous stool we have seen the indication to be to get rid of the presence of local irritants or correct nervous derangement. Sweep the bowel clean of offending contents by a full dose of laxol or castor oil; then bismuth in large doses, even a dram a day. Its effect is soothing, astringent and antiseptic, and may be aided by suspending in mucilage of acacia. After the acute stage, vegetable astringents and mineral acids are best. In a dysenteric case, calomel and ipecac are useful. The more rational mode is local applications to diseased parts by medicated enemata. Nitrate of silver heads the list in large injections of weak solutions. In watery diarrhea where everything is relaxed, and leaking, there are two prominent indications. Bring the nervous system to normal tone, check leaking, but never forget abdominal counter irritation. Atropin is a vasomotor stimulant, 1-500 grain with morphin 1/100 employed hypodermically. Champagne and brandy, lavage of rectum and stomach frequently check persistent vomiting. Rectal enemata of saline solutions restore serum to the blood. In pasty-white stools find agent to flush the bowel with bile. Podophyllin is one of the best, for it also aids the stimulation of glandular activity and pushes along the poisonous contents of the bowels. Astringents are contraindicated while the stools are pasty-white. They only increase the trouble by locking up the bowels tighter; after the stools assume a bilious color, if needed, they may be given. In each form it is generally advisable to withhold all food until the bowels are relieved. Thirst must be attended to by barley water and a little brandy. The dyspeptic form is largely a question of diet. Evacuate the bowel of its fermenting or decomposing matter, with laxol or castor-oil and aromatic syrup of rhubarb. Over-feeding is often at the bottom of this, mothers not being able to get it into their heads that a child should not be fed every time it whimpers. Cut down the food at least half, and feed not oftener than every two hours. The division into acid and alkaline, guides us as to food. In acid stools withdraw the carbohydrates, milk, etc.; administer beef juice, albumin water, meat broths; or if alkaline, give the carbohydrates and withhold the proteid diet. Modified milk meets the requirement in many cases. It is the rational food for infants. Cow's milk, having double the amount of albuminoids, must be diluted. It is a matter of vital importance that the differences in these forms be carefully observed. Study the stools, act accordingly.

The next was a paper by Dr. L. M. HALSEY of Williamsport, entitled "Headaches, Auto-intoxication a Factor."

The Committee on Prize Essays reported that Dr. G. C. BAYLISS had been awarded the prize of \$100 for the best essay.

Dr. J. W. STICKLER of Orange read a paper giving the results of efforts to protect by means of a scarlatinal inoculation. He had inoculated a number of colts and cattle, but this did not produce any milder form of the disease, as he had hoped. He reported a number of cases with his deductions. The average period of incubation was twenty-two and one-half hours. Vomiting occurred in twelve and one half hours. The average temperature was 99.2 degrees. The mucus from the throat as containing the poison was employed in these experiments. The early eruptive stage is exceedingly infectious. For disinfecting the throat we should use sponges saturated with the disinfectant, and use every precaution to prevent soiling the bedclothes. No toys, books, etc., should be allowed the patient unless destroyed immediately after use.

Dr. ALEX MCALISTER of Camden read a paper on

SERUM THERAPY IN DIPHTHERIA.

But little attention was given by the profession to the subject of diphtheria antitoxin before the meeting of the Eighth International Congress of Hygiene and Dermography at Budapest, Hungary, in September, 1894, when Roux presented a paper reporting 500 cases treated with antitoxin. Since then the remedy has been extensively used and reported upon in

every civilized country. Recommended by the great body of laboratory workers, endorsed by thousands of physicians both in hospital and private practice, and welcomed by the common sense of the people at large, antitoxin has become the most widely endorsed and most generally employed of all remedies. Though confronted from the first by the fiercest opposition, and materially retarded by the unbridled enthusiasm of some of its advocates, diphtheria antitoxin has, within the brief period of three years, proven itself to be specific in the full sense of that term. Emmet Holt in his new text book on pediatrics says: "Antitoxin is a specific remedy for experimental diphtheria in animals. Experience is now sufficient to justify the statement that it is specific in man, and just in the degree in which we can fulfill the conditions which are essential in experimental diphtheria." (Vol. 999.) And again: "Gratifying as were the earlier results with the serum treatment they have been constantly improving and there is every reason to believe that with larger experience both in the preparation and use of antitoxin still better results will yet be reached. Certainly there is no remedy for any disease that has more testimony in its favor than has now diphtheria antitoxin." (Vol. 1000.) These statements, which are fully endorsed by all the leading authorities, it will be noted, were made prior to the completion of the rich experience had with the remedy last winter, and before the results of the supplementary collective investigation of the American Pediatric Association were made known, of which the *Medical News*, of May 15, 1897, said editorially: "There can be no longer any doubt as to the value of the antitoxin treatment in all forms of diphtheria. The highest commendation should be accorded the American Pediatric Association for so persistently adding line upon line, precept upon precept, until a verdict of *proved* has been established beyond peradventure. The final word has been spoken, a fact is before us."

The above collective investigation showed that under antitoxin treatment 73 per cent. of operative cases of laryngeal diphtheria recovered and that only 39 per cent. of cases so treated required operation. Under calomel treatment only 27 per cent. recovered and 90 per cent. of all cases required intubation.

It is interesting to note how many eminent men in the profession, and how many prominent medical magazines, after openly opposing antitoxin, or treating it with stolid indifference, have joined the ranks of its advocates. Among many others, Virchow "yielded to the brute force of figures," deeming it ignoble to face facts in obstinacy, and Jacobi, who for twenty years has been a leading American authority on diphtheria, now finds in the failure to employ antitoxin in all cases of diphtheria a heavy shade of criminal neglect. The *Medical Record*, commenting on the first report of the American Pediatric Association, July 4, 1896, said: "The majority of the profession may properly continue the use of antitoxin, but the great silent, careful, powerful jury of the profession is not yet ready with its final verdict." Commenting upon the second report of the American Pediatric Association, May 15, 1897, the *Record* said: "The report is worthy of close study. Laryngeal diphtheria requiring operative interference furnishes the best test of the method of treatment. As the report mentions, before the days of antitoxin the best statistics could show only 27 per cent. of recoveries. Other factors remaining constant, the use of antitoxin has carried the percentage from 27 per cent. till it now reads 73 per cent. mortality, nearly three-fold increase in recoveries. The deliberations of the AMERICAN MEDICAL ASSOCIATION in its recent convention in Philadelphia, served to show how generally antitoxin is employed in the United States. The experiences of the last nine months both in the employment of the remedy and the collective study of results have been such and the evidence in its favor so overwhelmingly conclusive, that in a body of medical men such as convened at Philadelphia, the physician who shows an aversion to the remedy has his motive for so doing and his sincerity immediately put in question. Every legitimate objection to the remedy is fully overcome in the employment of concentrated antitoxin which was introduced during the spring of 1896 by H. K. Mulford Co. Philadelphia, and which is now generally endorsed. The question to raise is how to employ the remedy in order to obtain the largest possible results. It is this phase of the present status of the serum treatment of diphtheria that is of most vital importance. The superiority of the antitoxin treatment of diphtheria over all other treatments can no longer be reasonably questioned, while the methods by which the fullest possible specific effects of the remedy may be secured are not everywhere well appreciated. The supplementary collective investigation showed that many physicians, rendered timid by the glaring head lines in yellow journalism, administered doses having

from one tenth to one half the required number of antitoxic units. The results were proportionately unsatisfactory. The indications are that when a reliable product is employed generally in proper doses, repeated (if need be) within twelve hours, the general mortality from diphtheria will be reduced to less than 4 per cent., and that of laryngeal diphtheria to less than 10 per cent."

Regarding the opposition, it has been well said that there are today, in the whole civilized world, not more than three or four active opponents of the antitoxin treatment of diphtheria whose names were known to the profession before the introduction of antitoxin. While these have raised a great hue and cry it is well to remember that they do not constitute the medical profession nor create truth. There can be no virtue in opposition which persists in the face of impregnable figures and established facts. That the fear of untoward results from an injection of antitoxin which some physicians still entertain is utterly groundless, is a patent fact in view of the countless injections already made in all parts of the civilized world, the number aggregating probably upward of two millions. In this large number it is admitted that five deaths occurred which could not be satisfactorily explained. They can not be proven, on the other hand, to have been caused by the antitoxin. In all the extensive laboratory researches nothing has yet been discovered which could possibly or probably contaminate the antitoxic serum and result in sudden death when administered. In the five cases referred to, in three of which immunizing doses were given, untoward symptoms appeared immediately upon injection of part or all of the serum, and death followed in from five to eight minutes. Virile germs, ptomaines, etc., even when nurtured in artificial media, are not capable of such results in small animals, much less in human beings. The cases simply remain unexplained for want of inefficient data. The remote cause was not recognized and death was incidental to the injection, fear probably being the exciting cause.

Sudden deaths have always been a possible outcome of the diphtheritic infection and, inasmuch as the severity of the infection is not always appreciated, it may be presumed that in some of these instances the disease was not given the full share of blame. In the three instances cited, causes other than the antitoxic serum must be sought for satisfactory explanations. In the early days of hypodermic medication, sudden deaths were attributed to the use of the needle. Even to this day some communities will not tolerate the employment of hypodermic syringes. Quinin had its reported fatalities when first introduced. The coal tar derivatives, now so extensively employed, have been credited with deaths; so have morphin, ether, chloroform, alcohol, and many other standard remedies. It is questionable whether one of these medications, within the prescribed doses, has a record nearly as clean as that of diphtheria antitoxin, viz., more than one million injections and only five deaths which, to say the most, can not be satisfactorily explained. If it be conceded that there is an element of risk in the employment of antitoxin this must be placed at one two-thousandth of 1 per cent., while the gain in recoveries ranges from 25 to 30 per cent. over all older treatments. If it is possible to give too large a dose of antitoxin this limit has not yet been discovered. Rosenthal has given as high as 6,000 units in a single injection. In one case which he reported 15,000 units, and in another 16,500 units were administered during the continuance of the disease without untoward effects. Every case was followed by recovery. Dr. Sanor of Malvern, Ohio, reports the case of an infant nine days old successfully treated with concentrated antitoxin, potent 1,250 units being used within twenty-four hours. (Five hundred units 10 a. m.; 500, 6 p. m.; 250, 9 a. m.: case grave; throat and nose full of exudate; infant began to nurse at 2 p. m.)

Within the prescribed range of doses diphtheria antitoxin may now be administered with the same degree of confidence that characterizes our employment of any of twenty-five leading therapeutic agents, including quinin, morphin, alcohol, strychnin, etc. Idiosyncrasies to these drugs are to be expected. If idiosyncrasies to antitoxin exist they are confined to an occasional urticaria excited by an unripened serum. From the first as the powers and limitations of antitoxin became better appreciated, the dose recommended was increased and the interval in repetition decreased. As indicated in the recent report of the American Pediatric Association, the further decrease in the mortality rate from diphtheria will depend upon the more general employment of concentrated antitoxins reasonably early, without fear, and in doses of 1,000 or 2,000 units repeated, when need be, within ten or twelve hours. The best dosage at present recognized is briefly summed up as follows: In all ordinary cases of pharyngeal type give 1,000 units immediately upon making the clinical

diagnosis. If treatment is inaugurated late and the type be laryngeal, or the case be membranaceous croup, give 2,000 units. In every instance, if the disease is not arrested or the indications are that sufficient antitoxin has not been administered, repeat the dose, or give double the dose, within twelve hours.

Dr. J. W. STICKLER of Orange, gave a résumé of a paper entitled

SCARLET FEVER REPRODUCED BY INOCULATION: SOME IMPORTANT POINTS DEDUCED THEREFROM.

He explained why the inoculations were made, by saying that his original purpose was to prove that a protective virus had been discovered, but when it was found that genuine scarlatina was developed he discontinued inoculations. The individuals thus inoculated all had the characteristic eruption, tongue, and desquamation. The substance used was mucus obtained from the throat of a man who had a very mild attack of the disease. It was diluted with water, and one six-hundredth part of carbolic acid added. The inoculations were made with a hypodermic syringe, the point of which was introduced into the skin, but never through it into the subcutaneous connective tissue. The practical point to which Dr. Stickler called attention was the importance of knowing, with absolute certainty, that the contagium of the disease is to be found in the pharyngeal mucus. It also proves that scarlet-fever is contagious in the early eruptive stage of the disease. The use of information thus gained, in the sick-room, is manifest.

The discussion

IN THE TREATMENT OF APPENDICITIS, IS THE FREE USE OF THE KNIFE NECESSARY?

was opened by Dr. G. H. BALLERAY of Jersey City. He described the various forms of this affection and the need of early operation if any hope was to be expected of saving the patient. The subject was discussed by a number of those present, including Prof. J. M. Barton of Philadelphia. While many were conservative as to operating, the general view was for early action as soon as the diagnosis was completed.

Dr. JAMES M. BARTON of Philadelphia, said: I have been present at quite a large number of operations for appendicitis and can not recall a single instance where decided disease of the appendix did not exist where the surgeon had made the diagnosis of acute appendicitis. The great cause of death in appendicitis is from general septic peritonitis. But few survive in which it develops and but few of the fatal cases perish from anything else. In the surgeon's attempt to save life most of his efforts are directed to prevent this general septic peritonitis. Peritonitis is caused either by the appendix rupturing directly into the general peritoneal cavity, no protective adhesions having been set up, or by the rupture of the adhesions, which, for a time, have confined the abscess caused by rupture of the appendix. This abscess may rupture when it contains less than half a drachm, or it may distend without rupture until it holds a pint or more.

The first variety is usually known as the fulminating form. I operated on a case of this character, on a boy of 15 for Dr. Skillern of Philadelphia. It was on the morning of the third day of the disease, there was no lymph thrown out and no adhesions: the appendix had ruptured and extensive general peritonitis existed. Its presence was recognized before the operation, not only by the usual symptoms but by that of Richardson, viz., the absence of the sounds indicating intestinal peristalsis.

As an illustration of the second method by which the peritoneum is infected I operated on a man, here in Atlantic City, where there were very strong, extensive and vascular adhesions but they had ruptured and on the third day, when I first saw him, general septic peritonitis existed, and when general septic peritonitis exists, operation or no operation, it is almost surely fatal. To wait for ten days as suggested by the writer of the paper, before operation in such cases would be to wait too long.

Now if these cases had been operated upon before general peritonitis occurred what would have been their chances? What is the mortality when we remove an appendix when neither peritonitis or appendicitis exists? That is what we do when we operate between attacks. The mortality is stated by various operators to be less than 1 per cent., and my own experience makes me think that this is probably correct.

One of our members has reported here, in detail, seven cases treated by the internal administration of a poultice: he feeds them on poultices and seems to think favorably of the method: he reports two deaths out of the seven, a mortality of over 28 per cent. If they had all been operated on early in the disease what would have been the mortality? Probably less than 1 per cent. But we do not want to operate on all, we should have liked to have operated on the two the poultice did not save, but

early; if a case is to be operated on at all it had better be operated on early. Can we tell early in the disease what cases are going to have peritonitis if they are not interfered with? I think not. The diagnostic points of a fulminating case are well described by the writer of the paper, but unfortunately they are the symptoms after peritonitis has developed, when operation is of no use. We need more light on this subject, we need more observations on the early symptoms of the disease, we may then hope to be able to say, "If this patient be not operated on he will have peritonitis and will perish:" and to another, "You will undoubtedly recover without operation." At present we are not able so to say, and at present there is much greater safety in early operation than in delay. When we first began to operate in appendicitis I took quite a conservative position but as my experience increased I became more aggressive. I have never been sorry that I operated on a case, but I have several times regretted that I did not.

The society elected as its officers for the ensuing year: President, Dr. D. C. English, New Brunswick; first vice-president, Dr. C. R. P. Fisher, Bound Brook; second vice-president, Dr. Luther M. Halsey, Williamsport; third vice-president, Dr. John J. H. Love, Mount Clair; corresponding secretary, Dr. E. L. B. Godfrey, Camden; secretary, Dr. William Pierson, Orange; treasurer, Dr. Archibald Mercer, Newark. Next place of meeting, Asbury Park, fourth Tuesday in June, 1898, at 12:30 P.M.

Fifteenth German Congress of Internal Medicine.

Berlin, June 9 12, 1897.

(Continued from page 82.)

Unverricht's address was on the Pathogenesis of Epilepsy, which he considers merely a combination of symptoms, instead of a disease *per se*. He has been studying the attacks of convulsions produced in animals by irritating the cerebral cortex, and has become convinced that Kussmaul and Nothnagel are mistaken in attributing such attacks to the pons and medulla oblongata. He asserts that they not only originate in the cortex, but that it is responsible for the further development of the attack. After describing the interesting results of these experiments, which led to the discovery of a homolateral innervation of certain muscles and of a double decussation of cerebral spinal nerve tracts and also of a spot in the cortex, stimulation of which arrested the respiration, he proceeded to describe the attacks produced by irritating the cortex, which only differ from genuine epilepsy in degree, the greater or less violence of the attack. The most important feature of the attacks is that each is divided into two halves, corresponding to the stimulation of the two halves of the cerebrum. First the muscles of the opposite side contract, and then those of the other, in the same sequence, but if the attack progresses very rapidly, the contractions blend into each other and it is difficult to trace them exactly. He found morphin useless in controlling the convulsions, but noted the remarkable efficiency of chloral, which confirms his clinical experience. The importance of the cortex in this respect is shown by the fact that the convulsions are modified by removing parts of the motor region, the corresponding muscles not contracting. If one entire side is removed, the muscles of the other side alone contract, although there seems to be a secondary series of contractions, both tonic and clonic, accompanying the primary contractions of the uninjured side. His experiments also demonstrated that the posterior cortex possesses epileptogenic properties. Study of the arrest of the respiration induced by irritating a certain spot in the cortex, shows that there is first a peculiar "inhibition contraction," and secondly a phase of contractions affecting the muscles of expiration, and distinct from the third phase, which affects the muscles of inspiration.

The effect of the attack on the vascular system is four-fold: first, the pulse is accelerated as the convulsions commence; second, the pulse is rendered slower; third, the pulse is again accelerated, and fourth, returns to normal. This effect then passes to the other side of the body, showing that the attack is in two distinct halves. This effect is independent of the muscle contractions, as it persists after curare poisoning, when an exclusively vasomotor epileptic attack can be observed. Applying the results of these experiments to man, comparative physiology shows that the higher the animal, the more the motor functions are assumed by the cortex, consequently it is reasonable to suppose that epilepsy in man must be of a cortical nature as it is so decidedly cortical in dogs. Clinical observation also points unwaveringly to the cortex. He added that there may be also infracortical attacks. Hoffmann con-

siders the epilepsy that commences with myoclonus, evidence of the infracortical nature of the attacks.

Flechsig has found that the amount of bromin eliminated varies remarkably in different individuals, and that after a time the system becomes saturated with it. In proportion to the amount of bromin taken, the amount of chlorin eliminated is also increased, and if salt is administered with the bromin the latter is eliminated in still larger quantities. When bromin ceases to work he combines opium with it, which Rumpf also recommends for children.

Vierordt proclaimed his favorable experience with the Continuous Iodid Treatment. He stated that 50 per cent. of the cases of angina pectoris due to sclerosis of the coronary arteries thus treated by him in the last five years were remarkably improved. His method is $\frac{1}{4}$ to $\frac{1}{2}$ gram sodium iodid per dosis, or 1 to $1\frac{1}{2}$ to 3 grams per diem in milk or seltzer, followed later by potassium iodid in the form of Sandow salts, continuing this treatment for a long period with occasional intermissions, so that in the first year it is taken daily for nine months in all, and for long periods afterward. The iodid can be combined with digitalis, nitro glycerin, etc., in case of intercurrent heart disturbances. The effect of this long administration is remarkably favorable on the general health, appetite, etc., although in a few cases it had to be interrupted on account of stomach troubles. Iodin coryza was cured by interrupting the treatment and resuming it after a few days. Otherwise there were no inconveniences from its use: Vierordt has been administering it in this way for five years. He is inclined to ascribe its effect to the arrest of the sclerotic process, and the gradual decrease in the blood pressure, which is alone sufficient to explain the relief obtained in all cases of disturbances of the circulatory system, and especially in angina pectoris.

Behring said cellular pathology has proved barren of results in therapeutics, and organ therapeutics has also failed to win a place for itself, but Etiologic Therapeutics has tested remedies on animals made sick artificially, and we have learned for instance that the only remedy capable of curing diphtheria is evolved in the body itself, out of the living and dead infective substance, and the antitoxin of one animal has been found potent applied to others. The antitoxic powers of the organism are concentrated in the serum of the blood. Of all the antitoxins, the diphtheria has been found most effective. Better results would be secured from the tetanus serum if it were kept on hand more generally, so that it could be administered without delay. The value of Marmorek's streptococcus serum is dubious, and Maragliano's tuberculosis serum contains no antitoxins.

All of these blood antitoxins are absolutely harmless in sickness or health. The urticaria, etc., observed at times, are due to defective technique. Ehrlich's experiments with ricin have demonstrated that the antitoxin also neutralizes the toxin outside of the living body, which controverts the theory that the antitoxin works upon the living cell. All attempts to produce the antitoxin chemically have failed. It is not a chemical substance, but a power which can not be manufactured. As iron possesses the magnetic power, the albuminoids of the blood possess this antitoxic power. As the body is immunized more and more, the albuminoids attain a certain amount of this power, but never beyond this. Attempts to induce it with electrolysis have failed. The animal body is the requisite. The toxin determines the special character of the polarization of the normal albuminoids, but does not affect their chemical constitution. Passive immunization by means of prepared antitoxins which induce no reaction, is preferable to active immunization with the direct toxins. He announced that attempts are now being made to lengthen the period of immunity. Where the toxin is still unknown, as in septicemia, attempts to secure antitoxins are fruitless. The toxin of cholera, anthrax and glanders is still too weak for this purpose. He then described his recent attempts to produce a tuberculosis serum, with highly virulent, dry, pure cultures. Taking the minimal fatal dose program of weight of guinea pigs, as the standard m. Behring has succeeded in obtaining a tuberculosis toxin of 25000 T. m. The toxic value of Koch's new tuberculin measured in this way, shows that it is less than the old undiluted. It will prove useful in inoculations of animals, but does not seem to be adapted to therapeutic application on man. There are various substances in the tuberculosis bacillus, but the point of conferring immunity seems to be confined to one single tuberculosis toxin. Years must pass before this antitoxin will be secured sufficiently concentrated in animals for practical application.

Ewald reported his interesting experiments on dogs whose labyrinth had been removed. He stated that the functions of certain parts of the cerebrum to induce voluntary movements,

are substituted by other parts in case of removal of the former, and that the new methods of electric stimulation of the cortex prove that every point of the cortex corresponds to the same muscles. Usually, in normal conditions, only certain points are concerned in this function, but after the loss of a portion of the cerebrum, other portions substitute it. The muscle sense and the sense of touch are necessary to the regulation of movements, and can substitute each other. The muscle sense is seriously affected by the removal of the labyrinth, but as long as the "extremity zones" in even one half of the cortex remain, a labyrinthless dog can stand and walk very well, but if the other half of the extremity zone is removed the movements of walking are paralyzed. He removed at the Congress a small piece of the second half of the cerebrum of a labyrinthless dog he exhibited (0.52 gram), and the animal then became absolutely incapable of moving his legs.

One morning was devoted to presentation of remarkable cases, new instruments, etc., by Boas and others.

Liebreich delivered a long address denouncing modern pharmaceutical therapeutics, so aggressive in tone that the *Semaine Médicale* and some other journals refuse to publish it. He claims that the practice is to publish brilliant hopes instead of actual realities, without waiting for confirmation by actual experimentation on animals. Fürbringer reported sixty-three cases of tubercular meningitis, in which bacilli were found by lumbar puncture in forty-four. An important application is in the diagnosis of cerebral hemorrhage in doubtful cases. Lenhartz reported ten out of twenty cases of severe chlorosis relieved of the intense headache by removing the excess of cerebral fluid by lumbar puncture. Quincke suggested that in cases when the pressure in the brain persists after lumbar puncture, communication is probably interrupted, and the child can be relieved by puncture of the ventricle of the brain.

Eulenburg reviewed the various theories in regard to Basedow's disease and the latest acceptation, which is the modification in the quality and quantity of the blood as the *primum movens*, with alterations in the secretion of the thyroid gland as the secondary cause and a neurosis as the third factor. This combined theory indicates the therapeutics: hematopoiesis, circulation and nutrition are all to be favored, with everything that tones up the system outside of medication, dietetics, hydrotherapeutics, resort to localities at a high altitude, even in winter, and also electrotherapeutics and psychotherapeutics. All that can be said of the iodine treatment in this disease is that it is harmless: the thyroid preparations are ineffectual, as might have been expected. An operation is only indicated when there are local accidents threatening a fatal termination, impossible to control by other means.

Matthes reported that the disassimilation of nitrogenous substances is exaggerated in this disease, which he ascribes to the goitre. After the goitre has been removed the amount of nitrogen in the urine diminishes, but he has administered in such cases the goitre just extirpated, in the form of a powder, when the disassimilation of nitrogen at once begins to rise to its former figure. One patient thus taking his own goitre showed before operation an excretion of nitrogen amounting to 14.2; after the operation this fell to 10.2; 9.6, but when the goitre powder was administered, this rose to 9.15, 10.9 and 12.1.

SELECTION.

Enterorrhaphy: the use of a Carrot.—At the March meeting of the Chicago Medical Society, Dr. John B. Hamilton of Chicago presented a patient with the following remarks: I have here a patient that I wish to present to the Society and also specimens that relate to a subject which we recently had under discussion. You will doubtless recall to mind that we had the question of circular enterorrhaphy under discussion some time since, and the best manner of suturing the intestine after making section. I do not think we can more clearly illustrate that problem than by producing the subject of an operation which I described at that time and subsequently performed on the 3d day of February. The gentleman who sits here entered the Presbyterian Hospital the 1st day of February, or thereabouts, suffering from pronounced intestinal obstruction. An examination revealed a distinct tumor over the sigmoid flexure and a diagnosis of carcinoma of the sigmoid was made. The operation was performed on the 3d of February and the sigmoid removed, which I have here. I also have a section of the

growth under the microscope for your inspection. The specimen has contracted somewhat on account of being immersed in alcohol, but you will see by an examination that the entire lumen of the intestine was practically obstructed. There is another noticeable point about the specimen, and that is, neither the mesentery nor the serous coat of the intestine were involved in the carcinomatous growth, the carcinoma being confined to the mucous and muscular portions of the intestine. I present this specimen and the section on a slide under low power, which shows the epithelial nesting very clearly and its distinctly cancerous nature.

I have here a piece of carrot, such as was used in making the enterorrhaphy in this case. The operation was performed in this way: An incision was made in the median line, because I found the carcinomatous mass was distinctly movable: I then reached it, brought it through the opening, and snugly surrounded the intestine with a piece of rubber ligature at either end of the growth, leaving plenty of clear space. With padded forceps I seized the intestine a little outside of the carcinoma. Then the intestine was cut and the segment carefully separated from the mesentery and the mass was removed. The ends next to the incision were carefully cleansed inside with alcohol, after which the padded forceps were removed, and the remaining bowel cleansed down to the rubber ligature, so that not a drop of fecal matter escaped into the abdomen during the operation. Having done that, a little bobbin was made from a carrot taken out of a basket in the hospital, without any particular preparation of the carrot, except that the skin was peeled off, a central hole bored through it, and the tumbler itself dropped into a jar of alcohol until it was used, remaining there probably ten or fifteen minutes. Then passing the bobbin into the ends, the ends were brought together and a circular enterorrhaphy was done with Lembert's interrupted suture, so as to entirely encircle the wound and make sure that I had made it tight. The patient was returned to bed in forty-five minutes from the time he entered the operating room. I can not say exactly how long the operation itself took, but I noticed on the nurse's record it stated that the patient was absent forty-five minutes. If any of the members desire to examine the patient they can do so while the specimens are being passed around.

Dr. A. J. Ochsner—I would like to ask Dr. Hamilton what method he used in fastening the carrot in the intestine. Did you use the method of Mayo Robson?

Dr. Hamilton—I have for a long time maintained that if our suturing were properly done and our end-to-end approximation carefully executed, the carrot would take care of itself after it was once in the intestine. It was not sewed to the intestine, but simply held there in order to facilitate the sewing process, and the method used was described by me when this subject was discussed in this society on a previous occasion, but in the foreign case quoted, there was a groove cut in either end of the carrot and a circular suture was passed to press the gut into the groove.—*Chicago Medical Recorder*.

[NOTE.—This patient reported himself well in July, 1897, six months after the operation.]

PRACTICAL NOTES.

Aluminum Bronze Wire for Sutures.—Professor Socin of Basel, has been using for some time a soft, flexible wire for superficial sutures which he recommends in high terms in the *Therap. Woch.* of June 30. The alloy is 95 parts copper to 5 parts aluminum, making a wire 0.22 mm. in diameter, which is so flexible that it ties easily, but will bear a weight of 300 kg. It is sterilized by merely laying it in an oven a few minutes, or on a hot stove; threads easily and takes a very fine needle, and as it does not irritate, can be left in place longer. Its special field is in superficial sutures, as the ends of the wire might possibly injure the tissues in buried sutures.

Best Point for injecting insoluble Mercurial Preparations.—M. Möller of Stockholm has been experimenting to discover the least dangerous spot for injections, which he has found to be the superior buttocks, above the upper end of the great trochanter, where the danger of wounding a vein is least of all, if the injection is made in the superficial layer of the gluteus maximus or, better still, just above it.—*Sem. Méd.*, June 10.

Fissures of the Anus Cured with Cocain and Ichthyol.—J. Chéron states that this combination is as certain of success as a surgical operation, while it is much more readily accepted. He tampons the fissure with 1-10 or 1-20 cocain hydrochlorate for five minutes, and then drops one or two drops of pure ichthyol on it from a glass pencil. This process is repeated the following days, dilating the anus if necessary, and finally cauterizing the entire extent of the fissure with the ichthyol. Ten of these treatments will cure recent fissures; older ones require more, but never more than twenty.—*Gaz. de Gynecologie*, Feb. 1, 1897.

Treatment of Hepatic Involvement of Pavidic Origin. (Roussel).—Inject every other day 3 milligrams of strychnin arseniate as follows: Strychnin arseniate, 0.30 gram; sterilized vehicle, q. s. for 100 c.c. Each syringe contains 3 milligrams of the arseniate. Inject also every second day quinin lactate and antipyrin as follows: Quinin lactate, 20 grams; antipyrin, 20 grams; aseptic vehicle q. s. for 100 c.c. Each syringe contains 20 centigrams quinin salts and 20 centigrams antipyrin. The medication should be assisted by hydrotherapy; a cold douche every day.—*Journ. de Méd. de Paris*, June 20.

Hypodermic Treatment of Cerebral Apoplexy.—The *Journ. de Méd. de Paris*, June 20, observes that strychnin arseniate is clearly indicated after the attack. Huchard recommends injections of ergotinin according to Tanret's formula as follows: Ergotinin, 5 centigrams; lactic acid, 10 centigrams; aseptic vehicle, q. s. for 100 c.c. Each syringe contains $\frac{1}{2}$ milligram ergotinin. Dose, 1 to 2 cubic centimeters. Others recommend ergotin as follows: Bonjean ergotin, 20 grams; sterilized vehicle, q. s. for 100 c.c. Each syringe contains 20 centigrams of the active element. Dose, 1 to 2 cubic centimeters.

Eunatrol, a New Chologogue.—In the *London Therapist*, April 15, Dr. F. Blum of Frankfort-on-Main reports the use of sodium oleate as a stimulus to the biliary secretion. The commercial oleate being too crude to serve as a medicine, he caused a chemist firm to prepare for him a pure article, in the form of a white powder, having a low melting point and relatively free from rancid taste. To this preparation has been given the name "eunatrol," and its preferable administration being in pill form, each pill containing four grains eunatrol, with a coating of chocolate. Chologogues are undoubtedly indicated in various forms of liver disease, but there is a scanty selection. At the beginning of last year Stadelmann indicated salicylate of sodium and gallates as the only reliable chologogues. Sodium oleate is preferable to any of these. Its stimulation of the biliary secretion is rather more than less, while in the form of eunatrol pills it may be administered without discomfort or intestinal disturbance.

Remittent Fever of Mexico.—M. Perez describes this disease in the *Revista Medica* of June 15, and warns against ascribing it to a malarial origin, as it is more correctly of a typhoid nature and is not affected by quinin. It seems to be confined to children, is epidemic at times, and is accompanied by considerable constitutional disturbance, constipation in the light cases and diarrhea in the severe. The disease lasts two to four weeks and leaves the patient much debilitated. Perez has never known a fatal case, but fancies that it is increasing in severity. No medicines have been found effectual in aborting an attack: he administers calomel in the severe cases. It differs from typhoid by the lack of nervous symptoms and complications.

The pain in the epigastrium is continual, but not in the iliac fossa: there are no chills, and the fever resembles that of typhoid in its course.

Kleinwachter's Vaginal Suppositories.—A year or so ago L. Kleinwachter stated in a German gynecologic journal that in the cases of deformed pelvis, etc., in which the physician has to forbid childbearing, the purpose could be accomplished by using each time a 10 per cent. boric acid vaginal suppository, or one with 0.001 gram sublimate. Some unscrupulous firms over the border began to manufacture such suppositories, using his name, with a sensational subtitle, and advertising them extensively. He protests most emphatically against this abuse of his name and the misapplication of his announcement, in a letter to the *Deutsche Med. Woch.*, No. 16.

Electrolytic Epilation in Therapeutics.—Ehrmann claims that this is not merely a cosmetic operation, but directly therapeutic in its effects in some cases. He describes the technique in the *Therapeutische Woch.* of June 20, recommending his improved pointed steel needle, bent in the middle at a right angle so that its course can be readily followed by the eye. The current should never be over 2 milliampères and applied usually only 60 to 80 seconds, when the papilla should be destroyed, and a slight foam appear around the needle. Among the dermatologic cases he has thus cured was a coccogenic sycosis of nine years' standing.

Success of Mercury in Tuberculosis.—Fournier and others have recently reported surprising cures of cutaneous and osseous tuberculosis with mercurial antisyphilitic treatment, and Dubois has been using mercury in tuberculosis for five years with results that have surpassed all his expectations. Patients thus treated have been restored to health with astonishing rapidity, and although he does not venture yet to call them cured, still the improvement has been such that they have resumed their usual occupations and scarcely remember their pulmonary affection. He uses a thousandth solution of the bichlorid of mercury, injecting $\frac{1}{2}$ c.c. every other day in the subspinal or subclavicular region. By the end of two weeks he injects 1 c.c. He described twenty cases in a recent communication to the Académie de Médecine, which received his report with enthusiasm.—*Bulletin*, February 2.

Ichthyol in Ophthalmology is destined to occupy as important a place as in dermatology and gynecology, is announced by those who have made a special study of its effects in all kinds of conjunctivitis and blepharitis. Jacovidés in the *Revue Méd.* of February 3, describes his experience with it, and states that it affects all the inflamed tissues by vaso-constriction, having also an analgesic effect. It modifies and dries up the conjunctival secretions by its astringent action (except in neonatorum) and in cases of pannus it is invaluable in clearing up the cornea.

Aneurysms of the Aorta.—Prof. B. Gerhardt remarks that the last few years have established two important facts in regard to this affection. The first is the comparative frequency of latent aneurysms of the aorta, which occasion little if any disturbance and only a few slight vague objective symptoms, until they burst suddenly into a neighboring organ. The first indication of their existence is the paralysis of the left vocal chord, signaled by Traube. Auscultation will also sometimes reveal an arterio-diastolic sound, not perceptible at the emergence of the aorta, produced by contraction or dilatation of the aorta. The pulsation is also a valuable indication in such cases: also heart systolic coarse râle. The second point is the connection between aneurysms of the aorta and syphilis. M. Schmidt has cured aneurysms of the aorta with anti-syphilitic treatment, and Gerhardt suggests that in certain cases we may be justified in combining mercury with the usual potassium iodid treatment. The large canals that carry air into the lungs, blood into the arteries and food into the stomach cross before the third and fourth dorsal vertebrae, and they are here exposed to numerous mechanical influences and movements. Each can compress the others at times, and this region is a chosen location for carcinoma, as well as for aneurysms, which are frequently accompanied by syphilitic tracheo-broncho-stenosis. In tabes, also, aortic insufficiency is the usual heart defect. In 25 cases of aneurysms of the aorta in his clinic, 17 were men and 8 were women. In 13 cases the diagnosis was confirmed by the necropsy. Nine of the men had had syphilis (53 per cent.). Other causes were trauma, 5; potus, 2; over-exertion, 3; anxiety, 1, and anger, 1. In 8 cases there had been rheumatic antecedents.—*Deutsche Med. Woch.*, June 10.

THE

Journal of the American Medical Association

PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
 Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
 No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, JULY 24, 1897.

LIFE INSURANCE FEES FOR MEDICAL TOUTS.

The JOURNAL's editorial (July 3, 1897) on this subject has led to considerable inquiry as to the insurance company intended. As guesses entirely erroneous have been made, it is obvious that more than one company is guilty of the procedure criticized. It is also obvious that there is a very active war between insurance agents who are virtuously desirous of punishing the other company for practices of which some are equally guilty. The coincidence of the reduction of the fees of the life insurance medical examiners with the multiplicity of offers made to medical tout indicates that, as the JOURNAL pointed out, a very unsound state of things, financially speaking, exists in many life insurance companies. The JOURNAL has repeatedly urged the medical profession to take an active part in political affairs, for the reasons that the interests of the medical profession demand such action, and because the best interests of the community are intimately connected with those of the profession. Agitations in medical societies against reduction of life insurance fees have not yet evolved into any practical or well-directed action. The first step in this direction would be the organization of a proper committee in both State and local societies which could quietly exert pressure on the delinquent company by application with needed evidence to the proper public authorities. The same influence could be quietly employed

against certain banks, which as already pointed out by the JOURNAL, lend their depositors money on the stock of incorporated associations for the practice of quackery and the sale of nostrums. The difficulty in both cases would be to secure evidence. Agitation, however, if kept up would often prove sufficient to deter financial magnates either of life insurance companies or banks from misdirecting their energies in this direction.

The question raised as to the position taken by the JOURNAL, in regard to life insurance fees half a century ago, is answered by reference to the attitude of the leading medical journals of that time toward the fees then paid. The *Boston Medical and Surgical Journal* (June 21, 1855, p. 425) says anent life insurance fees.

It is a little remarkable that the profession in Boston has so long submitted to imposition on the part of life insurance companies. In London, chiefly by the exertion of a few public-spirited individuals, most of these corporations have been compelled to pay over to medical men whose opinions they consult the fees so justly their due; but here not only is the fee, when paid at all, ridiculously small, but some offices refuse to pay anything, leaving the physician to get it out of the applicant if he can. The amount insured in some instances is several thousand dollars. To protect themselves from loss a list of queries is presented by the companies to the physician, frequently ending with the modest request, "Do you advise us to take the risk?" And for the important information obtained how much do they offer to pay? One or two dollars in some cases, in others nothing. We should like to see an insurance company tender such a fee to a lawyer for an equivalent opinion. Five dollars is the lowest fee which any respectable physician ought to take for the examination of an applicant for insurance.

But we are told the medical opinion is for the benefit of the insured. Then why does the officer demand it? We never knew the applicant to desire such an investigation, though he may be compelled to submit to it in order to obtain his policy. The reverse is plainly the case. The opinion of a medical man is always of vital importance to a life insurance company. Without it they would soon be compelled to shut up their offices. If they choose to have the opinion, they ought to pay for it and pay liberally. The higher the fee the more sure they will be of getting good advice, for though we are always ready to serve the poor to the best of our ability without remuneration, yet the maxim that "an opinion without a fee is good for nothing" ought to hold good towards the rich.

The remedy is simple and in our own hands, if the profession will unite to protect themselves against a great imposition. Let every physician refuse to give an opinion as to the value of a life unless he receives a fair remuneration for the same; and let him insist on receiving the fee from the office who asks the opinion. In other words let him demand from corporations the same equivalent for his services that he does from individuals.

The method then pursued to secure medical tout was a little more ingenious and also, it must be admitted more disingenuous, since it enforced the practitioner to be a tout or endure pecuniary loss. The *Boston Medical and Surgical Journal* (Vol. lxx. p. 288) felt compelled to issue the following warning:

We advise physicians to be on their guard against life insurance agents who seek to induce them to insure their lives on the promise of an appointment as medical examiner for the company the agent represents, the position to be immensely lucrative, the physician to be the sole examiner. The position turns out not to be so very lucrative and somehow or other more than one physician finds himself to be the sole examiner. A certain agent of a New York company has been practicing this game successfully in this city.

Punishment of medical examiners as a means of reaching medical tout (who need not be examiners

at all, or might even be medical directors as in the Anglo-Bengalee case), would certainly be a most absurd injustice and ineffacious remedy. "Business" officials (agents and others), not the medical examiners, are the persons responsible for "tout" evil, which after all is but evidence of deeper financial unsoundness.

THE THEORIES OF ECTOPIC PREGNANCY.

Within the past ten years our notions in regard to ectopic pregnancy have been considerably modified: from being considered a very rare accident, it has come to be recognized as comparatively frequent; the older ideas as to its location have been largely given up; primary abdominal pregnancy is held by most recent writers as impossible and an ovarian one as at least very dubious. The tendency now is to consider all extra-uterine gestation as originating at least in the tubes, whatever its subsequent fate may be. The causes of the condition are, on the other hand, still debatable, and no one theory is admitted as generally acceptable. It is easy enough to suppose a mechanical obstruction preventing the passage of the impregnated ovum to the uterus, but the majority of cases of tubal pregnancy occur at or very near the ampullar extremity of the tube instead of in its middle or proximal portion, as would be presumably the case were this the general or universal cause. There is also the question whether the ovum can normally develop in the tube even when obstructed there, to be decided, and this has not yet been satisfactorily answered. We know that the uterus is in the highest mammals the normal place for its development, and there is therefore a reasonable presumption that the tubes have become more or less unfitted for this function.

If we could admit, with LAWSON TAIT and some others, that normal impregnation only occurs in the uterine cavity, and that its happening above this in the genital passages is altogether exceptional, then the question would be much simpler. Modern physiologies teach us, however, that it does occur higher, and there is ample evidence that the spermatozoa are not especially limited in their wanderings by any obstruction at the uterine extremity of the tubes. This fact, nevertheless, does not settle the question, but only complicates it, and it is making a pure assumption to claim that fertilization normally, or even commonly, takes place in the tubes. Reproduction is not altogether the same process in the littering animals that are commonly used for physiologic experimentation that it is in man, and it is unfair to deduce absolute conclusions as to the human species from observations upon them.

Admitting, as we must, that the uterus is the only normal situation for the attachment of the ovum, the question remains, What abnormalities of the ovum or tube can cause its lodgment in any other place? The

abnormalities of the ovum, except under special conditions, are unimportant: they could not be efficient in producing extra-uterine pregnancy alone. It is normal for the impregnated ovum to implant itself when it reaches a suitable location, and if the impregnation habitually occurs in the tubes it is good evidence that they are not normally suitable for its attachment and growth. Excessive size of the ovum is unlikely to be a cause; the Fallopian tube can allow passage to an egg of several times the diameter of the unfertilized ovum, and one must assume a very remarkable growth after fertilization to make this a possible cause of its lodgment in the tube. The fact already noted, that the great majority of tubal pregnancies occur in the widest part of the tube, is also against this supposition. If we can suppose any extensive enlargement of the unattached ovum, bathed as it is in a possibly nutritive fluid, this would be most likely to occur, according to SIPPEL's hypothesis, in cases of its transmigration from the opposite ovary across the abdomen, which must require a considerable time, while its ordinary passage through the tube must be a comparatively rapid one. This, however, like all other mechanical theories, requires us to assume that the tube can, under ordinary conditions, furnish a suitable nidus, which assumption has not been as yet fully justified. The same is true of any supposition of any alteration, roughness, etc., of the egg favoring its lodgment in the tube.

The question remains, therefore, as to what special conditions of the tube can render tubal pregnancy possible: and this really appears to be the important one. The possibilities of mechanical hindrance to the passage of the egg, pressure of tumors, kinks or excessive tortuosity, accessory tubes and ostia, etc., can be dismissed with a word or two: they are sufficient, provided the tubal lining can furnish a nidus. The question therefore narrows down to this. What are the abnormal conditions that will supply this requisite? The rather popular notion that inflammatory alterations, the relics of salpingitis, will do this, is based as much as anything upon the stated frequency of the occurrence of ectopic gestation after long periods of sterility, these latter being credited to tubal disease. While it is possible, for all we know, for alterations to thus occur in the tubal mucosa favoring this condition, it is not advisable to give them too much weight. A diseased uterine surface does not especially favor conception, and there is no special reason why we should suppose a morbid tubal mucosa should. It is moreover not uniformly found in tubal pregnancies, and therefore can not be considered as its general attendant, much less its essential cause.

An antiperistalsis of the tube has been suggested, and has received some credence as explaining the cases supposed to be connected with shock, sudden fright, sexual excitement, etc. This theory is defec-

ve in that like others it depends upon the assumption that the tubal lining is at all times ready under special extrinsic conditions to lodge the ovum.

Probably as satisfactory a hypothesis as any that has yet been offered is that proposed by J. CLARENCE WEBSTER in his recent work on Ectopic Pregnancy. He assumes a reversional state of the tubal mucous membrane that exists in certain cases and renders possible the attachment and growth of the ovum when other circumstances also favor it. This condition is not understood to insure the attachment, but simply to make it possible—there may be many variations in degree of the reversional process. It explains the repetition of tubal pregnancy in the same individual, that has been repeatedly observed, and precluding, as is very possible if not entirely probable, that the tubal nidus is unfavorable to nutrition and growth, it will explain also the long periods of sterility by the possible frequent occurrence of immediate early death of the germ before it has developed sufficiently to produce any serious disturbance. It is based upon good morphologic facts and there is no more reason why a minute functional reversional peculiarity should not exist occasionally than that such structural ones as bicornate uteri should occur. At best, however, it is only an hypothesis that has not yet had and may never have its truth fully demonstrated. Thus far we are in the speculative stage regarding the causation of extra-uterine pregnancy. There is not even any very good reason to suppose that the impregnated ovum can survive long unattached, even in the fluids of the body, and if this fact could be demonstrated it would help to clear the mist that overhangs the subject.

SKIAGRAPHY IN MEDICAL JURISPRUDENCE.

Recent decisions as to the admissibility of skiagraphs in evidence have created considerable medical comment, especially as the decisions of the courts are apparently in some instances contradictory. In quite a number of instances the skiagraph has been refused admission in evidence on the ground that its identity is not established to the satisfaction of the court. In other instances it has been refused admission on the ground that the procedure had not been shown to be sufficiently free from elements of error to have these properly eliminated from the consideration of the jury. In other cases, in direct defiance of the principles first outlined, the courts have admitted skiagraphs sometimes after foundation had been laid for their introductions and sometimes without this foundation. The greater part of medical criticism has been directed against the judges who refuse to admit the skiagraphs. It has been asserted in total defiance of experience gained in the case of the photograph, the X-ray-like light could not lie. The manipulation of photographs

was proven to be perfectly possible in certain frauds against life insurance companies. To judge from a recent case reported by Dr. GEORGE EVERSON of Brooklyn (*American Medico-Surgical Bull.*, July 10, 1897) such manipulation is equally possible in the case of the skiagraph. His case was that of a 14-year-old girl of luetic diathesis, who was taken to a reliable X-ray studio for a skiagraph of the left leg, previous to operation on June 3. The skiagraph shows at the middle and lower end of the tibia exostoses. The lower end of the tibia is more translucent, and extending to the fibula from below upward and backward is a straight foreign body. At the operation, five days later, an incision from just above the ankle joint to the tibial tubercle, exposed two eburnations, one at the middle of the shaft and one at the lower third, numerous osteophytes which do not show in the skiagraph, and on the tibial articular end formation of osteitis, but on diligent search no foreign body. The girl and her father insist that there could not have been anything in her stocking. The X-ray people can offer no explanation and plead ignorance. The night previous to operation the girl was sent to the studio for fluoroscopic marking with indelible pencil.

The astonishingly enthusiastic claims that have been made for the infallibility of the skiagraph constitute a serious danger to the physician in the case of malpractice suits. The apparent demonstration of existence of an unhealed fracture or of an imperfectly healed one, which a skiagraph furnishes to a jury, is a potent weapon in the hands of an unscrupulous attorney conducting a malpractice suit. Every plea made for admission of the skiagraph in evidence, unguarded by the old rules obtaining in the case of photographs, handwriting, etc., is a plea for methods whereby many a conscientious practitioner will be mulcted at the hands of an ordinary jury. Dr. EVERSON'S case significantly demonstrates how easily skiagraphs could be manufactured to fit a given suit for malpractice. Failure of identification of these skiagraphs would destroy their legal value theoretically, but they would be none the less without effect on the minds of the jury to whom they had been exhibited. If the X-ray be to play any part in medical jurisprudence, it must be subject to the time-honored rules of evidence which centuries of the English common law have shown to be best adapted to secure the rights of the individual. The medical journalists who are berating the judges for not ignoring these rules are preparing a scourge for the members of their own profession.

We also wish to call particular attention to the fact that recent callus between the fragments of broken bone is penetrated by the X-ray, is translucent and consequently appears in the skiagraph as a case of non-union. Many mistakes have occurred from inattention to or ignorance of this fact.

IS DIABETES INCREASING?

It has been claimed in a number of quarters without the claimants presenting statistical evidence, that there has been, during the last few years, a very distinct increase in the number of cases of diabetic mellitus in private and hospital practice, and while statistics in regard to private practice are difficult to obtain, there can be no doubt that this condition is far more frequently met with today by the general practitioner and the specialist in diseases of the urinary organs and nervous system than it was some years ago. That the disease is on the increase seems to be proved beyond doubt by a number of statistical papers which have recently appeared. As long ago as 1895 LEPINE, in the *Revue de Médecine*, in a paper upon "The Geographic Distribution of Diabetes Mellitus," showed that in Paris the increase in this disease was quite extraordinary. Thus from 1865 to 1873 there were only three cases per year in 100,000 inhabitants, but by a process of steady increase it was noted that from 1887 to 1892 there were twelve or thirteen patients per year to the 100,000 inhabitants. He also presented statistics from various German and English sources which supported the view that diabetes was a disease of increasing frequency not only in Paris but in other cities and countries. It is interesting to note too, that PURDY, in his book on diabetes, points out that in the United States census it is stated that the death rate from diabetes mellitus in 1860 was 72 per 100,000. This increased to 98 per 100,000 in 1870 and to 170 per 100,000 in 1870, while the result of the census of 1890 is 191 per 100,000. In other words, during the space of thirty years the increase of mortality from diabetes was approximately 150 per cent. It is certainly true that a certain proportion of this increase must be placed to the credit of improved diagnostic methods, and there can be no doubt that twenty or thirty years ago a certain number of cases of diabetes mellitus came to their death under a diagnosis of "carbuncles," "galloping consumption," or some similar term, simply because the physician was careless or did not know how to properly test the urine for sugar. While this very extraordinary increase of diabetes mellitus in the United States has taken place it is also a noteworthy fact that a similar increase has taken place in England and Wales, and this increase has occurred not only among the well-to-do and sedentary class, but also has extended throughout the entire population. Thus according to ROBERTS, the decade from 1850 to 1860 showed only 1,546 deaths from diabetes mellitus; whereas, in the ten years from 1884 to 1893, 17,794 patients were registered as dying from diabetes in England and Wales. As SAUNDBY in his well-known volume upon "Renal and Urinary Diseases" has pointed out, even if we allow for the increase of population, the increase in death rate is over 70 per cent. FOWLER has also shown

that the mortality from diabetes mellitus in New York City has increased from 42 to 105. A large number of additional statistics might be quoted from German authors showing the disease is also on the increase in that country. It seems hardly worth while, in view of the evidence that has already been adduced and that which is about to be given, to consume further space with their discussion.

Recently a paper has been published in the *Medical News* by HARE which shows that there has been a similar increase of diabetes in hospital practice in Philadelphia, and although we were informed by OSLER in his "Practice of Medicine" that out of 35,000 cases presenting themselves at the Johns Hopkins Hospital only ten cases of diabetes mellitus were found, we regret that hospital statistics in Philadelphia and in London are directly opposed to his results. Thus in the paper quoted it is shown that at St. Bartholomew's Hospital, for example, in the ten years beginning with 1860, there were 71 diabetics out of about 38,500 patients, whereas from 1870 to 1880 there were 139 diabetics out of less than 24,000 patients, and in the decade from 1880 to 1890 there were 197 diabetics out of less than 27,000 patients. So, too, at St. Thomas' Hospital in London, the decade from 1860 to 1870 shows 47 cases out of a little less than 10,000 patients, while the succeeding ten years 61 diabetics were treated in 13,500 patients, and from 1880 to 1890 there were 81 out of less than 20,000 patients.

It is evident, therefore, that the proportion of diabetes in hospital practice at the present time equals about 1 in 540 cases, and it is our belief that could accurate statistics be obtained it would be found that the proportion in private practice, or in other words in the higher walks of life, is far higher than this, perhaps as high as 1 in 200 or 1 in 250 cases.

CONCERNING THE DERIVATION OF THE BLOOD PLATES.

Our understanding of the origin of the blood plates is rather indefinite. While the idea that they were precipitates from the plasma has been abandoned and while they are now regarded as cellular derivatives, yet the opinions differ widely as to the cells from which they are derived. The general or most accepted view is that they owe their origin to a leucocytic disintegration, but many investigators attribute the plates to the red blood corpuscles. WLASSOW¹ observed peculiar extrusion and disintegration phenomena in the red corpuscles under varying conditions, which he regarded as evidences of this mode of origin. Very recently J. ARNOLD² of Heidelberg has made certain studies in this direction, the results of which seem to be of importance. ARNOLD observed that in mixtures

¹ Ziegler's Beiträge, 1894.

² Ueber die Herkunft der Blutplättchen, Centralbl. f. Allg. Path. und Path. Anat., viii B., p. 289 et s.

of blood with a 10 per cent. solution of iodid of potassium the red corpuscles show very marked appearances of processes of extrusion giving rise to bodies that seemed identical with the blood plates. This observation pointed out the necessity of studying the blood plates in vessels of the living animals, as other investigators had already commenced. Similar processes of extrusion were, indeed, observed in the red corpuscles in the mesentery of young mice; furthermore, that in vessels with quiescent blood an increase of blood plates took place under conditions that excluded their origin from leucocytes and from accumulation of those elsewhere in the circulation.

ARNOLD then studied the appearances in young guinea pigs only a few days old. The animal was fastened on its back to a stage with an irrigation apparatus, an incision made into the left side of the abdomen, and with some care it was then possible to so spread a loop of intestine that the vessels could be examined with the microscope. The field was irrigated with warm physiologic salt solution. Cover glass was found unnecessary and the objective was immersed directly in the fluid. The following were the principal forms of extrusion observed:

1. The red corpuscles may show globular or more oblong elevations that are usually lighter in color than the corpuscle and which possess a peculiar glistening appearance. With time they become still paler, their connection with the corpuscle thinner, and finally they separate. Immediately after the separation the formations are rather oblong, soon they become round, they lose their color, become granular and disintegrate.

2. The red blood corpuscles assume a mulberry form and the elevations separate one by one, or more simultaneously. The further changes are the same as those described under 1.

3. The mulberry-shaped corpuscles separate in two or more equally large, somewhat sharp-cornered pieces that become pale and finely granular. These pieces may disintegrate into a finely granular mass that may cover the wall of the vessel and partly fill the lumen.

These intravascular changes correspond therefore in a marked degree with the extravascular. The participation of leucocytes in this process could be positively excluded.

ARNOLD draws the following conclusions from his experiments.

1. The intravascular and extravascular processes of extrusion and fragmentation of the red corpuscles proceed according to the same type.

2. The intravascular and extravascular formations show marked variations in respect to form, size and amount of hemoglobin. They may be larger and smaller, round and those with corners, those with and those without hemoglobin.

3. The intravascular processes of this kind are, in

mammals, in genetic relation to the origin of the blood plates.

4. Blood plates are formed when the possibility of accumulation from elsewhere and of disintegration of leucocytes is excluded.

5. The disintegration of red corpuscles within the vessels and the further changes in the resulting débris may furnish material for the formation of a kind of thrombi.

CORRESPONDENCE.

Correspondence from Scotland.

To the Editor:—I have spent a few days in Glasgow, visiting the old Royal and the new Western Infirmary. It was at the former, I believe, where Mr. Lister began his career as a teacher and investigator, and where he developed our modern knowledge as to the nature of wound infection: researches that have been of incalculable benefit to the world, and given its author a place among the few, the immortal few, that were not born to die.

I was a little late at my first visit to the Royal and the operator (whose name I will not mention) was all ready to begin a Syme's operation for disease of the bones of the foot. To my amazement he reached out and gave me a hearty welcome by shaking me by the hand. I took my seat and watched carefully what he would do next as the patient was already anesthetized and he was ready to begin the operation. He dipped his hands for an instant into a 2½ per cent. solution of carbolic acid and began by making an incision from one malleolus to the other, down between the os calcis and other bones of the foot, turning his flap back and then dissecting the tissues from the bone from above downward. About this time, the patient began to have some bad respiratory symptoms. The doctor gave the anesthetizer some directions as to pulling the lower jaw forward and pulling out the tongue, then he went to the head of the patient, caught the angles of his lower jaw and throwing his head backward soon had him breathing better. Without sterilizing his hands in any way, the doctor then went on with the operation.

The next operation was amputation at the lower third of the femur for disease of that bone near the knee joint. The doctor washed and was just ready to make the first incision, when he was called to the telephone: he answered the call and without washing or in any way attempting to sterilize his hands, he proceeded to the amputation. After these operations the morbid specimens were carefully examined, and the first showed the internal cuneiform bone of the foot extensively diseased: in the second there was found a sequestrum in the center of the lower end of the shaft of the femur. The doctor explained that while the operations he had done might not seem sufficiently conservative, he was convinced that when bone disease, as in these two cases, was due to tuberculosis and not trauma, a radical procedure should be adopted, thus ridding the patient of every vestige of the diseased process.

This was the first surgical clinic that I witnessed in Scotland during my recent visit to Europe. I was in the same amphitheater where Mr. Lister first taught, witnessing an operation done by a pupil of his, and a man of considerable surgical distinction, and yet what a farce the whole thing was, viewed from an antiseptic point. The whole affair would have put a surgeon of Berlin into hysterics, and would be considered a farce by any modern surgeon who pretends to practice the technique of modern antiseptic surgery.

Everywhere in Scotland chloroform seems to be the only anesthetic used; and here, as everywhere else, everybody who

used this drug seemed to be in mortal fear of a catastrophe which might result in the death of the patient. Of the many operations that I have seen done here in Scotland, I do not remember seeing a single one finished without the operator showing more or less anxiety as to whether his patient was not going to be killed by the anesthetic that was being used. You ask any of them why they use this agent exclusively instead of a safer one, and in substance they will give you the same reply, here in Scotland we all use chloroform.

Mr. Macewen of the Western Infirmary is probably the most renowned surgeon now living in Scotland. His surgery has placed him in the front ranks as an operator in these two fields. I found him quite willing to accord to American surgery the distinction of having been the pioneers in the development of the surgery of the appendix. But here, as everywhere, I find that the men who look upon diseases of the appendix from a purely surgical standpoint, are not in accord as to the cases we should treat with the knife. The Doctor related to me the history of several cases of the foudroyant type, where perforation had evidently taken place at the outset of the attack, accompanied by a general peritonitis; and in all of these the Doctor had operated and all terminated fatally. I was the guest of too great a man to play the rôle of a critic; had I not been, I should have told him that these cases belong to a class upon which I would not operate and that in this matter I believed I was in accord with the majority of American surgeons. I saw some gynecologic work done in Glasgow. I suppose that it is not strange that one who has for his ideal the best work of the best men where gynecology, as far as surgery is concerned, really had her birth, would not be well satisfied with what he saw here.

Edinburgh.—It is thirty one years since I made my first visit to this renowned educational center, and it is twenty years since I was last here. Time has made sad havoc in the ranks of the men who taught me during these years. Lister and Mathews Duncan are in London, Symes, Spence, Bennet and the elder Simpson are all dead. In fact, I do not recognize among any of the prominent men who do the clinical teaching here today a single man who was on duty twenty years ago. Though perhaps my ideal of what constitutes a great physician and a renowned teacher may have changed with the lapse of years, still I think it would be no invidious comparison to assert that the medical faculty in Edinburgh University today are far from being the peers of those who taught us a quarter of a century ago. But in one thing I find them all like their predecessors, hospitable and polite toward their fellow physicians. Your card and a civilized and genteel deportment will accord to you, here in Edinburgh, a cordiality of reception that you will receive nowhere else on earth. Students and dresser are made to stand aside so that you may see the minute technique of every operation; and if you are staying some weeks in the city you are likely to be invited to the homes of the best medical men in the Scotch capital. Among the foremost surgeons and teachers at present in Edinburgh is Mr. Chiene, who succeeded the late Mr. Spence. He is a painstaking, neat, though slow operator, and an excellent teacher. His antisepsis, though in no way carried out with the rigor that one will find in Germany and America, is fairly and carefully executed. I saw him do several operations for varicocele by the ordinary open incision. He said that in all operations where the scrotum is to be opened most thorough drainage must be instituted, for it was not possible to tie the blood vessels so that a considerable oozing would not follow the operation. He did not believe, as was taught by many, that this disease had anything to do with the nutrition of the testicle. Furthermore, in a vast majority of the cases he operated simply for the psychologic effect upon the patient, for young men affected with this trouble are prone to become extremely melancholic, and you have got to do something to produce a profound impression upon their minds.

For the closing of wounds of nearly all kinds they use horse hair. They claim that its main advantage over silver wire, silk or silkworm gut is that it has a certain amount of elasticity about it, by which it will stretch if your wound edges swell, and thus not obstruct the circulation of the parts. Mr. Chiene claims that stitch abscesses are generally due to necrotic tissue that is produced by a too tight and too unyielding suture, and that the use of horse hair obviates this untoward event.

In operating for the removal of diseased lymphatics of the neck, he found some of them broken down and so infiltrated into the surrounding tissues that it was impossible to remove all the diseased mass, so he scraped out all that could be removed, and instead of draining these cavities swabbed them out with a strong solution of carbolic acid, and then closed up the wound with horse hair sutures. He says that these will usually heal without any secondary process of suppuration. In tying his horse hair sutures he gives them four turns and ties only a single knot, claiming that they will hold together, and are easily loosened, when you can press out any effusion that may have occurred in the deep part of the wound and tighten your sutures again, and so allow your wound to be permanently closed.

In a bone operation on the tibia he removed a large part of the shaft, and in dressing it he first cut narrow strips of oiled silk, coated with dextrin, and put one piece after another over the bone, allowing them to cover over the bottom of the bone surface. He now packed his gauze into the bone cavity, having a layer of this oiled silk everywhere between the bone and gauze. He claims a great advantage in this mode of dressing over that of packing the gauze in direct contact with the bone, as in this latter case your tender granulations are always torn off at each dressing, and thus the process of repair is materially interfered with. I saw him do an amputation at the hip joint in a very anemic patient with very little loss of blood. He amputated the bone about six inches below the joint, controlling the hemorrhage by an elastic bandage, and after all bleeding vessels were carefully tied he removed the remainder of the femur by an incision on the upper aspect of the thigh. Speaking in this connection of what he said Americans were wont to call Wyeth's mode of arresting bleeding in this operation, he waxed warm and declared that his predecessor, Mr. Spence, had done and illustrated this technique long before Wyeth ever wrote a book. Chiene said he had written to Wyeth, as well as to Dr. Keen, and had referred both of them to printed evidences of Spence's priority in this matter, but neither had paid any attention to his communication. The burning question of dispensary abuse seemed to be agitated quite as much here as with us in America. Chiene related an instance where he had recently done a charity operation in the infirmary, in which he found out that the friends of the patient were living at a swell hotel on Princes Street, and each paying £1 a day for their board. He said that here in Edinburgh there seemed to be no way of excluding these moneyed people from getting services that were intended for the poor, for by a curious old law and custom, no one who appeared at the door of this infirmary and demanded the services of any man, could be turned away. The only way in which he could get even with this class of drones was to give them a sound abusing.

I was discussing the treatment of croupous pneumonia with one of the leading physicians of Edinburgh, telling him of its terrible ravages among the old and middle aged at home. He seemed so non committal that I pressed him for a general outline of his management of these cases. His reply was, "Dr. C., I never had pneumonia myself, but were I attacked with the disease, I should choose a good efficient nurse and throw physic to the dogs." So the reader can see what I have learned concerning the management of this terrible disease in Scotland.

At a late meeting of those interested in sanitary matters at Aberdeen, a most curious state of affairs was disclosed as to

the condition of the rural population of Scotland, and especially of those who inhabit the outlying islands on the western coasts. One of the speakers asserted that the sanitary condition of these people was not a whit better than it was five hundred years ago. Their dwellings were covered with wet decayed thatch roofs: the interior of their houses was dirty and damp; the whole aspect of the thing was a disgrace to our modern civilization; but the most discouraging aspect of the whole thing was, that this people looked upon all efforts made to better their condition as an infringement on their natural rights, and so nothing could be accomplished in the way of their improvement. It was shown at this meeting that the lessened mortality in Scotland, which modern sanitary science has achieved, is the result of a better mode of life adopted by those who live in cities, and that the general mortality among the rural population is probably as high today as it was five centuries ago.

W. S. CALDWELL, M.D.

Freeport, Ill.

"Electropoise" and the Medical Profession.

PHILADELPHIA, July 14, 1897.

To the Editor: I am glad to see the letter of Dr. Kreider in the JOURNAL of July 10, and write to put physicians on their guard as to other publications than *Harpers Monthly* and the *New York Christian Advocate*. Several years ago I took the *Literary Digest*, but became disgusted because the advertising and even the reading columns were constantly used to humbug the public as to *electropoise*. I wrote letters of protest to the editors and publishers of the journal, but they only brought me answers of enthusiastic praise of the thing and advertisements and certificates *ad nauseam*. I tried by reason to show the publishers and editors that in matters of special knowledge expert and not lay opinion was only of value in judging of the work of a discovery, and I tried to get them to sound the medical profession as to their advertised article. It was of course useless and I renounced the publications of Messrs. Funk and Wagnalls. They evidently thought the advertiser's checks of more value than the support of the medical profession, and for a house laying claim to superior intelligence and piety I doubt not the managers have convinced themselves that in this case ethical interests are identical with commercial ones. The lesson is hard for our profession to learn, but it is one that we must learn before quackery will be less of a nuisance and disgrace to our people than it now is. But the lesson is at all times plain: The profession must bring its collective influence to bear upon the quacks in a commercial sense. They do not fear our contempt so long as we buy the periodicals they control and do not take measures to educate lay opinion.

GEO. M. GOULD, M.D.

May Engender Prejudice in Bicycling.

HOT SPRINGS, ARK., July 14, 1897.

To the Editor:—Anent Dr. Destot's account of "Paralysis of the Forearm from Bicycling," quoted in the issue of July 10 from the *Gazette des Hôpitaux*, it strikes me that the Doctor's unfortunate experience is sufficient evidence of his having been badly instructed in the art of riding a bicycle, and it should by no means have any prejudicial weight with those of us who might wish to prescribe the wheel as an available and useful exercise. One of the first errors an uninstructed beginner will fall into is throwing his whole weight forward on his arms and gripping the handlebar as a last hope between life and death, when in fact the entire weight of the body should rest on the saddle and pedals. There are few riders in this country who have not learned to ride without even touching the handlebar, and that, too, on rather rough roads, the steering being done by swaying of the body or now and then a mere touch of bars. Without going into details as to the

merits or demerits of cycling as a therapeutic agent, I certainly believe that Dr. Destot's account of his personal experience should be held *sub judice* until he becomes an adept in the art.

J. C. MINOR, M.D.

Medical Man and His Morals.

DAVIS, W. VA., July 17, 1897.

To the Editor: I have noticed the great improvements of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION in the last few years with pleasure.

In the number of July 10 I read an article on the "Medical Man and His Morals," which should be framed and placed in every physician's office. I think it one of the best editorials I ever read. What a life we doctors have to lead anyway; the temptations, the trials, the ups and downs of our life, changes many a man from what he might be to either a man or a devil. He is blessed or cursed at all times: some love and others hate him; one minute he is praised, the other he is blamed for something he can not help. But any man *who loves this life of ours* will go on to the end in spite of it all. In the death of J. Lewis Smith we lost a *great man*, one who leaves "his footprints in the sands of time," one who will never be forgotten. Fraternal yours,

B. M. SMITH, M.D.

Medical Touts.

MARION, N. C., July 7, 1897.

To the Editor:—Refer to your JOURNAL of July 3 issue, 1897, page 37, and advise me the name of the insurance society mentioned in the article headed "Life Insurance Fees for Medical Touts," or say if it is the ———, and extremely oblige,

Yours truly, A. A. MARSHALL.

ANSWER.—No reference to your company was intended by the editorial of July 3 on "Life Insurance Fees for Medical Touts." For obvious reasons, however, the JOURNAL can not give the name of the company whose offer was quoted. The offer itself is in the hands of the editorial staff and the quotation was *verbatim*.

ASSOCIATION NEWS.

The Jubilee Meeting.

What Our Exchanges Say of the Golden Jubilee of the American Medical Association, held in Philadelphia, June 1 to 4, 1897.

The jubilee meeting—the semi centennial—of the American Medical Association is now a thing of the past. During the first week in June this meeting held in Philadelphia was a magnificent culmination of fifty years of work of the organized body of the medical profession of the United States. It was the red-letter meeting of all the fifty years. The largest registration ever known—aggregating twenty-five hundred—was secured. The fullest attendance in the Sections, with the greatest amount of papers and the fullest discussion, was a part of this record. And nothing should make the membership prouder than the knowledge of the fact that from a scientific standpoint and from the standpoint of the Sections, the American Medical Association is growing stronger and better every year. Every Section of the meeting was crowded. Not only was the attendance the largest known in the history of the Association, but the character of the attendance was of the highest—a large number of the most prominent men of the profession of the United States being in evidence.—*Medical Mirror*.

The fiftieth anniversary of the founding of the American Medical Association was appropriately celebrated at Philadelphia, June 1-4, 1897. This occasion, in many respects remarkable, is furnishing an opportunity for much comment on the part of medical journals and in most instances they have bestowed unstinted praise upon the management and character of the meeting.

As a matter of fact there is much to commend and somewhat to reprehend in relation to both. The committee of arrangements, under the chairmanship of Dr. Hobart Amory

Hare, performed its part of the work in a praiseworthy manner. Dr. Hare, himself, displayed great generalship in the difficult task to which he was assigned and his lieutenants were well chosen. The difficult problem of registration when well nigh unto 2,000 men must be recorded was as well handled as it can be under a system that requires each committee of arrangements to formulate its own plans.

The interest in this Association is always of a two fold nature—namely, scientific and social. The scientific work done at Philadelphia will soon be published in the medical journals, hence need not here be commented on at length. The general impression at the meeting was that the scientific part of the program was about up to the usual average of the Association—not better, nor worse. The addresses of Drs. Flint, Keen and Hamilton were listened to with interest and each made some telling points—Flint in his introductory remarks, Keen in regard to the antivivisectionists, while Hamilton showed himself a master of his whole subject.

The addresses of Mayor Warwick and the Hon. Chas. Emory Smith on the first day, and those of the President of the United States and Governor Hastings on the second day, were all neat bits of rhetoric and some of them rose to a high plane of oratory, notably that of Governor Hastings. President McKinley condensed a great speech into a few words—a gift that is natural to him and which few possess.

The jubilee exercises proper on the third day might have been worse and there was abundant room to have made them better. The occasion afforded ample opportunity for hero worshippers to display their enthusiasm and otherwise it was a restful break in the routine. Dr. N. S. Davis read his address in good voice and the subject-matter was an interesting bit of history. The opportunity was here afforded to invite the president of the Medical Society of the State of New York to participate in the proceedings, at least by his personal presence; but it was lost, more's the pity. To completely ignore a great medical society, that was founded in 1806 and was the first organized body to give direction to medical education in the United States, in which also the American Medical Association had its birth and after which its form of government was modeled, was in our view an error if not a misfortune. These jubilee exercises were distinct and apart from the ordinary work of the Association, and during their conduct it would have been a graceful act for Dr. Davis to have welcomed the president of that society, nor would it have diminished the renown that is so justly accorded to the "Father of the Association" had he displayed a magnanimity that was worthy his exalted position and the occasion. The address of Dr. George Ben Johnston, of Richmond, on behalf of the State medical societies is a paper that will bear careful reading, and it furnished a bright coloring to a dark foreground. It was masterful in conception, in length and in material. The National Confederation of State Medical Examining Boards as an organization was also ignored at these exercises, although the individual boards were invited to participate. Unfortunately, however, they were not heard from on the stage, as the speaker selected by the jubilee committee departed for his home the previous evening.

The social entertainments were of the highest order. It would be difficult to bestow unmerited praise on this part of the program. Whether in the way of public receptions, luncheons, lawn and theater parties, or private dinners and entertainments, the whole series was managed with rare discretion. It was no ordinary task to adequately provide for such a number, and Dr. Hare with his lieutenant Dr. de Schweinitz, chairman of the sub-committee on entertainment, conducted these functions in a manner beyond criticism.

The hospitalities of the clubs—the Art, the Union League, the United Service, and others—were of an exceptional order. The entree was given by card to many of the visitors where luncheons, dinners and many home comforts were enjoyed. There were numerous private luncheons and dinners given by Philadelphians that were of the most enjoyable nature, and these after all furnished the best opportunity for agreeable acquaintanceship with the charming men and women who people the Quaker City. It was hard to keep pace with the rapidity of movement incident to all this round of pleasure, and before the end of a week many of the visitors found it convenient to seek the quietude of Greater New York for rest and recuperation.

We must not omit to mention the many clinics that were thrown open to invited guests where operations of all sorts were witnessed under the most extreme conditions of sanitation and asepsis. The new operating amphitheater of the Medico-Chirurgical college and hospital afforded an object lesson in showing what money can do when lavishly expended in perfecting and developing surgical asepsis in operative environ-

ment. The new clinic room of the old Pennsylvania hospital is a model of aseptic neatness, convenience and perfection, that attracted many visitors who gave unstinted praise to the old institution.

Finally, the excursion to Atlantic City on Friday was participated in by nearly 1,000 excursionists, who were entertained without expense until Saturday night. This afforded an opportunity for those who desired to visit the ocean and even take a dip in the waves, to do so under the pleasantest auspices, and was a generous ending to a week of lavish hospitality. Philadelphia's fame as a host did not suffer at the hands of the committee of arrangements of the jubilee meeting of the American Medical Association. The usual number of amendments to the constitution and by-laws were offered and as usual they were all voted down. It would appear that this Association does not care to have any new fashions introduced into its government. The old-time way is good enough for it.

The president, Dr. Senn, appointed Dr. Henry D. Holton, of Brattleboro, Vt., as official delegate to the British Medical Association at Montreal, August 31-September 3, 1897. No more appropriate selection could have been made. Dr. Holton, though one of the older members is one of the more liberal and progressive ones, and will represent the Association in its truest sense. Commodore Albert L. Gihon, Medical Director U. S. Navy (retired), Chairman of the Rush Monument Committee, received substantial encouragement that his labors, so zealously and almost thanklessly given for so many years, are at last to be crowned with success. At least such will be the case if the contributions promised on the first day by the several States should materialize.

The financial budget of the Association presented an incongruous momentary problem. The balance at last statement was \$9,075.74. The balance now is \$5,465.56, showing a loss for the year of \$3,610.18. Another curious fact is that the salary of the secretary is \$300.00 while the rent paid for the treasurer's office is also \$300. By a new rule the treasurer is to supervise the registration, for which he is to be paid \$100. The trustees are paid for attendance upon meetings of the board all the way from \$119.50, the highest, down to \$42.50 the lowest. A new executive committee is created that will undoubtedly present bills for attendance upon the meeting next year.

Denver, which secures the meeting next year, will find it difficult to follow Philadelphia in entertaining the Association, and a year from now may be a wiser if not a letter city. The *Western Medical Review* relates an amusing incident in the committee of nomination relating to the selection of the place of meeting, as follows:

"The fight for place of holding the meeting next year was a lively one while it lasted. While several cities extended an invitation for the Association to meet with them, only two went into the fight in earnest, namely, Denver and Columbus, Ohio. The former had an able champion in Dr. J. W. Graham, and the forces of Columbus were led by Dr. C. A. L. Reed. When the vote came to be counted it was seen that the quiet but hard work of Dr. Graham had secured the plum in the ratio of two to one. Columbus had a map, beautifully decorated with red lines running between Columbus and the important cities of the East, to show that Columbus was nearer the center of population. But the good effect that might have resulted from this lesson in geography was demolished when a representative from the Denver delegation got up and quietly said: 'Denver does not need a map to let people know where it is situated.' The laugh and cheering that followed showed that the point was well received. General satisfaction was evident among the members of the Association, as they expect an enjoyable time in Denver. It is to be hoped that the physicians of the West will aid the profession of Denver and Colorado in making the meeting next year a successful one, in point of numbers at least. Denver will attend to making it successful otherwise."
—*Buffalo Med. and Surg. Journal.*

Certain it is (*Fassell's Bureau of the Medical Press*) that in the history of medical gatherings there never has been one which was so entirely a success from every point of view. The attendance was beyond the hope of the most sanguine, the business and scientific work of the Association excited and held the interest of all its members to the very last, and was of that high order which has been its characteristic throughout the society's half century. *Medical Times.*

May 5, 1847, there assembled in the hall of the Academy of Natural Sciences in Philadelphia 250 delegates, representing some forty medical societies and twenty eight medical schools, constituting the organized medical institutions of twenty two of the twenty-six States then constituting the United States.

They adopted the Constitution, By-Laws and Code of Ethics of the American Medical Association substantially as we have them now, after the lapse of half a century. The National society has grown to over nine thousand members, and is today the most powerful, as it is the most unselfish and most honorable, medical association upon the earth. To be one of its members and loyal supporters should be the pleasure, as it is the privilege and duty, of every regular and scientific practitioner of medicine, surgery and obstetrics in the United States. Especially should every young graduate join his county and State society, so that he may early be in the way of membership in the great National medical union. To do otherwise is to forsake one's natural birthright and enjoy the fruits of the labor of others, without helping either to plant or to water. For the benefits of this great Association reach to the humblest practitioner of the farthest cross-roads, and to enjoy its widespread beneficence without adding to its strength and numbers is alike unprofitable and unhonorable.—*Indiana Medical Journal*.

The Association does not receive the support to which it is entitled. Every editor of a reputable medical journal in the United States should be a member, and an effort will be made by the newly elected officers to bring them into the fold. The meetings are not only valuable, they are exceedingly enjoyable. It is very pleasant to meet socially, and hear talk, and look into the eyes of an editor whose journal you have read with interest for years. The entertainments and receptions were many . . . but there is danger of too much attention being given to this feature of the meetings. Nothing should be allowed to interfere with the regular work of the general sessions and the Sections. Another danger is that too many papers are read before the Sections. Too little discrimination is shown by the officers of the Sections in arranging the program; so many papers are read that there is very little time left for discussing the most valuable part of the work. There ought to be a better grouping of the papers, and the president should appoint able men to open the discussions on papers and subjects of special interest.—*The Atlanta Medical and Surg. Journal*.

"The King is dead! Long live the King!" The Committee of Arrangements has settled up its accounts and adjourned *sine die*. . . . The Section officers have received congratulations on the large attendance and high character of the papers. . . . The American Medical Association changes its workers, but its work is continuous.—*Phila. Polyclinic*.

The fiftieth anniversary of the foundation of this great medical society was fittingly celebrated in Philadelphia last week by one of the most successful meetings recorded in the annals of the organization. The attendance was unusually large, the number of registered members being over two thousand, but so efficient was the management of the committee of arrangements that there was no confusion whatever, and the exercises were carried out according to program without a hitch. In addition to this being the largest it was also one of the most harmonious meetings that the present generation of members has ever had the good fortune to see.

Dr. N. S. Davis was rightly the central figure of the jubilee exercises, and any man might well be proud to occupy such a position as his, at a moment when two thousand physicians were present in person, and many thousands more in spirit, to do honor to the founder of the Association. Not only does the body owe to him in a measure its very existence in the form it now has, but his wise counsels have carried the organization through many periods of stress and danger. To few men is it given to watch their work for fifty years, and to see it grow and spread and finally become established firmly as a monument to his zeal more lasting than one of stone or brass. We trust the father of the American Medical Association will be spared yet many years to watch over and guide his fifty-year-old offspring.

The meeting, finally, will be memorable as the one at which the labors of Dr. Gibon, the indefatigable chairman of the Rush monument committee, were crowned with at least the promise of success. In a few moments pledges were given by men whom he had moved by his eloquent appeal for an amount many times greater than the total that had so far been obtained by years of toil and entreaty. Few men would have persevered in the face of apparent defeat, as Dr. Gibon has done, and when the monument is finally erected as a result of his untiring efforts justice will demand that his name be graven with that of Rush on the granite pedestal.—*Medical Record*.

The gathering of several thousand members of any profession leaves an impression which can not altogether be accounted for by the transactions of the men formally assembled. The spirit of the American Medical Association is in itself an

interesting development of a democratic country. The influence of the Association is tremendous. . . . The aims of the Association are the advancement of the welfare of the average physician, scientifically and otherwise. . . . There is only one point in the policy of the American Medical Association which the *Reporter* would criticise adversely, and even this disagreement is one of method, not of principle. We regard the attempt to codify any strictly ethical or moral matter as utterly futile. Law should be the attempt, not to make a bad man good, but to protect society from the overt acts of the bad man. A written or printed code of ethics can never be so accurately worded as to restrain a shyster nor to guide a man who wishes to conform to the dictum of his profession, but who lacks the instinct of good taste and propriety. On the other hand, the man who could satisfactorily use a code, needs no such assistance.

One of the noteworthy features of the American Medical Association is the number of satellite societies which its mass has attracted. The medical editors, the examining boards, the colleges, were all represented by independent societies, and the Academy of Medicine held an important two days' session before the American Medical Association assembled. It is rather a joke on the members of the last-named organization that, with all their college education, a glaring error in grammatical construction should have occurred on the first page of their announcement.

Some of the Sections published lists of papers three times as long as could have been presented in the utmost allowance of time at their disposal. It was openly charged by many in attendance that some of the papers had not even been written, their authors (?) merely wishing to see their names on the program.

We would repeat the recommendation that every society should have an editorial committee which should reject, curtail or abstract every paper not of suitable length and interest, with the same impartiality as if it were presented for publication.—*Medical and Surgical Reporter*.

The annual meeting of the American Medical Association at Philadelphia, which marked the fiftieth year of its life as an associated body, was a successful occasion—whether measured by the number of the members who attended or the enthusiasm of hosts and guests. Notwithstanding the vast number of titles announced, some very good papers were actually presented, read and intelligently discussed. This was especially true of the Section on General Medicine, one of the most difficult to keep within the bounds of scientific discretion.—*Boston Medical and Surgical Journal*.

The scientific aspect of the sessions was a marked success. The most important subjects of diagnosis and treatment were brought before the members. The papers were listened to with attention, and the discussions which followed were of decided practical value. The work of the Sections was also very satisfactory. In all, a warm enthusiasm seemed to prevail. The character of the papers and discussions in both the general and special sessions left nothing to be desired. No time was wasted; all was profitably occupied.—*Medical Bulletin*.

This magnificent Association, which is without a peer, we think, almost in the world, had by far its most successful convention this year, there being over 2,500 delegates from every State in the Union. Philadelphia threw open its doors to the visitors, and from the reports sent us by our representative, the opening meeting of the convention must have been well worthy of traveling a long distance in order to be present.—*Canadian Journal of Medicine and Surgery*.

To this annual gathering every State in the Union sends representatives in the persons of its most scholarly and conspicuous medical men, and to the deliberations of this Association are brought the fruits of enlightened and zealous laborers working in the fields of medical science all over the world.—*Colorado Medical Journal*.

The meeting was notable in many ways: Unusually large attendance; more general harmony and enthusiasm; and likewise a promise of complete rejuvenation—all of which is most pleasing to the medical profession at large, and the hope is being generally expressed that the success attained will bring very largely increased membership.—*The Medical Age*.

The professional event of the past week was the semi-centennial of this organization in Philadelphia. . . . Individually, personally and collectively the Philadelphia profession did the handsome thing for members of the American Medical Association. Scores and hundreds of members were invited to and did cross their nether limbs beneath the mahogany in hos-

pitable homes and in luxurious clubs. To individualize is out of the question. . . . The magnificent receptions at the Art Academy, Union League Club and at other places were beyond description. To go into further detail would mean the writing of a volume of no small size, which can not be undertaken.—*Cincinnati Lancet-Clinic*.

We are sure that we voice the feelings of the physicians of Ontario, when we wish long life and prosperity to the American Medical Association. Neither governments nor politics can divide the sons of Esculapine, and we know that some of the brightest men in the American Medical Association were born and bred in this "Canada of ours." We, therefore, earnestly hope that this great Association of physicians, the greatest in numbers and influence in America, may continue to grow with the growth of the Republic, and by the words and deeds of its many distinguished members still further ennoble the profession of which they are the bright exemplars.—*Canadian Journal of Medicine and Surgery*.

The semi-centennial jubilee meeting of the American Medical Association, just closed in Philadelphia, marks one of the most successful meetings, both from the scientific point of view and in attendance, in the fifty years of its history. The presence in Philadelphia of the President of the United States, who made an address before the Association, lent additional interest to the occasion. The physicians and citizens of Philadelphia vied with each other in catering to the enjoyment of the visitors.—*Medical Review of Reviews*.

The jubilee meeting of the American Medical Association was held in Philadelphia during the first week of the current month, and proved a phenomenal success, upwards of 2,000 medical men taking part in the proceedings. The JOURNAL of the Association for June 12 contains many interesting details concerning this organization, which ranks next in size and importance to that of the British Medical Association. We gather from among other items that there has been a fall of £800 in the receipts from advertisements. This has been due to the following fact: All the advertisers of proprietary preparations who desire to appeal to the profession in the pages of the JOURNAL have, since last year, been required to furnish for publication in their announcements a complete analysis or formula of their compounds. This the advertisers are now beginning to object to on the grounds that the continued publication of the formula gives every druggist an opportunity to enter into competition with the manufacturer of the specialty. Despite, however, this objection, the authorities of the JOURNAL have decided to continue their policy in this regard. The circulation of the JOURNAL, we learn, has nearly doubled in less than three years, the average weekly issue being now nearly 8,000. There seem to be prospects, then, of this Association, under its present management, surging ahead, and ultimately coming to assume a position of great importance in the American Republic.—*London Medical Press and Circular*.

The semi-centennial of the American Medical Association was celebrated at Philadelphia (14th instant) with becoming dignity and jubilation, while the offerings laid upon the altar of medical science were of sterling worth. Indeed, the Association comes to the acme of its manhood full of honors, having made a brilliant record and with promise of still greater achievement.—*Amer. Practitioner and News*.

The semi-centennial celebration of the founding of the American Medical Association was a pronounced success. The meeting was the best ever held from every standpoint. The registered attendance of members reached nearly 2,000; the number and character of the papers on the different Sections was such that it was with difficulty that the programs were finished in the schedule time; general addresses were of more than usual brilliancy . . . and the social entertainment was so extensive as to render it impossible for one person to take them all in. . . . There were several lessons to be learned from the past meeting, which point the way to better and more scientific work.

1. All motions, resolutions, amendments, etc., should be referred to the executive (*i. e.*, business) committee without debate in the general sessions, and let the committee's adoption or rejection of the same be practically final.

2. It should be the duty of the chairman and secretaries of Sections, to insist that all papers in their respective Sections be handed in at least a month before the meeting; these they should examine and those found inferior, or not up to standard, they should reject. By this method only the best will be read and more time can be allowed for discussion.

3. Let all social entertainment be subservient to the scientific work. There may be plenty of it, but let it be so arranged that it shall neither interfere with the general session nor the Section work.—*Southern California Practitioner*.

The American Medical Association, which held its jubilee meeting in Philadelphia last week, has probably experienced the most successful epoch that has ever occurred in its existence.—*Maryland Medical Journal*.

The meeting of the American Medical Association at Philadelphia was the banner meeting of the half century. In numbers it exceeded every other meeting, and in *tout ensemble* equal to any body of men that ever assembled.

The work done in the Section was of a very high order, the papers being nearly universally of decided merit and of scientific value.—*Mathews' Quar. Jour. of Rectal and Gastro-Intest. Diseases*.

The Jubilee Meeting . . . was a notable one in many respects. Not only was the attendance of 2,500 members unusual, but the deluge of papers presented in the various Sections attested the industry of the members during the past year.—*Am. Jour. of Pharmacy*.

It has been said that for a nation to feel that it has a past and a history is a wonderful encouragement to the growth of its moral forces. What is true of nations is true also of associations. The American Medical Association has now reached and passed the golden milestone of its existence. . . . Great achievements and a noble record, however, increase the responsibility of the present. Each annual meeting is an epoch-making event in the history of the Association.—*The Southern Practitioner* (quoting from the *Medical News*).

Many papers of great value were read, some of which will be noticed more particularly in the "Epitome." The President of the United States was present for some time on one of the days of the meeting, and the gathering, from the social as well as the scientific point of view, was a brilliant success.—*British Medical Journal*.

Certain it is that in the history of medical gatherings there never has been one which was so entirely a success from every point of view. The attendance was beyond the hopes of the most sanguine, the business and scientific work of the Association excited and held the interest of all its members to the very last, and was of that high order which has been its characteristic throughout the society's half century. As to social features, the medical men, medical schools, business houses and citizens of Philadelphia vied with each other in efforts to make the social an exceptionally prominent factor, and their success was appreciated by their visitors. It was the general verdict that Philadelphia stands unrivaled when she decides to open wide her arms in greeting and hospitality. The scientific work of the Association was of too wide a range to be given more than passing notice here. The twelve Sections held simultaneous daily meetings, and each Section claims to have done more work than the others. The attendance on Sections was in keeping with the general attendance, which was greater than that of any former meeting.—*The Medical Fortnightly*.

The meeting at Philadelphia was such as had never before been seen in the history of the organization. About two thousand members were in attendance and they were as wide awake and as good-natured a crowd as ever assembled. They had two objects in view—one was business and the other was pleasure, and they secured both at once. The program for the general sessions was full, and the programs for the Sections were so full that it was only by early opening, a sharp eye on the time-piece and a prompt use of the gavel that the various presiding officers were able to conduct their Sections through the prescribed work in the allotted time. The opinion seemed to prevail among competent judges in the various branches that the work of the Sections was of good quality when not too much hurried. The essays and discussions, if approved by the committee on publication, will in due course appear in the JOURNAL of the Association, and we can attempt no recital of the long list here. We would like to say, in passing, that the judgment of the committee on publication should not be final. The editor of the JOURNAL should have the privilege of accepting or rejecting papers, even after they have been passed by the committee, and this without recourse to the trustees.—*Cleveland Medical Gazette*.

The recent very successful meeting of this Association in Philadelphia, in point of numbers and enthusiasm, has demonstrated very conclusively that the professional spirit in that body has not been lessened, but is ever increasing and tending to broader and more thorough work. The general work of the American Medical Association seemed to the writer to partake of the many objectionable features of all such organizations, including those of our own. The bringing together of some two thousand men in one body is not conducive to the best conditions, and the meetings at the Academy of Music were practically unmanageable. This was not wholly the fault of

the president, whose voice was not equal to filling the large building, but, apparently, to lack of adherence to parliamentary rules, fatal to all large meetings. It was demonstrated, in the opinion of the writer, that this national medical organization has nearly reached a period in its history when its methods of work will require modification, if not an entire change in procedure, and this is equally applicable to dentistry. It is doubtful whether this will be recognized as a fact by the general medical or dental mind, but it must be conceded that the best scientific work can not find a congenial atmosphere in great numbers or in movable organizations. Time will bring about its changes, and to this may safely be left the future solution of the problem, and that with the assured consciousness that however popular present methods may be, there will come a period when these will be regarded as antiquated and valueless as a means of bringing forth the best work.—*International Dental Journal*.

SOCIETY NEWS.

Twelfth International Congress, Moscow.—Every arrangement has been made to secure the comfort of the members by the committee in charge, souvenir guides to the city, and pamphlets with other information will be distributed, interpreters will meet the incoming trains, a special restaurant has been opened near the Congress for the members, with a hall for postal, telegraph and telephone facilities at their disposal. Every place of interest in the city is open to the members and numerous excursions have been planned. The Congress will admit as members extraordinary all persons with scientific titles besides medical: pharmacists, veterinary surgeons and dentists, on payment of the usual fee. The *Presse Méd.* of June 19 contains full information in regard to Russian money, etc., with routes for travelers. The addresses are to be delivered by Krafft-Ebing, Lauder Brunton, Sternberg, Senn, Von Leyden, Lombroso, Loukanow, Virchow and Robert of Barcelona.

Congress of the French Society of Ophthalmology. Professor Panas delivered the principal address: "Auto-infection in Ocular Diseases." He does not believe that sympathetic ophthalmia is infected through the optic route, which explains the failure of enucleation and sections of the optic nerve to prevent infection. When one eye has been irritated by traumatism, the mate is subjected to a vaso-dilatation. If the person has toxemia we witness the evolution of sympathetic ophthalmia; if not, there will be merely functional disturbance. This forms an important indication for antiseptics, not only for the injured organ but for the entire system. De Wecker treats alcoholic amblyopia by injecting 60 to 10 c.c. Chéron's artificial serum, warmed, in ten to fifteen minutes. Three or four of these treatments improves the sight 1-10 (and even 1-20) to 1-4. He has also obtained fine results with it in post-operative infective accidents. Coppez has been very successful in experiments with ocular diphtheria with subconjunctival injections of diphtheria serum, combined with abundant subcutaneous injections and preventive injections in the sound eye. It combats the diphtheritic toxin, which he believes filters into the cornea by way of the lymphatics or by absorption. Abadie proposed a new pathogenesis of glaucoma. It depends upon the nervous system, but not on the fifth pair as accepted, but is due to a paralysis of the great sympathetic. Iridectomy only succeeds when it is complete, namely, when the diaphragm of the iris is cut through from its inner edge to the outer. He does not consider it necessary to cut out a piece, as the simple incision from edge to edge is sufficient, or merely the section of the ganglionic plexus, as he ascribes the affection to a vaso-dilating current which runs circularly around the iris. He suggests that section of the connecting branch of the cervical sympathetic may yet be found the cure for glaucoma. Koenig reported a case of apparent parenchymatous keratitis, which recurs each month at the menstrual period. Drangart reported 164 iridectomies and 84 sclerectomies, and he added that these operations, and preferably the former, will

certainly prevent blindness from progressive myopia, if combined with a general tonic and anti-arthritic treatment with near and distant glasses, carefully fitted to prevent bending the head, which he considers a factor in producing the affection. Each evening he instils one drop of pilocarpin, which prevents all complications. A. Antonelli states that certain peculiarities in the eyes described in the text-books as variations in the normal eye are, in fact, syphilitic stigmata. Among them are the dirty white, grayish or pale color of parts or the whole of the optic disc, with indetermined or jagged edges, often surrounded with a total or partial frame of pigment, small size of the arteries and large size of the veins, especially where they pass near the papilla, a slaty tint of the peripapillary region, or a granular appearance, which may resemble rudimentary pigmentary retinitis or diffuse choroido-retinitis. Similar alterations in color may be found in the peripheric region of the fundus oculi. He also states that we are justified in assuming the existence of ametropia and strabismus of syphilitic origin. The amount of the stigmata varies in the two eyes, which may cause anisometropia and imperfect vision. He adds that certain cases of monocular myopia, hitherto unexplained, were probably due to this cause, the varying amounts of the stigmata in the two eyes. These manifestations are of great service in suggesting the treatment, which is always useful both in improving the actual and preventing later and more or less serious manifestations.

Senate Bill 1063 Against Vivisection. The Medical Society of Mobile County, Ala., have adopted the following resolutions:

WHEREAS, A bill is now pending in the Senate of the United States, intended to render what is known as "vivisection" illegal in many instances, and to throw serious or fatal obstacles in the way of its performances in all instances, thus rendering it practically impossible; and fearing that the enactment of said bill into a law for the District of Columbia might lead to efforts for similar legislation in the several States; therefore be it

Resolved, That in the opinion of this Society all efforts at legislation, such as that referred to, are the outgrowth of a mistaken and mawkish sentiment that in seeking to protect animals from alleged cruelties—largely fanciful and exaggerated—would not hesitate to inflict greater cruelties on man by denying to medical science one of its most efficient means for discovering the true nature of diseases and for devising sanitary and therapeutic measures for the prevention and cure thereof. With such sentiment this Society has no sympathy. Had it dominated in the past, humanity would have been deprived of some of the greatest blessings ever conferred upon it; and were it to become dominant in the future, scientific medicine, now so promising of great achievements, would be disastrously checked in its progress. Be it further

Resolved, That we do hereby earnestly appeal to the Senators and Representatives to use their influence to prevent the legislation mentioned, thoroughly convinced as we are that a principle antagonistic to the best interests of the human race is involved, and one that should never receive the endorsement of a body so influential and enlightened as the Congress of the United States. Be it further

Resolved, That a copy of this preamble and these resolutions be transmitted to Senators Morgan and Pettus, and to Hon. George W. Taylor, member of Congress from this district, for such use as they may think proper to make thereof.

PUBLIC HEALTH.

A Precautionary Quarantine in Bulgaria of two weeks' duration has been established against travelers from Turkey. Constantinople is somewhat under suspicion.

The Color of Schoolroom Walls. The New York City Board of Education are to determine what color is best to be used for the walls of schoolrooms. A commission of oculists is to be selected for the purpose. The idea originated in France and not, as was to be expected, in Germany.

A Supposed Menace. The British ship *Maud* sailed into the port of San Francisco July 15 and was at once ordered into quarantine. On the voyage across the Pacific Ocean, from Calcutta, one of the crew died, it was supposed from the bubonic plague. Two others were ill with nearly the same symptoms but had become convalescent before land was

sighted. A careful guard was deemed essential for the interests of all.

The New School for Children with Tinea, Favus, etc., at Paris, connected with the Hôpital St. Louis, is just completed at an expense of 1,500,000 francs. The capacity is 270 residents and 280 partial residents, with a ward for the sick. There are two buildings, one for the children with tinea tonsurans and the other for favus and alopecia areata. The *Progrès Médical* doubts the wisdom of allowing any of the children to go home at all, for fear of imparting the disease to others in the family.

The Reduction of Death Rate in New York City.—The President of the Health Board in his latest formal report says that the death rate in the first six months of 1897 is less than for the corresponding period of former years. The deaths from contagious diseases are summed up in percentages as follows: 1894, 2.17; 1895, 2.23; 1896, 2.57; 1897, 1.49. Credit is given to the existing sanitary conditions, to wit, the asphalted streets in the tenement house districts, the cleanliness of the streets, the improved milk supply, the use of sterilized milk, the vacation of rear tenements, the medical inspection of children in the public schools and the vigilance of the health officers. From another source we learn that the central part of the State shows the lowest mortality from acute respiratory diseases.

Water Tank Inspection.—The New York City Board of Health, as the result of their first inspection, report that out of 251 tanks examined 115 were found to be in an unhealthful condition. These tanks are generally located on the roof and furnish, in the district above the aqueduct level, most of the potable water in the tenement houses. Where neglect or carelessness is shown the maximum penalty provided is a fine of \$200. Real estate owners or the more guilty janitors are the delinquents, and the discoveries made indicate that the official supervision should be made with the same regularity as the inspection of fruit, meat and milk. Sanitarians, notwithstanding some ludicrous fads, do certainly insist upon the "ounce of prevention."

The anti-English Feeling in Plague-smitten India.—The native press of India in the main tacitly advocates resistance to the search parties, notwithstanding that these volunteers for plague duty have been under the strictest control of well-trying and prudent officers. A London dispatch of July 3 quotes from one of these papers as a sample of the other: "If matters are not put right soon, the scenes of 1857 are likely to be re-witnessed there, as neither the Hindus nor the Mohammedans will tolerate the persecution of their wives and children for any length of time. It is the misfortune of the people that the honor, religion and modesty of women, safe even under Mogul rule, should be violated under the enlightened English government. We wonder why no notice is taken of the shameful doings of the soldiers in the Poonah. They are perhaps secretly instigated by the government to do these things in retaliation for the tortures once inflicted upon Europeans by the *tantia topi*, and to punish the capital of the Deccan for taking the lead in all public agitations. Let us hope that the government will take heed and mend its ways, lest disastrous consequences ensue."

Antitoxin in Boston, Mass. Dr. Samuel W. Abbott of the Massachusetts State Board of Health and a strong advocate of the antitoxin treatment of diphtheria reports that "in 1895 the percentage of fatalities to cases of diphtheria in which antitoxin was used was 13.7, while in 1896 it was reduced to 11.6. In the two years covered by the work of the State board, 451 cases have been treated with antitoxin, of which 58 have resulted fatally, or an average percentage for the two years of 12.8. This is compared with the figures for the years 1891 and following. The returns of the State were not made in such a way that the comparison can be carried further back, and the

figures include 'diphtheria and membranous croup.' Including all cases of these two diseases in the State, the percentage of fatality was as follows: In 1891, 23.5 per cent.; in 1892, 29.2; in 1893, 31.7; in 1894, 27.9; in 1895, 18.9. In 1895 can be seen, in the effect upon the general situation in the State, the effect of the beginning of the use of antitoxin." Still the skeptics will not accept the dictum quietly, averring that the disease in question has been made too comprehensive, that "the abundant testimony" is furnished by enthusiasts and that the cases are much less virulent, in fact much less common, notwithstanding the frequent reports to boards of health.

NECROLOGY.

JOHN EVANS, M.D., ex-Governor of Colorado, July 3, aged 83 years. He was graduated from the medical department of Cincinnati College in 1838, afterward appointed superintendent of the Indiana State Insane Asylum, and in 1848 became a lecturer in Rush Medical College. He was instrumental in founding Evanston, Ill., and for a time President of Northwestern University, Evanston. Through his efforts Chicago's first high school was built. The Pennsylvania railroad owes its present Chicago terminals to the railroad work of Dr. Evans, while the Methodist Book Concern and the *Northwestern Christian Advocate* were founded by him. A delegate to the convention which nominated Lincoln, he later declined the territorial governorship of Washington, but in 1867 accepted that of Colorado, in which State he remained and applied himself to educational and railway development, promoting the first railroad in Colorado.

RICHARD SMITH BACON, M.D., College Physicians and Surgeons, N. Y., 1865, died in New York City July 6, aged 58 years. He practiced medicine only about a year, being connected at the time with the Kings County and Maternity Hospitals. He moved to Flushing, L. I., in 1872, and served several terms as president of the village. Later he became associated with his brother, the late Dr. George W. Bacon, as an instructor in the Columbia Grammar School under Dr. Charles Anthon, the well known editor of Latin and Greek classics. Afterward he became head master and remained in the position until he was forced to retire a year ago.

ALFRED LEFEVRE, M.D., Cincinnati Medical College, 1845, father of Judge O. E. Lefevre of Denver, died of cancer of the stomach at his home in Kansas City, Mo., July 4. He was born at Troy, Ohio, in 1822, and was a direct descendant of Isaac Lefevre, a French Huguenot who came here in 1708. Until 1885 he practiced in Dayton, Ohio.

IRA BEMAN READ, M.D., Michigan, 1867, Bellevue, N. Y., 1868, died at his home in New York July 4 of laryngeal phthisis. He was the only son of Dr. Albert N. Read of Norwalk, Ohio, formerly a medical inspector of the United States Sanitary Association during the war, and who died about a year ago. Dr. Read himself was mustered out as a captain in the 101st Regiment of Ohio infantry, March 29, 1864.

ORSON S. ST. JOHN, M.D., died in New York City July 7. He was born in Buffalo, N. Y., in 1810, began the study of law in Cleveland, Ohio, and continued it in Cincinnati, but finally went to Philadelphia where he was graduated in medicine from the Jefferson Medical College. Possessed of ample means, he practiced medicine but little, devoting his life to study and travel. He was a modest retiring man of most amiable temper.

GEORGE F. FRENCH, M.D., Minneapolis, Minn., July 5, aged 60 years. Dr. French was graduated in medicine in 1862, from Harvard; later became surgeon U. S. Volunteers and assistant surgeon U. S. A.; professor obstetrics and gynecology, Minnesota Hospital College; president Minnesota Academy of Medicine, etc.

JAMES S. WHITMIRE, M.D., Metamora, Ill., July 15, aged 76 years. He was surgeon to the Sixth Illinois Cavalry and Fifty-sixth Illinois Infantry during the Shiloh, Corinth and Vicksburg campaigns, and one of the organizers of the Illinois Medical Society.

WILLIAM H. DIFFENDERFER, M.D., University of Maryland,

1843, one of the oldest physicians of Baltimore, was thrown from his carriage by a collision with an electric car, and died an hour later, July 7.

JAMES A. McLOCHLIN, M.D., New York University, 1874, a resident practitioner of New York City, died in Saratoga, N. Y., July 16. He was an original member of the New York State Medical Association.

JOHN H. WHEELER, M.D., Long Island College Hospital, 1879, died at his residence in New York City, July 7, aged 67 years.

A. W. RAMSEY, M.D., Hopedale, Ohio, July 5, aged 69 years.

A. S. ROGERS, M.D., Pavilion, N. Y., July 10, aged 55 years.—N. N. ST. JOHN, M.D., Wayland, N. Y., July 10, aged 78 years.—ALEXANDER NICHOLAS TALLEY, M.D., Columbia, S. C., July 6.—A. O. GILMAN, M.D., St. Cloud, Minn., July 16, aged 48 years.—HENRY W. DESAUSSURE, M.D., Charleston, S. C., July 10, aged 54 years.—A. L. BERGER, M.D., Professor of Obstetrics and Secretary of the Faculty, University Medical College, Kansas City, Mo., July 8.—ALVA P. COURTWRIGHT, M.D., Circleville, Ohio, June 23, from injuries received by being thrown from a carriage.

MISCELLANY.

Personal.—Dr. Charles A. L. Reed of Cincinnati has been made a Foreign Corresponding member of the National Academy of Medicine of Peru.

A Cheerful Fact for New York City.—A statistician catering for the good will of the Greater New York says that for the six deaths every fifteen minutes there are seven births.

Appointment.—The College of Physicians and Surgeons, Chicago the Medical Department of the University of Illinois—has chosen A. H. Burr, M.D., adjunct professor of practice of medicine.

A Jubilee Number.—The New Orleans *Medical and Surgical Journal* celebrates its fiftieth anniversary with the July issue, which appears in gala cover and is a fitting souvenir of the occasion. Except during the Civil War, this *Journal* has been in active service since 1844.

Victoria Jubilee Fund. The Victoria Diamond Jubilee Association of Chicago has raised \$7,000 to be distributed among Chicago hospitals. St. Luke's Hospital will receive \$3,000; the Presbyterian Hospital, \$3,000; the Mary Thompson Hospital \$500, and the Maternity Hospital \$500. The Association asks that the hospitals name the bed, room or ward thus established in honor of Queen Victoria.

Temporary Paralysis Caused by Antirabic Treatment at Paris. Four cases are reported in the *Journal de Méd. de Paris*, June 20—three fatal—and it states that the cases are in fact still more numerous. La Rendu introduced the subject at the Académie de Méd., describing his observation of a young man who took the treatment as a preventive measure after receiving a scratch during the necropsy of a rabid patient. He was almost completely paralyzed for a week.

Correction of Article.—Owing to miscarriage of letter, corrected proof of Dr. S. Solis-Cohen's article on "The Treatment of Exophthalmic Goiter and other Vasomotor Ataxias with Preparations of the Thymus Gland and of the Adrenals," published in our issue of July 10, was not received and the article as published contains several misprints. In particular, the first phrase of the last sentence in the second column, on page 65, should read as follows: "Whether the group of affections thus included would form in rigorous nosologic classification, an order, a genus, or a species," etc.

Diphtheria in Fowls.—A study of this subject in the *Archives Clin. de Bordeaux* for June concludes with the statement that diphtheria is practically the same in fowls and in man and that the cases accompanied by paralysis contain the Loeffler bacillus in a highly virulent form. In these cases the birds can be injected with the ordinary diphtheria serum every third

day, in the interscapular region between the wings, and animals that have been in contact with them injected as a preventive measure.

Transcendental Surgery. Efforts to Secure Absolute Asepsis, Gloves and Mouth Screens.—Prof. J. Mikulicz contributed a candid and most interesting article to the *Deutsche Med. Woch.*, of June 24, on the open secret that the results of asepsis are scarcely any improvement over antisepsis. The most scrupulous care by conscientious surgeons and assistants is insufficient to guarantee absolute asepsis as an actual fact. He has recently adopted in his clinic two innovations which he considers long strides toward the attainment of this ideal: gloves for the operator and assistants and a covering over the mouth of each person in the room. He finds from a long series of tests that it is impossible to render the hands perfectly aseptic. The manipulations required of the surgeon's fingers bring to the surface germs deeply ensconced in crevices impossible to reach by the most vigorous disinfection. He has therefore commenced to wear gloves at his work—not the rubber gloves recommended by Manteuffel and others, nor the long silk gloves advocated by Perthes in the *Cbl. f. Chir.*, of July 3, but the cheap gloves sold as "fine servants' gloves," waiters' gloves, which he buys in Breslau for 65 cents a dozen. They are linen or cotton and can be washed and boiled, and used over and over again. He first disinfects his hands as carefully as possible with the alcohol-sublimate method, and then draws on the gloves. They do not interfere with his operation, and even allow a firmer grasp of the threads and tissues. If the operation is short and aseptic, one pair of gloves is sufficient, but if not, he changes for a fresh pair two or three times, at the different steps of the operation. His assistants also wear the gloves, and change at the same time. If absolutely necessary to use the bare finger, he removes the glove for the purpose. Of course he does not wear them when opening up an infected focus. The constant agitation in regard to improved methods of asepsis and the catgut question, drainage, etc., proves that surgeons are not fully satisfied with the present methods at the best, and Mikulicz's suggestions have already been adopted by others. Küster, for instance, has commenced to wear the gloves and announces that he is pleased with them in every respect. Mikulicz has also found that germs are disseminated in the air from the mouth in speaking or coughing, floating on tiny bubbles of moisture. As moist germs are much more dangerous than dry ones, to reduce this evil to the minimum he limits the number of persons present at an "asepsis operation" to the smallest number possible, not even admitting more than six to ten students at most, and all present wear a sterilized piece of mull over their mouth, fastened to their sterilized cap: it can also enclose the beard if there is one. They soon learn to breathe through it as comfortably as a lady through her veil. Gestures takes the place of words as much as possible. Flugge, the bacteriologist, considers that a surgeon with a cough or tendency to sneeze, has no right to attempt an "asepsis operation." The germs that may linger on the patient's skin after disinfection are not usually so virulent as those on a surgeon's fingers, but still Mikulicz considers that drainage is frequently a source of infection as the germs of the surrounding region find their way into the wound along the drain, especially if near the anus, etc. He never attempts an "asepsis operation" in the clinical amphitheater before a crowd, but floods everything there with antiseptics. He recommends all surgeons to use antisepsis in operating at the residence, as only a perfectly aseptic room in especially equipped institutions will insure success. König acknowledged at the recent German Congress of Surgery that he had learned from experience that suppuration of the knee joint did not occur after patellar suture if the finger did not come into actual contact with the tissues, which is an argument in favor of gloves; even Kocher's pain-taking technique has failed to prevent suppuration in 5.7 per cent. of his radical hernial operations.

Colleges.

THE Medico-Chirurgical College of Philadelphia has extended its course of study to four years.

EIGHTY-two received degrees at the recent commencement of the Kentucky School of Medicine, Louisville.—The Hospital College of Medicine, Louisville, Ky., graduated seventy-six on July 1.—The forty fourth annual commencement of the medical department of the University of Vermont was held July 2. The graduates numbered 53.—The University College of Medicine, Richmond, Va., will open September 30 a new building having a capacity of 500 students. The large attendance of students during the past year necessitated greater facilities for the coming year.

Societies.

The following societies have recently held meetings:

- Illinois.**—The McLean County Medical Society, McLean, July 1. The Somerset County Medical Association, June 31.
- Indiana.**—Mitchell District Medical Society, West Baden, July 8 and 9.
- Indian Territory.**—The Indian Territory Medical Society South McAlester, June 30.
- Iowa.**—Iowa and Illinois Central District Medical Society, Davenport, July 8. The Botna Valley Medical Association, Atlantic City, July 10. Clinton County Medical Society, Clinton, July 6. Iowa Union Medical Society, Cedar Rapids, July 13.
- Kansas.**—Golden Belt Medical Society, Topeka, July 1.
- Kentucky.**—Floyd Belt Medical Association, Louisville, July 1. Midland Medical Association, Frankfort, July 8.
- Michigan.**—Northeastern Medical Association, Lapeer, July 8. Tri-State Medical League, Detroit, July 14 and 15. Upper Peninsula Medical Society, Sault Ste. Marie, July 8 and 9.
- Missouri.**—Central Missouri District Medical Society, Jefferson City, July 1.
- New York.**—Broome County Medical Society, Binghamton, July 6. Ontario County Medical Association, Canandaigua, July 13. Wayne County Medical Society, Lyons, July 13. Wyoming County Medical Association, Warsaw, July 13.
- Ohio.**—Clark County Medical Society, Springfield, July 8. State Medical Association, Put-in-Bay, July 9.
- Pennsylvania.**—Cambria County Medical Society, Cresson, July 8. Luzerne County Medical Society, Wilkesbarre, July 7. Schuylkill County Medical Society, Pottsville, July 6.
- South Dakota.**—Black Hills Medical Society, Hot Springs, July 10.
- Tennessee.**—Dickson County Medical Society, Dickson, July 6.
- Texas.**—Central Texas Medical Association, Waco, July 13 and 14.
- Virginia.**—The Roanoke Medical Society, Roanoke, July 9.
- Wisconsin.**—Central Wisconsin Medical Society, Evansville. Northwestern Medical Association, Stevens Point, July 14.
- Canada.**—Ontaria Medical Council, Toronto, July 9.

THE PUBLIC SERVICE.

- Army Changes.** Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from July 10 to 16, 1897.
- Major William H. Corhusier, Surgeon, upon the arrival at Ft. Monroe Va., of Capt. Richard, will be relieved from duty at that post, and is ordered to Angel Island, Cal., relieving Major Benjamin F. Pope, Surgeon. Major Pope, upon being thus relieved, is ordered to Columbus Bks, Ohio, for duty, relieving Capt. James E. Pilcher, Asst. Surgeon. Capt. Pilcher, on being thus relieved, is ordered to Ft. Crook, Neb., for duty.
- Capt. Charles F. Kieffer, Asst. Surgeon, upon the arrival of Capt. Pilcher at Ft. Crook, Neb., is ordered to Ft. Meade, S. Dak., for duty at that post.
- First Lieut. Henry K. Stiles, Asst. Surgeon, upon the arrival of Capt. Kieffer at Ft. Meade, S. Dak., is ordered to Columbus Bks., Ohio, for duty at that post.
- Capt. Benjamin L. Ten Eyck, Asst. Surgeon, upon the arrival of Lieut. Stiles at Columbus Bks., Ohio, is ordered to Army and Navy General Hospital, Hot Springs, Ark., for duty.
- Capt. Champe C. McCulloch, Jr., Asst. Surgeon, is relieved from duty at the Army and Navy General Hospital, Hot Springs, Ark., to take effect upon expiration of his present leave of absence, and ordered to Ft. Barrancas, Fla., for duty, relieving Capt. William C. Gorgas, Asst. Surgeon. Capt. Gorgas, upon being thus relieved, is ordered to take station at New York City and assume duties of attending surgeon and examiner of recruits, relieving Capt. Charles Richard, Asst. Surgeon. Capt. Richard, on being thus relieved, is ordered to Ft. Monroe, Va., for duty.

CHANGE OF ADDRESS.

- Audenried, Ada H., from Philadelphia to Secane, Pa.
 Brannon, C. S., from 295 Marshfield Av. to 801 Madison St., Chicago, Ill.
 Berry, W. F., from Lafayette, Ind., to Mt. Clemens, Mich.

- Campbell, A. W., from 358 W. Adams St. to 240 Wabash Av., Chicago, Ill.
 Gladmon, E., from 501 New Jersey Av. to 248 Delaware Av. N. E., Washington, D. C.
 Hatch, W. G., from Chicago, Ill., to Schleisgerville, Wis.
 Harmer, J. E., from 1602 K St. to 1314 F St. N. W., Washington, D. C.
 Krouser, T. A., from 721 W. Harrison St. to 520 Grand Av., Chicago, Ill.
 McGaban, C. F., from Aiken, S. C., to Bethlehem, N. H.
 Preucel, J. E., from 875 to 708 Milwaukee Av., Chicago, Ill.
 Pressly, A. J., from Grand Rapids, Mich., to 841 E. Madison Av., Cleveland, Ohio.
 Stover, Geo. H., from Eaton to Jackson Bldg., Denver, Colo.
 Stowell, C. H., from 1326 New York Av. to 2803 14th St. N. W., Washington, D. C.
 Tonn, M., from 6 Clybourn Av. to 278 Wells St., Chicago, Ill.
 Winton, H. N., from San Francisco to P. O. Box 143, Hayward, Cal.

No. 5.

ORIGINAL ARTICLES.

A FURTHER REPORT ON THE TREATMENT OF TUBERCULOSIS BY IODOFORM INUNCTIONS.

Presented in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, June 1-4, 1897.

BY LAWRENCE F. FLICK, M.D.
PHILADELPHIA, PA.

Preliminary to making this report it may be proper for me to say that for some years I have been substituting in the majority of my cases euophen for iodoform because of its less offensive odor. I have long since satisfied my mind that the benefit derived from iodoform is due to the nascent iodine given off from the decomposition of iodoform which takes place, either in the tissues of the body or in the blood. Finding iodoform very offensive and having been informed that euophen is even more rich in iodine than is iodoform, I was induced to take up euophen as a substitute, and have found it equally useful, if not more useful in the treatment of tuberculosis.

On Nov. 12, 1890, in a paper on "The Treatment of Tuberculosis," before the Philadelphia County Medical Society, I first mentioned the use of iodoform by inunction. In that paper I quoted no cases, but simply stated that I had obtained good results. On April 22, 1891, I reported ten cases to the same society and exhibited a number of them. I then summed up my report of the cases as: one, apparently well; three approaching a cure with fair prospects of entire recovery; four having the disease arrested and being in a comfortable condition; and two having had a relapse and doing badly.

On March 12, 1892, I made a further report on those cases in the *Medical News* and quoted five additional cases. By that time, of my first ten cases, four had died, three were apparently well, one was enjoying comparatively good health, and two had disappeared from observation. Of the five new cases, two were apparently well, one promised to recover, and two showed evidence of improvement.

It is now nearly eight years since I began this method of treatment; about six years since I reported my first cases and a little over five years since I made my last report. A further report on the fifteen cases quoted in my former papers will give a true picture of the ultimate results in the treatment of tuberculosis by any and all methods, and will offer a severe test of the value of the method of treatment with which I am dealing. In addition to those cases I deem it proper, however, to give an account of my results with the method of treatment since then, and I will therefore give brief statements of some new cases treated, with a summary of the results obtained in all cases treated of which I have memoranda.

Of the first ten cases reported, eight are now dead, one is apparently well and one has disappeared from under observation. Of the eight cases that have died, seven without doubt died of tuberculosis and one, after years of health, died of some acute abdominal trouble which developed during the lying-in period and which may have been tubercular. Thus it will be seen that ten cases which two years after the beginning of treatment gave the basis of a favorable report, after eight years, make a very gloomy showing. Expressed in percentages, the best that can be claimed, is 10 per cent. recovery, or if the case which died of intercurrent disease is counted as cured, 20 per cent. recovery with 80 or 90 per cent. mortality. It must be stated, however, that some of the cases that died gave up treatment probably earlier than they should have done and that the result might have been different in some if the treatment had been continued for a longer period. Of the five additional cases reported in 1892, two are dead, one is well, and two have passed from observation. Of the last two one is probably dead and one is probably well. This set of cases will show again almost the same result as the first ten.

Summing up the result of the fifteen cases, I can state positively that ten are dead, two are well, and three have passed from observation. Of these three, two are probably dead and one is probably well. The best that can therefore be claimed for the fifteen cases after a period ranging from five to eight years is about 20 per cent. recovery.

It will be of some interest to give a few details about these cases and I will therefore very briefly refer to them in numbers and state the course and termination of each case.

Case 1.—This case, which was especially interesting because of a local tuberculosis in the eyelid, in addition to the deposit in the lung, had recovered entirely, both of the local trouble in the eye and of the deposit in the lung. After recovery she had an acute attack of insanity, for which she was sent to an asylum for a brief period, but from which she entirely recovered. Subsequently she got married and had three or four children, remaining perfectly well during all of this time. Shortly before the termination of her last pregnancy she tripped and fell, bringing on labor somewhat prematurely. During her lying-in-period she developed abdominal trouble, which, judging from the data given me by a member of her family, may have been tubercular, and from which she died.

Case 2.—A school boy who had had the disease in a very acute form, was apparently entirely well at the end of six months. He remained well for a considerable period. He seriously objected to the annoyance of inunctions and refused to continue the treatment, although I urged it, because he was much exposed to reinfection by reason of other cases in his family. At the end of about a year he again developed an acute attack which ran a very rapid course and proved fatal.

Case 3.—A sister of Case 2 was far advanced in the disease when the treatment was begun, but showed, probably better than any other case, what can be accomplished under adverse circumstances by persistent and uninterrupted treatment. Her environments were the worst possible and her duties were of a character most depressing and wearing. All her family had either died of tuberculosis or were dying of it, except one decrepit brother who had had spinal disease and was entirely crippled. Living in a small badly ventilated house in one of

the blind alleys of our city, with poverty ever abiding in her household, she was compelled during her entire illness, covering a period of about five years, to do all the work for her family, which always included one or two invalids, and besides she had the anxiety of mind which most often come with an empty tarder. In spite of all her difficulties she used the inunctions daily and so pinned her faith to them that she declined to use any other treatment. Although her disease was always of a rather acute nature, she frequently having a high temperature while at the wash tub, she continued at her duties until the last, and lived about five years from the beginning of her disease. This is the more remarkable as almost every part of her body was affected with the disease, she even having large spots of lupus on her hands and fingers.

Case 4, 6, 7, 8, were reported dead in my last report and therefore need not be further spoken of here.

Case 5 gave up the treatment after having improved very much, but not having regained his health entirely, sought relief elsewhere and subsequently died of the disease.

Case 9 continues in good health up to the present time. The disease was entirely incipient with her and being so it is but fair to say that the diagnosis was somewhat in doubt. Clinically, however, she had all the symptoms of tuberculosis, so that it is proper to count her case in summing up the results of treatment.

Case 10, disappeared from observation, but I am inclined to think has since died.

Case 11 recovered so entirely after the first attack that I began to doubt my diagnosis. Within a year however, he had a recurrence for which he again came to me for treatment and from which he again apparently recovered. I then urged him to keep up his treatment indefinitely, but he only did so until he felt quite well. He subsequently had tubercular fistula when he again took up the treatment for a short period with good results and apparent recovery. About a year ago he developed the disease in acute form for which he sought some other method of treatment and from which he never recovered.

Case 12 is, at present entirely well. Her symptoms were somewhat acute in the beginning and the case looked unfavorable owing to the fact that she had involvement of the lymphatic glands in addition to the lung trouble. She has, however, not only recovered from her lung trouble but the glands have gone down to the normal condition.

Case 13 was of an acute character and when last heard from had a relapse while in the South where he had gone with a view of benefiting himself. In all probability he has since died.

Case 14 was improving under my treatment when I last saw her, but for a second time discontinued the treatment believing, in all probability, that she was well enough to get along.

Case 15 was entirely well when I last saw her some years ago. As she had been coming to me off and on when she had any fear of recurrence, I have reason to believe that is now well.

Of new cases that I have treated and that have shown some evidence of permanent improvement or cure I will now quote a few.

Case 16.—Male, aged about 28 years, white, was admitted to the Rush Hospital for consumptives May 17, 1892. At time of admission he had consolidation of upper lobe of one lung; had an annoying cough; some slight elevation of temperature; and gave a history of having lost about 40 pounds in weight. He was given a tonic, placed on iodoform inunctions and given nutritious food and a large quantity of milk daily. Under this treatment the lung cleared up and the cough disappeared, and he rapidly gained in weight so that at the end of three months he was discharged well and with a gain of 25.5 pounds. I have made inquiry about this case since and have had knowledge of him within a year, at which time he continued to be well.

Case 17.—Male, white, aged about 25 years, was admitted to the Rush Hospital for Consumptives early in 1892. He had been exposed to tuberculosis in his own family at home for a considerable period and was apparently laboring under an acute attack. He was thin, pale and delicate looking, and seemed to be a most unpromising case for treatment. The deposits in his lungs were not localized, but were apparently scattered in small patches over both lungs. He had had hemorrhages and his cough was almost constant. There were bacilli in the sputa. He was placed on tonic treatment with good food and plenty of milk and given inunctions of iodoform solution daily. For a long time there was no improvement in his case. He had most severe hemorrhages during his stay in the hospital, during one of which he was almost completely exsanguinated and was watched for death for several days. After about three months, however, he began to improve and at the end of six months was discharged with the disease apparently arrested. I have seen

him repeatedly since his discharge and quite recently, and he has remained well, although he has subjected himself to the severest tests, such as exposure to hardships and to such conditions as are usually looked upon as conducive to tuberculosis. He has moreover been exposed to contagion in his own home since then, as his father has developed tuberculosis, and he is in constant association with him.

Case 18.—Female, white, aged about 50 years, married, mother of a large number of children, came under treatment in the early part of 1891. She then gave a history of having had a cough for a long time which had been worse at certain intervals. When I first saw her she stated that she coughed a great deal at times; that she spat a large amount of green sputa; that she was pale at intervals; that she had a very poor appetite; and that she believed all these symptoms to be due to an attack of "grip" which she had had a year previous. The physical signs showed the presence of small deposits scattered all over the lungs, probably along the bronchial tubes, but no large deposit in any one place. An examination of sputa showed the presence of a very large number of tubercle bacilli. She had considerable variation of temperature and considered herself quite ill. I placed her on inunctions of iodoform in cod liver oil, gave her creosote internally and gave her phenacetin and quinin for her fever. She improved very slowly under this treatment, but yet the improvement was perceptible from month to month. In the early summer she was able to go to the seashore, where she continued to improve, and when she returned to the city her pulse was normal, her temperature normal; she had a fair appetite, had gained some in weight, not a great deal; coughed very little and spat scarcely any. Although not well, she believed herself to be in good condition. After that she enjoyed fair health, but had recurrences of exacerbations of cough, and I believe that she is still enjoying fair health, although I have not seen her recently.

Case 19.—Female, white, aged 70, mother of large family, came under treatment for a cough in September, 1892. She had had in recent years several sons die of tuberculosis and she had just nursed one during a long confinement to his room, where she had been his constant associate. Her cough came on shortly after her son's death, and upon physical examination it was found that she had almost complete consolidation of the apex of one lung extending below the angle of the scapula. I gave her tonic treatment and placed her on inunctions of iodoform. In order that she might have the benefit of climate in addition to what could be gained from therapeutics, she went to Florida in the fall and spent the winter there, during which time she continued the inunctions. When she returned to Philadelphia during the following April the condition of her lungs was very much improved. She continued treatment and spent the hot months of the following summer in the Pocono Mountains. At the end of a year's treatment her lung had apparently entirely recovered and all symptoms of the disease had disappeared. She has remained entirely free from tubercular symptoms since, although she has recently died from disease which may possibly have been tubercular. It is worth stating that this person was a most pronounced subject of gout and had been so from early life, and that the gouty diathesis may have played some part in her recovery.

Case 20.—Female, white, aged about 25 years, teacher, was taken sick with a hemorrhage during the summer of 1892. She had had a brother die of tuberculosis shortly before that time. She had consolidation of the upper lobe of one lung, from which no doubt the hemorrhage came, and had quite a severe cough. At the same time she had a pelvic trouble which looked as though it might be tubercular. I put her to bed and placed her on iodoform inunctions and gave her creosote internally. She improved rapidly and went away to the country for a short time in the latter part of the summer, while she continued her treatment. In the fall she resumed her duties as a teacher and continued the inunctions. The lung cleared up entirely and the pelvic symptoms disappeared after about six months' treatment. About a year subsequently she had a second mild attack, from which she also recovered and she has since remained well and is at present following her vocation as a teacher.

Case 21.—Female, white, aged 23 years, employed at book-binding, first developed a cough in the early part of 1892. She had been exposed to tuberculosis in her home by reason of her father and sisters suffering from the disease for several years. Physical examination revealed consolidation of the upper lobe of the left lung and she had the tubercular variations of temperature. I placed her on iodoform inunctions with tonics and treatment for temperature. She improved rapidly and recovered so far that scarcely any physical signs of lung disease could be detected upon the most careful examination. She

turned to her work, believing herself well, and declined to ve further treatment. She remained well until the spring 1894, a period of two years, when she again developed a ough, and upon physical examination I found consolidation the base of the left lung. She again had temperature variations, and this time some expectoration in which tubercle cilli were found. The treatment with iodoform was resumed and she was kept under observation continuously, but in spite everything that could be done the case took on an acute form and in the course of three or four months came to a fatal sue.

Case 22.—Female, white, aged 25 years, teacher, first developed tuberculosis about 1892, and came under treatment in ptember of that year. She had been exposed to the disease y helping nurse her father. When I first saw her she had consolidation of the apex of one lung with a very annoying cough, me variation of temperature, loss of appetite and accompany- g loss of flesh. She received tonic treatment and iodoform in- unctions with creosote by the mouth. The deposit broke down d a cavity formed. At this time the larynx became slightly volved, for which she received special treatment by Dr. Har- son Allen. She continued her inunctions at intervals, ceasing em when she believed herself better. When last seen, which as quite recently, she was enjoying good health, but still had a ough, a secreting cavity and some bacilli present in the sputa. urtherwise, however, she is apparently enjoying good health and believe that, could she be induced to use her treatment regu- rly and persistently, she would recover entirely.

Case 23.—Female, white, married, aged 44 years, developed ough September, 1892, which, although not alarming, oused the suspicions of her brother, who was a physician, cause it was accompanied with symptoms of lassitude and me loss of flesh. As the cough persisted, repeated careful aminations were made of the lung and it was finally discov- ed that there was an area of dulness along the spine between e spinal ridge and the shoulder blade, high up on the right de, indicating an enlarged bronchial gland. After a while this and broke down, and the discharged pus revealed the presence many tubercle bacilli. The case was placed on iodoform in- unctions and large doses of creosote, with such tonic treatment would suggest itself from time to time. Although the case as a most unpromising one, under the attention and close watch- g of her brother, who forced her nutrition in the most judicious nner, she improved, and the abscess which formed in the bron- ial gland apparently healed up without any new deposit hav- rmed anywhere in the lungs. The treatment was persevered in r about eight months, when a change of climate was determined pon. The case continued to do well and the patient has since aveled in Europe, apparently in good health. Occasionally mptoms occur which give some ground for solicitude, but to l appearances she is well.

Case 24.—Female, white, aged about 18 years, was taken ith a slight hemorrhage in the fall of 1892. Physical exa- ination revealed very little abnormal in the lungs, and the ealth of the patient was not much affected. Shortly there- ter, however, more active symptoms set in, and it was clear at there was a deposit in the apex of one lung. The young dy had during the year taken a trip on a sailing vessel with consumptive friend, and was on most intimate terms with er. Under iodoform inunctions and tonic treatment, and with rced nutrition, she improved very rapidly, and during the mmer of 1893, almost entirely recovered her health in the ocono region. During all this time she faithfully used the unctions of euophen. Early in 1894 she went South with a ew of escaping the severity of the northern winter, and while ere had a severe hemorrhage which was followed by most ute symptoms which necessitated her being brought home. he died of acute tuberculosis shortly after her return.

Case 25.—Female, white, aged 18 years, the only child of a ealthy man. Mother and only brother had died of tubercu- osis some years before. She had had a slight attack of influ- nza, during the convalescent stage of which her father took er to Florida, from whence she returned after some time with r persistent cough and some indisposition, accompanied with ally rise of temperature. A throat specialist was consulted, ho for a while treated her for laryngeal trouble. She came nder my treatment in May, 1893, when I found that she had onsolidation of the apex of one lung, with symptoms of begin- ing tuberculosis. She had been losing flesh rapidly and was a depressed, feverish condition. Under inunctions of iodo- orm and rest in bed she recovered from the acute symptoms a about four weeks, and was in proper condition for removal o the Pocono region. The treatment was continued and she apidly recovered her health. Her temperature became nor- al, her pulse became normal, and although a small cavity had rmed, resolution took place in the lung to such a degree that

very few physical signs of disease could be detected. By December of that year she presented the appearance of a young woman in perfect health and was able to endure a large amount of physical effort without fatigue. She had gained about 30 to 35 pounds and weighed 150 pounds. There being some difference of opinion in the selection of a winter climate, the case now passed from under my treatment. In a warm, enervating climate acute symptoms again set in, which led to a fatal termination at the end of about six months.

Case 26.—Male, white, aged 40 years, was taken sick with acute symptoms of tuberculosis during the early part of 1893. He had had a brother die of consumption six years before, and had himself had a cough, off and on, for six years prior to that date. He came to see me because of a hemorrhage which he had recently had. I found consolidation of the upper lobe of the left lung and all the typical signs of tuberculosis. I placed the patient on iodoform inunctions and tonic treatment, and gave him gradually increasing doses of creosote. He im- proved under this treatment, which he persevered in con- scientiously, and recovered his health to a very great degree, but never got entirely free from cough. By the summer of 1895 he had reached as high as 160 pounds in weight and pre- sented the appearance of good health. He continued his treat- ment, however, with short intermissions, and maintained a pretty even standard of health until the spring of 1896. At this time, after losing weight for a few weeks, he quite sud- denly developed an acute form after an attack of influenza, and was confined to his bed and lost weight very rapidly. The symptoms were so severe and his emaciation so rapid that it looked as though he must necessarily die. He persevered faithfully with his treatment, however, and made desperate efforts to force his nutrition even during the severest part of his illness. During the three months that he was confined to his room he dropped from 141 pounds, to which he had already been reduced before going to bed, to 125 pounds. He again began to convalesce, however, and to rapidly gain in weight, and by July of that year, less than two months after getting up, he again weighed 141 pounds, and by December had reached 167.5 pounds. At present, although he has recently had an attack of influenza, he is enjoying fair health and is attending to his business. He is, however, not entirely well, as bacilli were still present in his sputa when last examined, and he is of course in danger of an extension of the disease at any time.¹

Case 27.—Female, aged about 50 years, white, single, began to show symptoms of tuberculosis in the early part of 1892. Had nursed a sister with tuberculosis, and not knowing the disease to be contagious, had taken no precautions. She had been a woman of delicate health for years and was, in her normal condition, very thin and spare. She had a deposit in the apex of one lung, a slight cough, but no acute symptoms. Under iodoform inunctions and a tonic treatment she improved very much in health and gained quite a good deal in weight. She improved so much, indeed, that doubts began to arise in the minds of her friends about her ever having had tubercu- losis, and in fact, I was myself beginning to have some doubts about my diagnosis. This improvement continued during 1892 and the greater part of 1893. The inunctions, being found rather irksome, were discontinued, but the tonic treatment was kept up with occasional intermissions. In the spring of 1894 a recurrence of the disease took place which left no doubt of the diagnosis, as the disease manifested itself in a rather acute form. The inunctions were again resumed with some improvement, but the disease was never again brought under control. In the fall of 1894 the patient became confined to the house, and died in December, 1894.

Case 28.—Male, white, aged about 19 years, came under treatment for cough and slight fever in the early part of 1894. He had had one sister and one brother die of tuberculosis in recent years, was poorly nourished, rather anemic and pre- sented the appearance of being a bad subject for the disease. He gave a history which raised the question of syphilitic infec- tion, so that there is some doubt about the diagnosis. The symptoms, moreover, were not typical of tuberculosis and it was never possible to outline any definite involvement of the lung. He had, however, loss of flesh, elevation of temperature and pulse above the normal, all of which symptoms indicate tubercular deposit. Under treatment with iodoform inunctions with occasional rest in bed, tonics and forced nutrition he rapidly recovered. By the middle of 1895 he was appar- ently in good health. He has since enjoyed fair health and has had no recurrence of cough.

Case 29.—Male, white, aged 52 years, came under my treat- ment during the latter part of 1894. He was then in the third

¹ This patient has died of acute peritonitis, after a few days' illness, since the reading of my paper. Unfortunately, an autopsy was denied me.

stage of tuberculosis, having suffered from the disease for several years. His lungs were so generally affected that I did not expect him to live long and gave the most unfavorable prognosis. I, however, placed him on inunctions of euophen, put him to bed, gave him creosote and tonic treatment. Greatly to my surprise he improved, gained weight and recovered sufficiently to again be able to go out and be about. His expectoration decreased very materially, his cough lessened, and while he did not recover entirely, he regained a condition of health which enabled him, according to his ideas, to discontinue the services of his physician. I have seen the man recently and he is still enjoying about the same health he had when he discontinued his treatment. His case is remarkable because of its improvement when it had apparently advanced to a fatal condition.

Case 30.—Female, white, aged about 40 years, came under my treatment in the early part of July, 1894. She had been delicate all her life and had believed herself to be the subject of tuberculosis years before, but the symptoms which she related would indicate that her fears were ungrounded. The present attack came on after influenza and manifested itself by consolidation of the upper lobe of the right lung, persistent cough and slight elevation of temperature. Under inunctions which were practiced for a long time and tonic treatment the cough disappeared, the lung cleared up and to all appearances the patient got perfectly well. This condition of health continued until the spring of 1897, when she again had an attack of influenza which left the upper lobe of the right lung consolidated. She at present is again under treatment with the euophen inunctions and is improving, although the lung has not yet cleared up and she still has the rapid pulse so typical of tuberculosis.

Case 31.—Female, white, aged about 12 years, had been exposed to tuberculosis in the latter part of 1892 by the presence in her parents' home of an uncle who died there from the disease. She developed the first symptoms about May, 1893, when she began to lose flesh rapidly and had a persistent cough and fever. Clinically her case was typical tuberculosis in the first stage. She was placed upon euophen inunctions and given a tonic. Although her symptoms were so acute that I was induced to give an unfavorable prognosis, she improved very rapidly under the treatment and by September was nearly well. I have heard from her quite recently and she is now enjoying perfect health.

Case 32.—Female, white, aged about 32 years, unmarried, contracted tuberculosis from a sister who died of the disease. She came under treatment in the early part of 1895. When I first saw her she gave a history of having coughed for some years during the winter season without much affecting her health. She had not lost much weight recently and at the time weighed 129 pounds. She had cavities in the apex of the left lung and the presence of tubercle bacilli in the sputum. I gave her tonics, creosote in hot water before meals and directed her to use iodoform inunctions. She improved rapidly and by fall weighed 150 pounds. I increased her creosote gradually until she was taking 35 drops three times a day at the end of a year's treatment, when she weighed 161 pounds and presented the appearance of perfect health, although she still continued to cough and had bacilli present in the sputum. During the spring of 1896 she had a slight extension of the disease, owing to an attack of influenza, which reduced her to 150 pounds in weight and otherwise very materially retarded her progress toward recovery. She continues under treatment at the present time and presents the appearance of good health, weighing 167½ pounds, the highest point reached, but still has bacilli present in the sputa. The bacilli, however, are few in number and show degeneration.

Case 33.—Female, white, Italian, unmarried, aged about 25 years, came under my treatment in January, 1895, having been recommended to me by a fellow practitioner under whose care she had been for a year. She was at that time in bed, having been confined there for some weeks and was laboring under an acute form of tuberculosis which had advanced to the third stage. She had fever, sweats, annoying cough, considerable expectoration and had had some hemorrhages. Her prostration was great and her mental condition was so disturbed as to suggest the possibility of meningeal involvement. Physical examination revealed that the pulmonary trouble was pretty well confined to one lung, although in an active condition. Without hope of improvement I placed her on euophen inunctions and forced her nutrition all I could. Much to my surprise she improved so that during the spring she was able to sit up, and early in the summer was able to go out. She continued her treatment, and at my suggestion went into the pines of New Jersey during the hot summer months and lived out of doors as much as possible. She returned in the autumn very

much improved, having gained a great deal in weight and being entirely free from acute symptoms of the disease. The condition of her lung also showed marked improvement. Having heard of Maragliano's new treatment, and having met an Italian physician who had imported some of the serum and who was in a position to administer the treatment, she decided to take it and informed me of her decision. After a few weeks' treatment with the serum she had a severe hemorrhage, from which she died.

Case 34.—Female, white, unmarried, aged 35 years, came to me for treatment during the summer of 1895. She gave a history of a hemorrhage six years before followed by occasional attacks of coughs and delicate health. A recurrence of the hemorrhage took place about eight months prior to seeing me, after which she continuously had a cough, which had become much severer a few weeks prior to her coming under my treatment. When I first saw her she had acute symptoms of tuberculosis in the third stage, and physical examination revealed a large cavity in the right lung to below the angle of the scapula. There was also a deposit in the apex of the left lung. Her case looked very unfavorable, but its long resistance showed excellent resisting power and gave encouragement for treatment. She was, however, very much emaciated, only weighing 101½ pounds. I placed her on euophen inunctions, gave her creosote before meals and tonic treatment consisting of pepsin, hydrochloric acid and strychnia after meals. She improved very rapidly and went away from the city during the summer. When she returned in October she weighed 110½ pounds, was nearly free from symptoms indicating active condition of her disease, except that her pulse was accelerated, but considered herself very much improved. She continued her treatment, although less regularly, and in January, 1896, she was still in very good condition. She continued so well that she stopped her treatment. Quite recently, however, she has had a recurrence of the disease, for which she is now under treatment.

These are some of the cases that came under treatment at an earlier period than two years ago, and that were under treatment long enough to have given a fair opportunity to judge the results. Of the cases that came under treatment within the last two years, many show excellent results, but I will quote only a few.

Case 35.—Male, white, aged about 18 years, had been exposed to tuberculosis in his own family, from a sister dying of it. He was taken down during the summer of 1896. His first knowledge of his illness was by a hemorrhage which was rather severe and which was followed by cough and by much weakness. He had not yet lost much flesh, but became very pale and showed the presence of anemic murmur of the heart. Physical examination did not reveal much wrong with the lungs, although there was impaired resonance in one apex. After a very short time, however, dulness over the apex appeared and prolongation of expiratory murmur. Believing the disease to be tubercular, I placed him on inunctions of euophen and gave him a tonic treatment. He rapidly improved, gained some in weight, and by the end of the year was free from all symptoms of the disease as far as could be determined by physical examination. He continued his treatment, however. During the spring of 1897, he again had some exacerbation of his disease, as manifested by acute symptoms brought on by an attack of influenza, but at the present time he is enjoying fair health and promises to recover.

Case 36.—Male, white, aged 37 years, living in the Allegheny Mountains, contracted tuberculosis while nursing his wife who died from the disease in the early part of 1896. He had no family history of tuberculosis and had always enjoyed good health up to the time of his wife's fatal illness. When he consulted me he had been under treatment for some months with his family physician, and showed acute symptoms of the disease, but no evidence of having advanced beyond the first stage. He had had a recent hemorrhage and acute symptoms of pleurisy. Physical examination revealed a right sided chronic pleurisy with involvement of the apex of the lung. I recommended forced nutrition, the use of euophen inunctions and a tonic treatment. Upon his return home he began this treatment and several months afterward wrote me that he had entirely recovered his health, having regained all his lost weight and being free from cough and pleuritic symptoms.

Case 37.—Male, white, aged about 30 years, had been under treatment for four months before coming to me, during which time he believed himself to be constantly growing worse. He consulted me early in March, 1897, when he was laboring under a semi acute attack of tuberculosis, the deposits being scattered and there being probably a small cavity on the right side, which gave off a very large number of bacilli. He was

ry hoarse. An examination of the throat, by Dr. Harrison Len, revealed a congested condition of the larynx and an ulcer in one nasal passage. At this time he weighed 141½ pounds. Under inunctions with europphen; creosote, pepsin and hydrochloric acid by the mouth, he has rapidly improved so that at present he is almost free from cough, expectorates very little and weighs 160½ pounds.

Case 38.—Female, white, aged 23 years, came to my office for treatment in February, 1897. He gave a history of having been delicate since childhood, and of having suffered from her present illness for a year, during which time she has been under treatment. The cold from which she believed herself to be suffering had continued for a month prior to seeing me. At the time of her first visit she was laboring under a semimute attack of tuberculosis, with a small cavity, in the discharges from which there were tubercle bacilli. She weighed 100 pounds. I put her on inunctions of europphen; creosote and pepsin and hydrochloric acid by mouth. She has constantly improved since and at present is in very fair condition, weighing 97½ pounds.

A résumé of the cases that I have treated by this method during the last eight years will probably give the best picture of what can be expected from it. In order that the lesson may be the more practical I will divide the cases into classes:

TABLE 1.—Cases that came under treatment longer ago than two years.

Number of cases	77
“ “ now dead	38
“ “ now living	19
“ “ lost track of (probably living 11, probably dead 9)	20
Total	77

TABLE 2.—Cases that came under treatment within two years.

Number of cases	25
“ “ now dead	9
“ “ now living	9
“ “ lost track of (probably living 5, probably dead 2)	7
Total	25

TABLE 3.—Cases that were under treatment for a longer period than two months.

Number of cases	69
“ “ now dead	33
“ “ now living	26
“ “ lost track of (probably living 4, probably dead 6)	10
Total	69

Number of cases treated	102
“ “ probably dead	11
“ “ now dead	47
Total	58

Number of cases cured, that is, entirely free from all evidences of disease	15
Number of cases of disease arrested, that is, in good condition of health, but evidences of disease still present	16
Number of cases improved, that is, who attained a fair condition of health, but with no prospect of permanent improvement	15

Total	104
Number who died of intercurrent disease	2
Total number treated	102

The conclusions that I believe myself justified in drawing from this eight years' experience in the treatment of tuberculosis with iodoform and europphen are: 1. That incipient cases can almost always be cured by europphen or iodoform inunctions. 2. That cases advanced to the breaking down stage may be improved very much by this method of treatment and can sometimes be cured. 3. That the treatment ought to be continued even after acute symptoms have disappeared, and that it should be maintained until perfect health is reestablished.

As to the respective merits of europphen and iodoform, from a therapeutic point of view, both have apparently done equally well in my hands as far as the results are concerned. From an esthetic point of view, the europphen is much to be preferred because it is much less offensive in odor, and can be almost perfectly disguised. I have for almost a year discarded the use of iodoform. The formula which I now employ is as follows:

- Europphen 1 dram
- Oil of rose 1 drop
- Oil of anise 1 dram
- Olive oil 2½ ounces •

This makes an excellent preparation, giving a perfect solution and being in no wise offensive to the sense of smell. I instruct my patients to rub about a tablespoonful thoroughly into the inside of the thighs and into the arm-pits before retiring at night, and if they have any fear of odor, to sponge themselves with bay rum or bath whisky when rising in the morning. By following these instructions the most fastidious can satisfy themselves that they will not attract attention in public. The treatment is somewhat troublesome, but patients when they once discover that they are deriving benefit from it, not only do not object to its use, but are anxious to employ it. I have had very little trouble on the score of getting patients to persevere with the treatment during the acute or subacute stages of their illness, but only when they have apparently recovered their health. Most people settle for themselves the question whether or not they are well, and I find that when consumptives begin to enjoy a fair state of health they do not care to any longer submit to a troublesome treatment.

It is but proper for me to say further that the majority of cases that I have treated in this way and upon which I base this report, were among the poor and never had the advantage of climate, or of even temporary removal from the city. Indeed, many of them

did not even have the home comforts and the advantages in food which are so important in the treatment of tuberculosis. The results ought therefore to be judged upon a basis of unfavorable environments, for which reasons, in comparisons with other results, some allowance ought to be made. I have no doubt that in sanatoria favorably located, much better results could be obtained by this treatment.

I have long since been convinced that it is the iodine which gives the good results, and that the advantage of using europhen or iodoform through the skin lies in the fact that an even and continuous influence can be maintained on the blood by the gradual absorption of the drugs and the giving off of the iodine in the blood or tissues. I must confess that I have arrived at these views largely by exclusion, because they are the only ones tenable with our present knowledge of the etiology and pathology of tuberculosis. When tuberculosis has once advanced beyond the first stage it is only curable by the establishment of an immunity against new colonies of the tubercle bacillus. This is so because, when the circulation is once cut off from the existing deposit, cure can only take place by either getting rid of that deposit, or by walling it in. Usually nature makes an effort to get rid of the deposit through the process of degeneration and ulceration through the healthy tissues. But inasmuch as the germs have to pass through the healthy tissues when the broken down tissues are being thrown off, reinfection is almost certain to take place unless the individual possesses an immunity which makes it impossible for the germs to again find proper soil for development. This immunity must, moreover, be constant and sufficiently permanent to maintain an incongenial soil until all the germs have been ejected from the organism. The iodine which is given off from the europhen and iodoform into the circulation after its absorption by the skin maintains, I believe, to a certain degree, an immunity which makes new colonization difficult and in this way contributes toward a cure.

Where tuberculosis is still incipient, and where the circulation has not yet been cut off from the nodules, I believe that the iodine, when brought into the system through the europhen or iodoform inunctions, will almost invariably cure. Of the cases of this description that I have treated, most have recovered, although a number had relapses and subsequently died of acute tuberculosis. Some of these cases, however, were constantly exposed to reinfection from other members of the family and may have contracted new attacks.

It is but fair to say that an incipient case of tuberculosis is an unconfirmed case as far as diagnosis is concerned. The diagnosis in incipient cases must necessarily depend upon clinical symptoms, as there is not yet any broken down tissue and there is no possible way in which the tubercle bacillus can be demonstrated. The clinical symptoms of tuberculosis are, however, sufficiently striking and well enough defined to allow of a rational diagnosis. Where we have a rapid pulse, a daily rise of temperature with impaired resonance, or partial consolidation of a part of a lung, with prolongation of the respiratory murmur, there can be little doubt about the nature of the disease which the person is suffering from. We know, moreover, from past experience that persons in this condition, if allowed to go on without treatment, invariably develop into full-fledged consumptives. While there is, therefore, some doubt about the diagnosis of the

cases which I have quoted as incipient, they must be accepted as representative cases of their kind and must be allowed to pass as a basis for the conclusions which I have given.

It is proper for me to say, in conclusion, that much of the benefit which I have had in the treatment of the cases quoted in this paper was no doubt due to tonics and creosote. As indicated throughout the paper, I have used creosote in large doses in all cases advanced to the breaking down stage. In such cases I think better results are obtained by using both creosote and europhen than by using either drug alone.

OXYTUBERCULIN IN TUBERCULOSIS.

Read by title in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association at Philadelphia, Pa., June 1-4, 1897.

BY J. O. HIRSCHFELDER, M.D.

SAN FRANCISCO, CAL.

Ever since Behring introduced the antitoxin of diphtheria into medical practice, the attention of the profession has been directed to the discovery of a similar mode of treatment for all the other infectious diseases. We have a right to assume that the law of the antitoxins is one of general application, and that that observation which is true of one bacterial disease is true of all. Efforts, however, to produce antitoxins of other diseases than diphtheria, have not led to the striking results obtained in that disease. Various observers, first among them being Paquin in our country, and last Maragliano in Italy, have used serum of animals supposed to have been made immune to the bacillus tuberculosis, but the results, to say the least, have not equaled those in diphtheria. The association of the antitoxic principle with various other ingredients of the blood serum, has led to unpleasant results that have thrown discredit on the method, and have rendered it impossible to use the remedy in effective doses. As we certainly know that the antitoxins are elaborated, in the animal organism, from the bacterial toxins, it is not unreasonable to believe that such an alteration might be effected in the laboratory. Attempts have been made, through electrolysis, to convert the toxins, and have led to encouraging results in the hands of Smirnow, d'Arsonval and Charrin, as well as some others; but no practical application of the method has yet been made. None of the theories formulated to explain the production of the antitoxins has been universally received, nor has chemist analysis given data to permit us to recognize a difference between the toxins and the antitoxins, otherwise than through their biologic effects. The theory that the oxidation of the toxins leads to the production of an antitoxic substance, which I enunciated in August, 1896, is one that has in it an inherent element of probability, independent of clinical demonstration.

My experiments have been conducted mainly with the toxin of tuberculosis, and have led to verification of the hypothesis, in the experimental as well as in the clinical domain.

As stated in previous publications, I have produced this oxidation by the action of the peroxid of hydrogen at 100 degrees C. The method has been to filter a sterilized fully grown culture of the bacillus tuberculosis upon alkaline glycerin veal bouillon, and to add one-tenth the volume of ten volume solution of peroxid of hydrogen to such tuberculin; to maintain the mixture at 100 degrees C. for twelve hours, then to add the same quantity of the peroxid, and to repeat

the process until the quantity added shall equal that of the tuberculin used. The final mixture is then heated for twelve hours more; that is to say, the tuberculin is subjected to the action of the peroxid at 100 degrees C. for one hundred and twenty hours. The resultant oxytuberculin is darker than the tuberculin, is highly acid and somewhat turbid. It contains an excess of peroxid of hydrogen. In order to drive this off, the solution is made alkaline with caustic soda, which at the same time clarifies the mixture. It is heated for a short time, which darkens it still more, and is now found to contain no peroxid of hydrogen. To those unfamiliar with the peroxid of hydrogen, its persistence in a complex organic fluid is a matter of some surprise. Such I would refer to Danner's "Handbuch der Anorganischen Chemie," wherein the statement is made that some organic substances, such as urea, albuminoids and gluten, are without action upon hydrogen peroxid, while others are slowly decomposed by it, with the evolution of carbon dioxid containing oxygen. That tuberculin belongs to the class of those substances which are slowly affected by the peroxid has been absolutely proven, for I have produced characteristic tuberculin reactions, in consumptive patients, with tuberculin that has been treated for thirty hours with the peroxid of hydrogen, and fainter effects with some treated even longer. If we add alcohol to tuberculin a white, flaky precipitate occurs, that is readily soluble in water. If to the oxytuberculin absolute alcohol is added, a brown extractive-like substance forms, which is likewise soluble in water and from which solution it may be reprecipitated by alcohol. No matter how often the process of solution and precipitation occurs, the appearance of the precipitated oxytuberculin always remains the same. It resembles caramel very much in color and consistency. No chemic comparison has yet been made between the precipitated tuberculin and the oxytuberculin, but the appearance of the latter suggests partial oxidation. Absolute proof can not be attained until the elementary analysis shall have been made. The name given to the preparation has misled several, who supposed the oxytoxin was regarded as an oxygen carrier. This is not the case. The name was selected to indicate that we probably had an oxidized toxin.

Whether this oxytoxin be the substance which develops in the economy or not, it possesses certain very valuable properties such as are not present in any of those thus far found in the antitoxic serums. Most prominent among these is its inhibitory influence upon the growth of the germ. If we make our tuberculin alkaline by adding 3 c.c. of a normal carbonate of soda solution to a liter of the neutral liquid and mix it with an equal quantity of veal bouillon equally alkaline, the bacillus of tuberculosis will grow on it with great rapidity. If instead we use oxytuberculin prepared from the same tuberculin, absolutely no growth will occur. Not only so, but the inhibitory power of the oxytuberculin can be accurately gauged, so that its potency can be measured, and different preparations thus compared with each other.

The following experiment will illustrate the method: To 10 parts of alkaline glycerin veal bouillon were added water made three-tenths normal alkaline and oxytuberculin likewise three-tenths normal alkaline, in a series containing 10 to 0 parts of water with 0 to 10 parts of oxytuberculin; so that we had a gradually increasing strength of oxytuberculin from 0 to 50 per cent. Each of the flasks was inoculated with a rapidly grow-

ing virulent culture of bacillus tuberculosis, and it was found that as the percentage of oxytuberculin increased the growth became less and less vigorous, and was completely prevented in that containing 7 parts in 20. This sample of oxytuberculin having been diluted to 30 per cent. may therefore be designated as 300 per cent. strong. Unfortunately, some of the bottles became contaminated with other germs and only seven out of ten bottles could be preserved. The photograph (Fig. 1) clearly shows the gradually increasing inhibitory power of the substance.

In a similar manner any oxytuberculin may be standardized, so that when we use it we may know accurately how potent is the remedy that we are employing. Such a method of estimating the strength of a preparation is infinitely superior to that of judging it from its effect upon more or less resistant animals.

From the very beginning of the experiments it had been my purpose to find some means of knowing how long I should continue the oxidation in order that all the tuberculin should be changed into oxytuberculin and none of the latter destroyed. There was no chemic test known and all my efforts to find one were in vain. I was therefore compelled to make use of the reaction of tubercular guinea pigs to find the point at which no effective tuberculin could be found. It is clear that a certain amount of the tuberculin might be present but neutralized in its effects by the oxytuberculin. Under such circumstances we would get no deleterious tuberculin influence, but still not the best possible oxytuberculin action. In the manufacture of the oxytuberculin, I had gradually come to lengthen the time during which I heated the tuberculin with the peroxid of hydrogen, and had finally decided upon sterilizing for four days. Oxytuberculin so prepared gave excellent results and no reactions, until I happened to use large doses (40 c.c.) with a highly sensitive hospital patient. A slight rise of temperature occurred, which made me feel that all the tuberculin had not been converted. About this time I had discovered the inhibitory influence of the oxytuberculin, and I immediately concluded that this influence would teach me what was the best length of time to continue the oxidation. I reasoned that if my theory were right, as I continued the oxidation the inhibitory power must gradually increase until the maximum is reached, and as the oxytuberculin produced is gradually destroyed by further oxidation, from this point on there must be a gradual decline of the inhibitory power. Such, indeed, was the result obtained. I sterilized for 176 hours, adding the peroxid every twelve hours and removing portions of the lymph for comparison at 96, 120, 144 and 156 hours. The final oxytuberculin, that sterilized 176 hours, contains but 53 per cent of the quantity present in that sterilized only ninety-six hours, and in order to make a fair comparison, after free peroxid in all the preparations was removed by rendering them alkaline and heating, all were diluted to the same proportion with distilled water, the quantity added depending upon the degree to which it had been diluted in the process of preparation by addition of peroxid of hydrogen which had become changed to water. All of the preparations were then neutralized and 0.3 per cent. normal carbonate of soda was added. Each of the oxytuberculins was mixed with an equal quantity of standard veal bouillon and inoculated with a pure culture of the bacillus tuberculosis. As a control, standard veal bouillon was mixed with an equal quantity of water

to which 0.3 per cent. normal carbonate of soda was added, and was likewise inoculated with the same germ. The relative growth is shown on the chart and by the photograph of the bottles in which they have developed (Fig. 2).

the 156 hour preparation and in that sterilized 176 hours, was almost as great as in the pure veal bouillon. This simple little experiment not only confirmed our previous culture tests, but likewise taught that at least 120 hours and less than 144 hours are necessary

Figure 1.

Figure 2.

They show rapid growth in the veal bouillon, less in the 96 hour oxytuberculin, and hardly any in the 120 hour oxytuberculin, which had been diluted with water and veal bouillon to only 26.5 per cent. In the 144 hour tuberculin growth increased, was greater in to get the best results. In point of fact, as soon as I began to use oxytuberculin, so prepared, on my patients, immediate and striking results occurred such as I had not witnessed before. I shall now narrow the range still more by tests of oxytuberculin

It having been suggested that possibly the inhibitory influence exerted might be due to the action of the peroxid of hydrogen on veal bouillon, the latter was oxidized in a similar manner for 130 hours and no inhibitory effect found.

The results obtained in medical practice by the therapeutic use of this oxytuberculin, both in my own hands and those of such of my colleagues as have employed it have been more than encouraging. We have been so often deceived in our expectations that it is wise to be cautious before we accept a new remedy for tuberculosis, but the results obtained with oxytuberculin are so striking and so rapid that they can not be accidental. Injections are made into any part of the body under ordinary aseptic precautions. I begin with 5 c.c. daily, gradually increasing to 20 c.c. with which dose it is ordinarily well to continue. As much as 100 c.c., or the equivalent of 5 c.c. of Koch's concentrated tuberculin, has been injected into one patient

completed. The bacilli of tuberculosis in the sputum may rapidly diminish in number and in many cases disappear entirely. In visible tubercular infections, such as those in the larynx, the resolution of the tubercular infiltration can be watched with the laryngoscope. A number of such cases have been observed by me and by my colleagues. A case of tuberculosis of the skin was treated by local applications of oxytuberculin and rapidly cured. As confirmatory of the value of this observation I will refer to an experiment made on a dog. This animal was vaccinated upon the skin, with a virulent tuberculosis bacillus. Soon ulcers, shown by the enlarged photograph of the excised piece of skin, developed (Fig. 4). These contained the bacilli in pus and tissue. The dog was treated by injections of oxytuberculin and soon recovered, the ulcers disappearing and the skin assuming the normal appearance, as you can see from the photograph (Fig. 5).

Figure 3.

without the slightest unpleasant local or constitutional effect. The liquid causes no greater local disturbance than would any indifferent fluid. There is no reddening of the skin nor other sign of localized inflammation. In a few minutes the fluid injected is absorbed and the patient has no further inconvenience except sometimes a slight smarting at the site of injection. There is no reaction, no rise of temperature, nor any other unpleasant constitutional effect. In a short time marked results occur in early cases. The color of the patient improves, his cough and expectoration diminish and a feeling of vigor soon develops. This is especially evident in cases of the first stage where there is no fever. Where only slight fever is present the higher temperature soon diminishes, and in many cases becomes entirely normal. At the same time, the infiltration of the lung diminishes and gradually disappears, so that the most careful physical examination fails to reveal any deviation from the normal whatsoever after the treatment is

Of the cases that I have treated with the oxytuberculin, those who came in the very early stage of the disease before cavities were present, have been rapidly cured. By cure I mean a complete cessation of cough

Figure 4.

and disappearance of all symptoms of disease on the part of the patient, together with the return of a normal condition of the lung as shown by physical examination. Above all do I demand that the bacilli of tuberculosis shall no longer be found in the sputum.

Cases that were moderately advanced have likewise rapidly improved and some have entirely recovered.

Of the very advanced cases many have shown marked improvement and many whom I had declined to treat, as being too far advanced, but who pleaded so hard for treatment that I could not refuse, have surprised me by the wonderful improvement they have shown.

Some, in the last stages of the disease, who presented themselves with high fever, cyanotic and gasping, have died. No treatment should be expected to reach such cases. They throw a cloud upon the statistics, for they must be honestly reported with the more favorable cases. I shall therefore present to you statistics of all the cases I have treated with oxytuberculin, but request you not to judge by the advanced cases, for which I make no claim whatsoever.

In order to systematize our observations, I will divide the cases into four sets, depending upon the stage of the disease.

In the first stage, we find infiltration of the lung, with more or less pallor, loss of weight, cough with sputum containing bacilli of tuberculosis. These may be absent at repeated examinations and yet finally be found.

reports too favorable. It has been my purpose to be as skeptical as possible, and I have striven to make the showing rather less favorable than too much so. I find that the cases treated, with oxytuberculin insufficiently oxidized, did not give the same results as those treated with the newer preparation, and have therefore separated them into a distinct table.

THE CLINICAL SYMPTOMS, BACTERIOLOGIC FINDINGS AND POSTMORTEM APPEARANCES IN CASES OF INFECTION OF HUMAN BEINGS WITH THE BACILLUS PYOCYANEUS.

Presented in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association held at Philadelphia, Pa., June 1-4, 1897.

BY LEWELLYS F. BARKER, M.D.

ASSOCIATE PROFESSOR OF ANATOMY, JOHNS HOPKINS UNIVERSITY, AND ASSISTANT RESIDENT PATHOLOGIST, JOHNS HOPKINS HOSPITAL, BALTIMORE, MD.

[ABSTRACT.]

[From the Pathological Laboratory of the Johns Hopkins Hospital and University.]

The literature of the bacillus pyocyaneus with especial reference to its pathogenic effects in human beings

Figure 5.

In the second stage, we have infiltration of the lungs, with hectic fever, emaciation, large quantity of the sputum containing bacilli of tuberculosis, but no cavities.

In the third stage, we have cavities, but still a fair degree of vigor. There is no dyspnea when the patient is quiet, but marked shortness of breath on exertion.

In the fourth stage we have large cavities, with the usual signs of advanced consumption—the dyspnea is very decided even when at rest.

The distinctive features are:

Stage 1. Slight infiltration of the lungs.

Stage 2. Extensive infiltration of the lungs.

Stage 3. Cavities, with dyspnea on exertion and none when at rest.

Stage 4. Cavities with dyspnea when at rest.

Many of the cases have been seen by other physicians before and during the treatment. My colleagues have confirmed my observations and I am certain that they will agree that I have not erred in making my

was reviewed. Especial reference was made to the experimental work of Charrin on animals and to the human infections reported by Octtinger, Ehlers, Jadkewitch, Neumann, Schaefer, Karlinsky, Ledderhose-Jakowski, Gruber, Martha, Krannhals, Calmette, Monnier, Ernst, Fowler, Adami and Williams, Kossel-Blumer, Williams and Cameron, Lavender, Pes and, Gradenigo, and Le Noir. There can no longer be any doubt that in addition to the more or less accidental appearance of blue pus in surgical cases that the bacillus pyocyaneus is capable of entering the human organism and setting up disease processes of variable intensity sometimes of a violence leading to a fatal issue. The writer reported eleven such cases which had come under his personal observation. These eleven cases were independent of the instances in which ordinary blue pus occurred and are examples of infections in which the bacillus pyocyaneus could be held directly responsible for definite lesions. The frequency of such infections may be calculated from the statement

that out of some 800 consecutive autopsies made, eleven such occurred. That they were discovered depends upon the fact that a systematic bacteriologic study of all the autopsies made at the Johns Hopkins Hospital is insisted upon by Professor Welch. No detailed description of the autopsies and histologic lesions was given as they are to be reported in full later. The cases were from the wards of Drs. Osler, Halsted and Kelly. The autopsies were made by Drs. Welch, Flexner, Blumer, Livingood and the writer.

Case 1.—Thomas P., white, aged 20; operated upon for acute abdominal symptoms suggesting obstruction. At operation bowels greatly distended, wall of gut paralyzed, deeply congested; small intestine very friable; torn at one spot; death same night. At autopsy (March 10, 1893) general peritonitis, marked distension and hemorrhagic discoloration of intestine; necrosis and ulceration of surface of small gut; acute colitis; very marked enlargement of mesenteric glands with suppurating inflammation in some of them. *Bacillus pyocyaneus* present in enormous numbers (along with *bacillus coli communis*) in the peritoneal exudate and (pure) in the mesenteric lymph glands. Large masses of *bacillus pyocyaneus* on surface of gut.

Case 2.—Richard B., negro aged 40, with extensive skin disease resembling acute exfoliative dermatitis. Death from broncho-pneumonia. At autopsy Aug. 14, 1893, hemorrhages and thromboses were found in the neighborhood of the skin lesions. Broncho-pneumonia, necrotic foci in the liver, adherent pericardium, heart hypertrophy with fatty degeneration; *bacillus pyocyaneus* in the lung and in the cutaneous lesions. Another *bacillus* carefully studied, but not identified as any known organism, in the kidney, liver and spleen.

Case 3.—E. A. L., middle aged man, dead of peritonitis following operation for appendicitis. At autopsy, Nov. 10, 1893, fibrino-purulent peritonitis; broncho-pneumonia; pulmonary edema; most extensive diphtheritic inflammation of esophagus (with necrosis and hemorrhages), stomach and intestine, especially of the small intestine. Paralysis of wall of small gut with dilatation; acute nephritis; fatty degeneration of heart, liver and kidney; *bacillus pyocyaneus* present in enormous numbers on the surface of the esophagus, in almost pure culture. Histological study of sections from the esophagus and alimentary tract showed large masses of the *bacillus pyocyaneus* on the surface over the necrotic areas. Many of the necroses in the esophagus go into the submucosa. Extensive hemorrhages in neighborhood of necroses; thromboses of blood vessels of mucous membrane; hyperplasia of lymphatic apparatus.

Case 4.—James L. W. Extensive epithelioma of cheek and neck extending to mouth, lung, pharynx and bone. Metastases in cervical and axillary lymph glands. At autopsy, March 15, 1894, bronchitis, extensive broncho-pneumonia, chronic Bright's disease, congestion and edema of lungs; *bacillus pyocyaneus* in pure culture in broncho-pneumonic exudate.

Case 5.—Mary S., autopsy April 12, 1894, large sloughing and gangrenous spindle celled sarcoma of sacrum; extraperitoneal, filling up pelvis, larger than the head of a child. Caesarian section had been done about a year before. Linear scar in uterus; hemorrhagic purulent cystitis; ureteritis and pyelonephritis; old peritoneal adhesions; no fresh peritonitis; acute bronchitis; pulmonary emphysema; encapsulated trichinae in muscles. The *bacillus pyocyaneus* was obtained in cultures from the gangrenous part of the tumor; also in large numbers from the dilated pelvis of the kidney. *Streptococcus pyogenes* present in the lung, kidney and spleen, as well as in the sloughing tumor.

Case 6.—Lizzie K., white; autopsy May 29, 1894. Unresolved pneumonia with carnification of right lower and part of middle lobe; sub-acute pleurisy on right side with organizing exudate; hyperemia and edema of rest of right lung; emphysema, edema and congestion of left lung with multiple areas of consolidation in lower lobe; bronchi congested; mucus and pus in trachea; old pleural adhesions; encapsulated diaphragmatic empyema on right side; subacute suppurative pericarditis (pyopericardium with about 500 c.c. of greenish yellow pus); cloudy swelling of kidneys, slight chronic diffuse nephritis with beginning arterio-sclerotic change; liver deformed and fatty; spleen enlarged and rather firm; enteroptosis and gastroptosis; acute cystitis with ecchymosed mucous membrane. On the folds are hemorrhagic reddish black crusts capped with a grayish white necrotic layer. One hemorrhoidal mass ulcerated on the surface. Erosion of the cervix of the uterus.

From the necroses in the bladder great numbers of *bacillus pyocyaneus* were obtained in pure culture. *Micrococcus lan-*

ceolatus in the unresolved pneumonia, in the pyopericardium and in the empyema.

Case 7.—Theresa S. Autopsy June 15, 1894. Chronic pelvic cellulitis and peritonitis (uterus, tubes, ovaries embedded in dense fibrous tissue with old peritoneal pelvic adhesion); left ovarian abscess (greenish yellow burrowing pus); recto-vaginal fistula; ulceration of small and large intestine; perforation size of a dime in lower part of sigmoid flexure; acute peritonitis; marked dilatation of small gut, especially in lower part. On surface of small intestine beginning at a point 130 cm. above the valve shallow ulcerations begin to appear at first involving only the mucous membrane. Many of them have hyperemic bases with tendency to run along the edges of the cross folds of the gut. As the ileo-cecal valve is approached, the ulcers become larger and deeper and some of them measure 2x1.5 cm.; margin slightly undermined with ragged necrotic base. Peritoneal surface corresponding to ulcers, smooth; similar ulcers in cecum and ascending colon; ulcers in still greater numbers in transverse and descending colon; two large ulcers in rectum; mucous membrane of rectum absent for a distance of 6 cm. above the anus. Circular perforation of rectum 2 cm. above the anus communicating with vagina through posterior wall; mucous membrane of stomach hyperemic and ecchymosed. The ulcers differed from typhoid ulcers in that they were more shallow and were devoid of sloughs and medullary infiltration. Hyperemia and hyperplasia of mesenteric lymph glands; fresh vegetative endocarditis of mitral valve; pulmonary emphysema; purulent bronchitis with bronchiectases; acute fibrino-purulent pleuritis; double hypernephrosis with renal atrophy; elephantiasis vulvae; amyloid disease of spleen and kidney.

Bacillus pyocyaneus present in ovarian abscesses, bronchial exudate, in bladder, on mitral valve, in pelvis of kidney and in large numbers in the intestinal ulcers and in the peritoneal exudate. The *bacillus coli communis* was present in the peritoneal cavity, in the pelvis of the kidney, in the spleen and pleural cavity.

Case 8.—B. O., white. Autopsy June 17, 1894. Chronic productive endocarditis of mitral valve; mitral stenosis and insufficiency; calcified nodule in aortic valve; aortic insufficiency; general heart hypertrophy and dilatation; arterio-sclerosis; chronic passive congestion; cirrhosis of liver; chronic diffuse nephritis; catarrhal colitis with shallow ulcers; acute sero-fibrinous pleurisy on left side; acute peritonitis; fatty degeneration of the heart and liver; a few shallow ulcerations in large intestine, involving only mucous membrane.

Bacillus pyocyaneus in pure culture from the peritoneal cavity. *Bacillus coli communis* and a second unidentified *bacillus* in the pleural exudate. Cultures from kidney, heart's blood and bile, sterile.

Case 9.—T. S., male. Autopsy July, 1894. Extreme dilatation of pelvis of right kidney, containing purulent urine; abnormal opening of right ureter into part of renal pelvis; healed operation for femoral hernia; gallstones; pulmonary emphysema and edema; fatty heart, liver and kidney; chronic diffuse nephritis on right side; superficial erosions in large intestine, cultures from which yield large numbers of *bacillus pyocyaneus*; *bacillus pyocyaneus* also obtained from interior of gallstones.

Case 10.—Rosie W. Autopsy April 1, 1895. Diffuse carcinoma of stomach, involving omentum and gastric lymph glands; metastatic carcinoma of liver, kidney and peritoneum; acute broncho-pneumonia; healed tuberculosis; chronic nephritis; sub-acute and chronic pericarditis with a few tubercles in the pericardium. Cultures from pericardial exudate yield many colonies of *bacillus pyocyaneus*. A few colonies of *bacillus pyocyaneus* obtained from the peritoneal cavity and from the kidneys. *Streptococcus pyogenes* in the lungs and in the kidney.

Case 11.—Wm. S., white, aged 62 years. Autopsy Dec. 16, 1896. Sloughing and gangrenous ulcerative cancer of neck with extension into the surrounding tissues, including sternocleidomastoid muscle; pulmonary emphysema; hypostatic pneumonia; tumor metastases in lungs; arterio-sclerosis; fatty degeneration of heart and kidneys. In the pneumonic exudate and heart's blood the *bacillus pyocyaneus* was present. In addition there was a general streptococcus infection setting out from the sloughing ulcer.

After a recital of the above eleven cases personally met with, the writer proceeded to briefly marshal the evidence thus far available for the view that the *bacillus pyocyaneus* can be pathogenic for human beings.

It is well known that the pyogenic organisms in general can produce very different sorts of disease processes situated in very different parts of the body.

They may cause local infections of one or more of the mucous or serous membranes or may give rise to general infections and intoxications. Some of them are more prone to cause the local processes, others more often are concerned in the production of general infections. Even the same bacterium in different instances according to its virulence or to the varying resistance offered by its host can lead either to local or general processes.

The writer showed that the bacillus pyocyaneus can be concerned in acute local infections of the most various mucous membranes, of the skin, of nearly all the serous membranes of the body, and that it can give rise to general infection, and more often still to instances of general acute intoxication. There is some evidence also that the bacillus pyocyaneus can be the cause of chronic infections and intoxications in human beings.

Of the acute local infections due to it, ovarian abscess has been met with by the writer; three cases of liver abscess are mentioned by Kruse and Pasquale. Jakowski found the bacillus pyocyaneus present as the pathogenic agent in two out of 200 suppurative processes. In the mucous membrane of the alimentary tract superficial and deep inflammations of various sorts are common with this bacillus as an etiologic factor. Thus in the intestine there may be superficial erosion, acute hemorrhagic and necrotic enteritis, shallow ulceration or deep ulceration due to the action of this organism. The most remarkable lesions in the esophagus were found in the writer's Case 3. The mucous membrane of the stomach may be involved. Along with these lesions of the alimentary tract it is common to find paralysis of the wall of the gut, hemorrhages, necroses and ulcerations, accompanied by enlargement and sometimes by suppuration of the mesenteric lymph glands.

Suppurative processes in the middle ear (Gruber, Pes and Gradenigo), in the antrum (Kossel) and nasopharynx are not infrequently due in human beings to the bacillus pyocyaneus. Bronchitis and broncho-pneumonia may be due to this bacillus (Monnier and the writer). The latter has noticed the tendency to hemorrhages and to paralysis of the smooth muscle of the bronchi in such cases.

Severe hemorrhagic and necrotic cystitis, ureteritis and pyelonephritis with paralysis of the muscular walls have been met with by the writer.

In cutaneous and subcutaneous inflammations, the bacillus pyocyaneus has been met with in human beings. These may consist of gangrenous processes (Fowler and the writer), of suppurative phlegmon (Kraus and Buswell), of vesicular eruptions (Oettinger and Ehlers), or of acute exfoliative processes (the writer). The greatest care, however, should be exercised before making definite statements concerning the pathogenicity of the bacillus in cutaneous lesions.

Of the serous membranes which may be infected may be mentioned: 1. The pericardium, in cases thus far reported in association with the tubercle bacillus (Ernst and the writer). 2. The peritoneum, often in association with the bacillus coli communis (the writer's cases 1, 2, 7 and 8). 3. In meningitis (Kossel, Pesina and Honl). 4. In the endocardium (case 7). 5. In joint surfaces (Schurmayer). It apparently has not yet been met with in pleuritis, but doubtless will be found in this process.

That the bacillus pyocyaneus does enter the blood, giving rise to a general infection of the organism,

there can no longer be any doubt. The cases of Oettinger, Ehlers and Neumann show that it can give rise to a definite general hemorrhagic septicemia, accompanied by a vesicular skin eruption, yielding a clinical picture not unlike typhoid fever. The accidental experimental infection associated first with general symptoms, and later with a subcutaneous phlegmon produced in a human being by Kraus and Buswell is a unique observation and extremely important for the establishment of the pathogenicity of the bacillus pyocyaneus. In the writer's experience, however, the bacilli are very rapidly filtered out of the blood by the organs, and thus the cases in which at autopsy the bacillus pyocyaneus is found in several or even a large series of organs, are explicable (Cf. the writer's Cases 2, 7, 10 and 11).

In the cases in which local infection has occurred, and especially in those in which large surfaces like the mucous membrane of the alimentary tract have been involved the phenomena of *general acute intoxication* are common, giving rise clinically to fever, delirium, albuminuria and meteorism, phenomena which can also be produced experimentally in animals by means of injection of the toxins of the bacillus pyocyaneus. At autopsy one finds the pathologic evidences of intoxication; namely, vasomotor disturbances, hemorrhages, focal necroses, parenchymatous lesions in the heart and liver, spleen and kidneys. A very common phenomenon is paralysis of the smooth muscle of the intestinal wall, of the bronchial wall, and of the urinary bladder.

In view of the remarkable results of experimentation on animals, obtained by Charrin, chronic forms of infection with the bacillus pyocyaneus and intoxication with its products may be expected. Charrin has proven the possibility of producing as a remote effect of infection with this microorganism the most various acute and chronic degenerative processes in the nervous system, not unlike many of the syphilitic changes to which the nervous system is liable. It is interesting to find a human case reported by Jadkewitsch in which recurrent paralysis and other nervous phenomena existed in association with repeated infections in the same individual with the bacillus pyocyaneus.

It is evident, the writer concluded, from the data at hand, that the bacillus pyocyaneus is definitely pathogenic for human beings and is capable of causing a whole series of lesions, acute and chronic, of very different sorts. He laid particular stress on the cases of general infection and intoxication; on the various forms of intestinal ulceration, which are not at all uncommon; on the broncho-pneumonias; on the infections of the genito-urinary tract, and on the remarkable form of esophagitis which he reported.

Infections with this microorganism are not confined to children, as many authors believe, but are also relatively frequent in adults. The cases of pyocyaneus infection in human beings are in reality probably much more common than have been supposed, for so far the cases which have recovered have for the most part passed unrecognized.

The question of diagnosis during life was referred to. The general course of the disease, especially if associated with diarrhea and paralysis of the wall of the intestine, is important for diagnosis. The cutaneous blebs which sometimes occur are said to contain the bacillus pyocyaneus. It must be remembered, however, that the bacillus pyocyaneus is frequently

present in the normal skin, especially in its folds. Bacteriologic cultures from the urine, in suspected cases, will be helpful, as this bacillus has been shown by Le Noir and the writer to be present in the urine in some cases of human infection, and by the latter it was almost constantly found in the urine of animals experimentally inoculated with the bacillus. One difficulty met with in the bacteriologic diagnosis is the fact that the bacillus often grows colorless and may pass unrecognized unless special media favorable for color production be employed. The bacillus *pyocyaneus* is motile and serum diagnosis analogous to Widal's test for typhoid fever is applicable.

The cases, if recognized during life, are best treated by anti-*pyocyaneus* serum. The writer referred to the interesting fact that Bouchard had established the virtue of anti-toxic serum for infections with the bacillus *pyocyaneus* even before the serum treatment of diphtheria was inaugurated. On account of the rarity of the cases and the difficulty of recognition there has been no demand for such a serum and, for the present, cases of *pyocyaneus* infection even if recognized must be treated simply on general principles. Should these infections, however, prove to be common, and to be easily recognizable during life, doubtless the serum will be provided.

RELATION OF THE ALLOXURIC BODIES TO GOUT OR A URIC ACID DIATHESIS.

Presented in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY T. B. FUTCHER, M.B.

ASSOCIATE IN MEDICINE, JOHNS HOPKINS UNIVERSITY, AND ASSISTANT RESIDENT PHYSICIAN, JOHNS HOPKINS HOSPITAL. BALTIMORE, MD.

In the German contributions on the studies of metabolism in various diseases which have appeared since 1895, one meets very frequently with the terms "alloxurkörper" or alloxuric bodies, and "alloxurbasen" or alloxuric bases. Especially is this the case in the study of the metabolism of gout. A brief explanation of the circumstances leading to the adoption of these terms may be of interest.

In 1869 Miescher isolated a phosphorus-containing substance from the nuclei of pus cells to which Hoppe-Seyler gave the name nuclein. Previous to this date, xanthin and hypoxanthin had been known to chemists, but it was not until some time later that Kossel demonstrated that yeast nuclein could be made to yield phosphoric acid, hypoxanthin and an albuminous body, by the action of boiling water. Since then, hypoxanthin has been definitely proven to be derived from the nuclein of animal cells as well. In addition to hypoxanthin, four other proteid substances have been derived from nuclein, viz., xanthin, adenin, guanin and cystosin. Closely allied in constitution to these substances, but as yet not traced in their origin to nuclein, are carnin, paraxanthin, heteroxanthin, episarkin, epiguanin, derived from animal tissues, and theobromin, theophyllin and coffein, derived from vegetable structures. Whether all these will eventually be shown to be nuclein derivatives as well, remains to be seen, but as yet only the five above-named substances, viz., xanthin, hypoxanthin, adenin, guanin and cystosin have been shown to be such. Previous to 1895 all these substances were included under the common name of xanthin bases, while the

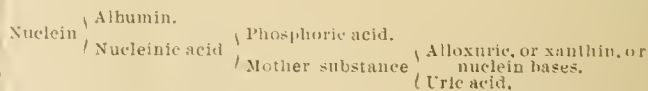

five definitely known to be derived from nuclein were frequently designated as the nuclein bases. Through the researches of Kossel, Horbaczewski and Fischer, it has been shown that uric acid, as well as the xanthin bases, is also a specific product of the nuclein derived from the disintegrated nuclei throughout the body. Fischer, and Kossel with his pupils, have shown that uric acid and the various xanthin bases all have a very similar chemical constitution. Each is made up of an alloxan and a urea nucleus according to the following scheme:

where the group to the left of the vertical line represents the alloxan nucleus and that to the right the urea nucleus, and as a result of this discovery, Kossel and Krüger designated them collectively as "alloxurkörper" or alloxuric bodies, and the xanthin bases as the "alloxurbasen" or alloxuric bases. So that when one speaks of the alloxuric bodies eliminated in the urine, for instance, one has reference to the combined amount of uric acid and xanthin or alloxuric bases excreted.

The close relationship between uric acid and the xanthin bases and the fact that both are derived from nuclein, is shown in the experiments of Horbaczewski. This observer found that by adding some oxidizing substance, as fresh blood, to spleen pulp or spleen nuclein, and then warming for several hours at 45 degrees C., he could obtain considerable quantities of uric acid, while on the other hand, if no oxidizing agent be added and only heat applied, he was not able to obtain any uric acid, but could obtain a corresponding amount of xanthin bases as indicated by the nitrogen contained in them. Horbaczewski believed, then, that nuclein gave rise to either uric acid or xanthin bases according as conditions favorable to oxidation were present or not. The formulae for the various xanthin bases show that they are simply less highly oxidized substances than uric acid.

The derivation of uric acid and the xanthin bases from nuclein may be illustrated in the following manner:

The quantity of alloxuric bodies eliminated in the urine is believed by many to be an accurate criterion of the amount of nuclein destruction going on in the body. Horbaczewski advanced the theory some years ago that uric acid is formed chiefly from the destruction of the leucocytes, and he believed that a great part of the nuclein produced in the body was due to leucocyte destruction. He found, that whenever there was a leucocytosis, there was almost invariably an increased elimination of uric acid. Thus, in leukemia the uric acid is always and often enormously increased. During the period of digestion leucocytosis more uric acid is eliminated than at other times of the day, and in infants, where there is a quite marked physiologic leucocytosis, relatively greater quantities of uric acid are eliminated than in adults. Although some have raised objections to this theory, there appears to be a general consensus of opinion that the uric acid

excretion is at least influenced by the number of leucocytes present in the blood. These observations suggest strongly, that at least one of the members comprising the alloxuric bodies, namely, the uric acid is rather intimately connected with the nuclein-containing constituents of the blood.

Since the publication by Krüger and Wulff¹ of their excellent method of estimating the alloxuric bodies in the urine, the study of metabolism in gout and other diseases has been much more satisfactory. The method depends upon the fact that uric acid and the xanthin bases are completely precipitated as insoluble suboxide of copper compounds by the action of copper sulphate and sodium bisulphid. The method is briefly as follows: 100 c.c. of urine, free from albumin, are brought to the boiling point and then 10 c.c. of a 13 per cent. copper sulphate solution and the same amount of a 50 per cent. sodium bisulphid solution are added by means of a pipette. The urine is again boiled until the precipitate becomes a greenish-black color, when 5 c.c. of a 10 per cent. solution of barium chlorid are added to facilitate precipitation. It is then allowed to stand for two hours and the precipitate filtered off on nitrogen-free filter paper. The precipitate is washed four or five times with water that has been boiled and cooled to 60 degrees C. The nitrogen present in the precipitate is determined in the usual way according to the method of Kjeldahl. This nitrogen represents the total amount of nitrogen contained in the alloxuric bodies, that is, the uric acid and xanthin bases nitrogen. Having made a separate determination of the uric acid, the nitrogen of the uric acid is calculated by simply taking one-third of the total weight of the uric acid found. The nitrogen of the xanthin bases is then determined by subtracting the uric acid nitrogen from the total alloxuric body nitrogen. If one determines the total nitrogen ingested in the food and the total nitrogen eliminated in the urine and feces, one can by means of the Krüger and Wulff method carefully study the metabolism of nitrogen in the organism.

The following table, giving the average amount of alloxuric body nitrogen eliminated in the twenty-four hours, as found by different observers in healthy persons, shows that the quantity varies normally between rather wide limits.

Kolisch gives 0.260 gram; Bazinsky, 0.250 gram; Krüger, 0.281 gram; Richter, 0.380 gram; Magnus-Levy, 0.506 gram; Weintraud, 0.470 gram; Laquer, 0.45 gram; Ueber, 0.3 gram; Fitcher, 0.499 and 0.551 gram.

Laquer found that one healthy individual eliminated only 0.2794 gram, while another healthy individual excreted 0.9417 gram of alloxuric body nitrogen in the twenty-four hours. By far the greatest part of the alloxuric body nitrogen is made up of the nitrogen of the uric acid. Krüger gives 0.2814 gram of nitrogen as the normal average amount of total alloxuric body; 0.0481 gram as the normal for the xanthin bases nitrogen, and 0.2333 gram the normal uric acid nitrogen. Krüger and Wulff give 0.0481 gram as the normal amount of xanthin bases nitrogen for the twenty-four hours. The proportion of xanthin bases nitrogen to uric acid nitrogen varies according to these observers between 1 to 2.1 to 1 to 7.6 for healthy persons. Krüger's average in nineteen analyses was 1 to 3.82. Laquer, on the other hand, gives the remarkable variations of 1 to 0.06 to 1 to 332.3 for healthy persons.

It is not the intention in this paper to enumerate

or discuss all the various theories that have been advanced relating to the etiology of gout. Some of the more recent views regarding this subject, however, will be briefly referred to.

In 1894 Neusser² described a peculiar granulation about the nuclei of the leucocytes in various conditions, the symptoms of which he believed to be due to a uratic diathesis. He called these granules "perinuclear basophilic granules." He demonstrated them by staining cover-slip specimens of dried blood with a modified Ehrlich's triacid mixture in which the basic constituent was relatively increased. He found them most numerous in the mononuclear leucocytes, both large and small, of the blood of patients whom he believed to be suffering from a uratic diathesis, although they were present in smaller numbers not only in the polymorphonuclear but also in the eosinophilic leucocytes. With this modified Ehrlich's mixture the granules took an intense black stain, selecting the basic ingredient of the mixture. They varied considerably in size and were always situated over or about the periphery of the nucleus, in direct contact with it, and never free in the protoplasm of the cell. They gave him the impression that they constituted some substance which had been squeezed out of the nucleus of the leucocyte. Neusser believed that these granules indicated an increased production of nuclein or its derivatives by the nuclei of the leucocytes, and suggested that they were probably of the nature of a nucleo-globulin in composition. The diseases in which he found these granules to be present in the blood, included not only true gout but also affections which he classified under the heading of "irregular gout," as muscular rheumatism, nervous asthma, skin affections, gastro-intestinal derangements, diabetes, leukemia, neuralgia and neurasthenia, in which he believed a uratic diathesis played a part. In many of these conditions he found that a leucocytosis was also present. Uric acid determinations were made in a large number of these cases and an increased elimination found, varying between 0.8 and 1.5 gram for the twenty-four hours. An increased proportion of uric acid to urea was also present, the ratio varying between 1 to 30 to 1 to 20, 1 to 50 being normal. Horbaczewski had previously advanced his theory that uric acid was formed largely from the destruction of the leucocytes of the blood. Neusser, having found that his cases showed an increased elimination of uric acid in association with the presence of the perinuclear basophilic granules, believed that the latter were responsible for this increased excretion. He further believed that his discovery of these granules was of importance from a diagnostic standpoint. For, in suspected cases of gout or in cases with obscure symptoms as muscular or neuralgic pains, he claimed it could be determined by a simple blood examination, whether a gouty diathesis were present or not.

It had been observed by French and other physicians that patients with gout rarely suffered from tuberculosis, the belief being that the gouty poison prevented the development of the latter. Neusser found in examining the blood of tuberculous patients, that those patients in which the disease ran a rapid course showed either an entire absence of the granules or their presence in exceedingly small numbers. On the other hand, cases of fibroid phthisis and those where there appeared to be a limitation of the diseased process in the lung by the formation of fibrous tissues showed large numbers of these granules in the leu-

cocytes. He accordingly believed that the more favorable course of this last type of cases of tuberculosis was due to a coexistent uratic diathesis as indicated by the presence of the granules. Neusser held that if the examination of the blood of a tuberculous patient revealed an abundance of the basophilic granules, a more favorable prognosis could be given than if they were absent, as he claimed the pulmonary lesions in these cases were more apt to undergo fibroid changes.

Kolisch,³ a pupil of Neusser, advanced a new theory regarding the etiology of gout. He believes that the kidneys not only have the function of excreting but also that of forming uric acid. Kolisch holds that the graver manifestations of gout only make their appearance when the functions of the kidney become impaired from any cause. In his studies on metabolism in gout, he finds that the total alloxuric bodies are increased in the urine. This increase is due to an increase in the amount of alloxuric or xanthin bases and not to an increase in the uric acid, which he in reality finds diminished. In nephritis, Kolisch found that although the total alloxuric bodies were eliminated in normal amount, yet the xanthin bases were markedly increased at the expense of the uric acid excreted. When the kidneys are healthy, the greater part of the alloxuric bodies is eliminated as uric acid but when diseased Kolisch holds that the uric acid becomes diminished and the xanthin bases increased. This leads him to believe that the kidney normally produces uric acid. He demonstrated the toxic effects of the xanthin bases on the kidneys by injecting rabbits and guinea pigs subcutaneously with hypoxanthin, for periods of one to two months. Definite parenchymatous degeneration was in this way produced. Having shown that the xanthin bases were also increased in gout, he believes that these bases are concerned in the production of the kidney affection which precedes the development of the disease. The observations of Kolisch on the urine, in nephritis have not received universal support, and Zuelzer found that there was no diminution in the uric acid excreted and that the proportion of uric acid to xanthin bases is normal. That the xanthin bases produce toxic effects is strongly suggested by the observations of Rachford⁴ who found a marked increase in the excretion of paraxanthin in migraine and epileptic attacks. Kolisch believes that many of the symptoms of gout are due to the increased amount of the xanthin bases in the circulating blood. He claims to have found that cases showing numerous perinuclear basophilic granules in the leucocytes always eliminated an increased amount of alloxuric bodies in the urine. Further, he believes with Neusser, that these granules indicate a uratic or gouty diathesis. However, he claims that they give rise to an increase in the xanthin bases, producing an increase in the total amount of alloxuric bodies eliminated, and not to an increase in the uric acid excretion as Neusser held.

Since Neusser's publication I have examined the blood of a large number of individuals, both healthy and diseased, for these perinuclear basophilic granules. In every case I have been able to demonstrate their presence. Further, the blood of many of the healthy individuals examined, and in whom there was not the slightest reason to suppose that the person was suffering from a uratic dyscrasia, showed the granules as abundantly as did any case of gout with typical joint lesions and tophi. I have not been able

to confirm the views of Neusser with regard to the relation of the granules in the various types of tuberculosis. They have been found in just as large numbers in patients in which the disease ran a rapid and fatal course, as in those where the pulmonary changes were more chronic and tended to fibroid contraction. In the latter cases Neusser claimed to have found the granules most abundant, and believed they indicated a more favorable course of the disease.

While working under Prof. Kraus in Graz during the previous summer, I had the opportunity of determining the amount of alloxuric bodies eliminated daily in a number of cases, in all of which these granules were present, but being more abundant in some than in others. The analyses were made, in each case, for a series of days in succession, and daily examinations of the blood were made, the same technique being followed from day to day. The result of this work, which has already been published, showed that there seemed to be no constant relationship between the relative abundance of the granules and the total quantity of alloxuric bodies excreted in the urine. Cases in which the granules were very abundant showed either a diminished, a normal or increased amount of alloxuric bodies, while on the other hand the granules may be scanty and the alloxuric bodies excreted in the urine increased. There seems, then, to be no definite association between the relative abundance of the granules in the leucocytes and the quantity of alloxuric bodies excreted in the urine as Kolisch claimed there was. It appears very doubtful whether there is any association whatever between these so-called perinuclear basophilic granules and true gout or uratic diathesis.

This view of the formation of uric acid in the kidneys was also held previous to 1847. The discovery in that year of uric acid in the blood of gouty patients, by Sir Alfred Garrod, led to the view that uric acid was formed in certain other organs and tissues of the body and was merely excreted by the kidney. From experimental evidence Sir Alfred Garrod⁵ has since concluded that uric acid is normally formed in the kidneys and that when it appears in the blood it results from its reabsorption after having been formed in these organs. Latham also is of the opinion that the final formation of uric acid takes place in the kidneys, where it is produced by the union of substances formed in the liver and conveyed by the blood to the kidneys. Luff, in the Gulstonian Lectures on the Pathology and Chemistry of Gout for 1897, claims that uric acid under normal conditions is produced only in the kidneys. Whereas opinions differ considerably as to the amount of uric acid eliminated in the urine in gout, the evidence seems to favor the view that during the intervals between the acute arthritic attacks and in chronic gout it is at least not increased above the normal. A good many hold that it is considerably diminished but that the daily elimination may reach normal or beyond normal during and just after an acute attack. The most recent work seems to favor the view that there is a distinct diminution in the uric acid excretion, especially in chronic gout. Kolisch, as already intimated, believes that there is a marked diminution in the uric acid excretion with a very great increase in the xanthin bases, making a total increase in the alloxuric bodies eliminated. It is to the increased xanthin bases that he attributes many of the toxic symptoms of gout. His views have received some confirmation by Weintraud who also found the

alloxuric bodies increased during the acute attacks of gout. Schmall,⁵ on the other hand, failed to find the increase in a case of gout which he studied.

Recently I have had the opportunity to study the metabolism in two cases of gout, the results of which are given below, and I can for the most part confirm the analyses of Kolisch. In both cases, and especially in case 1, the uric acid was markedly diminished, while both cases showed a remarkable increase in the xanthin bases nitrogen, particularly case 2. In case 1, the alloxuric bodies were not increased beyond normal, but there was, as just stated, a very marked relative increase in the xanthin bases. In case 2, the total alloxuric bodies were increased beyond what is considered the average for the normal individual.

Case 1, emphasizes a feature in the metabolism of gout which was pointed out by Vogel,⁶ namely, that in this disease there is a very marked retention of nitrogen in the system greatly in excess of what could be attributed to a retention of uric acid.

In the two cases here reported the nitrogen determinations were made by the Kjeldahl method. The uric acid was estimated according to Hopkin's modification of the Fokker-Salkowski method, and the alloxuric bodies by the Krüger and Wullf method. In both cases, the total nitrogen ingested, as well as the total amount excreted in the urine, was determined, so that it was possible to ascertain how much there was retained in the system or whether there was an actual loss from the nitrogenous tissues.

Case 1.—Gouty arthritis; tophi: chronic intestinal nephritis. H. C., male, shoemaker, aged 44, was admitted to the Johns Hopkins Hospital, in Dr. Osler's service, March 29, 1897. He had been admitted to the hospital on three previous occasions, the first time in December, 1892. While in the hospital, during the first and second admissions, he suffered from acute inflammation of several of the small and large joints. There was nothing on these occasions to suggest gout, so that the diagnosis of acute articular rheumatism was made. On his third admission, in May, 1896, it was quite evident what the nature of the joint affection was. On the helix and antihelix of the left ear were several small tophi varying in size up to a pin's head. There were also two minute tophi on the helix of the right ear. This discovery was positive proof that the patient was suffering from gout and suggested strongly that this had been the nature of his trouble all along.

On the fourth admission, in March of this year, these tophi were not so marked, but on microscopic examination were shown to contain the typical acicular crystals of urate of soda.

There was no family history of gout. He had taken liquor to excess since he was 15 years old. Up to 25 years of age he drank distilled liquors and after that chiefly malted liquors. He had had nephritis since his first admission, when albumin and casts were present in his urine. He had suffered from repeated arthritic attacks during the interval between the various admissions.

The attack for which he was last admitted began on March 25, 1897, with pain and swelling of the metacarpo-phalangeal joint of the right index finger, which afterward spread to involve the other metacarpo-phalangeal and wrist joints. On admission the metacarpo-phalangeal and first phalangeal joints were swollen, red and painful and the backs of both hands were swollen to a point considerably above the wrists. There was also some swelling and pain of the ankles and knees. The acuteness of the joint trouble had considerably subsided before the analysis began.

A careful study of the metabolism was commenced in this case on April 1, at 6 A.M., from which time on the urine was carefully saved each day. The experiment was divided into two periods. In period 1 the patient was not getting any medicine, while in period 2, 1 gram of hexamethyltetramin (urotropin) was given every four hours to see whether there was any increase in the uric acid elimination or on the metabolism of nitrogen generally.

The following diet was given daily throughout the experiment:

Breakfast.—Ham, 40 grams; bread, 60 grams; milk, 250 grams.

Dinner.—Ham, 40 grams; bread, 80 grams; milk, 300 grams; rice, 40 grams; sugar, 15 grams.

Supper.—Ham, 40 grams; bread, 60 grams; milk, 250 grams.

This food gave 1,391.35 calories daily or a little over 31 calories per kilogram body weight. These heat units were made up as follows:

Albumin 75.41 grams = 309.17 calories.
 Fat 31.69 grams = 321.60 calories.
 Carbohydrates. . 185.51 grams = 760.58 calories.

1,391.35

The feces belonging to the two periods were separated by giving a mixture containing vegetable carbon according to the method described by Von Noorden.

Krüger gives as the average amount of nitrogen in the alloxuric bodies, uric acid and xanthin bases 0.2814, 0.2333 and 0.0481 grams respectively for the normal individual. A comparison of the above table with these averages shows the marked variations, particularly in the uric acid and xanthin bases nitrogen.
 * The amounts are in cubic centimeters and grams. The urine contained between 0.1 and 0.2 per cent. of albumin and a few hyaline and finely granular casts.

One of the striking features in this case is the immense amount of nitrogen retained in the system, being almost one-half of the total amount ingested during the period. The amount of uric acid was extremely small throughout. The total alloxuric bodies were not increased. The relation of the xanthin bases nitrogen, to uric acid nitrogen, was markedly increased. As will be seen from the table, the former was always markedly in excess of the latter, whereas the normal proportion, according to Krüger, should be 1 to 3.82. There was eliminated, not only an absolute but also a relative increase of the xanthin bases, and in this respect the case agrees with the findings of Kolisch in his cases of gout. Neusser's granules were very abundant throughout period 1, but as will be seen from the table the total alloxuric bodies were not increased as Kolisch believes they should be.

The only appreciable effect of the urotropin was a slight increase of the alloxuric bodies but no appreciable increase in the uric acid. Neusser's granules were distinctly diminished during this period. There was less nitrogen eliminated in the feces during period 2 than in period 1.

Case 2.—Gouty arthritis; no tophi; mild interstitial nephritis. R. B., male, aged 46, tinner by trade, was admitted to the Johns Hopkins Hospital in Dr. Osler's service, on April 27, 1897, complaining of attacks of severe pain and swelling of the joints. There was no history of gout or rheumatism in the family. States that he had diabetes when 35 years of age, for which he received hospital treatment. For years he had been a heavy eater and drinker. No history of plumbism. His first attack of arthritis was in 1861, when the ankles and feet were painful, red and swollen. Since then he has had repeated attacks of arthritis, the ankle and knee joints being oftenest affected. Both great toe joints have been involved on several occasions. During the last two years the attacks have been more frequent, having had thirteen attacks during this period. On admission, there was considerable swelling and some edema over the dorsum of the right foot extending above the ankle joint. Considerable pain was complained of. The right knee joint was also slightly swollen. There was some thickening about the great toe joint on both sides. No tophi were found. Patient had embryocardia on admission, which disappeared in a few days. No cardiac murmur was to be heard. The urine contained less than .1 per cent. of albumin and a few small hyaline casts. The metabolism was studied in the same way as in Case 1. The patient was given a special diet, the food being accurately weighed out each day.

The accompanying tables give the results of the analyses:

This case showed on the whole a considerable increase in the total alloxuric bodies eliminated. The uric acid was diminished, while the xanthin bases nitrogen were increased to a very marked degree. In fact, I know of no records in which the nitrogen representing the xanthin bases were increased to the same extent. The quantity for the first day of the experiment, 0.7321 grams, seems incredible, yet the two determinations of the uric acid and alloxuric bodies corresponded very closely, the average of the two being used in the calculation. There was a gradual diminution in the amount of uric acid eliminated as the

joints improved. On the last day there was a slight rise. The total nitrogen eliminated in the urine daily varied considerably in this case, and this has been observed in gout by others. There was also considerable daily variations in the nitrogen balance. On the first and last days there was a greater excretion than intake of nitrogen, while in the other three days there was a retention in the system.

The perinuclear basophilic granules were fairly abundant in this case, but not so numerous as in Case 1. On the other hand, the alloxuric bodies were much

higher in the second than in the first case, again showing that there does not appear to be any constant relationship between the two.

Apart from this point, however, the cases rather go to confirm Kolisch's view that in gout there is a diminution in the uric acid and an increase in the xanthin bases elimination.

THE OCULAR EXPRESSIONS OF GOUT.

Presented in the Section on Practice of Medicine at the Forty eighth Annual Meeting of the American Medical Association held at Philadelphia, June 1-4, 1897.

BY CHARLES A. OLIVER, A.M., M.D.

ONE OF THE ATTENDING SURGEONS TO WILLS' EYE HOSPITAL; ONE OF THE OPHTHALMIC SURGEONS TO THE PHILADELPHIA HOSPITAL, ETC. PHILADELPHIA, PA.

When it is remembered that the visual bulb has within its structures a numerous network of blood vessels, and when it is understood that the eyeball is nothing more than a lymph-holding end organ which is constantly changing the greater part of its fluid constituents, it can be realized that in these structures there can appear all of the irritation and inflammatory changes that may be produced by either an undue amount of urates in the system, or the existence of uric acid and other abnormal products in the adjacent parts.

The presence of material in the outer coats of the eye, that is so similar to that found in any joint-tissue, and the close relationship that the bulbus itself in the orbit, bears to every ball-and-socket joint, both show how the external coverings of the organ, its encompassing capsules, and its attached muscles with their delicate sheaths can be seriously disturbed by fluid-change, inflammatory exudate, and inorganic deposit, as the result of a gouty diathesis.

The accessories too, so abundant in gland, vessel, lymph-channel, cartilage and periosteum, furnish an abundant soil for toxic reaction, abnormal accretion, and arthritic change. Nor do the associated nerves escape. Here the evil accompaniments of pressure, invasion, inflammation and degeneration, all exhibit themselves in many types of the disorder.

Take for example the lids, the conjunctiva, the lachrymal apparatus and the orbital contents. How characteristic are the swollen, tumid and angry lids, so excruciatingly painful at times, and so seldom, if ever, ulcerated! The inflammatory condition so rapid on onset; so barometric in character, and so quickly subsiding by the application of dry heat and the employment of constitutional measures, makes a symptomatic grouping that once seen is seldom, if ever, forgotten. The fleeting forms of conjunctival inflammation with slight or no excretion, the sensation of the presence of foreign body, the dense and not infrequent edema of the sub-mucous tissue, and the intense intolerance to light, must all be noted as expressions of the general disorder, and not believed to be entirely the consequences of colonization of localized bacteria. Lithiasis conjunctivæ or calcified infarcta occurring in the course of the Meibomian glands, are frequently seen in middle-aged and elderly subjects, and especially in men, as evidence of similar changes to be found elsewhere. At first causing no disturbance, but later, by perforation and exposure, producing all manner of irritative lesions by mechanical action, they may produce that most dangerous complication, desquamation of the corneal epithelium, with the usual train of infectious sequelæ. Keratitis, by some stated, peculiarly band-like in character, interstitial at times, and rarely, if ever, ulcerous in form, has been spoken of by a number of competent authorities.

Inflammation of the sclera both in the fibrous intima and in its overlying capsular and tendinous material, evidences, particularly in the male subject, an intimate relation to the general condition by a series of extremely fugitive signs that are in many cases pathognomonic. Circumscribed when superficial, it is not rarely associated with such intense dread of light and such sharp and frequently recurring attacks of lancinating pain, amidst copious gushes of hot tears, that the condition of the sufferer becomes truly pitiable. As suddenly disappearing by the local use of heat with pilocarpin at times, and the internal administration of large doses of alkalies, the comfort obtained is oftentimes phenomenal and truly appreciated.

So too with the deeper structures of the eyeball. The iris with its ciliary and choroidal prolongations may suffer intensely. Frequently sharp, excessively painful, devoid of much gross alteration, and at times provoked by accidental and operative traumatism, the anterior segment of the uveal tract becomes a treacherous ground for more deeply seated and more disastrous future outbreaks. More often the inflammation, which may be either plastic or serous in type, especially the latter, is marked and insidious. At times it is hereditary, with vitreous complications. As a rule it is associated with the general exacerbations and is untypical in form, and although, probably in many cases, especially in the serous variety, it is co-extensive with some more deeply seated inflammatory change, there is very little by which it can be separated etiologically from any other similar form of inflammatory reaction.

The local treatment in both of these types of disorder (always employing heat for the relief of pain), is dependent upon the coëxistent condition of the organ, taking care if any permanent success be hoped for, to resort to active and properly applied systemic measures.

Should the middle or the posterior thirds of the uveal tract be involved; that is, should the ciliary body with its contained muscles, and the choroid be inflamed, which fortunately is not so frequently the case, the diagnosis becomes less easy, the evil consequences are greater, and the treatment is less availing. It is probable that in this peculiar type of disorder, the existence of most of the forms of lenticular change and some of the varieties of glaucomatic process must be sought for.

Where the retina and optic nerve are concerned, the ophthalmoscopic picture becomes in many cases quite typical. Rapidly recurrent fine feathery hemorrhages with more deeply seated ones located throughout the retina and atonic broadening and flattening of the retinal veins and arteries, associated at times with some of the signs of incipient glaucoma, often appear early in the history of the case. Later, in the more chronic forms, inflammatory vessel-wall change, with shrinkage, atheroma and sclerosis, first manifesting itself in the veins and subsequently in the arteries, may be found. The easily recognized edema of the retina with its usual venous accompaniments generally confined to the posterior pole of the eye, followed by insidious though progressive inflammatory reaction extending both anteriorly by contiguity into the vitreous and the lens, and posteriorly into the choroid are now superadded. These, with the at times, peculiar glistening yellowish bodies found aggregated more particularly in the superficial layers

of the circum-macular region, may be considered as almost pathognomonic. Often low grades of neuritis which seemingly extend some distance back into the nerve-substance can be recognized, these ordinarily appearing monolaterally and generally found in middle aged subjects.

As a rule, untemporaneously binocular, generally first appearing in the visual field, and associated with defective vision: the retinal and optic nerve-groupings are not difficult of recognition. Prognosis is never good and incomplete blindness is almost certain.

From this clinical study, it will be seen, as before hinted, that the eyeball, with its accessories, is peculiarly prone to disturbance during the course of general disease; in fact, the organ in its every detail of structure, is liable to changes that are dependent upon gout.

GASTRO-INTESTINAL AND HEPATIC RELATIONS OF GOUT.

Presented in the Section on Practice of Medicine at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY CHARLES G. STOCKTON, M.D.

Professor of the Principles and Practice of Medicine and Clinical Medicine, Medical Department, University of Buffalo; Attending Physician to the Buffalo General Hospital.

BUFFALO, N. Y.

Murchison and Sir Dyce Duckworth, among other students of the subject, have associated the excessive formation of uric acid and the development of gouty attacks with disturbances of the liver. Under the name of lithemia or latent gout, Murchinson described a set of symptoms very commonly met with in this country; among the conspicuous symptoms is the appearance of uric acid, urates and calcium oxalate crystals in the urine in abnormal amount.

These cases of lithemia show evidence of disturbed primary digestion, congestion of the liver, headache, lassitude, malaise, but rarely evidences of deposits, arthritic or otherwise, that are characteristic of true gout.

The question has been raised, and I think justly, is lithemia gout or is it the expression of a toxemia resulting from habitual disorder of the digestive organs including the liver? Before answering the question it may be well to turn to some later views regarding the relation of uric acid to gout, and the origin of uric acid in general.

It would appear to have been conclusively shown by Sir Alfred Garrod, Sir William Roberts, and later by Arthur P. Luff in his recent Goulstonian lectures, first, that "uric acid is not normally present in the blood of man or other mammals nor in the blood of birds; second, that uric acid is normally produced in the kidneys only, and is formed from urea, probably by the conjunction of that substance with the glyco-cin in the kidneys."

Since the glyco-cin has its origin in the liver, we can readily understand how hepatic disorder might lead to disturbances in the amount and quality of the glyco-cin formed. We may therefore understand how hepatic diseases, either with or without gout, may be competent to derange urinary secretions. So it will be seen that an excess of uric acid in the urine does not necessarily mean a gouty diathesis. In fact, it has been shown by Pfeiffer that the uric acid output, instead of being increased in gout, is in point of fact diminished, and the kidneys seem to have lost in part their power of elimination; and although we find in

the blood of the gouty individual uric acid in the form of quadrates, and also find the deposits in the joints and other parts not in the form of uric acid, but in that of the biurate of soda, this takes place not because there is uric acid in the blood, but because of some reason that we do not yet understand.

This proposition, namely, that gouty deposits do not follow merely because there is uric acid in the blood, may be proven by the fact that in leukemia, and several other affections in which there is rapid growth and destruction of leucocytes, there is formed a relatively enormous amount of uric acid from nucleinic acid, and yet in these cases we find none of the ordinary symptoms of gout, no deposits of the biurate of soda in the tissues, but we do find the uric acid passing from the body, partly unchanged and partly in the form of urea.

It will thus be seen, 1, that gout does not depend upon the continued presence of the excess of uric acid in the blood; 2, that the formation of uric acid in the kidneys is disturbed in case of gout, probably as a result of some disorder of the liver; 3, that disorders of the liver unaccompanied by gout are capable of deranging the normal uric acid output.

Let us now return to the question already propounded. Is lithemia gout, or is it the expression of a toxemia resulting from habitual disorder of the digestive organs, including the liver? From experience gained in the study of functional disorders of the stomach the conclusion has been forced upon me that the great majority of instances of so-called lithemia are in fact cases of toxemia, in no true sense gouty in nature. As there are many causes of functional disturbance in digestion, so there are many causes of lithemia. It is readily admitted that gout is the occasional cause of the disorder of primary digestion, but the proportion of cases in which it is shown as an actual probability is extremely small.

Perhaps the full import of this position will be more clearly shown when it is pointed out that permanent relief of the condition does not follow the treatment directed toward gout, but that it does follow the right ordering of diet and the right management of the disturbed digestion in other ways. Undoubtedly it is true that digestive diseases aggravate gout, and I think that Luff has shown why it is that indiscretion in diet, particularly as regards certain kinds of food, are capable of exciting paroxysms of gout in gouty subjects. I have carefully and repeatedly studied the stomach contents in a few cases of gout, and find that quite uniformly there occur periods of marked hyperchlorhydria with delayed starch digestion and flatulence, followed by enlargement of the liver, which conditions, if not relieved, are likely to be succeeded by characteristic arthritic attacks.

At other times such indiscretions in gouty subjects excite paroxysms of gastralgia or angina pectoris, the latter usually accompanied by high arterial tension, and sometimes by the discharge of a large amount of pale-colored urine. Again, an acute eczema makes its appearance. I have found that the hyperchlorhydria occurring in the gouty is very intractable to treatment, and those remedies (acting through the nervous system) that generally prove useful in hyperchlorhydria depending upon reflex nervous causes, in gouty patients are of little value. Large and repeated doses of alkalies and potassium iodid give the best result.

Now, such patients may not observe a strict dietary

and may habitually lead sedentary lives. Such indiscretions may provoke attacks of auto-intoxication closely resembling those attacks seen in the non-gouty, yet it can not be too strongly insisted upon that gout is not the most common, but is rather an infrequent cause of such attacks of toxemia. In other words, it is shown that the condition in the gouty patient is distinct and requires a different management from the condition in the non-gouty. This brings us to the consideration of diet in the two classes of cases in question.

To those who have had the widest opportunity for studying gout there is a remarkable uniformity in the belief that all forms of proteids, particularly the dark meats, are objectionable in the paroxysms, and that a diet rich in such substance is likely to precipitate an onset of gout. Fruit juices and the fermented liquors are especially objectionable; on the other hand, farinaceous foods are well borne. In the case of the non-gouty lithemic, albuminoid foods are often the most suitable. Such a patient will find relief from a diet of lean beef, and will suffer if the starchy foods are taken in considerable quantity. It must be acknowledged that individual cases require individual diet and management, and to assume that all cases in which gout is not a factor, will do best upon a nitrogenous diet, is to make a careless generalization.

The careful study of the stomach contents and the adjusting of the diet according to the knowledge thus obtained, together with the frequent examination of the urine, meantime noting the increase or decrease of the body weight, the muscular activity, the state of the nervous system and the feelings of the patient, should be our guides in reaching a knowledge of the correct dietary. It may be set down as a rule that in all cases of lithemia, whether gouty or non-gouty, the fermented liquors and fruit juices are objectionable and sometimes act as a real poison.

An active life out-of-doors has a most beneficial effect on all cases, and this has been used as an argument to prove the identity of lithemia and gout. A little thought will suffice to answer this argument, for it will be remembered that such habits of life are most favorable for good digestion and proper behavior of the stomach, intestine and liver. This rule applies not only to lithemia, but to all digestive disorders.

These remarks are intended to prepare the way for the following conclusions: 1. That gout is a definite disease to which certain individuals are predisposed, but which depends for its development upon causes largely unknown. 1. Laziness and full nitrogenous diet and the use of fermented liquors predispose to the disease. 3. So-called lithemia, as the term is popularly applied, is not gout, but is an auto-intoxication depending upon gastro-intestinal and hepatic derangements. 4. The diet in gout should be largely free from nitrogenous substances. 5. The diet in lithemia must be ascertained by a careful study of the primary digestion, the urine and the general health of the patient, but a nitrogenous diet is often the most satisfactory one.

TREATMENT OF GOUT.

Presented to the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, at Philadelphia, Pa., June 1-4, 1897.

BY H. C. WOOD, M.D.

PHILADELPHIA.

I am expected to epitomize in fifteen minutes the

wisdom of the ages with regard to the most frequent of all conditions, probably, of the better class of the human race. I want in the first place, however, to clearly develop before you what I myself believe, that all our scientific knowledge of gout at the present amounts to little more than a mass of trundling expectation upon which hereafter shall be built some true knowledge. And I think that in the successful treatment of gout the understanding of this is the basis. There are three great manifestations of the same thing which is universally allied to itself. We have rheumatoid arthritis as one type; we have podagra or true gout, as the second type; and we have acute articular rheumatism as a third type. Let me give you just one illustration from family history, that of my own case, which represents the family history of all the better families in this city which have endured here for generations: A great grandfather leaving his descendants the results of high drinking and living in England, a few dollars and much gout, the one disappearing, the other continuing; a second generation whose history I do not know much of; a third generation, nearly the whole of which dying of gouty degeneration of the cerebral arteries or heart; a fourth generation, some of them developing attack after attack of acute rheumatism, half a dozen, eight, nine or ten in the life history of a single individual; one of them having true podagra; all of them plagued with the various manifestations that we know as nervous gout. There is a relation between these things, not the same thing, but they have the same basis, and this basis absolutely eludes our grasp scientifically.

Now, when we come to treat gout, if we purge ourselves of the false idea which we think we possess, we can recognize the importance of this great principle, not to attempt to treat gout at all, but attempt to treat the individual who comes before us. Let me take simply the question of diet. You know that we inherited from Sydenham the belief that gout was made worse by red meats and that they should not be used. I have seen gouty patients in whom a single piece of ordinary red roast beef would precipitate a furious attack. I have also seen many gouty patients who would not get well until they were put upon red meat. What is the diet for gout? There is no diet for gout. It is diet for the individual. I have seen gouty patients who, if they took starch or sugars, went right down; and I have seen gouty patients who had to take starch and sugars to be built up. Therefore the first principle in the diet of gout is to adapt it to the individual before us. You judge of the case by the effects of experiment. In a large majority of cases sugars and starches have to be cut off. In spare gouty patients starches often do good; farinaceous diet may be essential. You have to order your diet according to the individual. A milk diet is one which probably suits the large majority of patients. But that which suits the individual, the stomach, the digestion, will suit the gout or kill the gout.

When we come to the treatment of gout by exercise we find the one thing which does more good than anything else in almost every case, provided we direct the right amount of exercise. If we try to put into an ounce bottle, three gallons of exercise, we crack the bottle. Massage is a form of exercise, and it may be all that your patient can endure; fifteen feet of walking may bring on weariness or it may require some Alpine height. The same story, study your case. Begin with the slightest amount of exercise, but do not let

up. Be inexorable. Keep it within the point of causing exhaustion, and each day do an ounce more if necessary. That is the whole secret of exercise in gouty patients. Begin with a small measure and gradually increase the amount, and you will find it does more good than any drug. The bicycle is the great calisthenic of the world.

With regard to drugs, there are a great many people who tell you that salicylates do no good. Men do not get good out of salicylates because they do not use them properly. I do not believe that salicylates cure gout or rheumatism, any more than that bromids cure epilepsy. They simply aid in keeping down the diathesis. If there be any cure, it is exercise. If you use your salicylates on a case properly, and get no response, you have something more than ordinary gout or rheumatism to deal with. There are certain cases which approach typical gout such as we rarely see in America, in which colchicum does good, much more good than salicylates. I have seen two cases of typical English gout corresponding to Sydenham's description, and only two. We do not have it in this country. Those cases colchicum suits better than salicylates do. Sometimes, when the cases is on the border line, you will get the best results by a combination of colchicum with salicylates. If you have a strong robust man, he will stand it. Give him knock-down doses in addition to purging him and you will bring him through. But that treatment may be worse than the disease, and has to be used with caution.

In using salicylates the profession almost universally choose the worst salt they can find, and that is the sodium salicylate. It is, perhaps, not so bad as salicylic acid, but it is much more apt to turn the stomach, and is less effective and more depressing than the other salts of salicylic acid. The two salts which are truly useful are the ammonium salt and the strontium salt. The ammonium salt acts immediately and severely; the strontium salt acts slowly. If you have an acute case, use salicylate of strontium, or use the two combined. The strontium salt has this advantage, that it does not derange digestion anything like the other preparations, and many a time have I seen the best effects on the intestinal condition from the use of the strontium salt.

In a large majority of cases you will find that salicylates produce depression, and perhaps a little nausea, general wretchedness, and the patient refuses them. Nine times out of ten you can overcome those effects by combining your salicylate with digitalis and strychnin in the same prescription.

As to baths, you can not cure a diathesis by baths. It can not be done. But baths are useful, hot baths, steam baths, Turkish baths. Any man who values his own life, who has had a gouty grandfather, ought to take a Turkish bath once a week. You can not wash out ancestral traces in any other way. The kidney disease and the atheroma will be far less rife if we use the hot bath more than we do. The baths eliminate, give a temporary result, and are very useful when employed with the understanding that they do not cure the disease but relieve the symptoms.

A word about the Tallman-Sheffield apparatus or dry heat, which I have had a good deal of experience with this year. For about three months I had a large clientele using it all day long. In the first place, it is absurd to suppose that this is going to cure the gouty diathesis any more than that any other application will. In the second place it is my experience

that it has very little value in the rheumatoid arthritis. In the third place, it is of very little value in chronic inflammations, even of purely gouty character, in joints. But I had my office crowded with people seeking relief, and it is empty today and that is the best criterion of the result. If the results claimed for the treatment were obtainable, I could soon fill this hall with patients, for they all want relief, but every missionary I sent out converted the people to the wrong faith. On the other hand, when you have deposits in the tendons and outside the joints; when you have traumatic synovitis, whether in baseball men or other persons, the results of this apparatus seem almost marvelous. I have seen a pitcher's hand drawn up and disabled for three or four years, the condition pronounced by a distinguished physician as gout, treated by the dry heat method, and after three or four treatments the hand had become pliable and the use of it came back. So, in acute strains and tendinous inflammations, this dry heat is of great value. In subacute rheumatism it is of value through its sweating and local influence. It has to be used at high temperatures. I carried it up to 330 degrees F. You can scorch the lint wrapped around the limb without scorching the limb. It has no value at all, according to my experience, in old cases of rheumatoid arthritis, and very little use in rheumatism of the joints.

GASTROPTOSIS.

Presented to the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY CHARLES D. AARON, M.D.

INSTRUCTOR IN MATERIA MEDICA IN THE DETROIT COLLEGE OF MEDICINE, DETROIT, MICH.

There is a dislocation of the stomach with which the physician in general practice meets quite frequently. It is usually associated with dislocation of sections of the intestine and other organs within the abdominal cavity. Gastroptosis, a term for which we are indebted to Glénard, is that condition in which the greater curvature of the stomach lies permanently below the navel, and therefore outside of its normal position. This condition is more or less connected with the descent of the intestines and other abdominal organs termed enteroptosis. It is believed that the dislocation of the right kidney, called nephroptosis, plays a great rôle in the symptom-complex of enteroptosis, inasmuch as nephroptosis is always joined with enteroptosis. The fact is, the stomach may reach lower than normal in the abdominal cavity simply because the abdominal walls become flaccid and the ligaments which support the viscera relax. Abrams' reported a case of gastroptosis with voluntary oscillation of the stomach. While in certain cases gastroptosis is accounted for by a kind of predisposition due to heredity or acquired by the force of various conditions, it may be maintained that the majority of cases is accounted for by incidental causes. It may be due to excessive emaciation, exhausting diseases, loss of blood, frequent births, pressure of garments and pendulous abdomen. Every experienced practitioner is aware of the sad fact that tight lacing is to be charged with many of these pathologic conditions. Before we speak of these, I wish to say that certain neurasthenic or hysteric disturbances characteristic of ailments of the uterus and its appendages are also present in dislocations of the abdominal organs.

That the ligaments and mesenteries become relaxed is probably due most frequently to the weight of the abdominal organs, but Glénard cites amongst other causes of gastroptosis also those diseases of a gastric or intestinal origin which lead to a state of auto-intoxication and produce a weakening and exhaustion of both walls and ligaments. Another account made as to the etiology of gastroptosis is suggested by Fleiner.² It refers to the special relations occupied by the several organs packed into the abdominal cavity and accounts for the abnormal forms and positions as results of adjustment to given conditions. This alteration is especially significant in the upper section of the abdominal cavity, in which, as is well known, the stomach, liver, spleen and part of both colon flexures are situated. Fleiner cites the case of pleural exudative affections in which the organs lying below the diaphragm do not find sufficient room in the hypochondrium, and are therefore constrained to project themselves out of it. It is here where the lacing habit has its widest explanation. I may call attention to a third theory, that of Meinert,³ who has brought the phenomenon of gastroptosis into etiologic relation with chlorosis. While it is true that anemia is often coincident with gastroptosis, the probability is that the latter is the cause of the former. Chemic and microscopic analysis of the stomach contents has no value for the diagnosis of gastroptosis. All departures from the normal condition of the gastric juice may take place as they usually do and the motility of the stomach may be completely maintained.

It is also possible that the symptoms of gastroptosis may remain latent, while again insignificant incidents may produce functional disturbances due to a formerly unobserved displacement of the organ. The fact is that as in many other conditions, so also in this, the patient calls for assistance only when the disease has entered into an aggravated stage and has become plainly manifest. In all previous phases of the difficulty the patient seems to complain of light disturbances of digestion alone. But all the while the stomach and intestinal tract are in constant danger of effective disturbance. Independent of digestion and of the quality of the foods, the symptoms range from variable appetite to rabid hunger and loss of appetite, through almost every kind of irregularity. Abnormal sensations, such as are usual in abdominal disorders, set in. Pressure, fulness, hot burning sensations, belching, nausea and even vomiting may occur. These symptoms may be reduced by avoiding every kind of excitement by means of complete rest of both body and mind. Sometimes these disorders may simulate the whole series of gastric diseases. Epigastric pulsation, which is frequently present, is not only unpleasant to the patient but worries him very much and appears to him as a pulsating tumor. Constipation, which is a characteristic symptom of gastroptosis and which sometimes leads to intestinal catarrh, is always present. Nervous symptoms are quite common, and manifest themselves in the form of abnormal sensations in the stomach and back which often amount to severe attacks of pain. This backache is quite typical and never absent. The plexus of nerves connected with the dislocated organ may be the mediate cause of these phenomena, which may be produced by the occasional tuggings on them in the attempts to bend, and in quick movements.

The diagnosis of gastroptosis is usually made by locating the size, boundaries and position of the

stomach. For this purpose the usual methods are resorted to, viz., artificially distending the stomach with air or carbonic acid gas, by percussion after a quantity of water has been introduced and by passing a ray of light to illuminate the organ. Auscultatory percussion has recently received new help from the phonendoscope, which seems to become a somewhat popular method for marking out the organs of the abdominal cavity. While this method may be of material assistance when the introduction of the tube into the stomach is contraindicated, it seems to me that the results obtained do not always have an undoubted value. Manges⁴ says that he has been disappointed in auscultatory percussion of some of the organs. The successive tapping produces changes in the tone which are very confusing. He finds that it is necessary to employ vigorous strokes in order to get percussive reaction for deeply situated organs, such as the kidneys, spleen, etc., and he sums up the record of the phonendoscope by stating that the expectations raised by Bianchi are not entirely realized. It would seem that the phonendoscope would be of greatest use in the examination of the abdominal organs and that it would help substantially to outline the stomach. It is stated that its advantages lie in its simplicity and the relative rapidity with which satisfactory results are obtained. Sound reaction, however, will in the very nature of the case hardly be able to compete with reaction by light.

For the best means for mapping out the stomach we are indebted to Einhorn,⁵ who in 1889 succeeded in introducing an electric light into the stomach so that it became transparent through the anterior abdominal wall. It became possible by means of this method, which now passes under the name of gastrodigraphy, to determine the position and size of the organ, as well as its relation to neighboring normal or abnormal processes. By the force of extended experiments he could afford to make the assertion in 1892,⁶ that we can safely diagnose gastroptosis by means of transillumination. The fact that we are able to recognize the upper border of the stomach in cases of gastroptosis enables us by transillumination to recognize the low position of the stomach. It must be remembered that the stomach when sunk has lost more or less its area of contact with the diaphragm, and it is on this account that the area of illumination, as Kuttner and Jacobson⁷ have proved, shows no respiratory displacement. In cases of gastroptosis the organ has sunk with all its upper parts *in toto*, even with the cardia, small curvature and pylorus. On this account the anterior wall will be illuminated more or less, because a larger part of the stomach lies close to the anterior wall of the abdomen. Boas⁸ says that just as in cases of gastroptosis transillumination furnishes characteristic data, for in many instances it enables us to determine the position of the upper border of the stomach.

The treatment of gastroptosis is mechanical, dietetic and medicinal. Treves,⁹ however, reports a case of gastroptosis in which recovery was accomplished by abdominal section. The main purpose of the mechanical treatment is to support the dislocated stomach and along with it such abdominal organs as are abnormally movable at the same time, and to maintain them in their normal position as much as possible. This is usually accomplished by means of certain bandages. These should be constructed out of stiff material and should fit accurately. Their efficiency consists in a

pressure from below forward, upward and backward. I have modified the Ewald-Kuttner hypogastric supporter in such a manner as to prevent its gliding upward as most of the ordinary bandages do. A truss band fitting the body below the crest of the ilium and above the trochanter is connected with this supporter so that the pad of the latter lies just above the symphysis pubis. When tightened, the combination gives the desired pressure. Where this supporter (drawings of which I exhibit herewith) has been applied the patients seem to be relieved. It should be put on in the lying posture and be removed at night. In cases of gastroptosis where the symptoms are not relieved by the bandage, we may safely assume that the supporter does not fit or that it has been applied incorrectly. The bandage, upon proper application, exerts a pressure upon the hypogastrium from below upward, raises the intestines and invigorates the tension of the abdomen.

Every pressure upon the upper abdominal region should be avoided, and for this purpose sanitary garments are to be recommended. In cases where the abdominal walls have become flaccid and the muscles of the stomach need corresponding strengthening, their contractility can be promoted by the cold douche, faradization and abdominal massage. For the reposition of the internal organs the horizontal position is the most naturally helpful. In all difficult cases, therefore, prolonged bed rest is advisable.

In the *Muenchener Medicinische Wochenschrift*,¹⁰ an interesting method of treatment for enteroptosis is given by Günzburg. A small quantity of baker's yeast is prescribed, the size of a bean: the fermentation provoked by the yeast is reported to cause a degree of flatulence which holds and immobilizes the intestines and thus allows the stomach to revert to its normal position. Should the flatulence prove to be too great and provoke a feeling of distension, the quantity of yeast can be diminished. It is reported that this treatment gives the patient a sensation of comfort, produced by the action of the carbonic acid upon the intestine, this carbonic acid being developed in the digestive tract under the influence of yeast. The stools become more regular and abundant. The distension of the intestine carries the aorta away from the abdominal wall so that the patient does not feel the beating of this vessel. (I report this ingenious method, but I have had no experience with it.)

The nourishment prescribed in gastroptosis should be ample and nutritive. Caution should be observed on this account that the gastric difficulties of the patient have no relation to any affections of the mucous membrane of the stomach which may be present. For the treatment of the constipation incident to gastroptosis, fresh fruit and graham bread are to be employed. The medicinal treatment should be directed to the phenomenon of constipation alone, and should embrace the usual laxatives and alkaline salts. Boas¹¹ recommends strychnin, bismuth salicylate and resorcin.

PERFORATING WOUNDS OF THE EYEBALL.

Read at the Third Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Ill., Sept. 23, 24 and 25, 1896.

BY D. C. BRYANT, M.D.

OCULIST OF THE UNION PACIFIC RAILWAY.
 OMAHA, NEB.

Perforating injuries of the eyeball are quite common among railroad employes and occur in all forms and degrees from the slightest perforation of the cornea with the loss of scarcely a drop of aqueous humor to the complete opening up of the globe and the entire loss of all its contents. Perforating wounds of the eyeball, with few exceptions, should be looked upon as serious injuries and be treated with the care that such cases deserve. Beginning with the wounds in the anterior part of the eyeball a small cut with a clean and sharp instrument through the cornea is not generally a serious injury, unless the agent producing the wound be infected, or penetrates beyond the posterior surface of the cornea far enough to injure the iris, lens or deeper structure of the eye. But if this cut should be situated within the pupillary space, the injury would be a serious one, not on account of the resultant scar would interfere with the vision of the injured organ. If the opening should be sufficiently large, prolapse of the iris is almost certain to occur, followed by the dangers of infection, iritis, or deeper seated inflammations. If the agent producing the injury be rough or dirty, infection is liable to be carried into the corneal wound or into the anterior chamber, setting up a suppurative inflammation which may cause loss of a part or whole of the cornea, rendering the eye useless as an organ of vision for all time to come. Wounds extending deeper injure the iris or the lens or both. With the injury of the lens another danger is added to the case. As a rule as soon as the lens or its capsule is injured it immediately begins to swell and usually causes enough irritation to set up an iritis or cyclitis. The younger the patient the less the danger of these results occurring, as in children an injured lens with proper management will often break down, disintegrate, and be absorbed without causing any serious trouble. But railroad employes are not often below the period of adult life and an injured lens in these cases is a serious matter and is capable of doing damage in a number of ways, unless properly managed, as the opacity of the lens resulting from the injury causes loss of all useful vision until the lens itself is removed either by absorption or operative measures: the swelling of the lens substance causes iritis, or cyclitis, which may result in the destruction of the eye as a visual organ, or the swelling by increasing the intraocular tension may cause a traumatic glaucoma with the bad results following non-traumatic cases of this disease. Should a wound penetrating the anterior wall of the eyeball extend beyond the lens into the vitreous there will be in addition to the trouble already mentioned, danger of hemorrhage into, and infection of the vitreous, both of which conditions as a rule eventually cause the loss of vision, and oftentimes the latter causes destruction of the eyeball itself. The wound may not

be received in the anterior wall but back in the ciliary region, or still farther back through almost any portion of the sclera, although Nature has placed the eyeball so that the posterior half is well protected from external injuries. The results following injuries in these locations will depend upon the size and depth of the wound and on the fact as to whether the instrument producing the injury was aseptic or not. If the wound is large there may be loss of the entire vitreous and lens which means loss of the eye; if the wound is small and clean cut there may be very little damage done, no loss of vitreous, almost immediate union of a wound, and no bad results. Between these two extremes will occur cases of many different degrees of seriousness. As a rule the deeper the wound the more serious it is, not only on account of the mechanical injury done, but also the liability of carrying infection to the deeper structures. But whatever portion of the eyeball is penetrated by these injuries there is another factor, not yet mentioned, which adds an extra amount of gravity to any given case, and that is the retention, within the eyeball, of the agent causing the wound. It is true that a number of cases have been reported where eyes containing foreign bodies have retained more or less perfect vision, but these cases are in a hopeless minority, are considered so rare that they are always reported, and only serve to emphasize the danger which becomes manifest sooner or later in the greater majority of these cases. In all cases of penetrating wounds of the eyeball followed by inflammation of the deeper structures there will be more or less danger of sympathetic trouble in the other eye. The retention of a foreign body within the eyeball increases this danger. With this hurried description of these injuries, let us pass on to the "diagnosis of penetrating wounds of the eye," which is the part especially assigned to this paper in the present discussion.

Many of the severer cases could not be overlooked with the most casual examination, the wound being so large and gaping, the lips separated by fragments of iris, lens or vitreous. There are others, however, where the wound is so small or so clean cut as to make it absolutely necessary to exercise the greatest care and caution in making the examination in order to avoid a mistake in diagnosis, and in these the following mode of making examinations will be found very useful and satisfactory.

First, the history which the patient will give of the manner in which the injury was received, the kind of agent producing the injury, shape, size, material, force, and direction from which it came, and portion of eye struck, will give one some very valuable information in regard to the case. Thus the exact point of injury is often located by the patient which might be overlooked by the examiner unassisted by the patient's description. The size and shape of the foreign body, the material of which it is composed, and the velocity and force with which it was sent will be of great importance in deciding the depth to which the wound has extended. A description of the instrument inflicting the injury often decides whether or not there is a foreign body retained in the eyeball, a very important point indeed to be decided early; as, if the instrument is a penknife, a pin, needle, or pair of scissors, an examination of the article, finding it intact, shuts out the possibility of anything being retained within the eye. On the other hand, should the agent producing the injury be a small bit of iron, steel,

brass or copper, the chances are that if not caught in the cornea, or sclera, it has passed through and lodged in some of the deeper structures of the eye and the most thorough and painstaking examination should be instituted in order to discover and locate it if this be possible. It is always best to use a biconvex lens of two inches focus in making these examinations. By using the condensing lens for oblique illumination, small punctures which otherwise would be overlooked will be brought distinctly into view. In addition to this another convex lens can be used as a magnifying glass to enlarge images and will be another adjunct in making this discovery of the slightest wound more sure and certain. The examination should begin with the cornea, which being a bloodless membrane leaves little trace of small wounds or punctures and on this account the use of the magnifying glass and oblique illumination are almost indispensable. A faint dot or line of opacity usually tells the story of injury to, and perhaps an opening through the cornea. If the wound has penetrated deeper and the iris be injured, blood in the anterior chamber and perhaps a rent in the iris itself, adds to the evidence already collected. If the point of penetration is beyond the margin of the cornea in the sclera, even the most minute puncture usually leaves a dot of blood from the conjunctiva or subconjunctival tissue to mark the point of entrance. Blood in the anterior chamber may be the result of a penetrating or non-penetrating wound and should not be taken as conclusive evidence of the former unless the cut in the anterior wall of the eyeball can be discovered. A blow on the eyeball may cause a laceration of the iris filling the anterior chamber with blood and even dislocate the lens, without perforating the anterior wall. If the wound is in the cornea and is seen soon after the receipt of the injury the anterior chamber will be found very shallow or almost obliterated, the iris being pushed forward against the posterior surface of the cornea, the loss of the aqueous humor allowing the lens to push the iris forward. This, when present after an injury, is a positive symptom of perforation but in many cases, where the opening is small and clean cut, the wound almost immediately closes and in a few moments sufficient aqueous humor reaccumulates to refill the anterior and posterior chambers and this valuable diagnostic symptom disappears. Where the wound is larger a prolapse of the iris into the wound is positive evidence of an opening through the anterior wall. If the perforation is at or back of the ciliary region there will be prolapse of the ciliary body or choroid instead of the iris. In the larger wounds there may be not only prolapse of iris or choroid but also escape of lens, or vitreous or both. Wherever the wound is located, as long as it remains open, a valuable symptom will be present in the shape of diminished intraocular tension. This symptom is especially valuable in cases where small wounds through the sclera are hidden by bruised and swollen conjunctiva. Laceration of the sclera from a blow on the eye will present this symptom. After the first twenty-four hours an opaque lens will often establish the fact that the eye has been penetrated and the lens injured. Cases occur when the penetrating body is very small (as bits of metal, steel, iron, brass, etc.) where the most skilled eye surgeon will be in doubt for a short time, as to whether the foreign body has passed in and remains in the eye or not. Immediate search of the anterior part of the eye with convex lens and oblique illumination and of the

eeper parts with the ophthalmoscope may not reveal the foreign body or the path it has pursued, but after short time symptoms in the shape of opacities in lens or vitreous, or inflammations of the deep structures of the eye with corresponding loss of vision will remove any doubts that may have at first existed. Briefly, then, a correct diagnosis immediately (within a few hours) after receipt of injury can usually be reached in the more obscure cases by obtaining a careful history of the accident from the patient; by close examination of exterior surface of eyeball with convex lens and oblique illumination, by noting the depth of anterior chamber, by testing the tension of eyeball, by noting prolapse of iris or any portion of irveal tract, and last, if the media be clear, the ophthalmoscope may locate a foreign body or reveal a wound in the deeper structures of the eye. Later on swelling and opacities of the lens or vitreous and inflammatory trouble out of proportion to what would be expected from the visible wound, often point out the extreme depth of the injury, or the presence of a foreign body which before may or may not have been suspected. Detachment of retina with loss of vision months after the receipt of a small wound in the sclera may be the first positive proof of the penetrating nature of the injury. The short time allotted this paper does not allow any extended description of the management and treatment of these injuries, but as the final result depends so much on the treatment received the first few days after receipt of injury, I can not refrain from adding a few lines in regard to the early management of those cases which do not require immediate enucleation.

As there is no way of determining whether a wound aseptic or not these cases should all be treated as septic and palpebral sac be thoroughly cleansed with an antiseptic solution and any foreign substance in the sac carefully removed. Loose ends or fragments of cornea should be trimmed off and lips of wound brought in as nice apposition as possible. Any foreign body retained in corneal wound or in interior of eye should immediately be removed if possible with forceps or magnet, though no rude probing or exploring after unseen or unlocated foreign bodies should be indulged in. If the iris protrude through the wound and is uninjured, after being thoroughly cleansed, it should be carefully replaced in anterior chamber with probe or spatula. If this can not be done or if the iris be lacerated the protruding portion should be removed. If the wound be in or near the central portion of cornea, sulphate of atropia in two to four grain solution should be used with sufficient frequency to secure wide dilatation of pupil within a few hours time so as to remove the iris from the location of the wound and thus avoid further danger of prolapse. If the opening is near the periphery of the cornea a solution of eserin or pilocarpin should be used to prevent the iris from bulging into or through the wound. After the first twenty-four hours, or as soon as the edges of the wound are adhered the myotic should be changed to mydriatic. A bandage of gauze over a light pad of cotton should be applied for support of lacerated wall and to prevent friction of wound from movement of lids. This also shuts out the danger of further infection of wound from the atmosphere, practically making a closed wound. Cold applications are indicated in all of these cases, except the very mildest and are best applied over the light dressing already described. Experience has taught me

that as good results are obtained with less discomfort to the patient by the use of a small ice bag over the pad and bandage as by the use of cold in any other manner. This can be used more or less constantly according to severity of case, and obviates the necessity of the constant attendance of a nurse, which is absolutely necessary with the application in the usual way. Pain should be relieved and rest and sleep secured by the use of morphia, if necessary, as these conditions are as essential here, for the prevention of inflammation and the hastening of the reparative process, as in wounds in other portions of the body. If the wound be through the sclera and is of any considerable size, the edges should be brought together with sutures as this membrane, on account of its stiffness and inelasticity, does not allow the opening to close so that union between the lips of the wound can take place.

By following the above rules many of the milder cases, in a very few days, will be practically well, while the severer ones will be placed in the best condition possible for the prolonged and varied treatment which they will require, a description of which would occupy more time and space than is allowed this paper.

DISCUSSION.

Dr. W. A. WARD—I am not much of an oculist and have not had much experience, but it has fallen to my lot to have four cases of penetrating wounds of the eyeball. The first was one in which a piece of steel was lodged in the cornea and was readily removed but subsequently was followed by protrusion of the iris, the protruding part was removed but the iris became blocked in the cicatrix that follows, and remains in that condition today, although the eyeball is intact and is full size. The second case was one in which one-half of the washer of a rivet as a boiler-maker was clipping it off flew into the eye; the eyeball immediately filled with blood. An effort was made to remove it with forceps, it was a failure; it was then removed by the electro-magnet. In that case recovery took place, the eye cleared up but we have a dislocation of the lens, and of course impaired vision. The third case was one almost similar arising in the same way as the second. An effort to remove by the forceps, and a failure, and the electro-magnet succeeding, but the recovery was protracted; after two months the patient complained of a scratching; I examined and found a second piece and it was removed. That case recovered, but of course with impaired vision. The fourth case was the result of an explosion of the gas tube of the oil feeder on a locomotive, and that lacerated the eye so that all of the interior eye at once exuded, and of course there was no other way than to extirpate the remaining coats of the eye. Taken these two cases, the second and third, in my next case, if I should be unfortunate enough to have another, I would not delve, especially if the eyeball filled with blood, but would use the electro-magnet at once, and then I would make free use of the boracic acid solution.

Dr. BRYANT—I can not help saying something, these cases are very important cases, and the most important part of it to my idea is the early treatment as far as the railroad surgeon is concerned. The surgeon does not intend to treat these cases through, excepting the milder cases, but he must have charge for the first twenty-four hours, perhaps for two or three days. In my own practice I see most of these cases about the third or fourth day and some of them have not been treated at all, and in those cases so much damage has already taken place by inflammatory trouble that the results are not as good as if they had been properly treated nothing done excepting the eye has been cleansed. If the surgeon would use the free application of cold continuously these cases would come into our hands as if we had seen them first; except in cases where the foreign body is retained in the eye, which perhaps we might remove better than the general surgeon. But even those cases can be treated by the surgeon when the foreign body is in the anterior chamber; I do not know as a rule that the surgeons have a magnet, but if the ordinary surgeon would carry either an electro-magnet or a small magnet which is strong enough to remove small bodies from the eye and occupies no

space in a case, you will find you can remove most of these bodies without any trouble—in most cases the original wound is closed and we have to reopen it or make another wound, but the use of the cold and the moist dressing should always be begun immediately after the first dressing of the wound and continued for the first few days at least.

THE PERSONAL EQUATION AMONG TRAINMEN OF EQUAL OR GREATER IMPORTANCE THAN VISUAL POWER OR COLOR SENSE.

Read at the Third Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Sept. 23, 24 and 25, 1896.

BY ROBERT TILLEY, M.D.

CHICAGO.

After having one day examined a few locomotive engineers for visual power and the color sense in particular, I felt considerably dissatisfied and asked myself the question, what is the object of these examinations? The answer came immediately: To avoid accidents by the elimination of men with visual defects. Another question presented itself: But is this—the condition of the color sense and the visual power relative to form—all that can afford us information relative to the aptitude of the individual to perceive quickly and respond with judgment? Emphatically, no. There is another phenomenon, or rather several phenomena, the observation of which would add much greater certainty to our work and more personal satisfaction in its contemplation. These several phenomena consist of the time taken for the sensation to be carried from the retina through the optic nerve to the cortical substance of the brain; the time taken for comparison and ratiocination; the giving order for action and the execution of action.

The whole of these several operations takes but a very short time; but it is only a very short time, a small fraction of a second that determines an accident or an escape from the same. This fraction of time and its importance has been recognized by astronomers ever since serious calculations by different individuals have been made, and has been called the "personal equation," and it is only by taking notice of this fraction of time that their calculations can be made to agree. I have little doubt, gentlemen, that you will recall instances of marked rapidity of action and marked slowness of action, the latter being by far the most readily noted. I have been told of a case where the length of time taken up by the phenomena referred to above was so great that it was unsafe for the individual to venture out alone. There is no danger of such extreme cases being found among trainmen.

Now the exhibition of the instrument by which it is proposed to measure this personal equation is of very much greater importance than any collection of words attempting to discuss the matter. Consequently I am extremely sorry that it has been impossible to get the instrument here to exhibit to you. But all of you know the numerous unforeseen circumstances which arise in any original work. I know Mr. Bush of Rochester, who is making it, tried his level best to get it here.

The instrument at present is in appearance like an old clock, only about one-half or two-thirds the height. Accompanying it on a table is a small case supplied with keys corresponding to the red, green or white objects which will be made visible at will by the examiner. This small case is within easy

reach of the person being examined. In the large case near the top is a hole, across which is made to pass an object, white, green or red. The man being examined is requested to observe and touch the correspondingly colored key on the instrument on the table; and the time that elapses from the moment the object passes the hole in the large instrument to the time when the key is touched is the man's personal equation, which is shown by a line which is begun at the moment the object passes the large hole and is stopped at the pressure of the key. The length of this line is easily transformed into the fraction of a second. If a mistake is made by touching a green key when a red color appeared, or *vice versa*, that is recorded.

That is a very crude description of the external appearance of the device. The inward working, the instrument not being here, is omitted.

An instrument like this means a good deal of preliminary work before it is easily and readily applied. The average personal equation will have to be ascertained and may become a recognized item like the visual acuity. When the instrument is thoroughly mastered it will be a practical and useful instrument.

I am disposed to think that it will detect and show up a class of cases which not infrequently applies for personal damage without any real claim. I am interested in one such now on hand.

In 1892 I was asked to examine a man relative to his visual acuity. He claimed to have suffered a loss of vision in connection with a wound in the forehead. The report was that there was incipient atrophy—that in all probability it had nothing whatever to do with the accident—but that with the claim that vision was perfectly good beforehand and no proof to the contrary it would be very difficult to demonstrate to a jury that it was not caused by the accident.

There was a settlement made and now as he is blind, he brings suit again, claiming that he did not know what he was doing.

Now it is not at all unlikely that this is a form of atrophy associated with locomotive ataxia and that as the perception of sensation is often retarded in such cases, it is very probable that the claimant being examined by some such device as this within twelve months prior to the accident, he would have been relieved of his duties and the accident prevented.

DISCUSSION.

DR. D. C. BRYANT—I believe it is important to examine all these cases, not only in regard to color vision, but also as to the quickness with which they can perceive colors, and even more than that, the errors of refraction. On our own road within the last few years we have turned off a great many of the old engineers on account of the errors in refraction. In our own case we have been using something with which we can get at the quickness of the recognition of colors by which the employes could be tested. We have an electric light and flashing colors, which is much better than the old way of testing with colors and better than the permanent light—often a quick perception of colors prevents a smash-up. This has been employed for several years. One fault I find with the company, they do not have their men examined often enough and not enough of the men examined; the brakemen, conductors, engineers and firemen should all be examined, not only as to colors, but as to quickness in perceiving colors. With our own road nobody is obliged to be examined excepting the engineer; this is really an injury to the firemen as they spend from three to four years firing and then on being examined for engineers they are shut out for being color blind or on account of errors of refraction; whereas if they had been examined they would have spent their time in some other and perhaps higher position.

PENETRATING WOUNDS OF THE EYEBALL.

Read at the Third Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Sept. 23, 24 and 25, 1896.

BY T. J. REDELINGS, M.D.

SURGEON TO THE CHICAGO AND NORTHWESTERN RAILWAY.
MARINETTE, WIS.

The title assigned to this paper is so comprehensive in its scope, that I do not presume to touch upon all the phases which it might present, but will endeavor to emphasize such points as present themselves to my mind with especial force after a careful review of the available literature on the subject. It may be that I shall speak of some things common place and trite to many, but I do it without apology for the reason that the eye is so commonly misunderstood and consigned to the recuperative powers of nature. In injuries of the eyeball as in injuries of other parts of the body, much depends upon the first dressing the wound receives. The principles of aseptic and antiseptic surgery should be carefully followed in all their minor details. Wounds of the eyeball are so varied in their nature, that we shall consider them under separate headings.

1. Wounds of the cornea. By far the greater number of every surgeon's traumatic eye cases are injuries to the cornea by the presence of a foreign body. The indications in these cases are very clear. The eye should first be cleansed with a saturated boric acid solution, then cocainized and the foreign body removed by a spud or needle, with a minimum amount of injury to the cornea. If the injury is slight a weak antiseptic collyria dropped into the eye for a day or two and wearing of smoked glasses will be all that is required. If more extensive a compress and bandage, the application of heat or cold, whichever is more acceptable to the patient, with the use of eserin or atropin will add to the patient's comfort. If the offending agent enters the eye while hot my experience has taught me that it is quite as important to remove the brownish char as it is to remove the particle of iron, steel or emery which caused it. I have frequently seen very unpleasant sequelæ where this was omitted, and desire especially to emphasize this little precaution.

When the projectile is lodged in the cornea but penetrates the anterior chamber it can be removed by the keratotome or curved needle. If it falls into the anterior chamber it should be removed at once by an iridectomy; should it fail to escape with the aqueous it will be easily removed with the iris forceps.

Wounds of the cornea show a tendency to heal kindly. This has been conclusively demonstrated by the many operations which are made in it to reach the interior of the eye. Wounds accidentally inflicted are, however, not always clean cut and their edges not easily kept in perfect apposition. Asepsis and apposition are the two principal points upon which primary union in wounds of the cornea depends. These simpler wounds of the cornea carefully treated usually heal without a visible scar.

2. Injuries of the cornea involving the iris and lens. "Penetrating or incised wounds of the cornea are very generally followed by prolapse of the iris. The extent of the protrusion varies with the size and position of the wound. A small penetrating wound near the corneal margin is more likely to be attended with prolapse than a larger incised one near the center. The amount of prolapse to a certain extent is dependent on the size of the wound: but beyond one

of a limited range, such as is produced by the point of a pair of scissors or the blade of a penknife, the tendency to prolapse is diminished as the size of the wound is increased."

Prolapse of the iris always constitutes a formidable complication and usually taxes the surgeon's ingenuity to decide which of the two plans of treatment to pursue, operative or non-operative. The latter we think should always be given a trial. After the wound has been thoroughly cleansed the iris may be replaced with a spud.

A solution of eserin or atropin according to the location of the wound should then be applied to put the iris in a splint as it were. If the iris can not be retained in place by this method, recourse to the method of Gama Ponti can be taken²; this surgeon abscises the prolapsed portion of the iris, frees all adhesions to the margin of the ulcer, and covers the opening in the cornea with a flap of bulbar conjunctiva, which should be cut twice as large as the opening and pushed into the orifice with a blunt probe. A firm binocular bandage is applied, and the eye not dressed until the third day. Then it will often be found that the conjunctival flap has healed into the ulcer. A flat non-adherent cicatrix results, or in other words, an ordinary corneal scar without staphylomatous bulging and a circular pupil. Dr. Schweinitz reports several gratifying results by this method.

If the lens or its capsule is injured there will in all probability be developed a traumatic cataract. The point of injury is within twenty-four hours indicated by an opaque patch, which gradually increases until the whole lens becomes opaque. The rapidity of the formation of a cataract will depend partly on the extent of the injury, and partly also on the age of the patient. If the rent is large and the substance of the lens broken into, the aqueous humor will come rapidly in contact with the lens substance and its transparency be quickly destroyed. If the rent is small the development of the cataract will be very much more slow. It occasionally happens, but this must be considered exceptional, that a small wound of the lens capsule produces only a limited opacity. In relation to injuries to the lens Dr. J. Hirschberg of Berlin reports two cases of very especial interest at this point. The one a boy 14 years old, who while exploding a gun cap was struck in the left eye with a portion of the cap, the copper particle being easily visible in the lens, and the opacity being limited to the immediate site of the foreign body. The other a man 46 years old, who while discharging a gun was struck in the right eye by a piece of the gun cap. In the outer layers of a perfectly transparent lens could be seen a copper splinter 5 to 6 mm. in length. Only a light gray cloudiness of the lens capsule immediately over the foreign body was discernible. Of these two cases Dr. Hirschberg says the copper splinter in the lens was well borne for months and years without the development of a disturbing cloudiness: the eye read the finest print, and did not require operation.

Slight injury to the lens or capsule may, however, result in so stormy a swelling of the lens that the safety of the eye demands its immediate removal. This operation usually terminates happily.

3. Injuries to the ciliary region and the sclerotic. "A wound of the cornea even though the lens or iris

³ Deutsche Med. Woch., 1894. No. 14.

be implicated, is less fatal to the eye than a similar wound in the sclerotic." The hemorrhage in the former instance, is into the anterior chamber, and mixing with the aqueous humor it is rapidly absorbed; whereas in the latter, if hemorrhage ensues, it is into the vitreous, and frequently also between the choroid and retina. Blood in the vitreous is slowly absorbed, while irreparable damage is done to that portion of the retina which has been displaced by a blood clot. Wounds of the sclerotic sometimes heal with difficulty, and the difficulty increases as the location of the wound recedes from the margin of the cornea. This is probably occasioned by the fact that the margins of the wound remain patulous, the tissues of the sclerotic refusing to yield to the diminished size of the vitreous within it; hence it is that wounds in the sclerotic where only a small quantity of vitreous has escaped, there is a tendency for the lips of the wound not to come together, and a consequent inability for primary union. These wounds, however, unite quickly if the edges are brought in apposition by a fine silk suture. Dr. Bowman reported two cases illustrating this fact. "In the first patient there was a wound in the sclerotic which had remained patulous for three days, and in the second, no attempt at union had taken place one week after the accident, yet, in each case, immediate union followed after the edges had been brought into accurate apposition by a single fine suture." The occasional cystoid cicatrix, which is found, could, we think, be avoided by recourse to suturing. The danger of a wound to the eyeball is immensely increased, if the injury is located in the sclero-corneal region involving the ciliary body. The risk to the injured eye is very great, but the chief danger is the chance of the other eye becoming involved in a sympathetic ophthalmia.

Lastly, we come to consider briefly that class of wounds in which the projectile remains within the eyeball. Every penetrating wound of the globe should be especially examined with reference to the possibility of there being a foreign body within the eye. The history of the case should be carefully gone into with a view to ascertaining the exact nature of the material which struck the eye, whether large or small, by what force and in what direction it was propelled against the eye. The eye itself should be examined first superficially, then the iris and lens. If the wound in the cornea suggests the possibility that a foreign body may have penetrated it, and yet the foreign body is not visible in the iris or lens the pupil should be dilated with atropin to bring the lens into full view, because it may have lodged in the margin of the lens and behind the iris. Oblique illumination is of immeasurable value in this examination of iris and lens. If such an examination does not reveal the foreign body, and the conditions are favorable, a thorough ophthalmoscopic examination of the whole fundus should be made, and the foreign body located if possible. Unfortunately, however, these injuries are sometimes attended by hemorrhage, which entirely obstructs the view of the interior of the eye. Dr. Rohmer⁴ in a very able article on "Extraction of Metallic Foreign Bodies from the Posterior Segments of the Eye by the Electro-magnet," says: "When a foreign body reaches the deeper parts of the eye, it will cause disorder varying in intensity and gravity according to its size, the region of its entrance, its degree of

cleanliness, its chemical composition, the place which it occupies, and its action on the neighboring parts. After its penetration, the eye may be immediately and irrevocably lost from the extent of the lesion, escape of vitreous, hemorrhage or infection. Or the foreign body entered by a very small opening, and only caused an insignificant lesion, with partial or complete preservation of vision."

The location of a foreign body in the eyeball will in a measure determine the degree of tolerance, the different structures reacting differently to its presence. In the lens, for instance, a small foreign body may be borne well for years, and be ultimately removed with the schriveled and hardened cataract. In the posterior segments, however, a foreign body will rarely be tolerated. In the vitreous, choroid, and ciliary body, even though the foreign body became encapsulated there will sooner or later develop a plastic or purulent inflammation, with consequent destructive ophthalmitis.

The treatment of these cases will depend upon the nature of the foreign body. Coppez made the observation that in seventy cases of foreign body in the posterior hemisphere of the eye, forty-two were iron or steel, ten were lead-shot, ten fragments of cartridges or pieces of copper, six fragments of stone, one zinc, one wood.

If the foreign body is magnetizable it should be removed as soon as possible after the accident with the electro-magnet. From the statistics⁵ gathered at the clinic in Zurich by Hirschberg it is apparent that during the four years preceding the use of the electro-magnet in cases of metallic fragments in the vitreous, there were twenty-four cases treated, all of which were recorded as failures, that is, 100 per cent. During four succeeding years in which the electro-magnet with antiseptics were employed, of thirty-five cases there were only twenty-four failures, that is, 68 per cent. In his own practice without the magnet he did not have one successful case, during the first ten years. In the following ten years with a magnet, of thirteen successful cases, seven were noted as satisfactory, and six as mediocre. These figures certainly justify the use of this method, and we need not discuss this proposition at greater length.

If the foreign body is not magnetizable, the eye should be enucleated as soon as there are signs of obstinate inflammation.

SURGERY ONE HUNDRED YEARS AGO.

AN HISTORICAL STUDY

BY DR. GEORGE FISCHER.

DEDICATED TO THE GERMAN SURGICAL ASSOCIATION.

TRANSLATED FOR THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION
BY CARL H. VON KLEIN, A.M., M.D.

IX.—THE ACADEMIE ROYALE DE CHIRURGIE AT PARIS.
PIERRE JOSEPH DESAULT.

(Continued from page 179.)

Medicine had from the first not kept pace with surgery in France; the latter had always been pursued with partiality, while the former had been neglected, so that, with a few exceptions, French physicians had not made brilliant records. The chief reasons for this failure of medical study were, the too brief period devoted to it, the neglect of the supplementary studies, the selling of the doctor's degree, and above all the separation of medicine from surgery. This had cou-

⁵ Hirschberg: Centralbl. f. prak. Augenheilk., 1894, p. 284.

tinued in France, as in Germany, since that unfortunate time when the Catholic church forbade the clergy to perform any operation whatever. As a result the science sank to the level of a trade. Indeed, the Italian, Lanfranchi, who in 1295 had fled to Paris, taught both sciences, practiced both, and declared that their separation was an evil; but centuries must pass before the Revolution ushered in a wholesome reform. The political equality of physicians and surgeons, and of the sciences of medicine and surgery, had been established, and must have, as a consequence, the reunion of the two sciences. Suggestions for the improvement of medicine were sent in by different societies. Chaussier showed the absurdity of the separation of medicine and surgery, and exposed the abuse, on the part of the body surgeons, of extorting money and selling appointments (1789). The Royal Society of Physicians also, in an address to the national convention, contended for the inseparability. The propositions which were made agreed with the report or instruction by Talleyrand, one of the best minds which arose out of the Revolution; but the flight and capture of the King diverted the attention of the national convention from the subject of education, and Talleyrand's plan, along with others, was pigeon-holed. The convention met. The leaders of the Reign of Terror were reproached with wishing to banish science and the arts, as they decreed the suppression of the Academy and the societies and caused the persecution and death of certain scholars. The accusation is not entirely just. They abolished those institutions and those learned societies, because they had been privileged and endowed, and now the sentiments would not allow of the existence of any privileged body. They bore upon themselves the stamp of despotism, and their organization conflicted with the principle of equality; therefore they must fall. Lavoisier must die, not because he was a great scholar, but because he had been a tax-levier. Desault's imprisonment was the result of the personal hatred of certain rogues, but his scientific deserts hated him, for he remained under arrest only three days. A physician in Arras was denounced at the instance of his colleagues, and executed because he had a picture of the King in his room. It is also to be remembered, that much of the mutilation of works of art is to be ascribed only to subalterns; Henriot, the commander of the national guard, demanded that all libraries be committed to the flames. But no systematic extirpation of the sciences took place, and even at that time, among other things, the botanical garden in Paris, was considerably enriched. Then followed the strenuous persecution of the monasteries and the clergy; a mass of old parchment-rolls, which perhaps contained valuable manuscripts, was used for cartridges. According to the crude conception of liberty and equality which the mob had, even scholars, because of their prominent position, must be opposed to it; they were treated with distrust. All the destruction wrought resulted in less injury to science than the complete diversion of all forces to the field of politics, the consternation, and the death of many talented men upon the battlefield. All this thrust science to one side. During this time Vicq d'Azyr died, bowed with grief over the horrors of the Revolution. Excepting a law for military hospitals the convention did nothing positive. After the fall of the tyrants, the need of improvement in medicine again appeared in the foreground. Till 1792, when the Revolution abolished

public instruction in medicine, the separation of medicine and surgery had been rigorously maintained; when in the year 1794, at the suggestion of Chaussier and Fourcroy, the Ecoles de santé, described in a previous chapter, were founded, *medicine and surgery were again united*. Without doubt the Revolution accomplished this, instruction was essentially improved and practical clinics organized. According to the proposition of the physician and deputy Guillotin, whose name is immortalized in the executioner's ax, all academical degrees and titles should be abolished, and all practitioners should bear the name physician, which was changed in 1794 to officier de santé. In spite of many reforms, the social conditions left much to wish for. One who wished to practice must pay twenty francs a year (though advocates paid nothing), and officiers de santé were classed with furniture dealers, carriage-makers, hair-dressers and others, in the fourth tax-class.

Let us return to the French surgeons. In the first half of the eighteenth century, the scepter of surgery was held by *Jean Louis Petit* (1674-1750), before whom all contemporaries must bow. Even as a boy he studied anatomy under Littre, who lived in the house of his parents, and in his 12th year he began the preparation of those lectures which he afterward delivered to his students. Later he studied surgery under Maréchal, and in 1692 became military surgeon in the French army in Flanders, where he was charged with the supervision of a hospital in Tournay. After his retirement from the army (1700), he went to Paris, became master of surgery and began to give anatomic and surgical lectures. Some years after (1705), appeared the work on diseases of the bones (chiefly fractures and dislocations), upon which the young Petit laid the foundation of his later fame. This work, of which Boerhaave said "tractatus hic nunquam sibi parem habuit," was for half a century the best of its kind. Petit wrested the treatment of fractures out of the charlatanism of the bone-setters (*baillieurs*), and instead of straining after theories and hypotheses in the manner of his time, he gave his experiences and operations. It had hitherto been a general misfortune that only those who had no surgical practice were writers, while the practitioners seldom published their notes. The Paris Academy of Sciences and the Royal Society of London admitted Petit as a member, although according to the standards of that time he was no scholar. His reputation soon became so great, that the kings of Poland and of Spain invited him to their kingdoms and made him very flattering proposals, which, however, he declined. He worked many years on his celebrated "Traité des Maladies Chirurgicales," which, in three parts, only appeared after his death (1774), and contained a rich experience and a mass of new ideas. Petit wrote little, but his works were classics (mostly in the "Mémoires de l'Académie"), and there was no lack of venomous critiques against him. We have him to thank for the invention of the screw tourniquet, by which operations on the extremities became less dangerous; for the circular amputation: the operation for strangulated hernia without opening the hernial sacs, besides many improvements upon methods of operating. He was an eminent operator. *Le Dran*, one of the best of surgeons, officiated with him in the Charité. With clear comprehension and sound judgment he combined an easily understood diction, and distinguished himself above many of his

countrymen for a simple, fundamental exposition. Especially celebrated as a lithotomist, and as one of the first to perform the exartic. humeri, his works ("Obs. de Chir.," 2 Th., 1731), which offered improvements upon many methods of operating, were received by all nations with great applause; Cheselden, indeed, translated his "Traité des Operat." (1742). His works on abdominal wounds and gunshot wounds are good. *Morand*, who was first appointed to the *Charité* and afterward to the *Invalides*, owed his scientific education and rich experience to a firmness of purpose and great ambition, and his acquirements made him unsympathetic toward many of his vain colleagues, with their useless inventions of instruments. Never properly appreciated by his country, he declared that he was persecuted by his own countrymen as well as by foreigners (*Sharp*). Bitterly prejudiced against the *Académie de Chirurgie* for that reason, he withdrew from it entirely; so *La Martinière* and *Louis* could hardly succeed in giving him the position of body surgeon, which involved his assuming the duties of the secretary of the academy. He was appreciated in Germany; *E. Platner* translated his works and *Richter* said, in 1776, that a *La Peyronie*, *Le Dran* or *Morand* must soon arise, if the glory of the *Académie de Chirurgie* was not to fall. *Morand* endeavored to make surgery as simple as possible, and to spare operations ("Opusc. de Chir.," 2 Bde., 1768-72). He attained a reputation by the introduction into France of the side incision for lithotomy, after he had been sent to London by the Royal Society for the purpose of learning *Cheselden's* method. With him began the history of exarticulatio femoris, based upon experiments upon animals which he had two of his students make. He also recommended extirpation of the ovaries. In a demonstration of *Bilguer's* work on amputations, *Morand* showed himself as having a better mind and a far higher education than his German opponent. In *Garengot* much energy and mechanical ability were combined with some insolence, in that, in adopting the new methods of other surgeons, he suppressed the names of the discoverers, and ignored their claims. He was demonstrator in the surgical school, and in later years was military physician, and as such was very active in the Seven Years War. Besides anatomic works, he wrote on operations (2 Vols., 1720), and instruments (2 Vols., 1723), works which contained many improvements and were very popular at that time. The invention of the dental forceps is ascribed to him. Even his own countrymen considered him a braggart. *Quesnay* was more celebrated as a national economist than a physician. Appointed by *La Peyronie* as secrétaire perpétuel to the academy and as professor in the *Ecole de Chirurgie*, he became body physician to *Louis XV.*, who esteemed him highly, and ennobled him. Frequent attacks of the gout prevented him from employing himself in practical surgery. He wrote of suppuration, gangrene (so-called white gangrene), injuries of the head and trepanation. Imbued with a love of agriculture from his youth up, he advocated, in many political essays, the principle that the prosperity of the state depended on agriculture, and not on the mercantile and manufacturing system. Of almost the same age as *Quesnay* was *Arnaud de Ronsil*, who in Paris specialized on hernia, and was able to accumulate a mass of material, as the monastic nurses of the *St. Lazarus* were directed to send to him every patient suffering with strangulated hernia. His monograph

on hernia marked a new epoch. He was the first to accurately make known the symptoms and to tell how strangulated hernia was to be distinguished from adherent hernia, to treat herniotomy thoroughly, to describe hernia obturatoria and ischiadica, and to indicate the course of the art. obturat.: for the enlargement of the lig. Poup. he suggested the use of the blunt hook named from him, instead of an incision; and for fear of injuring the art. epigastrica in an operation for crural rupture he entirely avoided the scarification of the abdominal ring. He was demonstrator of bone diseases in the *Ecole de St. Côme*, but because of certain unpleasantnesses he went to London in 1746, where he practiced for thirty years. Besides the vain *De La Motte* and the eminent operator *De La Faye*, in Paris, there were in the provinces a few noted surgeons. *Le Cat*, in Rouen, was first a priest, then an architect, and finally a surgeon. As an able operator in lithotomy he became involved in a quarrel with *Frère Côme*, whose method he entirely discarded. *Le Vacher*, in Besançon, a son-in-law of *Morand*, was also known through his side incisions. In case of cancer of the breast he recommended an operation as the only remedy. *Verdier*, to whom *J. L. Petit* committed the management of his anatomic theater, was an anatomist rather than a surgeon. He showed that the bladder as well as the ovaries could be contained in the hernial bag. *Anel* was renowned as an oculist in the first half of the century; he wrote on hydrops of the lachrymal glands, and on lachrymal fistula ("de fist. lacr.," 1713), for which he recommended probing and injections with his syringe; he died in Turin in 1730. Then *St. Yves* and *Francois Poufour du Petit*, who measured the diameter of the eye, discovered a new method of depression of cataract, and already in 1727 undertook the extraction of cataract. The dispute over the nature of cataract, which had hitherto been regarded as a film over the lens, attracted *Antoine Maitre-Jean* and *Brisseau*, who demonstrated on a cadaver that cataract had its seat in the lens.

In the middle of the century lived *Antoine Louis*, a man who in science combined high aspirations and a tireless activity with a comprehensive knowledge of the history and literature of surgery and of medical jurisprudence. His services were more considerable as a teacher and writer than as a practitioner; he advanced surgery itself but little. In place of the tourniquet, he introduced into practice generally indirect digital compression in hemorrhages after amputation, although this was not now first employed, as I have shown in giving the view of *Malgaigne* and *Lister*. As one of the first who argued, in Latin, in behalf of the admittance of surgeons into the College, he took a vigorous part in the strife between the faculty and the College. With his passionate temperament, he became involved in quarrels with the monks in the *Charité*, left it, campaigned a little, and then undertook the presidency of the *College St. Côme*. After *Morand's* departure in 1764, he became secretary of the academy, and as such was extremely active. The younger surgeons demanded that the memoirs should not be confined to résumés, and attacked him sharply because of his opposition, and especially *Valentin* with much bitterness reproached him, asserting that he did not understand the first elements of surgery, knew no Latin, and reproaching him with his experience with a case of harelip in which he had recommended an English plaster instead of the suture; this silenced him. His great vanity would acknowledge

no equal, and his zeal for the academy now cooled to such extent that he discontinued the memoirs, gradually retired, and for the last eighteen years of his life was inactive. The University of Halle had conferred upon him—already a Doctor of Laws and an advocate in parliament—the degree of Doctor of Surgery, and the Academy of Vienna elected him to membership. Aside from his already mentioned work in the memoirs, which was for the most part very prolix, he devoted himself to simplifying instruments, allayed the fears of the public on the subject of being buried alive, and sought to rescue syphilitic cases from the hands of the quacks. Out of the nursery of a poor tailor, *Antoine Petit* raised himself to a professorship. He described two round anterior ligaments which extend from the uterus to the os sacrum, recommended injections through the nose by means of a bent tube for obstruction of the tuba Eustachii, and demonstrated upon a cadaver that the circulation in the thigh is not entirely stopped by ligature of the art. cruralis. The medical school in Paris owed to his generosity two new professorships which he endowed richly; he also founded, with his own funds, a hospital in Fontenai-aux-Roses, and provided for four physicians of the poor in the city of Orléans. *Sue* followed Louis as surgeon in the Charité; he held this position twenty-five years, and was also successor to his teacher Verdier, as professor of anatomy. His works on bandages and elements met with approval. The professor of surgery and inspector of the military hospital, *Hevin*, wrote a detailed work on foreign bodies in the esophagus, through which he saved Verduc's esophagotomy from oblivion; he also wrote on gastrotomy, which he repudiated, and on nephrotomy. *Le Blanc*, in Orléans, published a popular work on operations in which he repeated *Le Dran* and *Louis*. In Lyons, *Pouteau*, with his great partiality for moxas, was most prominent. These remedies had been entirely displaced by the hot iron method, but in 1760 he rescued them from oblivion and reintroduced them; he prepared them, as the Egyptians did, out of cotton, and recommended their use in severe rheumatic pains, dropsy, Pott's hump, tuberculosis, etc. He first made known *Fleurant's* method of opening the bladder through the rectum by means of a curved trocar, and described a method of lithotomy ("Mélanges de chir. and Oeuvres posthumes," published by *Colombier*). Together with a colleague, he offered a prize of 50 louis d'or for the best work on the nature of cancer poison. Another excellent surgeon was *David*, in Rouen, who in the same year as Pott, described the hitherto unknown curies of the spinal column ("Sur les effets du mouvement et du repos dans les maladies chir.," Paris, 1779). He furnished the first accurate description of necrosis (1782), as well as observations on psoas abscess. Lead preparations, and especially subacetate of lead, were introduced by *Gondard*, in Montpellier, into the treatment of various diseases. *Frère Côme* was known in Paris as a skillful, disinterested, though somewhat crude surgeon. He entered the Hôtel Dieu, then the monastery of the Feuillans, but without renouncing his profession. His methods by means of the lithotomic cuchié (1751) involved him in many quarrels. Further, he contrived a bent trocar for opening the bladder over the symphysis pubis, and the caustic from arsenic, which is named from him. The celebrated obstetrician *Larret* surpassed all his predecessors in this science, and did good service as a surgeon in devising a twisted band for the treatment of polyypus in the nose, and in the uterus.

We now come to the close of the eighteenth century. The German and French surgeons had one thing in common in that two of their number far surpassed the rest, and that both lived in the beginning and at the close of the century. Yet there was the greatest difference that the two German surgeons, *Heister* and *Richter* had indeed acknowledged gifts, while the French surgeons, *J. L. Petit* and *Pierre Joseph Desault* were great surgeons in the true sense of the word, for they possessed genius and experience, two qualities which must necessarily be combined. In spite of the great advancement which French surgery had made in the course of the century, at its close there still existed many needs and many mistaken ideas. There prevailed an unclassified mass of local remedies, which the surgeons modified and multiplied at their own will. There was an abundance of professional skill in the treatment of fractures, but on the other hand, the knowledge of their pathologic significance was slight. Almost daily a mass of instruments and operations were invented and modified. In wounds the tampon was greatly abused, in hemorrhages the bandaging was bad and they were compressed in a still worse manner. An extravagant use of trepanning was made. In the operation for harelip they strove too much after simplicity, at the expense of safety. The operations for rectal fistula were overdone, and the treatment of diseases of the urinal ducts was still in its infancy.

Now appeared *Desault* (1744-1795). As a poor village boy, he was instructed by the Jesuits in the ancient languages and mathematics; he made great progress in the latter and in order to maintain himself honorably he gave instruction in geometry. His father destined him for the priesthood, but in vain; he applied himself to surgery, but from his first teacher he was able to learn only shaving and bleeding. At the school in BÉfort, anatomy was his favorite study. After five years he went to Paris, where, at that time *Louis*, *Morand* and *Sabatier* shone as surgeons; *Verdier* and *A. Petit* as anatomists. "To learn was his first requisite; to know, his first sweet pleasure; to surpass the others, his first passion." After a six months' illness, in consequence of great exertions in the anatomic amphitheater, in 1766 (the same year in which *A. G. Richter* began to teach) he offered, for the first time, private lectures in anatomy. At first, he encountered endless obstacles. The professors became resentful when their lectures began to be deserted, and those of *Desault* (who had scarcely left school) to be crowded; envy and fear of being eclipsed by the rising star excited them. *Louis*, who had persuaded him to adopt the profession of teaching, attended his lectures a great deal in order to give them prestige through his own reputation. At that time, instruction in anatomy, in the detail of its descriptions, was still very inaccessible. *Desault* brought to its study a greater accuracy and system, and while he adapted it to the needs of the surgeon, he created surgical anatomy in France. In a few years public opinion regarded him among the greatest anatomists. He was not compared to the celebrated surgeons; jealousy sought, by the exaggeration of his fame as an anatomist, to overshadow his reputation as a surgeon. His career as a surgeon began with lectures on operations, and by his accurate descriptions *Desault* attracted a large number of students. He invented a new bandage for fracture of the clavicle, the regular setting of which had for centuries,

been thought impossible, but the test of it, for lack of practice, had to be left to others, and was successfully made in the Salpêtrière. For amputations he recommended the straight knife instead of the curved, an improvement which was recognized in the Hospital Bicêtre. He introduced again the direct ligature of the arteries, which seems to have been forgotten in France since Paré; it was first employed in amputations at Bicêtre. Louis, curious to see the result, feared the cords would be removed too soon, but after four days they had to be cut in order that the healing should not be retarded. These discoveries laid the foundation of Desault's fame in surgery, which now gained for him a professorship in the *Ecole pratique*, although, because of his poverty he was not a member of the *Collège de Chirurgie*. In spite of much secret opposition they made an exception and elected him to that body (1776). This gave occasion for his "Dissertation on the Extraction of Bladder Stones," a work marked by accuracy and conciseness. In 1779, he, with his friend Chopart, published the "*Traité des maladies chirurgicales et des opérations*," but later he would not acknowledge this work, which contained much that was old, incomplete and confused, so he had as many copies as possible bought and burned. In 1782, he became first surgeon in the *Charité*, and there prepared a cabinet of anatomic specimens. Three years later he removed to the *Hôtel Dieu*, where we have already become acquainted with him as a teacher. During his great activity in the hospital, Desault began to fill the gaps in surgical pathology. Disgusted with the superfluities in the system of surgical remedies, he limited their number. Bold in undertaking and persistent in carrying out his designs, he transformed almost every branch of the science of operations, returning to the utmost possible simplicity in methods of operating. He accurately described luxation of the radius, and devised a bandage for the little-known fracture of the olecranon, by which the bending of the forearm would be prevented. He adapted this to the analogous fracture of the patella. He also contrived a new bandage for the upper thigh. He made the bandaging of Theden in case of varicose ulcers universal, and recommended the use of the tent in case of scirrhus tumors of the rectum. He rescued many methods from oblivion such as the continuous extension in fractures, the ligature in case of umbilical hernia, the gorgeret of Marchetti in case of fistula of the rectum, and so forth. With diseases of the urinal passage he considered the puncturing of the bladder as a superfluous method. He was the first to show the great value of the flexible sound, which could serve at the same time as a conductor of food into the stomach, and to remove foreign bodies in the esophagus. The ligature for throat polyps, was simplified, the kiotome and an instrument for the extraction of foreign bodies from the bladder, by which lithotomy could be avoided, were invented. Desault attached his name to an operation for aneurysm and introduced into France the ligature of the artery above it, and suggested in certain cases a ligature under the sack. An amputation was, to him, only a last resort. He was the first in France to show the unsafe nature of the results of trepanning, the use of which must be limited; he showed also the advantages of tartarus emeticus in cases of concussion of the brain, etc. As an operator he was bold, skilful and simple, and sought to introduce good instruments to general use, discarding what were superfluous.

The many innovations through which he, a model of correctness in observation, gave to surgery a greater simplicity, almost entirely changed the form of the science: on this account the difference between the surgery of the books of his time and that of his lectures is extraordinarily great. Desault's practical mind widely extended the limits of his profession, and there began with him, as the founder of the surgico-clinical method of instruction a new epoch in French surgery, which was based chiefly upon anatomy and physiology.

Hitherto his teachings had become known only through his numerous students, and in being disseminated from mouth to mouth had frequently reached the world in a mutilated condition. In 1791, therefore, he began to publish a *Journal de Chirurgie*, with reports of his clinics (4 Vols.), according to Richter's opinion the most important contribution which had been made to surgery for a long time. In the latter years of his life, in order to fill in the gaps in this work, Desault chose as an assistant his favorite pupil, Bichat, whom he took into his house and to whom he dictated his ideas. (J. L. Petit had worked in a like capacity.) In this way the "Surgical Inheritance," published by Bichat (3 Vols., 1795) was written.

Desault was for a long time a member of the *Académie de Chirurgie*, but turned away from it, as the taste for medical association was lacking in him. Slow in thought and at times difficult of perception, he had no love of those empty hap-hazard disputes, and found no enjoyment in work of which the graceful style was the best part.

When the storm of the Revolution broke out he was almost the only one who continued to give surgical instruction; in spite of his faithful work in the *Conseil de Santé* for the regulation of the medical service he did not escape proscription. Not a day passed without new denunciations, until finally his implacable enemy, Chaumette, the president of the *Commune*, twice had complaint made against him on the ground that he had refused his services to the wounded. The *Committee of the Revolution* issued a warrant for his arrest (1793); he was arrested in the middle of a lecture in the *Hôtel Dieu* and according to the report of his persecutor was incarcerated in the prison of Luxemburg "for the honor of mankind." Numerous appeals from patients and students poured in, so that after three days they were compelled to liberate him. He resumed his lectures. In the following year he was chosen professor in the newly established *Ecole de Santé*, for which, however, he had no sympathy. The political disquiet, the fear of new proscriptions, the death of certain friends in battle and on the scaffold shocked him deeply: from this time on he became feeble. Suddenly he was stricken with a violent nervous fever. His pupils streamed in to take care of him; Chopart and Corvisart treated him. He was delirious from the first and died on the fourth day. The people said he was poisoned, because he died a few days after the death of Louis XVI., whom he had treated in the *Temple*; they said he fell as a sacrifice to his steadfast denial concerning any criminal intentions on the life of that child, and other similar stories.'

' The commissair of the *Temple*, Breuillard, asked him: "C'est un enfant perdu, n'est ce pas?" The answer was: "Je le crains, mais il y a peut-être dans le monde des gens qui l'espèrent."
The *Moniteur* for June 4, 1835, says: "La France l'Europe entière vient de perdre le citoyen Desault, officier de santé et chef de l'Hospice de l'humanité, le premier dans la pratique comme dans l'enseignement de l'art, qu'il a professé. Son nom est depuis longtemps célèbre dans tous les pays du monde où la chirurgie est en honneur, son nom ne périra point. Son pays lui doit d'immenses travaux et de nombreux

According to Bichat's account, Desault was a man of middle stature, strongly built. Sharp features, small eyes, a full forehead and round face gave his physiognomy a certain severe, though not forbidding, expression. His step was vigorous, his carriage noble, his gesticulation animated, his voice strong, his speech at times difficult, as if his lips did not always find the right expression for his feeling. His diction was seldom elegant but always expressive. He knew no other pleasure than to study and to teach. He early won the confidence of the public, but for a long time neglected it, in so much that, according to his own confession, up to the age of 32 he had not earned six livres in his practice. His rare zeal led him to sleep in the hospital, that he might be always at hand, although he was not compelled to do so. In spite of his noble and generous soul, which loathed all the machinations of intrigue, his spirited and passionate character often carried him too far, so that the students did not always enjoy gentleness on his part; yet he was easily calmed again. A thirst for fame possessed him; with this and with his aspirations for surgery he imbued all his students. Desault had many friends, whom he gladly met; yet jealousy also provoked enemies, whose aspersions he met with silence and contempt. There have been few surgeons who wrote so little and yet whose fame extended so widely. He was surrounded by the most favorable circumstances for developing talents and every year the enthusiasm of 400 students proclaimed his discoveries. His teachings spread through the surgical world with great rapidity. Bichat said that Desault had found his own peculiar way of observation and had little learning; his genius alone, with which science had little to do, was the source of his services. His judgment, in this case, as in the case of A. G. Richter, was at fault. Desault was certainly not learned in Latin flourishes and quotations which passed for learning at that time. Bichat himself admitted this when he denominated as superfluous that sort of surgical learning which moved a hundred learned pens to write that which fifty writers before them had borrowed from twenty others, who in turn had copied. Desault knew the writings of his countrymen and also of the English and Germans, wherein he distinguished himself above most Frenchmen. He understood how to make use of foreign material and with this kind of learning contributed materially to science. Medicine appeared to him as a dark labyrinth, in which men wandered at random. He also thought that it was not possible to practice both professions at the same time to advantage, and, fed by partisan spirit, was fixed in his opinion against obstetrics and even against medical assistance in surgery. His enemies are fond of quoting an assertion which has been ascribed to him, that surgery must be reduced almost entirely to the knife and that six months were sufficient to educate a good surgeon. Desault was a genius created for surgery, and left his mark on everything he touched. They were able to say of him that

if surgery had not existed it would have owed its origin to him.

His teacher was *Sabatier*, at first an anatomist, afterward *Morand's* successor in the Invalides and professor of operative surgery in the *Ecole de Santé*. Napoleon appointed him a member of the National Institute and also consulting surgeon. To his quiet but tireless progress surgery owed many improvements. Among many writings the most important, aside from an anatomy, is his "*Médecine Opératoire*" (3 Vols., 1796); clear and exhaustive, written possibly with too little critical spirit, it excelled the earlier handbooks. *Chopart*, sick and old before his time, wrote a long work on diseases of the urinary organs and introduced a partial amputation of the foot. When his truest friend, Desault, became seriously ill he did not leave him for a moment. They said that grief, possibly combined with an injury which he had suffered to his foot, contributed largely to his sickness immediately following; he died a few days after Desault. *Lassus*, in Paris, was very learned; he was a good teacher but made few original observations. The works of *Deschamps* contained nothing new; his eight-volume works on lithotomy was only of historic value. Desault's successor, *Pelletan*, whose activity in hospital work we have already mentioned, in his "*Clinique Chirurg.*" (3 Vols., 1810) described many interesting cases, and among them was the first accurate description of fatty hernias. We will return later to the French military surgeons.

At the end of the eighteenth century, there opened a new epoch in French medicine, as well as in surgery. The herald of it was one of the deepest thinkers and finest observers, which the history of medicine presents—*Navier Bichat* (1771-1802). He died at the age of 31, the creator of a new science, histology, and should be placed at the side of men like Aristotle, Bacon and Descartes, whose works, just as his own, mark an epoch in the history of human thought. His mind, richly equipped with the positive knowledge gained in Desault's school, had no less an object than, by an accurate study of the human organism, to tear down the structure of the old medical science and build up a new one. He perceived that the experiment which Cuvier had introduced to that end, did not suffice, and so he began to examine the tissues. Two years before his death, his "*Traité des membranes en général et des membranes en particulier*" appeared, and in 1801, his celebrated "*Anatomie générale*," in which it was shown that the whole human body consisted of twenty-one different simple tissues. He had examined each of these in its changes through differences in humidity, atmosphere, temperature, in different periods of life and in disease, in order to determine the normal and pathologic development. He realized that these investigations must in time come to be of the highest importance to pathology, and that medical observations were of no avail, if one did not know the seat of the disease. In another, just as celebrated work, "*Recherches physiologiques sur la vie et la mort*," he distinguished the various systems of which the organism is made up: the ganglion from the cerebral system, the organic from animal life. Bichat's doctrines had the greatest influence in the medical science of our century, and were received with the greatest applause throughout Europe. Too early, he became a sacrifice to his science; a restless activity in anatomic and surgical lectures, and in the anatomic amphitheater (in a sin-

En ce moment la République n'a point une armée dont les plus habiles officiers de santé ne soient les élèves de Desault. Telle fut la supériorité de ce grand chirurgien, que la postérité qui commence, nous a trop tôt pour lui, le nommera sans doute un grand homme. Desault fut un excellent citoyen; nos devoirs tyrans l'avaient persécuté. Ses derniers complaisants ont causé sa mort. Le jour du 1. prairial déterminé la crise désespérée qui l'a précipité à 49 ans dans le tombeau. Un de ses amis inscrivit à l'heure même des funérailles ces paroles sur son buste:

Porte du temple de Mémoire,
Ouvrez vous! Il l'a mérité.
Il veut assez pour sa gloire,
Et trop peu pour l'humanité.

gle winter he conducted 600 dissections, which kept him day and night in the atmosphere of cadavers) planted the germs of sickness; yet, when dying, he regretted that he could not complete his work. Corvisart could justly maintain to Napoleon, that no one had accomplished so much that was useful, in so short a time. In him an amiable reservation was united with strong passion; he counted fame as the food of his talent, and the hope of gaining it was the stimulus for all his work. Along with Bichat, Pinel and Corvisart in Paris, made themselves especially prominent in French medicine, in that they first insisted on the importance of objective phenomena and considered the anatomical element before all others. Pinel again brought forward the observation of nature, in his "Nosographie Philosophique" (1798) which was based upon the principles of Hippocrates. According to him, sickness was an abnormal variation of the various organic tissues; one must therefore consider the symptoms as external indications of disease, along with the variations of the organs, examine the seat of the disease, and only draw conclusion after a mass of phenomena had been observed. While supporting the old principles of the earlier school he gave French medicine the form of a physical science, and as an enemy of all manias for medical systems fought with the best results the Brown swindle in France. Corvisart recommended in his medical clinic the new medico-diagnostic method, and especially recommended the observation of the physical symptoms. To this end he rescued from oblivion the percussion method of Auenbrugger, and improved it (1808).

(To be continued.)

SOCIETY PROCEEDINGS.

The Mitchell District Medical Society of Indiana.

Proceedings of the Annual Meeting held at West Baden Springs, Indiana, June 8 and 9, 1897.

REPORTED FOR THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION EXCLUSIVELY.

FIRST DAY—MORNING SESSION.

The Society assembled at 9 A.M., and after hearing the reports of the officers and standing committees, adjourned to 2 P.M.

FIRST DAY—AFTERNOON SESSION.

The Society met promptly at 2 o'clock, with the Vice President, Dr. J. GARLAND SHERRILL in the Chair.

The first paper presented was by ADOLPH O. PFINGST, M.D.,

BLENNORRHEA NEONATORUM.

Until 1806 this disease was supposed to be due to scrofula, exposure of the eyes to the bright light, to cold, etc. Its relation to vaginal and urethral diseases was first pointed out by Schmidt in 1806. The true nature of the infecting material, however, was first made known in 1879, when Neisser demonstrated the gonococcus in the discharge from the eyes. Dr. Pfingst said that infection of the new-born child has usually taken place in transit. The child may, however, escape infection, and have the poison transmitted to it after birth by uncleanness of the attendant. Usually within twenty-four hours after infection there is abundant discharge of pus, along with chemosis of the conjunctiva, and swelling of the lids. The disease reaches its acme in from four to ten days, and the swelling of the lids, and chemosis of the conjunctiva recede by the twelfth day. One eye is usually first affected, the disease appearing on the second or third day after birth; while in from one to four days later, the second eye is affected. The disease in the second eye is seldom as severe as in the first. He believes too much reliance is placed on the nitrate of silver, and regards swelling as an indication for cold applications; in this stage of the disease the silver is apt to do harm. Attempts at making applications of silver lead to the aversion of the lids, a manipulation in the performance of which causes

abrasions of the cornea, thus providing for the ready entrance of the infection into the deeper structures. His method of applying cold is to have small pieces of linen, or small bits of cotton on a cake of ice, near the patient, and transfer these from the ice to the eye, and change every minute for an hour at a time. After two hours the cold applications are to be renewed as before. Every fifteen to thirty minutes the eye should be opened and flooded with some solution, as boric acid, or sterilized water. He believes the dangerous character of the disease should be thoroughly impressed upon the parents and attendants. After all swelling has subsided, he then begins with a 1 per cent. solution of nitrate of silver, increasing gradually to 3 per cent., making the application once every day, and following each application by irrigation with sterilized water. He has used argonin, experimentally, in a child five days old, and found it less irritating than silver, the disease yielding promptly to the treatment. His experience in two other cases has been equally encouraging.

Dr. DUDLEY S. REYNOLDS, being called on to open the discussion, expressed his approval of the sentiments of the essayist in regard to the irritating effects of nitrate of silver. He said he had not used the nitrate in any case for any purpose, for more than fifteen years. He cited the case of a man 27 years of age, in the second week of gonorrhoea, who came to him on Friday evening with the right eye red and watery; the patient complained of a burning sensation in it. He prescribed borate of sodium solution to be instilled into the eye every hour until the irritation subsided, and directed the patient to report the next morning at 9 o'clock. On the second visit the eye was swollen, and there was a discharge of bloody serum mixed with the tears. He at once sealed the left eye with Buller's shield, and sent the patient to the hospital, with the following prescriptions:

R. Sodii boratis	ʒ iij	96 00
Sodii chloridi	ʒ j	32 00
Acidi carbonici (C. P.)	ʒ ss	2 00
Aqua destillata	cong. j	4000 00

Misc. Ft. solutio. Sig.—Use as an irrigation for the eye every twenty minutes.

R. Balsam copaiba	ʒ j	4 00
-----------------------------	-----	------

Misc. Ft. capsulae No. 12. Sig.—Take one every three hours, with a cup of malted milk or beef tea (made of Armour's extract) alternately during the day.

The patient was allowed to drink water *ad lib.* The eyes were directed to be irrigated every hour through the night. This treatment was persistently carried out. The superior periphery of the cornea became clouded. The chemosis of the conjunctiva on the third day was so great that only a small portion of the vertex of the cornea was visible. The lids were simply pulled apart to allow irrigation to be done, no attempt at eversion being made. After the sixth day, the swelling having subsided, and the chemosis still being extensive inferiorly, it was drained out above by a superficial ulceration of the cornea. The treatment was not changed, however. On the eighth day the following was ordered:

R. Hydr. bichloridi	gr. j	065
Sodii chloridi	ʒ j	4 00
Aque destillata	ʒ vj	192 00

Misc. Ft. solutio. Sig.—Drop into the eye every evening, once after irrigating.

On the twelfth day there was no discharge from the eye, and the bichlorid solution was discontinued, the irrigation being repeated three times a day. The capsules of copaiba were continued all this time. There was now no urethral discharge. On the fifteenth day fluid nourishment was discontinued, and the patient was allowed to go to the table with convalescents. On the seventeenth day he was allowed to leave the hospital, having entirely recovered. The superficial ulceration of the cornea was limited to the periphery. There is to be expected from this plan of treatment almost uniform results, where it can be carried out rigidly. He does not believe anybody but a trained nurse can successfully conduct this treatment.

In closing the discussion, Dr. Pfingst said, he was pleased to hear Dr. Reynolds proclaim his opposition to nitrate of silver, and especially so, as he had suggested a successful substitute. He had formerly seen no case treated without it. He mentioned that Dr. Knapp of New York, had abandoned the nitrate of silver in such cases, and now relies upon ice and irrigation, in both infants and adults. Whether the ice or the irrigation is most important it would be difficult to say. Indications for the cold applications, however, are swelling of the lids. By request Dr. Reynolds gave his views on Credé's method of protecting the eyes of the new-born. He believes it impossible for the eyes to become infected during the period of birth, as the closed lids, protected as they are, at the line of

contact, by the lash, over which the veruix caseosa is spread evenly, the pressure of the maternal parts can only secure more complete closure of the lids. The period of incubation of the gonococcus is not greater than twelve hours from the period of inoculation. It will, therefore, appear at once, that it is impossible for inoculation to take place during birth, and show no sign of its presence for twenty-four or forty-eight hours after the birth of the infant; and, it may be truthfully stated that a majority of the cases do not appear until after the third day. He believes the attempt to instill anything into the eyes of the new born should be regarded as meddling interference, fraught with mischief only. This opinion is based upon a large experience at the Louisville City Hospital. He has known periods of time when Credé's method of protection was employed, and every eye so treated became subsequently infected with purulent matter. For months at a time, when no interference was permitted, no case of ophthalmia appeared. I am as certain, said he, than ophthalmia neonatorum is nearly always the result of inoculation by the nurse, or others handling the infant after its birth, as I am that three and two make five. He does not believe it possible for the eyes to become infected during the period of birth, excepting in badly managed cases of instrumental delivery. He feels assured that if neither the accoucheur nor the maternal nurse are allowed to touch the eyes of the child, they will almost certainly escape infection. Those eyes alone are in danger which are handled by the same fingers that handle the mother, or are engaged in handling infected persons.

Dr. EDMUND D. LAUGHLIN introduced the subject of "Minor Surgical Procedures," which in his judgment include the first handling of emergency cases. Many a case of comparatively insignificant injury assumes a more or less alarming gravity and importance by the careless manner of the first handling of the case before it goes to the hospital. He believes that the same antiseptic precautions should characterize the first touch in every case of mechanical injury that surgeons undertaking capital surgery observe. If persons likely to be called on to take charge of the injured or wounded at the time of accident, are to be selected from the laity, they should be properly trained in aseptic methods, in order that no dangerous infection result from the first handling of the patient. If surgeons allow themselves to manipulate injured parts with unclean hands, it can scarcely be expected that persons unfamiliar with the principles of aseptic and antiseptic methods may be safely entrusted to touch the wounded, even in conveying them to the hospital.

Dr. J. GARLAND SHERRILL of Louisville read a paper on

PERITONITIS.

He devoted the principal part of his paper to the discussion of the proper management of infected cases. He believes the amount and character of the infecting dose will determine both the degree of severity of the attack and the rapidity of its development. Tuberculous peritonitis is now regarded as clearly a surgical affection. The tuberculous peritonitis characterized by miliary nodules in the walls of the peritoneum, not complicated by tuberculous processes elsewhere, almost uniformly yields to the devices of surgery and no sort of medication will serve even to mitigate or delay the progress of such cases. In plastic peritonitis, saline purgatives are restorative and sometimes curative; in septic cases operation may save life, medicinal treatment never does. The indications for operation in peritonitis may be stated briefly as follows: When the focus of inflammation can not be reached through the natural outlets, when the patient exhibits anxiety and mental depression. If the pulse is above 140, of diminishing quality, although operative interference may be clearly indicated, the prognosis is grave and no delay should be permitted. He admonishes the profession against the use of opium in all cases, as it diminishes vital energy, obscures the intellect, arrests excretion and masks all the important symptoms by which the surgeon might otherwise be guided in his choice of methods.

Dr. ULRICH H. HON of Bloomington related a case in which he used opium, saline aperients, fomentations, stupes, etc., with a promptly fatal result, the patient and friends declining operative interference. He believed, however, it would be impossible to altogether dispense with opium.

Dr. PHILIP C. HOLLAND related a fatal case in which hepatic abscess ruptured in the inguinal region, discharging one gallon or more of fetid pus. In another case where the inciting cause was appendicitis, operation was followed by returning abscesses and the patient finally succumbed.

Dr. THOMAS A. HAYS thought the general practitioner must have some ready and promptly efficient agent for the relief of pain. He reported an interesting case of appendicitis in which he had consultation, and operative interference was decided

necessary; later the patient relapsed and presently a conical tumor appeared in the iliac region. The tumor ruptured spontaneously and the patient discharged large quantities of pus through the bowels. The patient finally recovered. Another case of recurrent appendicitis finally recovered without surgery. He asked whether Dr. Sherrill would advise operative interference in recurrent cases. Dr. Sherrill said in reply that the tendency to recur in appendicitis is one of the characteristics of the disease, and the time to operate is not always easy to determine. He knew of no rule that might be laid down for any considerable number of cases. When rupture takes place into the bowel no operation should be attempted, as recovery will almost necessarily follow. As a general rule, however, he would consider that the danger is far less than the danger of septic peritonitis from rupture. Although opium might be necessary in cases of hepatic calculus, because we have no better means of combating pain, he simply abhorred its use in all forms of peritonitis, and would include in this list all cases of appendicitis.

Dr. E. D. LAUGHLIN, whose experience has been large and who was one of the earliest operators in the field, adopting the report of Dr. Buck of New York in 1872, which, after full discussion in the journals, turned out to have an apparently scientific foundation, reported his own first experience in 1875. He well remembered the first case in which he used the knife, evacuating nearly a half gallon of pus from the peritoneal cavity. At that period he made no attempt at excising the appendix, but contented himself with evacuation of the abscess, irrigation of the cavity and drainage. He occasionally sees cases in which aconite and opium with hot or cold applications promptly secures relief. His rule in reference to the selection of cases for operation is this. He practices aspiration daily and as soon as pus appears in the aspirated fluid he operates; otherwise he relies upon medicinal treatment. His patients rarely die. His success is such that he feels entirely satisfied with his method. He regards irrigation and drainage as all sufficient. He asked Dr. Sherrill what he considers the best method of drainage, what kind of tube he prefers, and how he manages to keep it clean.

Dr. SHERRILL said, in reply, that the best drainage is by means of a glass tube, frequently sucking up the accumulation with a sterilized syringe, thus keeping the tube clear. In cases where there is much oozing of blood, he prefers to secure drainage by packing the wound with gauze, using only the pure sterilized material. In appendicitic cases, where the inflamed area is not in contact with the anterior abdominal wall, he always packs the wound with gauze before operating. He believes that whenever the disease produces a feeble and frequent pulse, with an anxious and careworn expression of countenance, the conditions demanding surgical interference are present. In all such cases he considers it little less than trifling with human life to delay.

Dr. ULRICH H. HON offered his protest against the sweeping denunciations of opium which had been made in this and other societies. He considers that an agent so long relied upon by the profession and people to relieve pain should not be lightly spoken of. While he uses it sparingly he considers it an absolute necessity, and the chief if not the sole reliance in neuralgia, and the pain of peritonitis, appendicitis and a large class of other affections.

Dr. SHERRILL thought that Dr. Price was rather too radically dogmatic in his denunciations of opiates, and while he himself will not consent to entirely give up its use, he is convinced that the indications for its use are very narrow and diminishing annually. He could scarcely think of any condition, excepting the pain of bilious colic, in which its use could not be dispensed with.

Dr. DUDLEY S. REYNOLDS said: The hour of necessity for revising and recasting the long established theories of pathology is now upon us. We can have no excuse for prescribing remedial agencies that overwhelm the sensorium, destroying the patient's consciousness of his suffering, when a reasonable familiarity with the principles of pathology might disclose the cause of the pain. If pain is due to local inflammation or simply to blood pressure, opium is positively contraindicated. The salicylates, pilocarpin, saline aperients and electricity may be relied upon in many of these cases: opium never. The so-called neuralgia of anemic persons may be relieved by systematic feeding. The pain of gastro-intestinal irritation, whether due to pressure of distending gases or the local irritation of abnormal ferments, will not only fail to yield to opium, but the patient's life may be endangered by its use, in obounding the sensibilities of the patient: while dangerous inflammatory processes may be kindled in the intestinal tract. In rheumatic or gouty pains the salicylates act promptly and efficiently; opiates add nervous prostration and still further obstruct all

the emunctories, thus aggravating all the conditions of the disease and limiting the chances of reëstablishing active elimination, upon which alone recovery depends. The pain of iritis is nearly always severe, frequently agonizing at night, but it yields promptly to the salicylates and is always aggravated by opiates. The same may be said of the early stages of inflammatory glaucoma. It is better to do nothing where no probable cause of pain can be discovered than to poison the vital centers with opium. Recent pathologic research, with a due consideration of our methods of diagnosis, will nearly always unfold rational principles of therapeutics. Ignorance overwhelms the patient's sensorium and flatters itself that the relief of pain at any cost is a consummation devoutly to be wished. That opium in some form will, for a long time, continue to hold an empiric place in the *materia medica* I do not doubt. That it has now or ever has had any scientific place I most emphatically deny. It is not a good substitute for atropin in bilious colic; it can not take the place of chloroform as a general anesthetic; its use in diarrhea is not only empiric, but positively pernicious, as it suspends peristalsis, which is nature's mode of expelling dangerous ferments.

On motion of Dr. Burton, a paper entitled "Empyema in Children," by Prof. Philip F. Barbour of Louisville was read by title and referred for publication.

On motion of Dr. Burton, the following Committee on Neurology was appointed: C. F. Askren, U. H. Hon, G. W. Burton and E. D. Laughlin.

On motion the Society adjourned to 8 P. M.

EVENING SESSION.

Promptly at 8 o'clock the Society was called to order by Vice President Sherrill.

Dr. WM. D. PENNINGTON of West Baden delivered an exceedingly well-written and appropriate Address of Welcome, in which he set forth why a medical society should meet at a health resort, and expressed officially a cordial welcome on behalf of the proprietors of the Springs and the profession of that locality.

At the conclusion of Dr. Pennington's address Dr. Dudley S. Reynolds of Louisville was called on to respond in behalf of the Society.

On motion of Dr. WM. V. MORGAN of Indianapolis, the President appointed the following Committee on Nominations: Prof. P. Richard Taylor, Louisville, chairman; Dr. G. W. Burton, Mitchell; Dr. Edmund D. Laughlin, Orleans.

On motion, the Society adjourned.

SECOND DAY—MORNING SESSION.

The Society met promptly at 9 o'clock, Vice-President J. Garland Sherrill in the chair.

Dr. ELIHU P. EASLEY of New Albany read a paper on

ALBUMINURIA, ITS CAUSES AND SIGNIFICANCE.

He pointed out those delicate changes in the blood supply of the renal organs, varying from slight congestion to inflammation, in which the albumin is eliminated in varying quantities, with or without tube casts; maintaining that elimination of albumin is simply one of the phenomena of blood pressure in the kidneys. Besides a wide variety of local irritants, this condition is often due to derangement of the heart's action. It attends certain organic diseases of the heart, and is a well-known condition in cases of prolonged pyrexia. A variety of toxic conditions of the blood which alter or disturb the blood supply to the kidneys, as well as those which affect their nutrition, are recognized as causes of albuminuria. Finally, it may result from any cause of faulty elimination of the debris resulting from physiologic changes.

Dr. B. MERRILL RICKETTS of Cincinnati, opened the discussion. He had no doubt that various forms of toxemia caused albuminuria. He recited a case of auto-infection in an aged man with prostatic enlargement, in which albuminuria was a symptom. In acute congestion of the kidneys lumbar nephrotomy has been found an efficient remedy for the constitutional symptoms. At the same time it has been known to promptly correct the albuminuria. It has been employed in both acute and chronic nephritis. In cases attended with general dropsy, drainage relieves the overtaxed renal organs. In a desperate case, Dr. Ricketts opened the abdomen, evacuating an enormous quantity of fluid and irrigating the peritoneal cavity with a normal solution of chlorid of sodium. He kept up the drainage by means of a tube, which he retained in the abdominal wall. The patient lived in comparative comfort for ten weeks. Muscular debility was greatly relieved by massage, while the symptoms of impending suffocation were completely controlled by peritoneal drainage. The amount of albumin in the urine was not altered in this case, but it is certain that the patient's life was greatly prolonged, and the state of his existence rendered vastly more tolerable.

Dr. JOHN L. MASTERS of Indianapolis, has observed in cases of albuminuria, attended with retinitis, that in proportion as changes in the retina would diminish by dietic and constitutional treatment, the albumin diminished *pari passu*; and he has no doubt of the fact that blood pressure, if not the cause, is a constant companion of that form of retinitis so often found in persons with albuminuria.

Dr. SHERRILL recited the case of a woman with pelvic disease, suffering with albuminuria, and a grave form of heart lesion. The necessity for surgical interference was so great that chloroform was administered, and an operation done, relieving the patient of a painful, and almost intolerable state, without influencing either the condition of the heart, or materially altering the amount of albumin in the urine. As a rule he fears to operate in such cases. In emergencies, however, he considers the use of chloroform comparatively safe.

Dr. RICKETTS, in answer to a question, said there was no contra-indications to necessary surgery in the mere presence of albumin, even with tube casts.

Dr. E. D. LAUGHLIN reported the case of a man 27 years of age with albuminuria, hyaline tube casts, and occasional attacks of hematuria. In this case the salicylate of sodium and bicarbonate of potassium in an infusion of gentian, regularly administered, gave prompt relief to the distressing headache, and finally brought about complete recovery. This was a desperate case, and extremely unpromising, but two years have now elapsed since the treatment was discontinued, and the man remains robust, strong and hearty, thus verifying Dr. Reynolds' views concerning the value of the salicylates in nephritis, as well as other local inflammations.

Dr. EASLEY, in closing the discussion, related a case of a pregnant woman who was promptly relieved of albuminuria by an infusion of stigmata maydis. As pregnancy advances, the disease may return, and it may be that other measures will have to be resorted to.

Dr. B. MERRILL RICKETTS of Cincinnati, read a paper entitled

PROLAPSE OF THE RECTUM, AND HEMORRHOIDS.

He denounces Whitehead's operation, and likewise what is known as the American operation. He considers postural treatment an important adjunct. He also believes that postural habits may greatly obviate the liability to prolapse of the rectum. In chronic cases of prolapse, of the third and fourth degree, he believes that section, and anastomosis offers the best means of relief. This, however, is by no means the only method to be employed. In extreme cases of the fourth degree he has for a long time practiced the process of reefing the intestine by a submucous ligature introduced by passing a small semi circular needle into the mucosa, keeping the point as nearly within the muscular wall of the tube as possible; the needle being armed with kangaroo tendon is brought out at the point of entrance, having described a complete circle. This tendon is then tied up tightly, and in the same horizontal plane a second, and then a third suture completes the necessary folding up or reefing of the tube. This folding together of the intestine is preferable to any attempt at invagination, as the subsequent inflammatory adhesions incorporate the confined tissues of the mucosa into a conglomerate mass with the surface of the muscularis. A second operation in the same case may be necessary to complete the reduction of the prolapse. This is rarely necessary, however, even in cases of the fourth degree. After a series of elaborate experiments in the preparation of suitable material for a suture, he has been led to prefer the kangaroo tendon because it may be relied upon to remain *in situ*, without softening, for at least thirty days, giving ample time to secure a fixed position of the parts in their new relation. In preparing this tendon for use he warns the profession against formalin, because it is not only highly irritating to the tissues, but makes the tendon friable, and insecure from its liability to break. Dr. Ricketts exhibited his needle, and presented each member of the society with one. It is curved about 195 degrees, and represents a section of a circle about two and one half inches in diameter. It is simply a strong steel needle.

Dr. WM. V. MORGAN of Indianapolis, has occasionally been rewarded with satisfactory results after linear cauterization. He has been occasionally successful, in cases of the first and second degree, by the introduction of kangaroo tendon just within the mucous line of the anal orifice, completely encircling the rectum at the inferior border of the sphincter. Placing one finger in the anus the kangaroo tendon is tied tightly and the knot pushed in so as to bury it from sight. This amount of contraction by a sort of puckering string, sets up irritation, restores activity to the contiguous muscular fibers, and secures the patient from a tendency to prolapse. He thinks that Dr. Rickett's operation is perhaps better in cases of the third and

fourth degree. He has occasionally practiced the method of dilating the sphincter by passing one finger at a time until the whole five were introduced, pushing the hand up in the rectum as far as the sigmoid. Where dilatation has been practiced in this manner, good results have frequently followed.

Dr. RICKETTS, in conclusion, spoke of excision of the rectum as high as the sigmoid, in severe cases. He expressed his unalterable opposition to clamp and cautery, which he has reason to believe is too often followed by secondary hemorrhage. He thinks there are some operators who advocate this plan, who could throw a good deal of light on the subject if they felt so inclined.

The next paper was

LACERATED WOUNDS OF THE EYE

By Dr. DUDLEY S. REYNOLDS of Louisville. He recited a number of cases of severe injuries to the eye in which ultimate recovery followed. One was an extensive laceration of the cornea, iris and crystalline lens, with a foreign body which had been in the eye for five days. The foreign body being removed, iridectomy was done and the lens underwent slow absorption, resulting in complete recovery, with good vision. Another case of a stone cutter, who had extensive laceration of the cornea, the iris and lens being involved, iridectomy was done and the lens extracted at once. In this case recovery followed. This patient returned to his business for several years and finally took charge of a small store, kept a set of books, and enjoyed good vision until the time of his death, which occurred recently. Another was a case of extensive laceration of the sclera, evacuating a large amount of vitreous humor and rupturing the capsular ligament of the lens, allowing the iris to protrude through the scleral wound. Iridectomy, with suturing of the scleral wound, was followed by recovery. The eye becoming cataractous, the lens was extracted eleven years subsequent to the original injury; and on April 13, 1897, the opaque capsule in this eye was divided with needles and the patient with +16.00 D. was able to read No. 1 Snellen. Although the field of vision is greatly contracted, acuity of perception is perfect. He recited another case of interest in which a guncap had produced an extensive laceration of the sclera, exposing the ciliary muscle. The wound united promptly, leaving the eye apparently free from any irritation. Remaining so for a few months only, it became irritable, and subsequently developed a typical form of inflammatory glaucoma, with ultimate loss of sight, and sympathetic irritation in the fellow eye, necessitating enucleation of the injured eye, and iridectomy in the fellow eye. Sight is so impaired that the man can not see to read, although he is able to pursue the business of a farmer.

Dr. JOHN L. MASTERS of Indianapolis, opened the discussion by calling attention to the great gravity of slight injuries where infection of the wound takes place. He pointed out the almost inevitable certainty of loss of sight in those eyes which are pierced by foreign bodies which can not be located and removed. He recited the case of a penetrating wound followed by absorption of the lens, in which good vision was ultimately obtained. Another case was cited, of a man shot in the face, destroying one eye, the other one being slightly injured. The destroyed eye was enucleated; there were no evidences of a foreign body in the other eye. In time it became irritable and cloudy; general treatment afforded temporary relief. Ophthalmoscopic examination showed a gray mass in the anterior portion of the choroid. Recurring attacks of dimness of sight, accompanied by irritation in the eye has been finally followed by cataract, and now there is bare perception of light. He thinks the cases recited by Dr. Reynolds are of great interest to every member of the profession, but they should be looked upon as extraordinary cases. They illustrate what may be accomplished when the foreign body can be removed from the eye.

Prof. P. RICHARD TAYLOR of Louisville, wished to emphasize the importance of the case recited by Dr. Reynolds, of the man whose eye was injured by the guncap as affording additional evidence of the unfavorable character of injuries of the ciliary muscle or ciliary body. Cicatricial formations in the ciliary muscle or body imprison the nerves and keep up a perpetual state of irritation and finally provoke the so called sympathetic inflammation, followed by blindness.

Dr. Masters might have added to his list of dangerous wounds from penetrating bodies, a large class where the infecting material enters with the foreign body: the infection being thus carried directly into the eye, inflammation is excited at once. It is therefore not sufficient that the foreign body be located and removed, but we should be well assured that no infection has accompanied the injury, otherwise we should at once enucleate the eye, and save the patient a prolonged period

of suffering and the dangers of constitutional infection, which have occasionally been overlooked with fatal result to the patient.

Dr. ULRICH H. HON of Bloomington presented a specimen of uterine mole, or hydatiform degeneration in the chorion. The patient was suffering with hemorrhage, and had voided a large mass of this material. On examination a considerable amount of retained cystic matter was removed, and the hemorrhage ceased. There was more than enough to have filled a quart vessel. The condition, though rare, is sufficiently well known. The mass resembles a collection of hydatids, being made up of a minute series of spheroidal cysts, which are the degenerate remains of the villi of the chorion.

Dr. WM. V. MORGAN pointed out the fact that these remains are, in medico-legal cases, always accepted as the products of pregnancy.

Dr. WM. J. PURKHISER of Salem read a paper on

MEDICAL EXPERT WITNESSES AND EXPERT TESTIMONY.

He pointed out the lamentable fact that courts of justice sometimes accord the distinction of expert to a thoroughly incompetent medical witness, thus continuing to bring the profession into ridicule. He thinks a better knowledge of medical jurisprudence is necessary to the maintenance of the dignity of the profession in medico-legal inquiries.

Dr. DUDLEY S. REYNOLDS opened the discussion by pointing out the character of the preparation which the law requires of a medical expert witness. He maintains that medical jurisprudence is one of the most important subjects taught in the medical colleges, and that it is not sufficiently appreciated by many institutions. If the medical expert witness duly informs himself in relation to the subject about which he is going to testify, carefully avoiding any manifestation of bias in opinion, he may escape the suspicion of having a personal interest in the success of the party-litigant in whose interest he was summoned. It is not expected that every man knows everything, and the medical expert witness should not hesitate to express his ignorance about matters concerning which he is uninformed; but the court will not hold him guiltless if that ignorance includes any matter of general information in the profession.

Dr. B. MERRILL RICKETTS spoke of the treatment of the medical expert witness by expert lawyers, who never lose an opportunity to bring the medical profession into ridicule when this testimony is damaging to one side or the other. He has a habit of defending himself on the witness stand, and recently had occasion to say to the judge and counsel that they knew nothing of such matters as the shortening of a leg after fracture. He defended himself by showing the ridiculous character of the questions of the counsel, and demanded the right to make himself understood to the jury and court, in the definition of a difference in the results of injuries in the thigh bone of children and adults.

Prof. P. RICHARD TAYLOR, chairman of the nominating committee, reported as follows: For president, J. Garland Sherrill of Louisville; vice-president, Wm. D. Pennington of West Baden; secretary and treasurer, George W. Burton of Mitchell; corresponding secretary, Ulrich H. Hon of Bloomington.

Executive Committee: Dudley S. Reynolds, Louisville; B. Merrill Ricketts, Cincinnati; Elihu P. Easley, New Albany; Edmund D. Laughlin, Orleans; William V. Morgan, Indianapolis.

The special committee on necrology reported through its chairman, Dr. Askren, a series of resolutions on the deaths of ex-presidents Riorden of Bedford and Charlton of Seymour.

The committee on sanitation and State medicine, of which Dr. U. H. Hon was chairman, reported a series of resolutions which were adopted. The committee was continued, with instructions to secure suitable papers, from the best informed persons, for the purpose of elucidating the recent sanitary laws of Indiana, to be made the subject of special consideration at the next meeting.

The chairman of the executive committee was instructed to arrange suitable railway concessions for the next meeting of the Society.

On motion, the Society adjourned to meet at West Baden Springs, Dec. 28 and 29, 1897.

PRAGTICAL NOTES.

A Remedy for a Form of Tinnitus Aurium.—Dr. F. Steiner (*Arch. f. klin. Med.*, lviii, 2, 3) in discoursing upon his conclusion that polyneuritis is a frequent complication of acute rheumatism, the basis being probably an epineuritis, recom-

mends the fluid extract of ergot as a remedy for the tinnitus aurium caused by the long continued use of sodii salicylate and potassii iodid.

The Treatment of Exophthalmic Goiter by Section of the Cervical Sympathetic.—Reclus and Faure (*Gaz. Hebdomadaire de Méd. et de Chir.*, June 24, 1897, p. 592) have reported a case of exophthalmic goiter occurring in a woman in her third pregnancy and following emotional disturbance. Medical treatment had been without benefit and electricity brought only passing amelioration. The exophthalmos was so pronounced that the eyelids could not be closed and the corneæ had suffered from the want of protection. The thyroid gland was greatly enlarged: the pulse ranged between 120 and 130; and the constitutional disturbance was profound. The cervical sympathetic was readily resected on either side through an incision along the posterior border of the sterno-mastoid muscle and improvement speedily ensued. By the seventh day the exophthalmos had almost entirely disappeared and the ulceration of the cornea had cicatrized. The swelling of the neck had diminished: the pulse was reduced to 90; the trembling was less marked; and the general condition was greatly improved.

Surgical Treatment of Tumors and Enlargements of the Thyroid Gland.—Paul (*British Medical Journal*, July 3, 1897, p. 1) reports twelve cases of adenoma of the thyroid gland, five of parenchymatous goiter and six of exophthalmic goiter treated surgically, and details the histologic appearances found in the structures removed. In the first twelve cases tumors weighing up to three-quarters of a pound, and in the remainder portions of the gland, some of a very considerable size, were removed, without a fatality. Healing was rapid in all, only a few patients being under surgical treatment more than a fortnight. In six of the cases of adenoma there was complaint of constitutional symptoms, and in all of these young active gland-tissue was present: in the remaining six, symptoms of mechanical obstruction only were present. In the latter the tumor was very small, colloid, fibrous or almost entirely cystic, with little or no active secreting epithelium. The patients suffering from mechanical obstruction alone were entirely relieved by the operation, while those in which constitutional manifestations also were present were additionally relieved or very much improved in regard to these. Of the five cases of parenchymatous goiter sufficient time had elapsed after the operation in only two to permit of the expression of an opinion. The removal of one lobe was followed by atrophy of the other lobe, with the establishment of perfect health and freedom from symptoms of myxedema. The immediate effect of the operation in the cases of exophthalmic goiter consisted in a marked amelioration of all the symptoms. In some cases the first improvement was so decided as to appear remarkable and to leave no doubt as to its relation to removal of thyroid tissue. This early improvement may be followed by slow progress, so that several years must elapse before a final judgment could be given.

Successful Treatment of Internal Aneurysms with Injections of Solution of Gelatin.—Lancereaux has tried injecting 50 c.c. of a sterilized 1 per cent. solution of gelatin in a 1 per cent. salt solution at 37 degrees C., as Dastre announced in 1895 that a solution of gelatin injected into the veins of a dog renders the blood much more coagulable. Lancereaux reported at the Académie de Médecine (*Bulletin*, June 22), the one case in which he has tried this treatment. The patient was a man of 46 who had been affected with an aneurysm of the first part of the arch of the aorta for two years. It had become as large as the head of a child, 14x15 centimeters, and was rapidly increasing with distinct expansive pulsation: the accompanying oppression and pain, dyspnea, etc., were most distressing and the thinness of the wall showed that the aneurysm was on the point of bursting, when the injections of gelatin were made as a last resort. Twelve injections as above (January to May)

relieved the patient of all his pain and reduced the size of the tumor 2 centimeters. It has grown firmer and the pulsation is no longer radiating but with the aortic current. He left the hospital to attend to his usual occupations, saved from certain death by this harmless and evidently efficient treatment, the only one known for internal deep aneurysms beyond the reach of surgical intervention. A slight redness at the spot of the injections in the gluteal region and a slight transient increase of temperature after the first injection were the only inconveniences.

Instrumental Evacuation of the Uterus.—Doléris has a comprehensive article in the *Journal de Méd. de Paris* of June 20, on the treatment of incomplete abortion. He states that instrumental evacuation of the uterus is neither a difficult nor dangerous operation, if it is performed with extreme gentleness and care, *without chloroform*, the bladder emptied first, using the fenestrated forceps, the swab and the curette as indicated, an attentive assistant pressing down the fundus, with repetition of the dilatation in the course of the operation and frequent intra-uterine and abdominal palpation, and the traction of the cervix with three-pronged forceps. He concludes by swabbing out the uterus with creosoted glycerin and a copious irrigation at 40 degrees with a dilating sound, finally packing it with iodoform gauze very slightly impregnated with creosoted glycerin at 5 per cent. (The gauze loses its absorbent powers if much impregnated, besides irritating the vaginal mucosa.) He renews the dressing every two or three days, with an intra-uterine irrigation each time. In 44 hospital cases of curetting the gravid uterus (33 post-abortionum and 21 post-partum), he has had neither accidents nor death.

Cholecystitis Complicating Typhoid Fever.—Mason (*Boston Medical and Surgical Journal*, May 13, 1897, p. 449) has reported the case of a woman, 30 years old, who came under observation in the third week of an attack of typhoid fever, with dry brown tongue, palpable spleen, rose spots and distended abdomen. Anorexia, vomiting and constipation had been prominent symptoms. Widal's serum test yielded positive results. There was no leukocytosis. Toward the end of the third week the patient complained of increasing abdominal pain that became localized in the right hypochondrium, where a tumor four inches in diameter developed, extending from the costal border toward the umbilicus. The swelling was very tender, absolutely dull on percussion and descended on full inspiration. The patient presented appearances of collapse and it was feared that rupture of the gall bladder distended with pus would take place. Cholecystotomy being concluded to be too grave an operation to undertake under the circumstances, the gall bladder was tapped at a point an inch below the costal margin and four and a half inches from the umbilicus. Three and a half ounces of sero-purulent fluid were withdrawn, pale in color, looking more like urine than bile. The aspirating needle moved up and down with the action of the diaphragm. No gallstones could be felt with the point of the needle. After its withdrawal a pad and a swathe were applied to prevent the escape of septic fluid into the peritoneal cavity. The relief to pain was immediate. On the next day all of the urgent symptoms had disappeared and they did not return. The pulse fell from 140 to 120 and defervescence followed in five days. The gall bladder gradually retracted; convalescence ensued, and when the patient returned for observation after a month nothing abnormal was found in this region. Examination of the fluid removed disclosed the presence of microorganisms that yielded the various reactions of typhoid bacilli.

The Radical Cure of Hernia by Implantation of Sterilized Sponge.—As the result of experimental observations upon rabbits in the Physiological Laboratory of the Johns Hopkins University, Platt (*Johns Hopkins Bulletin*, March, 1897, p. 41) was led to attempt implantation of sections of sponge in the inguinal

canal for the purpose of forming a firm connective tissue barrier to the descent of the bowel and adnexa in the radical cure of hernia. In the actual application of the method an incision about two and a half inches long is made directly over the inguinal canal, following its course, the lower end extending about half an inch upon the scrotum. If the hernia is down the operation is so much the easier. The canal if laid freely open. The sac, whether congenital or acquired, is opened in its entire length, the hernial contents reduced and the sac cut away close to the ring if congenital, while if acquired it is cut square off after being ligated as high up as possible and dropped beneath the ring. In the case of the congenital sac it is often necessary to leave the thin inferior layer *in situ* and adherent to the cord. Next a section of fine firm surgical sponge is cut about an inch and a half in diameter and an eighth of an inch in thickness. This is sterilized without boiling by immersing in a solution of soda, washed in sterilized water, treated with potassium permanganate and oxalic acid and then thoroughly washed in sterile normal saline solution. A radical cut is made in the section. The constituents of the cord are gathered together as high up as possible and placed in the center of the section and at a right angle to it. The edges of the cut in the sponge are now overlapped slightly and two sutures are inserted into the sponge to keep it in place on the cord, which now pierces its center. The section of sponge is spread out beneath the internal ring and the conjoined tendon is sewed firmly by two or more quilted sutures to Poupart's ligament, using a needle in a handle. The inguinal canal is now snugly sewed up with silk sutures and over all the skin is sewed with silkworm gut. It is absolutely necessary to use some kind of drainage at the upper angle of the wound, as there is invariably some serous oozing and swelling. This may be removed in twenty-four hours. The patient is confined to bed upon his back for three weeks. If a boy, it is well to use the Bradford frame, to keep him from sitting up and twisting about in bed. The skin sutures are removed on the ninth or tenth day, the wound being treated on ordinary antiseptic principles. After three weeks the patient is permitted to sit up in bed for a day or two; then he sits up for two or three days in a chair, and afterward he goes about as usual. It is unnecessary to use any support over the site of operation beyond a light strip of gauze to protect the fresh cicatrix from friction.

The Bacteriology of the Follicular Enteritis of Children.—The *British Medical Journal* quotes an article by Dr. Finkelstein of Heubner's clinic, from the *Deutsche medicinische Wochenschrift*, regarding two forms of the gastro-intestinal enteritis of infants that appear to be due to an infection. The source of the contagion lies in the stools. Two groups of the disease are to be distinguished, the dysenteric and the toxic. The actual cause of the disease must therefore be able to give rise to irritation of the mucous membrane, and to produce toxic products. The bacteriologic examination of the purulent masses in the author's case showed the presence of abundant rod-like microorganisms contained in the pus cells, and varying much in appearance. Often they were arranged in twos. All the different forms were shown to belong to a single microorganism. By cultivation a microbe possessing extraordinary resemblance to the bacillus coli communis in almost pure culture was obtained. The author then details his inoculation experiments. In mice it produced, when introduced with the food, a disease very like Löffler's mouse typhoid. The morbid appearances corresponded exactly to those described by Heubner as taking place in the epithelium in cholera infantum, but ulcerative processes were absent. The microorganism is only present in the glands, and hence the death of the epithelium must be due to a toxic action. The bacillus is also able to produce remote toxic effects. Growth on potatoes showed differences from

that of the bacillus coli, otherwise the differences were rather those of degree than kind. Experiments on animals yielded more important results. Virulent cultures of the bacillus coli were shown not to be able to act pathologically on healthy mucous membrane. A close relationship existed between the bacillus in question with the bacteria known to produce the manifestations in meat poisoning. Thus it does not appear correct to class this microorganism as the bacillus coli. The virulence of the microorganism varies greatly, and can be diminished by culture. As regards its pathogenic properties, it was found constantly present in over fifty cases of typical enteritis and colitis dysenterica. All cholera-like forms must not be grouped as follicular enteritis. If the microbe has lived and flourished in the milk consumed, the symptoms of intoxication may begin forthwith. It may be said that follicular enteritis passes through the stages of dyspepsia, intestinal catarrh, up to a cholera-like disease. When the intestinal epithelium is destroyed, the bacillus may get into the blood stream and produce a septicemia as well as hemorrhagic purulent metastases. Mixed infections are common. There are two forms of the general infection: one resembling typhoid, and the other giving rise to high fever, collapse and rapid death.

Partial Rupture of the Splenic Cord Without Fracture of the Spleen.—Watts (*British Medical Journal*, March 13, 1897, p. 654) has reported the case of a man 65 years old, who while partly under the influence of alcohol fell from a cart that he was driving. He was able to arise and walk to his home, a distance of a mile, where he put his horse away and sat down in a chair by the fire. His neck felt a little stiff, but it was free from pain. Three hours from the time of the accident the man noticed that he had no power in his right hand, then that his left hand was paralyzed and then that he could not move his legs. The paralysis came on so rapidly that it seemed to affect all of the limbs almost simultaneously. When the patient came under observation, two days after the accident, the respiration was entirely diaphragmatic. He answered questions rationally and presented no cerebral symptoms. Movement of the neck caused pain, but there was none when the head was held still and none in the course of the nerves. There was no bruising of the skin and no irregularity of the spinous processes. The patient was able to raise his arms from his sides to a horizontal position and he could also move them across his chest. He could flex but not extend his forearms. He could make no movement of hands or fingers. The knee jerks and the plantar jerks were wanting. Sensation was lost upon the trunk and lower extremities below the level of the third costal cartilage; there was no hyperesthesia above this level. There was loss of sensation also on the anterior and posterior surfaces of the forearms on their inner halves, on the whole dorsum of the hands, on the inner part of the palms and on the palmar aspects of the little fingers. There was retention of urine and the bowels were constipated. The pulse was 56, full and regular. The temperature was subnormal. The urine contained a trace of albumin. No alteration in the extent of the paralysis or of the aresthesia was noticed and the patient's mind remained clear until his death, which took place twelve days after the accident from edema of the lungs. Upon post-mortem examination the spinal dura mater was found to be torn transversely across in its left half and the cord beneath was likewise torn across for a corresponding extent. On antero-posterior section the cord was seen to be soft in consistence and grayish in color at the seat of rupture and for a half inch above the superior limits of the gray area being indistinctly defined by a somewhat irregular transverse line. This condition appeared to exist throughout the entire transverse extent of the cord. The rupture was seated exactly opposite the articulation between the sixth and seventh cervical vertebra; a little movement was possible at this joint, but the posterior common ligament was intact and there was no evidence of fracture.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, JULY 31, 1897.

THE ANTIVIVISECTION BILL.

We notice that the esteemed Senator GALLINGER of New Hampshire is extremely anxious about his antivivisection bill. The following occurred on the presentation of the Memorial of the AMERICAN MEDICAL ASSOCIATION on the subject—*Congressional Record*, July 2, 1897:

Mr. COCKRELL. "I present resolutions unanimously adopted at the annual meeting of the AMERICAN MEDICAL ASSOCIATION in Philadelphia June 2, 1897, remonstrating against the passage of Senate bill No. 1063, for the further prevention of cruelty to animals in the District of Columbia. I ask that the Memorial lie on the table and that it be printed as a document."

The VICE-PRESIDENT. "Without objection, that will be the order."

Mr. GALLINGER. "I will inquire as to what is the Memorial particularly?"

Mr. COCKRELL. "They are resolutions opposing the vivisection bill reported by the Senator."

Mr. GALLINGER. "Resolutions adopted by a medical association?"

Mr. COCKRELL. "Adopted by the AMERICAN MEDICAL ASSOCIATION at Philadelphia."

Mr. GALLINGER. "In this connection I desire to state that I entered a mild protest a while ago against the printing of numerous documents relating to this one bill. We have, I think, four or five different documents already printed. Some of them are in severe and unjust criticism of the committee, stating absolute untruths regarding the action of the committee. I do not object to the printing of the Memorial, and yet it does seem to me rather strange that when a

committee has considered a matter carefully, giving a long hearing to both sides, permitting the opponents of the bill to print 300 pages in the report of statements in opposition, that they should then flood the Senate with memorials, resolutions and protests, and that we should print them at the expense of the Government."

Mr. COCKRELL. "This Memorial consists of only two or three pages, and it is in appropriate form."

The VICE-PRESIDENT. "The Memorial will be printed as a document, in the absence of objection, and referred to the Committee on the District of Columbia."

It does not appear that there is need of any particular comment upon it, except to show the hostile attitude that the Senator has taken.

IDLENESS AND INSANITY IN PRISONS.

The following press dispatch tells a tale that perhaps deserves some editorial comment from a medical point of view:

New York, July 22.—Since the anticonvict labor law went into operation on January 1 twenty prisoners in the Kings county penitentiary have lost their reason. Madness began to assert itself without anything to attract public attention. It attacked the victims one at a time until last week, when nine convicts, under the dull torture of enforced idleness, went mad. Five of these unfortunate men were removed yesterday from the penitentiary to the State asylum at Matteawan. The remaining four will probably be disposed of today. Three are federal prisoners and their destination is the asylum at Washington. Madness in one case is laid at the door of mental torture, long sustained. In all the other cases enforced idleness—twenty hours of each day passed behind iron bars in trap-like cells—seems to give the explanation. The increase of lunacy as shown by figures among the male convicts is alarming. The records of 1890 show one case of lunacy; in 1891, three; in 1892, one; and for the three following years a total of four. Then prison work fell off and for the first seven months of 1896, a period corresponding to the time during which the anticonvict labor law has been in operation, nineteen prisoners lost their reason.

The prophecy was made when a similar measure was being pressed prohibiting convict labor in another State than New York, by the head of one of the chief penal institutions, that the result would be so large an increase of lunacy amongst the convicts that they might as well turn the prisons at once into asylums, only reserving a space for the necessary and inevitable preliminary lapse from reason to occur in. This was uttered as a rather forcible statement of the probable outcome of such a law as it appeared to him, but it is one that contained a large element of truth and only a moderate amount of exaggeration. Idleness and confinement would tax the resistance of an intellect that has abundant resources, and much more the untrained and more or less degenerate brain of the average prison inmate who has necessarily to be deprived to a large extent of the saving influences of companionship and association with his fellows. From a purely philanthropic point of view it is not a justifiable piece of legislation to enact laws that deprive men of their reason, and it may be a question whether if tested it might not come under the constitutional prohibition of cruel and unusual punishments. In case of prisoners convicted before the passage of such

acts, they constitute in spirit and in fact, if not in law, a most cruel and inhuman aggravation of the punishment to which they were sentenced.

There is an economic as well as a humane aspect in which the facts may be considered. Mental breakdowns under such conditions is not the most hopeful type of insanity and it promises to largely increase the burden upon the community. A convict may reform, many of them do to a certain degree, and make harmless if not very valuable members of society. It is the aim of philanthropists to bring this about and to make penitentiaries reformatories rather than places of vindictive punishment. If their function is to become manufactories of chronic demented it will be of very little advantage: the insanity added to the original evil tendencies will hardly make them any safer for the community while it will insure their becoming dependents upon the taxpayers. In no way it can be viewed as the anticonvict labor legislation advantageous or respectable.

It is probable that the labor unions and others who have favored these acts, gave very little attention to any possible consequences except the immediate results they had in view. It would not be creditable to them to suppose they would deliberately wish to condemn all convicts of all grades of guilt to a possible and even probable fate that is commonly described as almost or altogether worse than death, however true this may be, and yet this is just what they have practically done. It is useless to say that they can be employed without competition with outside labor, for if that were possible it would have been resorted to in the New York institution—it must be presumed that it was either impracticable or was made so by the wording of the law; no prison authorities would readily abandon their best resource for government as well as for profit in such institutions.

This is only one of many instances where inconsiderate law-making is done that ought to have been modified or avoided. If enlightened medical counsels could prevail, if medical men could take part in making our laws, or if something besides what is called practical politics could be more considered by our legislators, such a disgrace to the State as this inhuman and backward step in prison administration would have probably not occurred. It is not at all necessary that prison labor should injuriously compete with workers outside, but the outcry at the present time is too indiscriminating, and inconsiderate legislation is too often demanded with such results as are shown in the paragraph quoted.

THE NATURE, DIAGNOSIS AND TREATMENT OF COLLATERAL HEMIPLEGIA.

It is not our purpose here to dwell upon the diagnostic features of the various forms of paralysis of cerebral origin or upon the difficulties that not rarely

attend their differentiation. We wish rather to refer to an interesting observation made by ORTNER (*Deutsche medicinische Wochenschrift*, June 10, 1897, p. 372), in connection with cases of hemiplegia in which palsy and cerebral lesion are on the same side of the body—collateral hemiplegia—in contradistinction from the cases in which the two are on opposite sides—contralateral hemiplegia—and which if verified will prove an exceedingly valuable aid in diagnosis, as well as an important guide in treatment.

LEDDERHOSE maintains that in cases of hemiplegia dilatation of one pupil, and more especially unilateral papillitis, upon the same side as the paralysis of the extremities is indicative of a lesion upon the same side of the brain. Both of these symptoms are, however, so uncommon under the conditions in hand that they are of little actual diagnostic aid. The peculiarity that ORTNER points out as distinctive of collateral hemiplegia consists in the manifestation of greater respiratory activity upon the side of the chest corresponding with that of the flaccid muscles than upon the opposite apparently unparalyzed side. In ordinary cases of contralateral hemiplegia this insufficiency of the respiratory muscles is noted upon the same side as the weakness of the extremities, or of the face and tongue, that is, that opposite to the seat of the lesion.

In explanation of the apparently paradoxical relation between the distribution of the paralysis and the seat of the lesion in the cases of collateral hemiplegia it has been suggested that there may be imperfect, or even total failure of, decussation of the pyramidal fibers in the medulla, but of this proof is yet wanting. It has also been thought that the result might represent the indirect influence of the affected hemisphere upon its uninjured fellow, but such a condition should then be common and attended with paralysis of both sides of the body, more pronounced upon that opposite to the situation of the lesion. A similar objection may be lodged against the view that the disturbance is a more general one, such as may result from diminished consistency or edema of the second half of the brain. That the palsy might be attributable to an undiscovered lesion in the opposite hemisphere seems in the highest degree improbable and it is not more likely that it owes its origin to representation of both sides of the body in the cortex of each hemisphere.

The most probable explanation is that which attributes the condition commonly to an extra-cerebral (meningeal), cortical or subcortical lesion, causing primarily general muscular resolution and secondarily irritation of the muscles upon the opposite side of the body. As a result we have a tonic state of the muscles upon this side and a flaccid state of those upon the other (same side as the lesion), without, however, interfering with the activity of the muscles of respiration upon the latter side. The most common condi-

tion that gives rise to this train of phenomena is hematoma of the dura or internal hemorrhagic pachymeningitis, of which the symptom under consideration may be considered in some degree diagnostic.

In a study of thirty-five cases of collateral hemiplegia it was found that the onset was attended with loss of consciousness in twenty-four; and of thirty-eight cases the lesion was situated in or adjacent to the cortex in twenty-six, the internal capsule and the fibers passing through it escaping in all. Of twenty-seven cases of intracranial lesion in or about the cortex, with hemiplegia upon the same side of the body, in not less than seventeen was the lesion extracerebral, and in thirteen of these it consisted of hematoma of the dura or hemorrhagic pachymeningitis. From these facts the conclusion seems justified that so-called collateral hemiplegia is a relatively common manifestation of either hematoma of the meninges or internal hemorrhagic pachymeningitis and the diagnosis of these hitherto obscure and latent conditions is facilitated by the recognition of apparent paralysis of the members of one side of the body with unimpaired respiratory activity upon the same side.

The state of the respiratory activity is also a diagnostic index in cases in which symptoms of bilateral cerebral irritation exists, as failure of this function upon one side under these circumstances is indicative of the existence of an intracranial lesion upon the opposite side, alone or at least in preponderant degree. The establishment of a correct diagnosis in some cases of the kind under consideration will suggest surgical intervention, with a reasonable prospect of finding the lesion, and in many instances also of successful removal of the source of irritation and paralysis, with consequent recovery and saving of life. ORTNER is able to report five cases in which a correct diagnosis was reached upon the basis of the phenomenon to which he has called especial attention.

THE EFFECTS OF THROMBOSIS AND EMBOLISM OF THE CORONARY ARTERIES.

Instances of thrombosis and embolism of the coronary arteries of the heart, the resultant functional disturbances of which can be carefully studied, are of great value and interest because of the light thus thrown upon the circulatory conditions in the myocardium of man. Such cases sometimes furnish conditions that may be said to correspond to circumstances produced by well planned physiological experiments.

A recent and instructive case of this kind is one of thrombotic occlusion of the main stem of the right, and embolic occlusion of the left, coronary arteries of the heart in a 32 year old man reported by CHIARI¹ of Prague.

The postmortem examination showed, as indicated,

that the patient had died from complete occlusion of both the coronary arteries. The very beginning right coronary artery was occluded by a thrombus which had developed some days before death and which had been followed by myomalacic foci surrounded by beginning reactive changes. The left coronary artery was closed by the embolism of a fragment of the thrombus in the right coronary vessel. This embolism was the immediate cause of death. It occurred a few minutes before death and gave rise to a sudden collapse that lasted but a few minutes before the final stopping of the heart's beat. The cause of the thrombosis is referred by CHIARI to a, for such a young person, quite marked sclerosis of the beginning of the aorta and to the presence of a chronic nephritis. Of the cases in the literature that are in the main identical with this, CHIARI mentions those reported by HAMMER,² OESTREICH³ and BARTH⁴. In OESTREICH'S case it concerns a 32 year old man that died suddenly. Above the orifice of the right coronary artery was a pedunculated thrombus attached to the wall of the aorta; this thrombus covered exactly the ostium of the artery. In the left coronary artery was a long, yellowish-gray embolus. BARTH'S case was one of occlusion of the opening of the right coronary artery by a thrombus in the corresponding sinus Valsalvæ due to a beginning sclerosis at this point. A but little advanced sclerosis in the beginning of the aorta may therefore give rise to very serious consequences on account of consecutive, thrombotic, coronary occlusion; most frequently the right coronary artery is the one affected; but in two cases at any rate, namely OESTREICH'S and CHIARI'S, the left coronary artery has been closed by a secondary embolism.

The important fact to be learned from the case reported by CHIARI is that rapidly developed complete occlusion of the main stem of the right coronary artery need not cause immediate death; the occlusion may be nearly or quite latent. CHIARI thinks that in this case the occlusion occurred about two days before death, because at that time an abnormal condition of the pulse had been observed. The thrombosis had caused numerous foci of softening in the myocardium but the right ventricle had not been completely deprived of nourishment because it had carried on its usual function. LANGER⁵ showed by means of injection experiments that the two coronary arteries communicate with each other by branches that pass transversely across the anterior surface of the heart; furthermore that they anastomose through the vasa vasorum of the great vessels of the heart with the pericardial, the bronchial and even the diaphragmatic vessels. Hence the occlusion of the main trunk of one coronary artery does not deprive the entire cor-

⁵ S. Ber. d. Ak. k. d. Wiss. in Wien., June, 1880.

¹ Prager Med. Wochenschrift, Nos. 6 and 7, 1897.

responding vascular district of blood when the occlusion takes place gradually, as for instance, in case of uncomplicated sclerosis of the coronaries, then the collateral circulation may have time to develop to a considerable extent so that the disastrous consequences are in a measure warded off. The sudden occlusion of one or both main coronary trunks places greater demands upon the collateral circulation than can be met, and there may follow rather rapid suspension of the cardiac function. In HAMMER's case the occlusion of the right coronary artery was followed by a condition of collapse that lasted thirty hours; the pulse was gradually reduced to eight beats in the minute; after the second sound came a distinct rumbling noise which HAMMER connected with the shaking up of the diseased part as the healthy half contracted. In BARTH's case, which was not observed clinically, death followed after the patient had been feeling ill for several hours. In OESTREICH's case the occlusion of the right coronary artery was probably not complete, and this partial thrombus undoubtedly existed for some time without any symptoms. In CHIARI's case the symptoms during the time that only the opening of right coronary was closed consisted in some slowing of the pulse, which was slow and arrhythmic, small and weak.

Lastly, it may be well to indicate that the results of the observations concerning the occlusion of a coronary trunk in the heart of man do not correspond exactly with the results of experiments on animals,⁶ and to emphasize that great care should always be used in the application of the results of animal experiments to human pathology.

ATHLETICS IN RELATION TO HEALTH AND LONGEVITY.

Of all the things that enter into our tastes and aptitudes, but few excite more interest at present in the community at large than that of athletic sport. The thing itself, eminently Anglo-Saxon, is not among the tastes of the average French youth, who at the age of 16 usually takes to cigarettes, absinthe and a mistress, while most of our boys at college, keenly devoted to athletics and outdoor games, are incurring the fears of over-anxious parents as to the doubtful, if not deleterious, effect of this agency of modern education, concerning which many errors still prevail. One of the more current of these is that athletes are subject to organic disease and die young.

Regarding the three different educations that we receive, namely, that of the family, that from our school masters, and that of the world, the authorities own that mere book learning in itself is of little consequence in determining one's place in life, when compared with the inestimable value of good family

antecedents and training and the worldly attrition with well-chosen associates. With no intention to undervalue the worth of study and sound scholarship, most of us may recall the honor men of our school days, who have turned out to be mere prigs and book worms, while those who stood nearer the foot of the list have been the successful ones to whom life's prizes have fallen. To be sure, books have their use, but as a rebuke to mere bookishness there seems to be much significance in the remark of the late Professor HENRY of the Smithsonian Institution, regarding the agglomeration of medical books then in the Army Medical Museum, to the effect that it would be all the better for original research and the benefit of medicine, if some Calif OMAR would apply the torch and wipe out the whole collection. Of course this wholesale denunciation of books, when viewed with judicial calmness, is merely an enlightened common sense protest against these dumb teachers, which do less for practical education than well-regulated acquaintance and intercourse with men.

Our species being eminently gregarious, there is from a socialistic point of view no branch of education more valuable than the fellowship arising from the community of thought and feeling that obtains in all collections of young people engaged in outdoor games or athletics. Notwithstanding the acknowledged good of such recreations by historians and philosophers since the days of HIPPOCRATES, many popular fallacies yet prevail even among medical men, as to the effect of physical training and its bearing on health and longevity, and it would be difficult to equal the distortion of facts and temerity of language put forward in certain quarters in the howl against present day athleticism. Most of the published opinions that go to make up the popular notion relatively thereto, have emanated either from physicians having no practical acquaintance with athletics, or from sporting men who knew nothing of medicine.

Truth, as usual in such matters, lies between the two extremes. While a few exceptional cases break down and die young, it is now a well-ascertained fact that the beneficial effects of training and exercise tend to the benefit of the greater number by increasing health and longevity. The contention of this thesis was established in a paper embodying the experience of thirty years, read before the AMERICAN MEDICAL ASSOCIATION in Cincinnati, in which were cited many examples of athletes who lived to a hale and hearty old age.¹ The numerous macrobiotic instances therein cited are not open to the objection of being exceptional, since the writer's information and views have been supplemented by other observers in the same line, notably by JOHN BOYLE O'REILLY in his book about boxers; by the researches of Dr. J. MADISON TAYLOR of Philadel-

⁶Amelsson, Zeits. f. kl. Med., H. B., 1880; Cohnhelm, Virch. Arch., 1880; Von Frey, Zeits. f. kl. Med., B. xxv., 1894.

¹Popular Fallacies Regarding Athletes and Athletic Exercises. Journ. Amer. Med. Assn., Apr. 27, 1889.

phia (JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 1892, xviii, 705-710), who arrives at the same conclusions; by Dr. B. W. RICHARDSON of London, who, though disposed to condemn excessive athletics, concluded one of his last lectures at Oxford by saying that "good active sports and exercise in reason are amongst the clearest means of maintaining a long and happy life;" and last but not least, by the admirable essay of Sir MORRELL MACKENZIE, who ridiculed the sweeping statements that are still made from time to time as to the ruinous effects of exercise and training on the majority of those who find pleasure in the use and development of the strength with which nature has endowed them. In addition to the instances cited by these writers, others have appeared from time to time in the public prints. The former champion of the prize ring of England, JOHN GULLY, grandfather of the present speaker of the House of Commons, died at 80, and within the last few weeks the celebrated wrestler, MARSEILLE, whose prowess was witnessed years ago by many French grandfathers at country fairs, departed this life with the record of an octogenarian.

As an offset to the foregoing instances, we are often confronted with vague statements relating to the untimely death of several notables who have figured in the athletic world for the last twenty years or so; but in nearly every instance, as far as can be ascertained, the cause of break down was owing to immoderate indulgence, or the neglect of simple hygienic rules, resulting in such specific trouble as alcoholism, cirrhosis of the liver, or venereal disease. Dr. SARGENT of Harvard says from extensive personal knowledge he thinks the early demise of athletes directly attributable to free indulgence of gross appetites and passions and not to the result of athletic work.

We need only refer, in conclusion, to the accurate statistics collected by competent authorities, and to elaborate actuarial calculations, which demonstrate that oarsmen have in point of fact a longer expectation of life than others, and that the alleged baneful effects of boat racing are absurdly exaggerated. So prone, indeed, are the opponents of athletics to be blinded by prejudice, that these statistics have been abused even to the extent of quoting them as proof of the disastrous consequences, as we once heard a medical man do who, in citing the figures of Dr. MORGAN'S accurate investigation, mentioned the "seventeen" victims, but said not a word about the remaining *two hundred and seventy-seven*. The mistake of mourning over one broken-down athlete and refusing to be comforted by the thought of a hundred others who were benefited by physical training, finds its counterpart in the denunciation of swimming by certain people who say that good swimmers are sometimes drowned, yet they totally ignore the hun-

dreds who escape drowning from knowing how to swim.

Writing with the authority of experience and the maturity of observation, we therefore have forced upon us the induction that no good reason exists for the wholesale condemnation of athleticism. On the contrary, it is evident that the healthy exercise of the physical powers is one of the necessary pastimes of a manly and vigorous race, and that next to food and sleep athletics has the largest share in the recreation of human life and in counteracting the tendencies of this hyper-neurotic age.

UNITED STATES COURTS VS. POST OFFICE AUTHORITIES ON ABORTIFACIENT NOSTRUMS.

There is a decided conflict between the United States courts and the United States post office as to the status of abortifacient nostrums. According to a recent decision in Judge SEAMAN'S court, the United States Courts will enforce contracts for the sale of abortifacient remedies which are not permitted in the mails. The nostrum involved in the decision has been extensively advertised in the lay press as well as in the homeopathic journals as a "preventive of conception and a regulator of menstruation." In the case in which Judge SEAMAN'S court rendered judgment the manufacturer of this nostrum was sued for violation of contract by a woman who had obtained certain territory in southern Indiana. She asserted that after she had worked up a good trade in this territory, the manufacturers filled orders in it without paying the commission, and her claim was based on this alleged fact. As the territory involved is largely a rural one, the dangers to the health of both mothers and children can not well be over-estimated. If the ordinary theory of law be correct, contracts to perform illegal acts such as the sale of this nostrum, are null and void. It can not be pleaded in the present instance that there is no evidence tending to show that the nostrum was of the character described. The United States post office authorities have already excluded it from the mails. It would therefore be no arrogation of authority for the United States district attorney to ask that the case be thrown out of court on the ground that the enforcement of the contract is against public welfare. As the Milwaukee Medical Society is in the court district and as the case will probably be appealed, that Society could render a great service to itself, to the local profession, to the profession and people of the United States, by inducing the local district attorney to do his duty. In this way the Milwaukee Medical Society could teach certain nostrum venders a very telling lesson.

CONCERNING THE EDITORIAL MANAGEMENT.

We clip the following from "A Journal of Reform and Progress in the Medical Sciences," under the

head of "current comment." The truth is that every article connected with, or relating to the Ophthalmic Section that has appeared in the JOURNAL in the last three or four years, has been written by some member of the Section, and if our esteemed contemporary will re-read that "memorable diatribe" to which he refers, he will see there is nothing in it objectionable to the Section as a body, nor has anything of the kind ever appeared in the pages of the JOURNAL.

"There has been a revival of generous proportions in the editorial rooms of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, and the Spirit has warmed the hearts of the special editorial writers since that memorable diatribe against the Ophthalmic Section of the National Association. The current issue of the JOURNAL goes out of its way to praise the Section quite as much as, a short time ago, it abused it. The JOURNAL has a large safety valve—praiseworthy editorials are by the editor, objectionable ones are by a special collaborator whose name it is not considered desirable to mention."

THE NEW SPELLING.

In answer to a valued contributor who objected to dropping the final "al" from the words *physiological* and *biological*, the Editor recently wrote:

"In regard to request for change of spelling I have to say that the JOURNAL long ago adopted the recommendation of the American Association for the Advancement of Science. However, your reprint will appear spelled as you wish. I quite sympathize with your feeling in the matter, but I suppose that our ancestors—some of them at least—raised a protest when the word 'arme' had the final 'e' dropped; the word 'legge' lost one 'g' and one 'e'; when the word 'thighe' lost its final 'e.' These happen to occur to me as I sit here, as specimens of how our language has grown by excision."

We print this because of other protests of the same character; in Vol. XXII, p. 25 will be found more specimens of the same sort.

CORRESPONDENCE.

The Section on the Practice of Medicine at the Late Meeting of the Association.

BUFFALO, N. Y., July 26, 1897.

To the Editor:—Your editorial in the JOURNAL of July 3, entitled "The Late Meeting of the Ophthalmic Section of the AMERICAN MEDICAL ASSOCIATION," must have attracted the attention of all your readers. The ASSOCIATION meeting was so notable in all respects that there may be danger of losing sight of the great excellence of the work in the various Sections.

It may not be out of place to emphasize once more the high estimate universally expressed of the work done in the Section on the Practice of Medicine. Knowing from experience how difficult it is to arrange a program satisfactory to all of a large body of physicians, the list of papers read and the discussions brought out are recalled not only with gratification but a certain amount of wonder.

It ought not to be necessary to reiterate the titles of papers nor to point out the wide range of subjects covered. It must be a satisfaction to remember that all parts of the country contributed and on adjournment the members separated with

increased feelings of mutual respect. The suggestion is ventured that this program be preserved as a model for Dr. John H. Musser's successors in office. Very respectfully yours,
CHAS. G. STOCKTON, M.D.

PUBLIC HEALTH.

Thyroid Gland Extract as a Galactagogue.—The *Inter-colonial Medical Journal* of Australia contains, among other papers, an interesting communication by Dr. R. R. Stawell upon this subject. The value of a reliable medicine that would promote the secretion of milk would be immense, so that Dr. Stawell's results will have an interest for many practitioners. He details only nine cases, and, while admitting that this is but small clinical experience from which to generalise, concludes with some reservations that extract of thyroid gland is an efficient galactagogue. The dose given was from three to five tablets per diem. In view of Dr. Stawell's results we think that medical men are justified in giving the treatment a trial.

Detection of "Preservatives."—The use of preservatives in milk and butter has increased very largely during the last few years, in fact, during the summer months the practice of adding a preservative to milk may be said to be general. The preservative which finds most favor with the milk trade, is that known as "formalin," a more or less strong solution of formic aldehyde. Boric acid, borax, or a mixture of the two, are occasionally used for milk, and very largely for butter. From the public health point of view, this question of the addition of preservatives is most important. Whether or not such substances, in the quantities usually added to food, are injurious to health is still considered to be unsettled; but there can be no doubt that under the "Sale of Food Drugs Acts," the purchaser has a right to demand that the articles so doctored shall be labeled as containing a foreign ingredient. A very delicate method for detecting "formalin" in milk is O. Hehner's test, which consists in diluting the milk with its own volume of water, and carefully floating it over a little concentrated sulphuric acid, containing a few drops of ferric chlorid solution, contained in a test tube. In the presence of formalin a violet ring develops at the junction of the two liquids. This color is permanent for several days, if care be taken to prevent the tube being shaken. Carried out in this way one part of formalin can readily be detected in 200,000 parts of milk. In the absence of formalin, a brownish-red color develops, after some hours, not at the junction of the two liquids, but lower down in the acid.—*Public Health* (London), March.

Ptomain Poisoning by Pork.—Dr. Wynter Blyth reports, in the *London Sanitary Chronicle*, the cases of a boy and girl, aged respectively 11 and 5 years, who were brought to death's door by the ingestion of boiled pork, on a Saturday (March 27). Forty-eight hours later, the father, the boy and the girl were seized with choleraic symptoms, and at 2:30 on Monday afternoon the mother became similarly affected, but in a lesser degree. At 11 A.M. of that day, the boy and the girl had high temperature, the father choleraic symptoms, cramp, numbness of the feet and hands, and smarting of the eyes. The father, the mother, and the boy got better by about Tuesday, but the girl by Wednesday morning was almost pulseless, with cold extremities, and very nearly died. She, however, revived, and ultimately recovered. The pork was examined by the medical officer of health on April 1, on Wednesday, that is, four days after it was bought, three days after it had been boiled. At that date its appearance and odor were perfectly normal, but on passing it through a small sausage machine the finely divided fiber had a distinct stale smell. The pork was analyzed by Gautier's process, and ultimately a crystalline substance not in normal pork was separated. This substance was alkaline in reaction, gave fine crystals when united with hydrochloric acid, and

precipitates with the ordinary alkaloidal reagents (save the chlorids of gold or platinum). So small a quantity was, however, obtained, that it was not practicable to examine it farther or to determine whether the substance was really a poisonous "ptomain," although this is naturally the inference. It may be suggested that the ptomain was in quantity in the meat on Sunday, and what the writer found was a small residue which had escaped destruction in the process of putrefaction.

Reforms for Hospitals and Reformatories.—The "Greater New York" has many unanticipated problems to solve, some of which belong to the semi-penal institutions, where poverty is a non-recognized crime. The New York State Board of Charities not long ago received a report on the condition of the Kings County Hospital, showing insufficient accommodations and not enough of restrictions in the admission of inmates. This hospital combines what in the city of New York itself would be divided up into the workhouse and almshouse, hospital and places for acute cases. It is astonishing, says the report, to find that any of the work is well done in this overcrowded, improperly equipped and ill-constructed hospital for the poor of one of the largest cities of the world. The Board has also received the report of the inspectors of the various reformatories in the State. The House of Refuge on Randall's Island is found in good condition and neatly kept. "We earnestly recommend," the report says, "the separation and the removal of the girls' department from that of the boys' in this institution. This evil in the development of our juvenile reformatory system is so patent and embarrassing that this committee urges positive and immediate action on the part of the Board to initiate this separation." The same recommendation is made in the case of the Rochester State Industrial School. Much serious comment is likewise made upon the reformatory system of the "Excelsior" State particularly in its dealings with juveniles, classed as first offenders. The Board holds that the present system is making more real criminals than it reforms. In the case of juveniles, male and female, especially under 16, commitments should be made directly to the reformatory as a guardian rather than as a penal institution. This course is followed in France, and none of the juveniles sent to reformatory or correctional institutions of that country are committed as convicted of a felony, but as a precautionary measure. The root of the evils in question is not so much with the hard-working officials and a hampered medical profession, but with so called "statesmen" and pretended political economists. Public weal is one matter—appointments quite another. Between the trades unions and the tax-payers the honest humanitarians have but little consideration.

The Duality of Vital Statistics.—Vital statistics are as a barometer in which the sanitarian sees indexed the sanitary necessities of any locality, and traces its accordance or otherwise with those laws of health by which its death rate is either diminished or increased. Every one is aware of the *wonderful duality of statistics* and how they can be used and mixed by a skilful hand so as to furnish materials for any taste, and to prop up any shaky theory. Appealed to in evidence of conclusions thoroughly diverse, they often remind one of Meyrick's story of the chameleon, anent the description of which the two travelers so materially differed—the one asserting that its color was green, while the other swore it was blue. The umpire called in to decide pronounced it black as jet, and the beast itself, when produced, was found white as snow. So is it that statistics are appealed to for every purpose, and are often in the hands of party advocates or prejudiced opponents little better than a pack of cards in the hands of a skilful conjuror. Still, statistics can not be set aside or unduly underrated. Those vital statistics which it is the registrar's duty to collect are of such a nature as not to be capable of easy distortion. Each

locality or district can separate them for itself, and learn those special lessons which they are fitted to convey. To show the practical use to which these statistics may be put, take the system originated many years ago in Leith, and now in force in Glasgow. The city is divided into a number of what might be called sanitary districts, each registrar supplies the sanitary authorities with a return showing every birth and death in each street; these figures are tabulated, and by a little comparison the undue mortality of any place within the districts is authoritatively ascertained, the causes of death enumerated, and other information bearing upon the health of the city indicated. Such a course is evidently approved by the framers of the new Public Health (Scotland) Bill, as there appears a clause providing that every registrar shall send a return of the deaths in his district to the medical officer of health, although the payment indicated in the bill is quite inadequate. However advantageous to the general work of sanitary reform may be the results of registration as embodied in the publications of the registrar-general, it must be evident that for local application they require to be more fully and minutely analyzed. Some physiognomists, it is said, derive their chief pleasure from the examination, not of the more prominent features of the human countenance, but of the minute lines, curves, and wrinkles such as escape the notice of the general observer. Public money invested in the direction of obtaining these statistics is advantageously invested, and ought not therefore to be stingily applied. The public reap the benefit in that improved sanitary condition which throws a life-guard round their homes, promotes their daily comfort, drains the prolific sources of disease, and robs the epidemic of its deadly strength. Public authorities may expend much labor and means in seeking to promote the social and sanitary well-being of their constituents, but without some intelligible basis from which to start, and some reliable data to direct, they can not be expected to attain commensurate results. Those who, from their position are qualified to aid them in their urgently important work ought to be dealt with in a spirit of liberality, indicating, on the one hand, their earnestness of purpose, and ensuring on the other hand, that the best thing being done in the best way will produce the best and most enduring results. Such an onerous and responsible position is held by every registrar in Scotland, and particularly by those called upon to act in the leading centers of population, but the recognition of this fact by local authorities is the exception and not the rule. Looking to the remuneration of other public officials who are not burdened with a tithe of the registrar's responsibilities, nor surrounded by any statutory civil and criminal penalties, it must be admitted that the provision made for registrars is most inadequate. — Mr. John Archer in *Sanitary Journal* for April.

European Sanitaria for the Treatment of Tuberculosis. Dr. Kaurin of Christiania, Norway, has published in *Lugvildens-skaben* the results of his observations concerning the tuberculosis retreats on the continent. In Switzerland he visited Heiligenschwendi, in the Canton of Bern, 1,100 meters above the level of the sea. It is also surrounded by forests and faces toward the south. The climate here is more severe: in winter the thermometer descended to -37 degrees C., and in June the maximum temperature is +15 and minimum +7 degrees C. The treatment employed was hygienic-dietetic and was followed by good results. In the Canton of Graubunden he visited Davos, an Alpine valley, situated 1,560 meters above the level of the sea. The two small villages there are now yearly visited by more than thirteen thousand people having tuberculosis. The mean temperature is +2.6 degrees C., and the mean barometric measurement 631 mm. The snow covers the fields until May and +20 to +30 degrees C. is frequently recorded. From so severe a climate the patients return home much improved in health. In spite of the elevation, there

seems not to be any disposition to hemoptysis; whereas it is contraindicated to send patients up there with developed anemia, neurasthenia, heart or laryngeal affections. Here in Davos there is a very peculiar institution, a school sanitarium for boys and girls sent by families disposed to tuberculosis, or with incipient phthisis. Boys and girls with poor health are sent up there also, and healthy children from the neighborhood frequent the same school. From Switzerland the author visited some places farther north in Sudster Mountains and praises Gobersdorf, which is situated 560 meters above the level of the sea. Here, as in Davos, the patients with fever are kept out in the fresh air, and with good effect. Here, also, as in other places, 24 per cent. are cured. In the suburbs of Berlin he visited the barracks of Doeckert, situated in a large pine grove and given up to the Red Cross Society, for the benefit of tuberculous people. The cost per day is three marks per capita. Here, as well as in Malchow and Blankenfeldt, are two hospitals for tuberculous patients from Berlin hospitals, and situated on the plains irrigated by the Berlin sewers. The result is very satisfactory. In Malchow and Blankenfeldt the cost per day is only two marks and the treatment does not last more than forty-four days. Even if not cured in this short time the patients go back to their homes in the city improved in health and trained to a better mode of living. The celebrated establishment at Falkenstein in Nassau, of which Dr. Dettweiler is the director, is situated 400 meters above the level of the sea, surrounded by extensive forests on the southern slope of Taunus Heights. Not far away is Ruppertsheim, a sanitarium for a poorer class of people, costing from two and a half to five marks a day. The climate is dry and a little windy, with a good deal of rain in spring and fall; in the winter the thermometer falls below the freezing point, generally to 8 or 10 degrees Celsius, and a little snow falls. The temperature changes slowly. The buildings are three stories, with corridors for patients on the front—open but protected with canvas against rain and direct sunshine. The regular treatment, lasting three months only, is based on the Bremer-Dettweiler method, the open-air treatment, the treatment in the corridors, and abundant nourishment, with regular exercise to strengthen the heart, and the disinfection of the sputa. Medicine is not much used; mostly to relieve symptoms. The result is very satisfactory, the percentage of cured being 24 (13 per cent. entirely cured and 11 per cent. able to resume work). Of 99 cured, 72 remained well for three to nine years after treatment, 15 had a relapse, and of those 12 were again cured after a renewal of the treatment. The little village, Falkenstein, close by, with 800 inhabitants, seems not to suffer from this so-much dreaded neighborhood, inasmuch as the death rate from tuberculosis here is less now than formerly.

BOOK NOTICES.

The Menopause; a Consideration of the Phenomena which Occur to Women at the Close of the Child-bearing Period, with Incidental Allusions to their Relationship to Menstruation: also a Particular Consideration of the Premature (especially the Artificial) Menopause. By ANDREW F. CURRIER, M.D. Cl. 8vo. pp. 309. New York: D. Appleton & Co., 1897. From A. C. McClurg & Co., Chicago.

This book is not only entertaining from a literary standpoint, but it is meritorious from a professional point of view.

The author's chapter on the artificial menopause is interesting, but rather disappointing. Surely there must be sufficient experience in the after-effects of ovarian and tubal extirpations, to say nothing of hysterectomies, to have made more definite statements and more extensive observations. One must admit the truth of what the author says, but there is much more to be gathered.

The general trend of the book is to combat the view that the

period of the menopause is a period fraught with danger. On the contrary, that period should be considered as a physiologic process and be passed with as little pathologic sequence as the menstrual period came on. The book is on a very practical topic and we are sure it will be well received.

A Short Practice of Midwifery, Embodying the Treatment Adopted in the Rotunda Hospital, Dublin. By HENRY JELLETT, B.A., M.D., etc., with a preface by W. J. SMYLY, M.D., late Master of the Rotunda Hospital. With forty-five illustrations and an appendix containing the statistics of the Hospital for the last seven years. pp. 323. Philadelphia. 1897. Price \$1.75.

This little volume will prove acceptable not only to those who desire a brief account of the practice of the great Rotunda Hospital, but to those interested in keeping pace with the progress of modern midwifery. Aseptic methods are taught and we regard the work as an excellent epitome and well worth careful study by students everywhere.

Crime and Criminals. By J. SANDERSON CHRISTISON, M.D. Chicago: The W. T. Keener Co. 1897.

This is very evidently not a systematic treatise on criminology, as the author admits. It is only some brief sketches, mostly of a few not uncommon or specially prominent types of criminal defectives. It is popularly rather than scientifically written, and the author states in his preface that the work is largely a reproduction of newspaper articles which, it would appear from his preface, have aroused attention both in Europe and America. He has therefore collected them and published them, with some additions, in book form for the benefit of the public.

While the style of the book is generally readable, the author would have done well had he revised it more carefully in some parts. The publishers have done their work well; the make-up, illustrations, etc., are very good.

ASSOCIATION NEWS.

Committee on Transportation.—*To the Editor:*—The committee on rates to Denver in 1898 has been appointed by President Sternberg as follows: Dr. W. H. Daly, Pittsburg, Pa., chairman; Wm. Pepper, Philadelphia, Pa.; X. C. Scott, Cleveland, Ohio; J. D. Griffith, Kansas City, Mo.; C. M. Drake, Atlanta, Ga.; L. H. Montgomery, Chicago, Ill.; H. O. Marcy, Boston, Mass.; J. W. Graham, Denver, Colo. The President says: Dr. Daly writes me that the committee is already industriously at work and that a rate of one-half and thirty days time seems to be the certain outcome of their labors."

Yours very truly,

W. B. ATKINSON, M.D.

Section on Ophthalmology.—Members of the Section on Ophthalmology, and others interested, who have not already subscribed for the bound volume of the proceedings of that Section for 1897, may obtain a copy when issued by sending name and address and \$1 to the JOURNAL office, or to Horace M. Starkey, 70 State St., Chicago. These orders should be sent in within the next two weeks.

SOCIETY NEWS.

Indian Territory Medical Association.—At the regular semi-annual meeting of the Indian Territory Medical Association held at South McAlester, I. T., June 29 and 30, 1897, the following officers were elected for the ensuing year: President, E. N. Allen, M.D., South McAlester; first vice-president, G. W. West, M.D., Eufala; second vice president, J. B. Roletter, M.D., Oklahoma City; secretary, LeRoy Long, M.D., Caddo.

New Jersey Medical Examiners.—The annual meeting of the State Board of Medical Examiners of New Jersey was held at Jersey City, Monday, July 5. Dr. George F. Wilbur of As-

bury Park, was elected president: Dr. E. L. B. Godfrey of Camden, secretary, and Dr. A. Uebelacker of Morristown, treasurer. There were sixty-eight candidates who reported for the June examination, of whom 12 per cent. were rejected.

French Congress of Surgery, to be held at Paris, October 18, will discuss the questions of "Contusions of the Abdomen" and "Indications for an Operation and Treatment of Cancer of the Rectum." Sec. L. Picque, Rue de l'Isly 8, Paris.

Twelfth International Medical Congress.—*To the Editor:*—In a letter dated July 7 Dr. H. Kümmell, surgical director of the New General Hospital (Neues Allgemeines Krankenhaus) of Hamburg, in the names both of the local Hamburg and the General Imperial Committees of the Twelfth International Congress, begs to invite American Congressists to inspect the hospital and the new hygienic establishments. The medical men will be at the hospital daily from 10 A.M. to 2 P.M.; still they request American Congressists to kindly notify them, if possible, of the days of their intended visits. Very respectfully.

New York, July 19, 1897.

A. JACOBI.

Mississippi Valley Medical Association.—Meeting at Louisville Oct. 5, 6, 7, 8, 1897. The Executive Committee met recently at Louisville, in conjunction with the local Committee of Arrangements, the following being present: Drs. Stucky, Grant, Mathews, Love, Holloway and Reynolds. It was determined to make the coming meeting the largest and best in the history of the Association, and everything points to a fulfillment of this endeavor. The railroads will make a round-trip rate of one and a third fare, or probably one fare. The address on surgery will be delivered by Dr. J. B. Murphy, Chicago; the address on medicine by Dr. John V. Shoemaker, Philadelphia. Title of papers should be sent to Dr. H. W. Loeb, Secretary, St. Louis, Mo.

The Neuron at the German Congress of Internal Medicine.—Goldscheider remarked in his address that we assume now that each neuron with its axis cylinder and dendrites is a functional and nutritive unit, communicating by contact alone with the rest, but if a sufficiently powerful stimulus is applied, it will be transmitted like a wave, entirely around the whole of the central nervous system, preferably following the routes offering the least resistance. Each neuron has an individual standard of excitability—a limit that must be passed before it shows the effect of the excitation. This limit varies under different conditions. Slight excitation increases the excitability of the neurons, but violent excitation decreases it and is followed by hypo-esthesia of a whole region. Such a condition exists in hysteria, while on the other hand, neuralgia and the tachycardia accompanying neuralgia, produce a hyperexcitability. The same stimulus in these conditions produces a much more intense excitation than in normal. Psychic conditions also affect it. These variations in the standard of excitability of the neurons must be borne in mind in organic diseases of the nervous system, in which the lesion does not account for all the phenomena observed. In tabes, for instance, we do not know whether the lightning pains precede the establishment of the lesion, or whether the subjective troubles are caused by it. Substitutions and compensations are accomplished by an increase in the faculties of hitherto inactive neurons. We know that stimulation of certain portions of the skin will affect the viscera, showing a connection between the cutaneous sensory neurons and the sympathetic neurons. The effect on the brain during sleep, of the stomach and intestine loaded with food, can be compared to the effects of cutaneous pruritus. Therapeutics must not be restricted to remedy the auemia or hyperemia of the nervous elements, but also aim to affect the irritability of the neurons. In case of hyperalgesia of one member, for example, the pain can be reduced by acting upon the neurons of the symmetric member; electrization, for instance,

will increase the excitability of the neurons, while massage and hydrotherapy may divert and thus reduce it. These measures open or close the road to excitation. The stimulus of cold or hot baths removes the sensation of fatigue. Various measures can be used to assist the will, too weak to determine alone a motor action. Suggestion, for instance, which can be considered an excitant of the neurons. Thermic influences also have an incontestable effect on the vasomotor and trophic neurons. Even in certain degenerative processes dynamic action on the neurons may have a useful therapeutic effect. The assumption of a dilation or contraction of the blood vessels is not an adequate explanation of the effects of thermic stimulation. The entire nerve substance is affected in a certain measure by its exciting effect on the trophic neurons. He advocated in conclusion "dietetics of the neurons" as more effectual than all pharmaceutical means in progressive degenerative conditions of the nervous system. M. Sternberg of Vienna added that the standard of excitability in the individual neuron (the *Neuronschwelle*), is the result of the equilibrium between the force applied and the resistance, and is therefore necessarily variable. "We have been concentrating our attention on the study of degenerative processes in the nerves, but in nature everything is not always either *black* or *white*. There are intermediate stages, which have not yet been sufficiently studied."

NECROLOGY.

JAMES S. WHITMIRE, Metamora, Ill., who died July 15 (*vide* JOURNAL, p. 200) received the degree of M.D. from the Medical Department of Illinois College in 1847. He afterward studied in Rush Medical College and while there was awarded the first *ad eundem* degree ever conferred by that college, his thesis embodying investigations made by him concerning iodine as an antidote to rattlesnake venom. In 1856 he also received the degree of M.D. from Jefferson Medical College. As surgeon of the Fifty-sixth Illinois Volunteer Infantry, with rank of Major, he participated in the battles of Iuka, Miss., and of Corinth, and after the latter had the reputation of performing the only successful hip operation (performed on a Confederate soldier) that had been done in the Western Department up to that time. Dr. Whitmire was the first to use a 6 per cent. solution of carbolic acid as a subcutaneous injection in erysipelas. (Reprint from "Physicians and Surgeons of America.") He had been a member of the Illinois State Medical Society since 1850; helped organize the Woodford County Medical Society; and was a member of the N. C. Illinois Medical Association and the AMERICAN MEDICAL ASSOCIATION.

DELLOS A. CRANE, M.D., at Holland Patent, N. Y., July 22, aged 76 years. He was a graduate of Castleton Medical College, Vermont, class of 1844; was well known in Oneida County, and up to his death was a special Pension Examiner from the date of his appointment in 1865.

WILLIAM H. MCNAUGHTON, M.D., for two years Health Officer of Watervliet, N. Y., July 22, from consumption, aged 34 years.

EDWARD M. HIGGINS, M.D., Hot Springs, Ark., July 18, from apoplexy, aged 43 years. He received his medical degree in 1877 from Queen's University, Kingston, Ontario, of which city his father is a resident, and there Dr. Higgins was spending his vacation.

WILLIAM C. WEST, M.D., Geneseo, Ill., died at his home July 10, 1897, of suppurative pancreatitis. Dr. West was born in Maryland Feb. 27, 1835, and had been an active practitioner for thirty-four years, having been graduated from the College of Physicians and Surgeons of Keokuk, Iowa, 1863. He was a member of the AMERICAN MEDICAL ASSOCIATION, of the Illinois State Medical Society, and for a number of years a leading member of the American Microscopical Society. His remains were taken to Monroe, Mich., for burial.

RESOLUTIONS ON THE DEATH OF DR. BERGER.—At a regular meeting of the Alumni Association of the University Medical

College, Kansas City, Mo., held on Monday, July 12, 1897, the following resolutions were unanimously adopted:

WHEREAS, it has pleased the Almighty Providence to remove from among us by the act of a cowardly assassin, our honored and beloved friend and teacher, Dr. Lyman A. Berger, be it

Resolved, That his untimely death in the prime of professional life and usefulness, fills our hearts with deepest sorrow, and has created a lamentable vacancy in our faculty.

Resolved, That in the demise of Dr. Lyman A. Berger our profession has lost a trusted member and a zealous and valued colleague, and our Alma Mater a faithful and kind hearted friend.

Resolved, That his efforts in behalf of medical education in materially advancing the progress of the University Medical College are greatly appreciated; and as the founder and patron of its obstetrical clinic he has permanently contributed to its usefulness and earned the lasting gratitude of not only our Association and the medical profession, but of the community at large.

Resolved, That we fervently sympathize with the grief-stricken family, who have lost an exemplary husband, a devoted father and a true physician.

Resolved, That the foregoing resolutions be spread on our minutes, a copy thereof be sent to the bereaved family of the deceased, and the same be published in the daily papers of our city, the local medical periodicals and the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

B. ALBERT LIEBERMAN, M.D., Chairman,
A. L. HUNT, M.D.,
B. L. SULZBACHER, M.D., Committee.

ROBERT HUBBARD, M.D., Bridgeport, Conn., July 18, aged 76 years. In 1862 he was commissioned surgeon of the Seventeenth Regiment Connecticut Volunteers. After a few months' service he was promoted to surgeon of brigade under General Howard. For meritorious conduct at the battle of Chancellorsville, Dr. Hubbard was promoted to be medical inspector—assistant medical director—on the staff of General Devens. At the battle of Gettysburg, he served as medical director in charge of the Eleventh Corps. When the Eleventh Corps was ordered to Lookout Mountain he again served as medical director under General Hooker, and in that capacity took part in the battles of Lookout Mountain, Missionary Ridge and Ringgold.

MATTHEW P. LYON, M.D., died at Camden, Wash., May 18, aged 79 years. He crossed the plains to California in 1849, and has resided in Washington since 1878.

JOHN N. BEACH, M.D., West Jefferson, Ohio, July 17.—Paschal Davis, M.D., Keokuk, Iowa, July 16.—Henry C. Hinkle, M.D., Oakland, Cal., July 13.—Tyler Hull, M.D., Dimondale, Mich., July 17, from blood poisoning.—Alfred Marshall Mayer, M.D., July 13, aged 66 years, and for the past twenty-one years professor of physics at the Stevens' Institute of Technology, Hoboken, N. J.—Selden W. Noyes, M.D., Higganum, Conn., July 12, aged 51 years.—P. L. Garvey, M.D., Oakland, Ill., July 11.—Prof. D. Hofer, Munich.—A. Nocquart, Brussels, professor of path. anat., from infection at a necropsy.—Schützenberger, professor of chemistry at the Collège de France.—Legros, professor of phys. at Brussels.—G. Fissore, professor of med. path., Turin.—T. de Carvalho, professor emeritus of surgery, Lisbon. Cernea, professor of int. path. at Jassy.

MISCELLANY.

Personal. Dr. Frederick Holme Wiggin has been appointed a delegate from the New York State Medical Association to the British Medical Association meeting at Montreal.

Dr. W. W. Potter has been reappointed health officer of Spokane, Washington.

A Medical Lending Library has been recently opened in connection with M. Boas' medical book store in Berlin, which circulates valuable antiques as well as the most modern works.

A Museum of Hygienic and Sanitary Appliances, with a library of appropriate literature and a hall for addresses on this subject, has just been opened in Moscow.

The Professional Fifty-year Jubilees at V. Koelliker and Professor

Lefebvre have just been celebrated with affectionate zeal by their friends at Würzburg and Louvain, respectively. The former is 80.

Women to be Admitted.—It is understood that hereafter women will be admitted as students into the medical classes of the College of Physicians and Surgeons of Chicago.

Extirpation of Struma in Hypnosis.—The operation lasted forty-five minutes; no pain was felt and the patient recovered in nine days. She was a woman of 38, especially susceptible to hypnotic suggestion, which had previously relieved her of neuro-rheumatic pains several times. —*Cbl. f. Chir.*, June 26.

Chain Instead of Weights for Precision Scales.—The inconveniences of the tiny weights required for delicate scales have been obviated by the substitution of a chain fastened to the beam, graduated, and moved by a lever from outside the case. The chain is arranged so that weights can be used as usual when desired. Serrin, in *Nouveaux Remèdes*, June 24.

Monument Erected to Duchenne of Boulogne.—A portrait medalion of the great neuro-pathologist was uncovered with appropriate ceremonies recently in Paris, inserted in the wall of the pavilion that bears his name in the Hospital de la Salpêtrière. The bas relief below represents Duchenne applying the electrodes of an inductive machine on a patient, with the inscription: "Duchenne de Boulogne, 1806-1875, Electrification localisée. Physiologie des mouvements. Neuropathologie."

Exclusion of an Extensive Lupus with Skin Grafting.—Matagne describes in the *Gaz. Méd. de Liège*, June 17, his operation to relieve a girl of 16 of a lupus, 12 by 9 centimeters on the arm, which had developed fourteen years before, after vaccination with vaccine from another person. He tested the patient with tuberculin before attempting to operate, and completed the excision with transplantation of skin from the thigh. Five years have passed since without a relapse and the patient seems absolutely cured.

Production of Light by Living Creatures.—Dubois confirms authoritatively his recent announcement that the light produced by the pholas dactylus is caused by the combination of an enzyme insoluble in alcohol, soluble in water and destroyed by heat (luciferase), with a substance soluble in alcohol (luciferin). Both of these substances are found associated in the walls of the respiratory passages of the pholas, and can be extracted from the tissues by alcohol and water in turn. By combining the alcohol solution of luciferin and the aqueous solution of luciferase with plenty of oxygen the light is produced.—*Cbl. f. Phys.*, May 1.

Three Laparotomies on One Patient for Sarcoma of the Adnexa.—Five years after a septic adnexitis consecutive to a criminal abortion, a malignant sarcoma developed in a pyosalpinx; extirpation. One year later the sarcoma grew again in the adnexa and abdominal wound; extirpation, with slight injury to the intestine. Again the sarcoma developed in the intestinal wound, but extirpation this time was soon followed by the death of the patient. The necropsy showed fatty degeneration of the internal organs. There had been no metastasis of the malignant growth, which had been thus successfully fought for nine years.—*Cbl. f. Chir.*, June 26, from *Liecknicki viestnik*, No. 3, 1896.

National Charities Conference at Toronto, Canada, held early in July, was a symposium of excellent ideas, despite certain bureaucratic tendencies. Necessarily morals rather than sanitation or dispensary abuses claimed most of the attention of the readers and speakers. The veteran received a large share of attention during a morning session, and "Homes" were discussed in their practical phases and limitations. "Practical Charity and Jewish Methods" was the suggestive title of one paper, and the "Value of Investigation and Dangers Incident to it" was that of another. Children were well cared for,

as may be gathered from the subjects of the essays, an example being afforded by the address of William P. Letchworth of the State Board of Charities, New York, which was entitled "Dependent Children and Family Homes." We trust above all that pride of opinion did not mar the amenities of debate, and that clamor did not interfere with the enjoyments of reform.

"**About Children**" is announced by the *Medical Gazette* Publishing Company. The author is Dr. Samuel W. Kelley, Professor of Diseases of Children in the Cleveland College of Physicians and Surgeons, the editor of the *Gazette*. Advance orders will be filled in September.

The Mission Hospital at Sitka, Alaska, is doing splendid work. The building contains ten rooms and two large wards. It is in charge of a resident physician who lives in a cottage on the grounds. The matron and head nurse is a graduate of the Buffalo Hospital Training School. She has four native girls in the training school. The hospital was built for the care and the treatment of the children of the mission, but natives and even whites are admitted in emergency cases. During last year nearly 200 were treated in hospital and 1,160 were given dispensary relief; 93 surgical operations were performed.

The Birth Rates of France and America.—The lay press seems to be in the throes of a hot canvass over the relative morality of France and America, so far as suppression of their relative population is concerned. The *Chicago Inter-Ocean* furnishes the following summary: "While in France the birth rate is 22 per 1,000, in Nevada it is 16.30 per 1,000; in Maine, 17.99 per 1,000; New Hampshire, 18.4 per 1,000; Vermont, 18.5; California, 19.4; Connecticut, 21.3; Massachusetts, 21.5; Rhode Island has 22.5 per 1,000, a little more than France; Wyoming has 21.8 per 1,000, and Oregon 22.5. If it were not for immigration, the population would be gradually falling off, and according to statistics the inhabitants of New England and the Pacific coast will be replaced by another race within a period varying from sixteen to 200 years."

Koch's New Tuberculin.—Nencki, Maczewski and Logucki (*Presse médicale*, No. 46) publish some critical remarks on the new preparation of Koch, which merit the attention of the profession. Nencki observed while trying the new tuberculin on a patient, after every injection a considerable reaction with general indisposition, chills, fever, etc. Examining the tuberculin which he used for the injections he found it containing numerous pneumococci, staphylococci and streptococci. Two other bottles which he opened with every aseptic precaution contained the same bacteria. Inoculated on sterile nutrient media they grew very well. It seemed very probable that during the manufacture of the product, as published by Koch, a contamination could easily occur. In spite of this Koch does not believe that an improvement of his method can be thought of. It is evident that such contaminations can lead to considerable danger for the patient, and it will be necessary that the manufacturers furnish sufficient guarantees for absolute purity of their products by a severe and reliable control, before they can be generally tried as to their efficacy.

Population of Russia.—The St. Petersburg correspondent of the *New York Times* under date of June 10 writes: "The published reports of the Russian census, taken last January, are interesting from many points of view. According to the results now known, the population of the whole Russian Empire is a little less than 130,000,000. This is without counting certain provinces of Caucasia and Turkestan and the inhabitants of Northern Siberia, the exact figures of which have not yet reached St. Petersburg. St. Petersburg has 1,267,000 inhabitants; Moscow a little less than a million without the suburbs. The most interesting figures of the census are those concerning Warsaw and Odessa. The Polish capital, which in the

days of Polish independence had less than 50,000 people, now has a population of 615,000 souls. Odessa's rapid growth is even more remarkable, for a century ago it was nothing but a poor fishing village, and it now has over 400,000 inhabitants. The towns of Riga, Lodz, Tiflis and Astrakhan have likewise increased in a remarkable manner.

Tricks on the Charitable.—The New York State Board of Charities in reporting on the modes of placing out dependent children, states substantially that "the worst of these is by an individual claiming to represent the 'National Children's Home Society' of Chicago, under a charter granted by Illinois to the 'American Educational Aid Association.' Some three years since he applied for an incorporation of a branch of the society, which was refused. In spite of the failure to obtain approval, he has continued to solicit funds and place out children. He has been responsible, apparently, to no supervising authority for the funds which he has secured from the benevolent. As high as 40 per cent. of the subscriptions raised by this soliciting agent was by agreement retained by him."

Higher Medical Education.—The *Alchemist and Neurologist* (April, 1897) waxes wroth over "State medical detectors called examining boards" and refers to "a new proposition to examine the professors." The *reductio ad absurdum* is rather pertinently put by the question, "but if the faculties are to be examined by a board of examiners who will examine the examiners and attest their qualifications?" We agree in spirit with the paragraph that "defamation of American medical colleges by little mediocrities in medicine has about reached the limit of toleration by the friends of medical education in the profession." To this we may add the truism that critics are seldom originating geniuses.

More Rigor in Medical Examinations.—The Massachusetts medical practice act has been made more rigorous in operation by the decision of the State Board of Registration in Medicine to increase the requirements at examination. Formerly the graduates of medical schools were asked only two questions under each of five topics and the non-graduates five. Now all are required to be examined on ten, and they must average 70 per cent. on the total in order to pass. In recent examinations about 25 per cent. of the applicants have been rejected, and the proportion may be increased by the added restrictions. There will be no dearth, however, in the supply of doctors. At an examination this week the candidates numbered 225, and 24 of them were women. Under the operation of the law there has been, it is said, a distinct elevation of the practical ability and moral quality of the medical profession. It has resulted, also, in a marked improvement in some of the medical schools, which have stiffened their requirements.

Chronic Abscess of the Brain, with Rupture into the Frontal Sinus.—Zamzsal (*Wien. medizinische Presse*, June 26, 1897, p. 1190) has reported the case of a man, who complained of pain in the left frontal region, with intermissions and exacerbations. The left upper eyelid was the seat of a large cicatrix, resulting from a blow received eight years previously. The patient was lost to observation for nearly two years, when he returned on account of copious epistaxis. Other than the existence of albuminuria and enlargement of the left ventricle, with a slight peculiarity in speech and signs of mild mental perturbation, no abnormality was noted. Despite measures directed to the control of the epistaxis the bleeding was repeated, the symptoms grew gradually more pronounced, coma set in after the discharge of a considerable quantity of blood and pus from the nose, and death followed. Though no reference to post-mortem examination is made, the opinion is expressed that in consequence of the traumatism an abscess developed in the left cerebral hemisphere, rupturing after a long period of latency into the frontal sinus.

A Fifty-four Year Medical Course.—A medical student has just graduated in Warsaw, 75 years old. He commenced his course in 1843, but was forced to suspend it for lack of funds, and became a teacher for twenty years before he was able to return and resume it. He then partially completed the course when he became involved in the political uprising in Poland in 1863, and was sent to Siberia, where he worked in the mines for thirty-two years, when he was pardoned and returned to Warsaw to graduate at last.

The Old Pharmacopœia to be Used.—The supreme court of Ohio holds, in the case of *State v. Emery*, Dec. 1, 1896, that the reference, in Section 3 of the pure drug statute (87 Ohio Laws, 248), to the United States Pharmacopœia, is to the edition in general use when the statute was enacted, which was that of 1880. The sale of a drug, which was equal to the standard of strength, quality and purity laid down in that edition, it continues, is not rendered unlawful because it is below a higher standard laid down in a subsequently revised edition, though that edition was in general use when the sale was made. And a copy of the subsequent revised edition is not competent evidence on the trial of a prosecution under the statute. The reason given for this decision is that it is not to be supposed that the legislature intended to adopt, by reference, as part of the penal laws of the State, an edition not then in existence, and of which the legislature could then have no knowledge, and that to hold otherwise would be equivalent to holding that the revisers of the book could create and define the offense—a power which belongs to the legislative body, and can not be delegated.

Cyclotherapeutics.—M. Siegfried (Berlin, Nauhaim) has derived great benefit in certain cases from specially constructed tricycles with adjustable seats, pedals and cushions and made comfortable, and ordered as the therapeutic measure under the strict supervision of the physician, never allowing it as a sport to be indulged in at will. He describes in the *D. Med. Woch.* of July 1 the remarkable results attained in a few specimen cases of heart and spinal troubles, gout and relapsing polyarthritis, rheumatics with ankylosis of the joints and atrophy of the muscles. Patients confined for years to invalid chairs are restored to life and activity, attend to their business and take a daily tricycle ride alone. The cyclotherapeutic treatment is often extremely painful at first and is commenced very gradually, with baths, etc., with frequent intermissions. The special tricycles for this purpose are manufactured by the Adler bicycle works of Frankfurt-a.-Main.

Seal Upon Physician's Lips no Shield for Unlawful Acts. In the case of *Hauk v. State*, where the supreme court of Indiana affirmed a conviction of producing an abortion, the court holds, Feb. 16, 1897, that the rule declared by the statute, which forbids a physician to reveal in evidence matters discovered by him in the course of professional attendance or treatment of a patient, is intended to protect the latter and not to shield one who is charged with perpetrating an unlawful act upon the patient. The statute, it insists, can not be so construed as to permit a party charged with crime to invoke it as a weapon of defense in his own favor instead of its being used as a protection to his victim. This interpretation, in its opinion, accords with reason and is supported by authority. On these grounds the court holds that it was not error to permit the physician who attended the patient in question, at the request of the defendant, at the time of her alleged miscarriage, to give evidence of what he discovered upon an examination of his patient during his attendance, and also the fact that the miscarriage occurred while he was present as her physician. The fact that her death may have resulted from the improper treatment of her physician or otherwise, it further holds, would not operate to defeat the conviction, under the statute, of the one who produced her miscarriage by an unlawful antecedent act.

Gleanings.—*Extractum secale cornutum* found a specific for diabetes insipidus in two cases by M. Benedikt. Dose: 3 grams in fifteen doses for five days. . . . Case of chronic diphtheria complicating erysipelas, resisting serum treatment, in observation four months (Jessen). . . . Perforating peritonitis from gastric ulcer, treated by absolute deprival of food and drink by mouth or rectum; large doses of opium and two to three injections a day of salt solution, 300 to 500 c.c., which prevented thirst and kept the circulation normal. Complete recovery (Lenhartz), *D. Med. Woch.*, July 1. . . . Pulmonary lithiasis in girl of 19, twenty calculi, largest weighed 2 centigrams. *J. de M. de Paris*, June 27. . . . Felix Semon, the German laryngologist in London, created a baronet during the Jubilee. . . . To supply air to cultures of the Koch bacillus to promote growth, Lucatello starts the colony on a strip of gauze suspended in a 2 liter jar, with the lower end touching the glycerined bouillon. . . . Experiments with ovarian juice in twenty-five cases showed no effect except upon the nervous system, which was excited, especially the sexual sphere. *Gaz. degli Osp. e delle Clin.*, June 20. . . . Virulent pathogenic germs of anthrax found in the feces of immunized animals. *Gaz. degli Osp. e delle Clin.*, June 17. . . . Success of the permanent sound and deambulation in troubles caused by hypertrophied prostate (Bazy). As efficient as surgical intervention. . . . New sign of tricuspid insufficiency, a pulsation in the second intercostal space, near the left edge of the sternum. *Presse Méd.*, June 12. . . . Violent fever, hypertrophied spleen, etc., lasting a week, with albuminuria, caused by a twenty-nine hour bicycle ride. Another case had a four week typhic fever after riding 45 kilometers, with phlebitis, myositis and myocarditis. Both typical auto-intoxication from over-exertion. *Presse Méd.*, June 12.

Study of the American Medicinal Flora.—The Sub-commission of the Pan-American Medical Congress appointed to study the medicinal plants of the United States has entered into an association with the Smithsonian Institution for that purpose. The attention of our readers is called to the respective circulars issued by these organizations as follows:

"The Smithsonian Institution has undertaken to bring together all possible material bearing on the medicinal uses of plants in the United States. Arrangements have been made with a body representing the Pan-American Medical Congress, the Sub-commission on Medicinal Flora of the United States, to elaborate a report on this subject, and the material when received will be turned over to them for investigation. The accompanying detailed instructions relative to specimens and notes have been prepared by the Sub-commission. All packages and correspondence should be addressed to the Smithsonian Institution, Washington, D. C., and marked on the outside '*Medicinal Plants for the U. S. National Museum.*' Franks which will carry specimens, when of suitable size, together with descriptions and notes, free of postage through the mails, will be forwarded upon application. Should an object be too large for transmission by mail the sender is requested, before shipping it, to notify the Institution, in order that a proper authorization for its shipment may be made out.

[Signed]

S. P. LANGLEY, Secretary."

Instructions Relative to Medicinal Plants.—The Pan-American Medical Congress, at its meeting held in the City of Mexico in November 1896, took steps to institute a systematic study of the American medicinal flora, through the medium of a general commission and of special Sub-commissions, the latter to be organized in the several countries. The Sub-commission for the United States has been formed and consists of Dr. Valery Havard, U. S. A., Chairman; Mr. Frederick V. Coville, Botanist of the U. S. Department of Agriculture; Dr. C. F. Millsbaugh, Curator of the Botanical Department of the Field Columbian Museum, Chicago; Dr. Charles Mohr, State Botanist of Alabama; Dr. W. P. Wilson, Director of the Philadelphia Commercial Museums; and Prof. H. H. Rusby of the New York College of Pharmacy. This Sub-commission solicits information concerning the medicinal plants of the United States from every one in a position to accord it. The principal points of study are as follows:

1. Local names.
2. Local uses, together with historical facts.
3. Geographical distribution and degree of abundance in the wild state.
4. Is the plant collected for market, and if so, *a.* At what season of the year? *b.* To how great an extent? *c.* How prepared for market? *d.* What is the effect of such collection upon

the wild supply? *c.* What price does it bring? *f.* Is the industry profitable?

5. Is the plant, or has it ever been, cultivated and if so give all information on the subject, particularly as to whether such supplies are of superior quality, and whether the industry has proved profitable.

6. If not cultivated, present facts concerning the life history of the plant which might aid in determining methods of cultivation.

7. Is the drug subjected to substitution or adulteration, and if so, give information as to the plants used for this purpose.

While it is not expected that many persons will be able to contribute information on all these points concerning any plant, it is hoped that a large number of persons will be willing to communicate such partial knowledge as they possess. It is not the important or standard drugs alone concerning which information is sought. The Sub-commission desires to compile a complete list of the plants which have been used medicinally, however trivial such use may be. It also desires to collect all obtainable information, historical, scientific and economic, concerning our native and naturalized plants of this class, and, to that end, invites the coöperation of all persons interested. Poisonous plants of all kinds come within the scope of our inquiry, whether producing dangerous symptoms in man, or simply skin inflammation, or, as "loco-weeds," deleterious to horses, cattle and sheep. In this respect, the general reputation of a plant is not so much desired as the particulars of cases of poisoning actually seen, or heard from reliable observers. It is believed that much interesting knowledge can be obtained from Indians, Mexicans and half-breeds, and that, consequently, Indian agencies and reservations are particularly favorable fields for our investigation. Such knowledge will be most acceptable when based upon known facts or experiments.

In order to assist in the study of the habits, properties and uses of medicinal plants, the Sub-commission undertakes to furnish the name of any plant-specimen received, together with any desired information available. Owing to the diversity in the common names of many plants it will be necessary for reports, when not furnished by botanists or others qualified to state the botanic names with certainty, to accompany the same with some specimen of the plant sufficient for its identification. While the Sub-commission will endeavor to determine the plant from any portion of it which may be sent, it should be appreciated that the labor of identification is very greatly decreased, and its usefulness increased, by the possession of complete material, that is, leaf, flower and fruit, and in the case of small plants, the underground portion also. It is best to dry such specimens thoroughly, in a flat condition under pressure, before mailing. While any convenient means for accomplishing this result may be employed, the following procedure is recommended: Select a flowering or fruiting branch, as the case may be, which when pressed shall not exceed sixteen inches in length by ten inches in width. If the plant be a herb two or three feet high, it may be doubled to bring it within these measurements. If it possess root leaves, some of these should be included. Lay the specimen flat in a fold of newspaper and place this in a pile of newspapers, carpet felting, or some other form of paper which readily absorbs moisture, and place the pile in a dry place under a pressure of about twenty to thirty pounds, sufficient to keep the leaves from wrinkling as they dry. If a number of specimens are pressed at the same time, each is to be separated from the others by three or four folded newspapers or an equivalent in other kinds of paper. In twelve to twenty-four hours these papers will be found saturated with the absorbed moisture and the fold containing the specimen should be transferred to dry ones. This change should be repeated for from two to five days according to the state of the weather, the place where the drying is done, the fleshiness of the specimens, etc. The best way to secure the required pressure is by means of a pair of strong straps, though weights will do. The best place for drying is beside a hot kitchen range. When dry the specimens should be mailed between cardboards or some other light but stiff materials which will not bend in transit. It is a most important matter that the name and address of the sender should be attached to the package and that the specimens, if more than one, should be numbered, the sender retaining also specimens bearing the same number, to facilitate any correspondence which may follow. The Sub-commission requests that, so far as practicable, all plants sent be represented by at least four specimens.

[Signed]

H. H. RUSBY, M.D.,

Chairman of the General Commission, New York Coll. of Phar.

VALERY HAVARD, M.D.,

Chairman of the Sub-commission, Fort Slocum, David's Island, New York.

Washington.

WASHINGTON ASYLUM HOSPITAL.—The Commissioners have appointed Dr. D. Percey Hickling visiting physician to the Washington Asylum Hospital.

CORONER APPOINTED.—The Commissioners have appointed Dr. William P. Carr the coroner for the District of Columbia, vice Dr. Charles M. Hammett resigned.

A DEATH FROM HYDROPHOBIA. Health Officer Woodward, Deputy Coroner Glazebrook, Drs. Thompson, Barker and Winter have made a postmortem examination of the case of the young man who died during the present week of supposed hydrophobia, from a dog bite, and will have a bacteriologic test made by Professor Norgaard of the United States Agricultural Department. This is the first time the human body has been so examined in the District.

A NEW QUIZ CLASS.—Dr. F. S. Nash, late U. S. N. has started a quiz class to prepare physicians for entering the medical department of the Army and Navy and Marine-Hospital Service.

HOSPITAL BABIES MAY CRY.—The crying of infants in the Washington Hospital for Foundlings has been the cause of considerable complaint by residents in that vicinity and resulted in a charge of "nuisance" being preferred to the courts and investigated by the grand jury. The grand jury refused to indict the Hospital as a nuisance or gag the babies, and makes the following report: "Complaint having been made in due form of the Washington Hospital for Foundlings as a nuisance, we, the grand jurors, after careful inspection and investigation, hereby submit the following report: We personally visited the Washington Hospital for Foundlings, and found the same to be in excellent sanitary condition and a well-conducted institution. While there is some annoyance from the crying of babies during the warm season, as has been testified to by reputable citizens, we know of no remedy to stop it, and do not think the grievance of those complaining sufficient to justify us in declaring this humane and useful institution a nuisance. We recommend, however, that the authorities be requested and, if possible, required to double their present force of nurses for night duty, as the present force is inadequate to properly care for the children. We further recommend that if it be possible to do so, the children be removed to the country during the heated term. Should a suitable place be obtained for these helpless infants during the warm months it would be of great benefit to the children, besides removing the existing cause of complaint of the residents, as they allege no annoyance at other seasons."

ANNUAL REPORT OF THE HEALTH OFFICER.—The annual report of Health Officer Woodward has been transmitted to the Commissioners of the District and is now printed as a public document. There occurred during the year 5,737 deaths. Of these 3,216 were white and 2,521 were colored. The general death rate was 20.71 per thousand. This is the lowest point reached for the past twenty-two years. A satisfactory feature of the year's mortality table is the very considerable diminution in the deaths from "zymotic diseases." The entire number of such deaths recorded was 891, while during the preceding year it was 1,054. In certain diseases of this class the death list shows an increase. Thus the number of fatal cases of diphtheria rose from 75 to 110; of whooping-cough, from 22 to 65, and of grip from 53 to 118. The decrease in the total number of deaths of this class is accounted for by the diminution in the number of fatal cases of measles from 70 to 3; of scarlet fever from 13 to 1; of croup (so-called), from 9 to 6; of typhoid fever, from 228 to 147; of malarial fever (so-called), from 84 to 57, and of diarrheal diseases, from 468 to 358. The number of deaths from diphtheria has not during any previous year fallen so low since 1889. The actual number of cases of this disease which were reported was 618. There is no previous record of any year with but a single death from scarlet fever. He says while it is not entirely safe to base conclusions upon this improvement in the death rate for a single year, yet its coincidence with the closing of a very considerable number of surface wells; with the replacement of more than a thousand box-prives by water-closets, and the proper drainage of the premises; and with a closer supervision of the milk supply

is very suggestive of some relation of cause and effect, and possibly justifies us in expecting still further improvement in the future. The present fall in the typhoid fever death rate is especially satisfactory, as it had continually increased since 1887. The death rate from this disease for the past year (.53 per thousand) is the lowest since 1884, and is considerably lower than that for the past twenty-two years (.64). The number of deaths from tuberculosis was 858, while during the preceding year there were 977. The number of deaths from suicide was 57, an increase of 9 over the corresponding figures for the preceding year, and an increase of 6, or almost 15 per cent. over the highest number previously recorded. The average number of suicides per annum during the past twenty-two years has been 17.2. The number of births reported was 4,573, which is probably at least one-third less than the number which actually occurred, owing to the carelessness of the physicians in making the returns.

THE PUBLIC SERVICE.

Army Changes. Official List of Changes in the Stations and duties of officers serving in the Medical Department, U. S. Army, from July 17 to 23, 1897.

First Lieut. Henry R. Stiles, Asst. Surgeon, so much of the order as directs him to report for duty, is amended so as to direct him to report for duty at Ft. Preble, Maine, relieving Capt. Henry S. T. Harris, Asst. Surgeon.

Capt. Robert R. Ball, Asst. Surgeon (Ft. Adams, R. I.), extension of leave of absence granted is extended until Oct. 15, 1897.

Capt. Marlborough C. Wyeth, Asst. Surgeon, upon the arrival of Lieut. Lewis at Ft. McPherson, Ga., will take station at Baltimore, Md., and assume the duties of attending surgeon and examiner of recruits, relieving Capt. W. Fitzhugh Carter, Asst. Surgeon. Capt. Carter will report Oct. 4, 1897, for examination as to his fitness for promotion, and on completion thereof ordered to Ft. Assiniboine, Mont., relieving Capt. George E. Bushnell, Asst. Surgeon. Capt. Bushnell, upon being thus relieved, ordered to take station at Boston, Mass., and assume duties of attending surgeon and examiner of recruits.

Capt. George McCreery, Asst. Surgeon, is relieved from duty as attending surgeon and examiner of recruits at Boston, Mass., and ordered to report at the Soldiers' Home near Washington, D. C., for temporary duty, relieving Capt. Charles M. Gandy, Asst. Surgeon.

Capt. Walter D. McCaw, Asst. Surgeon, upon the arrival of Capt. Wells at Ft. Ringgold, Texas, is relieved from duty at that post, and ordered to Ft. Thomas, Ky., for duty.

First Lieut. Benjamin Brooke, Asst. Surgeon, is relieved from duty at Ft. Thomas, Ky., and ordered to Army and Navy General Hospital, Hot Springs, Ark., for temporary duty at that hospital.

Capt. Frank R. Keefer, Asst. Surgeon, is relieved from duty at Washington Bks., D. C., to take effect upon the expiration of his present leave of absence, and ordered to Ft. Sam Houston, Texas, for duty.

First Lieut. Alexander N. Stark, Asst. Surgeon, upon the arrival of Capt. Keefer at Ft. Sam Houston, is relieved from duty at that post, and ordered to Washington Bks., D. C., for duty.

Capt. Charles M. Gandy, Asst. Surgeon, upon the arrival of Lieut. Stark at Washington Bks., is relieved from duty at that post, and ordered to Ft. Mason, Cal., relieving Capt. George M. Wells, Asst. Surgeon. Capt. Wells, on being thus relieved, ordered to Ft. Ringgold, Texas, for duty.

Capt. Henry S. T. Harris, Asst. Surgeon, on being relieved at Ft. Preble, is ordered to Ft. Washakie, Wyo., relieving Capt. Joseph T. Clarke, Asst. Surgeon. Capt. Clarke, on being thus relieved, is ordered to Columbus Bks., Ohio.

So much of paragraph 16, S. O. 162, A. G. O., July 16, 1897, as relates to the officers hereinafter named is amended to read as follows:

Capt. Frank R. Keefer, Asst. Surgeon, is relieved from duty at Washington Bks., D. C., to take effect upon expiration of his present leave, and ordered to Ft. Walla Walla, Washington, for duty.

Capt. William D. Crosby, Asst. Surgeon, upon being relieved from duty at Ft. Missoula, Mont., is ordered to Ft. Sam Houston, Texas, for duty.

First Lieut. Alexander H. Stark, Asst. Surgeon, upon arrival of Capt. Crosby at Ft. Sam Houston, Texas, is ordered to Washington Bks., D. C., for duty.

Capt. Henry S. T. Harris, Asst. Surgeon, upon being relieved from duty at Ft. Preble, Maine, by First Lieut. Henry R. Stiles, Asst. Surgeon, is ordered to Ft. Washakie, Wyo., for duty, relieving Capt. Joseph T. Clarke, Asst. Surgeon.

Major William C. Shannon, Surgeon (Jackson Bks., La.), leave of absence granted on surgeon's certificate of disability is extended three months on surgeon's certificate of disability.

Major Paul R. Brown, Surgeon (Ft. Hamilton, N. Y.), ordered to report to Col. Charles C. Byrne, Asst. Surgeon-General, president of the Army retiring board, appointed to meet at Ft. Columbus, N. Y., for examination by the board.

First Lieut. William E. Richards, Asst. Surgeon, is relieved from duty at Ft. Grant, Ariz., and ordered to report Sept. 20, 1897, for duty at Ft. Apache, Ariz.

First Lieut. William F. Lewis, Asst. Surgeon, upon the arrival of Lieut. Richards at Ft. Apache, Ariz., is ordered to Ft. McPherson, Ga., for duty.

Capt. William H. Arthur, Asst. Surgeon, will be relieved from duty at Ft. Myer, Va., on Oct. 1, 1897, and ordered to Philadelphia, Pa., and assume duties of attending surgeon and examiner of recruits, relieving Capt. Rudolph G. Ebert, Asst. Surgeon. Capt. Ebert, upon being thus relieved, ordered to report Oct. 4, 1897, for examination for promotion, and upon completion thereof ordered to take station at Ft. Missoula, Mont., relieving Capt. William D. Crosby, Asst. Surgeon. Capt. Crosby, on being thus relieved, is ordered to Ft. Preble, Maine, relieving Capt. Henry S. T. Harris, Asst. Surgeon.

Capt. Charles M. Gandy, Asst. Surgeon, is granted leave of absence for two months and ten days, to take effect upon being relieved from temporary duty at the Soldiers' Home near Washington, D. C., and will, upon the expiration of leave of absence, report for duty at Ft. Mason, Cal.

ORIGINAL ARTICLES.

RHEUMATOID ARTHRITIS, WITH REPORT OF TWO CASES.

Presented to the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, at Philadelphia, Pa., June 1-4, 1897.

BY DAVID RIESMAN, M.D.

ADJUNCT PROFESSOR OF CLINICAL MEDICINE, PHILADELPHIA POLYCLINIC;
DEMONSTRATOR OF PATHOLOGIC HISTOLOGY, UNIVERSITY
OF PENNSYLVANIA.
PHILADELPHIA, PA.

Despite the increasing literature on the subject of rheumatoid arthritis, the ultimate nature of the disease is far from clearly established, and even at this date we do not positively know just what affections of the joints should be grouped under the name. Nothing so clarifies the nosographic atmosphere as the discovery of causes—only through causal knowledge are we able to separate diseases that are similar and to assign to them a definite place in our systems. How easy it has become for us to define typhoid fever, diphtheria, and malaria, since their etiology has been determined. As we are still unable to point out the true cause of rheumatoid arthritis, it would, I believe, be better, following the example of Virchow, Garrod, and others, to use the phrase *arthritis deformans*, as that expresses the most prominent symptom and is non-committal on the score of pathogenesis.

Morbid anatomy.—The lesions produced by arthritis deformans vary considerably with the period or stage reached by the disease. The earliest changes probably always take place in the articular cartilage, and consist in a perpendicular fibrillation of the hyaline matrix of the surface layers. Almost synchronous with this is a proliferation of the cartilage cells. Softening and fatty processes develop later and cause erosion and disappearance of the cartilage, especially at the lateral parts of the joints, where pressure is greatest. Islands of cartilage may remain and undergo thickening. In the deeper parts of the cartilage ossification may take place. Very marked alterations also affect the synovial membrane and capsular ligament, which become irregularly thickened and distended from the formation of numerous villous processes. Chondrification and even ossification may take place in the latter, and by detachment free bodies may be formed. The bone changes are very striking. In those places where the cartilage is eroded, friction leads to polishing of the exposed bone. In the subchondral areas bone absorption takes place—here it can not be due to friction—and the amount of destruction may reach astounding proportions. While all these changes are in progress new bone is being formed in other parts of the joint, and thereby extensive irregular osteophytic outgrowths are produced, which may entirely surround the joint and contribute to the enlargement. Partial or complete ankylosis,

not rarely in strange positions, is a common terminal result.

At times the disease is strictly limited to parts of the articular surfaces, as in the cases reported by Bennett.¹ In one of these the scapulo-humeral joint was normal, but the lesser tuberosity of the humerus was ground down to its base and the inner lip of the

bicipital groove was gone. In a radius, from another case, the depression for the scaphoid bone was cut clean away, while the fossa for the semilunar bone was free from disease.

Next to the arthritis the most important morbid change is an atrophy of the muscles in the neighbor-

¹ Bennett: Dublin Jour. Med. Sc., 1895, C., p. 383.

hood of the affected joint. The muscles are paler than normal, and microscopically are seen to be smaller, but their striation is preserved.

The symptoms and manifestations of arthritis deformans permit us to distinguish several clinical varieties which, following in the main the systematic writers, I would designate as follows: 1. *Arthritis deformans* of severe type. 2. *Arthritis deformans* of mild type. 3. *Localized form*, and perhaps, 4. *Arthropathy*, or that form associated with gross lesions of the nervous system. Although it is customary to separate sharply the severe form from the mild, we must admit that there are many gradations bridging the chasm between the mildest, Heberden's nodes, and the severest, the terribly deforming variety.

rather unsightly than inconvenient, though they must be some hindrance to the free use of the fingers." (Commentaries, 1818, p. 109.) The affection gives rise to an enlargement of the terminal joints of the fingers, which may be spindle-shaped or abruptly nodular; in time, deflection of the last phalanx occurs, and, differing from the hand as a whole, which is tilted toward the ulnar side, it takes place toward the radial side. There is also a slight rotation. It is commonly stated that the thumb is not affected, but while, as a rule, it escapes, it does not always do so, and I have recently seen two cases in which it was involved. Heberden's nodes are found most commonly in women, and begin to develop at the menopause or later. They occur also at an earlier period before the catamenia have ceased

Time is too brief to enter into the symptomatology of the various forms, but I would call your attention to the revelations of the Roentgen ray when employed in the study of this disease, by passing around these radiographs kindly made for me by Dr. Stern. It may not be out of place to say a few words about the nodes to which Heberden called attention in the following words: "What are those little hard knobs (*digitorum nodi*) about the size of a small pea, which are frequently seen upon the fingers, particularly a little below the top near the joint? They have no connection with the gout, being found in persons who never had it; they continue for life, and being hardly ever attended with pain or disposed to become sores, are

I show a pencil sketch of a hand (p. 259) the seat of early rheumatoid changes, from a woman of 40, in whom the disease developed two years ago, a month after an attack of diphtheria. I may add that the patient has had three attacks of articular rheumatism, the last fifteen years ago, and has suffered for a number of years from exophthalmic goiter. Menstruation is regular.

Although the disease, when it manifests itself as Heberden's nodes, shows usually no tendency to spread, I have seen it do so in some cases that were under 50 years of age when the malady commenced. (In one patient it was associated with deformity and stiffening of the wrists.) For this reason I have ven-

tured to assert that we can not separate Heberden's nodes sharply from the other forms, and am of the opinion that they are a manifestation of the same disease and are not a variety of gout. As we see the condition in aged women and men, it is generally not progressive.

Heberden's nodes are very common in women who have done much washing, but I have seen them in those who have never toiled at the wash-tub.

When we come to consider the pathogenesis of the disease, we are confronted by a multiplicity of theories that is quite perplexing. They may be classified in the following way:

1. *That the disease is a form of chronic rheumatism*, a theory maintained by Tooth, Charcot, Mitchell Bruce and others. Against this may be urged: *a*, the rarity of endocarditis and other visceral lesions in arthritis deformans; *b*, the exciting causes of true rheumatism can generally not be traced in the typical severe form of the other disease; *c*, the frequency of the affection in women, the reverse being true in the case of rheumatism; *d*, the usual failure of the salicylates.

2. *That the disease is a product of the mixture, in varying proportions, of the inherited taints of rheumatism and gout*, causing in one case the gouty element, in another the rheumatic element to preponderate.

3. *That it is allied to gout and is due to uric acid*, which causes the joint changes, but is again dissolved out, while in gout it remains in the joints (Haig). The view that arthritis deformans is a modified form of gout has long been abandoned. The factors leading to the development of the two diseases are totally

different; the preponderance of the female sex, the absence of tophi, the occurrence of arthritis deformans in early childhood, all serve to distinguish it from gout.

4. *That it is of nervous origin*. In favor of this are the symmetric distribution of the lesions, the muscular atrophies, the absence of visceral lesions, and the general *bien-être* of the patients, which in a sense corresponds with that seen in many cases of chronic spinal sclerosis. The nervous theory appears under several phases: *a*, It has been held, as suggested many years ago by J. K. Mitchell, that arthritis deformans is primarily a *spinal disease*. The great resemblance between the joint changes of rheumatoid arthritis and the arthropathies of tabes dorsalis and syringomyelia might seem to lend support to this view; however, in true rheumatoid arthritis the spinal cord, when examined, has always been found normal. Yet there may be nutritive changes in the cord that elude our search. *b*, The disease has been ascribed to a *peripheral neuritis*, largely on the strength of the changes found (Pitres and Vaillard) in the nerves contiguous to the joints, but these neuritic phenomena are more likely consequential or at the most synchronous rather than antecedent, and accompany arthritic muscular atrophies of other kinds. *c*, The disease is a *trophic affection*—a trophoneurosis. Under the vague head of trophoneuroses we are accustomed to class a number of affections, such as scleroderma, Raynaud's disease, acromegaly, characterized by marked structural changes, for which we have no satisfactory explanation. The nervous system undoubtedly governs the nutrition of all parts of the body, whether by reason of its power to regulate the blood supply or through the exercise of a direct trophic influence, must for the present be left unanswered. It is conceivable that, as the joints are under the control of the same forces, a disturbance of the latter might bring about nutritional changes in the articular structures. But the factor that underlies the nervous disturbance remains hidden. *d*, *Uterine or utero-ovarian irritation* acting reflexly through the nervous system (Ord, Armstrong).

5. *That it is infectious*. This view was first promulgated by Schueller (Laugenbeck's *Archiv. klin. Chir.*, 1892, Bd. 45, Heft 1; *Berlin. klin. Woch.*, 1893, Sept. 4), who found a bacillus in the joints with cultures of which he was able to produce articular changes in animals quite analogous to those observed in man. More recently Bannatyne, Wohlmann and Blaxall (*Lancet*, April 25, 1896) have found a peculiar bacillus, both in the joints and at times in the blood, with which, however, they were not successful in producing unequivocal joint changes in animals.

I have given these theories at some length, with comments upon some, but in the end it can only be said that our present knowledge does not warrant a final decision on the question of the pathogenesis of arthritis deformans.

It is unnecessary to enter into a detailed account of the symptoms of the severe form, that associated with marked deformity and great restriction in mobility of the joints. I give here a summary of two cases, as they illustrate the symptoms quite well:

Case 1.—Mrs. F., whom I saw with Dr. Clarke of Philadelphia, was born in Pennsylvania, of Irish parents. She has been married sixteen years and has had eight children, the youngest of whom is 5 years old. The family history is exceptionally good. Mrs. F. was never very strong; menstruation began at 12 years of age, and was always regular except when inter-

rupted by pregnancy and lactation. From her 17th to 38th year, the latter being her age at the time the present disease began, she was subject every spring and fall to peculiar weak spells characterized by palpitation and a feeling of debility. Ten years ago she had an attack of acute cystitis. The *arthritis deformans* began five years ago, during her last pregnancy, with pains, soreness, and stiffness in the cervical vertebrae, and on the evening before her confinement the left shoulder and arm became similarly affected. During the puerperium the other joints were involved in the following order: Right shoulder, right knee and ankle, left knee and ankle, and by the end of the sixth week both elbows, wrists, and hands. She also had slight stiffness, soreness, and tenderness in the temporomaxillary joints. Pain has disappeared in the joints most severely diseased. Her present condition is as follows: The left elbow is somewhat enlarged, especially on the inner side, and slightly flexed; pronation and supination are restricted, and there is distinct grating on movement. The left wrist is quite stiff, backward motion being particularly limited; grating is also present. The natural contour of the wrist has disappeared, and the forearm, wrist, and hand present a continuous, unbroken outline. The back of the hand is sunken in, and the knuckles are unduly prominent. There is atrophy of the interossei and of the thenar and hypothenar eminences. Preternatural mobility of all the knuckle joints, including the metacarpophalangeal joint of the thumb, is present. The middle joints of the fingers are slightly enlarged and tender to the touch; the last joints are apparently free from disease, but with that of the thumb are hyperextended. The right elbow is enlarged and partly flexed; rotation and supination are more limited than on the left side, and the wrist is completely ankylosed and immovable. The right hand is almost like the left, except that the hyperextension of the last joints is confined to the middle and ring fingers, and is but slight. There is marked roughening and grating of the knuckle joint of the right index and enlargement of the head of the metacarpal bone. The finger is so loose that it can be rotated in a considerable arc on its longitudinal axis. Pain is absent in the joints. The nails of both hands tend to be longitudinally ridged. The cervical spine is affected, the rotary movements of the head being embarrassed. There is impaired mobility of both shoulder joints.

Lower extremities.—The right knee is enlarged and its motion impaired, especially extension. The patella does not float; the synovial capsule is thickened. Motion gives rise to pain and to cracking audible at a distance. The movements of the right ankle are impaired; the toes are stiff, but not markedly deformed. There is slight edema of the leg. The left knee is less affected than the right; the edema of the foot and leg is marked.

Upon moving the larynx a loud, rasping and grating sound is produced by the friction of the roughened cartilages on each other; the voice is somewhat hoarse. The joints of the lower jaw are slightly stiff and the mouth can not be opened to its full width. The thyroid gland is not enlarged. Hands and feet are cold and moist; sweating of other parts, the patient says, is rare. There is no pigmentation except on the instep, ankle joint, and lower part of the leg; its appearance was preceded by a severe burning sensation in the pigmented areas. The heart sounds are normal, the pulse 112. The patient enjoys fair general health and has a good appetite. She has used crutches for a year, but walks with great difficulty and is absolutely unable to climb stairs. She is gradually getting shorter in height on account of increasing flexion of the knees. Blood examination: hemoglobin 80 per cent.

Of special interest in this case are the involvement of the laryngeal cartilages, the absence of pain in the articulations most extensively diseased, and the great resemblance which the joints bear in their appearance to the arthropathies of spinal diseases. It is worthy of note, too, that the arthritis began during pregnancy.

Rheumatoid arthritis, like diabetes mellitus, appears to be more baneful the younger the patient attacked. In adolescence and early adult life recoveries are rare. The following case illustrates the possibility of arrest and partial cure of the disease:

Case 2.—Miss Martha M., a milliner, 23 years of age, was always healthy, fond of society, and a passionate dancer. Constipation and occasional headaches were her only ailments. The family history is of interest, as the mother is a sufferer from a rather severe form of rheumatoid arthritis the disease came on at middle life and began with the formation of Heberden's nodes. The father is afflicted with chronic bronchitis and emphysema, and is subject to digestive dis-

turbances, probably lithemic in nature. In the summer of 1893 Miss M. visited the World's Fair, and very injudiciously wandered about the grounds every day until almost exhausted. On her return she went to Atlantic City, and one day, September 4, while bathing had a chill, but recovered quickly and walked with friends until very tired. On the following morning she had a peculiar pricking feeling in the bottom of both heels, which abated somewhat the next day, but did not entirely disappear. Very soon it spread to the balls of the toes on the right foot and later also to those of the left. On Sept. 25, 1893, having stood at the ironing-board for two hours, the pain in the feet became excruciating, and she felt as if she were "walking on hair-brushes." She also experienced acute darting pains in the region of the heart, which somewhat hampered breathing. She was compelled to remain in bed for some time, but had no fever. The metacarpophalangeal joint of the right thumb and the right wrist now became diseased, and were swollen and stiff on motion. She had to be carried down stairs, but was for some time able to walk up stairs unaided. When lying down or sitting with the feet elevated she had no pains. From October 14 she was in bed three weeks, but without any benefit, and at the beginning of 1894 the great-toe joints, the ankles, and the knees became swollen and stiff. She was unable to stand on her feet; it seemed to her as if they were terribly bruised and unable to bear the weight of her body. Her appetite was good and apart from the joint trouble she had no complaint except transitory precordial pains.

I saw the patient at her home March 6, 1894. She was a tall, pale, blonde young woman, fairly well nourished and refined. The left ankle was swollen, but there was no pitting, tenderness or redness of the skin. Both feet seemed to be unnaturally thick, yet were well arched; severe pain was caused by compressing the toes at the heads of the metatarsal bones. The metacarpal joint of the right thumb was greatly enlarged, through an increase in size of the head of the metacarpal bone. Abduction of the thumb was restricted. There was neither tenderness nor spontaneous pain; considerable atrophy of the first dorsal interosseous muscle existed. The grasp of the right hand was almost *nil*. The right wrist was enlarged but not painful or tender; pronation and supination as well as flexion of the right forearm were greatly limited. A soft blowing systolic murmur was audible at the apex of the heart. The bowels were so constipated as to yield only to enemata.

The treatment first employed consisted in alternate hot and cold douches; they were of no benefit. Counter-irritation was also fruitless. On March 14 she had a febrile attack, during which the heart murmur grew louder, gallop-rhythm was superadded, and a soft systolic murmur became audible at the aortic cartilage. Dr. S. Solis-Cohen saw her with me at this time. Under the use of ammonium salicylate the acute symptoms rapidly vanished, but despite various forms of local and internal medication the joint disease progressed, spreading from the ankles, which were both involved, to the knees. The latter became irregularly enlarged and painful, and assumed a state of flexion, but were neither red nor tender to the touch. By May the flexion was very pronounced, the patient being unable to stretch the legs. I then applied an extension apparatus, such as is used for fractured thigh, to both legs, and was able to secure complete extension in about six weeks.

The patient's temperature was as a rule normal or but slightly elevated; the pulse was rapid, 96 to 100; the extremities, particularly the hands and feet, cold and clammy. At long intervals slight febrile movements occurred, rarely lasting more than twenty-four to forty-eight hours. The tongue was nearly always coated, but the appetite and the digestion were usually good. The knee jerks were exaggerated, and there was ankle-clonus; the plantar reflex was present. Sensibility to touch, heat, and cold was not disturbed. The atrophy of the first dorsal interosseus of the right hand grew perceptibly greater; gradually, too, the power of movement in the hand and arm became so restricted that the patient could not comb her hair, and had to feed herself entirely with the left hand. The urine was variable, but usually had a high specific gravity, 1028-1036; once it was only 1011; on one occasion it reduced bismuth subnitrate and turned Fehling's solution green without precipitation; it was free from albumin, and often alkaline in reaction.

Toward the end of June a marked but transitory improvement occurred. In July the dorsal portion of the spine became stiff and painful and the trunk movements restricted. A blister was applied and proved very efficacious; the disease did not spread and perfect suppleness gradually returned. In August the patient's condition was very bad; all the affected joints, feet, ankles, knees, right wrist and hand, were stiff; the skin over the small joints was cyanotic; and she complained of shooting pains in the joints and stiffness of the neck. The

right index and right thumb were preternaturally movable, and distinct grating could be heard and felt. In September the darting pains attacked the left thumb and an enlargement of the metacarpophalangeal joint followed. About this time Dr. Pepper saw her with me and agreed as to the nature of the case. At his suggestion, hypodermic injections of the double chlorid of gold and sodium were given twice daily. Later on I placed the patient on thyroid extract, but almost immediately alarming toxic symptoms, those of thyroidism, developed, and the remedy had to be abandoned. Throughout these months she was taking tonics, cod liver oil, arsenic, syrup of the iodid of iron, etc., and also received inunctions of cod liver oil; occasionally salicylates were given; faradic electricity was also tried. By November the legs had again become flexed and extension was reapplied and kept on for two and a half months. Bone-marrow was administered for a few weeks in 1895, but without practical result. The disease continued to advance—the right shoulder became involved, and atrophy of the shoulder and scapular muscles occurred. The circumference of the right arm at the axilla was 3 cm. less than that of the left. At no time was the patient's condition influenced in the slightest degree by change in the weather.

The use of strontium bromid was now begun and, whether *propter hoc* or *post hoc*, the patient began to improve; in April, 1895, she was able to walk around the bed by holding on to the railing; on July 1 she walked out into the yard, but the following day had a relapse and was again confined to bed, internal treatment being continued and systematic massage being given. Improvement now became continuous and progressive, and in November she ventured out and walked eight city squares the first day. Last year and this spring she again worked at her trade, and recently consulted me as to the advisability of getting a bicycle. She tells me she has almost forgotten her long illness, the vestiges of which are, however, unmistakable, though they do not trouble her any. The heart murmur has entirely disappeared; there is now only slight accentuation of the second aortic sound; the pulse is regular but a little rapid. Motion in the shoulder, knee, and ankle joints is perfect; the deformity of the right wrist has nearly disappeared, and that of the right thumb is greatly lessened. Abduction of the thumb is, however, still restricted, and there is occasional crackling in the knee joints when she rises from the sitting posture. The ankle clonus can no longer be elicited.

To recapitulate: A young, healthy woman, with a family history of rheumatoid arthritis and lithemia, was taken ill after a sea bath with peculiar pains, soon followed by joint enlargement, destruction of cartilage, atrophy of the muscles, and contraction of the joints, all fairly symmetric. A heart murmur was present; the knee jerks were exaggerated, and there was ankle clonus. After continuous confinement to bed for seventeen months, improvement set in and was followed by a practical recovery.

The treatment was so varied and manifold that definite conclusions can not be drawn from it, but I beg to call attention to the following points: 1. The importance of preventing contractures and the efficient value for this purpose of the extension apparatus. I am convinced that had it not been applied the patient, although the disease is arrested, would now be unable to stand or walk. It has also occurred to me that an analogous device for the arms in certain cases might be of great service. 2. From the apparent effects of strontium bromid in this and other cases I am led to the view, still tentative however, that it has: *a*, an influence over the pains; *b*, perhaps a power to limit the progress of the disease.

A Characteristic Symptom of Lesions in the Posterior Cranial Fossa is the peculiar dyspnea whenever seated upright, relieved by resuming the reclining position. The breathing becomes very slow, deep, snoring, and interrupted by frequent pauses half a minute long. Two new observations are described in the *Deutsche Med. Woch.*, of June 10. One was caused by a tumor in the fossa, left of the basis cerebri, the other by thrombosis arteriæ basilaris, both fatal.

THE CARDIO-VASCULAR AND RENAL RELATIONS AND MANIFESTATIONS OF GOUT.

Presented to the Section on the Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association held at Philadelphia, Pa., June 1-4, 1897.

BY N. S. DAVIS, JR., M.D.

CHICAGO.

That gout and its varied complications are due to toxemia, possibly to uric acid or to other substances which vary in the blood as it does, is generally admitted. Interstitial nephritis, the common renal complication of gout, is so well understood that I need not dwell upon it in this discussion. There are a few points, however, in the course of development of the lesion to which I wish to call attention, for in most text-books and monographs sufficient emphasis is not placed upon them.

It is, of all renal diseases, the most insidious in onset, and it is intermittent in progress. The kidneys are attacked now and again by uric acid or the toxic agent of gout in microscopic areas, which produce active lesions of almost microscopic size. It is true when we examine a kidney which illustrates interstitial nephritis that we find almost the whole parenchyma involved to a greater or less extent, but this extensive lesion has been slowly developed and is due to the confluence of minute changes which have been wrought intermittently. I have spoken of active lesions of microscopic size. These result in a destruction of glomeruli, tubules and arterioles, and when this destruction has been wrought the scar tissue which is left is inert and represents only a loss of renal function.

If the renal changes of gout are looked at in this way they will explain in part the symptomatology of the affection. As the glomeruli are attacked one after the other, not all of them or most of them simultaneously, and as those attacked today may atrophy and become useless before others are involved, the filtration of water from the blood will be modified only by the very few Malpighian bodies actively affected at the time. Therefore only traces of albumin appear in the urine, in marked contrast to the large quantities which appear when the kidneys are involved in parenchymatous inflammation. The atrophic and destructive changes which involve the renal epithelium cause a degree of renal insufficiency to slowly develop. The endarteritis which often obliterates the caliber of the arterioles and the destruction of capillaries in the diseased areas increases blood pressure. This causes the elimination of abnormally large amounts of urine by those glomeruli and renal tubules which are as yet unaffected and healthy.

The insidious and intermittent development of these lesions explains fully the pathognomonic symptoms: polyuria, with traces of albumin, few renal casts, diminished elimination of urinary solids and high arterial tension.

High arterial tension in gout is due in part to uric acid or other toxic substances in the blood which increase the tonus of the arterioles. The destructive agent, whatever it is, that attacks the kidneys produces also arterio-sclerosis or atheroma in the arteries of other tissues. The thickened and rigid walls of the arteries impede circulation, which stimulates the heart to contract more forcefully. This is a second factor producing increased blood pressure. Arterio-sclerosis in the kidneys, in the central nervous system, in the

various tissues of the body, often produces serious or fatal complications in those who have a gouty diathesis. Because the walls of arteries are weakened by disease and stretched by blood under unusual pressure aneurysms sometimes develop in the smaller or larger arteries. The smaller ones are frequently the cause of apoplexy.

The commonest and most characteristic cardiac change associated with gout is hypertrophy. The left ventricle is chiefly thickened, although when the heart is hypertrophied both ventricles are affected more or less. The cardiac hypertrophy is, without doubt, due to increased work which the heart has to do because of the destruction of some arteries and capillaries and diminished caliber and rigidity of others. These changes in the arteries generally necessitate compensatory cardiac hypertrophy and as the arterial changes become more widely diffused, little by little and intermittently, the cardiac hypertrophy slowly increases so long as the nutrition of the individual is good. Ultimately cardiac compensation becomes impossible, cardiac fatigue, dilatation and exhaustion develop. Endocarditis and pericarditis almost never complicate gout. In this respect the contrast with articular rheumatism is striking. It is true that deposits of urates have been found on the valves in gout, but such cases are extremely rare and exceptional.

These various changes in the kidneys, arteries and heart may occur in podagra or characteristic gout, but are more frequently seen independent of it and often themselves constitute the most marked manifestations of a gouty diathesis.

Treatment, to be of value, must be hygienic. It will aim to prevent the accumulation in the blood of those substances, uric acid or whatever they may be, which produce the vascular, cardiac and renal changes. Necessarily treatment must be continued for a long time. By removing the cause of these complications of gout their progress may be brought to a halt and a patient may be made comparatively comfortable. It is impossible to restore renal tubules and glomeruli which have been destroyed. But it is rare that the renal changes are so extensive that they, of themselves, will prove destructive of life. In almost every instance, when the disease is recognized, enough healthy renal tissue exists so that if its cause is removed the kidneys will continue to do their work fairly well, and maintain a condition of physiologic health even though they are anatomically much deformed. The same can be said of the inhibition of the growing cardiac and vascular lesions by suitable treatment.

CHRONIC INFLAMMATION AND ULCERATION OF THE DUODENUM, WITH RESULTANT REFLEXES.

Presented to the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY JOHN M. ALLEN, A.M., M.D.

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE AND PRESIDENT UNIVERSITY MEDICAL COLLEGE, KANSAS CITY, MO. LIBERTY, MO.

The duodenum is abundantly supplied with arterial blood. Its veins empty into the portal vein, any obstruction of which, either from the lungs, liver or heart, produces passive congestion of this organ. Its nervous connection with the brain is by branches from the par vagum and with the spinal cord by branches

from it, with the sympathetic system by branches from the solar plexus, and with the thoracic plexus by the splanchnic nerve. It has within its structure the plexus of Meisner and Auerbach. It is studded with the glands of Lieberkühn and Brunner, and with solitary glands as well as lymphatics. It is the physiologic receptacle of the chyme which is often perverted by functional disease of the stomach or over-repletion, either of which may be highly irritating to the duodenum. It also receives the secretion from the liver and pancreas and performs, possibly, as important a function in the digestive process as does the stomach, and is as frequently subject to physiologic hyperemia. Indeed, there is no structure in the human body which is so often exposed, both internally and externally, to as many varieties of disease-producing forces as the duodenum. It is directly connected with the brain, spinal cord and sympathetic system as no other portion of the alimentary canal is, which fact makes it the great reflex center of this canal.

Careful analysis of a large number of cases of reflex irritation supposed to have originated at other points of this canal, disclosed the fact they always originated in the duodenum. It is far more frequently diseased than one would infer from the scant literature on the subject.

In my clinic at the University Medical College of Kansas City, Mo., 10 per cent. of the cases had chronic inflammation and ulceration of the duodenum. In my private practice the percentage is about the same. As compared with chronic gastritis—or so-called catarrh of the stomach—it is far more frequent. In 17,000 clinical patients I found 666 of duodenal disease, and only one case of chronic gastritis and one of ulcer of the stomach. In fact, I never saw a case of chronic inflammation of the stomach, excluding chemic and other irritants as causative, that did not proceed by extension from inflammation of the duodenum. It is most often found between the ages of 20 and 40, but it frequently occurs in childhood, the result of enterocolitis or cholera infantum. It occurs in females more often than in males because of their more numerous reflexes.

Typhoid fever is the most frequent cause. Other causes are phthisis pulmonalis, functional disease of the stomach, croupous dysentery by extension, the exanthematous fevers, particularly rubeola, acute inflammation of the organ, passive congestion, burns, acute inflammation associated with pneumonia, which obstructs the bile ducts, producing what the older writers called bilious pneumonia, and reflex irritation, the result of disease of the uterus and appendages.

Brown-Séquard asserted years ago that reflex irritation was sufficient to arrest secretion and nutrition, and produce inflammation. This fact is beautifully illustrated in severe burns of the skin, which, by reflex irritation, result in acute inflammation of the duodenum, and *vice versa*, irritation of the duodenum will produce inflammation of the skin, as in urticaria and *eczema*. In childhood we have a clear example of the effect of irritation of the intestinal canal, producing reflex irritation of the nerve centers, attended with functionary changes in the blood of these centers, thereby producing convulsions.

Esquirol, Pinel, Cullen and others believed and taught that gastro-intestinal irritation was a frequent cause of insanity, yet they were not able to give a reason why this should be so. In the light of mod-

ern science and our knowledge of reflex irritation producing fluctuatory changes in the blood, they were not far wrong, as is illustrated by the following case:

Case 1.—June 10, 1875, Mr. P., aged 35, no hereditary tendency to insanity, a well-to-do farmer, had always enjoyed excellent health until three years before, when he had an attack of typhoid fever with serious bowel complications; during convalescence there was no restriction in his diet, which had much to do in leaving him with a chronic inflammation and ulceration of the duodenum. In 1877 he presented himself to me for treatment. I found him suffering with melancholia, with suicidal tendency, dependent upon reflex irritation caused by chronic inflammation of the duodenum. I placed him under treatment for this disease. As soon as the irritation was controlled he began to improve, and so continued steadily until restored to health.

In the last twenty years I have treated seven other cases of insanity, the causes of which could be clearly traced to reflex irritation produced by disease of the duodenum. Four of these cases were the after-effects of typhoid fever; two of them were from functional diseases of the stomach, and the remaining one was from acute duodenitis, associated with pneumonia, which became chronic.

Epilepsy as caused by reflex irritation.—Statistics show, excluding traumatism, heredity and alcoholism as causative forces in producing epilepsy, more than one half of the cases of this disease begin in childhood. It is my opinion that a very large percentage is the result of reflex irritation caused by chronic inflammation of the duodenum, as is illustrated by the following case:

Case 2.—May, 1870, I was called to see a child 2 years old. *History.*—The previous summer, while teething, he suffered for six or seven weeks with enterocolitis; for five or six weeks before I saw him he had been suffering from unconscious spells of *petit mal*; the day before he had *petit gravior*. Diagnosing epilepsy dependent upon reflex irritation caused by chronic inflammation of the duodenum, I placed him under treatment for this disease and he eventually recovered.

Case 3.—In November, 1880, I was consulted in regard to a child 8 years old, who had begun to have *petit mal* in July, 1880. The disease was now *petit gravior*. There was not sufficient history of intestinal disease to point in that direction for cause, excepting malnutrition, nor was there any hereditary history of epilepsy or neuropathic diathesis. January, 1881, the child died of broncho-pneumonia. Postmortem examination revealed two ulcers in the upper portion of the duodenum surrounded by zones of inflammation.

I have treated seventeen other cases of epilepsy, between the ages of 2 and 17 years, caused by reflex irritation excited by duodenal disease. Those I have seen during the first six months of the existence of the disease have recovered: one at the end of the second year recovered; of those in whom the disease had existed over three years only one recovered, the others were not benefited. I think it is fair and logical to believe that if the cases are seen early a large percentage of them can be cured: but when the epilepsy has existed for more than two or three years, although you may relieve the cause of the irritation, the fluctuatory changes in the blood become a fixed habit, and is more difficult to treat than the primary cause of duodenal irritation; add to this the strong possibility of changes in the structure of the nerve centers, caused by perverted nutrition, the result of the functionary changes in the blood plus habit, and the case then becomes hopeless. In a large majority of the cases of duodenal disease the patient suffers more or less from neurasthenia, but there are cases in which it is the prominent effect of reflex irritation.

Case 4.—Age 34, female, married, mother of four children. Family history perfect: said to have had lacerated cervix uteri, for which she was operated on with the assurance that a cure

of this would relieve her neurasthenia. This was in 1881; she was not benefited by the operation; had had typhoid fever in 1880. I saw her in 1883, when she had suffered from neurasthenia since the middle of 1881. I diagnosed chronic inflammation and ulceration of the duodenum with resultant reflexes. I placed her under a course of treatment and at the end of four months she had entirely recovered.

Pharynx and nasal cavities.—It frequently happens that we find pharyngitis and rhinitis associated with chronic duodenal diseases. I report the following case: Four years ago Prof. J. E. Logan of the University Medical College of Kansas City, Mo., referred a case to me for treatment, with the statement that the rhinitis, which was attended with distressing sneezing, was caused by reflex irritation. On examination of the patient I found her suffering from chronic inflammation and ulceration of the duodenum, caused by long continued functional indigestion of the stomach. I placed her under treatment for duodenal disease only, giving no attention whatever to the nasal or pharyngeal inflammation. She rapidly improved, ceased sneezing within a week, and at the end of four months was perfectly well.

Diseases of the skin.—That urticaria is entirely dependent upon reflex irritation originating in the duodenum can not be doubted. The same is true of many of the forms of eczema, a fact which I have verified in a large number of cases by diagnosing the existence of duodenal disease, the successful treatment of which entirely relieved the skin disease.

Pruritus of the skin.—A case of this disease had been under the treatment of several distinguished dermatologists without relief. I diagnosed chronic duodenal disease following an attack of rubeola producing reflex irritation. The patient was placed under treatment, and as soon as the duodenal disease began to improve, thereby lessening the reflex irritation, the pruritus began to subside, and she was entirely relieved.

In duodenal disease the functional action of the heart is interfered with. It is either increased in frequency and decreased in force or merely decreased in frequency. I have seen it, in different cases, vary in number of strokes from 35 to 120 beats per minute. In many cases the reflex phenomena appear in the lungs, in which there is sighing respiration or asthma. Anemia of the brain is not uncommon. Local hyperemias of the brain with insomnia is also very common.

Over twenty-five years ago my attention was called to the character of food recommended for diabetic persons, which then had no better reason for its use than "that it was best," also to the exclusion of saccharin matter with no better explanation than the above. About that time I treated two cases of pachymeningitis, which were followed by diabetes mellitus caused clearly from irritation or pathologic changes near the fourth ventricle of the brain. I soon learned that opium had no controlling influence in the cases whatever over the amount of urine secreted, differing in this from any case in which I had used it before. Finding later that chronic inflammation and ulceration of the duodenum always preceded all the cases of diabetes mellitus which I treated, I concluded that the real benefit of opium was its controlling influence over peripheral irritation, thereby lessening the reflex influence. My attention was then called to the close relations between this disease and diabetes mellitus. Since that time I have carefully examined more than thirty cases of diabetes mellitus, and found that this disease of the duodenum had preceded every one of

them. Seven of these cases I have verified by post-mortem examinations. In each I found chronic inflammation and ulcerations of the duodenum. There was no other pathologic change of structure except in one where the liver was affected.

It may be a question whether the relation of these two diseases is the result of peripheral irritation producing reflex irritation, thereby affecting the nutrition of the nerve centers that preside over the conversion of starch and other matters into saccharin matter, or whether it is the interruption of the function of the duodenum and its accessories which arrests or prevents normal metabolic and anabolic changes in our food, and by natural selection the defective products of saccharin matter (glucocids) are taken up by the absorbents and depurated by the kidneys.

The principles that should govern the treatment of this disease and its reflexes are as follows: 1. The organ should be given rest from physiologic hyperemias by excluding oleaginous, saccharin and starchy foods; the nutrition of the patient should be maintained by stomach digestion, rectal alimentation and absorption of the skin. The remedies indicated are those which control reflex irritation and intestinal germicides. If there exists anemia of the nerve centers of the brain, it should be relieved by such tonics as nux vomica, strychnia, arsenic; if general or local hyperemias, by bromids. If tonics are indicated, the hyposulphates of lime, soda and potassa, or the bitter tonics. The iron preparations are injurious. In cases of diabetes mellitus add to the general treatment from 15 to 20 grains of bicarb. of potassa after each meal. Purgatives should be avoided, except those that act on the large intestine. These should be alternated with enemias.

DISCUSSION.

Dr. BORDMAN REED of Atlantic City, N. J.—Up to this time I had not been led to believe that there were as many reflexes from the duodenum as my friend Dr. Allen has given us to understand he has found. I should be inclined to question whether all of his cases were true reflexes, and also whether they came from disease limited to the duodenum. I should be strongly inclined to think that most of the cases he has reported were cases of intestinal toxemia from inflammation of the small intestine. In fact, it is very difficult to differentiate disease limited to the duodenum. The duodenum is a very small portion of the intestine, and its structure is very similar to that of the small intestine below, so that I can not understand how Dr. Allen can be certain the disease was limited to that short distance. The great burthen of evidence from other sources would lead us to believe that the results were more from toxemia, the absorption of various toxins, than from reflexes. However, I am inclined to believe that there are also reflexes from that region. I think we are apt to take too narrow a view of disease. Haig, in his famous book on uric acid, attributes nervous diseases to uric acid causes. On the other hand, Bouchard attributes them to toxemias, and others to other things. I think it probable that all of these agents are concerned in the production of nervous diseases.

Other authorities have differed somewhat from Dr. Allen with regard to the relative frequency of diseases of the stomach and intestine, particularly with regard to ulcer. Andral reported the proportion of ulcers in the duodenum and stomach as 1 to 40. Another author gives 1 to 9. Ordinary round ulcer is much more frequent in the stomach than in the duodenum. The duodenum is also liable to the catarrhal type of ulcer, but the usual kind is the round ulcer due to an excess of acid passing down from the stomach. My own studies and experiments on the acidity of the gastric juice have shown me

that a great deal of nervous disease is attributable to an excess of hydrochloric acid in the stomach. The excess of acid may pass into the duodenum and produce irritation, sometimes ulcer, and probably sometimes catarrhal disease. It is a large subject. We should welcome contributions from every quarter, but not be dogmatic in our conclusions.

Dr. ALLEN—The anatomic, physiologic and pathologic points made by me in my paper have not been objected to by my friend Dr. Reed. He objects to the relative frequency of gastric inflammatory processes and those of the duodenum. Answering, I would say that wherever there did exist a question of doubt requiring differential diagnosis between these diseases, the stomach in each case was washed out and its contents thoroughly examined, chemically and microscopically, for the debris of inflammatory processes, which protected me from any possible mistake. The same care was taken in the investigation of the possibilities of the existence of inflammatory diseases below the duodenum, and they were not found. The statement of Dr. Reed that I am not supported by the literature on the subject is true, but he must bear in mind that the literature on the subject is so very meager that I am justified in concluding that investigators have overlooked this very important portion of the alimentary canal. The Doctor attempts to explain some of the phenomena attending these cases by the absorption of toxins. As toxins are never absorbed by normal structure, but only where there are inflammatory processes, there might be a question of doubt as between the causes which produce the phenomena of the cases reported by me. The phenomena themselves can not be explained by the Doctor's theory, but can scientifically be explained by reflex irritation.

DIAGNOSIS OF ASCITES.

Presented to the Section on Practice of Medicine at the Forty-eighth Annual Meeting of the American Medical Association at Philadelphia, Pa., June 1-4, 1897.

BY JAMES TYSON, M.D.

PHILADELPHIA, PA.

The object of this brief communication is to call attention to a symptom which I think has hardly received sufficient attention at the hands of clinicians and which I know to have been misinterpreted. I allude to tympany in the flanks and its significance in the diagnosis of ascites. It is generally taught that the *absence* of tympany in the flanks is characteristic of ascites; while its presence can not be regarded as consistent with any considerable degree of accumulation of liquid in this region. A case now in my wards at the Hospital of the University of Pennsylvania illustrates the possibility of error arising from a too strict adherence to this guide. A woman, aged 37 years, was admitted with mitral stenosis and insufficiency, with passive congestion, enlargement and tenderness of the liver, ascites and general anasarca. When lying on her back the lower abdomen was somewhat bulging, and over this region and laterally on both sides as far as a vertical line drawn through the anterior superior spinous process of the ilium, distinct fluctuation and a succussion wave could be elicited. Behind this, distinct tympany could be brought out by percussion in both flanks. It was usually more marked on the right side. So marked was the tympany, and so much in contrast with what seemed usual that experienced men who saw her thought that the condition could not be ordinary ascites but must be a collection of fluid, circumscribed by adhesions. A trocar was introduced and seven pints of clear serum drawn off, such as constitutes an ordinary ascites, emptying the abdomen completely of fluid. As the fluid reaccumulated, the original signs appeared and were followed by another tapping, when an equal amount of fluid was drawn off. This was repeated several times.

Having had this experience with the patient referred to, I proceeded to examine carefully every case of

ascites I met in the wards, and in quite a number I could bring out, by percussion, an area of tympany located as described. It varied in extent and distinctness, and in no case was it as marked as in the woman referred to. It was, however, easily recognizable, though not always in each flank, sometimes being more marked in one and sometimes in another, while it was sometimes present in one and absent in another.

I then proceeded to examine the text-books available and found more frequent allusion to it than I had expected. Thus, in Leube's "Specielle Diagnose der Inneren Krankheiten," vol. i, p. 381, 4th ed., occurs the following: "So kann man unter percütirend neben der Niere nach der Linea axillaris hin, einen schmalen Streifen tympanitischen Schalls finden. Es rührt dies davon her, dass das Colon ascendens und descendens in ihrem hinteren Umfang vom Peritoneum nicht überzogen sind, und deswegen hier kein Transudat liegen kann," *i. e.*, by percussing from the neighborhood of the kidney downward in the axillary line a narrow zone of tympany may be found. This is because the posterior portions of the ascending and descending colon are uncovered by peritoneum in this situation, and on this account no transudate can lie there).

Passing to Strümpell, second American edition 1893, p. 462, I find "the resonance on percussion of the deepest and most dependent portions of the abdomen may be misleading in this way, that *even in ascites* a narrow zone may be tympanitic. This should be remembered."

Turning to American text-books, Da Costa, eighth edition, p. 712, quotes Bacelli that "in ascites there is a deep tympanitic sound during percussion in the region of the intestines, while an ovarian cyst presents dullness on the side in which the cyst has its origin, and a tympanitic sound on percussion on the other." I can not discover that reference is intended to the point to which I allude. In John H. Musser's new work on "Medical Diagnosis," I find no allusion to it, nor in James T. Whittaker's recent "Theory and Practice of Medicine." I find in Osler, p. 508, second edition, the usual statement, *viz.*: "In the dorsal position, with a moderate quantity of fluid in the peritoneum, *the flanks are dull*, while the umbilical and epigastric regions into which the intestines float are tympanitic." No mention is made of occasional tympany in the flanks.

Wood and Fitz on page 969 of their recent text-book say, "if the intestines contain no gas, or are adherent to the abdominal wall or the mesentery is so short or the quantity of fluid so large that they are prevented from floating to the surface, the dullness is no longer characteristic; but the resonance of the intestines may be found in the lower abdomen *or in the flanks*, in either of which places it may remain even if the patient changes his position." The fact is here pointedly stated, but its connection by a semi-colon, with what precedes, would seem to refer it to an unusual condition of the small intestine rather than with the constant situation of the ascending and descending colon. In his article on "Ascites," in Pepper's "American Text-book of Medicine," Dr. Fitz makes practically the same statement.

Dr. Henry M. Lyman expresses the fact much more directly than any other American author, for on page 411 of his recent text-book he says: "If the intestinal canal be free from fecal contents, the region of the cecum and the descending colon will emit a tympanitic sound on percussion, even though the adjacent regions are occupied by dropsical fluid." This is precisely correct.

Of the older but still comparatively recent authors of text-books, Austin Flint, Sr., Henry's edition 1894, p. 530, says: "The exceptional cases in which this test afforded by percussion is not available, are those in which the intestinal coils are fixed by morbid adhesions. This is rare in a case of purely dropsical effusion."

In neither Roberts Bartholow's, Alfred Loomis's or Frederick T. Roberts's text-books do I find the fact referred to. C. Hilton Fagge, on page 309, vol. ii, (American Ed., 1886), says: "Again, when in ascites the border of the dull region is percussed freely, the left hand finger being pressed backward as much as possible, one can often detect a resonant note from the presence of intestine beneath."

Niemeyer (Humphreys' and Hackley's Translation, N. Y., 1870, p. 623), has an interesting paragraph, as follows: "Bamberger advises us to pay particular attention to the spot between the crest of the ilium and the twelfth rib, for in ovarian tumors at that point we generally find the full sound of the larger intestine; in ascites we do not. *Still he acknowledges that this sign occasionally fails.*" Now this is precisely the situation in which the tympany in ascites is occasionally met.

My own book contains a somewhat bungling allusion to it, heightened by a typographical error. On page 386 will be found the following: "There are also two sites posteriorly where a tympanitic note may be produced by percussion, *viz.*, upward (should be *downward*) from the neighborhood of the kidney on each side behind the mid-axillary line, because in this situation in the ascending and descending portions of the colon with the posterior portions uncovered by peritoneum, and therefore inaccessible to the fluid." Evidently in writing this I did not realize the actual facts or I would have made it clearer in the text, though the understanding is quite different if instead of the word "upward" we read "downward." I had evidently read the paragraph in v. Leube without having realized the condition itself. Since I have studied it my notions are clearer and more definite, and it seemed to me worth while to take an opportunity to call attention to the subject and impress it by the models of Steirges after sections of the frozen cadaver, here exhibited, in which the portions of the colon thus exposed are clearly seen. It is to be remembered that the condition is also influenced by various degrees of distension of the colon as well as by the quantity of ascitic liquid.

DISCUSSION.

Dr. ROCHESTER of Buffalo—I was puzzled this winter by a case in the hospital. There was distinct tympany in the right, and slight tympany in the left flank. I tapped and removed fluid.

Dr. HERMAN B. ALLYN of Philadelphia—I have a case in the hospital now which presents this condition of tympany in the flank. I still thought fluid was present, and on tapping withdrew several pints, but, on reaccumulation of the fluid, tympany did not occur. It would seem that it may sometimes exist, while at other times it may not or that it may be a temporary condition.

Dr. TYSON—I rise to confirm what Dr. Allyn says. We found considerable variation in the amount of this tympany at different times and previous to successive tapings. One flank was almost always more tympanitic than the other. It goes without saying that the quantity of fluid makes some difference. You can understand that if there is a large quantity of fluid in the peritoneum pressing upon the colon, there will be less tympany from the colon than in cases in which there is less compression. But I have observed the tympany in large abdominal effusions.

A FURTHER REPORT ON ISCHOCHYMIA (DILATATION OF THE STOMACH).

Presented to the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY MAX EINHORN, M.D.

NEW YORK, N. Y.
