THE report on the proceedings of the Board of Trade under section 24 of the Railway and Canal Traffic Act has just been published, and contains much that is interesting and instructive. The Commissioners express their belief that the classifications and schedules which they have prepared are such as will protect the interests both of the traders and the railway companies, and they give their reasons for adopting or rejecting the different courses which were suggested with regard to the various points upon which they had to decide. They found it absolutely impossible to ascertain the cost of carriage of the different classes of goods, and have had to fall back upon existing maximum rates as modified by the actual charges in force, for a basis upon which to form their own proposals. It will be a matter of surprise to many,—as it probably was to the Commissioners themselves,—to learn the extent to which "special" rates, as distinct from the ordinary class rates, have been granted. It is stated that on the Great Western Railway the proportion is half special and half class; on the Midland, 75 per cent. special and 25 per cent. class; on the Great Eastern, 55 per cent. special; on the London and North-Western, 73 per cent. special; on the North-Eastern, 61 per cent. special. The Commissioners remark that the Railway Companies have built up a traffic remunerative to themselves at rates, generally speaking, much lower than those at present authorised by Parliament, and, consequently, they came to the conclusion that "it is equitable to make a reduction in their present powers and to fix rates based, to a great extent, on existing rates, but with a reasonable margin of profit for possible changes of circumstances injuriously affecting the cost of or the returns from the carriage." The report, as a whole, is distinctly on the side of the traders, and, as the *Times* observes, the companies will find in the Board of Trade a new and formidable opponent should they persist in objecting to the proposed terms, and thus force the matter upon the attention of a Parliamentary Committee.

THE reports of the proceedings of the Trade Union Congress seem to become every year more and more melancholy reading; a mingling of absurd and Utopian aspirations for legislation in which everything shall be in favour of the working-man, coupled with displays of temper, personalities, and violent language which serve to indicate how far those who indulge in them would be fitted for the legislative responsibilities which they crave. The Parliamentary Committee, which consists of reasonable and logical men, is

attacked for not bringing in Bills for objects which every rational man knows they would not have a chance of obtaining a hearing for. One member of the Congress proposes that a general conference of labour associations should be called to consider the best method for payment of members of Parliament; another, amid "much uproar," moves that no labour candidate should receive support "unless he were in favour of the nationalisation of land, shipping, and railways!" And the same men who are crying out for these wild schemes are proposing to increase their own and the national prosperity by arbitrarily limiting the hours of productive labour!

IT appears that the unsatisfactory condition of affairs in the Tyne ship-building trade, to which we alluded on the 9th ult., still continues, and that nearly 1,000 men are now on strike. The dispute is one of unusual occurrence, as it is a struggle between two bodies of workmen, and one in which the employers occupy a passive and neutral position. Unfortunately for the latter, however, they are obliged to stand by and see orders going out of the district owing to the delay which the strike has occasioned in the completion of vessels. It will be remembered that the dispute turns upon the apportionment of the work which shipwrights (or carpenters) and ship-joiners are respectively entitled to do; and that Mr. Burt (who had been appointed arbitrator) gave an award which the joiners refuse to accept. Their action in thus repudiating the award and coming out on strike has naturally had the effect of alienating public sympathy, and it has, at the same time, probably opened the door to the shipwrights getting hold of work which is acknowledged to belong to the joiners' list. If this has occurred, however, it is clearly the strikers' own fault, and the Trades' Council of the District have just passed a formal resolution "withholding sympathy from any body of men who dissent from the award of a regularly-appointed umpire." It was the singularity of the dispute which led us to allude to it at the outset, but it appears to be as far off settlement as ever, and to have assumed a much more serious aspect than was anticipated. The latest advices from the district state that the Wear joiners have now decided to support their Tyneside fellows, and that it is not unlikely that the whole shipbuilding trade of the North may be brought to a standstill unless the other Unions affected speedily take the matter in hand and endeavour to bring about a settlement.

IN opening the new Museum of Science and Art and the National Library, Dublin, on the 29th ult., the Lord Lieutenant observed that he had noticed with pleasure what good use Irish workmen had made of the excellent Irish stone and marble of which that edifice is composed. "I sincerely trust," he said, "that the durability and beauty of these native products may be more largely recognised in the future, and, in consequence of increasing demands for them, important industries may be established on a sound footing in several parts of the country where hitherto there has been insufficiency of work to employ the population." This remark entirely coincides with the views that we have frequently expressed in these columns. No matter how poor Ireland may be in respect of other mineral wealth, there can be no question as to the richness of the country from a stone- and marble-producing point of view; yet its resources in these respects are comparatively neglected, owing chiefly to want of capital. Beautiful marbles, that could be very cheaply raised and worked, and immense tracts of granite (that of Wicklow and Wexford is the largest, granite *massif* in the kingdom) lying both along the shore, within easy reach of carriage, and inland, are as yet untouched, save here and there by the opening of a solitary quarry for local purposes. The Carboniferous limestones of which the greater part of the country is composed yields

durable building stone of many tints, and with a little expenditure of capital and proper introduction could, in many instances, be brought to successfully compete with other better-known kinds in the market. We feel sure that the Lord Lieutenant's hopes will some day be fully realised.

THE recent report of the Foreign Office on Emigration to the Argentine Republic is another of the very useful series which that Department now issues. It gives in a short space many useful hints to intending emigrants. Argentina is one of the finest and most promising countries in the world, but that is no reason why emigrants should rush there in an indiscriminate manner. But it is obvious that the greatest drawback to English emigrants is the desirability of knowing the Spanish language. In 1889, 5,967 English emigrants landed in Argentina, against 88,647 Italians, 71,151 Spanish, and 27,173 French. Thus, it is equally clear that a knowledge of Italian would also be desirable. But, all the same, there is a sufficient English element in the Republic to enable an Englishman of the right sort to make his way. "Navvies without families are sure to get immediate employment." This should be good news in this country, where railways have now been pretty well completed. "For surveyors and engineers, lucrative employment offers. . . Architects, builders, and experienced contractors, with means, will find competition not as keen as in other parts." It is also stated that "all immigrants are landed, lodged for five days, and sent to any part of the Republic they may select free of expense." But, of course, they should have formed before-hand an idea of the part they desire to settle in. The English immigration clerk at Rosario also states that "there is always employment in the larger towns for the artisan handicraftsmen, more especially for carpenters, masons, shoemakers." This is exactly what one would expect to hear from a growing country. But the English mason has to compete with excellent workmen in the Italian emigrants. The same gentleman gives as the rate of pay for carpenters three to seven dollars per day, for painters two to four, for masons five to eight, and bricklayers two to four dollars. Account, of course, must be taken of the value of paper money, but it does not affect men much who are not receiving money home. The fine climate is a great advantage, especially in the case of masons and bricklayers, who are thus pretty sure of continuous employment.

A WRITER in the *Times* last week drew attention to the fact that the Western Australian strike was that of workmen earning very high wages, and he draws the moral that poverty is not necessarily a motive-force of strikes. The letter was well-timed, but it only expresses what most thinking men have already perceived, that once trades unions became very powerful, strikes would occur, not in order to obtain wages upon which men could live reasonably well, but upon which they would be able to obtain more than the mere necessities of life. It is contrary to all the teachings of history, and to all the experience of mankind, that power in the hands of the masses should be used with moderation when distinct personal advantage can be gained by its arbitrary employment. It is perfectly obvious that the labour-question has yet to undergo much greater developments, and he would be a bold man who would venture to prognosticate the course of the struggle between capital and labour. The subject is one which cannot be too carefully and seriously studied, more especially as everything seems to show that the struggle must yet become more severe. There may yet come a time when communities will not only have to bear the burden of taxation, but also of high charges caused by the arbitrary power of organised labour.

A RECENT addition to the Illustrated Biographies of Great Artists is the two small volumes containing the lives of

Millet, Rousseau, Diaz, Corot, Daubigny, and Dupré. These artists are classed together as "The Painters of Barbizon," or, as appears at the head of each page, "The Barbizon School." Another work on these same painters has also appeared this year, by Mr. D. C. Thomson, "The Barbizon School of Painting." This loose wvy of grouping these painters as one school is very characteristic of a good deal of the art criticism of the present day, which uses inaccurate phrases which sound well. A "school" of painters is one which is characterised by certain marked similarities; and by classing certain artists together as a particular "school" the student at once is able to recall at any moment the cardinal features of their work. But the painters who compose the so-called "school" of Barbizon have no common characteristics. They passed part of their lives in the same picturesque village, and that is all. Rousseau, for example, was a great landscape-painter, with nothing akin in his work to the peculiar treatment of Millet's pictures. It would be just as sensible to class the artists who live near each other in a particular part of Kensington as the "Campden Hill School." We call attention to this loose way of writing of these artists, because artistic criticism, if it is to be of any value at all, should be thoroughly accurate. It is perhaps, indeed, using somewhat inaccurate phraseology ourselves to call these popular biographies art criticisms, for they are not real criticisms in any sense of the word. They are handbooks which may well be used as aids to memory, but they are very valueless for any higher purpose.

A WELL-KNOWN bookseller in Edinburgh, Mr. William Finlay Watson, who died in 1881, by his will bequeathed to the National Gallery of Scotland his collection of paintings, drawings, autographs, manuscripts, miscellanea, written and printed books, literary papers, curiosities, &c. Under the will the sister of the deceased, Miss Helen Aberdein Watson, was to have the use of the collection during her lifetime, and after her decease, the Trustees of the Gallery were to select from it whatever they thought worthy of a place in the National collection. Miss Watson died a few days ago, and the collection is now at the disposal of the Trustees of the Gallery. The collection contains numerous examples of rare and valuable etchings and engravings, several of which Mr. Ruskin declared to be invaluable. Amongst other works the collection contains Wilkie's original sketch for "The Penny Wedding," two early works of Turner, as also paintings by Holbein, Vandvke, Hogarth, David Roberts, Alexander Naysmith, &c. Several of these works are portraits which will be valuable acquisitions to the Scottish National Portrait Gallery. Amongst them are portraits of Queen Mary, Darnley, Edmund Spenser, Shakespeare, George Buchanan, Charles I., Christopher Columbus, the Admirable Crichton, Henry Mackenzie, Smollet, James Watt, and others. Miss Watson was herself an enthusiastic collector of antique curiosities, her proclivity taking the appropriate lady-like direction of old china and drapery. These she has left to the Scottish Museum of Science and Art. They embrace a dressing gown of Napoleon I., the tea-tray, cup and saucer from which Robert Burns drank tea with "Clarinda," &c.

IN the course of operations upon St. Giles' Cathedral, Edinburgh, consequent upon the formation of the Chambers Memorial Chapel, the workmen came upon the arm bone of the patron saint, St. Giles. This relic was, it appears, originally enclosed in a valuable casket enriched with jewels. At the Reformation, the Magistrates sold the casket and appropriated the proceeds, but, with characteristic Scottish caution, hid the relic itself in anticipation of the possibility of a future rise in the price of relics, then at a low ebb. If now offered for sale, it may yet realise a considerable sum, which might appropriately be applied to the decoration of the

fabric. It is alleged by some that the Kirk is rapidly tending towards Rome, but the time is hardly ripe for reinstating the relic in its original place, although the effigy of the Saint has been recently installed over the new and richly-decorated west doorway, a cause of much scandal to rigidly orthodox Presbyterians.

ONE of the provisions in the new Allotments Act is that the parish school-room shall be used for meetings in connexion with the allotment of a village. It is obvious that this provision is another instance of the necessity of village halls. The village school is by no means in many instances the best place for public meetings, especially where the best kind of school furniture exists. School furniture must from time to time be improved; the ordinary bench and desk is not always the best form of article. Every meeting means some disarrangement of school furniture. Often also meetings disarrange night classes, &c., which are held in the school-room. The fact is that a village hall should be found in every village of any size; it can always be used as a reading-room, and its very existence would enable many meetings and gatherings to take place which are now impossible.

AN Oxford correspondent writes: "The *Durham County Advertiser* of the 29th, in referring to Mr. Claude de Neuville's drawing of an interesting old building at Oxford, known as St. Giles's Old Parsonage, states that it was 'purchased by the Executors of William of Durham, in 1219.' Dr. James Ingram, in his 'Memorials of Oxford,' informs us that it was originally a hospital, said to have been founded by Ailwin Godese. It is described in the MSS. of University College as a cottage, which led Wood to think that it had been alienated from the use of a hospital as early as 1219, when it was, among other things, purchased as above-mentioned. But we find it denominated 'Le Spitel' nearly 200 years afterwards, — namely, in the will of John Ocle (Oakley), of Oxford, dated 1390, in which he leaves a small legacy to each poor person then in the hospital."

ANOTHER important competition for a monument to the deceased Emperor William I. has been decided, this time for the Province of Westphalia, the site chosen being on the well-known Wittekinds-mount of the Forta Westphalica (see page 110, ante), and again we hear that Herr Bruno Schmitz has gained the first prize. It is certainly remarkable that so young an artist should be successful in all these monument competitions he takes part in, and whatever style they are designed in!

THE old silk-mill at Derby, which fell in a few days ago, was established on an island in the Derwent, by John Lombe, in 1719. When Crotchet's attempts to introduce the art of silk-throwing into this country had failed, Lombe went to Italy, where he is said, at the risk of his life, to have obtained access to some manufactories by bribing the workmen, and to have committed to paper by stealth the results of his observations. However, he takes out a patent, on September 9, 1718, for "three engines," whereof he says:—"I have at very great expense and hazards found out, discovered, and brought into this kingdom the art of making the three capital engines or sets of working tools called in Italy II inganators or incauratori—fillato, and filotto, . . . to work their fine raw silk into orgazine [sic], which are now used in Bologna, Piedmont, and some other foreign parts."

His specification contains, in Italian, some technical terms, in respect of which he writes, "there are not proper English names for things that have never been known or used here": and water was to supply the power. Lombe leased the island from the Corporation, and there built his mill,—five stories high and 200 yards in length,—which was considered a wonder of the age. He brought over two Italian workmen, one of whom, according to

William Hutton, who was employed in Lombe's mill in 1730, turned traitor, and poisoned his master at the instigation of a woman who had been sent from Italy for that purpose. Lombe died, after a long illness, about seven years after opening the mill, which his relative, Sir Thomas Lombe, carried on. The building has since been used as a steam laundry; but of late years has been in a ruinous state.

THE improvement of that branch of the River Pleisse which passes through Leipsic has been taken in hand, and for this purpose the waters have had to be turned off on a considerable length of the course, so that the rays of the August sun fall on the black mud at the bottom. The work itself (alterations on the embankments, &c.) is being done with all possible speed, and we also note that the upper layer of the filth is gradually being cleared away; but it seems most discreditable that the municipal authorities of the city should sanction the carrying-out of a work, dangerous at any time in a sanitary point of view, in the hottest month of the year. Even if the official representatives are not "in town" at present, and perhaps also not the members of the "upper thousand," the bulk of the inhabitants are in the city, the schools having had their holidays in July; and as the stench in the vicinity of the water-way is excessive, and numerous well-inhabited mansions overlook the course, it is indeed a wonder that disease has not yet broken out. Looking at the death-rate of the town, we find the percentage nearly twice as large as the London one; in fact, statistics show that this Saxon city ranks among the unhealthiest in the civilised world; a fact not to be wondered at, considering the bad drainage and wretched state of sanitary arrangements in general.

LAST year Dr. R. J. Petri undertook a series of experiments at the Charlottenburg Polytechnic, in order to test the efficacy of textile air-filters for excluding micro-organisms. A short account of these experiments was published in the "Proceedings of the Institution of Civil Engineers." A measured volume of air containing germs was passed through a filtering-cloth, and the result was ascertained by cultivation experiments on gelatine. The cloth used was a cotton fabric especially made for the purpose, and contained a weft of eighteen to twenty threads, and a warp of nineteen threads to the centimetre. The volume of the air passed through was 161.75 cubic metres per square metre of filtering surface. Dr. Petri found that this cloth failed to keep back the germs, as in one cubic metre of filtered air there were 2,900 bacteria and 13,500 spores of fungi. Some experiments were made with another cloth of closer fabric, and which had been used as an air filter for some time. This gave far better results, although there were 510 germs of bacteria and 320 fungi spores in a cubic metre of air. It was found that a cloth which had been used for seventeen months had retained approximately 6,780,000 bacteria and 8,570,000 fungi spores per square metre of surface. These results were calculated to upset the belief of those who were trusting to the efficacy of air filters of this nature, and in a recent number of the German publication *Zeitschrift für Hygiene* (Vol vii., p. 379), Dr. Karl Müller, who is a member of a firm engaged in the production of air filters, criticises Dr. Petri's experiments, the results of which he considers not to be reliable. There are, he says, two kinds of air filters, "germ-proof" and "dust-proof." The former consists mainly of ten layers of a thick, closely-woven, and very rough material. The layers are arranged in a series of bags or pockets, the surfaces of which are placed at an angle to the direction of the air-current, the angle varying between three and five degrees. This disposition of the cloth, it is claimed, has a very great influence on the efficacy of the filter. In the dust-proof filters only one thickness of cloth is used. Dr. Müller com-

plains that Dr. Petri did not conduct his experiments under conditions suitable to testing the filter. The latter caused the current of air to pass at right-angles to the surface of the cloth, which, further, was strained by the passage of large volumes of air at an excessive velocity. Moreover, the cloth was not sterilised to begin with. On the whole it would seem that further experiments are required before we can say definitely that a "germ-proof" filter has not been made, although it seems too much to expect that, by any arrangement of layers of cloth, micro-organisms can be altogether arrested. Upon the value of "dust-proof" air filters there is, or rather should be, no need to enlarge; their advantages are plainly manifest and consistently neglected.

ELMSTONE COURT, together with the ancient manor of Elmstone, in the lathe of St. Augustine, Kent, which will be offered for sale shortly, is identical with the Elmstone of the Conqueror's survey, being then held of the Abbot of St. Augustine's, Canterbury, by one Ansfird. It afterwards passed to the Leyborne family: in 53 Hen. III. Roger de Leyborne renders homage for Elymerstone to Roger de Cycoestre, Abbot of St. Augustine's, before many witnesses. Dugdale says that for failure of an inheritor the manor escheated to the Crown on the death of 41 Edw. III., of Juliana, daughter of Thomas de Leyborne, popularly styled the "Infanta of Kent" by reason of her great possessions. King Richard II. settled it upon the Priory of Chiltern Langley, Hertfordshire, which retained it until the Dissolution. Henry VIII. bestowed it *in capite*, at one-twentieth part of a knight's fee, and then valued at 15*l.* per annum, upon his Attorney-General, Walter Hendley. In Hasted's "Kent" (1790) the court-lodge is described as standing "near the south side of the parish, having round it a moat which is supplied by a spring rising just above it, the water from which runs . . . towards the river" [Stour]. A part of the old manor-house, or court-lodge, is incorporated in the present dwelling.

IN reference to the durability of iron bridges, some interesting tests have been made upon a link taken from the Kieff suspension bridge by order of the Russian Public Works Department, Professor Belebubsky carrying out the operations. This bridge was built over forty years ago by Vignolles, who fortunately made provision for a number of spare links being left. This has enabled the tests in question to be made. These links are 12 in. by 1 in., and 12 ft. long. One of the links was taken out of the bridge, being replaced by one of the spare ones. Four test pieces, 1 in. by 1½ in. by 8 in., were cut in the direction of the length from the used link, and the same from another spare link. One 4-in. specimen was also taken from each of the two links in a transverse direction. The tensile strength of the 8-in. test-piece from the old link was 21.8 tons per square inch, the elastic limit 11.1 tons per square inch, the elongation 14.05 per cent., and the contraction 17.35 per cent. of the area. The corresponding figures for the new link specimen were:—Tensile strength 22.2 tons, elastic limit 11.93 tons, elongation 13.42 per cent., and contraction 18.75 per cent. In the specimens taken across the grain, the tensile strength of the link taken from the bridge was 14.9 tons, elongation 2.1 per cent., and contraction 1.6 per cent. The corresponding figures in the new, or rather unused link, were: Tensile strength, 17.32 tons; elongation, 6.0 per cent.; contraction, 6.8 per cent. The tests are satisfactory, as the variation in the figures given in the tests is not greater than might occur between different samples of wrought iron. The superiority of the unused link shown in the transverse test may appear marked to those who have grown accustomed to the more homogeneous metal of which we now more frequently have records, but those who remember how extremely various were the

results obtained by tests of wrought iron, when made across the direction of rolling, will not place too much importance in these figures. It might have been wished that considerable tests could be made on the material of more rigid structures than suspension bridges, but this, of course, is a far more difficult matter. It is also to be hoped that in the fulness of time experiments will be made with steel bridges, especially the high carbon steels now becoming popular, which may prove a very different material for withstanding the effects of vibration to the tougher rolled iron, with its interposed layers of slag.

WE read in an evening contemporary that the Peabody Trustees have arranged with Lady Somers, as ground-lord, and the St. Pancras Vestry, for the erection of a large block of workmen's dwellings upon the site of the Polygon, in that parish. The Polygon stands within Clarendon-square, in Somers-town, a district where, as also in the neighbouring Agar-town, of late years considerable clearance has been made for the extended premises and works of the Midland Railway. Clarendon-square has deteriorated very much since the days when William Godwin occupied a house in the Polygon, after his marriage with Mary Wollstonecraft. The latter died here in 1797, and was buried in the neighbouring burial-ground of (old) St. Pancras.

THE correspondence about "sky-signs" which has been going on in the *Times* for the last few days has more of point and reason than some of the letter-writing about odd-and-ends which is encouraged in the daily papers at this season. The rage for advertising in the present day is constantly leading to new methods of display, and it is in the nature of things that each new system that is adopted should be more obtrusive and more self-asserting than all previous ones, since that is really the main motive for adopting it. In these days nothing is sacred from the enterprising advertiser, and we have no doubt that it is only the risk and cost of the erection that prevents us from seeing Pears' Soap advertised along the top of the range of the Alps, in letters large enough for half Europe to read. The town sky-sign is a much more objectionable because much more prominent form of advertisement than the wall-placard; and the only check to its multiplication *ad infinitum* seems to lie in the fact that too great a number of these signs would be in each other's way and defeat their own object. There is room, however, for quite enough of them to form a most serious disfigurement to a city, as well as a new source of danger in high winds and in fires; and it is therefore satisfactory to observe that the firm whose sign has been most complained of in the correspondence referred to have determined on its removal. Messrs. Hudson do not admit the truth of all that has been said against their sign, but they admit that if everyone else in Ludgate-bill put up the same kind of erection the result would be most objectionable, and they therefore intend to remove theirs and avoid setting a bad example. In adopting this sensible course Messrs. Hudson are probably doing themselves much more benefit than they would have gained from the continuance of the obnoxious sign, and they are perhaps also unintentionally heading a movement against this form of advertisement, for it is not unlikely that others will seek, by the removal of similar signs, to gain the same commendation for public spirit which Messrs. Hudson have justly received.

#### "MASONIC REPRINTS."

THE Lodge Quatuor Coronati, No. 2,076, London, has continued its archeological labours in the interest of the history of Freemasonry since the review of Vol. I. of the Reprints, which was inserted in the *Builder* for Sept. 28, 1889, p. 218-9. That Vol. I. included the reproduction of the great "Masonic Poem," existing in MS., the date of "about 1300"

being now ascribed to it (first half of fifteenth century formerly). This was accompanied by a very able "Commentary." There are now before me Vols. II. and VII., both bearing the date of 1890.\* The latter may be at once described as containing a lithographed facsimile of the 232 pages of the quarto volume entitled "The New Book of Constitutions of the Antient and Honourable Fraternity of Free and Accepted Masons," by James Anderson, D.D., London, 1738, in the vulgar year of Masonry, 5738. An interesting "Introduction" by Mr. W. J. Hughan gives an account of this compilation, which first appeared in 1723; and writes of it, "But whatever may be its merits or demerits, according as we look at the volume leniently or critically, the fact remains that to it, and to it alone, we are indebted for a history of the Grand Lodge of England, from its inauguration in 1717 to 1723, when the official records begin, and from that period for an able extract of the Proceedings; hence the work has been described as the "basis of Masonic History," and "the Father of English Masonic History." This volume being now scarce, it has been selected as one of the series of Reprints, and could not have been more faithfully represented.

Volume II. is of a different character. It contains in Part I. a facsimile and transcript of a manuscript in the British Museum, considered to be the second oldest of the Constitutions or Old Charges of Masonry, and from its having been issued in 1861 in a fairly good manner by the late Matthew Cooke, it is styled the "Matthew Cooke Manuscript" to distinguish it from the earlier one (noticed in the *Builder* of 1889 as above) now called the "Regius Manuscript." The date of "not later than the first half of the fifteenth century" has been given to it by Mr. E. A. Bond, of the British Museum, while by others the latter part of fifteenth century. Part II. is a facsimile and transcript of a similar "Constitution" in manuscript in the Lansdowne collection in the Museum, of a date of "circa 1560" or about "1600." Part III. is a facsimile and transcript of another such manuscript in the Harleian collection to which the date of "beginning of seventeenth century" has been assigned by Mr. Bond, while "after 1721" is considered right from its containing certain "New Articles" (which first appeared in print in 1722), but the Harleian MS., 1941, which also has them is ascribed to "cir. 1670."

If of the Regius MS. no history is attached, there is some to this one of Mr. Cooke, for there is little doubt that it was known to Dr. Anderson before 1723; and the "Woodford MS." is an almost verbatim copy of it, made in 1728 by Wm. Reid, Secretary to the Grand Lodge, for Wm. Cowper, "Clerk of the Parliament," who himself had been Grand Secretary. While a transcript is here given in Volume II., there is at the same time a modern reading printed for the benefit of the unlearned in old English. The Secretary of the Quatuor Coronati Lodge, Mr. G. W. Speth, commenting upon this manuscript,—the Cooke MS.—considers that it is probably not more than fifty or sixty years earlier than the time of its author; but I consider that it is evidently the book in use among the Masons of some particular part of the kingdom, when and where our author was associating with them. And further than this, it is the purest, least altered copy of these Constitutions that has at present come down to us, and therefore the most valuable, far exceeding in intrinsic value the metrical version presented to us in the Regius MS. It consists of a commentary preceding a version of the "Old Charges"; the subsequent "Constitutions" make this commentary a part of the book itself. He considers the rhymed version, the Regius MS., is composed from a later original than the prose version or Cooke MS.

The Lansdowne MS. is written on one side only of four sheets of stout paper, measuring about 18½ in. by 13 in., while the Harleian MS. is of twenty pages, measuring 7½ in. by 5½ in., the writing leaving very small margins. The chief interest attached to this last is that it contains "The New Articles," consisting of clauses determining who may be elected a Free Mason, "the said society, company, and fraternity of Free Masons shalbee regulated and governed by one master and assembly and wardens—at every yearely general assembly; and noe person

\*Quatuor Coronatorum Antigrapha." Masonic Reprints of the Lodge Quatuor Coronati, London. Edited by G. W. Speth, P.M., Secretary. Volumes II. and VII. Margate: Printed at Koble's Gazette office. 1890.

shalbee accepted a Free Mason or know the secrets of the said society until hee hath first taken the oath of secrecy hereafter following."

It will, therefore, be seen that there are in this Volume II. three versions of the "Old Charges" of various dates and of various merits. No one can doubt that each was written for the use of a Lodge of Masons; that "when" is doubtful, and the "where" quite unknown. The earlier MSS. were also, no doubt, used in the operative Lodges at the admission of an apprentice. This Cooke MS. contains the line (621) that Athelstan's son "lerned practyke of that sciens to his speculatyf. For of speculatyf he was a master." If the MS. he of the date given here to it, namely, say about 1430, or even to the end of the fifteenth century, it shows, I consider, a *very early* use of the term, for can the word "speculative" be found used earlier than 1530? The word occurs neither in the Lansdowne nor Harleian reprints; nor in the 1738 reprint of the old Constitutions now presented, nor in any other copy to which I have had access. This line 621 has been often quoted, but perhaps its absence from so many copies may not heretofore have been observed. Have the learned commentators on these manuscripts considered the point, especially in their chronology and classification of them? It is stated that the fac-similes of these two interesting manuscripts are the work of Mr. F. Compton Price, and that they will hear the most rigorous inspection and comparison with the originals. I can honestly add my testimony to the apparent great care bestowed upon them, and the beauty of their execution. WYATT PARWORTH.

#### THE TRADE UNION CONGRESS.

THE annual Congress of Trade Unions is being held this week at Liverpool, and, according to all accounts, is being much more largely attended than usual.

The opening proceedings took place on Monday, in Hope Hall, when about 450 delegates were present. Mr. J. Swift, of Manchester, took the chair in the first instance, and in his opening remarks referred to the great changes which had been made in the status of trade unions and unionists since the Congress last met in Liverpool (in 1875).

On the motion of Mr. Peters, President of the Liverpool Trades Council, Mr. William Matkin, general secretary of the Carpenters and Joiners' Society, was unanimously elected President of the Congress. Having taken the chair, he called upon Mr. Broadhurst, M.P., to read the Report of the Parliamentary Committee, from which the following passages are extracted:—

#### Employers' Liability.

"The last Congress was looking forward with considerable anxiety to the action the Government would take with respect to the above question during the session that has just expired. Although the Government promised to deal at an early period with the matter, they did not introduce their Bill until some time after the commencement of the session. Immediately the Bill was made public, your committee held a full meeting, and unanimously instructed the secretary to move that the Bill be read a second time that day six months whenever the second reading stage should be reached. This decision, which was not arrived at until after a long and careful examination of the terms of the measure, was based upon the following objections,—namely, that while the Bill was in many respects an improvement on that of 1888, inasmuch as it abolished a great many complicated parts of what was then known as clause 3, yet it retained the principle of contracting out of the Act, maintained the doctrine of common employment, and limited our existing common law rights; while the clause relating to seamen was declared by the secretary of the Seamen's and Firemen's Union to be useless and inoperative except to about 5 per cent. of the men engaged in the mercantile marine. Taking all these circumstances into consideration, your committee were of opinion that it was better to oppose the progress of the measure, and to await the advent of a new Parliament, when the ballot-box will clear men's minds with regard to our just requirements; and a new Government, of whatever party it might consist, will introduce a broad measure, giving to the working-classes the same law as is at present in force for the benefit of the general public. For more than this we have never asked, and with less we shall never be contented."

**Factory Act Amendment Bill.**

"Your committee, in conjunction with the committee of the textile factory workers, in the early part of the session, invited a number of members of Parliament connected with the textile and other districts most directly affected by the Bill, to meet them in conference at the Westminster Palace Hotel, London. Some forty members attended the meeting. Sir Henry James presided. Mr. Birtwistle explained the objects of the proposed changes in the law, and at the close of the conference it was resolved:—'That the members of Parliament representing textile and other districts most directly affected by the proposals, should form a committee for the purpose of conferring with the representatives of the employers and employed, and discussing with them the provisions of the draft Bill, with the object of coming to some common understanding.' This committee was appointed, and consisted of nineteen members, with Sir Henry James as chairman, and Mr. R. G. C. Mowbray, Mr. H. Byron Reed, and Mr. George Howell as joint secretaries. During the Parliamentary session several conferences took place between this committee and the employers and operatives' representatives, but up to the present they have not been able to come to an understanding upon all points, as the employers, while agreeing to certain modifications of the present law, which are very desirable, and will be of considerable utility, strongly object to some of the main features of the Bill, and we are afraid that no satisfactory agreement can be arrived at with the employers, and that there is no other course left open to us but to introduce the bill drafted on our own lines."

**Engineers' Certificates Bill.**

"After many conferences, and the expenditure of much labour on the part of your chairman, and the representatives of other societies interested in this question, the Bill has been re-drafted. It was again placed in charge of Mr. Fenwick, M.P., who, from causes quite beyond his control, was unable to secure a debate, or make any progress with it during the session."

**The Labour Conference at Berlin.**

"One of the most notable events of the year was the conference that was held at Berlin, at the invitation of the Emperor of Germany, to consider the question of international labour legislation. We are not inclined to attach too much importance to this gathering, but it is undoubtedly a distinctive step forward, and it has enabled European Governments to become acquainted with the comparatively advanced position which labour occupies in this country. As soon as it was definitely announced that a conference would be held, your Secretary had interviews with members of the Government, and suggested that direct representatives of labour should be sent to attend it. He submitted a number of names of competent workmen for this purpose, from which the Government ultimately selected three—Mr. Barnett, Mr. Burt, and Mr. Birtwistle. We believe that some fruitful results of the conference are to be seen in recent legislation in Germany, and in the increased interest displayed by European nations in the labour question and the condition of the workers."

**The Quarries Regulation Bill.**

"The Quarries Regulation Bill was re-introduced by your secretary, but through lack of opportunity, coupled with the determined opposition of the Government, no progress was made with it. We measure it a most desirable one, and served a better fate."

**Picketing.**

"For some time past the Congress and the committee have been repeatedly appealed to with regard to the law on this subject. The law is, however, perfectly clear, and cannot be mistaken in the permission it gives to peaceful picketing. If those engaged in trade disputes necessitating this means of protection could obtain the information which they could easily get before undertaking the work, there is no reason why they might not conduct picketing successfully and without any liability to prosecution. This, indeed, has always been our intention. In a recent case at Bristol, arising out of the bakers' strike, some men were committed for trial, and the Bristol Trades Council, after consultation with us and adopting our advice with regard to the defence of the men, expressed the satisfaction of hearing a judgment given by Mr. Justice Cave, at the Bristol Spring

Assizes, in which he clearly upheld the rights of workmen in this matter. The essential parts of the judgment were reprinted and sent out to the trades in a circular we issued last May."

**General Remarks.**

"The past year has been one of remarkable activity in the labour world. There are many and various reasons for this increased life. In the first place, combination is perfectly free and recognised by law in the Trade Union Acts, and the law of contract, if not perfect, at any rate leaves little to be desired. Increased interest is taken in workmen's movements by the press, and enormous prominence is now given to labour agitation by newspapers which, in the days which have scarcely passed, had nothing but sneers and misrepresentation when they did not utterly ignore the efforts of the workers to better their condition."

The balance-sheet of the Parliamentary Committee showed that the income for the past year amounted to 1,121*l.*, comprised of subscriptions, 795*l.*; sale of Congress reports, 139*l.*; delegates' fees to Congress, 175*l.*; and that, after meeting the various items of expenditure, there was a balance in the treasurer's hands of 371*l.*

The consideration of the report was adjourned until after the delivery of the President's address.

**The Organisation of Labour.**

On Tuesday, Mr. Matkin delivered his Presidential address. In the course of it he is reported by the *Liverpool Post* to have said:—"Those seers of the press who assert that the present labour revival is spasmodic and consequent on good trade have evidently lost sight of certain material facts. There have been periods of commercial activity before, and necessarily with them increased labour organisation. But in no case has there been the slightest approach to the remarkable developments we have so recently witnessed. It is, therefore, necessary to go deeper than to the state of commerce to ascertain the cause. It cannot, of course, be disputed that the Anglo-Saxon is pre-eminently endowed with great organising faculties. Our colonial expansion, our system of government, our successful local representative bodies, our ancient guilds, and our host of voluntary successful enterprises, all bear testimony to this. Trades unionism is, in fact, an offspring of this spirit. It is practically an hereditary quality. Now, what more natural than when the working classes were educated, came into possession of a cheap literature, and had the advantage of a free Press, these organising qualities should be developed, and that trade combinations should spread rapidly? The present labour revival is, in fact, a distinct

German Emperor. Although naturally reluctant to discuss a subject upon which there is so keen a division of opinion, I should be false to my duty and to the important results which the people expect from the congress, if I did not pointedly express an opinion upon the eight hours' question. In doing so, may I draw your attention to the significant fact that although a substantial trade revival has existed for nearly two years during which the trade union development has been remarkable, still few general and concerted efforts have been made to establish the eight hours day by means of voluntary efforts. I am not complaining of this; on the contrary, I believe the unions have acted up to the measure of their strength and of their opportunities. If therefore they have, through a variety of causes, been unable to begin the struggle for this inestimable boon, it seems to me that an additional argument has been supplied for legislation. If the eight hours day is not secured when trade is good and when the unions are necessarily at their strongest, it is obviously impossible for them to obtain it when commercial depression sets in and the unemployed clamour at the gates of capital. I have no fear that an eight hours Bill will injure British trade, sap the independence of the workmen, or practically destroy our unions. On the contrary, let me draw your attention to the significant fact that the application of the Factory Acts to the textile trades of this country, and the consequent legal regulation of the hours of labour, has not ruined the cotton trade, and has not to any marked degree played into the hands of the foreigner. Similarly, in the manufacture of machinery, a developing trade demonstrates that the nine hours system has not worked the havoc on our commerce that fearsome prophets foretold. Indeed, many facts justify the conclusion that reduced hours, by developing the physical and mental powers of the individual, really leads to cheaper production."

We will next week briefly record some of the further proceedings of the Congress.

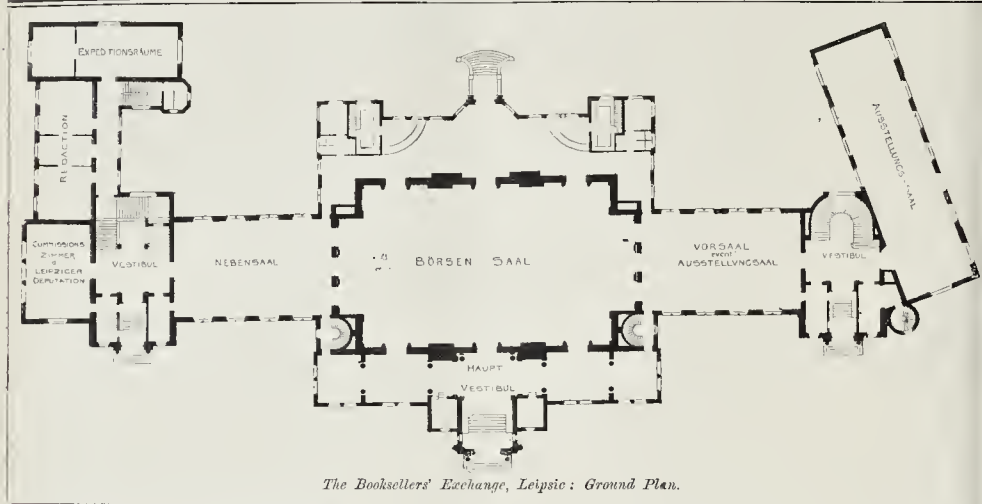

**MOSS FLOWER'S ADJUSTABLE GRADIENT INDICATOR.**

This handy instrument, now on view at Stall 34 in the Brighton Health Exhibition, has been devised for laying down gradients and ascertaining the rate of inclination of existing gradients, and will be of great use to architects, surveyors, civil and sanitary engineers, builders, sanitary inspectors, clerks of works, and others. By its use, drains can be accurately laid to any required fall, as will be seen by the accompanying illustration and description of the instru-

ment:—A is a brass plate accurately graduated to the most useful rates of inclination, including 1 in 6, 1 in 7, 1 in 8, 1 in 9, 1 in 10, 1 in 12, 1 in 15, 1 in 18, 1 in 20, 1 in 24, 1 in 30, 1 in 36, 1 in 42, 1 in 48, 1 in 50, 1 in 54, 1 in 60, 1 in 70, 1 in 80, 1 in 90, 1 in 100, 1 in 150, and 1 in 200. B. C. is the limb carrying the spirit-tube, and works about the pivot at C. Suppose the gradient required for drain is 1 in 30, the limb B. C. is raised to the line marked 1 in 30 on graduated plate A, and is held firmly in this position by a clamping-screw. The level is then ready for use, and the accuracy of the gradient can readily be determined by applying the bed D. E. to the uppermost surface of pipe, or straight-edge, and if the gradient is as required, the bubble will float midway in the spirit-tube contained in the limb B. C. Its adaptability for ascertaining the rates of inclination of existing gradients will afford a ready means of showing at once whether existing drains have a sufficient fall at any particular point, by unearthing the same and applying the bed of the level to the drain-pipe, raising the limb B. C. until the bubble floats midway in the spirit-tube, clamping up, and reading the index.

The instrument is inexpensive and simple in construction, and is made of boxwood, plated

The Booksellers' Exchange, Leipzig: Ground Plan.

with brass. It is only 9 in. in length, the accompanying diagram showing its application not being drawn to scale.

Illustrations.

THE NEW BOOKSELLERS' EXCHANGE, LEIPSIK.

THE new Booksellers' Exchange at Leipzig, which has been designed by and erected under the superintendence of the Berlin architects, Messrs. Kayser & Von Groszheim, shows elevations in a style similar to that used on the German gable houses of the sixteenth and seventeenth century.

The building, which not only contains the Exchange-hall proper, with its vestibule and offices, but also two large halls to be used for special exhibitions, and on the first floor a library and rooms for the collections of the Graphic Museum, is considered to be exceedingly well planned, and has the advantage of being arranged so that it can all be used as an entire whole for festivities or receptions; or it can be used in separate blocks, attainable from without by means of separate entrances, and entirely disconnected from one another.

The material used is brick, the facings being of freestone; the superficial area covered is 2,625 square meters, and the total cost was 700,000 marks. A plan of the building is appended.

COURT-HOUSE FOR LOS ANGELES, CALIFORNIA.

This building, which has occupied about two years in erection, is now structurally approaching completion.

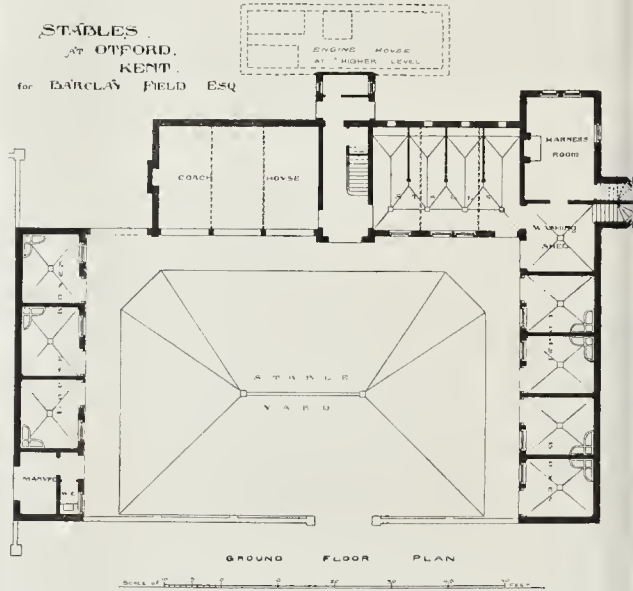

It occupies a commanding site on an elevated plot of land, bounded by Fort, Temple, and Buena-Vista streets on three sides, and by the County Police-station on the fourth.

The building is traversed by a spacious corridor the whole length, on three floors, communicating with principal and two secondary flights of stairs, and giving access to the six court-rooms, judges' chambers, witnesses' rooms, offices for the various civic functionaries, and large apsidal-ended chamber for board of supervisors, together with library, strong-rooms, and well-arranged toilet requisites for each department, janitors and engine-rooms, &c.

The structure is erected upon concrete foundation; the basement is of granite, the upper external walls of red and buff Arizona sandstone, internal walls of brick, and partitions and floors of corridors, court-rooms, &c., of hollow firebrick and concrete, supported on rolled iron joists; the roofs are slated, and have buff terra-cotta ridge cresting and finials, &c., and the tower and turrets are covered with copper.

The heating is by means of hot water circulation; the inlet ventilation is supplied by "Tobin tubes," and for lighting both gas and electric light will be adopted.

STABLES for OTFORD, KENT, for BARCLAY FIELD ESQ

The tower is utilised for water supply tanks on two stages, and the upper portion has an observation-room, affording a magnificent outlook over the whole city of Los Angeles and a vast extent of surrounding country.

The lower portion of the internal plastered walls will be finished with moulded and panelled dados, the ceilings of court-rooms coved, and moulded, and panelled; the floors of principal rooms, oak and parquetry, and glazed tiles for corridors, &c.

A Hall of Records, designed in unison with the Court-house, is proposed to be erected on a portion of the site, so that the whole business of the city and county can be conducted in close proximity.

The building was won in open competition by Messrs. Curlett, Eisen, & Cuthbertson, architects, of Los Angeles and San Francisco; and is being erected by Mr. O. E. Brady, of San Francisco, at a cost of 750,000 dolrs, under the immediate superintendence, of Mr. Curlett.

STABLES, OTFORD, KENT.

THESE stables were erected at the same time as the house previously illustrated (see *Builder* for October 16, 1886), and at some little distance from it, upon the estate of Mr. Barclay

Field, near Sevenoaks. The buildings adjoin the kitchen garden, and are (as well as the engine-house for electric lighting and pumps from well) upon a steep slope, which had to be excavated for the stable-yard and buildings. For these latter the contract was 3,353l. The materials are red brick, with half-timber work above, filled in with plastering and finished with tile roofs. The upper story contains coachmen's living rooms, lofts, &c. The perspective view was shown in the Royal Academy exhibition in 1889.

THE NEW RESERVOIRS AT MONTMARTRE.

WE gave last week illustrations and a description of a number of the picturesque fountains which formed the ancient means of water-supply to Paris. We give this week an illustration of one of the latest and most important additions to the modern system of water-supply to the same city, the section and elevation of the Montmartre reservoirs. This, it must be admitted, is not picturesque, though an effort has been made to give to the exterior a certain imposing and bastion-like character, and the upper surface of the construction has been

*Royal Academy Exhibition, 1889.*

PHOTOGRAPH BY J. MARTINE LAM, ANDERSON & SONS, E.C.

at as a terrace garden. A model of the whole occupied a conspicuous place in the pavilion of the Paris Municipality in the great Exhibition of 1889.

The construction of the reservoirs was entrusted to M. Journet, as engineer, under the direction of M. Bechmann, Chief Engineer of the Sanitary Department. The reservoir is near the church of the Sacré Cœur, and overlooks the whole north quarter of Paris. It is a monument of this conspicuous position that some attempt has been made to give the structure a definite architectural character, and with this object the late M. Diet, architect, was commissioned to design the exterior.

The structure is composed of two distinct and separated portions, forming two reservoirs, a parallelogram in plan, the other with its exterior walls forming segments of a circle: the former, as will be seen from the section, has no stories, the latter three.

The lower stories of each reservoir receive and distribute the water of the river, raised to a height of 75 mètres by the engine at the foot of Montmartre hill, and which pumps directly from the pumping station at Bercy, on the banks of the Seine.

The middle story of the larger reservoir and the upper story of the smaller one receive and distribute the water collected from the reservoirs of the Dhuis at Ménilmontant. The upper story of the large reservoir is to feed a further reservoir situated in another portion of the high ground of Montmartre.

The reservoir has occupied two years in construction, at a cost of 1,024,000 francs.

#### THE SANITARY CONGRESS AT BRIGHTON.

LAST WEEK\* we printed the substance of the address of the President (Sir Thomas Crawford, K.C.B.), and we also gave a description of the Health Exhibition. We now conclude our account of the Congress by giving summaries of and extracts from various papers read thereat.

##### *Earth versus Water.*

Section I., "Sanitary Science and Preventive Medicine," was presided over by Dr. G. V. Moore, F.R.C.P., who took as the subject of his address "The Living Earth." He said he applied the epithet "living" to the dark-coloured inert mould which the countryman sees in the fields and gardens, and which the town dweller finds in the flower-pot which holds his struggling geranium. Having shown that the black vegetable mould which lies upon the surface of the earth, is largely composed of organic matter, and that the micro-organisms of the soil are very active in producing changes in organic matter added to the soil,—changes usually in the direction of oxidation, he proceeded as follows:—

"Supposing comma bacilli to exist in dejecta, what is the best way to stop their multiplication and accidental passage into drinking-water? Clearly to dry them and place them with other saprophytes. If they be hurried in the upper layer of vegetable mould, the sun will dry them; or, even if it be raining, the long filter will stop their passage downwards. The growth of saprophytes will kill them; and if the ground be cultivated, the comma bacilli will be destroyed and nitrified, and pass upwards into the crop, and not downwards into the wells. If, on the other hand, the dejecta be mixed with water, and he taken in an impermeable pipe through the living humus of the surface, to the dead mineral subsoil where the sun does not reach to dry them, and where saprophytes to eat them up exist not, the danger of their finding their way through crevices and cracks into drinking-water appears to me to be very great indeed. That the under strata of the soil are a very inefficient barrier against filth contamination has been demonstrated in all our large towns, and especially in London. In that city the sewer rooms of the houses are almost universally below the level of the street, and the house-drains leave the house at the lowest point to reach the sewer at a lower level still. Underground drains, however well laid, are sure to leak in time; their contents escape, and water continually escaping at one point is sure to work a channel for itself, and take its natural course to the nearest stream or well. Still more sure is it to happen if the house-drain leads to a cesspool, a contrivance which necessity

invented as soon as we had water under pressure, and began to use it as our only scavenger. In London, a city renowned for its innumerable wells, we have had to close every one of them, and as the excessive dirtiness of the air makes rain-water not available for domestic purposes, we have become absolutely dependent upon the water companies, and it is only quite recently that the public has become alive to the fact that the causes which poisoned the surface wells are equally poisoning the Thames and the Lea, and the other sources of London water. No thinking being can feel easy about the London water supply, and it is to be hoped that some day the public mind will be roused to an appreciation of the fact that if we want pure water we must make some serious attempt not to foul our wells and streams. I am convinced that in our sanitary arrangements we have not sufficiently distinguished between the living mould of the surface and the dead earth of the subsoil. The living mould is our only efficient scavenger, which thrives and grows fat upon every kind of organic refuse; our only efficient filter, a filter which swells and offers an impassable barrier to infective particles, a filter which affords a sure protection to our surface wells. When we perforate the living humus with a pipe and take our dirty water to the subsoil, we, as it were, prick a hole in our filter, and every chemist knows what that means." Dr. Poore then went on to argue in favour of the exclusion of excremental matter from the sewers; such matter, he contended, should be hurried in the "living earth," every day, and household slops should be applied to the top of a different piece of cultivated ground every day. In conclusion, he said that "a nation that foms its streams and starves its soil is in danger of poisoning and inanition. A nation which imports a great part of its food and a great part of its manure, and systematically and by Act of Parliament throws all its organic refuse into the sea, is undoubtedly living on its capital. Our capital just now is undoubtedly considerable, but we are in a fair way to run through it; and when we have done so who can forecast the future?"

The conclusions arrived at by Dr. Poore were strongly criticised by Sir Douglas Galton, who contended that water was as great a purifier as earth, and that towns with water-carried sewage had proved to be far more healthy than towns where the pail system was in vogue,—and the pail system was what Dr. Poore's proposals implied.

In the same section, Dr. James Turton, M.R.C.S.E., Chairman of the Sanitary Committee of the Brighton Town Council, read a paper "On some Points in Relation to Septic and Infectious Diseases." In the course of it, he said that last year he was called to attend several members of a household suffering from general malaise, headaches, and occasional vomiting. The house drainage was good, but an unpleasant smell was noticed in the kitchen, and the symptoms attacked only the servants and those members of the family who were in the habit of entering the kitchen. He had the flooring taken up, when several of the joists were found to be rotting in places, and emitting the odour complained of. The putrid wood was removed, and a better provision made for ventilating the space beneath the floor. Since then there had been no illness in the house.

Alderman Joseph Ewart, M.D., F.R.C.P., read a paper on "The Sanitary Advance of Brighton." This paper embraced a review of the (a) site, environs, and climate of Brighton; (b) arterial drainage; (c) house drainage; (d) the electric light in its sanitary and hygienic aspects; (e) reinforcement of the health department; (f) the death-rate; (g) the effectual dealing with unhealthy houses and areas; (h) the more frequent removal of dust, rubbish, and ashes; (i) the construction of a destructor; (j) the provision of one or more bath-houses; (k) the accommodation of dairy cows beyond the boundaries of the borough; (l) further extension of bathing accommodation for males and females in northern part of town; and (m) the construction of a grand swimming-bath, so situated as to meet the convenience of the people of the town generally, in which all the boys and girls of the rising generation should be taught the art of swimming as an integral part of physical training.

Dr. A. T. Schofield, M.D., read a paper on "The Value of Hygienic Knowledge to Women." Professor Corfield gave a lecture on "House Sanitation from the Householder's Point of View."

Dr. Arthur Newsholme, M.D., Medical Officer of Health for Brighton, read a paper on "The Bearing of School Attendance upon the Spread of Infectious Diseases." He advocated (1) the compulsory notification of measles and whooping-cough, as well as of scarlet fever and diphtheria; (2) the complete isolation of infectious cases and the quarantine of children in infected houses; (3) that whooping-cough in a house should be no exception to the rule, but should preclude all children of the same house from attending infant schools; (4) that the Medical Officer of Health should give prompt and direct intimation to the head-teacher, of any case of infectious disease among his scholars, and instruct him as to the duration of the infectious period; (5) that teachers shall be strictly forbidden to send children to inquire the cause of absence of absentees, and that a special officer should be appointed for each school to visit such absentees. Further, he urged the importance of instructing parents and scholars in the laws of health. Much mischief in spreading infection was done in ignorance,—an ignorance which was so crass and pertinacious that it was difficult to realise that the sin was not being committed against light and knowledge. With the adoption of these measures he believed that the necessity for the compulsory closure of schools would be very infrequent.

##### *A National Health Service.*

The Hon. F. A. R. Russell read a paper on "A National Health Service." He said that the objections to the exercise of a strong and uniform State control and supervision did not hold in respect to infectious diseases. Those evils arose from causes which were well known, and could be greatly reduced by the application of certain well-known principles by a central authority, having the advantage of full information concerning the distribution of infectious diseases throughout the country from day to day, and of the services of sanitarians of the highest skill and ability. Most localities did not take such interest in bringing their districts to a high degree of salubrity, and many Medical Officers received so small a salary that their occupation as such was disregarded in comparison with their private practice, which they were still allowed to pursue. In fact, the Sanitary Acts in many small towns were a failure, and through this failure the whole nation suffered. A neglected village might be the cause, through milk, water, or ordinary intercourse, of destructive epidemics in neighbouring or even distant towns or counties. Infective diseases ought, like fire, to be under the constant and effective supervision of an authority for the whole area over which the destructive power was likely to spread if unchecked, and that area, in the case of infection, was the whole country. A Ministry of Health might learn from the notification already adopted by over three-fourths of the country, the distribution and progress of various diseases, and its officers might be continuously conducting a campaign against them by the best known means. The conditions which favoured the spread of infection were so well known that there would be little difficulty in arresting an outbreak at its inception. The experience of the Westminster Sanitary Aid Association was that even in the midst of a crowded population, and in the case of so easily caught a disease as scarlet fever, it was possible to confine the fever within very narrow bounds. The Sanitary Aid Association of Hastings almost put an end to infectious illness in that town, although, of course, many visitors must have resorted thither before being perfectly safe. In fact, few Local Authorities had attained the degree of immunity from zymotic disease which was really possible for the whole nation to reach, if willing to conform to certain rules which were beneficial both to the sick and the healthy. Diseases arising from impure conditions of water, or air, or milk, could be easily reduced in their places of origin, and prevented from spreading by isolation and disinfection. But the amount of knowledge, training, and authority required to deal adequately with them was such that no body other than a Government or National Department could fitly undertake the task. And when these infections were constantly travelling beyond county boundaries, even a County Council could not keep their ramifications within view. The plan recommended by

\* See pp. 168-171, ante.

the Joint Committee on State Medicine, of the British Medical and Social Science Associations, still appeared the best which could be devised. By it there was to be created, instead of the many local authorities now existing, one elected and representative body, clothed with all executive functions, whether municipal or sanitary, within the area of its jurisdiction. The Health Officers of the County Boards were to be men of high scientific attainments and acknowledged ability; paid adequate salaries for superintending the whole or a division of a county; to these were to be added Medical Officers of a district, and all were to form one great Department of the State, under the presidency of a Minister of Health, but all these officers were to be under central control, so far as making up one great body of workers for general State medical purposes. The fact was that infectious disease was not merely local, and could not be dealt with effectually by Local Authorities, because if one was active, another was negligent, and they could not attack the enemy with anything like the force or precision of a trained brigade. There was no escape from the urgent need of State control in respect of epidemic and spreading diseases, for a single neglected district was a danger to the whole nation.

Mr. W. H. Collins, F.R.S., read a paper on "The Alleged Danger to Public Health arising from Effluvia Nuisance from Gasworks." He indicated certain ameliorative processes which have been adopted in some of the largest and best gasworks in this country.

#### Baths for the People.

Professor T. Roger Smith, F.R.I.B.A., presided over Section II, "Engineering and Architecture," and took as the theme of his Presidential address the subject of "Baths." Commencing by describing the Roman theme, of which he said that Professor Atchison's lectures at the Royal Academy last year\* had given the most learned and complete account known to him, he went on to speak of "Turkish" baths and vapour baths. Coming to the subject of cheap and popular baths, he said that a very considerable number of establishments, some of them opened as private speculations or by small companies, but for the most part provided under the Public Baths and Washhouses Act, existed.

Mr. Rosher stated the number of public baths in England having a swimming-bath as part of their installation at 200, out of which seventy were in the metropolis alone. The avowed aim of many of these was to reach the general mass of the people. In addition to the washhouses, we found in one of these establishments one or more swimming-baths and a series of warm baths. Proceeding to examine the nature of each of these provisions, and premising that those who desired further information as to the Baths and Washhouses Act and its results would find it in a compact and serviceable form in the comprehensive report of Mr. Ernest Turner on the subject, prepared at the time of, and in connexion with, the recent Paris International Exhibition, the Professor said the swimming-bath is necessarily a more or less public institution. It is in its nature large and expensive to establish and maintain, but it is almost unequalled as affording to great numbers a means of healthy, pleasant exercise, and as furnishing an opportunity for the young and others to acquire the valuable art of swimming. No pains should be spared to make it attractive as well as convenient. A swimming-bath of modern construction is a large tank, usually long in proportion to its width, shallow at one end and fairly deep at the other, walled in and roofed over, with a floor all round and numerous dressing-boxes. The interior should be light and airy, the water bright and clean, and the dressing-boxes should secure some degree of privacy. As the swimming-bath, if successful, will be worked pretty hard, it is necessary to have the means of rapidly and thoroughly cleansing every part in use, and of quickly emptying and refilling the bath. Gas should be provided. In some cases provision may be made for employing the bath as a room for public meetings or a gymnasium, or in some such way during the winter time when it is not in request. Let us look into the means of carrying out this programme. The most important part of the whole, the swimming-bath tank, requires to have extreme care bestowed upon its construction, lest it should

leak. Portland cement concrete is so well fitted for constructing the bottom and sides that it is not now likely that, save under exceptional circumstances, any other material will be used; formerly brickwork backed up by clay puddle was the best material available, but there was more chance of leakage, and it is said that defects were not infrequent. The pressure of the water against the bottom and sides is not formidable in amount, but the various weights are quite sufficient to cause a partial failure if the foundation gives way, so every care must be taken to ensure an uniform and solid foundation for the bottom, and similar support for the sides, as the smallest settlement will be followed by a crack, and the crack by a leak. Cement concrete is not itself water-tight, and a lining of almost pure cement is required. The actual face of the tank should be of glazed brick or tiles, though when economy is of importance this may be dispensed with. Bands of dark brick or tile running from end to end of the bath are sometimes introduced into the bottom as a guide to swimmers in swimming races. It is desirable to put in at least the foundations of the external walls before beginning to dig for the bath tank, so that the excavation for the baths, when once made, shall not be again disturbed. If the tank be dug and concreted first, the subsequent disturbance of the earth in digging for the footings of the enclosing walls may be enough to cause a crack. Any outlets and inlets required should be decided, as to both size and position, before beginning; and the valves, sluices, &c., put in as the concreting goes on, so that there may be no excuse for disturbing the work and cutting holes in it. I know of one successful case where the side walls of the tank were first formed in trenches, and then the dumping, or great mass of earth in the middle, was got out, and the bottom put in last of all; but there is some risk of making a bad join, and it is better to excavate the whole before beginning to concrete, and then to do the bottom first, and to bestow especial pains and not to stint material in making the join between bottom and sides. The water at the shallow end should be rather over 3 ft. deep, sloping to about 6 ft. at the deep end, and it is not uncommon to have the deepest point about 10 ft. short of the end, so that persons diving in may plunge into the greatest depth. However this may be, every part of the bath must slope sufficiently to one point, to enable the water to be completely run off from the bottom. For cleansing purposes the corners and the join between the bottom and sides should all be rounded so as to prevent any lodgment for dirt. It is desirable to have along the shallow end a perforated pipe with water laid on, so that when the bath has been emptied the attendant may be able, when necessary, to turn on a shower of water while the tank is being cleaned out. The depth of the water should be legibly painted at the sides in several places. The edge of the paving should be rounded, and between it and the water there should be a space of about 6 in., and here a stout tank rounded handrail, or an iron pipe 2 in. in diameter, should be securely fixed on brackets for bathers to hold. The perforated pipe already alluded to may serve this purpose where it occurs. It is desirable also to fix spittoons at regular distances round the edge of the bath, and there should be a stout step-ladder at each corner. The dimensions of the tank must be settled with regard to the probable number of bathers and the means disposable. Every additional foot adds to the cost of original construction and of maintenance, but adds also to the value of the bath to the bathers. For a public bath, less than 25 ft. width and 60 ft. length of water area is not desirable. The length may, with great advantage, be increased to 70, 80, or 90 ft., then the bath should be 30 ft., or even more wide. At most baths there will be swimming clubs, and these festivals have to be considered. Less than 5 ft. width will not do for a racer, so that not more than five competitors could well race in a 25 ft. wide bath, and four would be more comfortable. It is rather desirable, in the interests of the races, to have the length an even number of feet divisible by ten, then three laps make a similar number of yards, and 60, 70, or 80 yards can be swum readily in a bath 60, 70, or 80 ft. long. The water delivered into the bath, whether pumped up or from the mains of a water company, will be too cold for bathing in most states of the weather; and how to warm it is a most

important point, for it is not only essential to be able to raise the temperature from the point at which it is delivered, which may probably be from 50 deg. to 60 deg., up to say 75 deg., or at least 72 deg. Fahrenheit, but it ought to be uniformly raised through the entire mass of water in the bath. If there are cold zones or hot zones in the water, bathers will not like it, and a bath that is disliked will be of comparatively little use to its owners or the public. In some cases hot water and steam is circulated in pipes within the bath itself, the pipes being, as a rule, fixed in a recess formed in them in the walls of the bath. In others a lot chamber is formed outside the bath tank, a filled with hot-water pipes or steam pipes, and the water is admitted into this cool and returned to the bath warm. In another arrangement the water is drawn off from the bath heated in a furnace, and returned warm. Sometimes steam is simply blown into the bath itself, an expeditious but noisy way of raising the temperature. Most of these plans are more or less reliable to heat the water unequally, and more than one of them there is apt to be introduced a pipe, or a jet, or a something which is found to get too hot for bathers to touch without injury. The plan the results of which, so far as my experience extends, are the best, is one differing from all these. It was put up for me at the baths of the Carpenters' Company at Stratford, by Messrs. Fraser, and I can speak strongly of the success of this apparatus as a means of warming the water uniformly and effectually, and helping to keep it fresh. At the deep end of the bath, and near the bottom, an iron pipe is introduced, which is carried (outside the tank) back to the shallow end, and to which the water has free access. The course of this pipe is introduced an air chamber, into which a powerful jet of steam under considerable pressure is thrown; it acts upon the contained water on the principle of a Giffard's injector, and hurries it on, so that it is returned into the bath, travelling at some speed, and of course the water that takes its place is drawn out at the same speed. The steam mingling with the water in the chamber raises its temperature, and the result is that a stream of warmed water is always pouring in near the corner of the shallow end of the bath, while an equal quantity of cold is always leaving at the opposite end. The temperature, by this simple means, gradually and equably raised to what is required, and is easily maintained; and what is satisfactory is, that the warmth is found to be uniform all over the bath, and that the water is always in gentle motion it keeps remarkably clear. A method resembling that of Messrs. Fraser, but carried further, is that of Mr. C. H. Rosher. He employs either a steam-jet just described, or a pump, to effect circulation of the water in the bath tank during the heating process; but he admits the heated water at the bottom of the tank, distributes it over the floor of the bath by disc diffusers. It is claimed that this method promotes uniformity of temperature, and rapid heating, and prevents steaming from the surface of the bath and loss of heat. With this system of heating this engineer combines a second improvement, directed to secure economical working of a bath. The heaviest expense in working a swimming-bath is usually the cost of water. It will take about 60,000 gallons of water to fill a bath 25 ft. by 80 ft. This, at 6d. per 1,000 gallons, a usual price, will cost 12 1/2 s.; and should the bath be refilled daily except Sundays, the expense would be 9s. per week for water only, in addition to the cost of fuel used in warming the incoming water. Mr. Rosher proposes to filter and to aerate the water by appropriate machinery placed in a small chamber formed for the purpose, and so to render the same supply fit to last much longer. Filtration will, it is considered, remove the solid impurities, such, for example, as those which the settlement of dust on the surface of the water occasions. Aeration will oxidise, and neutralise some organic impurity. I believe this system has been successful at Woolwich and other places, where it has been tried; and there can be no doubt that a plan which will diminish the amount of water used in a bath without rendering it less pleasant or less healthy, promises to effect a very great economy in working. Other plans for filtration have, I believe, been brought forward, but this is the most complete that has come under my notice, and it only one which includes a provision for constantly re-charging the water with air. The rest of the swimming-bath may be dismissed

KAYSER AND VON GROSZHEIM, ARCHITECTS.

are briefly. There should be a platform not less than 4 ft., and better, 5 ft. to 6 ft. in clear depth at the sides, and 10 ft. at the ends, and the deep end a stage should be erected for sitting. The interior should be bright, but direct sunshine on the bathers is undesirable. A bath is best lighted by a series of ample side and end windows, but generally there is not room for that, and a great skylight has to do duty, which it does very well. There should be ample ventilation, under the control of the attendant, and not of the bathers. Ventilation in a swimming-bath is a little difficult to maintain without discomfort to the bathers, especially when the atmosphere is much colder in the air in the bath. A few steam pipes, or hot-water pipes, to warm the dressing-boxes are of essential service, both to aid in this and to keep the place comfortable in cold weather, though it must not be forgotten that the large masses of tepid water in the heat into the chamber that contains it, are should be, near the entrance, several shallow bath supplied with hot and cold water and a tepid spray—often called a soap hole—bathers who come in from dirty work and are to wash themselves clean before plunging into the swimming-bath. A small laundry for towels and bathing-dresses should adjoin, and be worked by the same boiler as supplies steam for heating water for the swimming-bath and the warm-baths. It will include some sinks, a boiler, a centrifugal wringer, and a hot-closet; and my experience, as far as it goes, that the hot-closet will be better worked, and more certainly, if it has an independent furnace, and is heated by hot air, than if it be obtained from a steam-coil. Professor Smith then proceeded to describe in detail the arrangements of that part of an establishment for public baths which provides warm baths for individual bathers. In his concluding remarks he said:—It must be admitted that, while the operation of the Baths and Washhouses Act has brought means of bathing within the reach of large numbers of people, it has not gone far enough, believe it has been the experience of the managers of many of these establishments, that they are not frequented to such an extent as to make them self-supporting; and it needs no consideration to see that the prices charged, though very moderate even if they reach the maxima fixed by the Act, do not place the bath within the reach of every class of working people; while the mere fact that these establishments must be on a considerable scale, and therefore cannot be very close together, removes them from the easy access of some of those who would use them if they could. Can we give the bath never to the doors of the people, can we give them a cheaper bath than anything accessible at present? In London and other crowded towns and cities, I have no doubt that simple, cheap, and accessible bathing establishments, formed in crowded neighbourhoods, set up as a rule in existing buildings, adapted to the wants and the purse of the poor, would be popular and largely used; and my impression is that they could be made to pay their expenses, and possibly to yield a profit to those who established them. If so, better openings for practical benevolence exist than the multiplication of applications of this sort under prudent and careful attention, and I wish the subject may attract the attention of philanthropists. Alluding to means of cheapening baths, the Professor mentioned the spray-baths provided by Mr. C. C. Hooper at Donnington, near Newport, in Shropshire, where a private bath with clean towels is sold for one penny. He said that a trial of the same is about to be made in London, on the owners' Company's estate at Stratford. He referred to Mr. David Grove's spray-baths to Mr. E. A. Reynolds's spray-baths as likely to be of very great service in meeting a public want for cheap baths.

Mr. Alderman Hallett read a paper on "The Brighton Waterworks," which were subsequently adopted by the members of the Congress.

Mr. R. E. Middleton also read a useful paper on "Waterworks Regulations" with regard to bearing on sanitation. He quoted the regulations of the Liverpool Corporation Waterworks *in extenso* as being, perhaps, as complete as any others. He pointed out that, as most desirable, in the interests of the consumer as well as of the water companies, only reliable plumbers should be employed, and that the regulations of the Manchester Corporation Waterworks, he said that No. 15 of those regulations, by which criminals were allowed to be flushed direct from the service pipe if a self-closing tap were used, did not appear to be judicious.

*Improvements at Brighton.*

Mr. F. J. C. May, Borough Engineer and Surveyor of Brighton, read a paper on "Brighton as a Health Resort." In it he gave a short review of the many important works executed during the year 1888 to 1890, mainly from the plans and under the superintendence of Mr. Philip C. Lockwood, M.Inst.C.E., the late Borough Engineer. Referring to the question of baths, Mr. May said that the Corporation had decided to try the experiment of a system of cottage baths dotted about in the poorest and more densely-populated districts; this will have the effect of avoiding long walks to a central large bathing establishment. It will, indeed, be taking the baths to the people, and it is hoped will be a popular movement. The first institution of this kind is being constructed at the present time at Brunswick-place, North. Here a large house has been hired by the Corporation for a term of years, and is being fitted up with eight baths, four for men and four for women, supplied with both hot and cold water. The establishment will be under the care of a man and his wife, who will reside on the premises. From the interest already taken in the progress of the operations by the class of persons for whose use it is intended, there is every reason to believe the experiment will prove a success. In his concluding remarks, Mr. May said "Having given a brief description of the work already done, it will not be out of place, nor betray any official secrets, if I state that it is not the intention of the Corporation to remain satisfied with what has already been done; but, on the contrary, that there is a strong determination to progress in every direction, and to keep pace with the march of science in the interests of the public health. A public abattoir; a refuse destructor; a grand extension of the sea defences eastwards in the parish of Rottingdean, with suitable drives and promenades; a scheme for the better utilisation of the Tenantry Downs; a yacht station opposite Kemp Town; various street improvements to relieve the congestion of some of the more crowded thoroughfares; and a new Town Hall, are matters which are already engaging the attention of the Corporation."

Mr. W. H. Collins, F.C.S., read a paper on "The Necessity for Improvements in the Sanitary Arrangements of Dairy Farms, and for their more careful Inspection by Sanitary Authorities." He fully proved his case.

Mr. C. Hooper read a paper on "Industrial Dwellings."

Mr. John Hanson read a paper on "The Use of Black Ash Waste in the Treatment of Sewage and Foul Water."

*The London Sewage Question.*

Mr. Richard F. Grantham, M. Inst. C.E., read a paper on "The Disposal of the Sewage of London on the Maplin Sands." The paper dealt with the proposal for reclaiming a large portion of the Maplin Sands, and for distributing the sewage of London over the reclaiming surface. Reference was first made to the conclusions of the Royal Commissioners on Metropolitan Sewage Discharge, viz., that some process should be used to separate the solid from the liquid portions of the sewage, and that the solid matter deposited as sludge should be applied to the raising of low-lying lands, or be burnt, or be dug into land, or be carried away to sea. The effluent should then either be distributed on land by means of intermittent filtration, or discharged lower down the river Thames at Hole Haven. The steps taken by the London County Council towards the fulfilment of these recommendations were described, and the utility of the steps as a permanent measure, in the opinion of several eminent authorities, was pointed out. Other methods of disposal were also referred to. The difficulties in the way of irrigation and filtration on land were alluded to, and a list of towns was given to show the maximum quantity of sewage applied per acre per twenty-four hours on their respective sewage-farms, from which a deduction was drawn that not less than 10,000 acres would be required for the proper disposal of the sewage of London. It might well be doubted whether so large an area could be properly devoted to such a purpose near the present sewage outfalls, and the cost of obtaining and laying out the

land would be very great, especially as a new line of railway had recently been made through that part of Essex, near the Northern Outfall. It was feared that, assuming that the chemicals now used did not sufficiently clarify the sewage, the discharge at Hole Haven would cause as great a nuisance to the river there as it has higher up. It was, therefore, proposed by the author to conduct the sewage away to the Maplin Sands as more advantageous than the alternative of utilising it on Canvey Island, in being further removed from any seaside resort, in being larger, and in course of time making an addition to the agricultural area of the country instead of absorbing any part of it. The general outline of the scheme and the dimensions of the culvert were then described, and the quantities of earthwork and concrete required are stated. The surplus excavation for the culvert would be utilised in forming the embankments of the area of the lands proposed to be reclaimed, which was estimated at 10,000 acres. In order to show the capacity of that area—the surface of which was sand—for absorbing and filtering large quantities of sewage, reference was made to the Craigentiny Meadows at Edinburgh, and other places, and taking for examples the volumes of sewage applied at those places, and the results of experiments made to ascertain the degree of purification at certain rates of filtration, it was proposed to lay out the area when reclaimed partly for filtration and partly for irrigation, dividing it into plots by arterial drains to carry off the effluent, so that the whole volume might be disposed of and ultimately discharged into the Swin Channel without endangering the oyster fisheries, and without risk of nuisance to Southend and other places. The cost of the scheme was estimated at 4,500,000*l.*, exclusive of the cost of land.

*The Iron Process for Disinfecting Sewage.*

Major C. R. Conder read a paper on "The Iron Process as applied to the Disinfection of Sewage in Barracks and Dwelling-houses." This process was invented by the late Mr. E. R. Conder, M. Inst. C.E., and was described as a self-regulating chemical process for application to closed drains on various scales. The proportional dosing of the sewage with iron in solution was thus rendered practical at small cost. The result was the disorganisation of the sewage into inorganic elements, producing a silt easily dried, and a pure effluent within requirements of Rivers Pollution Committee. The offensive odours were destroyed and the bacterial germs killed, as shown by Government analysis. Its *house application* was by an instrument called the "Ferrometer," intended for about ten people, and requiring to be filled and cleared once a month. This had been applied at Windsor Castle, Buckingham Palace, at various houses of the Marquess of Bute, and by the Duke of Wellington, Lord Salisbury, Lord Lorne, and in some 300 cases in country houses to the satisfaction of those who had adopted it. In its *drain application*, at present the process was only working in England on a small scale. It was adopted at Chichester barracks by the War Office, in 1886, and paid for under agreement that it should first be reported satisfactory by the Commanding Engineer. The number of persons provided for was about 1,000. The process was further adopted by the Admiralty at Eastney Barracks, Portsmouth, in 1889, and after six months trial had been reported successful, and negotiations commenced for applying it for 2,000 persons. The Admiralty analyst reported the destruction of bacterial germs in the treated samples. On the property of the Duke of Northumberland at Alnwick, it had been applied to the Castle and to 1,500 persons in the property, and reported by the clerk of the works to be the best process with which he was acquainted. At Grange-over-Sands, in Lancashire, it was applied in 1889 to 300 persons, and the results found satisfactory. The Inspector of the Local Government Board having given a favourable report, the Local Board of Health was empowered to raise money for the development of the drainage system; and that having been carried out, the process was now being applied to the new drains, and had been reported successful. In these cases the form of instrument consisted of tanks and cones placed in pits by the drains, but the principle was the same as that of the household instrument. Further applications on a larger scale were now commencing at Halifax, in Yorkshire, and at Toronto and other places in Canada. The ad-

Described and illustrated in the Builder for October 12, 1889, p. 261.

vantages claimed for the process were—(1) That it can be applied immediately without alteration of existing drains; (2) that it destroys the sewer gases from the point of application, and not merely at the outfall; (3) that the effluent may be discharged direct into any stream without injury to the water; (4) that the expense is very small, and the application simple to maintain; (5) that the silt is inoffensive, and has been shown to make a good manure. The success of the method depended on the proper apportionment and correct position of the apparatus, and on the saving of labour due to the automatic action which secures a constant application. The difficulty hitherto found in dealing with a bulky and offensive sludge was thus overcome.

Among the papers read in Section III., "Chemistry, Meteorology, and Geology," were the following:—"On the Climate of Brighton," by Mr. F. E. Sawyer; "On Lead-poisoning from Soft-Water Supplies," by Mr. Percy Frankland, F.C.S.; "On a Case of Well-pollution undetected by Chemical Analyses," by Mr. A. W. Scatliff, D.P.H.; and on "The Ill-effects of Floods on Health," by Dr. A. Haviland.

The last day of the Congress was mainly devoted to excursions and visits to various works and places of interest in the locality of Brighton, and in the evening the Congress was brought to a close by Dr. Richardson's "lecture to the working classes," which was very poorly attended. It dealt with the question of hours of labour, the lecturer going very far in favour of the adoption of the eight-hour limit, and hazarding strong doubts whether "Bank Holidays" as at present observed do not do more harm than good to people.

#### DISC CUTTING-TOOLS.

THE new Martignoni tool—the sole right of manufacture of which has been acquired by the Machinery and Hardware Company, Limited, of London—is deserving of attention. Its object is to replace the present straight cutter on the lathe by a disc-shaped cutter of slightly spiral form, with a tooth formed in its periphery like a single tooth of a circular saw. This tooth, which is ground out of the disc and sharpened by an emery wheel on its inner side, forms the cutter. The disc itself is held in position on the lathe or other machine-tool by a strong spindle set at a right angle to the plane of the disc. This spindle is inserted in a cylindrical tube, the two halves of which, being clamped together by a set screw, hold it perfectly secure. The loosening of this circular grip enables the tooth of the disc to be brought up to any desired position on the bar, rod, or metal to be turned or planed, the action of the ordinary tool-carrier of the lathe, when the disc is fixed, bringing it up to cutting distance for a thin or thick cut as desired.

What is claimed for the new tool is—that it is easier to take out for grinding or exchange; that there is no loss of time in fettling and no constant loss of material by short ends; and thirdly, that a higher speed and a deeper cut than usual can be obtained, as well as cleaner than is possible with an ordinary cutting-tool. We concur in the former statement; and in the second to the extent that fettling is dispensed with, the disc being homogeneous in its metallic state and the tooth being able to be sharpened up to the smallest residue of metal capable of supporting the tooth against its work. The tooth might still even be ground out of the residual disc of smaller diameter, so that the final loss of metal might be very small indeed. The wood-cut shows the disc tool with its one

cutting-tooth, and the spindle by which it is held in position. The new tools can be further made of other patterns than simple turning tools. There are already tools made for screw-cutting and spiral or ring groove cutting. The screw-cutting by one of these special disc tools is a very pretty operation, the holder being so made that any desired angle for the cutting-tool can be obtained. In this way it is prac-

ticable to make a clean thread of a screw by one cut—the work thus will be done in shorter time than at present, and the running into the material avoided.

For boring purposes the disc-tool is held in the holder by a conical-ended spindle, the holder being formed of a long square bar bored through horizontally, with a recessed taper surface, in which the spindle of the disc fits.

There appears also to be less vibration in the new tool than in the old, and this consideration is one of much value.

#### FRYER'S REVOLVING COWL.

FRYER'S patent revolving chimney-cowl and ventilator, of which we give a small illustration herewith, appears to possess some advantages worth notice. It has a square base, gradually tapering off towards the head, and thus forms practically a continuation of the chimney-stack. The inlets, which are "honetted"

over, are so arranged on the four sides of the base that the outer current is drawn upward. The cowl is claimed to be noiseless in work, and free from friction, the bearings moving in oil, and the cowl revolving with the slightest current of the air. The cowl has an entirely open head, which allows the smoke to escape freely. There is a hinged flap on the top of the head, allowing easy access to the bearings. The cowl is made of galvanised iron, all parts being rivetted. The manufacturers are Messrs. J. D. & W. Fryer, of Brecon.

#### Books.

*Engineering Estimates, Costs, and Accounts: A Guide to Commercial Engineering.* By A GENERAL MANAGER. London: Crosby Lockwood & Son.

THIS is an excellent and very useful book, covering subject-matter in constant requisition in every factory and workshop. The preparation of estimates is one of the most important, as well as one of the most difficult and varied, of the duties to be performed in an engineering establishment. At the same time, it is one with which the young engineer gets least acquaintance. The matter of estimates is more one of commercial accounts and personal judgment than of actual engineering. Thus, whilst the articulated pupil is familiarized with mechanical details, it is rarely that any useful amount of commercial knowledge is imparted. In this way, the road to managerial and other responsible salaried positions is in a large measure closed to the engineer. In the early formation of businesses, the want of experience in this direction is embarrassing. The primary object of the book before us is to remedy this defect, and to aid those who have a healthy ambition to rise in their profession to salaried positions. The principles and conditions which control the preparation of estimates are set forth with great perspicuity, and are fully illustrated by a number of tangible examples. Not only is it primarily necessary that the capital invested in an industry should earn its legitimate profits by selling the productions for larger sums than the gross cost of

manufacturing them and delivering them to the buyers, but it is also most important that the effects of competition should be well considered in framing those tenders which are sent out with a view to securing business. In this view the present book is invaluable, not only to the young engineer but also to the estimate department of every works; we may add, too, of considerable service to the principals themselves by the display of varying practices which is given, and the breadth and soundness of their views set forth. Not only are there details for large establishments, but there are equally valuable details for small works where the technical and commercial duties are performed by the same person. In the preparation of estimates, materials and workmanship are the two main bases of the calculations. The kinds and qualities as applicable to various classes of work, and to particular portions thereof, are admirably dealt with in an extensive series of actual examples, thus furnishing to the inexperienced thoroughly firm foundations for his labours, and reminding the experienced of the chief points in many subjects of consideration. The taking out of quantities is a fundamental process in estimating, and very practical examples are given. Very pertinent remarks, too, are appended on the differences and allowances between unfinished and finished work. The experiences of one place and of one period have to be carefully checked: the conditions of workmanship being also modified by the introduction of new tools and appliances. Patented inventions also tend to disrupt old arrangements.

The matter of patterns again is one of much moment, and the suggestions, therefore, as to how patterns in stock may be altered are very valuable.

The most perfect way of estimating is to set forth all the items, adding to the total of probable cost a proportion of the working expense of the establishment, including management. In this way the gross cost to the manufacturer is ascertained, and the principal adds thereto the profit he thinks he can get from his customer. The other and more general method is to reduce the materials and workmanship to standard rates. This mode gives at once a selling price to the buyer, but furnishes no indication of the exact cost to the maker.

The labour rates and duties are well put forward, alike for ordinary and for odd-work. Jobbing orders are lucidly dealt with, and the grounds for higher remuneration in such cases well reasoned out. In steam engines, boilers, heating apparatus, and various other matters, the information and illustrations are equally practical. The author's labours conclude with an essay on manufacturing book-keeping.

The book contains 250 pages, and is a matter of a couple of days' close reading. No one, however, can appreciate it properly without actual perusal; and it probable that even the most experienced will be benefited by so doing.

*The Uses of Plants.* By G. S. BOULGER, F.L.S., F.G.S. (Roper & Drowley, 1889).

THE object of this volume is best explained by the sub-title, "A Manual of Economic Botany," as it is devoted to an account of the vegetable substances employed as food and medicines, and in the arts, and especially to additions to the list which have been made during the past fifty years. It is intended as a popular manual, but the subject it deals with so extensive that the book is necessarily far more than a classified catalogue of the materials employed, the names of the plants from which they are derived, and the countries from which they are imported. The excellent synopses and general indices, occupying thirty out of the 224 pages, make it a useful book of reference, and the numerous references in foot-notes to other works enable the student to go to the original sources of information made use of by the author. There are no illustrations, which is a great defect in a book of this kind, where the physical characters of vegetable products were described in terse and technical language.

The difficulty of classifying objects derived from so many different sources and employed for so many different purposes is very great, and Professor Boulger has thought it best to arrange them according to their uses, except in the case of medicines, which are arranged botanically. Thus, he divides woods and timber into those required for making walking sticks, for ornamental work and furniture,

works of construction. It would appear that a substitute for box-wood for the engraver is a great desideratum at present, and that of the twenty kinds of wood which have been put forward our common lawther is the best,—a fact which, we believe, is little known in our country districts. It is distressing to our patriotic feelings to read that such common kinds of timber as oak, beech, birch, and ash are largely imported from the Continent and America, while there is so much of it in this country which cannot find a profitable market. The difficulty lies, no doubt, with our expensive inland carriage, and as the railways are not likely to afford much assistance in this respect, it is to a revival of our long-neglected land navigation we must look for help for our pressed forest industries. Dr. Shilich, of the forestry department of Cooper's Hill College, recently stated that we spent twenty millions annually on the importation of timber, and that with proper cultivation of a fourth part of our waste lands this deficiency in our supply could be met.

The section on paper materials is among the most interesting in the book, and we learn from that not only are numerous new fibrous plants available, but that some of our soft, white woods are being used for paper-making. The time has not yet arrived, we fear, when rags will be dispensed with, and the insanitary results associated with their importation got rid of. On the other hand, while wood is being made into paper, waste paper is being used as a substitute for wood, and is being converted to coach panels and tram wheels, and even to "black patent leather." With the development of this industry we may hope for the disappearance of the disfigurement of our streets and parks by waste scraps of paper. We find no account of the source and botanical character of peat-moss, now so largely imported from abroad and employed as bedding for horses and cattle, nor of the much-increased growth and use of the tomato as an article of popular consumption. The statistics of imports are somewhat antiquated, the most recent having reference to the year 1886; but keep pace with our ever-widening commerce and the development of new industries would require an annual revision and issue of the book.

*Handbook of Athletic Sports.* Edited by ERNEST BELL, M.A. Volume I.: Cricket; Lawn-Tennis; Tennis; Rackets; Fives; Golf; Hockey. Volume II.: Rowing and Sculling; Sailing; Swimming. London: George Bell & Sons, 1890.

The first volume of this series affords a curious enough anything but a unique example of the capability of many writers on games to put themselves in the position of those who have no acquaintance with the game supposed to be described, and to give a clear and logical description of it. According to the editor's preface, the object of this series is "to give in a concise form, by writers whose eminence in their respective branches enables them to speak with authority, a clear description of each game, with practical directions and hints, such as will be helpful to the beginner and the more advanced player." If that is the object, the book does not answer to it, in regard to all events to the two most important and popular games described. No one who was ignorant of cricket and lawn-tennis could gain a clear idea from this book of how the two games are played, or of their general principle. The authorised rules are given, but rules do not explain a game. In the Hon. E. Lytton's satire on cricket there are many remarks and hints, written out in a very desultory and haphazard manner, which are useful and suggestive to young players who have learned the game; but there is no clear general statement of the principle and details of the game, or of the ends to be kept in view in howling, hitting, and fielding; there are diagrams of a different placing of the field for fast and slow bowling, but no explanation of the reasons for that; there is a long dissertation on "bowling 'lobs,'" but the reader is not told at a "lob" is. If it were our business to write about games, we would undertake to do, within the compass of one column of this journal, a description of the game of cricket in which the uninformed reader would gain clearer idea of it than he will be able to gather from Mr. Lytton's ninety-two rambling pages.

It is not much better with lawn-tennis. The

rules are appended, but there is no logical and concise description of the principle and method of the game, which is what a reader ignorant of it naturally looks for. There is a chapter on "the volley," but he is not told what a "volley" is, and so on.

The section on the older game of tennis proper, by Mr. Julian Marshall, is much better done, and here the author gives a complete description of the progress and method of the game. Golf is also intelligibly described. But cricket and lawn-tennis, the most popular and widely played of the games included, are not; and the sections concerning them ought to be re-written, if the book is to fulfil the object professed in the preface.

Vol. II, which treats of rowing, sailing and swimming (which, by the way, are not "sports," but arts) is much more satisfactory, and indeed within the space allotted could hardly be better done. "Rowing" is done by Mr. Woodgate, "Sailing" by Mr. E. F. Knight, and "Swimming" by Messrs. M. and J. R. Cohett. All three writers (for we may consider the two swimming writers as practically one) are careful to remind the reader that mere book-knowledge cannot do more than put a man in the right way of learning what can only be really acquired by actual practice; but at the same time the instructions are so practical and so clearly worded that any tyro who had studied them would enter a boat or enter the water with a distinct idea as to what he had to aim at and what to look out for. The sailing section is especially well done, and contains a good deal of information which is permanently useful for reference; and if this short treatise were studied by those who ambitiously put themselves into sailing-boats at watering-places, without in any sense "knowing the ropes," they would know a little better what to do in an emergency than they sometimes do, and would be aware of some dangers into which people run, and sacrifice their lives, through pure ignorance that there is any danger. The section on swimming has also the merit of being remarkably clear in its description of the methods of swimming, so that a beginner can really learn from it what he ought to try for, at all events. This second volume of the series can be cordially recommended as a very useful one.

"The Great Tower for London" (compiled and edited by F. C. Lynde, A.-M. Inst. C.E., and printed and published for The Tower Company, Ltd., at the office of *Industries*, 358, Strand) is a sixpenny pamphlet containing illustrations and descriptions (the latter being, however, very incomplete) of the sixty-eight competitive designs for the tall tower which Sir Edward Watkin and his friends propose to build at Wemly Park, or somewhere in that vicinity. We sincerely trust that the tower will never be built; but whether it be built or not, the present pamphlet will remain a curious and interesting record of the competition. But it is to be regretted that the compiler's work has been so hastily and meagrely performed. The details given are not always accurate, and we are informed that the cost of one design (No. 19, by Mr. J. W. Couchman) is over-stated to the extent of more than 800,000*l.* As all the illustrations are engraved to the uniform scale of 300 ft. to an inch, their comparative height and bulk can easily be seen. Some of the designs, as we pointed out at the time of their exhibition, are fearfully and wonderfully conceived, and many of the designers (or is it the compiler?) are indelicately reticent in their descriptive notes. — The "Gas Consumer's Diary," with full directions for reading the index of a gas-meter correctly, and for checking gas accounts (London: The Blackfriars Printers, Ltd., 3, Salisbury-court, Fleet-street) will be found very useful, and well worth the twopence for which it is to be had. — The Report of the North-Eastern Sanitary Inspection Association for the year 1889-90 (Newcastle: Standard Chambers, Neville-street) shows a marked advance on the reports of previous years. It records much useful work done, and we are glad to see that it is directing attention to the question of school ventilation, in which there is much room for improvement in many districts.

**FOUNTAINS AT GLASGOW.**—At the same time that the Douton fountain was presented to the City of Glasgow, as mentioned in our last, Messrs. McIlwain, Steven, & Co. presented their fine iron fountain which was exhibited in the Glasgow Exhibition, and which has now been erected in Cathedral-square.

Correspondence.

To the Editor of THE BUILDER.

HOT-WATER SUPPLY.

SIR,—Lately I have put into my house a range which was much recommended to me, but which has a very small boiler, without a manhole, and so placed as to be inaccessible without opening brick-work. When, on my return home, the arrangements were explained to me, I wrote to the maker, and am by him assured that the circulation is so rapid as to prevent incrustation, however hard the water be. I admit that the circulation is rapid, but should certainly not have ordered the range had I understood the form and position of the boiler. The article in your number of July 12 induces me to ask you if there is any hope that the rapid circulation will prevent incrustation; for myself I fear that, though it might serve for the soft waters of northern counties, the very hard waters of the colliery will soon choke the whole boiler.

\* The rapidity of circulation is governed by the heating power of the boiler, *inter alia*, a poor heating boiler is not successful in creating a rapid circulation. Now, an efficient, or powerful boiler is a desirable thing in every sense, except its liability to become incrustated more quickly than one of average power, supposing it has regular use. With "very" hard water, the boiler under ordinary circumstances cannot last more than two years, unless provision is made for, and attention is given to, its regular cleaning. Rapidity of circulation can only be due to rapidity of heating; a rapid heating boiler is one that "furs" most (under the circumstances named), but the rapid movement tends to carry the precipitated matter into the flow-pipe also more than it would do otherwise.

"A SANITARY NOTE FROM GREENOCK."

SIR,—Under the above heading, on page 130, *ante*, there is a long article in which, *inter alia*, the system of trapping and ventilating the house-drains at Glasgow is attacked, and facts are found with the Greenock officials for recommending drainage to be done in Greenock on the Glasgow plan. Now, "X. Y.," on pages 130 and 131, does not really find any fault with the Glasgow system of trapping the drains, but with the system in which he says the drains are ventilated. He condemns the practice of the ventilating fresh-air inlet gratings being directly over the traps, because, as he says, when a water-closet, *e.g.*, is let off, bad air may flow up through this "X. Y." advises that "all air openings to or from traps and drains should be carried up as high as the main roof." Now, I do not consider this to be at all necessary in general practice. I have not done it for inlets even of mansions where the expense would have been no obstacle had the plan been worth the candle. I have no objections to siding with "X. Y." in a general condemnation of the inlet ventilating gratings being put in directly over the traps, and especially when those traps are on the pavement and close to building, or the entrance to it. Independent of risk of smells coming up, the traps are often choked at tenement houses, when the gratings are right over the traps, by children putting down umbrella wires, and sticks, &c., through the gratings. Now, in practice, I find that the chokeage of the traps and complaints of bad smells from the grating can be easily cured without going to the expense, &c., of carrying up ventilating-pipes to the roof, *viz.*, by putting a strong iron plate, 8 in. or 10 in. square, over the trap, for examination and cleansing, and then having the fresh air inlet grating a couple of yards, or less or more, according to circumstances, to one side. This has been a common practice in Glasgow for years back, and if Greenock follows suit, the grounds for the objections made by "X. Y." vanish, especially if the work is properly done.—I am, &c., W. P. BUCHAN.

Glasgow, August 30, 1890.

**DEPLETION OF WATER-SUPPLY BY MANURE.**—In the current volume of the Proceedings of the Institution of Civil Engineers some particulars are given of some investigations made by MM. Florent and Brouardel to ascertain the course of an epidemic of typhus fever at Havre. The conclusion they came to was that the outbreak was due to pollution of a spring at Cotillon from whence water-supply is derived. It appears that towards the end of the years 1889 and 1887 the cultivated plateau of Gannville, which covers the water-yielding layers of Cotillon, had been manured for the first time with the contents of the refuse tubs of Havre. The formation is chalk, under which is a layer of clay, and upon the outcrop of the latter the water appears as a spring. The investigations undertaken show that a chalk spring under these conditions may be polluted at its source. Even a thickness of 22 to 27 yards of chalk does not offer sufficient security against pollution, because contaminating substances may pass through the fissures of the chalk.

## The Student's Column.

## HOT-WATER SUPPLY FOR BATHS, LAVATORIES, &amp;c.—X.

TANKS, CYLINDERS, &amp;c.: continued.

**W**HEN regard to the pressure of water from pipes into closed vessels, it should be remembered that the same strain is exerted upon the internal surface of the cylinder or tank with whatever sized supply pipe may be used, whether it be  $\frac{1}{2}$  in. or  $1\frac{1}{2}$  in. or larger. The result may be stated as follows. If the water within a pipe having an internal area of one square inch exerts a pressure of 1 lb. for every 2 ft. 4 in. of its vertical height on every square inch within the cylinder, a pipe having an internal area of half this size will only exert half the pressure, *i.e.*, half a lb., or a pipe having an internal area of two square inches will cause a pressure of 2 lbs., but with the  $\frac{3}{4}$ -in. pipe the pressure of half a lb. will be felt on every half square inch in the cylinder, and with the 2-in. pipe the 2 lb. will be exerted on every two square inches, so that the total result is precisely the same.

In purchasing tanks or cylinders it is very desirable to get them from makers who have a reputation for good quality work. No doubt there are small firms who supply excellent goods, but to purchase tanks or cylinders at a low price will almost certainly be found to be false economy, and nothing is more annoying than to find, when charging a new apparatus to test it, that the tank or cylinder leaks at the joints or rivet holes. It is also inadvisable to use these reservoirs of too light a quality, *i.e.*, those tested to a less pressure than they will have to bear. This is very often done with impunity, as, of course, the makers' tested pressure does not indicate the bursting point, and where the pressure is only a pound or two over the maker's test marks no harm will ensue, but it is far better to have the reservoir a trifle too strong, as we have not only to think what it has to withstand now, but also that it will be expected to do the same work several years to come, when it is beginning to suffer from wear and tear.

If a tank is of a large size, or unusual shape, it should have "stays" (rods extending from side to side) within it, as immediately pressure is exerted the sides are pushed out, and it has a tendency to become as round in shape as it can get.

The following are sizes of tanks and cylinders customarily chosen as being suited for ordinary domestic purposes where no special requirements exist. With the smallest form of apparatus having two taps (scullery and bath), 25 gallons; this size, however, will be found insufficient if the demand is more than moderate, by reason of a large family occupying the house, and 30 or 35 gallons would be found more suitable; but regard must be had to the capabilities of the range-boiler; there are exceedingly few 3 ft. ranges that have boilers capable of working satisfactorily with a larger reservoir than 25 gallons.

In a little larger house, say nine or ten rooms, 40 or 45 gallons will be found a convenient size, the kitchen range being 4 ft. (or 3 ft. 6 in. with a fair-sized fire and boiler); in larger property the size must be judged according to the number forming the household, and even the number is no sure index, as baths are indulged in much more by some people than others, and the style of living regulates the quantity of hot water required in the scullery, and it is the bath and scullery taps that make the greatest inroad upon the store of hot water. Sixty gallons is a full size for a residence of some pretensions, and it is unusual to exceed this size in private residences, except in mansions of the largest class, and with a large staff of servants (in which case an independent boiler would probably be required). Too large a reservoir is very objectionable, as it renders the work of the boiler almost futile; it is not so much a great store of hot water that is required as a moderate amount that can be renewed quickly.

## PIPES, TAPS, AND OTHER FITTINGS AND APPLIANCES.

The kinds of pipe commonly used in this work are wrought-iron steam tube, galvanised ditto, wrought-iron gas-tube, and lead pipe. There are other kinds less commonly used, such as copper tube, &c.

The tube which has preference in the south of England, and which can safely be recommended before any other, is that first mentioned on the above list. This pipe is in general appearance much like gas-tubing, except that its substance is much greater, and in quality of metal it excels the latter; it can always be distinguished by its being coloured a dull red (except when it is galvanised), whereas gas-tube is always a natural black. Everyone having a reputation to uphold uses the steam-tube; and, although a great deal of gas-pipe is to be found, it will generally be discovered in speculative work of a poor class. The difference in cost between steam and gas tube is about 30 per cent.

There is very little galvanised tube used or needed in hard-water districts, as the only object of the galvanising process is to render the tube fairly rust-proof, and so prevent discolouration of the water and weakening of the pipe itself by oxidation. Now the lime which, as already explained, is the cause of the hardness of water, is one of the best of rust-preventives, and it fulfils its usefulness in this direction by coating the internal surface of the pipe with a thin film of carbonate in a very few days, and the rust difficulty is then quite obviated. In soft-water districts, however, some non-rusting tube has of necessity to be used, as water without lime in it always seems to act so vigorously in rusting iron, and the plain steam-tube in these districts causes a good deal of trouble by its being eaten away rapidly and discolouring the water to a greater or less extent. Galvanised tube, if well galvanised, overcomes the difficulty almost perfectly, but care has to be used in fitting it up, as it will not do to forge this pipe in any way (that is, heat it for bending or setting purposes), as the galvanised surface will be injured and rusting ensue, and wherever a pipe is cut and screwed, also, the interior of the socket-joints are all places where rusting cannot be helped.

Pipes are sold which are galvanised on the outer surface only, but it is almost unnecessary to point out that this must be avoided, as no benefit is obtained by the extra outlay. Caution is also necessary to see that when galvanised steam-tube is ordered, the steam quality and strength is obtained, as this material is not kept in stock by everyone, but galvanised gas-tube is.

When galvanised tube has, of necessity, to be used, it is, of course, somewhat necessary to have the boiler galvanised also (or of copper) as the rusting takes place in these almost as badly as in the pipes; but both galvanised pipes and boilers should only be used when circumstances make it requisite, as the acid bath and subsequent galvanising process are considered to be rather detrimental to the iron.

Lead pipes and copper boilers and reservoirs are most commonly used in the North of England, particularly in the Manchester and Liverpool districts, where the soft water requires every consideration. Lead pipes certainly do not rust, but there are other disadvantages connected with this material; for instance, it has been forcibly brought to people's attention that soft water has as vigorous an action on lead (the lead of commerce) as it has upon iron, and the lead which is separated or taken into solution by the water has brought about many serious epidemics of lead poisoning, or plumbism, in various districts, and this lead to the introduction of tinned lead pipe, that is, lead pipe having its interior surface of metallic tin, which is not acted upon by soft water in the way described.

Lead pipe has another drawback, and that is its softness, which permits of its being easily stretched or bulged and weakened by every strain that it is subjected to; on this account it is almost impossible to use the sudden shutting plug cocks with lead piping, as the jar or concussion that is occasioned every time a tap is shut soon does serious injury, weakening the pipe and necessitating repairs. This is most noticeable with the taps at the bottom of the house, where a considerable pressure of water may exist, and in these situations the slow-closing screw-down taps should always be used with lead pipes.

**SALE OF RAY LODGE ESTATE, MAIDENHEAD.**—This property, belonging to the Misses Lassell, was sold at auction last week for 20,000*l.* The sale was keenly contested, and it is understood that, whilst the house and grounds will be left intact, the remainder of the land will be devoted to building purposes.

## GENERAL BUILDING NEWS.

**THE NEW SCIENCE AND ART MUSEUM, DUBLIN.**—On the 29th ult., the new Science and Art Museum and National Library at Dublin was opened by the Lord Lieutenant. The new buildings are situated at right angles to Leinster House, the premises of the Royal Dublin Society, and formerly the town residence of the Duke of Leinster, on the Kildare-street or western side, in the space where the horse show used formerly to be held. The architects are Messrs. Deane & Son, of Dublin. The occasion of the last visit of the Prince and Princess of Wales to Ireland was also the ceremony of laying the foundations, and the ceremony was performed by His Royal Highness the Prince of Wales on April 10, 1855. The builders are Messrs. Bockett Brothers, of Dublin. The Museum building was in November last handed over to the Science and Art Department. In June of the present year the sister building for the reception of the National Library of Ireland was completed. The style of architecture is Italian of the sixteenth century. The cost of the buildings approximately is set down at 120,000*l.* The façades of both buildings, which face each other, are over 200 ft. long. They consist of two rotundas, with colonnades and pavilions. In the centre of the Museum building is a large court, 135 ft. by 75, and opening from it are twenty-four galleries of rooms for the exhibition of objects of interest. On the occasion of the opening ceremony, Mr. Thomas N. Deane, the architect, was knighted, an honour which the Lord Lieutenant said, was "a fitting recognition of the services which Mr. Deane had won in his honourable profession and of the excellence of his latest work."

**BATHS, STAFFORD.**—At a meeting of the Stafford Town Council on the 2nd inst., the Public Health Committee presented plans for baths, the erection of which they recommended at an estimated cost of 10,000*l.* The scheme includes a large public swimming-bath for gentlemen, gentlemen's private baths, six ladies' baths, dressing-rooms, &c. The buildings will be three stories high, will be situated on the Green Bridge, with a frontage to the River Sowe. Underneath the premises there will be a boat-house. One of the large baths will hold 50,000 gallons of water, and a smaller one 15,000 gallons. Considerable discussion took place concerning the committee's proposals, but ultimately the minutes were adopted.

**CHURCH FOR SEAMEN AT CARDIFF.**—A meeting of the building committee for the new Church and Institute for Seamen at Cardiff was held last week on board H.M.S. *Thetis*. Resolutions were passed, and that of Mr. James Allen, amounting to 4,410*l.* and the lowest, was after full discussion, accepted. Mr. E. M. Corbett is the architect.

**THE FOUR OAKS RACE-COURSE, SUTTON COLDFIELD.**—It has been decided within the last few days to offer, in building lots, the well-known Four Oaks Race-course, Sutton Coldfield, near Birmingham. There are understood to be more mortgages on the property to the extent of some 30,000*l.*, and the mortgagees have consequently stopped the operations of the Four Oaks Race Company, and have just put the property up for auction. 35,300*l.* was reached, but the reserve price not having been reached, the estate was withdrawn, and the auctioneer announced that it would be put up into building plots. The estate is 245 acres in extent, and it was formerly used as the seat of the late Sir John Hartopp, who resided at Four Oaks Hall, which still stands in the centre of the race course. Another house known as the Dover House stands on the outskirts of the enclosed race-course area, which is 198 acres in extent. Part of the ground is covered by a coppice known as the Lad Wood, and a belt of timber also runs round the greater part of the boundary.

**NEW HOSPITAL, BIRMINGHAM.**—On the 26th ult. the Marquis of Hertford laid the foundation-stone of a new hospital to be built in Edmond-street, Birmingham, for diseases of the ear and throat. The building is to be in the Queen Anne style of architecture, and will be built of red brick with terra-cotta dressings, and roofed with red tiles. It will consist of five stories. The ground floor is to be used by the out-patients to the number of 200, the second floor will contain the rooms for the dispenser, and the secretary. There will also be a strong-room, and a mortuary, the latter approached from the outside. The first floor will contain two day rooms, two meeting-rooms, operating room, ward, matron's apartments, baths, with all modern sanitary appliances. The second floor will contain three wards, house surgeon's apartments, nurses' rooms, linen room and baths, and all the necessary sanitary arrangements. The third floor will contain kitchen, scullery, and four bed-rooms. There will be accommodation for twenty in-patients. The building will embody the best modern improvements and requisites necessary for a new special hospital. The architect is Mr. J. A. Cossins.

**NEW FREE CHURCH FOR INVERNESS.**—The Inverness Dean of Guild Court have granted the necessary warrant for the erection of a new church for the Free North congregation in Bank street, Inverness. The new building, which is to be erected from designs by Messrs. Ross & Macneil, will cost about 8,000*l.*

**MODEL LODGING-HOUSES, NEWPORT.**—Some model lodging-houses, situate at the corner of Dock-street and Corn-street, and erected of plain stone-work, with fire-brick dressings for the windows, have just been completed at Newport. Mr. John Linton is the contractor and Mr. E. A. Lansdowne is the architect. The total cost of the premises has been put 3,000*l.* for the shell and 750*l.* for fittings and finishing.

**SMILING MERCAT CROSS.**—At a recent special meeting of the Stirling Town Council intimation was made that a gentleman, who did not wish his name to be made public, had kindly offered to bear the whole cost of restoring the ancient mercat cross of Stirling, which it is proposed to re-erect on its old site in Broad-street. The offer was accepted, and the thanks of the Council awarded the unknown donor.

**NEW SCHOOLS, MILES PLATTING, LANCAASHIRE.**—The foundation-stone of new Roman Catholic schools, to be erected in Varley-street, Miles Platting, was laid on the 30th ult. The buildings are intended to provide for the accommodation of 550 children, and will cost 2,485*l.* The building is to be erected on a reserved site. The dressings used is being built by Mr. M. G. G. of Oldham, and on the designs of Mr. Leonard Stokes, F.R.I.B.A., London.

**WATERWORKS AND ENGINEERING NEWS.**

**GLASGOW WATERWORKS AND SEWERAGE.**—The works of the Glasgow Waterworks, lately advertised to be completed open competition for the best scheme for the waterworks and sewerage of the town. A London engineer was engaged as assessor, and, acting on his advice, we understand that the committee have unanimously adopted the scheme submitted by Mr. W. H. Radford, of Nottingham. The Glasgow Council has this week decided to carry out the waterworks at once under the supervision of the superintendent. In the waterworks scheme Mr. Radford proposes to bring the water by gravitation on a mountain stream at Glenmorgau, having a watershed of 1,700 acres, the intake being situate about three miles from the town. Filter-beds, and a special reserve of 100,000 two days supply, will be situate on a hill near the town, the pressure sufficient to command the roof of the highest building in the town when the consumption is at a maximum. The gravitation main will deliver 3,640 gallons a day at the service reservoir. Water, with the usual fittings, will be laid in every street. The population to be supplied is 12,000, and the estimated cost of the engineering works is 1,000*l.* In the sewerage scheme Mr. Radford proposes to lay new pipe-sewers in every street, the sewage being brought down to the outfall works by gravitation. The present sewers are proposed to be conveyed the street surface water into the sewer. At the outfall works the sewage will be treated by duplicate gas-engine and centrifugal pumps and treated in tanks by chemical precipitants, followed by filtration in filter-beds, the effluent being conveyed to the river Suir. There is a tank under the engine-house for storing the night sewage, here will be arrangements for flushing, inspection, and an overflow. The estimated cost of the sewerage works is 8,000*l.*

**WATER SUPPLY OF DUNDEE.**—Recently a committee of the Dundee Water Commissioners had a meeting with Lord Airlie, at Cortachy Castle, with the object of having the 8,000,000 gallons of consumption water from Lintathen reduced to 6,000,000 gallons daily, but no arrangement was decided.

**STAINED GLASS AND DECORATION.**

**WINDOW, EMANUEL CHURCH, WESTON-SUPER-MARE.**—Another of the windows on the south side of the church has been filled in with stained-glass. The general design harmonises with that of the adjacent window. The subject is "Christ walking on the Sea, and Peter essaying to go to Him." The window is the design and work of Messrs. Joseph H. & Son, College-green, Bristol.

**MALLOW CHURCH, IRE.**—A baptismal font has been erected in Malloy Church in memory of late Mr. James MacNaughton, of Smithfield. It is made of Caen stone, and the design of Mr. J. Macvicar Anderson, London. The font, which is octagonal, is supported by eight columns, and on each side an appropriate symbol has been carved.

**THE CHAMBERLAND PASTEUR FILTER.**—Dr. Berlioz, of Berlin, has been making some experiments with the Chamberland-Pasteur filter, a pressure filter, with porcelain cylinders, which, it is claimed, would give water free from bacteria. A water used was that of the Berlin Waterworks, which becomes infested with bacteria when allowed to stand for a time. The results arrived at were that the filter in question would only give water free from germs for a period of four days at the most. After three days or so the filter was found to contain an active and prolific water bacillus, which followed shortly after by bacteria. The latter was described as appearing to grow through the pores of the filter.

**FOREIGN AND COLONIAL.**

**FRANCE.**—The towns of Roubaix and Turcoing, which in their progressive extension have for some time been approaching each other, will soon be united by a new bridge, which is to be driven from the centre of the one town to that of the other. The National Museums Committee has decided to send to Marseilles the bust of the celebrated caricaturist Daubier, who was a native of the town. The bust is the work of M. A. Lenoir.

—At the town of Saintes, in the Lower Charente, a commemorative tablet has been placed on the house in which the late Jules Castagnary was born, who died in 1888 when occupying the position of Directeur des Beaux Arts. A permanent exhibition of the works of living artists born or resident in the department of the Lower Seine is to be shortly opened at Rouen, in one of the galleries of the museum. There has been discovered at Mariette, a small place frequented by Parisian landscape-painters, a regular factory, as it may be called, for the manufacture of pictures with the signature of Courbet, which have been extensively sold in Belgium and Switzerland.—M. Dubois Pillot, one of the founders of the annual exhibition of "artistes independants," died recently at Puy, at the age of 44. He was a devoted disciple of "Impressionism."—A National School of Industrial Art is to be founded at Roubaix in October. —At Perigueux the "restoration" of the celebrated Byzantine tower of the Cathedral of Saint Front has just been completed. The cupola and the forty-two shafts round the base of the museum. It appears, entirely rebuilt.

—In the competition for a new church at Aix-les-Bains, the design of M. Arthur Berlin of Chambéry has been selected for execution. The second premium has been awarded to M. Joseph Allix of Lyons.—A competition has just been opened for the construction, in the grounds of the asylum of Vesuz, of small, isolated pavilions for paying patients. In the diocese of Nancy a large church is in course of construction, for which about 200,000 francs of subscriptions are already collected.

—At Lyons the statue of Henri IV. which decorated the facade of the Hotel de Ville, has been seriously injured from the effects of one of the violent storms which various places in France have lately been visited. We regret to hear that M. John Lewis Brown, the well-known Parisian artist, is dangerously ill.

**AUSTRIA.**—The new great Natural History Museum in Vienna is now fully finished, both as regards exterior and interior. We have already given a description of the building.

**CARFELD.**—A serious accident happened here on the 10th ult. During a thunderstorm, accompanied by heavy rain, the front wall of a three-story building (erected some thirty years ago) gave way and fell inwards, causing the whole building to collapse. Of the forty-eight people in the building at the time of the accident, the official report states that twenty-six were killed.

**WÜRZBURG.**—The municipal authorities have been busy with a scheme for a new bridge over the river Main, to be erected at the south end of the city; and it has now been decided to open a competition for a suitable design for this piece of work, 550,000 marks to be entirely carried out in freestone. The new bridge and 150,000 marks extra for the necessary alterations of the embankments pertaining to the work. No difficulty will be experienced with the foundations, the bed of the river showing a durable limestone formation.

**ROSENBERG.**—On the 25th of last month a statue of the deceased King Ludwig I. was unveiled here with all due ceremony, the likeness of the monarch having been placed in the famous "Wallhalla" of the town. The monument is worthy of note for the quality of the material used, the stone of the statue (a block some 9 ft. high, weighing 400 cwt.) having been brought from the marbles of Pizzo Bianca, and showing a very fine grain and colour.

**MISCELLANEOUS.**

**THE ENGLISH IRON TRADE.**—The English iron market is somewhat quieter, and its tone is not quite so strong as it was a week ago. There has, however, been no essential weakening of prices. The only giving way has been in pig-iron. The Glasgow warrant market has been easier, and, owing to this, consumers of Scotch makers' iron have been buying less freely, without, however, bringing down makers in their quotations. Mid-diesbrough iron has been more sensitive, and No. 3 foundry has dropped 1s. 3d. a ton, to 46s. Hematites, on the other hand, have resisted the reaction, and are quoted by makers 6d. a ton higher. In Lancashire, Staffordshire, Derbyshire, and Lincolnshire, no reduction has been made. Manufacturers iron keeps firm, and some makers even ask more money than last week. Black sheets have been advanced 2s. 6d. a ton. There is only a moderate business in steel, but prices have a hardening tendency. A better tone prevails in the shipbuilding trade, and is due to more orders having been placed. Engineers continue well employed.—*Iron.*

**DISCOVERIES AT SILCHESTER.**—The explorations which are being carried out on the site of the Roman city of Silchester, a few miles distant from the Alderminster or Mortimer stations of the Great Western Railway, under the personal direction of Mr. G. E. Fox, Mr. W. H. St. John Hope, Mr. Mill Stephenson, and Mr. W. K. Forster, of the Society of Antiquaries, are (according to accounts which we have seen, especially a long article in the *Reading Mercury* for the 30th ult.) being attended with most satisfactory results from an antiquarian point of view. Until the present work nothing was known of the great western gate of the city except its site, but the present excavations have disclosed most interesting remains of this gate, under which passed the traffic along the main road through the Roman city. The roadway at the west gate was spanned by two arches. Amongst the massive fragments of the masonry uncovered is the impost of the gate, from which two arches sprang, and the mouldings on one side may be noted out away in order to allow the doors to shut against it. There are found to be two guard-rooms on each side of the gate, those on the south being most perfect. The wall here has a thickness of 12 ft., which decreases as it rises from the ground level, and it is backed by a great mound of earth. One point for investigation is whether or not this mound is of earlier Celtic origin. A paving of flints forms apparently a pathway to the top of the mound. At the west gate a fragment of a fine Corinthian capital has been found. As it has no connexion with the structure it was apparently brought there for some purpose during the occupation of the city. The remains of the west gate are admirable specimens of masonry, large blocks of oolite and other stone having been employed. A house has been excavated at the north-west corner, the museum, in fact, standing on a corner of it. Traces have been found of another large house at the north-east corner. Between the two houses there is a considerable open space of ground. The explorers are led to conjecture that in each square there may have been a certain number of houses with much open ground, consisting of court-yard and gardens. From its size and from the remains it is considered that the house excavated was that of one of the wealthier inhabitants of the city. During the excavations, and principally at the *insula*, a large number of objects of antiquity have been unearthed. These have all been carefully labelled and classified, and occupy shelves in the temporary office. The exploration is being carried out with the sanction and approval of the Duke of Wellington, who owns the site of the city, and with the co-operation of the Duke's agent, Mr. Walter Mousley, and the tenant, Mr. Cooper. His Grace has also promised to give the site of the museum and to contribute towards its erection.

**PICTURES AT LIVERPOOL.**—The annual picture exhibition opened this week, the private view being last Saturday. The exhibition includes several of the most noted pictures of the year already exhibited in London; Sir F. Leighton's "Bath and Psyche," Mr. Collier's "Death of Cleopatra" (which does not seem to give much satisfaction, the critic of the *Liverpool Daily Post* rightly complaining that the pathos of the subject is killed by the prominence given to the architectural surroundings), and Mr. Holman Hunt's "Flight into Egypt," about which much sentiment seems to be expended. The exhibition is said to be quite equal to its predecessors, and local artists are well represented.

**PROPERTIES FOR SALE.**—By auction, at Llangollen—(1) Tyndwr, overlooking the Vale, together with the neighbouring Pengwern House and farm lands—extending over 1,053 acres in all, and yielding a rental of about 1,320*l.* per annum. The mansion and Pengwern House will be put up in two lots of 419 and 473 acres respectively; the remaining twenty-one lots consist of various small holdings, all under cultivation. (2) Plas-pen-y-Nant, newly rebuilt, with 140 acres, finely situated, above the Vale and the River Dee. Pengwern Hall was in olden times the home of Tudor Trevor, and of Bromfield, circa 1225, from whom the Mestyn family claim their descent. By auction at Edinburgh—(3) The Clunie Estate, Perthshire, comprising 1,360 acres (of which 890 are arable), situated in the Stormont District and watered by the Luanan, a tributary of the Isla. This property contains Loch Clunie, wherein is the island, reputedly artificial, on which George Brown, Bishop of Dunkeld, built a former fastness of the Earls of Arlrie. The ruined castle stands a rival to Eillock, or Sanghar, in Dumfries, as the imputed birthplace of the "Admirable" James Crichton (died 1551). On the loch's western side was a hunting-seat of Kenneth MacAlpine, scourge of the Picts. In the parish of Clunie,—the Keltic Clunie, or green pasture among the woods,—are numerous tumuli and cairns, vestiges of combats between the natives and the Romans. (4) Invermay, in Strathearn; about 3,890 acres, with a rental of 2,642*l.*, excluding the mansion and shooting, at an upset price of 95,000*l.* The house stands on the western slope of the Ochil Hills; its policies stretch to the May's bank, and include the subject of Mallet's ballad, "The Birks of Invermay." That small but beautiful river rises in the Ochils, and, flowing through Forteviot, enters the Earn about a mile above Dupplin Falls. In its course are two celebrated falls: the "Humble Bumble" and the linn of Muckeris.

Here, too, are some ancient remains: Forteviot formed a Pictish stronghold; on heights above this May be a Roman camp, and close to Forzandenny the large circular stone fort, known as Castle-law, supposed by some to be of Danish construction, overlooking Strathraue and the cascade of Gowrie.

IRON ROOF FOR GREAT RANGES OF TEMPERATURE.—A description is given in a foreign technical publication *Zeitschrift des Vereins Deutscher Ingenieure*, 1890, p. 15) of the iron roof for the Finland State Archives Office at Helsingfors, which has been designed to withstand the wide ranges of temperature that are experienced in that country. The hall which this roof covers is 73 ft. 5 in. in length, by 43 ft. 2 in. wide. The principals, which are of ordinary construction, are 8 ft. 3 in. deep in the centre, with depressed tie. They are carried on roller bearings at each end, to admit of free elongation and contraction of the exposed roof-surfaces, trusses, and rafters. The ceiling, which is framed in iron, is at a level of 2 ft. 6 in. below this tie-rod, and its rigidity and protection from excessive variations of the external temperature are secured by the extension of the king and queen rods to a parallel tie below, built into the wall at each end, the intervening space being filled in with brick vaulting.

TECHNICAL INSTRUCTION AT KING'S COLLEGE, LONDON.—We have received from Professor Banister Fletcher some particulars of the proposed work of the Department of Technical Instruction at King's College. In Building Construction and Architecture, we learn that the Carpenters' Company, acting in connexion with the Council of King's College, have resolved on establishing at King's College in the Strand, evening lectures on Building Construction and Architecture, and Drawing Classes. The lectures will be given on Mondays, from 7.15 to 8.15, by Professor Banister Fletcher. Each course will last twelve weeks or thereabouts. The subjects include Foundations, Brickwork, Building Stones, Timber, its several forms and uses in building; Limes, Cements and Concretes, Masonry, Fireproof Construction, Carpentry (roofs and their construction, Plastering and Materials, and Plumbing and Sanitation. The Drawing Classes and Classes of Design will also be held on Mondays, from 8.15 to 8.15, by Professor Banister Fletcher, assisted by a demonstrator. Students nominated by the Carpenters' Company, for either the lectures or the drawing classes, will pay half fees. There will be an examination at the end of each term. The first course will begin on Monday evening, October 6. We also learn that the Carpenters' Company (Harben's Gift) acting in connexion with the Council of King's College, London, have resolved on establishing at King's College classes for instruction in wood-carving. These classes will be held on Munday, Wednesday, and Friday, in the day from twelve to four, and in the evening from six to nine. The teachers will for the present be Messrs. Barnes, Curran, and Howard, all practical wood-carvers, and Members of the Institute of British Wood-Carvers. Each course will last twelve weeks or thereabouts. The fees for these lectures and classes will be very low. Professor Banister Fletcher has also sent us the syllabus of the classes of architecture, building construction, and modern practice, which he will conduct in succession to Professor Kerr. These courses are intended to furnish full information in the theory and practice of architecture and building construction, and in the application of the principles of mechanics to construction. They are also specially arranged to enable architects' pupils, improvers, and other gentlemen intending to follow the profession of architecture, to prepare for the progressive examinations of the Royal Institute of British Architects as set forth in their "Kalendar." We learn that in connexion with these classes Professor Banister Fletcher is forming what he hopes will become the most useful architectural and building construction museum in London. In addition to the cost incurred by the Carpenters' Company in relation to this work, they are spending 6,000,—"Harben's gift,"—in building a room at King's College for wood-carving, and 1,500, in improvement to the carpenters' workshop.

RECENT PATENTS:

ABSTRACTS OF SPECIFICATIONS. 5,358.—CHIMNEYS AND VENTILATION: T. A. Megginson and another.—According to this invention, an outer casing and an inner flue are so arranged that by the passage of the wind an up-draught is caused, and the smoke or foul air exhausted from the shaft. 6,380.—WALLS FOR BUILDINGS: H. Muller.—This invention relates to a method of dispensing with framework in building-up walls by means of plates. Buildings are made so that they are provided with double or multiple walls, forming air-spaces, the walls being built of plates artificially produced in any material containing magnesia, the plates being connected with each other so that they form a rigid self-supported structure. 13,007.—Bolts, &c.: H. Benzon.—By this invention bolts are made with a secret or not observable locking appliance, mainly for the purpose of preventing the unauthorized opening by children and other persons, and specially as a safeguard against burglars, as they cannot be forced by a jemmy or other sharp tool. A locking appliance in combination with a catch on the plate.

11,103.—CLOSET CISTERNS: G. A. Muller and others.—

This invention relates to cisterns having syphon discharge, the distinguishing feature of the invention being the construction of the stand-pipe in such a form that a portion of it is nominally above the water level, but can be submerged to suit the circumstances. 6,922.—SASH-FASTENERS: E. G. Whitehead.—By means of a lever, rod, and spring, a catch is arranged to hold the window-sash in any desired position. The invention is principally useful for railway-carriage windows. 6,239.—BRICKS: D. Hart.—According to this invention, bricks are made of any material or color, but on one or more sides of each brick, a square-shaped projection is formed the whole depth of the brick, and about one-third of its entire width. On the opposite side are formed cavities corresponding in shape and dimensions with the projections. Thus each brick fits into the other and strength is secured.

NEW APPLICATIONS FOR PATENTS.

Aug. 18.—19,922, G. Helmore, Window Sash Fasteners.—12,944, R. Marsh, Decorative and Adjustable Frames for Tiles. Aug. 19.—13,007, H. Lake, Machine or Apparatus for the Manufacture of Metal Lathing.—13,032, V. Kneie, Self-flushing Cisterns, applicable to Water-closets. Aug. 20.—19,659, H. Lamplough, Paving and Flooring.—13,778, T. Fawcett, Machinery for Making and Pressing Bricks.—13,105, A. McLean, Decorative Artificial Stone. Aug. 21.—18,476, G. A. B. C. Gabe, Water-closets, Pipes, Sials, &c.—13,141, W. Drayson, Water-closets.—13,155, L. Jahn, Firing of Pottery.—13,156, S. Jenkinson, Protector for Wood-working or other Machines.—13,163, A. Garner and E. Clock, Air-tight Cover, particularly applicable for Cisterns. Aug. 22.—13,293, Emson & Hewitt, Syphon Flushing Cisterns.—13,316, A. Grainger, Concrete Ventilated Building-block for building purposes.—13,318, E. Greenwood, Ventilating Rooms.—13,227, C. Bonne, Manufacture of Cement, such as Portland or Slag Cement. Aug. 23.—23,274, E. Hinde, Manufacture of Bricks, Kirkan, Construction of Kilns or Ovens for Burning or Baking Pottery, Bricks, Tiles, and the like.—13,306, G. Parini, Spring Door Hinges.—13,315, G. Reiffner, Roofing Tiles.—13,318, W. Money and others, Construction of Windows and Sashes.

PROVISIONAL SPECIFICATIONS ACCEPTED.

6,904, G. Martin, Glazing Sash-lights and Skylights.—C. and E. Woodfill, Window-fastening.—9,065, T. Stretcher, Waste-preventer.—9,100, A. Baker, Drains and Sewers.—9,011, F. Peake, Gate Hinges.—H. Hitchin, Window-fasteners.—10,614, W. Morison, Door-closer.—10,761, L. Posgate, Litter-sifter.—10,944, A. Booby, Ventilator.—11,181, J. Morris and A. Ramsden, Flushing syphons.—11,841, J. Bishop, Ventilation.—12,136, T. Harries, Grates.—12,301, W. Clark, Syphon Water-waste Preventer.—12,508, F. Frisicatte, Flushing Apparatus.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to Opposition for Two Months. 15,140, J. Knye, Relining and Opening Doors.—10,243, J. Schwärmer, Sewer for Traps.

SOME RECENT SALES OF PROPERTY.

ESTATE EXCHANGE REPORT.

AUGUST 20.—By T. G. Wharton (at Caterham): The residence called "Albert Lodge," and 2 acres, Upper Caterham, 1, 395*l*. AUGUST 21.—By T. G. Wharton (at Walton): 1 and 2, Anderson's Cottages, and the "Prince of Wales's" beer-house, Walton-on-Thames, 1, 2,100*l*. AUGUST 21.—By Debenham, Fenner, & Co.: "Ray Lodge," and 25a, 1r. 36p, Maidenhead, Berks, 1, 20,000*l*. "Allen's," "Dillons," and "Westlands" Farms, containing 143a. 3r. 17p, Cuckfield, Sussex, 1, 2,000*l*. "Ashfields" Farm, containing 47a. 1r. 1p, 1, 1,000*l*. "J. K. Coleman" 15, 20, 22, and 30, Upper-st. Plaitow, 1, 72*l*. 16a, 630*l*.—By Broad & Whitehead (at Barking): 10, 11, and 12, Back-lane, Barking, 1, r. 35*l*. 2*l*, 210*l*. and the Broadway, and 2, 3, & 4, Back-lane, 1, r. 52*l*. 10*l*. 65*l*. AUGUST 27.—By Jones & Son: 7, 14, Oley-pl. Stepney, u.t. 5*l* 9*l*, g.r. 2*l*, r. 49*l*. 13*l*. 1, 3,000*l*. Lower Chapman-st., St. George's, East, an improved rental of 22*l*. 6*l*. u.t. 10*l* 9*l*, 65*l*.—By J. Bott: 257 to 307 (odd) and 285 and 287, Railton-rd., Herne-hill, u.t. 50*l* 9*l*, g.r. 50*l*, 1, 2,000*l*.—By J. **SOUTHAMPTON**.—For constructing the new pier at Southampton. Mr. James Lemon and Mr. E. Cooper Poole, joint engineers. Quantities supplied by Mr. J. H. Bilsard and Mr. H. J. Weston:—  
 J. Nowlen & Co., Westminster .. £33,283 0 0  
 E. Howell, Poole ..... 29,611 0 0  
 E. C. Freer & Co., London ..... 29,589 0 0  
 E. J. London & Co., Newport .. 28,880 0 0  
 Mon. .... 27,425 0 0  
 J. W. Roe & Co., Southampton .. 26,438 0 0  
 Morgan, Isted, & Morgan, Southampton ..... 26,247 0 0  
 J. Bull, Sons, & Co., Southampton .. 26,189 0 0  
 A. Thorne, London ..... 26,142 0 0  
 H. J. Sanders, Southampton ..... 26,142 0 0  
 [Engineers' estimate, £29,500.]

**SOUTH SHIELDS**.—For the erection of police-courts, fire brigade depot, residence for chief constable, and officers' quarters, at South Shields, for the South Shields Corporation. Messrs. Perkin & Bulmer, architects, Leeds:—  
 W. J. Robertson ..... £15,330 0 0  
 R. Goodwin & Son ..... 13,142 0 0  
 C. Nichol ..... 13,036 0 0  
 Obank & Sons ..... 12,835 0 0  
 Haswell & Wall ..... 12,820 0 0  
 Tyne & Graham ..... 12,650 0 0  
 Simpson ..... 11,967 0 0  
 Reid, Blight, & Co. .... 11,963 0 0  
 R. Allison ..... 11,913 0 0  
 Middlemas Bros. .... 11,650 0 0  
 R. D. Scott ..... 11,618 0 0  
 J. Ellet ..... 11,580 0 0  
 Armitage & Hodgson ..... 11,487 0 0  
 J. Howe, West Hartlepool\* ..... 10,985 0 0  
 \* Accepted.

**TOTTENHAM**.—For alterations and additions at the "Antwerp Arms" Church-road, Tottenham, N. Mr. John E. Pinder, architect, Bridge House, South Tottenham:—  
 Yardley & Son ..... £673 0 0  
 F. Vollar ..... 658 0 0  
 H. Knight & Son ..... 595 0 0  
 J. Linzell ..... 572 0 0  
 Stockwell ..... 450 0 0

**TUNBLIDGE WELLS**.—For the erection and completion of three attached houses, for the Hon. J. M. O. Hyng, J.P. Mr. W. B. Hughes, architect, Tunbridge Wells:—  
 Penn Bros. .... £4,920 0 0  
 T. Ryder ..... 4,420 0 0  
 R. Langridge ..... 4,329 0 0  
 White & Humphreys ..... 4,308 0 0  
 Strange & Sons ..... 4,306 0 0  
 J. Jarvie ..... 4,373 0 0  
 R. Ayard, Maidstone (accepted) .. 4,293 0 0

**WOOD GREEN** (Middlesex).—For alterations at the "Lordslip Tavern," Lordslip-lane, for Mr. J. C. Pitt. Mr. E. Howard, architect and surveyor, Tottenham:—  
 F. Vollar ..... £595 0 0  
 Yardley & Son ..... 550 0 0  
 A. Monk (accepted) ..... 535 0 0

*Shop and Warehouse, Wycham.*—List of tenders for this work has been sent without sender's name being communicated to us, and therefore is ineligible for insertion.

**SUBSCRIBERS IN LONDON AND THE SUBURBS**, by prepaying at the Publishing Office, 19s. per annum (or 4s. 6d. per quarter), can ensure receiving "The Builder" by Friday Morning's post.

**TO CORRESPONDENTS.**  
 J. E. M. (we cannot insert lists of tenders without the amounts).  
 -W. C. (too small).—E. G. G. (see answer to J. S. M.).—C. G. (no space this week).—L. H. (we have no space for "duplicated letters").—C. A. A. (hardly worth notice).  
 All statements of facts, lists of tenders, &c. must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline pointing out books and giving addresses. Note.—The responsibility of inserted articles, and papers read at public meetings, rests, of course, with the authors.  
 We cannot undertake to return communications.  
 Letters or communications (beyond news notices) which have been applied for other journals, are NOT DESIRED.  
 All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

**TERMS OF SUBSCRIPTION.**  
 "THE BUILDER" is supplied gratis from the Office to residents in any part of the United Kingdom at the rate of 1s. per annum *PREPAID*. To all parts of Europe, America, Australia, and New Zealand, 28s. per annum. To India, China, Ceylon, &c. 30s. per annum. Remittances payable to DOUGLAS FORDREINER, Publisher, No. 46, Catherine-street, W.C.

**HOWARD & SONS**  
 25, 26, 27, BERNERS STREET, W.,  
 MANUFACTURERS AND CONTRACTORS  
 Deal Dadoes, from 1s. 2d. per ft. super.  
 Oak Dadoes " 1s. 8d. " "  
 Walnut Dadoes " 1s. 11d. " "  
 Oak, 1 inch Parquet Floors, laid and polished, from £7, 11s. a square.  
 Solid 1-inch Oak, straight boards, laid and polished, at £6, 18s. a square.  
 Solid 1-inch Oak Parquet for covering Deal floors, laid and polished, from 45s a square.  
 Oak Wood Tapered Dadoes, from 1s. per foot super.  
 Walnut or Mahogany, from 1s. 3d. per foot super.  
 Ditto with Heavy Mouldings, 4d. ft. extra.  
 Ditto, ditto, with Gilded or Painted Panels, prices according to sketches.  
 Prices given for all Interior Work, Doors, Architraves Over-doors, Chimney-pieces, Stoves, and Hearths.  
 Architects and Surveyors' attention particularly called to the above Quotations for  
**BILLS OF QUANTITIES.**  
 HOWARD & SONS  
 Tender for Contracts for any Joiners' work, or Ornamental Plaster. Painting, Plain or Decorative, Wrought-Iron Work, Stained Cathedral Glass, and any other Interior Work.

### Pavements and Roads.

THE book published under this title\* contains the results of a special inquiry into the subject set on foot by the New York technical journal named on the title-page, and which has apparently been induced by special circumstances to enter with remarkable earnestness on the collection of statistics in regard to pavements and roads. Those who may have been in New York a few years since can probably endorse the view we advance, and the opinion of most people, viz., that for its size and importance, it was the most disreputably paved city in the civilised world. A very large sum (3,000,000 dol.) has, however, been voted to place it more on a par with other places, and the subject has consequently become one of exceptional interest there as well as in other American cities. In the course of its search for special knowledge, the *Engineering and Building Record* of New York has amassed a large amount of evidence from many quarters; and, without expressing any very particular opinions, or indicating any sort of bias, it has been good enough to compile everything which it has obtained relating to the subject which was likely to be of practical utility into a volume of over 400 pages, bringing it quite up to date in these matters. It also instituted a competition, with prizes of 15*l.*, 10*l.*, and 5*l.*, for essays on the subject, and received as many as twenty-one, three of which have been published, in a more or less condensed form, in the volume; extracts have also been made from several of the others where a point of value happened to have been introduced. We have had to rely so long in England on Clark and Law's work as the standard authority on roads and streets, in which several of the chapters, which should be most important, were written so long ago as to be now obsolete, that we have the less hesitation about treating at some length the consideration of the work now under review.

The first part of the work more especially relates to streets, and comprises chapters on

\* "Pavements and Roads." Reprinted from the *Engineering and Building Record*, New York.

stone, wood, asphalt, and brick pavements,—firstly, for the carriage-ways, and, secondly, for the footways; the first cost, the cost of maintenance, and specifications of each kind are noted and commented on. The second part is devoted entirely to roads, and the third part to the above-mentioned essays. England, France, and Germany are chiefly taxed for the information comprised in the work, but the experiences of the Department of Public Works in India are occasionally alluded to, and, in fact, one of the essays is by a gentleman who was employed in that Department for many years. The book commences with a valuable memorandum from Mr. Clement Dunscombe, detailing the work in Liverpool streets, more particularly with respect to stone. With regard to the foundations for paving first-class streets in that city, the concrete is made in an exceptional manner, as follows:—

"The ground having been excavated, thoroughly consolidated, and properly graded to the requisite depth and shape, a layer of broken stone (or other material) is spread evenly over the surface, and thoroughly wetted from the rose of a watering-can. A stratum of mortar (1 part by measure of cement to 5 or 6 parts gravel, thoroughly mixed dry, and only enough water then allowed to flow on it to make the material damp enough after it is incorporated to retain its form when a portion is taken in the hand and pressed) is spread over this, and a second layer of stone added. The stone is then beaten in with a heavy flat beater. Other layers of mortar and stone are added, and thoroughly beaten in until the required thickness is obtained, the final layer of cement mortar (to complete the full specified thickness of 6 in.) being smoothed off to an even and uniform surface."

The quantity of broken stone is equal to that of the cement and gravel, and has to pass through a 2½-in. ring in every direction, and be clean and free from foreign matter. The gravel has also to be clean, and excludes all stone which will not pass a 1-in. ring, but includes sand. The cement must not leave more than 10 per cent. residuum on a No. 50 wire sieve, and give a tensile strength of 400 lbs. per square inch after seven days immersion. The concrete must set for ten days before paving is begun upon it. Mr. Dunscombe attached a high value to the accurate gauging of setts, considering that if the gauging was done at the quarries, even though the cost might be thereby increased to the extent of 1*s.* 6*d.* per ton, a considerable eventual saving resulted, as the width of the joints of the setts cannot be too small. He believed that wide joints were on many

grounds open to objection, and that where these joints are grouted in lime or cement instead of pitch and creosote oil, they often become receptacles for all filth. He considered that it was a mistaken notion to suppose that the width of the joints made the pavement in any way safer, as it was the inequalities of the sets which gave sufficient foothold.

The Liverpool traffic is very considerable, and it is interesting to compare it by the rule frequently accepted (of tons per yard width of carriage-way per diem) with that of certain London streets, which are given further on in the work, on information chiefly obtained from a paper written by Mr. Howarth, M.I.C.E.:—

	Tons.
Liverpool... Bath-street and New Quay ..	1,150
London... Parliament-street ..	1,106
"    Oxford-street (average) ..	1,055
Liverpool... Great Howard-street ..	981
London... Leadenhall-street (average) ..	904
Liverpool... North John-street ..	692
London... Brompton-road ..	648
Liverpool... Lord and Church streets (average) ..	458
London... Regent-street ..	558
"    King's-road (average) ..	500

The stone paving in Liverpool is executed entirely by Corporation workmen, and with the most durable stone procurable, and, as an instance of the economy which results from the adoption and retention of this principle, it is stated that setts taken up in North John-street (above mentioned) after fourteen years' wear showed no measurable amount of wear.

The setts for the various classes of streets vary as follows:—

	I.	B.	D.
For first-class streets ..	3¼" × 3½"		× 6¼"
Ditto with exceptionally heavy traffic ..	3½" × 3½"		× 7½"
Second class ..	4" × 4"	(to 7")	× 4"
	or 3" × 5"	(to 7")	× 5"
Third-class ..	4" × 4"		× 4"

One-quarter of an inch in deviation is allowed in these dimensions. The joints of the setts are filled with hard, clean, dry, fine shingle, and the setts rammed until the joints are full, when they are run with a hot mixture of coal-pitch and creosote oil, and the whole covered with half an inch of sharp gravel. The original cost is as follows:—

First class, per superficial yard...	13 <i>s.</i> 6 <i>d.</i>
Second " " "	9 <i>s.</i> 9 <i>d.</i>
Third " " "	8 <i>s.</i> 4 <i>d.</i>

This includes concrete foundations, &c.;

but it is doubtful whether it includes establishment charges, and there is, of course, no contractor's profit to reckon for.

To this valuable contribution are attached a series of excellent sections illustrating the different classes of street-pavings of Liverpool.

Now, in connection with the re-paving of New York under the three-million-dollar vote, it was specified by the Special Commissioner that 1-in. joints would be permitted, and he went so far as to say that although from 8 in. to 12 in. was specified for the length, they might be as much as 25 in. in length without harm. For this opinion he was very properly taken to task by the *Engineering and Building Record*, who "regretted that so competent an executive officer should so far forget himself as to talk on a subject on which he cannot be expected to be an expert (and evidently has a great deal to learn), and announce the dangerous doctrine that the department's specifications are not expected to be enforced." Other persons lashed out in the press on the same subject, and it is evident that the public eye was wide awake and intelligently watched the execution of this important work.

Cincinnati followed suit with a vote of 2,000,000 dols. (part for stone and partly for asphalt pavement), and other American cities for large amounts. Topeka, Kansas State, determined to use a large quantity of Sioux Falls stone, which, after a long wrangle there and elsewhere, was determined to be called granite. It is in reality a quartzite, and far more nearly allied to sandstone (though much tougher) than it is to granite, but it is not surprising to hear of its being spoken of as "granite," which often seems to be taken to mean anything except common stone. Amongst the many published comparisons on this work between various kinds of pavements for streets, is one by Mr. P. Rice, City Civil Engineer of Cleveland, Ohio, between asphalt and stone, and he sums it up as follows:—"In discussing sheet pavements, *i.e.*, asphalt, a standard of comparisons might be outlined as follows:—First, moderate cost; second, durability; third, resistance; fourth, secure foothold for horses; fifth, healthfulness; sixth, noiselessness." With due deference to Mr. Rice, such order of importance must vary in accordance with the nature of a street, the fifth and sixth items, and especially the sixth, having frequently primary importance. However, he continues as follows:—"First, sheet pavements do not satisfy the first requirement much better than dressed block; second, I should give dressed block the preference as regards durability and ultimate cost; third, the resistance to traction is undoubtedly less on sheet pavements; fourth, such few experiments as have been made indicate fewer accidents to horses on sheet pavements than on granite, but do not think it would hold good for medina (a hard sandstone); fifth, both sheet pavements and dressed blocks are healthy, and the asphalt filling of the latter fulfils all sanitary requirements; sixth, sheet pavements, perhaps, fulfil the last requirement better than stone, but there is the sharp click and ring of the horse's foot, although the vehicle itself makes little noise. In making repairs in the case of a stone pavement 50 to 75 per cent. of the old material can be used over again, but in the case of a sheet pavement it is worthless." Finally, he advised against laying asphalt pavements in any of the thoroughfares of Cleveland.

Mr. Rice was soon taken up by the asphalt men, one of whom, Mr. E. P. North, of New York, said that putting first cost and durability first was equivalent to a man "dressing himself in flannel shirt and stagey boots." He argued that noiselessness and minimum resistance to traction were closely associated with healthfulness in pavements, for the nearest approach to a perfect pavement, in a sanitary view, seemed accomplished by a pavement which was impervious to fluids, presented no inequalities in which solid and fluid fecal or other matter can lodge, and admitted of cheap and thorough cleaning. He

said that "there was another point which should not be overlooked: horses, besides doing more work, last longer, and there is less expense in repairing running gear and harness on such pavements than on any other."

The same gentleman drew a pleasing picture of the condition of the streets of some American cities as follows:—

"In New York, which may be regarded as the capital city of this country, one sighs for the quiet and repose of an active boiler-shop when the garbage carts of the city pass through its best residence streets; and Philadelphia, the home of our oldest and stateliest families, has 'pavements fringed with murderous stones.' And in most of our cities one can count, in the words of Coleridge, 'two-and-seventy stenches, all well-defined and genuine stinks,' any pleasant summer day."

He however excepted Washington and Buffalo.

Whilst on the subject of stone paving, we notice some well-selected extracts from the periodical statistical reports of Colonel Haywood. From them we gather that the average annual cost (entire) of granite paving in the City for about thirty-three years back has been 93d. per square yard, as against 2s. 03d. for wood. This includes cost of construction plus cost of maintenance, the duration of granite being taken at twenty-five years and of wood about seven years. On London Bridge, with its enormous traffic, granite lasted twelve years, the wear in that time being 2 in., and the cost 2s. 3d. per square yard per annum. In the Poultry the wear on granite was 1½ in. in six years. (Nature of granite not stated, though a matter of very considerable importance.)

There is a gentleman whose writings are frequently quoted throughout this work, who appears to have made paving and road work a special study, and who is apparently an indefatigable collector of statistical information on the subject,—a certain Captain F. V. Greene, of the United States Corps of Engineers. This writer briefly states that,—

"The average life of granite blocks under heavy traffic in London is fifteen years, during which time the wear is about 2 in., when the edges become so rounded that the pavement is as rough as cobble stones. They can then be taken up, redressed, and laid on streets of lighter traffic, when they will last for twenty years more, during which time the wear is another 2 in. The blocks are then so worn that they have not a sufficient depth for a pavement surface, but can be sent to the crusher and broken up for concrete."

There is very little doubt that the damage to vehicles and the increase to traction demand a re-dressing of granite blocks more frequently than is customary, but workmanship on granite is so expensive that the operation is put off as long as possible, until, in fact, the paving is (as described by Captain Greene) similar to cobble stones, and its reputation seriously damaged. In St. Louis some experiments on the durability of street materials were made a few years ago by rolling a two-wheeled cart backwards and forwards over two strips of the pavement under test, each of which were 22 in. wide. The tires were each 2½ in. wide, and loaded up to 800 lb. per inch, or nearly 2 tons total weight. The samples were weighed before and after testing, and after a test equal to 8½ years traffic, the granite blocks had worn scarcely appreciably, while limestone had lost 10 per cent., asphalt blocks 14 per cent., and fire-brick 9 per cent. of their thickness, many of the latter being broken.

Comparisons of other kinds between various classes of paving will be treated on at the close of this article, but we will now turn to what is recorded in this volume about wood pavements. The subject is commenced by reprinting entirely the paper which was read by Mr. G. H. Stayton in 1884 before our Institution of Civil Engineers, together with the discussion which took place thereon. From this valuable paper it appears that there were at that time in London no less than 1,718 miles of streets in the charge of various authorities (in addition to 248 miles not yet taken over), giving a total of nearly

2,000 miles, and that they were covered in the following manner:—

Asphalte .....	13½ miles.
Wood .....	53 "
Granite .....	280 "
Macadam .....	573 "
Filits or gravel .....	798½ "
	1,718

and that 40,000 vehicles and 100,000 horses were employed. The author very pointedly remarked that as the estimated value of the vehicles, horses, and their harness was about 5,000,000£, the wear and tear, *i.e.* annual loss, must depend largely on the condition of the carriage ways. This is a point often alluded to, but scarcely appreciated, or indeed capable of being estimated, until we find ourselves in the presence of such a large figure as five millions sterling. Now, in tractive power alone, we find (by reference to Captain Greene's observations published in this work) that the various experiments made by Morin, MacNeil, Romford, Gordon, and others, give the following results:—

10 lbs. of tractive force are required to draw 1 ton on level ground on iron.
15 " of tractive force are required to draw 1 ton on level ground on asphalt.
21 " of tractive force are required to draw 1 ton on level ground on wood.
33 " of tractive force are required to draw 1 ton on level ground on best stone blocks.
50 " of tractive force are required to draw 1 ton on level ground on inferior stone blocks.
90 " of tractive force are required to draw 1 ton on level ground on average cobble stones.
100 " of tractive force are required to draw 1 ton on level ground on macadam.
200 " of tractive force are required to draw 1 ton on level ground on earth.

It is a singular commentary that in comparing this table with that of the mileage of the London streets we see that the largest proportion of street is paved with the material which requires the greatest exercise or waste of power on the part of the horses, and *vice versa*. The same holds good, of course, of the strain on the harness. Taking the proportional value of the horses and harness in London at four millions, it may be estimated that if the gradients and other conditions were suitable for such a description of pavement, the saving on horses, harness, and vehicles by using asphalt in place of any other material would, after allowing for the proportionally greater traffic on some of the streets paved with asphalt and wood over those paved with other materials, would be equal to about half a million sterling per annum, which would represent an approximate average of £300 per mile of street per annum in cost of maintenance! or, in other words, if the saving in transportation is proportional to the load carried, there would be a saving of the power of about 12,000 horses on the number now required for the London work. Captain Greene worked out similar details for New York, and reported that the transport in the streets of that city cost 22 cents per ton-mile, and that by railway ¼ of a cent per ton-mile, or as 1 to 36, a somewhat remarkable difference. But even discarding those cases in which, owing either to gradient or to other causes, it is not considered advisable to use the better classes of pavement, it is manifest that the great indirect saving in cost of traction must go far to counterbalance the increased cost (if any) of the maintenance of such pavements.

Mr. Stayton's paper on wood pavements, and the experience of Washington, U.S.A., tend to show the extreme importance of a good concrete foundation, the last-named city having founded their wood pavements so badly that after an expenditure of four million dollars, the wood as a pavement lasted so short a time that it was quite discredited, and has been very much, if not entirely, replaced by asphalt. In Chelsea the total cost of the wood pavement averaged 10s. 4½d. per yard. Many trials of various woods are recorded, and the blocks found most suitable were those cut from Swedish yellow deals (Gothenburg thirds); but the result of heavy traffic upon various kinds of wood unquestionably demonstrated that of

hard woods, pitch-pine takes a high place: the price, however, was considerably in advance of fir, and the irregular sizes of the deals created much difficulty. All work in Chelsea was executed by the workmen of the Vestry, the blocks being supplied by contract. Mr. Stayton urged that ample and competent supervision should be provided against the acceptance of unsound blocks. He said:—"The operation of inspecting each block is undoubtedly tedious: for example,

hurry of the work, many blocks were laid which escaped rejection, but assuredly these will be the first to fail." Mr. Stayton's researches enabled him to produce some very instructive statistics on cost and on wear, which are well worthy of examination. From them we have prepared the annexed tables: (a) of first cost, (b) of relative wear, and (c) of proportional relative cost of the wood pavements in those streets in London which are recorded in the work under review:—

A.—COST OF WOOD PAVEMENTS IN LONDON STREETS.

By whom laid.	Place.	Cost per square yard.	Number of years guaranteed free of cost to Vestry.	Contract for maintenance per square yard per annum for x years.
Asphaltic Wood Company	Oxford-street.....	s. d. 13 6		s. d. 1 2 for 15 yrs.
Ditto	Strand.....	13 6		1 0 for 12 yrs.
Ditto	Fleet-street.....	15 0		
Ditto	Regent-street.....	12 6		
Ditto	Brompton-road.....	13 9		
Henson's Wood Company	Oxford-street.....	16 6 (1)		1 0 for 15 yrs.

the Chelsea works, where the timber supplied was of fair quality, it was found necessary to separately sort out, reject, and mark about one block in twenty, the rejections being 96,000 out of a total delivery of nearly two millions; and there is little doubt that, owing to the

With respect to the different systems, it may be observed that as nearly all the wood-paving companies concerned are stated to have either failed or failed to carry out their contracts for maintenance, it is probable that the rates tendered by them for maintenance were, as a rule, far too low, and as Colonel Haywood

reported in 1874, that the mean total cost per annum of wood-paving for heavy traffic was 2s. 7½d. per square yard, and for lighter traffic 2s. 4½d. per square yard per annum, this result is not a matter for surprise. The annual wear of wood appears to vary from one-twelfth of an inch per annum per 750 tons of traffic per yard width per diem, for plain pitch-pine pavement, to a little over two-fifths of an inch for asphaltic. In perusing this portion of the work, we notice a considerable number of typographical errors of importance, such as 10 shillings, 12 shillings, and 17 shillings, &c., in place of 1s., 1s. 2d., and 1s. 7d. per square yard for maintenance.

Mr. Stayton entered into very careful calculations as to the actual cost of wood pavement in Chelsea to extend over periods of fifteen and twenty years, including first cost, repairs, renewals every seven years (which he estimates as a fair average life for wood pavement under a traffic of from 500 to 700 tons per yard width per diem), and interest on loans, but not including cost of cleansing and sanding (estimated at 5d. per square yard per annum), and he claimed that the total cost is represented by 1s. 9d. per square yard per annum. On these grounds he justified the economy of removing the macadam from King's-road and Sloane-street, where it had cost 1s. 11d. per square yard for repairs (not including cost of cleansing). In Westminster at the same time it had been as follows:—

	s. d.
Parliament-street.....	2 19
Whitehall.....	2 10½
Victoria-street.....	2 0
Great George-street.....	1 8
Piccadilly.....	2 8½

All of which have (as we know) now been repaved with wood.

Mr. Stayton considered that it would be preferable to adopt 5 in. in place of 6 in. blocks, the smaller depth being sufficient, and more economical by 10s. per thousand than the larger, which would be equivalent to a reduction of 1½d. per sq. yard per annum. This depth appears to have been already adopted in several London streets, especially in Kensington, and with satisfactory results. He also considered the plain system of paving preferable to any other—i.e., blocks laid on the concrete in their natural state, with the fibres vertical, and with intervening spaces, ¾ in. wide, filled in with cement grout (1 to 3), the joints being kept parallel by the addition to each block of three cast-iron studs driven into its side. He attached a good deal of importance to the expansion of wood, which generally occurred during the first twelve months or so after completion of the work, and this was provided for by leaving a space near the footways of from 1 in. to 3 in. in width, filling up the space temporarily with sand, subsequently completing with cement grout, and pointing in cement.

It was not to be expected that Mr. Stayton's paper would be otherwise than freely handled by the talented body of experts to whom it was submitted, and especially by those who were favourable to the use of asphalt, and those who preferred the blocks to be either creosoted or pickled, but we must refer the reader to the work itself, or to the Proceedings of the Institute of Civil Engineers, for further information on this head. But Mr. Stayton in his replies furnished a good deal of additional interesting matter, and some subsequent correspondence from other members of the Institution contained much that was valuable, but for which we are unable to afford space, further than to quote an observation made by Mr. W. H. Delano as follows:—"The standard traffic of 750 tons per yard width per diem seemed a misleading formula, for the wear and tear of a road did not depend so much upon the weight passing over it as upon the speed at which that weight travelled. There was also the important element of width of tire, the state of the atmosphere, the camber of the road, and the mode of traffic, cross, heavy, one side empty, the other loaded, &c. Take the new Paris three-horse omni-

C.—ANNUAL COST OF WOOD PAVEMENTS.

System of Wood pavement.	Situation.	Traffic weight per yard width per diem in tons.	Annual cost per square yard for first cost, renewals, repairs, and interest on loans (exclusive of cleansing) if spread over a period of fifteen years.	Proportional relative cost, based on a reduction to an uniform traffic of 100,000 tons per yard width per annum. (Deacon's scale.)

Improved (pitch-pine)	King's-road	558	3 2	1 6½

buses, carrying, when full, forty-six people, including driver and conductor, weighing, when full, 5½ tons, the width of the wheel tires being only 3½ in., running at a speed of seven to nine miles an hour, and compare the same weight on a 4½-ft. wide smooth cast-iron roller dragged at one mile and a half an hour. The latter improved a road, whilst the former rapidly destroyed it."

Returning to the subject of cost of wood pavement, the contract for maintaining Piccadilly is 3s. per yard for a period of fifteen years, and that by the same Company (Improved) for Paris is 3s. 2d. per square yard per annum, which probably gives a not unreasonable profit to the contractors if they are held tight to the terms of their contracts. The work contains a reprint of a very complete article on the wood pavements of Paris, including the specification and terms of contract prepared by the Departement des Ponts et Chaussées, and also specifications from Mr. Strachan and Mr. Livingston, the Surveyors of the Chelsea and the St. George's Vestries, the former for the proper supply of all the materials requisite for a wood pavement (including those for foundations), and the latter for the execution of similar work by contract. Reference is also made to the reports and papers on this subject of Mr. Park Neville, Mr. O. H. Howard, Mr. Deacon, and Mr. C. Dunscombe.

Dr. Love, who is the compiler of this work, has treated the subject of asphalt as extensively as he has treated that of wood, including amongst his contributors Colonel Haywood, Captain F. V. Greene (who, as Vice-President of an Asphalt Paving Company, should be slightly discounted when he institutes comparisons between asphalt and other kinds of paving), Mr. W. P. Rice, of Cleveland; Mr. E. P. North, Mr. E. Towle, Mr. Dunscombe, &c. He has also published some valuable specifications,—viz., those for Paris (including the Instructions of 1884) and those for New York and Buffalo. Working out the total cost per annum extended over a period of sixteen years, we gather from Mr. Dunscombe that in Liverpool,—

Asphaltic 1 in. thick	costs 6½d. per sq. yard.
" 1½ "	" 9½d. "
" 2 "	" 1s. 1½d. "
" 2½ "	" 1s. 2½d. "

In London the pavements of asphalt have cost as follows:—

Val de Travers	1s.
Limmer	9½d.
Société Française	11d.

but this appears to be for maintenance only, and not to include a proportion of first cost.

In some parts of America especial attention appears to have been directed to the preparation of bricks suitable for paving, and the crushing strengths of some of them compare very favourably with some of the less durable stones,—so much so that for light traffic they are in considerable favour in many towns; their advantages are said to be cheapness, smoothness, and cleanliness, freedom from noise and non-absorbance; their disadvantages are lack of uniformity in the material, and the liability of incorporating in the pavement bricks of a too soft and porous nature, which crumble the first winter under the action of frost. They are considered to be superior to macadam and wood, and, for a maximum traffic of 3 tons, also superior to granite.

Dr. Love has devoted a considerable space in his work to curbs (including a novel form of iron curb invented by M. Nicot, a French contractor), to footpaths,—treated of by Mr. H. P. Boulnois, Borough Engineer of Portsmouth, and Mr. Strachan, of Chelsea,—and to tramways. He has also treated on that difficult subject,—namely, how to control the many different parties who for one cause or another are perpetually breaking up the streets. Cleansing, watering, and the removal of refuse are also dealt with, and interesting statistics given of the relative cost of these often-neglected items of expense on the different kinds of pavement.

Mr. Wheeler's article on roads, their repair and maintenance, which was especially written for the National Cyclists' Union, is here reproduced, and M. Waddington, lately French Ambassador to London, has contributed a few useful notes on the administration of the public roads in France. The versatile Captain F. V. Greene has also contributed a most admirable article on roads, including sections of an excellent form of tram-rail, which will not whip off your tyres or twist the spokes out of your naves. The editor has scanned the pages of *Engineering*, and got a good deal out of them about rollers and rolling,—a

matter on which so many persons differ. A treatise by Mr. C. Herschel, of Boston, is republished, in which the whole subject of roads is very clearly and almost exhaustively treated.

As we have before said, the editor rarely expresses any personal opinion about the matters which he has collected and compiled into a very valuable work. We do not say that it is presented to us in a very perfectly readable form, or that it might not be slightly readjusted with advantage; but there is very little of it that is not worth reading, and the editor has exercised great soundness of judgment in the selection of his materials.

NOTES.

THE recent notice of the Bank of England in regard to the investment of dividends on Consols is of much general interest and importance, and is a very distinct step in advance and along the path of thrift. The Bank will, in future, invest the dividends as they become due on less than 1,000l. of Consols. An order for the investment of dividends must in the first place be given to the Bank; from that time forth the dividends will be invested, the Bank charging a commission of one penny in the pound, which will be deducted from the dividend. The dividend will not be invested until the month after it has become payable, so that if any holder of Consols wishes to make use of a particular dividend he can do so. That this easy method of saving money will much promote thrift we cannot doubt. An artisan, for example, may have his fifty pounds worth of Consols, which, after he has given due notice, will go on accumulating as a provision for old age. The limitation of the amount to 1,000l. is specially intended to make the new arrangement beneficial to small investors, and we sincerely hope that in a long time it will be the endeavour of every man in a small way of business to have his holding of Consols gradually accumulating and increasing.

A CORRESPONDENCE has for some time past been carried on in the *Times* on the subject of the relative merits of trial by jury and trial by a judge without a jury. We have more than once pointed out that in nearly every case arising out of building disputes, a trial by a judge, assisted by a skilled assessor, is the most satisfactory. Of course, when a case involves the examination of accounts, or of many details, as is the case when a builder brings a claim for extras, the reasonableness of which is disputed by the building owner, the only satisfactory tribunal is an arbitrator. But both in these cases, and in every other which arises in connexion with buildings, such as whether commission is payable on the sale of an estate, the main thing which parties desire is that the case shall be heard with as little delay as possible, without waste of money in preliminary proceedings. It is in interlocutory proceedings which are the basis of our litigation. In nine cases out of ten they have no effect on the ultimate issue. One special value of the Arbitration Act of 1889, was that persons can now enter into a binding submission to arbitration without invoking the aid of the Law Courts by applying to have the submission made a "rule of Court." But in every dispute, if the parties really know what is the actual bone of contention, it should be possible to come to an issue without pleadings and all the legal skirmishing which now often occurs.

PUBLIC attention has this year been noticeably called to the many street accidents which occur in London from time to time. It is obvious that measures should no longer be delayed to facilitate the passage of foot-passengers across the most crowded thoroughfares of the Metropolis. The stoppage of the vehicular traffic even two or three minutes in order to allow foot-passengers to cross is one of the most

serious causes of the derangement of the wheeled traffic, without taking into account the dangers run by pedestrians. The remedy for this state of things is plain and easy. At certain points along the most frequented thoroughfares subways or bridges should be built. These would not only relieve the traffic at these particular points, but at other places, for many foot-passengers would make their way to these points who at the present time cross in any place where they happen to be. There is a subway at Westminster under Bridge-street for the use of Members of the Legislature. This shows that the same work could be constructed in other parts of London. But in many places probably bridges across the street would be best. They might often be constructed so as to be ornaments to the streets. They could be made of light, well-worked, and well-designed ironwork, or of stone. For example, as regards the placing of these bridges, one is much wanted near the Law Courts; more than one is required in the City near the Mansion House. A subway or a bridge should be constructed in Piccadilly, near St. James-street. But the point we are now insisting on is not the actual places for these works, but the absolute need for their existence. In some places they might even be made to pay for themselves, as recesses might be constructed which would be rented for newspaper or flower stalls.

IT is interesting to note, as a sign of the times, that questions relating to the necessity for the removal of insanitary property are not opposed now as they were formerly. The Salford Town Council have just passed a resolution to the effect that it would be well to proceed at once with a comprehensive scheme for dealing with the insanitary dwellings of the borough. At the meeting of the Council, when this resolution was passed, it was stated that there were two classes of property proposed to be dealt with: that which was absolutely unfit for habitation, and that which was fit for habitation, but which it was desirable to remove for purposes of re-arrangement of sites, &c. As to the first class of buildings, steps were being taken to remove them; but the second class could only be dealt with under a scheme. In most schemes for the removal of insanitary buildings it is frequently necessary to remove dwellings perfectly fit for habitation, and no one, we think, can object to this if the improvements which result from such removals, by the re-arrangements of sites, are desirable, and add to the importance of the locality. At the meeting of the Salford Town Council there seemed to be a unanimous agreement as to the necessity of the proposed improvement, and it was stated that the Health Committee would bring before the Council a comprehensive scheme for the demolition of the particular block which had been referred to, and would ask the Council to provide the necessary funds.

IN reference to the much-spoken-of German National Monument Question (see *Builder*, pp. 372, 444, *ante*), designs have been invited from a limited number of artists, whose names have not been officially mentioned, among whom, however, we are able to name Messrs. Rettig and Pfann and Bruno Schmitz, the first and second prize-winners of the last great competition. The invitations to compete, which have been distributed by special command and under direct supervision of the Emperor, promise each competitor 4,000 marks for his trouble, in consideration of which sum the design becomes the property of the Imperial Government, and they also promise that designs of special merit will receive premiums up to a value of 12,000 marks some 600*l.* Not a word is stated as to who will award the premiums. The "programme" for the required designs includes little besides a notification that the proposed extension of the "Schlossfreiheit" is to be the site for the monument, and that the latter is to be in the form of an equestrian statue (in accordance with the Reichstag decision of last session), a few

measurements, and a request not to omit the architectural "laying out" of the neighbouring ground. The designs, which are to be sent in by next April, and will then be publicly exhibited in Berlin, are to be partly in model form and partly in geometrical drawings.

IN the list of German cities most visited by Englishmen, Dresden certainly takes a prominent position, but the city has for many a long year been relying on former laurels, and it is only within the last ten years that the catalogue numbers of the collections have shown a perceptible increase. A revival in architectural activity is also now perceptible; municipality, government, and royal household having given their architects and engineers plenty of commissions, and private companies and persons having followed this example; so that, if the general management prove a good one, Dresden, some ten years hence, will certainly be able to find a place in a list of the better class of recently-improved towns of the Empire; at the same time having the advantage of being able to show street fronts of a good freestone, the use of this material, within easy reach of the builder, being usual. Among the new buildings, we may mention the now nearly-completed "Albertinum" (sculpture museum and State record office) and the gigantic block, in course of erection, destined to contain the offices, schools, and exhibition halls of the Saxon "Academy," both of which have found room on the far-famed "Brühlsche Terrasse," on the left side of the river; and we must not forget the huge "Ministry of Finance," the foundations of which can be seen on the opposite side of the water. Among the larger schemes which are still on paper, we hear of a new central railway station, a much-needed new post office building, and a large block for the municipal offices; whilst among those already worked out and about to be taken in hand next spring we may count the proposed fourth Elbe Bridge and the extensive embankment thoroughfare which is to be laid out on the right hand bank of the river and will form a practical connection between the four large bridges; also the two large covered markets over which so much time has already been spent at the city "Board of Works." The street fronts in the town proper are undergoing a rapid change, new hotels, shops, and office buildings finding their way into the narrow streets, and more especially in the newly-opened-up thoroughfares which have been cut through the slums some years ago.

THE sanitary condition of Barnstaple (North Devon) is the subject of a report by Dr. Barry to the Local Government Board, dated July 21. Fatal cases of diphtheria have occurred there, the spread of which appears to have been assisted by want of isolation, but the report as to the sanitary circumstances of the district discloses the usual kind of conditions which precede cases of diphtheria and typhoid. House refuse is generally stored in uncovered ashpits, which are emptied "at long intervals" by the occupiers and the contents used on the land. Excrement disposal is usually by pit privies, "many of which remain unemptied for long periods." In no place is there any public scavenging; the inhabitants being apparently left to clean out their filth receptacles in accordance with their own perceptions or their own indolence. "At Branton the houses at the lower portion of the village have wells which are liable to pollution; these are sunk only 15 ft. to 20 ft. in the gravel, and as the old square drain used as a sewer is laid in this gravel, fouling of such wells or of some of them must necessarily occur." Dr. Barry reports that the inspectors make regular inspections, and appear to have a good knowledge of the deficiencies of their district, but that by-laws as to dealing with unemptied privies and other receptacles are not sufficiently enforced. Under date July 31 Dr. Barry also reports on the sanitary condition of Easingwold rural sanitary district. Here we have a repetition

of the same conditions: rubble drains; wells sunk in contiguity to middens and leaking drains; middens frequently of large size, "and as the scavenging is left to the occupiers, accumulations of filth are frequent." This is recurred to several times in the report: "excrement disposed of in uncovered middens which at the time of my visit contained enormous accumulations of filth and ashes," and similar remarks are made about various houses or groups of houses in the district. The key to all this is in the sentence "As the Sanitary Authority do not undertake the removal of refuse the inhabitants have either to undertake this work themselves or to arrange with farmers or others to do it at their convenience; a mode of procedure which invariably leads to the storage of large accumulations of filth." It is the same story here as in other rural districts; ignorant persons must have sanitation forced upon them by authority, or they will never have it at all. To leave accumulations of dirt saves trouble, and that is a sufficient defence of it to the uneducated mind. In this report again it is stated that the Medical Officer of Health, Mr. E. Buller Hicks, has a thorough knowledge of his district, and has brought its shortcomings frequently to the notice of the Sanitary Authority, but "much of his advice has been unheeded, or has been attended to in a makeshift manner only." If the Sanitary Authorities are so indolent and careless of their duty, how can we wonder that the people are no better?

IN reference to the class of reports quoted from in the preceding paragraph, we may add that it would be well if the Local Government Board would turn its attention to the sanitary condition of some of the villages on the East Coast which are now becoming largely frequented as watering-places. The town of Cromer appears now to be on the way to a good sanitary condition, though there is much to be done there yet; but the village of Overstrand, two miles off, which is now rapidly rising to the dignity of a watering-place, is in the most primitive state in regard to sanitation. Four years ago (when we gave some sketches from the district in the *Builder*) Overstrand was but a fishing village. Several terraces of "marine villas" have now sprung up, besides two or three detached houses of a better class, and there is talk of a new street and a large hotel. In that case the main attraction of the place, as a quiet seaside resort, will be gone; but that is all the more reason why the drainage should be looked after. What drainage there is appears to be taken to a couple of big cesspools, how often emptied we know not; a grating over one of them is close to the main gangway to the beach, and after heavy rain, smells abominably, and as the ground is of a very permeable character, it is not surprising that leakage should have taken place, and that a rivulet of pure sewage should have been seen occasionally down the face of the cliff. A Sanitary Inspector at Overstrand would find some of the same incidents mentioned by Dr. Barry in his above-named reports; middens which the owners are left to empty at their own will, and which are therefore never emptied till dire necessity compels it (a remonstrance from visitors generally producing some indignation), and pumps from which water for all purposes is drawn, standing over wells in happy proximity to the middens aforesaid. Two or three cases of diphtheria are known to have occurred not long since, though the inhabitants have become discreetly reticent on this subject. Under what Rural Sanitary Authority is Overstrand? A very sleepy one, apparently, if any. Lower Sheringham, on the other side of Cromer, has already its big hotel, apart from the village; the latter we only know by a cursory visit, but if the smells of Lower Sheringham are any indication of its sanitary condition, it must want the doctor badly. While speaking of this neighbourhood, we cannot but express the greatest regret also at seeing the beautiful down between Cromer

and Overstrand, known as the "lighthouse hills," offered as building land for residences. This is one of the most beautiful heights on the English coast, and its proximity forms one of the many attractions of Cromer and Overstrand; to build on it would be to deprive Cromer of the best of the very attractions which draw people there, and would therefore probably in the end prove a very doubtful benefit even to the landowner.

TO serve for a public-house by sign of the "Sir Paul Pindar" has been the latter-day fate of one of our best relics of a London merchant-prince's residence nearly 300 years ago. From a brief letter addressed to the *Standard* last week we learn that what yet remains of Sir Paul Pindar's home in Bishops-gate-street-without will, in all likelihood, very soon be "wrecked," having been acquired, together with some adjoining property, by the Great Eastern Railway for the extension of their Liverpool-street terminus. We understand that the demolition will ultimately extend to all the property between the ends of Worship-street, in Norton Folgate, and Liverpool-street. It is stated that Pindar—a contemporary, in his boyhood, of Gresham, and son of Thomas Pindar, or Pinder, of Wellingborough—built this house upon his return from Italy at the end of Elizabeth's reign; and he is said to have been visited here by her two successors on the throne when they wanted to borrow of his ample gains. At the Turkey Company's instance, James I. despatched Pindar, in 1611, to, as the epitaph says, "the Turkish Emperor." He returned, greatly enriched, after nine years' absence. Having benefited his Royal masters to his own serious embarrassment, Pindar died in 1650, aged eighty-four years. He was enthusiastic for architecture, and contributed 10,000*l.* towards the screen and south transept for Inigo Jones's work at old St. Paul's. Pindar's house and its park-ledge in Half-Moon-street have been frequently illustrated. Their later aspect may be seen in several views at the Guildhall Library, where also is a copy of Schnebellie's plan of the old London Workhouse, the house, lodge, &c. We may also refer our readers to J. T. Smith's "Ancient Topography of London" (1812), and Wilkinson's "Londina Illustrata." Smith gives a drawing (made in 1792) of the interior of a first-floor room, showing the ornamentation of its ceiling, panels, wainscot, and chimney-piece,—decorations which, as he tells us, were cut away in 1811 in order to render the room "a little comfortable." The Pindar coat-arms were found beneath a sheet of metal fastened on to the ceiling. Reduced from its pristine proportions, deprived of its large garden planted with mulberry-trees, mutilated and defaced without and within, this old house still retains portions of its exterior towards the main road. A solitary gable rises above the first and second floors, of which latter the windows project oriel-wise far beyond the ground story. The whole front forms a specimen of domestic work, in wood, richly carved, so singular of its kind, that we trust some steps will be taken to save it from destruction. A magnificent ceiling was removed to the South Kensington Museum from the house next door (southwards), which some consider to have been part of Pindar's house, and since pulled down. The Reverend Thomas Hugo contributed a paper to the London and Middlesex Society (printed in their Transactions, 1837), descriptive of this house, and of some plaster ceilings in various tenements at the rear, highly decorated with figures, wreaths, shields, ribbands, and the like. A clearance has lately been made on the site of these houses for purposes of the railway.

THE death of Miss North should not be allowed to pass without brief notice. She possessed in a remarkable degree the power of portraying flowers. This kind of still-life art

\* Yet his epitaph at St. Botolph's-without describes him as "an inhabitant twenty-six years, and household benefactor to this parish." Many particulars of his career are set out in the MR. of the funeral sermon preached by Nehemiah Rogers.

is one which is, generally speaking, too purely imitative to be ranked very high. For decorative purposes it is of value, but in our opinion to hang portraits of flowers round a room is nearly as bad as placing artificial flowers on a table. But Miss North used her special gift not only for the advancement of knowledge, but as a means of enabling the people of this country to become acquainted with the appearance of the flora of nearly every country under the sun. Miss North's collection of the portraits of flowers at Kew will be a perpetual monument to her indefatigable zeal in portraying the flowers of the world, and will be a continual source of interest, pleasure, and recreation to thousands. It would be useless to enumerate the countries in which Miss North had travelled. In 1870 she visited Canada, the United States, and Jamaica, and her last journey a few years ago was to South America. Since that time her health has been gradually failing, and she has lived in complete retirement at her house in Gloucestershire, ever interested in her garden, which was a treasure-place of rare and beautiful plants collected in all parts of the world.

THE silly knot of persons at St. Albans who thought it worth their while to propose a testimonial or monument to Lord Grimthorpe for amusing himself by disfiguring their Abbey, have got the snub they might have expected from their genial idol. Lord Grimthorpe's letter to a local journal on the subject discloses a new phase of his self-appreciation, however. A little while ago we suggested that the motto over Wren, "Si monumentum requiris, circumspice," would be an ingenious sarcasm to erect over against St. Albans. Lord Grimthorpe however, we find, actually adopts Wren's epitaph as the one most appropriate to himself, only pointing out that Wren "did not pay for the building." It appears therefore that Lord Grimthorpe seriously imagines that his work at St. Albans has set him on a level with the designer of St. Paul's! Such vanity would be a spectacle for amusement if unfortunately the results of it were not so permanent. That it "will be there for many centuries" is probably true, for it is solid building enough; but it will be there for the laughter and not for the admiration of posterity.

#### LETTER FROM PARIS.\*

THE distribution of medals and diplomas in connexion with the Great Exhibition is to commence immediately, and to be carried on continuously in the order of the classes and groups. It has been delayed partly for the engraving of the diploma form, which has occupied no less than seven months. It is expected that the condemned buildings on the Champ de Mars will be removed by the end of the month, and the treatment of the buildings to be preserved will then be taken in hand. MM. Bouvard and Formigé will in the first instance replace all the essentially temporary work on their respective buildings by solid materials, before the special use of these buildings is actually entered on. It is said to be pretty well settled now that the Palais des Beaux-Arts will become the permanent abode of the long-talked-of Musée des Arts Décoratifs.

As we have before mentioned, it was formerly intended that this Museum should be built on the site occupied by the ruins of the Cour des Comptes. What will become of the latter if the Government ratify this new idea is then the question; and probably there will be no course but to remove and sell the ruins of the Cour des Comptes as old materials, and leave the site free for other purposes. Every one in Paris will be very glad to see the last of them, the remains being both unsightly in themselves and having disagreeable memories connected with them.

There is talk also of transferring the offices of the Minister of Finance, which since 1870 have occupied a part of the Louvre, to the site in the Boulevard St. Germain now occupied by the War Department, the latter being transferred to the Hotel des Invalides, too large now for its remnant of pensioners, and where the headquarters of the Military Staff are already es-

tablished. By this arrangement, the Louvre buildings will be left entirely free for artistic objects. All the *personnel* of the museum could be installed in the Pavillon Flore and the Pavillon Marsan, and the State would possess the whole immense palace for its collections. If these projects are not immediately realised, the arrangement for them seems to show that the Direction des Bâtimens Civils is awaking a little out of its proverbial torpor.

In the Louvre itself further alterations have been going on, and the Salle Rude, closed for some time past, is now re-opened and enriched with some of the splendid bronzes of Barye, and also some of the various works of Carpeaux, including the well-known group of "the Dance." The Salle des Sept Cheminées has totally changed its aspect. In that room are now exhibited the "Sacre" of David and the "14th Brumaire" of Bonhot; while in the Salle de Beauvais the ceiling has been "marouffé" with the immense decorative painting by Carpeaux Duran, "Gloria Mariae Medicis," which since its appearance at the Salon of 1874, has been the subject of violent polemical criticism. This canvas, originally intended for the Luxembourg, has been placed in a framework designed in the style of "La Sicile," with escutcheons with the arms of France and of the Medicis. Lastly, we have to mention at the Louvre the legacy of sketches by Carpeaux left by the late Philippe Barry, and the re-exhibition of a number of splendid miniatures of the fifteenth and sixteenth centuries which have been for years hidden in the store-rooms of the Louvre for want of space to show them.

The repairs at the Pont Neuf have uncovered the ancient piling, about which there is some interest. These piles, which date from the year 1602 at least, the time when the bridge works were being most actively carried on,—or perhaps from 1578, the year when Henri III. laid the first stone,—are in a state of perfect preservation. A little smaller than the piles in use to-day, they are mostly square in form, and in those days were driven by immense mallets worked by hand. The foundation-stones appear in a sound condition; they terminate in steps to which the piles serve as base, and which were probably formerly above water, the level of the Seine having been lower then than since the water has been confined between quays. In spite, however, of this surprising state of preservation of the foundations, there has been a perceptible settling in the bridge, which has called for immediate attention.

Another structure, not quite so old, but vulnerable for a railway structure, the Gare des Sceaux, has been giving the same kind of trouble, cracks having been heard and crevices seen in its walls. It has been necessary to shore it up at once. The excavations which have been made for the purpose of repairing the walls have revealed the fact that a part of the station is built over some old quarries, and a considerable amount of underpinning has been necessary to render the buildings secure for the limited time for which they are required, until the completion of the new terminus on the Place Medicis.

In the Garden of the Luxembourg a bronze-bust of Delacroix has just been placed, a fine work by Dalou, who has also executed the allegorical group for the pedestal, representing "Le Temps portant la Renommée." The principal face of the monument will bear the simple inscription—

À EUGÈNE DELACROIX  
SES ADMIRATEURS.

The work will probably be inaugurated towards the end of September. In connexion with this subject we may mention that the Commission des Musées Nationaux has selected the following works to be added to the Luxembourg collection: in sculpture, "La Sirène" by M. Puech, and the "Gilliat" of M. Carlier; in painting, "Les Bûcs" by M. Quignon; "Le Rêve" by M. Richemont; "La Vache Blanche," by M. Julien Dupré; "La Forêt d'Arques," by M. Gosselin; a still-life painting by M. Desgoffe; an "Etude de femme" by M. Carous Duran, and a "Halle de Cavaliers" by M. John Lewis Brown.

On the right bank of the Seine the buildings of the new Sorbonne are being carried on without interruption, and on the left bank the exterior of M. Bouvard's new Bourbe is nearly finished. Of the design of this building we have before spoken. Not far from it the works connected with the Belleville rope railway are nearly completed. This new means of getting to the summit of the Twentieth Arrondissement will probably be completed and opened for

\* Unavoidably postponed from last week.

traffic in October. A still more important class of new works, perhaps, will be the substantial school buildings which the Municipality is shortly about to erect on the sites where wretched wooden barracks have been run up as schools, provisionally, since the time when, eight years ago, Parliament made gratuitous primary instruction obligatory. About eight to ten million francs will be spent on these permanent schools.

Two years ago, on the occasion of the annual congress of architects, we gave a description of the Russian church in Rue Daru, which up to the present time has been the only church in Paris dedicated to the orthodox rite of the Greek Church; but it is announced that another church for this worship is to be erected shortly in the Rue Bizet, near the Arc de Triomphe, in the centre of the favourite residential quarter of the Hellenic colony in Paris. It is a Greek resident, M. Demetrius Tzani Schilizzi, who has given the sum of two million francs for the work, which is to be in Byzantine style and surmounted by three cupolas.

The Railway Company "de l'Est" has just commenced some important works for the enlargement of the Gare de Strasbourg, which for a long time back has been quite insufficient for the traffic.

M. Poilpot's new panorama of "Les Engagements Volontaires de 1792" in the Bastille neighbourhood, has only been opened to the public for a few weeks before it has been destroyed by fire. Without having, of course, the high artistic qualities of the panorama of the Battle of Rezonville, by two such masters as Detaille and de Neuville, the work of M. Poilpot offered nevertheless a very interesting spectacle, especially as a picturesque restoration of a corner of old Paris. The spectator, supposed to be standing on the Pont Neuf, witnessed a scene full of life, framed amid the remarkable buildings contiguous to the two arms of the river, and looked across the quarter of the Arsenal to the wooded height of Chaillot, where the Trocadero now stands. M. Poilpot, thanks to his assiduous researches, had revived a great deal of the ancient aspect of Paris, and among archaeologists the merit of his work in this respect was admitted.

The Académie des Beaux-Arts held a sitting recently to award the grand prix de Rome in architecture. The first prize has been awarded to M. Pontremoli, a native of Nice, and a pupil of MM. André and Lalou. The "deuxième premier" was awarded to M. Sortais, pupil of Mm. Daumet and Gaudet, who in 1888 obtained the "premier second grand prix," which this year has been carried off by M. Louis Varcollier, pupil of his father and of M. Ginain. M. Bossi, pupil of M. Pascal, obtained the "deuxième second." The subject of the competition was "Un Monument à Jeanne d'Arc," and the instructions indicated the side of a hill above the Seine, and in the neighbourhood of Rouen, as the supposed site. The competitors had reason to be grateful for this instruction as to site, which lent itself to such effects as successive terraces and porticoes, or an immense staircase leading up to a shrine before which was an equestrian statue of the heroine. The works exhibited, though very interesting, did not however strike us so much from the point of view of idea as of execution.

The Jury of the École des Beaux-Arts has given judgment on the competition for the first class of architectural students, the subject being "Un Théâtre de Grand Opéra." Second medals were awarded to M. Guilbert, pupil of MM. André and Lalou, and to M. Cargill, pupil of MM. Daumet and Girault, and to M. Duquesne, pupil of M. Pascal.

There is an intention of modifying the regulations of the École des Beaux-Arts, so that in future (if the Minister confirms the decision of the superior Council of the École) the ateliers, of which the direction is confided to certain artists named by the Government, will be freely open to young students without a preliminary competition. Besides this, the subjects of anatomy, modelling, architecture, and history will not be so important as that of design, and will serve only to assist in the classification of the pupils. One effect of this will be that we shall not again see, as has been the case, a pupil who has taken a high position for design being refused his position for not having given the correct date of the First Crusade. A man may certainly be an able sculptor, painter, or architect, without being strong in history.

We may mention lastly that a school of design for girls has been formed in connexion

with the School of Decorative Art which is to be installed, it is expected, in the old buildings of the Hôtel Dieu. M. Dutert, the architect of the Palais des Machines, has been appointed joint inspector of the school of design.

We have to record the death of M. Georges Coutan, a decorative designer, and the husband of Mme. Laure Martin (Coutan, herself a talented sculptor; and also that of M. Emile Levy, who died suddenly when just about to commence the decoration of the Salle des Caryatides in the Hôtel de Ville, in the first instance assigned to Cabanel. Levy was sixty-four years of age, and was a pupil of Ahel, Pujol, and Piot. He obtained the Prix de Rome in 1854, and received medals in the Salons of 1859, 1864, 1866, and 1867; he received in the latter year the Cross of the Legion of Honour, and a medal of the first class in the Universal Exhibition of 1878. Among his principal works may be named "Ruth and Naomi," the great work entitled "Musique Sacrée et Musique Profane," "La Danse," and "La Prière aux Champs." He had recently been commissioned to decorate the Mairie of the Sixteenth Arrondissement. He was an artist of talent, a pastellist of the first rank, and excelled especially in female portraits and in allegorical compositions of a somewhat archaic style.

#### HAMBURG CONGRESS OF ARCHITECTS AND ENGINEERS.

THE Amalgamated Societies of German Architects and Engineers held their ninth congress at Hamburg during the last days of August. Of the German societies, the greater number of the larger ones (some thirty with 6,000 members) form or rather belong to the national amalgamated "Society of German Architects and Civil Engineers," and it is this powerful body that, besides having its annual meeting of deputies, has its biennial gathering (held each time at a different town), at which instructive sight-seeing, accompanied by good lunches and dinners, meeting of old friends, not without boisterous merriment, are the order of the day, and at which conventional speeches, lectures, and debates, whatever be their intrinsic value, only come into secondary consideration. The number of members present at such a biennial gathering greatly depends on the advantages which the elected town promises its visitors. If the town, besides having ordinary or special advantages for sight-seeing, neighbourhood, &c., happens to be known as a rich and hospitable one, and if there happens to be an energetic architectural society on the spot to take the management of the reception in hand, there is sure to be a good contingent of members present; and if the town at the same time be a popular one, and have some special patriotic feature for the "Fatherland" lovers within easy reach, the attraction will be greater still, and the numbers will probably exceed the usual average.

So it has proved at Hamburg, where, instead of the 700 expected guests, 1,300 appeared, and although this number is very small in comparison with the number of architects in the Empire, and although the most esteemed of the profession were, for the most part, absent, and the field was nearly entirely in the hands of those who excelled more in wit or popularity than in their work, the show was certainly a stately one, and the gathering as a whole a great success.

It would take too much space to follow up the doings at the Congress day by day; yet it may be well to state that our friends over the sea ought to think themselves lucky to have a possibility of being received as they have been at Hamburg, by the authorities, the companies, and private persons. From the official opening day on the 24th, to the close on the 28th, the time was so instructively and enjoyably filled up as is seldom the case, and it was not till the Hanse city had been left, and the excursions to Lübeck, Kiel, and the North Sea-Baltic Canal had been successfully completed, that the visitors had any time for the much-needed rest after such a week of hard sight-seeing and late hour festivities. We may mention that every portion of the town and its surroundings was visited, mostly in groups under able and practical guidance, that all Government and municipal buildings or works were open to inspection, and that the proprietors of the numerous picturesque, well-planned, and luxurious villas had thrown open their homes, partly for inspection, partly for hospi-

talities. Inspections were done on a large scale, half a dozen steamers being employed on the harbour and Elbe, and quite a flotilla of boats and tugs on the Alster, and when it came to the grand patriotic part, i.e., the visit to the newly-acquired Helligoland, two first class American passenger steamers (the *Columbia* and the *Moravia*) were lent by the Hamburger Packetfahrt-Gesellschaft, the managers of which entertained the whole of the company to a sumptuous dinner on board. The town gave a banquet; at Blankenese a dinner was given; on the Alster lakes an "Italian night" with fireworks was arranged, and on the Elbe, outside the town, the rows of villas celebrated the passing of the guests with a general illumination and successive fusillades of rockets, forming effects not easily forgotten by those present. In fact, in and outside the city, authorities and civilians all vied in their attempts to do their best for the visitors.

As observed, at these gatherings the lectures, with their debates, come into secondary consideration. The early hour at which the lectures were started caused the splendid hall in which they were held to have (excepting on the opening day) a more empty appearance than necessary—a fact, however, by no means surprising to those who know what an evening festivity among old German friends means. The lectures, which, as a rule, were well received, mostly took the form of papers read by their authors before publication, and they are now to be found printed full length in our foreign contemporaries and in the Hamburg local press. The discussions that sometimes followed were of a very poor kind, so that, interesting as the topic might be, there was throughout a certain feeling perceptible that the "work" was but a farce, and that the sooner it was done with the better.

As the papers in themselves were of value, it will only be right to mention them, especially as the amount of labour each of them contains ought not to be undervalued. The most popular lecture, we believe, was the one read by the president of the Hamburg Society, Herr Andreas Meyer, on the first day, under the title of "Hamburg and its Buildings," and it was, certainly, thanks to this concise description of the town that the visitors got a clear idea of what was to be seen, without having waded through the large volume bearing the same title, which has been published for the occasion and contains very minute details. A paper read by Professor Hubert Stier (Hanover), before a very good audience of architects was exceedingly well received. In accordance with the heading, "Results of German Architectural Competitions during the last Twenty-two Years," the Professor gave, besides general comments, some very interesting statistics about the 258 competitions opened in the Empire since 1868. To Banath Holbrecht (Berlin) fell the highly-interesting theme, "Street Building in Cities, with Special regard to their Future Requirements of Underground Connection," and in this paper comparisons with London arrangements played an important part. Under the title, "Contemplations on Style," the editor of a Berlin contemporary, Herr Fritsch, read a somewhat lengthy but able paper, in which he made comparisons with the styles of former times, referred to the expected future development, and the means that should be employed to keep this development on a natural basis. For the civil engineers an excellent paper on "Wide-span River and Valley Bridges" was read, and the day before the trip to Helligoland a very suitable lecture was given on "Modern Steamships and their Machinery." In all cases the lecturers had taken special care to prepare their subjects, and it may be expected that the amount of material collected will be turned to some good account, either as a basis for future discussions in the different societies, or as preparatory essays for hooks about to be published.

In 1892 the gathering will be held at Leipzig, but we are afraid that this town has been ill-chosen, the contrast between the two being too great.

OPENING OF A NEW BRIDGE IN BELFAST.—The new Albert Bridge, built by the Belfast Corporation at a cost of 36,000*l.* across the river Lagan, the foundation-stone of which the Duke of Clarence and Avondale laid about a year ago, and which is intended to take the place of the old stone structure which collapsed four years ago, was opened by the Mayor of Belfast on the 6th inst.

THE BRITISH ASSOCIATION FOR THE  
ADVANCEMENT OF SCIENCE.

ALTHOUGH this year's meeting of the British Association (which has been held in Leeds for a second time, after an interval of thirty-two years) has not been so largely attended as last year's meeting, it seems to have produced a fair number of interesting papers in the various sections.

The President, Sir Frederick Abel, in his opening address, dealt mainly with two subjects,—Applied Electricity, and Explosives. We give a few condensed extracts from it:—

*Electric Lighting.*

While the prediction made by Siemens, eight years ago, that electric lighting must take its place with us as a public illuminant, has already in a measure been fulfilled, important progress is being continuously made in developing and perfecting the arrangements for the generation of the supply, its efficient distribution from centres, and its delivery to the consumer in a form in which it can be safely and conveniently dealt with and applied at an outlay which, even now, does not preclude a considerable section of the public from enjoying the decided advantages presented by electric lighting over illumination by coal-gas. Yet our recent progress in this direction, encouraging though it has been, is insignificant, as compared with the strides made in the application of electric lighting in the United States, as may be gauged by the fact that while in America the number of arc lamps in use in April of this year was 235,000, and of glow-lamps about three millions, there are at present only about one-tenth the number of the latter, and one-hundredth the number of arc lamps, in operation in England. In some important directions we may, however, lay claim to rank foremost in the application of the electric light; thus our large passenger ships and our warships are provided with efficient electrical illumination; to the active operations of our navy the electric light has become an indispensable adjunct; and our system of coast defences by artillery and submarine mines is equally dependent for its thorough efficiency upon the applications of electricity in connexion with range-finding, with the arrangement and explosion of mines, and with the important auxiliary in attack and defence, the electric light. Other important applications of the electric light, such as its use as a lighthouse illuminant, for the lighting of main roads in coal mines, and even for signalling purposes in mid-air, through the agency of captive balloons, are continually affording fresh demonstrations of the value of this particular branch of applied electric science.

*Power Electrically Transmitted.*

The Paris Electric Exhibition afforded interesting illustrations of the performance of a variety of work by power electrically transmitted, including a short line of railway constructed by the firm of Siemens, which was a further development of the successful result already attained in Berlin by Werner Siemens in the same direction, and was, in its turn, surpassed by the considerably longer line worked by Messrs. Siemens at the Vienna Exhibition. Various short lines which have since then been established by the firm of Siemens are well known, and one of the latest public acts in the valuable life of Siemens was to assist at the opening of the electric tramway at Portrush, and where the idea, so firmly rooted in his mind from the date of his visit to the Falls of Niagara, in 1876, of utilising water-power for electrical transmission,—a result first achieved on a small scale by Lord Armstrong,—was more practically realised than had yet been the case. Since that time Ireland has witnessed a further application of electricity to traction purposes, and of water-power to the provision of the required energy, in the working of the Bessbrook and Newry Tramway; while London at length possesses an electric railway, three miles long, to be very shortly opened, which will connect the City with one of the southern suburbs through a tram-subway, and, although including many sharp curves and steep gradients, will be capable of conveying one hundred passengers at a time, at speeds varying from thirteen to twenty-four miles per hour. During the past year a regular service of tramcars has been successfully worked, through the agency of secondary batteries, upon part of the large tramways of North London, with results which bid fair to

lead to an extensive development of this system of working. The application of electricity to traction purposes has, however, received far more important development in the United States; at the commencement of this year there were in operation in different States two hundred electrical tramroads, having a collective length of 1,641 miles, with 2,346 motor-cars travelling thereon. Further extensions are being rapidly made; thus, one company alone has thirty-nine additional roads, of a collective length of 385 miles, under construction.

*Electric Welding.*

The successful practical realisation of Joule's predictions in regard to the application of electric currents to the welding of iron and steel, and to analogous operations, through the agency of the efficient machines devised by Professor Ellhu Thomson, was demonstrated to the members of the Association by Professor Ayrton at Bath two years ago, and was shown upon a larger scale to visitors at the Paris Exhibition last year, and recently to highly interested audiences in London by our late President, Sir Frederick Bramwell. At the Crewe Works, Mr. Webb is successfully applying one of these machines to a variety of welding work. With such practical advantages as these, electric welding bids fair to receive many useful applications. Another very simple system of electric welding, especially applicable to thin iron and steel sheets, hoops, &c., has been contemporaneously elaborated in Russia by Dr. Bernados, and is already being extensively used. The required heat at the surfaces to be welded is developed by connecting the metal with the negative pole of the dynamo-machine, or of a battery of accumulators, the circuit being completed by applying a carbon electrode to the parts to be heated. This mode of operation appears to have been practised upon a small scale, some years ago, by Sir William Siemens, to whom we also owe the first attempt to practically apply electric energy to the smelting of metals.

*Science applied to Mining.*

Reference was made to the production of new explosive agents for mining and quarrying purposes, to the improvements of safety-lamps, and to the provision of serviceable, safe, and portable electric lamps for use in mines. The recent legislation in connexion with mines is (said the President) certainly deficient in any sufficiently decisive measure for excluding from mine-workings certain forms of lamps which, while fairly safe in the old days of sluggish ventilation, are unsafe in the rapid air-currents now frequently met with in mines. It is, however, very satisfactory to know that the strong representations on this subject made by the late Commission, combined with force of example, and with the conclusive demonstration of the superiority of other lamps, have led within the last two years to the very general abandonment of the unprotected lamps in favour, either of simple, safe, modifications of these, or of other safe and efficient lamps. In one important respect recent improved legislation has failed to effect a most desirable change,—namely, in the substitution of safety-lamps for naked lights in workings where small local accumulations of fire-damp are discovered from time to time. There appears little doubt that one of the three fearful explosions which have occurred within the last twelve months (the explosion at Llanerch Colliery, near Pontypool) was caused by the continued employment of naked lights in a mine where inspection constantly revealed the presence of fire-damp. This explosion, and two other terrible disasters—at Mossfield Colliery, in Staffordshire, and at Morfa Colliery, near Swansea—which have occurred since the last meeting of the Association, may have seemed to weaken the belief that the operation of the recent Mines Regulation Act must have resulted in very substantial improvement in the management of mines and in the conduct of work by the men. Happily, however, there is a consensus of opinion among those most competent to judge—*i.e.*, the Government Mine Inspectors—that very decided benefits have already accrued from the operation of the new Act. We may hope, moreover, that the operation of the Act is paving the way to more comprehensive legislation in the near future; for it can scarcely be doubted, by the light of recent sad experience, that there are directions in which both masters and men still hesitate to adopt, of their own free will, measures or regulations, methods of working or appliances and precautions, which

are calculated to be important additional safeguards against mine accidents, and which are either left untouched or only hesitatingly and imperfectly dealt with in the recent enactments.

*Railway Routes to the East.*

In the Geographical Section, on the second day, Sir Frederic J. Goldsmid read a paper on "Railway Routes from Europe to India." It was intended as a supplement to one read in June, 1878, at the Royal United Service Institution, on "Communication with British India under Possible Contingencies." The main object on that occasion was to advocate the construction of a line of railway connecting the eastern shores of the Mediterranean with the western coast of India by a direct, convenient, and politically expedient route. It was not originally laid down with any precision what should be the actual course taken by the through line to India when branching off from the Lower Euphrates. Surveys and reports by recent travellers had now rendered it easy to supply this link of rail, one which might be appropriately called the Baghdad-Bandar-Abbas section, or, more minutely, the Baghdad-Sibráz and Sibráz-Bandar-Abbas sections. As to the route from Bandar-Abbas to Karachi on the east, and from Tripoli to Baghdad on the west, any doubts or difficulties that presented themselves were already ripe for discussion, and their solution would not be treated as dependent upon further travel and research. It was proposed to carry the line from Baghdad through Persia, Arabistan, either by way of Dizful and Shustar, continuing along the recognised track from the latter place to Bebehan; or by an alternative route down the left bank of the Tigris, and *via* Havelzab to Ahwas, whence Major Wells, R.E., had furnished full details of the route from his own experiences. The same officer had made, moreover, very valuable suggestions on the mode of reaching Sibráz from Bebehan. After mentioning other routes available, Sir F. Goldsmid said that he had great faith in the drastic remedy of the iron rail and locomotive to awaken a slumbering but active-minded people, for whom it would be a novelty of high price and usefulness. He did not, however, disguise the fact that the scheme of railway which he described had not had its origin in the mere wish to benefit a particular nation, but rather in the intention of putting in a 900-mile link in the inevitable great line, which would some day connect England with her Indian Empire, and which should be as readily available to passengers and goods as any of the more popular and successful lines at home.

*Cable Tramways.*

In the Mechanical Science Section, on the third day, Mr. W. Newby Colam read a paper on "Cable Tramways." He thought that the present was not an inopportune time for bringing this subject under the consideration of the British Association, because the conditions imposed upon the public had so changed of late as to make it necessary to adopt some system of locomotion whereby the public could be carried at cheaper rates, and more quickly than by the plodding horse. He briefly referred to the various means of utilising electricity, air, steam, gas, and ammonia for street traction, and considered that only two of them had been working a sufficient time to afford a commercial test which would survive. These, he said, were the cable and steam locomotives. Of the electrical motors undergoing commercial trials abroad, he was of opinion that the storage system was the only one likely to be seriously entertained in this country for street purposes. The author hoped that the day was not far distant when it could be proved that this means of applying electrical locomotion in streets could be worked at a fair remuneration over the average roads, because he considered it would then have a big field of operation. He, however, had formed the opinion that electrical engineers had many difficulties to surmount before this class of motor could face the varied work of ordinary streets and pay well in this country. Steam engines were, in his opinion, not likely to receive much attention in the future for the purpose of traction through streets, but he thought they would be found useful as a means of connecting districts. Under the circumstances, he suggested that the cable might be found the mechanical power to supersede horses in cases where horses were clearly not capable of meeting the new

conditions of travel. The author next described the origin of cable tramways. He said success had attended almost every inauguration in America and elsewhere, notwithstanding quite necessarily large capital outlays. There are present 501 miles of cable tramways at work, which carried last year in the States nearly eight hundred millions of people, or nearly double the passengers carried in Great Britain and Ireland. Abroad dividends of 74 per cent. had been earned, and in England they were now being worked at 4 per cent. of the gross receipts. Mr. Colam gave his opinions as to the requirements to be observed in designing cable tramways in order that they might meet with the approval of local authorities and ensure economical results. He described two lines he had made in Edinburgh, and he ventured on a prediction that the low construction and equipment cost of such a system would not fail to attract the attention and demand the consideration of tramway authorities. In concluding his paper, the author spoke of the remarkable success which had attended the working of cable tramways in Chicago and also in the Brooklyn district of New York.

*The Utilisation of Compressed Air.*

In the same Section, Professor A. Lupton read a paper on "The Pneumatic Distribution Power." In his opening remarks, Professor Lupton said he did not intend to go over ground which had already been trodden by other engineers, and on similar occasions to the present. He said he should chiefly confine his observations to the experience which had been derived from the working of this system in Birmingham, and he remarked that the subject had of peculiar interest in Leeds, because local authorities had obtained an Act of Parliament for the use of compressed air throughout the borough. He showed how the supply of this air through a meter induced economy on the part of the consumers, and he divided the section with numerous interesting particulars as to the use of this air in the propelling of trams, in the working of the electric light, for various domestic purposes, and in Paris for the emptying of cesspools. At considerable length he showed the great advantages of a power suitable for large or small motors that could be cheaply and safely introduced in workshops, houses, and shops—a power that could do the heavy work of a millcourse or sawworks, and the light work of the tailor, maker, printer, hairdresser, and grocer; that would drive dynamos for electric lighting; that had many other applications, as was, he said, universally admitted. In Birmingham there were steam-engines of 1,000-horse power which compressed air to a pressure of 10 lb. above the atmosphere, and delivered into pipes which were laid in the streets like gas-pipes, and over four miles of the pipes were now laid. The works had only just been completed, but already there were forty customers for air power, some of them at a distance of one and three-quarters miles from the compressing station. The saving of power by friction in the pipes was so slight that no ordinary gauge could show it—practically, there was no loss of power due to this distance. The engines of consumers varied in size from 1-horse power to 50-horse power. At one works they were using about 100-horse power, which drove five engines, also the blacksmiths' fires. Blast of the cupolas for iron smelting, and was also used for several novel processes, commencing labour and material, that had been covered since the power was laid on. Some novelty had been found in getting a good boiler, but Mr. Abrahams had now invented and patented a meter that was correct within 1 per cent. There was now a demand for the power which gave satisfaction to those who had tried it. Some people had actually moved into the district for the sake of the convenience of having power without having to erect a boiler and chimney. Comparing the mechanical results with the prophecies that were uttered in 1866, he mentioned that then it was alleged by him that the engines as designed could not be heated, but they had been now safely set to work. It had also been asserted by some that a loss of power in compressing was such as to be 25 to 30 per cent. was the maximum portion of the original steam-power that could be used by the consumer's engines. The results, however, had entirely confirmed the statements of the engineers, Messrs.

Sturgeon and H. Robinson. At one works visited by him (Professor Lupton) the indicated horse-power of the consumer's engine was equal to 73 per cent. of the indicated horse-power of the steam-engines at the compressing station,—a result which he considered very satisfactory. This result was partly due to the re-heating of the air in a stove, where the sweepings of the workshop were consumed without cost. In consequence, he said, of these satisfactory mechanical results, the Air Compressing Company were about to extend their works. The Professor went on to say that compressed air could be used for working tramways under the patents of Hughes and Lancaster. Under this system a pipe was laid in the streets for the supply of compressed air to the cars, which cars carry the machinery for propulsion, and can ascend any gradient that a locomotive can mount, and take in fresh supplies of compressed air at every stopping-place, an operation which can be effected without actually stopping the car. An experimental car on this principle had been run on the Chester Tramway.

*A Possible New Process for Copying Drawings.*

In the Chemical Science section, on Tuesday last, Mr. A. G. Green read a paper entitled "The Action of Light upon the Diazo Compounds of Primuline and Dehydrothiolumidine: a Method of Photographic Dyeing and Printing," prepared by himself, Charles F. Cross, and Edward J. Bevan. In the course of the paper Mr. Green said it had long been observed by him that the diazo compound of primuline was very sensitive to the action of light, being readily decomposed thereby, and losing its property of combining with phenols and amines. Upon this fact they had now founded a photographic process, by means of which designs can be produced in fast colours upon cotton, silk, wool, linen, or other fabrics. It can also be applied to wool, xylonite, celluloid, paper, or to gelatine films upon glass, thus affording a very wide range of employment.

The process, which is a very simple one, merely depends upon the fact that if a material containing diazotised primuline be exposed to light under a design, those parts which are acted upon by light will be decomposed, whilst the parts protected from the light will remain unaltered, and consequently, on subsequent development with a phenol or amine, will produce colours, whilst the decomposed portions will not. The details will, of course, depend somewhat upon the material to be treated. Paper for copying drawings, &c., is coated on the surface with primuline by means of a brush or roller. For the production of gelatine films upon glass the primuline is incorporated with the gelatine before being applied to the glass. In place of ordinary primuline the homologues already mentioned may be used. For silk and wool the primuline may be replaced by dehydrothiolumidine-sulphonic acid, by means of which colourless backgrounds may be obtained. Concerning the reaction which occurs when the diazo-primuline or the diazo-dehydrothiolumidine is decomposed by light, nothing definite could as yet be said, except that the diazo group is completely destroyed; for on treatment with sodium hydrosulphite (true hyposulphite) it cannot be converted into the amido-group (reforming primuline or dehydrothiolumidine). The reaction may consist in a replacement of the N<sub>2</sub> group by OH or by H, or may be even more complex. Although it could not be affirmed that this reaction to light is a property of the diazo-compounds of this group of bodies only, yet it is certain that they possess an extreme susceptibility to light, far greater than that of other diazo-compounds, whilst at the same time they are far more stable to heat. It is thus possible that this property may depend in some way upon the sulphur which they contain.

The President (Prof. T. E. Thorpe) remarked that Mr. Green's discovery was another instance of history repeating itself. The old process of reproducing architects' and engineers' plans on a blue background with white lines was likely to be run very hard by the one they had had unfolded to them by Mr. Green. When Sir John Herschell occupied the post he (Professor Thorpe) now filled, on the occasion of the previous meeting of the British Association in Leeds, the blue background process was in full vogue; now they were likely to have another in its place.

Professor Hummel and Mr. C. H. Bothamley also spoke, and in reply,

Mr. Green stated that as yet he had not succeeded in getting an absolutely white background, but he believed that it would ultimately be obtained.

*Permanency of Colours*

In the same Section, Professor J. J. Hummel, of the Yorkshire College, concluded a paper on "Fast and Fugitive Dye Stuffs" with the following words:—"I do not forget that many people abhor excessively bright colours, and the much-maligned aniline dyes are considered on this account most unworthy of our attention; they jar on the æsthetic taste, they are crude and inartistic. No doubt this is perfectly true, when they are used singly, and are inharmoniously arranged; but, given a good range of brilliant colours, it becomes possible, by their varied combination, to produce the most thoroughly pleasing and attractive shades of greys, and olives, and browns, and the thousand and one delicate tints beloved by the artist, and they yield, when desired, such as possess a richness and life and body of colour, compared with which the older colours are poor and lifeless. Let the artist, inexperienced perchance in the application and proper use of coal-tar colours, confine his attention if he wishes to the more sombre and older dye-stuffs, but do not allow him to persuade you that there is neither beauty nor permanence, or other quality of excellence, in any of the coal-tar colours of to-day. Employ them aright, with discretion, with intelligence, and they will not fail to recommend themselves to your better judgment. Rather than describe their discovery as useless, even from an artistic point of view, I would say, all honour to the founder of the coal-tar colour industry. If, in the beginning, he gave us the fugitive mauve, did he not afterwards labour hard and successfully in the cause of the fast artificial alizarin? All honour, then, I say, to Dr. Perkin, who has been instrumental in giving to the world not only fugitive but fast coal-tar colours."

A short discussion followed, in the course of which

Professor Hartley (Duhlin) observed that as the result of experiments he had made he had come to the conclusion that they might expect water-colour drawings to last 400 years, provided they were protected from the influence of direct sunlight. Indigo was sometimes considered a fugitive colour, but whether it was or not depended very much on the nature of the indigo and on the drawing-paper. Even the best drawing-paper was invariably acid, and a wash of indigo on such paper was bound to be affected by the acid.

*Coal-fields in South-East England.*

In the section of Geology, Prof. A. H. Green, F.R.S., presiding, Mr. W. Topley, F.R.S., read a paper by Mr. W. Whitaker, entitled "Suggestions on Sites for Coal Search in the South-East of England." In the course of some preliminary remarks he explained that as the result of our knowledge acquired in late years it was known that the beds were thick in the south of Kent and in Sussex, and that a great depth would have to be gone to in order to reach the mineral. If they sank near the North Downs, or to the north of that, the beds would probably be found to be thin, and the coal, if present, would be reached at a much less depth. The paper set forth that the general question of the rise of older rocks beneath the Cretaceous beds of South-eastern England was now so familiar to geologists that there was no need to discuss it, but the practical application of their knowledge of the subject was in its infancy. Having regard to the great expense of making the deep trial-borings that would be needed in the search for coal, it was clearly well, as far as possible, to select sites where a good amount of work had been already done. The object of this paper was to point out that there were such sites, and that they were favourably placed for the search. Sites were then noticed, beginning at the south-east, near the only place where coal had yet been proved in the large tract in question, and working thence westward and northward.

Professor McKenny Hughes commented on the actual direction and amount of the dip of the Devonian and Silurian rocks discovered in the borings north of London having been ascertained, and argued that the coal basins would be found on the dip side of these points. Geologists had been formerly accurate, and they now asked the confidence of the public with regard to the existence of south-eastern

coal measures. There was the aesthetic question; but if by the development of these fields the solution of the smoke question was forced to completion, the present work would greatly benefit the country. But wherever there were coal seams they must have the long chimney, since the progress of civilisation could not be stopped. If landowners could be induced to co-operate and to agree upon borings in a reasonable and systematic way, the disfigurement of a large area might be saved, while a new industry could be introduced, and trade in that part of the country resurrected.

Mr. W. A. E. Usher and Mr. De Rance combatted Professor Hughes's views, Mr. De Rance remarking that it by no means followed that the coal measures lay conformably upon the more ancient Paleozoic rocks, which might have been turned on end and eroded before the more level coal measures were deposited on the upturned edges. Therefore the dip of the more ancient rocks would be no clue to the position of the overlying coal measures. The borings at Burford, to the west of Oxford, showed coal measures in the secondary rocks.

#### Ordnance Survey Maps.

In the Geographical Section, on the 9th inst., Mr. Henry T. Crook read a paper on "The Present State of the Ordnance Survey, and the paramount necessity for a thorough revision." He said that it was strange that, when the need for accurate maps was daily increasing, there should be a falling off in the sale of the national maps, for the making of which the nation had paid an enormous sum. This was mainly attributable to the fact that the maps did not meet popular requirements. The Ordnance Survey Department had undertaken more than it had the means to carry out in any reasonable time. The Survey had suffered severely from constant Parliamentary interference; and the result was that after more than a century's existence the Department had not completed one of its works. It had not yet produced on any scale a uniform map of the British Isles. Besides other disadvantages, the important question of price affected the sale of the ordnance maps. An outlay of at least 7s. 6d. was necessary to procure the ordnance sheets of a district in handy portable form. Of the whole of the southern counties of England no satisfactory topographical map existed, and for the remainder of England and Wales the utility of the existing maps was destroyed by antiquity. The system of agency monopoly greatly restricted the circulation of the maps, and prevented the public at large from obtaining them readily. The establishment of a revision department was absolutely necessary, which could only be done by increasing the proportion of the annual grant devoted to revision. This would not be done unless strong representations were made to the Government. Mr. Crook then read to the section the following letter from Sir Charles Wilson, Director-General of the Ordnance Survey:—

"The Ordnance Survey Department cannot be held responsible for the obsolete character of many of the maps, or for the system under which they are now sold to the public. No one can be more sensible than the Director of the Survey of the pressing need of a revision of the maps; but the question is really one of money, which it is for Parliament, and not for the Department, to decide. I think you underestimate the pressure which has from time to time been brought to bear upon the Government to complete the 25-in. survey of Great Britain; and however much we may regret it, we can scarcely be surprised that the survey was pushed forward at the expense of revision. The result is that in many places revision must now be virtually a re-survey. The present system under which Ordnance Survey maps are sold by sole agents for England and Wales, Scotland, and Ireland respectively, was adopted, as you remark, contrary to the advice of the Director of the Survey. Mr. Chaplin, however, under whom the survey was then conducted, is stated, in reply to Mr. Webb, last session, that 'when a favourable opportunity occurred a change in the system would be carefully considered.' I believe that under a proper system the sale of the maps would be enormously increased. I must point out one or two errors in your generally accurate paper. The 6-in. map of the kingdom was completed in March last; that of Ireland has long been completed, and officially recognised as the basis for all dealings in land and for valuations for local assessment. About one-half of the 6-in. map of Ireland has been revised to date on that scale. Until recent legislation with regard to land in Ireland, the 6-in. map was considered large enough for all practical purposes by those who used it, and the necessity for a 25-in. survey has only been felt during the last few years."

Sir Douglas Galton said it would be well if the British Association could be induced to address the Government on the subject, in order that the whole question of the position of the Survey, and of the sale of the maps, might be thoroughly agitated and discussed, especially now that they had transferred the Survey from the Office of Works to the Board of Agriculture,

where no doubt Mr. Chaplin would be most anxious to do everything he could to promote the welfare of those who wanted maps,—the former being one of those who was most urgently in need of them. He therefore strongly urged the section to pass some resolution on the subject. Perhaps the Council might be requested to consider the question during the recess, so that some strong representations to the Government might be made. They were all very much indebted to Mr. Crook for having brought the subject forward.

After some further discussion, on the motion of Sir Douglas Galton, it was resolved that the Council should be requested to consider the matter in the recess, and that strong representations should be made to the Government on the subject.

#### Measurement of Elongation of Test Samples.

In the Mechanical Science Section, Mr. J. W. Wicksteed read a paper on "Measurement of Elongation in Test Samples." He stated that when a bar of metal is stretched with a longitudinal pull, it first extends generally throughout the whole of its free length, after which, especially in best iron, mild steel, and copper, it extends locally about the place of final fracture. The "general" extension continues so long as the bar offers increasing resistance to the pull, and from the end of that stage to final fracture the extension is local. The general extension is unaffected by the shape or proportions of the specimen, and may be correctly expressed in units of its own length. The local extension bears no relation to the length of the specimen, and should therefore be expressed in standard units of length. The usual engineering practice of the present day is to measure the total extension, and to express it in percentage of the original length of specimen; but this practice makes it difficult to draw correct comparisons of ductility between different experiments, unless the specimens have been all made to the same pattern. It also prevents the value of the material being discriminated as between capability for stricture and the capability for stretching without loss of strength. The author described a method for separating the measurement of the general extension from the local, and recommends a column in test reports of "per cent. general extension," leaving the present column of "per cent. contraction of area" to record the capacity for stricture, and the present column of total extension in inches, from which the local extension can be deduced by subtracting the recorded general extension from the total as measured after the sample is broken.

Next week we may notice briefly one or two other papers read before the Association.

#### AWARDS AT THE BRIGHTON HEALTH EXHIBITION.

THE preliminary list of awards at the Brighton Health Exhibition, of the contents of which we gave an account a fortnight ago, was made known on Friday last, but an official copy of the list has not reached us. We select (and correct) the following from the list as published in the *Standard Daily News*:—

#### Medals.

Clemens, Abell, & Co., for street-sweeping machine.  
W. H. Allen & Co., for sanitary publications.  
London, Brighton and South Coast Railway, for exhibit of railway rolling-stock and appliances.  
J. Stott & Co., for mercantile gas governor.  
G. M. Hammer & Co., for school furniture.  
F. C. Calvert & Co., for carbolic acid preparations.  
Washington Lyon, for steam disinfecter.  
Barnantoffs Works, Leeds, for decorative pottery and falence; also for decorative glazed falence fireplaces.  
Moule's Patent Earth Closet Company, for earth closets.  
Joseph Cliff & Sons, for "Ceil" stop-sink; also for Imperial porcelain bath.  
J. Tylor & Sons, for "Ariston" stop-sink water-closet.  
Hayward Bros. & Eckstein, for self-locking coal-plate; also for self-sprinkling retreating pavement and roadway lights.  
John Greenall, Portland-street, Manchester, for steam washer.

#### Certificates.

Merryweather & Son, for improved india-rubber hose.  
Sanitary and Domestic Engineering Company, for gradient indicating block.  
Thomas James Moss Flower, for adjustable clinometer; also for Watts' aspirator for testing drains.  
C. Kite & Co., for wall inlet ventilator.  
Brighton Waterworks, for Baber's water hydrant.  
Clemens, Abell, & Co., for improved chain-pump; also for street watering van.  
Joseph Cliff & Sons, for white enamelled fire-alloy sink; also for Wimer's channel beads; also for Stokes's gully; also for Beachliff disconnecting trap.  
J. Tylor & Sons, for lavatory basins and fittings; also

for weir overflow valve water-closet for lead trap; also for "Column" water-closet.

Bostel Bros., for lavatories.

John Smeaton, Son, & Co., for Imperial spray bath; also for excholor dust-shoot.

Burn & Baillie, for combination bath; also for hinged grating for overflow of bath; also for lavatory with overflow which can be cleaned; also for improved urinal; also for cast-iron drain-pipes, inspection chamber, and trap; also for brass traps for baths and sinks; also for indiarubber expanding plug for drain-testing.

Doulton & Co., for special urinal.

Bostel Bros., for collar-joint for connection of soil-pipe to water-closet.

D. T. Bostel, for union-joint for connection of soil-pipe to water-closet.

Imperial Smoke Consumer Company, for boiler covering bricks.

J. Haines, for china stop-pail.

George Hammer & Co., for church fittings.

H. Helm, for cast and sheet iron ventilating gratings, with Louvre valves; also for round ventilating valves.

Hayward Bros. & Eckstein, for meta-flap outlet ventilator with "hit and miss" front; also for ornamental "hit and miss" air bricks; also for "The Southwark" universal Venetian ventilator.

Smith, Collier, & Co., for Venetian blind fittings.

Beves & Co., for wood machinery.

Henry Cresswell, for decorative tiles and pottery.

J. Haines, for artistic pottery and porcelain.

Eagle Range Foundry Company, for Eagle grate.

C. G. Reed & Son, for stoves, mantelpieces, and brasswork.

Peters, Bartsch, & Co., for chemical heat retainers.

## Illustrations.

### COMPETITION DESIGNS FOR PARLIAMENT HOUSES, ROME.

THE two designs here illustrated were among the premiated designs in this important competition for a grand Parliament House for Rome, which was decided early in the present year, but which, like some large competitions nearer home, proved an abortive affair, the committee appointed to consider the designs declining to recommend any one of them for execution, though bestowing premiums on several. There is a dignified character about the two which we illustrate, by Signor Moretti, and by Signori Broggi & Sommaruga, which renders them worth illustrating as designs, though they are not destined to enter into the stage of execution.

Forty-nine designs were submitted, from among which eight only were selected for serious consideration. Of these, the designs by Signori Broggi & Sommaruga, Moretti, Quaglia, Benvenuti, Ristori, and Basile, received each a premium of 5,000 francs; and those by Signori Giampietri, Manfredi, and Magni, received each an honourable mention and a premium of 3,000 francs.

Signor Moretti's design, of which we give the principal elevation, was generally regarded as architecturally the best. The three domes which mark the three main internal divisions of the building, are obviously to a certain extent inspired by the style and treatment of the Pantheon dome. The design by Signori Broggi & Sommaruga was generally regarded as next in merit. We give the plan of this, which is a fine one in some respects, but the principal external feature is very ponderous in effect. Both designs may be of interest, however, as examples of modern Renaissance design by architects of the land of the Renaissance.

### MONUMENTAL BRASSES.

THE two brasses which form the subject of our illustrations are declared by many good authorities to be the two finest examples which exist in England at this present time. A few brasses in England present quite a different appearance to the majority; they are for the most part of a large size, and rectangular in shape; the background of them is filled in with elaborate cany and diaper work. They are a foreign workmanship. To this class Abbé Thomas Delamer, at St. Alban's, belongs. The majority are let into stone casements or matrices, of a shape corresponding to the figure, and in that of Sir Robert de Bures, Acton, Suffolk. This is one of the few early fourteenth century cross-legged knights. A full description of it is given in Waller's series of Monumental Brasses.

For the benefit of those especially interested in brasses I may mention that there is no at Cambridge an Association of Brass Collectors (shortly called "C.U.A.B.C."); the correspond-

ing secretary is Mr. R. W. M. Lewis, of Corpus Christi College. The subscription is merely nominal, the sum of 5s. conferring life membership on those who wish to join. All the latest "brass news" is published in their papers, which also contain a very useful exchange column; by this means members living in distant parts may exchange their rubbings.

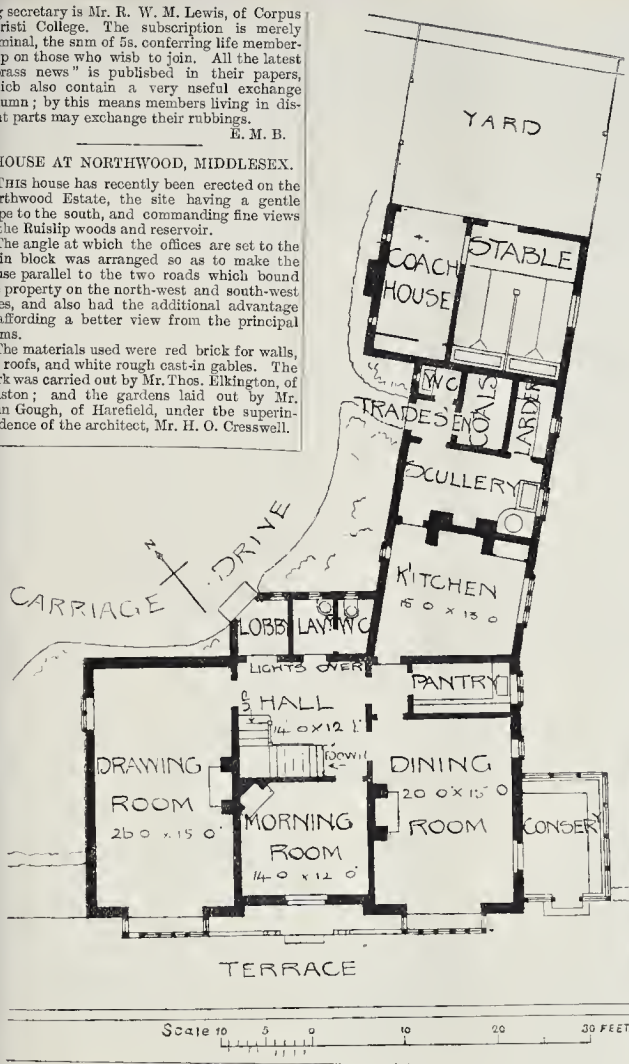

E. M. B.

HOUSE AT NORTHWOOD, MIDDLESEX.

This house has recently been erected on the Northwood Estate, the site having a gentle slope to the south, and commanding fine views of the Ruislip woods and reservoir.

The angle at which the offices are set to the main block was arranged so as to make the house parallel to the two roads which bound the property on the north-west and south-west sides, and also had the additional advantage of affording a better view from the principal rooms.

The materials used were red brick for walls, tile roofs, and white rough cast-in gables. The work was carried out by Mr. Thos. Elkington, of Dalston; and the gardens laid out by Mr. John Gough, of Harefield, under the superintendence of the architect, Mr. H. O. Cresswell.

House at Northwood: Plan.

HOSPITAL CHAPEL, ILFORD.

The ancient chapel, dedicated to St. Mary and St. Thomas of Canterbury, was founded by Adeliza, Abbess of Barking, in the reign of Stephen; and had a prior, chaplain, and thirteen poor brethren, who were lepers. It was endowed with the tithes of Barking parish, and strict statutes for it were drawn up by the Bishop of London in 1346. At the Reformation its revenues were valued at 16*l.* annually. Queen Elizabeth granted these tithes and the site to the Fanshaws upon the condition that it was maintained as an almshouse for six poor men, with a chaplain to perform Divine service in the chapel.

The estate is now vested in the Marquis of Salisbury, who is master of this semi-ecclesiastical establishment, and pays the yearly stipends. The chapel dates from the fifteenth century, and prior to the recent alterations was a long narrow building, 74 ft. in length, by 16 ft. wide; it was the only place of worship for the inhabitants of Great Ilford until the erection, in 1830, of the parish church. Recently the church had fallen into a bad state of repair, the walls being 6 in. out of the perpendicular. A deep classic moulded cornice was erected about 1740; in the restoration this was

found to be 2 ft. above the old wall-plate level, which was nearly all destroyed. The wall-plate now is at the original level. The face of rafters was plastered; this has been all taken off, and the face boarded with ribs nailed on at various intervals. The division of chancel is formed by ribs and cusping. The chapel is now 92 ft. long inside the walls. The south wall has been partly knocked out, and five bays formed, and a small one at the west end, this being the entrance to the baptistry. The windows in the south side were in a bad state of repair, the stone works being made up with cement and tiles. These have all been carefully restored, and three new windows inserted, and one in the westward of new aisle. A new Rose window has been inserted in the west-end of the nave, with a doorway under it. The new aisle is 10 ft. 6 in. wide, and runs the whole length of the building; at the interior end are two vestries, these are connected with a new cloister from the chaplain's-house to the chapel. A chapel is being formed at the east end of the aisle, which is fitted up with a baldachino, the drapery and embroidery of which is being made by Messrs. Morris & Co., of Oxford-street, who are about also to put some stained-glass windows in the chapel. Two new iron screens are being made, one for the chancel and one for

the Lady chapel; the choir stalls are in progress—these are being made in Indian teak. Mr. Watson, of Ilford, was the builder, Mr. J. Martin Brooks being the architect for the restoration.

FROM AUSTRALIA.

COLONIAL ARCHITECT'S DEPARTMENT, NEW SOUTH WALES.

FOR many years the architectural work of the Government of New South Wales has been carried out by an official known as the Colonial Architect, and a large staff under his command. The work of the Department consists of public buildings of all kinds throughout the colony, from the little hush lock-up on the mountains or troopers' quarters in the far west, to imposing stone edifices, such as the Post-office, the Lands Office, or the Colonial Secretary's Offices. Court Houses, Gaols, District Post and Telegraph Offices and Lands Offices, and all other public buildings, with the exception of schools, have been carried out and also kept in repair by the Colonial Architect's Department, and its duties are so extensive as even to include the supply of coffins for the pauper inmates of the various benevolent asylums. To administer such a Department successfully is no mean task, and this has been done by the late Colonial Architect, Mr. James Barnet, F.R.I.B.A., who has just retired after thirty years' service. Most of the best work of the country was thus in the hands of one man, and it has long been a grievance with the profession in Sydney that such should be the case. Advantage has, therefore, been taken of this opportunity to re-organise the Department, and henceforth it is stated that all Government works of over 5,000*l.* in value will be thrown open to public competition under conditions yet to be settled. The carrying out of those under 5,000*l.* in value, and the maintenance of existing buildings, of which there are a large number, will be the duty of the new "Supervising Architect," as he is to be called, and Mr. Walter Liberty Vernon, F.R.I.B.A., has just been appointed to the post. No better choice could possibly have been made by the Government. Mr. Vernon is a gentleman in the prime of life, of robust physique, urbane manners, considerable professional skill, and the strictest integrity. He practised in London and Brighton until the year 1883, when he removed to Sydney in order to obtain a more favourable climate than that of England, and with the happiest results. His work here has comprised several large and important buildings and many smaller ones, and for part of the time he has been in partnership with Mr. W. W. Wardell, F.R.I.B.A., the *doyen* of the profession in Sydney. During the last three years, since Mr. Wardell's resignation, he has acted as one of the hon. secs. for the Royal Institute of British Architects in Australia.

Whether the new scheme of competition for Government work will work out satisfactorily has yet to be proved. Judging by recent information to hand from the old country it has been thought that the system of competition for large Government works has not been found altogether desirable, and that a reversion is likely to be made to the older and safer method of appointing an architect of tried skill and knowledge for each important building. At any rate the forthcoming competitions will afford employment to the many architects and assistants in Sydney who at the present time have practically nothing to do, but the spoils will fall to the few. The usual result will follow, that work of greater value will be done by the competitors in the shape of drawings than the successful architect will receive in the way of commission.

GLASGOW ARCHITECTURAL ASSOCIATION.

The usual monthly meeting of this Association was held on Tuesday, the 2nd inst. After the usual business had been disposed of, Mr. Fairweather read a paper on "The Early Period of Greek Architecture," being the first of a series of three on Greek architecture, the next being "The Middle Period," and the third "The Late Period." The essayist went over the history of early Greece, beginning at 1830 B.C., when Inachus, a Phœnician adventurer, arrived in Greece at the head of a small band of his countrymen. After giving an account of the tomb of Atreus at Mycenæ, Mr. Fairweather passed in review most of the buildings of the period now remaining. Mr. Potts opened the discussion, at the close of which Mr. Fairweather was awarded a very hearty vote of thanks for his interesting paper.

## THE TRADE UNION CONGRESS.\*

On the third day of the Congress, there was a renewal of the lively scenes to which we made reference last week. But without entering into a narration of the causes of these exciting interludes, we append a few notes as to some of the resolutions arrived at by the Congress.

*Factory and Workshop Disciplinary Fines.*

Mr. W. J. Davis moved—"That this Congress is of opinion that factory and workshop disciplinary fines should be made illegal; and that the Parliamentary Committee be and is hereby instructed to urge the Legislature to adopt such amendments to the Truck Acts of 1831 and 1887 as shall make such practices a contravention of the said Acts." This was seconded and almost unanimously adopted, after being amended by adding words to it suggesting that all fines whatsoever should be made illegal.

*Public Contracts and Fair Wages.*

Mr. Shipton moved—"That this Congress instructs the Parliamentary Committee to take such steps as they may deem most effective to secure at the earliest moment, in all Government work and municipalities, the full payment of the current rates of wages recognised by the organised industries of the United Kingdom." He said that the Government system in vogue at present was to let the contract at the lowest possible price. The consequence was that the firm who had the contract was avoided by all good, skilled workmen, and the whole system was one of degradation to labour and subservience of efficient workmanship, resulting in pernicious scamping in Government work.

This having been seconded by Mr. T. Shaw, Mr. C. Matkin said he thought the resolution hardly strong enough. He moved as a prefix to the original motion—"That this Congress considers the system of contracting by schedule, adopted by the Government as a means to the employment of cheap labour, and consequently the lowering of wages below the standard rates of wages of the district, is detrimental to the prime interests of the community; and also is of opinion that a clause should be inserted in all contracts prohibiting sub-letting and piece-work, and that no contract be accepted from any firm that does not pay the recognised rate of wages of the trade affected in the town or district where such work is being done; and further, the Congress pledges itself to oppose all candidates for Parliament, municipalities, or other local bodies, who do not pledge themselves to do all in their power to support the above resolution." He believed the Congress should lay down a policy for the Parliamentary Committee during the next twelve months, if they expected anything to be done.

The amendment was accepted by Mr. Shipton. Mr. Corbett proposed to further amend the resolution by adding after "municipalities" the words "and all contracts for the same."

Mr. Weighill supported the resolution. Mr. John Burns expressed the opinion that Mr. Shipton's resolution went as far as the majority of trade unionists wished to go. It would improve matters slightly, but not to the extent that would justify the Congress in passing it in its present form. He exemplified his contention by saying that the London compositors were themselves protected entirely by the other local bodies, who do not pledge themselves to do all in their power to support the above resolution. He said that the London compositors were themselves protected entirely by the other local bodies, who do not pledge themselves to do all in their power to support the above resolution. He said that the London compositors were themselves protected entirely by the other local bodies, who do not pledge themselves to do all in their power to support the above resolution.

After a great deal more discussion, the resolution was temporarily withdrawn in order that it might be re-modelled so as to include cases which were not within its scope as originally drawn.

Subsequently Mr. Shipton read the resolution as re-drafted. It was as follows:—"That this Congress condemns the system of contract by schedule adopted by the Government and other public bodies, as it conduces to low wages, scamped work, and inferior materials, which are pernicious to the public interest. The Parliamentary Committee is hereby instructed to take such steps as may be most effective to secure the insertion of a

clause in all contracts prohibiting sub-letting; that no contract shall be given to any firm which does not pay all its workpeople at the recognised trade union rates of wages in the respective localities where any such work may be done, either by those directly employed by Government or municipalities or contractors having contracts from these bodies; also demands that where the factory clause is inserted and violated the penalty should be rigidly enforced."

A prolonged discussion followed, in the course of which several members protested against the re-modelling of the resolution, which, however, was ultimately carried almost unanimously.

*Factory Inspectors.*

Mr. Holme, in the absence of Mr. Birtwistle, moved—"That this Congress, whilst gratefully recognising the reform which has recently been effected by the appointment as factory inspectors of men having a practical acquaintance with the conditions of factory life, regrets that as yet no steps have been taken by her Majesty's Government to give effect to the repeated and pressing demands of previous Congresses for a considerable addition to the staff of factory inspectors." He contended that an increase of factory inspectors was urgently wanted. The factory laws were daily broken with impunity.

Mr. Lyons said he would second the motion if Mr. Holme would accept the word "technical"—he meant inspectors having a technical acquaintance with the conditions of factory life. The reason why the factory inspectors could not do their work properly was because they did not understand the trickery of the sweaters and the manufacturers. Something should be done to alter this state of things.

Mr. Holme declined to accept Mr. Lyons's suggestion. The motion was seconded by a delegate, after which Mr. Lyons moved, and Mr. Bradford seconded, the suggestion as an amendment. The latter speaker said the greatest hindrance to the work of the inspectors was their lack of technical knowledge of factories and of trades. He thought it might be suggested to the Government that they might do without the knowledge of Latin and Greek in regard to the appointment of factory inspectors, and impose upon them as a condition that they should have a thorough knowledge of the trades and industries which they were going to inspect.

Miss Whyte at some length urged the necessity for female inspectors being tried in regard to factories where women are employed.

Mr. Davies supported the resolution. For six and a-half years he was himself an inspector of factories, and he came to the conclusion that the districts were altogether too large. For instance, he and another inspector had to work a district 100 miles long by forty broad, and containing from 10,000 to 14,000 factories and workshops, and which it was impossible for two inspectors to attend to efficiently. He had come to the conclusion that the Factory Acts were a fraud upon the best-regulated factories.

After some further discussion, the motion, with the suggested amendment, was agreed to.

*The Qualification of Enginemen.*

Mr. J. Swift moved the following resolution:—"That this Congress regrets that no favourable opportunity presented itself during the past Session of Parliament to debate the Bill having for its object the future examination of persons in charge of steam engines or boilers, and the granting of certificates as to their practical fitness for such a duty. That the Parliamentary Committee be instructed to arrange for the re-introduction of this Bill next Session; and should any other Bill be introduced relating to steam engines or boilers, that an effort be made to have included the principle of examination and granting of certificates as to the practical fitness of all persons placed in charge of steam-engines or boilers." He said that for twelve or thirteen years a resolution had been adopted by the Congress in favour of the Bill making it compulsory that enginemen and boiler attendants should possess certificates of competency. Some time ago a Bill approving this principle was introduced in the House of Commons by Mr. Fenwick, and was rejected, but Mr. Fenwick was informed that if the Bill had not been of such an extreme nature, it would have received a greater support. A new Bill had since been prepared, and they believed it would

be acceptable to those who had opposed the former measure. He mentioned that in 1879 there were seventy-two boiler explosions, by which twenty-eight persons were killed. One striking feature of the returns was that not one single explosion took place on board steamers on which there were certified engineers. The insurance companies' returns showed that out of twenty-four cases of explosions, seven were attributable to pure negligence on the part of the attendants.

Mr. Whitburn seconded the motion. He considered that they should call on labour representatives in Parliament to demand that questions like this, involving the safety of human life, should be considered as questions of urgency. They did not want this Bill to create a monopoly, but simply to protect themselves as skilled workmen.

The motion was unanimously agreed to.

*The Employer and Workman Act.*

Mr. P. H. Holmes moved—"That it be an instruction to the Parliamentary Committee to endeavour to effect such a change in the Employer and Workman Act, 1875, as to cause section 11 to apply to male adults in the same manner as it does to female young persons and children." He urged that they should be put on a level with women and children, and that if they were unavoidably kept from their work, the wages which they had earned should not be retained. They claimed the same justice for themselves as their employers did. They had a perfect right to demand that the law of their country should give them perfect equality with those who employed them. They did not consider that their employers had any right to deduct money out of their wages.

Mr. Roy seconded.

Mr. Keir Hardie moved as an amendment that section 11 should be so extended as to include payments for materials necessary to the carrying on of the work and for the necessary conveniences for the workers. The reason for this proposal was that there were certain charges made, especially against women and young workers, which ought to be rendered illegal, and which the extension of the clause would make illegal. It was recently the law in a factory that each worker should pay a penny a week for the peg on which they hung their clothes whilst they were at work. To-day it was the rule in certain factories that girls were charged a penny a week for the rooms they occupied whilst at work. Others, again, were charged 25 to 50 per cent. above the cost price for the materials they used, and they were compelled to purchase their materials from their employers. Others, again, paid threepence a week for keeping their workroom clean, and they themselves had to perform the work, the money being to provide brushes and soap. In another case reported to him, on indisputable authority, a penny a week was charged for the lavatory accommodation of the workers.

Mr. Holmes accepted the amendment, and the resolution as amended was agreed to.

*Labour Disputes and Conciliation.*

Mr. Charles Hobson moved—"That this Congress is of opinion that the formation of joint boards, composed equally of employers and workmen, is highly desirable, as being well calculated to result in a better understanding between them, and the settlement of vexatious questions affecting the interests of both; and hereby urges the trades councils and other organised bodies of workmen to bring the subject before the chambers of commerce and other bodies of employers, with a view to the formation of such boards."

Mr. Stuart Uttley seconded. He said that whatever might be said to the contrary, the great bodies of working men were those who should take up this matter of conciliation.

Mr. Davies strongly held the opinion that to adopt conciliation boards was to turn the clock of trade unionism backwards. He moved, as an amendment, "That, whilst believing in the utility of conciliation boards in settling labour disputes, and many of the labour problems of the day, we are of opinion that the best parties to compose such boards are those directly interested in such matters, either a workman or employers, as the interference of outsiders would be met with resentment." The disputes should not be left to persons and others, who know nothing about labour. Working men formed themselves into a strong union which could force up the price of labour simply by the force of trade unions.

Mr. Aston said that by binding themselves to

\* See p. 186, ante.

gether they would obtain their demands. Outside interference, he believed, caused resentment.

Mr. Wardley thought a third party should be called in before ill-feeling was engendered, and before there were great losses. He was strongly in favour of the resolution.

Mr. Bloor supported the resolution. It was next moved and seconded that the question be now put. For the motion 123 hands were held up, and 59 against. The motion was declared carried.

The amendment was, on a vote, rejected by 126 to 70.

Mr. Paterson moved the omission of the last sentence of the resolution. He explained that in Durham the representatives of the employers and workmen had settled their disputes without the interference of the Chamber of Commerce, or other outside bodies.

Mr. Boyle seconded. The mover of the resolution, Mr. Hobson, accepted the amendment, as it did not alter the principle. The resolution, as amended, was carried.

*Proposed Labour Exchanges.*

Mr. Quelch (on the fourth day, September 4) moved the following resolution:—"That, in the opinion of this Congress, in order to carry out more efficiently the organisation of the large mass of unorganised labour, to bring into closer combination those sections of labour already organised, to provide means for communication and the interchange of information between all sections of industry, and the proper tabulation of statistics as to employment, &c., of advantage to the workman, it is necessary that a Labour Exchange, on the model of the Paris Bourse du Travail, should be provided and maintained by public funds in every industrial centre in the kingdom." There was, not, he thought, a single delegate present who would deny the necessity for such an institution in every industrial centre, and the only points of difference likely to arise were as to the methods of acquiring and maintaining them. He contended that they should be the property of the municipality, established by public funds, and controlled by organised workmen for the benefit of organised workmen. There might have been a time when some objection could have been raised to this, not now, when they were using every effort to get the control of municipal and administrative bodies it seemed only right it should be one of the functions of these bodies to supply places of meeting where the general work of labour organisation might be carried out. He had a sketch of the Paris Bourse du Travail, and from that might be seen the great value of the Bourse to workmen. He hoped that some steps could be taken to secure the better organisation and complete emancipation of labour.

Mr. J. Walker seconded the motion, but it was once shelved by the expedient of moving and carrying "the previous question."

*The Eight Hours Question.*

Mr. G. J. Marks moved "That, in the opinion of this Congress, the time has arrived when steps should be taken to reduce the working hours in all trades to eight per day, or a maximum of forty-eight hours per week; and, while recognising the power and influence of the trade organisations, it is of opinion that the readiest and best method to obtain this reduction for the workers generally is by Parliamentary enactment. This Congress, therefore, instructs the Parliamentary Committee to take immediate steps for the furtherance of this object."

This having been seconded, Mr. Paterson moved, as an amendment:—"That, in the opinion of this Congress, it is of the utmost importance that an eight hours' day should be secured at once by such trades as may desire it, or for whom it may be made to apply without injuring the workmen employed in such trades; further, it considers that to delegate this important question to the Imperial Parliament, which is necessarily, from its position, antagonistic to the rights of labour, will only indefinitely delay this much-needed reform."

After a long and exciting discussion, the Congress voted on the amendment, when there were: For the amendment, 173, and against it, 81; majority against, 8. The original resolution was subsequently put to the vote, when the figures were: For the resolution, 193, against it, 155; majority for, 38.

*Workshop Accommodation.*

Among the motions discussed on the fifth day (Friday, September 5) was the following, moved by Mr. Lewis Lyons:—"That it be an instruction to the next Parliamentary Committee to bring the following before the Government of the day:—Any person who desires to open a factory or workshop must give notice to the Chief Inspector of Factories, at the same time to furnish particulars of that branch of industry which is intended to be carried on, a plan of the construction and interior arrangements of the establishment, and of the number of workpeople to be employed." He stated that for men and women engaged, not only in his trade, but in many others, the cubic space allotted was not sufficient. Instead of having from 400 to 600 cubic feet of breathing-space, they had only 120 feet or 180 at the highest.

Mr. Hollings seconded. Mr. Parnell moved the addition of the following words, "And that on receipt of notice from the person desirous of opening a factory or workshop, the chief inspector of factories shall, within six days from the receipt of such notice, cause the sanitary and technical inspector to visit such place, and see whether it was sufficiently lighted and had proper sanitary arrangements for workers of both sexes, and was properly ventilated in proportion to the number of persons to be employed therein; and in all cases there shall be not less than 600 cubic feet of space provided for each person employed."

Mr. Lyons said he would accept that addition.

Mr. King thought it was ridiculous to expect that a man could say before he started business how many workers he was going to employ. If he gave notice to the inspector the latter would see that the cubic space allotted was sufficient. He would, therefore, move that the words of the resolution after the words "carried on" should be omitted.

Mr. Davies seconded the amendment. It would, he said, be quite impossible for a man to intimate the number of people he intended to employ before opening a workshop.

Mr. Lyons accepted the amendment, and the resolution as amended was agreed to unanimously.

*Election of Secretary to the Parliamentary Committee.*

For this appointment, vacated by the retirement of Mr. Broadhurst, M.P., there were three candidates, viz., Mr. Fenwick, M.P., Mr. G. Shipton (Secretary of the London Trades' Council), and Mr. Threlfall. In the first balloting the voting was:—Fenwick, 171; Shipton, 147; and Threlfall, 76. As no one candidate had a majority over the other two, a second ballot was taken between the two highest, which resulted as follows:—Fenwick, 197; Shipton, 181; majority for Fenwick, 16.

This practically concluded the business of the Congress, although a number of resolutions were discussed at Saturday's meeting. On Saturday there was a great procession of trade unionists through the streets, those belonging to the building trades forming, according to the *Liverpool Post* (which has given very full reports of the Congress throughout), a very imposing part of the procession.

**COMPETITION.**

THE TATE WELSH INTERMEDIATE SCHOOL COMPETITION.—The award in this competition was made known last week, and in the assessor's (Mr. Ewan Christian) report the names of the successful competitors were placed in the following order:—Messrs. Phillips & Folgate, Cardiff and Newport; Messrs. Baker & Hughes, London; Mr. T. E. Prayce, London; and Mr. R. Crisborn, Bangor. It is intended to publish the assessor's report.

THE PLYMOUTH MASONS' STRIKE.—The strike of masons at Plymouth, which has lasted seven weeks and stopped some important building operations, ended on Saturday, the 6th, in a compromise. The men, who made no demand with regard to wages or hours, required the total abolition of piecework, and that, with slight exceptions, no dressed stone should be brought into the town. The masters refusing these demands, nearly three hundred men struck, and the contest was continued on both sides with great obstinacy. However, on Saturday night, representatives of masters and men met, with the result that the dispute terminated, the masters undertaking to abolish piecework and the men forgoing the other demand.

**THE SHEFFIELD WATERWORKS.\***

The town of Sheffield is supplied with water by gravitation from the elevated moorlands lying to the west and north-west, the gathering-grounds forming part of the western slope of the backbone of England. The rainfall has been continuously gauged for the last fifty-four years, and averages rather more than 40 in. in depth per annum. Of this it has been ascertained from actual experience that during a period of three consecutive dry years nearly 20 in. can be collected, stored, and distributed.

The system of reservoirs may be divided into the high-level and the low-level, the distinction having reference, not to absolute height above the sea, but to the means available for conveying the water from the storage reservoirs into the various service reservoirs near the town.

*High-level Reservoirs.*—The high-level reservoirs are situated at Redmires, about six miles in a direct line from the centre of the town, these reservoirs being among the earliest of the large works constructed by the late Waterworks Co. They consist of three reservoirs—the Upper, Middle, and Lower Redmires—with the Oaken Clough Dam and Catch-water. They receive the flow from 2,108 acres of drainage area, and have a total storage capacity of 670 million gallons, the gathering-ground comprising the upper part of the valley of the River Rivelin. The water from the high-level reservoirs is conveyed down a water-course, open for the greater part of its length, but covered in at the lower end, into the Hadfield or Crookes service reservoir, having a capacity of more than 21 million gallons, whence the supply is taken for the higher parts of the town.

*Low-level Reservoirs.*—The low-level system comprises two reservoirs upon the River Rivelin, originally constructed for mill compensation purposes, in consideration of water taken from the high-level system. Under the Sheffield Waterworks Act of 1853 these Rivelin reservoirs reverted to the Waterworks Co., compensation to the stream being provided for by the flow, over a notch-gauge or weir, of 7 cubic feet per second during twenty-four hours of every working day. The other portion of the low-level supply is composed of four reservoirs in the adjoining valley of the River Loxley, these being the Strines, Dale Dike, Agden, and Damflask reservoirs. There is also upon the River Rivelin, immediately above the mill-compensation gauge, a small reservoir called the depositing pond, constructed for the purpose of regulating the flow of water for the mill gauge. The total capacity of the low-level system of storage reservoirs is more than 3,000 million gallons, details of which are shown in the accompanying table, which also shows the area of water-shed draining down to each system of reservoirs. The water collected in the Strines, Dale-Dike, and Agden reservoirs is conveyed through a tunnel, passing under the high ridge which divides the Loxley from the Rivelin water-shed; and uniting at the depositing pond with the water from the Rivelin reservoirs, passes through a conduit and tunnel to the service reservoirs at Crookesmoor lying immediately west of the town.

*Existing Reservoir Capacities and Areas of Gathering Grounds.*

Reservoir.	Capacity.	Gathering Ground.
	Gallons.	Acres.
<b>HIGH-LEVEL.</b>		
Redmires Upper.....	343,000,000	—
Redmires Middle.....	287,500,000	—
Redmires Lower.....	139,500,000	—
Total of High-level.....	670,000,000	2,108
<b>LOW-LEVEL.</b>		
River Rivelin {		
Rivelin Upper.....	48,500,000	2,870
Rivelin Lower.....	175,000,000	
Depositng Pond.....	8,000,000	
River Loxley {		
Agden.....	629,000,000	2,999
Strines.....	513,000,000	2,580
Dale Dike.....	480,000,000	1,489
Damflask.....	1,155,000,000	3,747
Total of Low-level.....	3,017,500,000	13,895
Total of High-level and Low-level.....	3,687,500,000	15,703

In the valley of the River Ewden, lying immediately north of the Loxley valley, the Corporation of Sheffield have power to construct two

\* A paper by Mr. Edward M. Eaton, Engineer, read at the Sheffield meeting of the Institution of Mechanical Engineers, on Wednesday, July 30.

other reservoirs, namely, the Broomhead and Moorhall reservoirs, for receiving the flow from a drainage area of 6,496 acres; but these works have not yet been commenced.

**Summary of Supply.**—The total drainage area of the works is 15,703 acres. The total available water during three consecutive dry years is 19,460,000 gallons per day of which an average of 9,113,472 gallons per day has to be sent down the streams as compensation water, leaving 10,346,528 gallons per day for the supply of the town and district. It will thus be seen that nearly one-half of the available supply of water has to be sent down the rivers for the benefit of the mill-owners and other riparian proprietors.

**Redmires Middle Reservoir.**—In order of date the first storage reservoir constructed was the middle reservoir at Redmires. This reservoir has an embankment 1,012 yards in length, the greatest depth of water being 36 ft.; and it is provided with two overflow weirs or by-washes, respectively 70 ft. and 104 ft. in length. Water is drawn off by means of valves placed in a masonry shaft and discharging into the lower reservoir, the valve-shaft being connected with the bank by a wooden bridge constructed in 1824. This bridge is now much decayed, and is on the point of being replaced by a bridge made of iron.

**Redmires Lower Reservoir.**—The next reservoir in point of age is Redmires Lower, constructed in 1847. The depth of water is 29 ft., and the length of the bank is 590 yards. Here both the water for supply and the flood-water are conveyed through a valve and overflow-shaft into a culvert passing through the bank, means being provided on the outer slope of the bank for passing surplus or flood-water into the Wyming brook and River Rivelin; while the water required for the town is taken into a gauge basin, measured through a notch, and sent down the watercourse into the high-level service reservoir.

**Redmires Upper Reservoir.**—The Redmires Upper reservoir, constructed in 1853-4, receives the water from its own gathering-ground, and also, by means of a catch-water drain, the additional yield of the Oakon Clough drainage area. This reservoir has a bank, 750 yards in length, the water being drawn off by means of two lines of pipes, 14 in. in diameter, laid through the bank, terminating at their inner end in a vertical cast-iron valve-tower or shaft.

These three Redmires reservoirs may be taken as types of the old practice of reservoir construction in this country. The predominant features are banks of earthwork with a puddle wall in the centre, the depth of water rarely exceeding 40 ft.; and the absence or insignificance of masonry or brickwork.

**Rivelin Reservoirs.**—The same general features distinguish the next two reservoirs to be described, namely the Upper and Lower Rivelin reservoirs. These two reservoirs were constructed under the Sheffield Act of 1845, to be vested in the mill-owners, who had full control over them, and power to draw off water from them as they thought fit. They were of a capacity agreed upon between the Waterworks Co. and the mill-owners; and having a gathering-ground far in excess of their storage capacity, a by-pass channel or river diversion was constructed, by means of which excessive floods were prevented from entering the reservoirs, or when these were full the whole flood from the drainage area was diverted past them. Each reservoir is provided with an overflow weir or by-wash, and water is drawn from them by means of a pipe 24 in. in diameter.

These five reservoirs, namely the three at Redmires and the two on the Rivelin, were designed and constructed by the late Mr. John Towlerton Leather, who from 1830 to 1865 was the engineering adviser of the late Water Works Co. Since the latter date the engineers responsible for the large and important reservoirs upon the Loxley have been Messrs. T. & C. Hawksley.

**Depositing Pond.**—In the Rivelin valley the depositing pond, also constructed by Messrs. Hawksley, is principally remarkable for its fine overflow weir and by-wash, capable of conveying away the heavy floods which are occasionally discharged from the area of nearly 5,000 acres draining down to this point.

**Agden Reservoir.**—In the Loxley water-shed, the first reservoir constructed was that upon the Agden Dike, having a storage capacity of 629 million gallons, the embankment being nearly 100 ft. high and containing 900,000 cubic yards of material. The water is drawn off

from the reservoir by means of a valve-shaft and a culvert laid through the bank, controlled by two valves which are worked by gearing upon the top of the shaft. From the outlet culvert the water discharges into a gauge basin, where provision is made by means of a slot gauge or orifice for passing a measured quantity of compensation water down the stream. The measuring opening or slot is made capable of accurate adjustment by sliding jaws of steel, which when adjusted are locked by two padlocks; the key of one is in the hands of the clerk to the mill-owners, while that of the other is kept at the Waterworks office; it therefore requires the consent and presence of both parties to make any alteration in the measuring apparatus. The same description of slot gauge is in operation at each of the four reservoirs upon the Loxley.

**Strines Reservoir.**—The Strines reservoir at the head of Bradfield Dale has a bank 418 yards in length, the water being drawn off by means of a shaft and a culvert through the bank. This embankment, in common with those of the other Loxley reservoir, has an inside slope of 3 to 1; the outer slope is  $2\frac{1}{2}$  to 1, and is strengthened by level benchings.

**Dale Dike Reservoir.**—Immediately below the Strines reservoir is the Dale Dike reservoir, upon the site of, but considerably smaller than, the ill-fated reservoir which was destroyed by the disastrous inundation on March 11, 1864. The embankment which was then destroyed crossed the valley obliquely, about a quarter of a mile below the present bank; and before the reservoir was completely filled with water a landslip led to a settlement in the outer slope of the embankment, causing the puddle wall to subside and the water to flow over the top of the bank. In a few minutes the reservoir was destroyed, and the valley down to Sheffield was inundated, causing the death of 214 persons, and the destruction of an enormous amount of property. The Water Company paid no less a sum than 373,000*l.* in respect of injury and loss sustained, the disaster being happily unique so far as regards this country.

The embankment for the new reservoir was made higher up the valley, in order to avoid the treacherous ground upon which the old bank stood; but it may be interesting to state that the pipes which ran under the old bank, and which were alleged to have caused the disaster, are still in the ground, and are as tight and strong as the day they were laid. The water is drawn out of the present reservoir by means of a tunnel driven through the solid rock round the end of the embankment; two valves are provided, one behind the other, and the gearing for working them is placed in a small house near the overflow weir; the outlet from the tunnel is in a line with the foot of the by-wash. This reservoir was completed and filled with water in 1875, but was not found necessary to be brought into use until the exceptionally dry year 1887.

Rather more than a mile below this reservoir, and at the junction of the Dale Dike with the Agden Dike at Low Bradfield, is the mill-compensation gauge, over which is passed for the use of the mill-owners a quantity of water equal to 10 cubic feet per second during twenty-four hours of every working day. In a small house alongside this gauge there is a recording-machine, designed by the writer for the purpose of continuously measuring the water flowing over the gauge-bar.

**Damflask Reservoir.**—Immediately below this mill gauge is the tail end of the largest, and in some respects most important, reservoir belonging to this undertaking, the Damflask reservoir, which is the lowest upon the river Loxley, and has a storage capacity of 1,158 million gallons, with a depth of water of 85 ft. The water is drawn off by means of two culverts through the bank, each provided with a valve-shaft on the inner end. Having regard to the great size of the reservoir, the embankment is not long; but the works in connexion with it are enormously heavy and costly. When the reservoir is filled with water up to a certain height it has been ascertained that a band of rock upon the south side allows the water to pass through the joints and fissures, to reappear as a spring at the bottom of the embankment. It was foreseen that this might prove to be the case, but, as it was uncertain what the quantity of water passing might be, it was considered better to defer remedial measures until the reservoir was filled and proved. To stop this percolation, a filling trench is being cut through the pervious rock into the underlying shale, which will be

filled with puddle, so as to stop the water from passing away. At the foot of the embankment is placed the mill-compensation gauge, which has three slots or openings similar to the already described, while in a little house adjoining is another recording gauge, similar to that at Low Bradfield.

**Distribution.**—After leaving the storage reservoirs and being received into service reservoirs at Crookesmoor, the water is distributed throughout the town and district of supply means of main pipes from 24 in. to 5 in. diameter, laid in zones. The service-pipes are mainly 4 in. in diameter, 3-in. pipes being laid in short streets and courts. The total length of the distributing-pipes is nearly 300 miles. The total daily quantity of water distributed is about 6 $\frac{1}{2}$  million gallons, of which exactly one-third is for trade and manufacturing purposes and for supplies in bulk to local authorities and distributing water themselves.

When water was first supplied to Sheffield under constant pressure in 1863, the daily consumption was 40 gallons per head of the population supplied, of which only about 23 gallons per head was for trade purposes. Now, and many years past, the quantity consumed without restriction or limitation, for all purposes other than meter supplies, has averaged not more than about 13 gallons per head per day. This happy result is due to the rigorous restriction, so far as practicable, of fittings and apparatus of an inferior character, combined with unceasing vigilance in suppressing unnecessary waste of water.

**Self-Recording Gauges.**—At each of the service reservoirs a self-recording gauge, similar in construction to those at Low Bradfield and Damflask reservoir, is fixed for the purpose of measuring the water supplied to the town. These recorders have been in use since 1878, and the result of their working has been to disclose several facts relating to the supply of water, of a character very interesting to those engaged in the practical management of water works. So far as Sheffield is concerned, the least draught upon the reservoirs is between three and four o'clock in the morning, maximum draught being between eleven and twelve noon; while the fact of the stopping of work for dinner between twelve and one o'clock is strikingly manifested. Our experience indicates that in proportioning pipes for town supply, although the average daily flow through the pipes may be taken at 100, provision must be made for passing 50 per cent in excess of this quantity.

In connexion with the system of pipes for water-supply, it may be interesting to compare the two specimens of pipe exhibited, each being 5 in. inside diameter. One of these is modern cast-iron pipe, as now laid in the streets of Sheffield; the other is a wooden pipe formerly used, which was taken out of the ground during May last, after having probably lain there nearly if not quite a century. The wooden pipes were made upon the Waterworks premises, and the last of them was about sixty to seventy years ago.

**Quality of Water.**—The water supplied to Sheffield may be taken as a fair type of excessively soft upland waters supplied to most of the large towns in the North of England. The hardness varies at different periods of the year, rarely falling below two degrees of Clarke's scale, and seldom exceeding ten degrees. The extreme energy displayed by these soft waters in attacking metals exposed to their action is well shown by the specimens now exhibited of wrought-iron screw-nuts, bolts, and washers. These have been wholly immersed in the water to a considerable depth for a period of more than forty years, and the manner in which the pure metal has been eaten away is most remarkable. It has been found also that steel blades, such as razors, pocket- and table-knives, and also suffer complete deterioration to a considerable depth from the surface of the metal when immersed in the water for several years. It has been proved by the recovery from time to time from the reservoirs of bundles of steel articles, which had doubtless been placed there in connexion with trade outrages in the past. The steel was found to have been converted into plumbago, whole bundles of blades being capable of being scraped with a penknife. This fact should be taken into consideration in the use of cast steel, when it is continuously immersed in water of character.

The Corporation of Sheffield supply water

more than 320,000 persons. The revenue from rates is 90,000, per annum. The capital of the undertaking, as shown by the accounts to March 25, 1890, has been upwards of 2,115,000.

Correspondence.

To the Editor of THE BUILDER.

"SALARIES OF CLERKS OF WORKS."

SIR,—I notice in your issue of the 30th ult. a letter from Mr. Dalton concerning clerks of works, affected by the ludicrously low salary offered in the case of the Amersham job.

With much of Mr. Dalton's letter I perfectly agree, but I must protest against the assumption that men are to be found who, while capable of performing the duties of a clerk of works, are yet so utterly devoid in honesty of purpose as to be guilty of accepting an appointment at a miserably low salary rather than be out of a job, and then to constitute themselves at the earliest opportunity by turning the interests of their employers. Such a transaction is tantamount to an encroachment of all vile trash that has lately been so lavishly bandied out concerning clerks of works in general. I maintain that if a man is capable of dishonesty he is not likely to prevent him from indulging in wicked propensities even when in receipt of a liberal remuneration.

Now, Sir, a clerk of works worthy the name is not man to take up a job under such beggarly circumstances. The person who is the most likely to do for it,—aye, and to be accepted,—is the young pretender with plenty of assurance, and sufficient means of building construction materials as to enable him to answer satisfactorily a few theoretical questions if put to him for purpose of testing his competency. It is from an appointment of such as these that disaster and credit are certain to follow, with the equal certainty of the odium and disgrace attached to it, cast upon the shoulders of the *bona-fide* Clerks of Works who have acquired their proficiency out of a lifetime of practical experience, through all the grades from a journeyman upwards.

J. WOODLEY.

SQUARE TURNING.

SIR,—Will any of your readers give me the name of a firm who turns square wooden pillars? I shall be obliged by your insertion of this query.

E. F. BEHRNS.

The Student's Column.

HOT-WATER SUPPLY.—XI.

PIPES AND COCKS: continued.

It must have been noticed by nearly everyone that when a plug-cock is closed at all sharply, where a tolerable pressure of water exists, that a somewhat loud noise is heard in the pipe, and the pipe sometimes shaken. It is when this noise is heard that the strain is exerted which injures metal pipes.

It has to be remembered that water is not only an incompressible substance, and in this respect resembles a solid body, so that when we suddenly stop a stream of water flowing under a high pressure within a confined area considerable resistance must be expected, and it exerts itself chiefly in the vicinity of the cock where the greatest pressure is felt. Shutting off 50 ft. below the cold-water cistern causes a pressure of about 21 lbs. to be brought to bear every square inch of pipe surface near the cock in question; if the tap is closed slowly the pressure is reduced to a minimum, but if closed abruptly the strain assumes the character of a shock.

The thin lead pipe referred to overcomes this trouble to some extent, as thin is weaker and of a more rigid nature than lead, and, of course, not so much so as iron. It is the different strains brought to bear in this respect that have not only the effect of bulging and weakening lead pipe, but also an even worse effect in causing the pipe to be stretched lengthwise, which ill effect is of greater consequence than the bulging. An instance of this recently came under notice (in London) in which lead pipe of a very fair weight had been used, but which proved to be a very marked one, owing partly to insufficient hooking up, and partly to a considerable length being hooked up to a high, straight casing in which it was difficult to give it good support. The fact was that the horizontal pipe sagged down between the hooks, and the vertical pipe time lengthened several inches by its own

weight and the pressure of water within it, so that in a few months it was exactly as fig. 20. In this instance the contractors were com-

FIG 20

pelled to renew the whole apparatus in iron at their own expense.

When the flow and return services are lead pipe it is generally necessary to have the end nearest the boiler of iron, the former material being fusible at a moderately high temperature, and fusing is likely to occur if the pipes are furled or if the boiler is emptied (by a workman) immediately after the fire is extinguished and before the surrounding metal and brick-work have lost any of their heat.

An important point which, up to the present, has only been just touched upon, is the size of pipes most suitable for different services and purposes. This, like many other matters connected with the hot-water supply, is greatly regulated by the fur difficulty, which makes it necessary to use much larger pipes than are needed in soft-water districts. There is a definite limit as to the size of pipes; and although comparatively large pipes are always recommended for the two reasons about to be explained, yet to increase the pipes beyond a certain point is most disadvantageous.

A large pipe is considered to be conducive to a freer circulation,—that is, the water can travel from boiler to tank at a greater speed on account of the lessened friction, and it is certainly beneficial for the water to leave the boiler as fast as possible when it has absorbed heat; but this advantage alone would not be generally considered of sufficient importance to warrant the great cost of larger pipes and the increased labour in fixing them. The reason which sanctions the greater outlay will be found, in nearly every case, to be the wish to lengthen the time in which pipes become furled up and require renewal.

One-inch pipe is very largely used for the main flow and return services, and it is a size that will give excellent results so long as the passage within it remains an inch, and even when the incrustated deposit has reduced the bore to 3/4 in. there is very little to complain of (unless the apparatus is on an extensive scale); 1 in. may, therefore, be considered a suitable size in soft-water districts for general domestic work; but if the apparatus is of a large size, in a hotel or institution, 1 1/4 in., and in some instances 1 1/2 in. should be recommended.

In hard water districts, 1 1/4 in. is best for ordinary residence work, but if, in a tank system, the flow and return pipes are of considerable length, an economy may be permitted by reducing the size to 1 in., say 30 ft. from the boiler, as the incrustation will be found in almost every instance to be much less at the tank end of a long pipe than near the boiler. In a cylinder apparatus, unless very small, the short flow and return from cylinder to boiler should always be 1 1/4 in.; all other pipes in this system may be smaller.

In the tank system the expansion-pipe and cold supply for moderate sized work may both be 3/4 in., but for a good sized residence, where a fair demand for hot water exists, the supply-pipe should be 1 in., and the expansion should be increased to 1 in. also. The sizes of the draw-offs services should be, 1 in. pipe for baths, 3/4 in. for scullery, pantry, housemaids' sinks and general purposes, 3/8 in. for lavatory basins and any small purpose; these sizes, for draw-off services, are usually adopted in both small and large works on any system.

In the cylinder apparatus the primary flow and return should be 1 1/4 in., as mentioned; the rising main or secondary flow may be 3/4 in. in small property, but never less than 1 in. in work of a fair size; if this pipe is returned (forming a secondary return) this may be 3/8 in. or 3/4 in., according to the magnitude of the installation, and the cold supply should be either 3/8 in. or 1 in. (with a full way stop-cock), also according to the importance of the work in hand. The great objection to a small cold supply service is

that it reduces, i.e., checks the flow of water from the taps of the apparatus.

When a pipe becomes furled, the bore becomes reduced in size, and would, if permitted, eventually become quite stopped, ending in an explosion at the boiler; but an explosion from this cause has most probably never occurred, as, before any real danger exists, such violent noises and vibrations are noticed that an experienced man is called in, owing to the apprehension of danger that arises. It is generally when the bore has been reduced to about 3/8 in. (depending, however, upon the power of the boiler) that the noises are first heard, and which are caused wholly by the steam being unable to escape freely; usually the flow-pipe gets the greatest share of the fur, in which case the violence arises by some proportion of the steam forcing itself into the return pipe.

A 1 1/4 in. pipe will last nearly double the time a 1 in. pipe will before giving trouble, as, in the first place, a 1 1/4 in. deposit is longer in accumulating on a 1 1/4 in. than on a 1 in. surface, and when the former has a 1 in. deposit it is still fit for a great deal of service; whereas the latter is upon the point of giving trouble. It should be mentioned that it is commonly the case for the supply of hot water to become lessened and somewhat uncertain when pipes are badly furled, commencing before the noises are heard.

It is quite possible to have the pipes cleaned of fur when the occasion arises, but this necessitates their removal, and a somewhat lengthy job afterwards in heating and hammering them, and it will be found as cheap and decidedly better to replace them with new.

OBITUARY.

MR. JOHN BELCHER.—We record with much regret the death, at the age of 73, of Mr. John Belcher, F.R.I.B.A., formerly of 5, Adelaide-place, E.C. Mr. Belcher, who retired from practice in 1870, was well known in the City as an architect of varied and considerable attainments. He erected many important buildings in the City of London, as well as numerous mansions and country houses throughout the country. His son, Mr. John Belcher (now of 20, Hanover-square, W.), after a short partnership with his father, succeeded to his practice.

MR. THOMAS JACKSON.—The death is announced of Mr. Thomas Jackson, architect, Belfast, at the age of 83. He commenced to practise in Belfast nearly sixty years ago, having been articled to the late Mr. George Dymond. The *Belfast Newsletter* gives a long list of his works, which are to be found not only in Belfast, but all over Ireland.

GENERAL BUILDING NEWS.

THE NEW FRUIT AND VEGETABLE MARKET.—The *City Press* says that the contractors who are engaged on the erection of the new fruit and vegetable market have already made considerable progress with their work. The market, which is to take the place of the old market in Farringdon-street, is being built at the corner of Charterhouse-street and Farringdon-road. At present the efforts of Messrs. Rudd & Son, the contractors, are centred upon the substructure of the building, which has been designed by the City Architect, and will be carried out under the auspices of the Markets Committee of the Corporation. The first thing, of course, is to clear the site, and this part of the operations has been entrusted to Mr. Nathaniel Fortescue, who, with the aid of a number of excavators and three steam cranes, is removing the debris at the rate of about 300 loads a day. It is carted down to Blackfriars Bridge, where Mr. Fortescue has a "shoot," and is then sent away in barges, to be used in the filling-up of a vacant space at Dagenham. Nearly thirty carts are all day long going backward and forward between Farringdon-road and the bridge. Several weeks will elapse before the site is in full possession of the contractors for the sub-structure. The basement will be used by the Great Northern Railway Company. An arrangement with the Corporation, and the rails will be carried underneath Charterhouse-street to the Central Provision Markets, where the Railway Company will have a general goods depot, with, of course, access from above. Steel columns will be used, and these will rest upon a foundation of concrete and blue Staffordshire bricks. On the tops of the columns, massive girders, also of steel, will rest, and the interstices will be filled in with brick arches and concrete. The Provision Markets facing the site will have to be shored up, so as to allow the putting in of columns, &c., in new positions, and allow the railway to be carried through. There will, in fact, be a reconstruction of the market basement. It may be added that, on the north side of the market there will be somewhat similar works carried out by the Great Northern Railway, and that on the street level there will be erected warehouses by the company.

**PROPOSED NEW TOWN HALL FOR NEWCASTLE.**—A special meeting of the Town Hall and Municipal Offices Committee of the Newcastle Corporation was held on Monday. It was unanimously agreed that the City Engineer (Mr. Laws) should prepare tracings to show the street improvements deemed necessary in connexion with the four Town Hall sites, namely, Fenkle-street, Eldon-square, Singleton House, and a new site that was suggested by Mr. Edward Stout, including the whole of the ground on the east side of Pilgrim-street, bordered on the north by Blackett-street, and as far back as Carlisle-street, showing a new street line in continuation of Market-street to a point at the top of Trafalgar-street, opposite the entrance to the Blyth and Tyne Railway Station. It was also agreed that Mr. Laws should prepare at the same time a plan showing a new street line from Grey-street to the Haymarket, skirting the proposed new Town Hall, should it be eventually decided by the Council to erect one in Eldon-square.

**NEW METHODIST FREE CHURCH, GRAVELLY HILL.**—The United Methodist Free Church lately erected at Gravelly Hill, Birmingham, in memory of the late Alderman M. J. Hart, was opened on Tuesday last. The church stands at the junction of Tanworth and Lichfield roads, and accommodates nearly 500 people. The pulpit has been carved in pitch-pine and mahogany, by Messrs. Jones & Willis, from the designs of Messrs. Ingall & Son, architects of the church. The total cost of the church is over 4,000.

**THE QUEEN'S HOTEL, CARDIFF.**—According to the *Western Mail*, the directors of the Queen's Hotel Company, Cardiff, have decided to rebuild the existing hotel. The building will consist of five floors exclusive of the basement, and will be five windows in length. The structure will be in the Renaissance style, and will be faced with red bricks, with terra-cotta ornamentation. The main entrance will be in the centre of the building, but there will be another one at the southern corner. The windows of the upper stories will be circular projecting bays on both the extreme ends of the building, working right up two floors, and finished in ornamental masonry. The total cost of the work is estimated at between 12,000 and 14,000. The new building has been designed by Mr. J. P. Jones of Cardiff.

**THE ULSTER BANK, DUBLIN.**—A branch office for the Ulster Bank, Dublin, which occupies a site immediately opposite the Houses of Parliament, is rapidly approaching completion. The front of the new building has been constructed of Ballinascloe limestone. The frontage is only 42 ft., but the height of the building is nearly 100 ft. The entrance is approached by a flight of steps leading to a porch. Ample accommodation is being provided in the interior. The central apartment has a vaulted roof, and at the end furthest from the entrance is a circular apse. Care has been taken to ensure sufficient light in all the offices. It is contemplated to light the bank by the electric light. The building will cost something like 20,000. Messrs. Samuel Bolton & Sons are the contractors, and the carving is the work of Mr. Eneary. The architect is Mr. Thomas Drew of Leinster-street, Dublin.

**NEW WESLEYAN CHAPEL, WREXHAM.**—The Mayor and Corporation of Wrexham attended in state the opening of a new Wesleyan Chapel at Wrexham, on the 6th inst. The new building is of stone, and has been constructed by Mr. Gethin, of Shrewsbury, from plans prepared by Messrs. Wadlington & Son, of Burnley, and has cost over 6,000. A tower with a spire has been built at the east corner of the front of the chapel. The seating capacity is 650, and a large school adjoining will find accommodation for 330.

**ST. HUGH'S R.C. CHURCH, LINCOLN.**—Mr. Albert Vears, of London, is the architect for this new church.

**SCHOOLS, NEWPORT, MON.**—Some two years back the United District School Board of Newport advertised for designs for schools at the Spring-garden site, to accommodate 1,000 children in three departments, and many of the local architects submitted plans for the same. The Board, after selecting two sets of drawings as most suiting their requirements, marked these drawings "A" and "B," and forwarded both sets to Mr. Bruce Vaughan, architect, for adjudication, who advised the acceptance of plans marked "B," the author of these being E. A. Lansdowne, of Newport, and the schools have now been carried out under his supervision by Mr. William Price, builder, of Newport, for a sum of £9,055. 16s. 7d. The fireproof flooring has been executed by Messrs. Haman & Rogers, Manchester. The heating and lavatory arrangements are by Messrs. Adams & Co., and Mr. Henry Richards, of Newport, acted as clerk of works.

**THE ASSOCIATION OF PUBLIC SANITARY INSPECTORS OF GREAT BRITAIN** will visit the Crematorium at Woking, Surrey, on Saturday, September 27. Mr. J. G. Seaman is Honorary Registrar-at-Law. Hon. Secretary of the Cremation Society of England, will give an address on "Cremation" early in the ensuing Session.

## FOREIGN AND COLONIAL.

**PRAGUE.**—As our readers have seen in the daily papers, owing to the flooding of the waters, the "Karls Brucke," the oldest and most celebrated of the seven bridges which cross the River Moldau within the precincts of the town, has been partially destroyed, three of the seventeen arches having broken down, carrying with them the upper portions of their respective piers and the interesting sculpture borne by the latter. The celebrated structure, the foundations of which were commenced 1357, may be considered as having been the most interesting historical curiosity in the city, and that it has now been so severely damaged is owing mainly to the apparent carelessness of the municipal authorities, who never troubled themselves about its state of repair, and, at the same time, permitted the weakening of the bridge by the laying of gas and water-pipes, the construction of tramway lines, and the transit of heavy cars. Among the many structural accidents which have been caused by the late floods we may note the appearance of some dangerous cracks in the embankment walls. Traffic has been prohibited on the whole length of the wall.

**BRUNSWICK.**—The annual meeting of the German Public Health Association will be held here next week. Among the many lectures those on "Hospitals for minor towns and rural districts," "Filters in water mains," and "Workmen's homes," promise to be of special interest.

**DRESDEN.**—The so-called "International" Exhibition of Water-colours and Drawings, for which room has been found in the halls and class-rooms of the "Saxon Technical College," in spite of a catalogue in which the figures go up to 2,500, is but a poor concern, the hanging committee having apparently laid more stress on "quantity" than "quality" when selecting the exhibits. There is some interest in the large collection of original sketches published in the better-class comic papers of the empire. Many of the works introduce architectural subjects, in which the ignorance of the rudiments of architectural forms is somewhat startling.—The far-famed collection of the "Grüne Gewölbe" of the old "Schloss" will be closed to the public for some time hence, a restoration and extension of the two wings having been taken in hand, which, when complete, will show some interesting "German Renaissance" work.

**FRANCE.**—The Minister of Fine Art is to inaugurate, on the 28th, the monument raised at St. André de Herizot. —M. Yves Guyot, the Minister of Public Works, is to proceed to Lyons shortly, to inaugurate the new Pont Lafayette, and M. de Freycinet, the War Minister, is also to lay in the same city the first stone of the Ecole de Médecine Militaire. —The inhabitants of Eyguères, are about to raise a monument to their citizen Jules Roche, mining engineer, who took part in the expedition of Colonel Flatters in 1881, and was killed abroad. —The Council Général of the Seine-et-Oise have made a concession to the Société Decauville for the establishment of a line of narrow-gauge railway between Versailles and Epoué. The company has applied for a concession for a line of 150 kilometres between Magny-en-Vexin and Villeneuve-St.-Georges. This line, which would traverse the districts of Magny, Bouchouville, Etampes and Corbeil, would render great service to a populous neighbourhood. —M. Alphonse had been appointed Curator of the Champ-de-Mars Palace. —At Tréguier a grand monument to St. Yves, the patron saint of Brittany, has been inaugurated with much ceremony and public festivities. —M. Arques, the engineer, residing in Paris, has purchased for 600,000 francs the historic château of Hautefort, near Périgueux, once the property of the family of Damas d'Hautefort. —It is hoped that the new Museum at Leon will be opened in the spring. It is to be situated in the old Lycee buildings. —A fine marble group, "Jeanne Mère," by M. Hector Lemaire, has been presented by Baron Alphonse de Rothschild to the Museum of Dieppe. —The recent cyclone which has done so much damage in various parts of France has among other things seriously injured the chapel of Dreux, which contains the tombs of the Orléans family. The fine windows executed after the designs of Le Sueur have suffered much, and some of the sculptural and the facade have been seriously injured (apparently broken by the force of the wind). —At Anney-le-Vieux the mould or matrix has just been completed for the great bell called "La Savoyarde," for the Church of the Sacré Cœur at Montmartre. The design includes a great deal of ornament of a Romantic type, and some of the sculptures are of the best. The casting in bronze will not, however, be proceeded with till towards the close of the year.

**NEWTON HEATH BREWERY.**—The contract for the Newton Heath Brewery, loose boxes and infirmary, has been let to Mr. James Bryon, builder and contractor, of Bury, his total estimate being 2,511. The architects for the work are Messrs. Maxwell & Tuke, of Manchester.

## MISCELLANEOUS.

**PROPOSED "HANOVER EXHIBITION."**—The Star Exhibition of last year at the New Gallery is followed next January by an exhibition of pictures and objects of interest connected with the Heil of Hanover, which will include not only portraits of the Royal Family, but also those of the most famous statesmen, lawyers, divines, commanders, naval and military, and the representatives of literature, and science. The Committee are confident that it will be possible to bring together of the most remarkable and instructive series of portraits of public characters ever displayed, and that the artistic success of the Exhibition will assuredly be the result of the works of such artists as Reynolds, Gainsborough, Romney, Kneller, Thornhill, Raeburn, Flaxman, Lawrence, Cosway, Wedgwood, &c. The Committee have every ground for this confidence, if their request for loans adequately responded to. In an artistic sense, an Exhibition ought to have a serious end beyond that of the Smart Exhibition.

**FROST-RESISTING CEMENT MORTARS.**—Herr Bohner has recently been making some experiments with a view to testing the influence of frost on the quick-setting properties of cement mortar, the results of which he has communicated to a German publication. It is well known that hydrochloric acid or a saturated solution of sodium chloride, &c., is used to set a mortar, &c., extremely hard, and Herr Bernhofer made mortar consisting respectively of 1 litre (about 1 1/2 pints) Portland cement and 1 litre of lime, each of it being mixed with 3 litres of river sand and a solution formed of 1 kilogram (about 2 1/2 lbs.) of crystallised soda and 2 litres of water. These mortars were placed in a hot oven for four days, and for four hours and a half, the temperature ranging between 15°C and 31 1/2 below zero. The specimens were placed in a hot oven for three hours. The experiments were entirely satisfactory, as the frost, which the mortars had been exposed had produced no injurious effects in the specimens. Furthermore, the specimens made to set in water, so that the mortars retain their hardness, and also whether quantity of soda used can be reduced. The Portland cement thus treated is put down as costing 32 1/2 cubic yard, whilst the lime mortar is stated to cost 21. 5s. 6d. per cubic yard.

**THE NORTH YORKSHIRE AND LANCASHIRE RAILWAY.**—There is every prospect of real communication being shortly established by a line from Lancashire to the north-east coast of England. The North Yorkshire and Lancashire Railway, which was intended to accomplish this, was projected some eight years ago, but was abandoned owing to opposition to the scheme. The promoters are now making every effort to get the project, however, bestirring themselves in the matter. Several public meetings have declared in favour of a revival of the project, and we believe that Messrs. Martin and Fenwick, of Park-place, Leeds, were the engineers for the original scheme, & have been instructed to prepare plans for an application to the Board of Trade for a concession, & that the new line should commence at Hatfield junction with the Midland and Lancashire & Yorkshire Railways there, and proceed in a northerly direction, by Cracro, Linton, and Gillington, to Kettlewell; thence by a tunnel in Wharfedale, down Coverdale and Middleham, Spensbourne, and then, passing under the Bell Busk Railway, will run direct to Darlington. —*Leeds Mercury.*

**UPPER NORWOOD ATHENÆUM: VISIT TO FIELD HOUSE.**—Among the many educational signs of the times, not the least is the establishment of a number of local societies having for their object antiquarian, historical or archaeological pursuits; and among these societies the Upper Norwood Athenæum, which was established in 1877, has lately been making rapid strides. It now numbers about 100 members, and on Saturday afternoon last sixty gentlemen (members and friends) paid a visit by permission of the Marquis of Salisbury to Hatfield House, under the escort of Mr. Mid-Pope, the honorary secretary. On arriving at house a descriptive paper was read thereon by Mr. Pope. As Hatfield was visited by the Architectural Association in 1858, when a very exhaustive and interesting paper was read by Mr. J. A. Spence, we must refer our readers to the *Builder* of September 1858, and to the following month when an illustration of Hatfield House was published by us.

**THE ENGLISH IRON TRADE.**—The slight depression noticeable in the English iron market lately has passed off. There is a decidedly better feeling in prices are firm, and expectations are of a further advance in steel. The pig-iron market recovered from its late reaction. Scotch pig-warrants have been steadier, and makers are at Middlebrough pig-iron is 6d. a ton dearer. Most of Bessemer iron in the north-west hold firm, their quotation of 5s. 6d., although heavy warrants are quoted 5s. 6d. Finished iron continued animation, with an upward tendency in the market. The following table of enquiries are coming forward for new ships, engineers are also booking more work than lately.

*Iron.*

LEGAL.

COMPENSATION: THE GREEN-STREET IMPROVEMENT.

GABRIEL E. THE VESTRY OF ST. MARTIN'S.

This case, which came before Sir P. H. Edlin, C.J., at the County of London Sessions last week, as an inquiry, under an Act of the reign of George III., known as certain Angelo Taylor's...

Mr. Bidder, Q.C., was for the claimant; Mr. Inch, Q.C., and Mr. Gill were for the Vestry. Expert witnesses were called on both sides to prove the value of the property. It appeared that was bought by the claimant, Mr. Gabriel, in November last, at public auction, for 3,325l. 10s. 6d. He then he had entered into an agreement with Mr. Hoesgood, a builder, to grant the latter a...

A CLAIM FOR WAGES.

At Marlborough-street Police-court, on Monday, Messrs. Stephens, Bastow, & Co., builders, of Leeward-road, Wandsworth-road, were summoned by a number of their workmen for wages which they alleged to be due in respect to a job in South Collyer-street. Mr. Bernard Abrahams, solicitor, appeared in support of the summons; and Mr. Messie, solicitor, conducted the defence. Several of the men were called, and from their evidence it transpired that on their applying for their wages on Saturday, August 23, they received sum of money on account, and were told that they could not be paid in full, because the architect's certificate had not been received. On the following Monday and Tuesday they went to work, and continued at work till about nine o'clock on the morning of the latter day, they remained on the premises during Tuesday, it did not work, and on the Wednesday morning going to the job and hearing that no money was becoming they applied for and obtained the same on Monday, twenty-eight in number. They claimed to be paid up to the Wednesday night, inasmuch as they were not discharged, but the firm August 30 had paid them only up to the Tuesday morning. Some of the men then resumed work, but others insisted upon their claim for wages and legal expenses. For the defence it was stated that although the men were not formally discharged, they were told that they would not work they might take their tools and go. They were not engaged under contract, and therefore could only claim for the work done to date. Moreover, although they were not discharged, they practised discharging themselves by declining to continue to work, and made no other claim at the time the balance of the wages was paid. Mr. Hannay, in giving his decision, said at by ceasing to work the men had committed an act for which they might at once be discharged; it as they were not formally discharged they were strict legality entitled to pay for the whole of the week. But he thought that, under the circumstances, in equity, it would be very harsh and unfair to make the masters pay for that for which they never considered, and he would therefore make no order in the case. -Times.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

4,396.-CARPENTERS' CRAMP: S. J. Ainge.-This invention is constructed of several bars or straps of iron, which are joined together by means of a pair of powerful toothed jaws, actuated by right or left screws. When the screw is turned the sides of the jaws are drawn simultaneously together, and the jaws, which are united and operated by a ratchet of the straps, which act as levers-are brought into contact with the floor-joist, which they grip so as to hold the slabs, while at the same time the same one of the bars presses against the floor-board at an oblique angle it may lie with respect to the joist, and does it into and retains it in the desired position. It is adapted to slabs of various thicknesses, and is in the making of doors, windows, &c. 4,393.-FIRE-RESISTING FLOORS: H. Stanton.-In order to dispense with the use of concrete in addition to the slabs it is proposed to use cast-iron plates or tiles used to support a floor or ceiling of tiles or slabs. The slabs below the joists protect them from action of fire and also of water, and the heat is taken below them leaves an air-space, that the heat is distributed or radiated instead of coming at the joists. 4,392.-METHOD FOR CEILING, &c.: C. Babin.-According to this invention, a double wire-netting is applied in the manufacture of fire-proof ceilings, walls,

&c. Each of the two nettings employed is held by connecting wires, at the distance which is best adapted for fire-proof lining, and the two nets may be rolled up easily for storage.

13,192.-STOPPERS FOR DRAINS: J. Jones.-According to this invention, a rim of rubber or elastic substance is compressed between two plates operated by a screw. Drawing the plates together forces the rubber between the edge, and makes a water-tight joint.

6,406.-WATER-WASTE PARVENTERS: F. S. Stroeter.-By this patent the delivery of water to the closet-pot is controlled through a valve through the medium of a sort of dash-pot, or hydraulic connexion, whereby the closing of a delivery-valve is independent of the pull-handle.

9,323.-ROOFING OR SHEATHING TILES: W. Fairweather.-This invention relates to tiles of clay or other material for exterior architectural use, and consists of surface tiles of rectangular character constructed so as to cover the edges of adjacent tiles at the junctions or termini of different planes in which the sheathing or roofing is laid, and to fit such parts as the ridge, the hip, the valley, or the eave of the roof. The tiles can be made ornamental as well as useful.

9,397.-WHITE PIGMENTS: J. Gordon.-This patent refers to what is claimed as an improved process for making white pigments of lead, in which galena, in a finely powdered condition, is injected into the upper part of a furnace heated with coke, the galena being oxidised and converted into a fume.

NEW APPLICATIONS FOR PATENTS.

Aug. 25.-13,330. A. Cashin, Securing Knobs or Handles for Locks and Latches, and for Knob Roses.-13,331. J. Hamblet, Ornamental Flooring Tiles.-13,334. H. Deane, Cooling Rooms and Spaces.-13,371. H. Harris and W. Power, Electric Bells and Indicators.-13,374. J. Benz and J. G. Benz, &c., for drying and burning bricks, pottery, &c.

PUBLIC APPOINTMENTS.

Table with 4 columns: Nature of Appointment, By whom Advertised, Salary, Applications to be in. Lists various public roles and their salaries.

Those marked with an Asterisk (\*) are advertised in this Number. Competitions, p. iv. Contracts, pp. lv. and vi. Public Appointments, p. xviii.

READING.—For the erection of a new hospital, vagrant and receiving wards, &c., at the Workhouse, &c., Reading.—For the Reading Union Guardians. Messrs. Charles Smith & Son, architects, 184, Finsbury, Reading.

Table with 4 columns: Entrance Block and Receiving Wards, Vagrants' Wards, Hospital, Total. Lists financial details for various construction projects.

\* Accepted for hospital. † Accepted for entrance block and receiving and vagrants' wards.

DON.—For alterations to coach-builders' shop on in Romford-road, Forest Gate, for Mr. W. M. C. J. C. Pawley, architect, 66, Victoria-street, London. £538 0 0

LONDON.—For rebuilding the "White Hart," Cornhill-road, Stamford-street, S.E., for the New London Brewery Company. Mr. G. E. Niblett, architect and surveyor, Hackney. £290 0 0

DON.—For general alterations and shop fittings, at the Workhouse, &c., Reading. £400 0 0

LONDON.—For alteration to "The Bell," Borough Market, for Mr. W. E. Bishop. Messrs. Eadie & Meyer, architects, 8, Railway-approach, London-bridge. £580 0 0

LONDON.—For alterations and additions to the "British Lion," Putney-bridge road, for the New London Brewery Company. Mr. G. E. Niblett, architect and surveyor, Hackney. £521 0 0

LONDON.—For alterations at the "Crown and Scupper," Brompton-road, for Mrs. Hollyman. Mr. G. E. Niblett, architect and surveyor, Hackney. £1,907 0 0

LONDON.—For pulling down and rebuilding Chelsea Church House, Chelsea Old Church. Messrs. Mackmurdo & Horn, architects, 20, Fitzroy-street. £1,052 0 0

MALDEN.—For alterations and additions at Motespur Park, for Mr. Charles Blake. Messrs. Edmonstone & Gabriel, architects, 42, Old Broad-street, E.C. £1,250 0 0

PENZANCE.—For the erection and completion of a new Fire Brigade Station at Penzance. Mr. George H. Small, Borough Surveyor, Penzance. £182 0 0

PLYMOUTH.—For the erection of a new warehouse at the corner of East-street and Market-lane, Plymouth, for Messrs. Spooner & Co. Mr. W. Dunn, London, and Mr. W. N. Spooner, Plymouth, joint architects. Quantities supplied by Mr. John H. Dwellley, Plymouth. £4,284 0 0

POULCHESTER.—For the erection of new stables, coach-house, &c., and additions and alterations to the "Cormorant" P. O. Mr. Wm. Yearley, architect, Gosport. Quantities supplied: £717 16 10

ROWLANDS CASTLE (Hants).—For the erection of a residence, &c. Mr. Wm. Yearley, architect, Gosport. £800 0 0

SHIREGREEN (near Sheffield).—For the construction of sewers at Shiregreen, near Sheffield, for the Worley (Sheffield) Union Rural Sanitary Authority. Mr. Geo. E. Beaumont, surveyor, Grenoside, Sheffield. £400 8 0

### Ventilation of Dwelling-houses.

**V** referring a few weeks ago to the resolution passed by the Journeymen Tailors' Union that all tailors' workshops should be supplied with an adequate amount of fresh air for person, by means of "modern ventilating appliances," we observed that the, though perfectly right in principle, asking for a luxury which is to be found only few even of the most costly and well-ventilated residences of the wealthier classes in this country. Dwelling-houses of the lower class are still habitually built with no system of ventilation, save in a few exceptional cases; and as to the smaller and middle-class town or country houses built on speculation, any idea of a system of ventilation would be regarded by their builders, if it were even that of all, as commercially out of the question, involving an expenditure out of proportion to the return that could be expected in rent; and until the tenants of these houses attach so much importance to a scientific ventilating system as to be willing to pay a higher rent for a ventilated house, it is only reasonable that the speculator-builder should take such a view. But while the tenants or purchasers of houses in this country are sublimely indifferent on the subject; and even in the case of houses especially for a private owner under the supervision of an architect, it is very rarely that the client makes any demand on his architect for the provision of a system of ventilation.

It is not to be pretended that the problem of ventilating ordinary dwellings is in any way the same footing as that of public buildings. A theatre, church, or any other meeting-room is under quite different conditions from a dwelling-house. In a room a number of persons are packed together far more closely than in a dwelling-house, in proportion to the cubical contents of the building; the individuals composing the crowd cannot in general change their position at pleasure, but must put up with what is meted out to them where they are. The occupation of the building is

only for a limited portion of the twenty-four hours. The building consists mainly of one large chamber, much easier to deal with collectively than the numerous small apartments of a dwelling-house; and while the crowded state of the building renders mechanical means of ventilation an absolute necessity in order to secure a satisfactory result, the necessary expenditure for this can generally be arranged for in such cases, as a portion of the working expenses of the building, without extravagance; and in large blocks of offices, especially such as are under State control for official purposes, a central ventilating power of some kind, either mechanical or in the shape of an exhaust chimney, can generally be applied economically to change the air of the whole building, all the apartments in which are mostly in use at the same time and for the same number of hours.

How different is the whole case in a true dwelling-house. Here we have a building which is inhabited the whole of the twenty-four hours, divided into small apartments which are in use at various times, the bedrooms being empty, except at short intervals, while the sitting-rooms are in use; and the sitting-rooms entirely empty at night, while the bedrooms are in continuous occupation. In the average middle-class house the expense of a continuously-active mechanical means of ventilation, or even of an exhaust shaft in continuous working night and day, would be prohibitive. But even in large mansions where the owner could afford to keep up such a system, it would be necessary, unless there were to be a great waste of power, to have elaborate arrangements for cutting off the ventilating action from rooms not in use, concentrating it at night on the bedrooms, and by day on the other portions of the house, which complicates the problem very much, and renders a central system by no means so obviously applicable to even the largest class of dwelling-house as to a public building.

A central system has however in all cases one obvious advantage, that by admitting the whole of the air for ventilation by one main inlet, for distribution thence, the temperature of the air of the whole house can be regulated in the simplest manner and at the least cost. It is this fact especially which seems to have fascinated Drs. Drysdale and Hayward, who now publish, under the somewhat high-sounding title of "Health and Comfort in Housebuilding," a third edition, with con-

siderable additions, of the work\* in which they recommend the system on which they have ventilated their own houses. The authors in their preface to the third edition express a mild and dignified surprise that a new edition should be called for, inasmuch as in a certain "Dictionary of Engineering," 1874, their system was described as "a truly scientific and rational one," with other expressions of approval; and after such an opinion they had hoped "there would have been no further need of a work like this, but that the practical points would have been incorporated by this time into the ordinary literature of architects, sanitarians, and engineers." This is a good deal to expect as a result from the commendation of a single not very widely-known publication (which we observe is issued by the same firm who publish the work thus commended); but the authors write in the true spirit of doctrinaires, who have formed a system theoretically satisfactory to themselves, and cannot understand how its perfectly satisfactory character should not be equally apparent to every one else. Finding however that their principles have not yet been generally admitted or put into practice, and that "we have even in new houses the same patchwork ventilation of single rooms with cold air, against which our book was directed, a new edition is therefore called for." This is a somewhat lofty position to assume, and we decidedly contest the right of the authors to pose as the only infallible guides to house ventilation. They have the credit however, of having contrived a general system of ventilation for dwelling houses by a central exhaust and a central inlet, with very trifling expense in the working, though not without considerable expense in the first installation; and considering the usual neglect of ventilation, already noted, in building dwelling-houses, every reasonable effort to bring about an improvement in this respect should have due attention.

The authors' system, which has been noticed in former years in our columns, is, we may remind the reader, that the external air should be admitted into a chamber warmed (except in hot weather) to whatever temperature is thought desirable; admitted thence into a central lobby

\* "Health and Comfort in Housebuilding; or, Ventilation with Warm Air by Self-Acting Suction Power," &c. By J. Drysdale, M.D., and J. W. Hayward, M.D. Third edition. London: E. & F. N. Spon; 1890.

which is kept from immediate communication with the outer air, and warms the fresh air reservoir for the house; and thence passed through openings near the ceiling into the several rooms. From the rooms it is led by tubes to a collecting foul air chamber at the top of the house, from which it is drawn by a down-cast suction pipe, delivering into an up-cast flue surrounding the kitchen flue, the heat of which forms the extracting power. The chimney flue for this purpose is required to be in the centre of the house, the actual chimney being a circular metal pipe, which takes the smoke and heat from the kitchen fire, while the space around this, and warmed by it, constitutes the upcast extract shaft, "which must be so tall as to reach several feet higher than any other chimney of the house, in order to provide a long syphon for the purpose of increasing the suction from the foul-air chamber, by abstraction of the heat of the smoke." The idea, it will be seen, is that the kitchen fire, being always in use in the daytime, is an exceedingly economical exhaust power, the only loss being the waste heat which would in any case go up the kitchen flue. But the authors claim that in addition to this, the syphon form of the down and upcast flues, with the latter forming the longer leg, produces a draw even when the kitchen fire is not in use. We give this in their own words:—

"This is not a matter of theory only, but has been proved by direct observation in house No. 2, in the foul-air chamber of which strips of silk are hung over all the inlets, in order to indicate the current. These have been observed to be always blown in the right direction, even during the summer when the kitchen fire was not in use, and though all the windows are, for the sake of keeping out the cold air the blacks and the dust, made fast and not to be opened. . . . In fact the whole system becomes then another form of the Watson ventilator, with the inlets distributed throughout the whole house."

"House No. 2" means the second of the two houses of which plans and sections are given as illustrations, and which we shall probably not be wrong in concluding are the houses built or arranged by the two authors for themselves. The remark as to the windows all being kept tightly closed brings forward another feature of the scheme, one object of which, we are told, is to prevent air entering the house by any other entrance than the one main inlet specially provided. The object of this is to ensure that no air should enter the house in cold weather except such as has been artificially warmed. The authors are particular in pointing out that they do not propose to warm the house by hot air, or to dispense with fireplaces or other means of warmth in winter, but only to warm it up to what they consider a healthy standard, and to avoid draughts of cold air. If we remember right, this system of shutting up the windows completely was made one of the strongest points by Dr. Hayward in originally propounding his scheme; but there seems to be a degree of doubtfulness about it now. At all events mention is made of a house in which the authors' plan was carried out as a warm-air heating scheme as well as for ventilation; "fireplaces were rejected, the windows closed hermetically, and the entire warming was effected by means of hot air." It is not surprising to learn that "within a year or two, fireplaces were introduced, and the windows made to open." We should think so. Anything more stuffy and unhealthy we can hardly imagine; and this was, it appears, a house built by a medical man for his own abode!

Where the air is merely warmed to what is considered a healthy and normal temperature for breathing, the results need not be so disastrous; but even in this case we should like to ask whether it is seriously maintained that in summer weather, with all windows kept closed, no assistance to ventilation afforded by fires in the rooms, and with the kitchen fire, which is used as the exhaust, not burning, this central syphon ventilator draws into a house all the fresh air that is necessary or desirable for a healthy state of living? We can only say that we are absolutely

ceptical on the point, and should be sorry to live in summer, or even spend a day in, a house so constructed.

The non-use of the kitchen fire, however, was an exceptional circumstance. But taking the system in its normal working order, with the kitchen fire burning hotly and creating a good pull on the extract and inlet system, is this a satisfactory or healthy way of arranging a house for living in during summer weather? It is impossible that air admitted through this system of a cellar opening, and then a central lobby, and thence into the rooms, can have the healthy freshness of summer air admitted direct through the open window. The very idea is enough to give one a stifling sensation. We will go further, and ask whether it is even in winter the ideal of a healthy house to close all windows and pump air in through a steam coil in a cellar? The authors are desirous apparently to impose on the public, as the only right thing, the system which pleases and astutes them. Possibly they are peculiarly constituted; or again possibly they have rendered themselves abnormally sensitive by constantly brooding over effects to keep out the outer air from their houses. Certainly their dread of open windows is something almost amusing: they return to this point again and again; open windows are bad enough in the daytime, but at night, in a bedroom, they seem to be regarded as absolutely poisonous. That is their individual experience, perhaps. We will offer them another individual experience, that of a person whom we will call "X," who has for years been in the habit of having one or more of the windows opening on his staircase (which forms a sort of central lobby from the top to the bottom of the house) open all day in all weathers (except driving rain), and the staircase filled direct with outer air; who habitually and in all seasons comes down to a breakfast-room with windows wide open, and sleeps in a bedroom with a "window-board" to raise the sash and let air in at the meeting rail. The only ill effect that X, and his family have ever experienced from this is the feeling of being half-stifled in the houses of some of their friends, who share our authors' dread of open windows. The learned authors will say perhaps that X must be a person of unusually robust health. But is not that putting the cart before the horse? Is it not possible that the robust health is exactly due to the habit of living in a free circulation of out-door air, instead of shutting it out by all possible means? In the artificial life of cities our belief is that the more "open-air" people can render their lives, as a rule, the longer and healthier will those lives be. But of course it stands to reason that people who have for half their life time cooped themselves up when in their houses will have become nervously anxious about draughts; they have artificialised their constitutions and require to be treated as greenhouse plants, and that is just what Drs. Drysdale and Hayward are encouraging.

Accepting the fact that there are many invalid and delicate people in the world, the authors' system carried out to its full extent no doubt offers a good expedient for a house for those who are already such; but the adoption of the system in full would, to our thinking, only tend to increase people's susceptibility to cold and to produce a delicate and valetudinarian race of people. Let us therefore dismiss these closed windows, hoping to hear no more of them. Leaving the windows of the house in their ordinary condition, capable of being opened whenever required, there is no doubt much of ingenuity and value in this scheme of the central extract, as of course there are many occasions when the windows of occupied rooms cannot comfortably remain open. But there are objections to its application to a house in the manner described which cannot be overlooked. In the first place, we cannot altogether accept the dictum that the exhaust system, dependent on the heat of the kitchen fire, will act sufficiently during the night when the fire is always low

and sometimes out altogether. But it is exactly at night that the admission of slightly warmed fresh air into the rooms is valuable. Bedrooms scarcely ever have enough ventilation; they are always close the morning, as every one knows; and because there is not that frequent going in and out and consequent movement and placement of air which occurs in a sitting room in the daytime. It appears therefore that the Drysdale-Hayward system is rarely to fail more or less at the very time when it would be of most value. Second it requires a house to be planned for it, we cannot always be conveniently done even building a new house, and application of the system to existing houses is in most cases the authors acknowledge, very difficult. We admit, however, that it is difficult to obtain any efficient system of house ventilation that has not been foreseen and provided in building the house. Thirdly, the ventilating openings into rooms from the central lobby are likely to seriously militate against privacy. A conversation in the lobby tones must be to some extent overheard in the lobby, or so we shall expect. Fourthly, recurring to what we said at the outset as to the different conditions of a dwelling-house from those of a public building, we question whether the principle of a general system of ventilation for a whole house meets the requirements of the case. In a dwelling-house different rooms are used under different conditions. There is no occasion on which the want of ventilation in most dwellings is so much as at a large dinner party. The dining-room is then under somewhat the same conditions on a smaller scale, as a public meeting room. It is filled by an abnormal number of persons crowded together in unproportion to the cubic contents of the room. A system of ventilation therefore, which changes the air of the room sufficiently often to supply the needs of its ordinary number of daily occupants, is inadequate for a dinner-party. The objection becomes even stronger in the case of an evening or afternoon "at home," in a drawing-room is often packed with nearly as close as they can stand. The author alludes to this, stating that the extract from the drawing-room must be adequate for ventilation when the room is full; but a general ventilating system which would be adequate for this would be excessive for ordinary occasions.

The idea of the central lobby and the rooms deriving their supply from it appears to us objectionable in a threefold manner: (1) as often interfering with convenient planning; (2) as being what we should call stuffy in its results; (3) as destructive of privacy. There is another objection made as to the mode of inlet proposed, i.e., through the cornice of the room, which the authors find fault with what is called the Tobin system for projecting fresh air towards the ceiling of the rooms, by which it mixes with the foul air at the top of the room and drags some of the latter down again; yet they themselves propose the plan of an inlet at the top of the room, with just the objection to it. The exit is to be at the room on the opposite side. In that case one of two things must happen; either the air admitted does not descend at all, but is drawn across the ceiling to the outlet, or it descends, it does so after mixing with impure air at the top of the room, having traversed a warming cellar and a lobby out from all connexion with the outside. And this is called supplying fresh air to the room!

The main idea of utilising the kitchen fire as an economical form of extractor has doubt its value, but it requires to be guarded against the undesirable elements which the authors have unnecessarily associated with it. It is no use either for the hermetically sealed windows or the central lobby with all its various inconveniences. If the warming chamber in the basement be adopted, flues should lead from it direct to each room, with

st as easy as to lead extract flues from each room. They should not discharge into the room at the ceiling, but at a height of about a foot from the floor. This is impossible of course with the central lobby system, because of the wall still more effectually interfere with privacy. The inlets would have to be arranged in a decorative manner, but it is not so difficult to do that on the wall of the room than on the cornice, and we should then spare also the necessity for the portentously large cornices which are figured in the authors' sections, and which are anything but conducive to architectural refinement of effect. The outlets should all lead from the top of the rooms. Considering that the heated air produced from the ordinary occupation of a room rises to the ceiling, this is a natural and commonsense, in fact the scientific method, of arranging it; inlets low, extracts above. Extra inlets should be made for drawing room and dining room provide for occasions when the rooms are full of people, and all inlets in the various rooms should be capable of being readily opened and closed whenever desired. By this means there need be no extra demands on the street power when extra ventilation was required for crowded entertaining rooms, as the inlets to the bedrooms and other rooms in use could be shut off and the current incoming air directed through the extra inlets in the entertaining rooms instead. Arranged in this manner, there would be no necessity for a special plan of house in order to make a system work, a necessity which is practically an almost fatal obstacle to the employment of the authors' system. Only people who are possessed with a ventilation mania could consent to plan houses in a special and even by no means convenient manner simply for the purpose of adapting them to a scheme of ventilation. Houses are not built for the mere purpose of being ventilated, any more than theatres are built (as some people seem to think nowadays) for the mere purpose of making exits from them; and a system which makes that demand will never come into general use. It is opposed to common sense. We have still the defect to encounter, that the extract worked by the kitchen flue is weakest at night, or may even cease to act appreciably, and that the system in that case would be a partial failure as to the ventilation of bedrooms at night, which is really more important than that of sitting-rooms by day under the ordinary conditions of everyday life. The adequate ventilation of bedrooms is really the most difficult problem in house ventilation, as it is only in a minority of cases that fires are used, and those most necessarily be left to go out in the course of the night. The separate ventilation of sitting-rooms for everyday occupation is not a difficult matter, because when fires are used, warmed air can be admitted from behind the grate, and the fireplace is itself an extractor; and at times when fires are not wanted the windows (*pace* Dr. Hayward) can be opened. The class of extract ventilators which create an updraught by the impingement of the wind upon them are some of them exceedingly effective when there is wind stirring; but unfortunately they are powerless at the very moment when we most require ventilation, when the weather is calm and sultry. Perhaps our authors' system promises more of a result than can be obtained by other means, except costly ones, granting a little extravagance in the manner of making up the kitchen fire for the night. With a house fitted with a complete system of hot-water heating, worked so as to retain its heat through the night, it is easy to induce an incoming current of warmed air through a coil under the window-board, communicating with an external opening. But this is a more expensive installation than can be afforded in many middle-class houses. In such cases we are still of opinion, in spite of the denunciations of the authors against the admission of external air into bedrooms, that the simple device of the closed sash with a deep bottom rail, allowing a vertical inlet for air behind the meeting-rail,

is at all events less injurious to the health of the occupants than sleeping with no ventilation at all. Still, if it can be kept acting adequately through the night, the authors' system, with the limitations above stated, is the only tolerably inexpensive one which has been proposed for keeping up a change of air in bedrooms at night, without opening the windows; and if it can accomplish that object, that will perhaps prove to be its chief value: but the inlets must not be made at the top of the rooms.

NOTES ON THE NEW EDUCATION CODE.

HE new Code of Regulations as to Elementary Schools came into operation on September 1. It contains some points of special interest to our readers. The first is that Drawing has now been made an obligatory subject for boys in the older schools—that is, for boys who are not in the infants' department. It also has its place as one of the optional subjects in boys' classes throughout a school. This recognition of drawing as a necessary part of elementary education is an important step. It marks the beginning, it cannot be doubted, of a system of technical education in England. It is a very tentative beginning, but it is real one, and it is in accordance with national habits to do things in a piecemeal and unsystematic manner. Our neighbours across the Channel would have produced a beautiful system, which, in the long-run, would very likely have no more important results than our own shy beginning. It will be interesting to observe what results follow from the commencement. But at the present moment the most difficult practical question is the way in which this new subject is to be taught.

In large schools in large towns there are teachers more or less ready; in the rural districts it presents grave difficulties. The ordinary certificated teacher cannot, as a rule, teach drawing. In due time drawing will, no doubt, become one of the subjects in which every teacher can impart information to pupils. It may be doubted, indeed, whether the teaching of drawing under these conditions will be of much value, though it may no doubt give opportunities to boys who have some talent with a pencil to show what they can do, and so obtain a place in the technical schools, which must in time become a part of our educational system. So far as we can see, the best plan for the present, at least in a large number of districts, will be for a certain number of districts to combine and support a common drawing-master. We are by no means sure that this will not ultimately prove to be the best permanent plan, but it seems at any rate to be the only way by which for some time to come districts in rural places, or districts in moderate sized towns, can satisfy the requirements of the new Code.

The second point of importance in regard to the new Code is Schedule VII, which is entitled, "Rules to be observed in planning and setting-up Public Elementary Schools." According to Article 85, these rules apply *primâ facie* to new premises and enlargements only. But as the Education Department must be satisfied that all existing schools are healthy, properly constructed, supplied with suitable offices and accommodation, it would appear that indirectly the schedule is to a large extent binding on existing schools. Take, for example, Article 15 (b) of the schedule, which states that "all playgrounds should be properly levelled, drained, enclosed, and fitted with some simple appliances; a portion should be covered, having one side against a wall." If this regulation is obligatory in the case of a new school, why should it not be so in the case of an existing one? We are inclined to think that though the Department may say that such a regulation *must* be complied with in the case of a new school, it will practically enforce it also in the case of an existing school by saying that such a school does not comply with the Article 85,

the purport of which we have already given, if this regulation is not followed. It would be impossible to give verbatim the whole of this schedule; if our space permits, we may on a future occasion reprint it for the use of our professional readers. It will be useful, and it may even be amusing. For example, the first article under the heading "Building Rules" is entitled "Planning and Accommodation," and the first section begins by telling us that "In planning a school the first thing is to seat the children in the best manner for being taught." We shall next expect to see in an engineers' manual some such advice as that in planning a dock for ships the first thing is to construct it so that ships may get in and out and be unloaded. It is really too ridiculous that such solemn official truisms should be gravely printed in such an important document as the new Code. Practical information, as that "the proper width for a schoolroom is 18 ft. to 20 ft. (according to length) or 22 ft., is useful, though it appears to be singular, to say the least of it, that the proper width of a schoolroom should be defined, but that no directions are given as to its length. According to the ordinary reading of this regulation, a schoolroom may be as long as you please, but it may not be wider than 22 ft. The schedule contains eighteen headings which refer to structural matters. No. 4 is walls and roofs; No. 5, entrances; and so on. Most of the directions are of an elementary character where they are of a general nature: where they are special, they are more important, because they state details which must be complied with by those builders and architects who are engaged in erecting school buildings. It is a little surprising that such a series of regulations was not before published, and it is probable that its very publication will enable it from time to time to be amended as its practical results are observed and new inventions and improvements are brought into existence.

THE CONVERSION OF TIMBER BY MACHINERY.

BY SAMUEL W. WORSSAM.

N the conversion of large logs of timber,—hard or soft,—into flitches and boards, the tools generally used are the circular saw, the frame saw, the horizontal reciprocating saw, and the band saw. The first-named is in most universal use, by reason of its great producing power and the facility with which it can be manipulated, although at the same time the most costly, alike as to waste of stuff and absorption of horse-power.

*Circular Saws.*—For a log of 36 in. scantling, a saw of at least 78 in. diameter and 6 easy b.w. gauge is necessary; this means a wide kerf, with a corresponding waste of material. The cost of such a saw is 45*l.*, and the angular velocity 450 revolutions per minute, giving a speed at the periphery of 9,225 ft. per minute. Forty-five horse-power indicated is absorbed in driving a machine carrying so large a plate, and the average rate of cutting is 8 to 10 ft. per minute for hardwood and 18 ft. for soft.

The saw works in a rack bench with travelling table running on rollers for the log, and weighs 9 tons, the cost of the same for logs 36 in. x 40 ft. long when fixed ready for work being 325*l.* It may not be out of place to remark here that, up to the present at least, it has not been found practicable to run saws of greater diameter than 78 in., although larger saws have been made. One was exhibited in 1862 of 87 in. diam., 5 full b.w. gauge, and cost 60*l.*

Occasionally, for logs of greater dimensions than 3*ft.*, two circular saws are employed, one working above the other on separate spindles, but this arrangement is not recommended owing to the difficulty of getting the saws to run conjointly in a true plane.

*Frame Saws.*—The second machine in the list,—the frame saw,—has the advantage of the circular when logs have to be sawn into

boards, inasmuch as many and much thinner saws can be used simultaneously; thus, for converting a 36-in. log into 1-in. boards, thirty-four saws are requisite, each of 13 h.v. gauge, whereby there is much less waste of wood as against the circular-saw having 6 slack b.w. gauge. The number of strokes of such a frame carrying thirty-four saws is 120, and the cost of the set, with hook buckles, tillers, and keys, 45*l*. Such a machine weighs 12 tons, and the price for barks, 36 in. by 40 ft. long, fixed ready for working, is 600*l*. The average rate of feed, which is intermittent, for hard wood is 8 in. per minute, for soft 15 in. The blades are keyed in a swing-frame, the tension on each being about 1 ton to every inch of width; a travelling rack or drag carriage running on rollers serves to carry the log.

On a comparison of these two modes of conversion, it is clear that for hoards the frame-saw is more economical and productive: as a matter of fact, the circular should only be employed in ripping logs into fitches, which are subsequently re-sawn by the frame into thinner stuff or leaves.

The next reference is to the horizontal saw-frame, which usually carries but one blade. The saw runs at a high speed and cuts inwards and outwards of the stroke, the guides of the swing frame being fixed obliquely in such manner that the saw-teeth clear the cut at each half stroke. This saw, albeit somewhat slow in production, is, owing to its thinness, very saving of stuff, and specially serviceable for opening up costly woods which have to be re-sawn when their character is ascertained. For barks 36 in. by 40 ft. long the weight of the machine is eight tons, and the cost fixed for working, 400*l*. The saw is 6 ft. 6 in. long by 6 in. wide, and 15 b.w. gauge, and makes 190 strokes per minute. The indicated horse-power necessary for a machine of this character is 12 horse-power. In hard wood the average rate of feed, which is continuous, is 2 ft. per minute, in soft 4 ft.

A duplex horizontal saw-frame has lately been patented for operating two saws independently of one another. These are strained in separate swing-frames situated back and front of the main standards, driven from one crank shaft and reciprocated alternately to be in equilibrium.

A vertical single-blade frame is now and then serviceable where limited motive power and ground space only are available; but it is rarely run at high speed on account of risk of vibration, increased production being attained by increase of stroke.

**Band Saws.**—To advert to the band-saw—the last enumerated—is to trench on debatable ground and fish in troubled waters. This, although one of the most important innovations in the wood-working machine category, has given rise to greater controversy among manufacturers and users than any other. Few of these agree as to its merits and demerits as a means for the conversion of heavy work. In France and the United States its employment is universal, whilst in this country, where it originated, it has hitherto failed in finding favour. There may be many explanations for this; the difficulty with the saw itself, due to inferior quality and consequent breakages, the want of skill in the operative, and the impracticable design of the machine. Our sawyers apparently do not appreciate the fact that a band-saw requires greater care in manipulation than either of the other types mentioned. The French and Americans, on the other hand, have given to it their most careful attention, and with satisfying results.

Unquestionably for heavy work, given a good saw, carefully designed machine, and skilful hands, the band-saw is better adapted than any other, alike for the saving of horse-power and economy of production, apart from the fact that the travel of the saw being continuous it turns out superior work, which requires less subsequent dressing.

The highest quality of saws are manufactured by M. Perin, of Paris, who has made it his task to ensure that they shall withstand the necessary strain and tension they have to

bear without fracture. He has likewise introduced simple modes of re-joining or brazing them when this does occur. Means have been devised to reduce the risk of snapping, which frequently arises from the too rapid cooling and contraction of the blade after ceasing to work. Modifications of the saw guides have been effected with a similar object.

In the States, webs of so great a width as 8 in. are in operation, but there is no gain in this; on the contrary, blades not exceeding 4 in. or 5 in. are found superior in not requiring so great tension and correspondingly heavy pulleys, and being liable to less friction in the kerf. The saw must be perfectly parallel in width and thickness, and of uniform temper and set throughout; the form, space, depth, and set of teeth should be carefully studied. The gullet shape of tooth, i.e., teeth with half-round throats, is preferable for soft wood, and the hand-saw for hard.

In practice it is found advisable to have small, loose, adjustable pulleys situated immediately above and below the stuff, and bearing against the inner flat face of the blade to obviate the necessity of straining it to a straight line between the points where it leaves the pulleys, whereby a lesser degree of tension and tautness is necessary. This is an important factor which has not been sufficiently recognised by designers and manufacturers. Any plan lessening the tension of the saw minimises the chance of breakage, and lessens the otherwise requisite strength of the pulleys and standards of the machine.

Referring to the machine itself, this should be substantially and proportionally constructed, with pulleys not less than 6 ft. diam., the upper one being as light as consistent with strength, it having to be driven by the saw from the lower. The rims of the pulleys should be lagged with wood, or covered with leather or india-rubber, to make an elastic cushion for the saw, although the writer has knowledge of a large machine, running for some years, the pulleys of which have no covering whatever; they are turned slightly convex, and the blade runs like a belt on riggers. The pulleys may have flanges, but these should serve only to prevent the attendant when mounting the saw from passing it at the back of them and damaging the finely-sharpened teeth. Should the blade unduly press against these flanges, or any fixed runner or guide, it will immediately buckle and swerve from the true line of cutting. Care must be paid to the design of the tension appliance to provide against the contraction and expansion of the saw whilst working.

With all these points strictly attended to, no reason can be adduced why this class of machine should not be as approvingly received at home as it is at present abroad.

In this country the prevailing type of band-saw machine is the vertical, which for logs 3 ft. by 40 ft. long, costs, when fixed ready for working, 480*l*., and weighs 10 tons. The saw pulleys are each 6 ft. in diameter, and make 300 revolutions per minute, giving a travel to the saw of 5,700 ft. This itself is 42 ft. long, 4 or 5 in. wide, 17 b.w. gauge, and costs 8*l*. to 10*l*.; 20 horse-power ind. is absorbed in operating it, and the rate of feed, which is continuous, in hard-wood is 3 ft. per minute, and in soft 6 ft. The log is advanced to the saw on a table running on rollers.

In France these figures somewhat differ, as there the machines are of less solidity, many of them having the travelling-tables made partly of wood.

For logs 1<sup>00</sup> by 4<sup>00</sup> long, the cost of a machine fixed ready for work in Paris is 9,250 francs. The pulleys are 2<sup>00</sup> in diameter, having the rims coated with buff leather, and making 350 revolutions per minute. The saw is 10 centimètres wide and 14 dixièmes de millimètre gauge. The indicated horse-power absorbed is 20 h.-p., and the rate of feed in hard wood 1<sup>00</sup> per min., in soft 2<sup>00</sup>.

For re-sawing fitches 24 in. deep by 6 in. thick, a double hand-saw machine is coming into vogue; in this case, the two saws run

independently of each other, although the pulleys are on the same standard. To insure uniform travel of the saws, they are worn from one counter shaft only. One blade is longer or shorter than the other, according to circumstances.

For fitches 24 in. deep and 6 in. thick at a machine costs, when ready for work 370*l*., and weighs 6 tons. The diameter of each pulley is 4 ft., and makes 250 revolutions per minute, giving each saw a travel of 4,375 ft. per minute. The initial length of each web is 32 ft., width 2½ in., and 18 b.w. gauge, and costs 4*l*. The indicated horse-power consumed is 10; rate of speed in hard wood 4 ft., in soft, 12 ft. The fitch is fed by the saws by adjustable vertical rollers.

Band-saw machines are designed and constructed to operate vertically and horizontally, but the former type is generally selected, and that here treated of.

There are some other machines used in conversion of barks, such as those for cut veneers, &c., but these are omitted for present, as not coming strictly within the scope of this article. S. W. V.

## NOTES.

**THE** collapse of the Southampton Dock Strike is another piece of evidence that, powerful and active as have been the labour combinations of the last few years, they are not omnipotent. The fact is that an existing general contest between capital and labour, there are, as it were, armies engaged on each side in different places in different parts of the world. The victory rests with that army which is best disciplined, organised and commanded. The analogy to actual warfare may be paralleled in other particulars. The fact, however, which is becoming more and more clear, is that in the future the success of labour combinations over capital is likely to grow less and less. For a long time unions among workmen did little more than raise the rate of wages to a more reasonable standard, and obtain a legitimate recognition for the claims of the artisan. Such unions were essentially protective of the interests of the labourer. It is now changing its aspect, it is becoming aggressive. It is not so much protective, and is a force attacking capital rather for the purpose of humbling the employer and exalting the labourer, than protecting the real interest of working men at large. This stage being reached, it is obvious that public sympathy will be turned to the employers, and also that the latter will combine generally to resist aggressive unionism. The very important Ship Federation is an instance of this tendency. The result must be a series of checks to trades unionists whenever they have no legitimate ground for their warfare. It is also clear that in this country the labourers sooner or later be divided into two camps, those who are unionists, and those who are non-unionists. It takes time for men to see that there can be a tyranny of labour as well as any other ruling power; but as soon as it becomes evident, we are much mistaken if many artisans will not prefer to be free men rather than be under the dominion of trades unionist organisers.

**A** KIND of shudder must have run through all the civilised world at bearing of the burning of part of the Alhambra. We do not of those who think that there can be again be in the world as fine architecture as there has been, but there are some buildings which seem to stand quite apart in their combined artistic and historic interest, and the destruction of which would be a loss to the whole world, which could never be made good. The Alhambra, like the Taj Mahal, Mark's, and the Ducal Palace, is unique, and it is to be hoped that double vigilance will be exercised over the safety of the remaining untouched. The catastrophe reminds one also that we have been told only a

years ago that the Ducal Palace at Venice is full of combustible material, and exposed to the greatest risk from fire in the case of the slightest accident setting anything alight. The misfortune in these cases is that the people who have the immediate custody of these precious buildings are not those who care most for their preservation. It is the outside world that attaches anxiously for the safety of the Ducal Palace, the burning of which would probably be regarded by most of the Venetian official authorities as only an opportunity for erecting "more commodious premises" on the site. And as to the Alhambra, we learn from the *Times* telegram that "At a Cabinet Council held last night it was decided that a Government delegate should go to Granada to estimate the amount of the damage caused by the fire at the Alhambra Palace, and to report upon the possibility of restoring it." The Council might save themselves the trouble of the latter inquiry. They cannot store it, at all events.

NOW that drawing has been made one of the obligatory subjects in public elementary schools the question naturally suggests itself—will it be made one of the ordinary elementary subjects in schools for the upper classes? Will the sons of professional men in the small schools, and in the great public schools, be taught drawing as part of the ordinary school course? The public schools are not quick to change their system, and it must be admitted that in regard to drawing they have hitherto been behind the rest. There are already artists enough and to spare, and an elementary knowledge of drawing is really a necessity of ordinary life. Not only for many subjects of study is it useful; it is also required in many details of daily life. Does a householder wish to have a new cupboard in his hall, a sketch of the article which is in his mind will explain his wants to the workman better than half-an-hour of verbal or two pages of written description. And we may put this argument on one side, and cause how can the private and public schools of England any longer refuse to regard drawing as a necessary part of a boy's education, when sons of artisans and labourers are in future to be taught the use of the pencil, and when drawing has been placed on a par with reading and writing in the elementary educational system?

MR. W. J. LOFTIE recently called attention in the *Times* to the acts of vandalism which are committed in Egypt. He pointed out that oftentimes portions of ancient monuments are broken up by the natives, in order to avoid the fact becoming known that they are in possession of these articles, such possession rendering them liable to punishment. But the preservation of ancient monuments nearer home is not an easy task, and considering that the preservation of the lives and property of native Egyptians has only recently, thanks to English and English officials, become an accomplished fact, we must not take it too much to heart if the monuments of ancient Egypt are not yet as safe as we could wish. But even the preservation of monuments in Egypt may be effected by a little English vigour and management, and we would suggest that were Mr. Loftie, and others interested as he is in ancient relics, to make representations to the Egyptian Government, to English officials, and the English Foreign Office something could very soon be done to put this matter on a better footing. But when we abuse the Egyptian officials, and the Egyptian fellahs, we must not forget the modern Goth, who, in the guise of an English or American tourist, traverses Egypt seeking some monument to disfigure with his initials, or some relic which he may purchase for his lobby in Kensington or Boston. Strict legislation against the acts of Vandalism committed by artists is as necessary as better laws for the preservation of Egyptian monuments against destruction by the fellah.

WE are glad to see that the Church of England Temperance Society has made representations to the Boards of the several English Railway Companies in regard to the supply of proper filtered water at stations. Suitable drinking fountains should be placed on every platform, and every refreshment room should be supplied with a proper filter where cold fresh water can be obtained. While we advocate these things, it is also well to give a word of warning. Drinking fountains and filters, unless carefully looked to, may become a serious danger to health, and the traveller, who at present may have to travel troubled with a thirst, may after all be better off than one who, having assuaged his thirst at a railway drinking fountain, has imbibed the germs of typhoid fever. It is for this reason that large properly-constructed cisterns, fitted up with a proper filtering apparatus, and placed in a cool position, well protected from dirt and air, are much safer than the smaller filters which are often seen in private houses and hotels, which are seldom as receptacles of dirt. But that drinking fountains, from which wholesome water may be obtained, should be found in every station we cannot doubt. The season of thirst is passing away, and that of cold is coming. We would, therefore, urge upon railway companies not only to put up drinking fountains, but to take better measures to warm waiting-rooms. The open fireplace warms only a narrow circle immediately around it, and it produces draughts. Every waiting and refreshment room should be uniformly heated by hot air or water. This is one of the greatest needs of the travelling public.

IN a communication to *La Construction Moderne*, September 13, an architect, M. Taravant, suggests the bold idea of hanging the centreing for large bridges instead of building it up. According to a diagram accompanying his article, he proposes carrying up a temporary wall in brickwork or masonry above the central portion of the pier between two intended arches of a bridge, and suspending from this a light system of iron bracing arranged somewhat like an inverted cantilever on either side of the central support, and to this system of iron bracing the timber centreing is to be fixed, following the quadrant form necessary for the half arch, which would be built on the centreing round the iron ties. How these are to be cut out and removed from the masonry afterwards is an important question, the answer to which may be given in the remainder of the article, which is decorated with an "à suivre" at the close. We presume it is hardly proposed that they should remain in the masonry. M. Taravant claims that on this principle much wider-span arches could be built than by depending solely on a built-up timber centreing. The advantage of the system, if it can be brought into use, would be most apparent in the case of viaducts on very lofty piers. For bridges of low proportions we doubt if it would offer any advantage either constructively or financially.

FROM some correspondence in the *Coventry Herald* it seems that the question what to do with the bells of St. Michael's is still a subject of agitation. The only point on which every one seems to be agreed is that the old tower will not stand a swinging peal of bells. The Rev. A. Starkey, the vicar of Ryton, writes to protest against erecting them as chiming bells, rightly saying that only by ringing do you get the full effect of bells. On the other hand he deprecates building a new campanile near the church, from fear of interfering with its architectural effect, and proposes building one at some distance on a site of its own, simply that Coventry people may have their bell peal again. That would be quite a mistake. The ringing of bells in peal has been associated with the church for ages; it would seem purposeless and lose half its beauty when "secularised." We believe it would be quite possible to build a campanile in contiguity to the church which would not

spoil it architecturally, and that no other course will meet the case. It is desirable to have the bells rung and not chimed, and to have them rung in connexion with the church; and to build the new campanile is the only way in which this object can be carried out.

MR. ST. JOHN HOPE wrote to the *Times* of Monday a letter, dated from "The Museum, Silchester," which ought to command attention from the commonsense and reasonable views which the writer takes as to what can and cannot be done at Silchester. Mr. Hope is one of the professed antiquaries (there are not too many of them) who does not allow his antiquarian zeal to betray him into a forgetfulness of facts and possibilities. He is speaking only too truly in saying that "no English Government and no such body as the Hampshire County Council will ever spend money on the acquisition of any site of antiquarian interest." Mr. Hope does not "bring railing accusations," he contents himself with simply stating the fact, which is indubitable. We are not clear that it is even the duty of a County Council to do so; County Councils were appointed for other ends. A Government is less restricted in its functions, and might very properly expend money on such objects under certain conditions; but no one can expect the Government of this country to indulge in such weaknesses. Mr. Hope's suggestion is that a more permanent Museum should be built on the site, for the safer housing of objects found, and that excavations should be continued, but on a system of covering up each portion as soon as all information has been extracted from it that is possible, in order to preserve the remains from disintegration by the weather. A regular system of planning each uncovered portion and connecting it with the rest should be carried on, so as to have in time a complete plan of the Roman city, with bench marks left on the ground which will render it easy in future to uncover again any part that may be desired, for inspection, without unnecessary disturbance of the ground.

IT is much to be regretted that there should be apparently an intention of discontinuing the services at the Whitehall Chapel on account of the small attendances; and we believe that one reason which has been given as accounting for this slight attendance is the correct one, viz.: that most people imagine that the services are not open to the general public, and require an application to an official for admittance. We were asked the very question only a few days since. We will therefore do our part towards making it known that the Sunday services at the Chapel Royal are as freely open to all comers as those of any other church in London.

THE discussion as to architects and engineers, started by M. Bourdais in *L'Architecture* of August 16, has had to be brought to a close by the editing committee, after a lengthy reply from M. Bourdais in the number for September 13, summing up with the dogma that the union of the architect and engineer is the most desirable ideal for the production both of "constructions décorées" and of "décorations construites." The same number contains an enthusiastic communication from M. Frantz Jourdain, decrying all attempts to mix up the architectural profession with engineering, and summing up with the exhortation "Let us remain architects and try to become artists." In the course of his letter he asks whether MM. Dutert, Bouvard, and Nenot came out of the "Ponts et Chaussées" or out of the Ecole Centrale, and whether they have not designed all their work (the large Exhibition buildings and the new Sorbonne) themselves. He admits that they did employ engineers, "payés à l'heure," to make their calculations, as they had draughtsmen to draw out their designs neatly, and "vérificateurs" to verify and regulate the quantities and estimates. "But this insignificant and ephemeral collaboration robs them in no

way of their personal merit and responsibility in the work": nor is the public deceived in the matter. The names of the architects of the Exhibition buildings, the men who gave them their form and design, pass, we are told, from mouth to mouth in common conversation: "ceux des ingénieurs contrôleurs sont restés dans le paisgrey," which seems to be the French form of the English name for a well-known neutral tint. There is more truth in this remark than would be quite palatable to engineers. M. Jourdain heads his letter with a quotation from "Guy de Maupassant"—"Quand vous voyez un ingénieur, prenez un fusil et tuez-le." This reminds one of Blake's remark on being shown some engineering drawings—"Ah, sir! these things we artists hate!" The French architects have certainly the faculty of being amusing in these kind of discussions, which we fear cannot generally be said of our own countrymen; how much of this elaborate "chaff" is to be taken seriously is another question.

#### BRUCE CASTLE AND THE MANOR, TOTTENHAM.

THIS historical and ancient estate, now covering about 20 acres, is placed in the market, with a view to its development for building purposes. It stands in Lordship-lane that leads from the high road to Wood Green. Hard by is the parish church of All Hallows, restored and partly rebuilt in 1876-7. In the graveyard lies Margaret, wife of Mr. Samael, civil engineer, and daughter of the Ettrick Shepherd. The property derives its name from having been the home of Robert, father of Robert Bruce, King of Scotland.

Computed at five hides or 128 acres, and valued at 25*l.* 15*s.* with 3 oz. of gold, the original Tottenham Manor, as undivided, belonged, *temp.* Edward the Confessor, to the Earl Waltheof, the Waldef of Domesday survey. Waltheof was son to Siward, Earl of Northumberland, to whom, as likewise to Maedliff, Thane of Fife, is attributed the defeat of Macbeth. He married, in 1068, Judith, the Conqueror's niece, and daughter to Odo, Earl of

de Balliol, and Henry de Hastings, descendants of David, Earl of Huntingdon. These are the competitors for the Scottish crown at the death of Margaret, the Maiden of Norway, upon whose claims Edward I. was invited to adjudicate.

Robert de Brus's son Robert, Earl of Annandale and of Carrick, is said to have retired to this manor-house upon his return from a crusade in Palestine. Dying in 1304, he bequeathed his share to his son and heir, Robert I. Upon the latter's revolt from England all his lands in this country were confiscated by Edward II. And so in course of time this part of the manor, being then held by a knight's service and valued at 10*l.* The two other portions were styled Pembroke and Balliol or Dawhneys. Bruce Castle, having suffered escheat to the Crown, was granted, in 1514, to Sir William Compton, Groom of the King's Bed-chamber. Compton set about to rebuild the house on a plan pretty much as we now find it. It appears to have been completed in 1516, for on the Saturday after Ascension-day in that year,

Key Plate, probably German Medieval Work.

Cover of a small Book, stated to have belonged to Queen Elizabeth: Silver Arabesque on Gilt Ground.

EXAMPLES OF DECORATIVE WORK.

#### EXAMPLES OF DECORATIVE WORK.

THESE two examples of the employment of decorative conventional foliage form a characteristic contrast in style and feeling, while both exhibiting the same general idea, that of foliated ornament drawn in flowing scrolls from a central or starting point. The Gothic design is thin, sharp, and crisp; the Renaissance one elegant, flowing and soft in its forms. Both are good examples of their class.

PRIZES FOR DESIGNS FOR FURNITURE, &c.—The Council of the Society of Arts hold a sum of 400*l.*, the balance of the subscriptions to the Owen Jones Memorial Fund, presented to them by the Memorial Committee, on condition of their spending the interest thereof in prizes to "students of the Schools of Art, who in annual competition produce the best designs for household furniture, carpets, wall-papers and hangings, damasks, chintzes, &c., regulated by the principles laid down by Owen Jones." The prizes will be awarded on the results of the annual competition of the Science and Art Department. Competing designs must be marked "In competition for the Owen Jones Prizes." The next award will be made in 1891, when six prizes are offered for competition, each prize to consist of a bound copy of Owen Jones' "Principles of Design," and the Society's Bronze Medal.

Albemarle. William I. had given it to his nephew-in-law, together with the earldoms of Huntingdon and Northampton. After the execution, at Winchester, of Waltheof, as a suspected traitor, in the year 1073, the manor, for an interval enjoyed by Judith his widow, devalued upon their daughter Maud, who brought it in marriage to King David I., son of Malcolm III., Can-Mohr. David I. was confirmed by Henry I. in all of Waltheof's titles and possessions.\*

As thus annexed to the earldom of Huntingdon, Tottenham Manor passed to Simon de St. Liz (Maud's first husband), and to his son and grandson of that title; and, on their failure in line, passed by royal grants to the Kings Malcolm IV. and his brother William the Lion, grandsons of David I., who died in 1153. William the Lion bestowed it upon his brother David, Earl of Huntingdon, whose son John, surnamed Le Scot, inherited from his mother, Maud, the earldom of Chester. John married Helen, daughter of Llewellyn of Wales, and died without issue. In 1254 a survey was taken for dividing the land between his co-heirs: Robert de Brus, John

Henry VIII. meets his sister Margaret, Queen of Scots, "at Maister Compton's hous hesside Totnam." Compton set up his coat-of-arms in the old porch; and is supposed to have built the three detached towers, one of which, near to the well, still stands. In 1605 it is thought by Thomas, Earl of Dorset; twenty years later Edward, Earl of Dorset, conveys it to two individuals, whose name is familiar in connexion with the history of the Grosvenor estate, London—Thomas and Hugh Audley. The Audleys, however, parted with the property within twelve months to Hugh Hare, elevated Baron Coleraine on August 31, 1625. His descendant, Henry, third Lord Coleraine, demised his estates to his natural daughter, Henrietta Duplessis, who (as the tale goes) being an alien could not succeed; yet the will, being legally executed, harred the heirs-at-law; so the property again escheated to the Crown. But a grant thereof was obtained by a private act in favour of Alderman James Townsend, who had married that lady. This James Townsend added an east wing on to the house which Lord Coleraine had new fronted with coigns and red brick. In Dr. Robinson's "History of Tottenham" (1840), is a plate copied, we gather, from Wolridge's picture, showing the Castle

\* For some particulars of Waltheof's parentage and career see Charles Kingsley's "Hereward the Wake."

as it appeared in 1686,\* with another that shows the house as it was fifty years ago, with a third story added in lieu of the four gables. The front has a lofty central tower, with galleries and cupola, flanked by two octagonal towers half engaged. On September 24, 1789, Thomas Smith, of Gray's-inn, buys Bruce Castle, with sixty acres, for £8,000. In 1827, John Ede, who pulled down the west wing, sells it, with fifteen acres, to the brothers T. W., Edwin, Frederick, and Rowland Hill (afterwards secretary of the Post Office), sons of Thomas Wright Hill, of Hazlewood School, Birmingham, who here established a boys' boarding-school that has continued to our own time. Dr. Robinson mentions a singular custom of this manor. At the death of the owner or tenant, his body was carried to the church through an opening made in the wall of the house, instead of through the porch. David I. of Scotland gave the church to the priory of Holy Trinity, London; Henry VIII. bestowed it upon the Cathedral of St. Paul.

#### THE PROBABLE EFFECTS ON WAGES OF A GENERAL REDUCTION IN THE HOURS OF LABOUR.

In the Section of Economic Science and Statistics, at the Leeds Meeting of the British Association last week (Professor Alfred Marshall, the President of the Section, in the chair).

Professor J. E. C. Munro, Owen's College, Manchester, read a paper on the above subject. In the course of his remarks, he said—A fixed, unvarying day for every worker is impossible, because (apart from the varying degrees of intensity of labour in different industries) of the necessity for preliminary work before the bulk of the labourers can begin their daily toil. We may assume for the purposes of this paper that a "normal week" for all skilled industries, due allowance being made for preliminary work, would correspond to forty-eight hours. From this point of view industries may be divided into three classes. 1. Those in which a normal day has already been established. In Cornwall, for instance, an eight-hours day has been in force for a long period of time in the mining industry. 2. Those in which the reduction would be of a moderate amount. Under this class may be placed industries where the reduction would not exceed 8½ hours per week—e.g., if the working week were reduced from 56½ to forty-eight hours. (3) Those in which the reduction would be very substantial in amount. A general reduction in the hours of labour will at first reduce the net produce available for distribution amongst producers. It is true that any improvement in the efficiency of labour due to shorter hours, the impulse that may be given to the invention of labour-saving appliances, or greater economy in the use of labour, will tend to lessen the reduction in produce; but in all industries of the second-class (i.e., where the reduction is moderate in amount), a class that includes most of the skilled industries of the country, the reduction in produce will at first correspond very closely to the reduction in hours. It has been suggested that the net production could and would be maintained (if not increased) by the employment of the unemployed. Such a suggestion implies that there is a class of unemployed possessing the requisite physical powers, mental intelligence, and technical skill required in the industries where the hours of labour are reduced. No such assumption can be granted. Indeed, there is ample ground for contending that, as far as skilled industries are concerned, the bulk of the unemployed do not possess the necessary skill to engage in them. The length of the hours of labour is not the chief cause of want of employment. Excessive hours of labour are themselves the result of causes which would largely remain in force even if the hours of labour were shortened, and whilst the shortening of hours might benefit in one way the unfortunate class whose condition is described in the "Lords' Report on Sweating," it will not of necessity maintain or improve their wages. Shorter hours of labour may co-exist with poverty, especially where the supply of unskilled labour is large and combination is absent. Low wages are largely responsible for the long hours of the unskilled worker, and the first step towards the amelioration of his position would be a rise in wages rather than a shortening of hours, as the latter would follow

the former. Let us, however, assume that by the employment of additional hands the net produce (say in a year) is maintained. We have now the same amount of net produce as before, but a greater number of producers. In other words, though the total produce is the same, the production per producer per year is reduced, and from the point of view of distribution the net production per head per annum is of greater importance than the net produce. Before considering on which of the classes of producers loss in production will fall, the question arises, Will the loss be restricted to those industries (a) in which the reduction takes place, or will it extend to other industries (b)? If the (a) producers consume their own products the loss will fall on them; but, as a rule, one form of wealth is created in order to be exchanged for another form, and hence to the extent that the (b) producers are consumers of the (a) produce they will participate in the reduction of the net produce. If the demand of the (b) producers continues in intensity they may have to bear the whole loss; on the other hand, the demand may fall off to such a degree that the (a) producers will suffer; but the probability is that the loss will be shared between the two classes, and therefore all industries will tend to be affected. A reduction of hours in some trades will tend to affect all other trades, inasmuch as by the migration of capital and labour the reduction in the net produce may be spread over all industries. Whether the capitalist or the labourer will bear the loss will depend largely on two considerations, viz., (1) the extent to which labour or capital migrate to foreign countries, and (2) the effects of the reduction of hours on population and on capital. The effects on capital are so important as to require separate consideration; and since population will not be directly affected we have only to consider the possibility of capital and labour migrating to other countries. In this respect capital has the advantage. Owing to the growth of banking and financial houses, and the development of foreign trade, capital possesses an international organisation, and can be promptly and readily directed to the best openings. Labour, on the other hand, moves slowly; it deteriorates by non-use, and possesses no international organisation. It is, therefore, highly probable that a large share of the reduction in the net produce, due to shorter hours, will be thrown upon labour. It remains to consider how far the foregoing conclusions may be effected by (1) monopolies; (2) combination; (3) methods of paying wages. (1) A monopolist, whether a private person or a group of persons, or a municipality, or a State, will usually be able, according to the intensity of the monopoly, to throw the whole or part of the loss due to a reduction in the hours of labour in his industry upon those who use the article or the service subject to the monopoly. (2) Combination may be resorted to by labour as a method of preventing outside labour from coming into an industry. To the extent that combination enables producers to control the production of a given article, to that extent a trade may escape sharing in a loss due to a reduction of hours in other trades. (3) Hitherto the methods of paying wages have not been taken into account. As a rule, wages in the skilled trades are paid by piecework; the spinner and the weaver receive a certain rate of wages for every yard they spin or weave respectively; the miner is paid by the ton, and the bricklayer by the yard. In other trades wages are paid by the hour, whilst in the unskilled industries wages are paid by the day of a varying number of hours. A reduction of hours where piecework prevails would not *ipso facto* affect the "rate" of wages, but would lessen the "amount" of wages, inasmuch as a fewer number of yards would be woven and a fewer number of tons obtained in the shorter hours. The wages earned in a year would be reduced in proportion to the reduction in hours. But this would not leave the capitalist in the same position as before, as he would have a smaller gross return on the same amount of fixed capital; and if he has only been receiving an economic return before, a reduction in the "rate" of wages may be required to prevent a migration of capital into some other industry. Where wages are paid by the hour similar results would follow. In both the above cases the method of paying wages is such that a reduction of hours reduces automatically the "amount" of wages without affecting the "rate" of wages; but

where labour is paid by the day the method of payment will, if no alteration takes place, continue the same wages as before for a smaller amount of labour. In so far as the net produce is diminished a check will be given to the accumulation of capital. Capital will tend to avoid undertakings where the reduction of hours lengthens the time of completion. Where interest is paid on capital out of capital during the construction of the works, any extension of time will necessitate a corresponding increase in the capital required, just as any contraction of such time will reduce the capital required. Hence we reach the conclusion that the reduction in the hours of labour may check the accumulation of capital and cause at the same time an increased demand for it, and so raise the rate of interest. The adoption of a double shift, say of eight hours each, instead of one shift of, say, ten hours or twelve hours, will increase production more than the reduction of hours diminished production, and as such a system is only possible in certain trades, its sudden adoption will affect relative values. Turning to the products of labour that are bartered between nations, a reduction in the hours of labour may (1) destroy the gain arising from international trade, or (2) only diminish it. Where an exporting country possesses a monopoly of production arising out of climate or natural resources, it will be able to make a better bargain in the export market than if such a monopoly did not exist. To the extent that a country reducing its hours of labour possesses a monopoly of production, it may throw a large portion of the loss on its foreign customers. But a monopoly that depends on special productive power may be destroyed by a reduction in hours, and foreign customers may be able to obtain better terms from other States. The main conclusions, then, at which we have arrived may be summed up as follows:—1. That a reduction in the hours of labour which is neither universal nor uniform will tend to reduce the net produce available for division amongst the producing classes, but such reduction may be lessened or counteracted by greater efficiency in labour and in the use of capital. 2. Capital will be able to throw a portion of the loss on labour, and labour generally will be affected. 3. That any check to the accumulation of capital due to the reduction in the net produce will tend to raise interest and lower wages, but this may be avoided to some extent by the more economic use of capital. 4. That the reduction in hours will not necessarily lessen the number of the unemployed, inasmuch as it will not increase the purchasing power of the consumer, and will not affect the chief causes of poverty incident to our present organisation of industry. 5. That the position of the chronic unemployed or residuum will not be materially improved. 6. That in so far as additional labourers are employed to maintain the net produce, it will be at the expense of other workers, if the net produce remains the same but the number of producers increases.

In the discussion which followed (we condense somewhat from a longer report in the *Leeds Mercury*).

Sir Douglas Galton said he wished to emphasise the very great importance of the health of the working man. Health depended largely upon diversity of occupation, and the more we concentrated our working men on special work, the more necessary it was that working men should have leisure hours for recreative purposes. He should advocate, and hoped to see some day, a larger number of gymnasia in our towns, and other means for physical recreation. We might then hope that our population would increase in stamina and strength, and we might, perhaps, hope to rival the ancient Greeks, who devoted so much time to these exercises. He was strongly opposed to an eight hours day being brought about by Act of Parliament.

Professor A. T. Hadley (Yale College, U.S.A.) said that some years ago it happened that in the State of Massachusetts the hours of labour in the factories were ten per day; in Connecticut they were, generally speaking, eleven, and a careful investigation was made ten years ago by Colonel Wright, of the United States Labour Bureau, into the effect of this difference. The result was surprising, for the statistics showed that the output per day was slightly greater (although only a nominal difference) in the ten-hour mills of Massachusetts than in the factories of Connecticut, where eleven hours per day were worked. A suggestion that this

\* See also the corresponding woodcut in Hone's "Year Book" (1845).

was due to the health of those working eleven hours being injuriously affected, and that consequently they did not work so well as those who enjoyed the extra hour for recreation, was thoroughly investigated, but was found not to meet the facts of the case. In the end it was discovered that the difference was largely due to the fact that the workmen at the Massachusetts mills were of a superior class to those in Connecticut. There was a process of natural selection going on amongst those who did not mind the long day and could not stand the increased pace, and those who cared more for the extra hour of leisure and minded less the necessity for increased exertion. When men worked shorter hours they must increase their output in order to compete with those working longer hours. Suppose there was a general reduction of hours, and the output was maintained, things would go on as usual; but if the output were lessened, there must be an increase in the cost of production, and, in consequence, a diminished demand for the goods.

Mr. Sydney Webb said he did not agree with Professor Munro when he laid such stress on the almost inevitable necessity of the production being so much reduced by a reduction of the hours of labour. Experience showed that a reduction of the hours of labour had been accompanied by an increase of production. It was, of course, unfair to suppose that a similar increase would hold to a corresponding extent by the reduction from ten hours to eight, or from eight to six. Although Professor Munro argued well in favour of an eight hours day, he was too much afraid that prices would rise merely because the cost of production had increased. The cost of production had little to do with prices, and he could not see how it would have much to do with capital which was not employed at the margin.

Professor Sidgwick remarked that a great deal of Mr. Webb's argument seemed to ignore the fundamental propositions of Professor Munro's paper. He (the speaker) agreed to a great extent with the chief economic conclusions of that paper. He agreed with Mr. Munro as to the very different effect that this change would have upon different industries, producing thereby, as a natural result, a disturbing effect in the exchanges as among the industries. He would also lay stress on the fact to which Mr. Munro directed attention, that it was *prima facie* absurd to have the same rule applied to all industries, considering the very varying degrees of hardness in the work when they passed from one industry to another. He held it reasonable to expect that in most cases the decrease in produce as a whole would be very material, and more than they could expect to be counteracted either by the improvement in the personal quality of the labour or by the improvement in the instruments, or their adaptation to labour so far as that improvement was caused by the change. It was sometimes supposed that loss would be prevented by a change in the proportion of the employed. Though, no doubt, a certain increase must be expected when the change occurred, still, if they looked at the causes of the want of employment, they would find that they were not of the kind that this change could tend permanently to remove, and they could look forward to no gain from that cause; and, as had been said, the disorganisation of the industry would largely operate in the opposite way. As to the question of the adaptation of capital, he thought the most important suggestion was the double shift. He had always been interested in the question whether great gain in the efficiency of labour might not come from more extensive use in manufactures of the double shift, and if the introduction of the normal week took place he should hope for some compensation in that way.

Mr. G. G. W. Balfour, M.P., replied to some of the arguments advanced by Mr. Sydney Webb.

Mr. John Leech remarked that the curtailment of the hours of labour must inevitably enhance the cost of production, it being generally conceded that a limitation of the hours of labour would not be accompanied by a corresponding reduction of wages. The cost of the articles produced would be increased, and that would in all probability have a serious effect upon our foreign trade, and also upon our home trade. With our present system of fiscal arrangements we should be compelled to receive from foreigners a great number of articles for home consumption that we now supplied ourselves, and we should be unable to export to

foreign nations many goods we now made in consequence of the increased cost. Unless we could arrange that the hours of labour in foreign countries should be limited to the same as in our own country, we should be at a great disadvantage.

Mr. R. H. Inglis Palgrave said it was probable that some persons there had had the price of gas raised in consequence of the increased cost of production. He happened himself to be interested in that manufacture, and to the great regret of those concerned in the management, within the last few days the price of gas had had to be raised, simply and solely in consequence of the rise in the cost of production.

Mr. J. H. Levy said that Great Britain was a country that carried on its trade to a much larger extent with the use of capital than other countries; that was to say, the production of our goods was much more that of capital than of labour. Now, if they proceeded in the way we are employed at work; but any legislative enactment to insist upon these reduced hours would simply produce such a derangement of economic arrangements at home as would absolutely destroy a very large amount of our foreign trade. To his mind, the tyranny which Trades Unions was exerting over a large number of the labouring population of our country was forcing them to take measures which were contrary to their real interests.

Mr. Stephen Bourne remarked that he longed for the time when eight hours would become the privilege and right of labour in this country. Although he had been accustomed for fifty years of his life to do a larger amount of labour than that himself, he believed that eight hours a day was quite a sufficient period for a man to be employed at work; but any legislative enactment to insist upon these reduced hours would simply produce such a derangement of economic arrangements at home as would absolutely destroy a very large amount of our foreign trade. To his mind, the tyranny which Trades Unions was exerting over a large number of the labouring population of our country was forcing them to take measures which were contrary to their real interests.

Professor Munro having replied, The President, referring to some tabulated statistics in Prof. Munro's paper, asked whether they would believe that in this civilised country the Government had hitherto positively refused to attempt to collect industrial statistics. This was the only civilised country absolutely devoid of these figures. What they wanted was an expression of public opinion in favour of the Government providing the few thousand pounds required for an Industrial Census Department, organised on economic grounds, and managed by economists or by men of business. The establishment of such a department would bring about a gain to the country very much greater than the trifling amount it would cost. Proceeding to discuss points raised by Professor Munro, the President said that the fundamental weakness in the argument of those who favoured a reduction in the hours of work was that it would raise wages, and he had also seen it assumed that one effect of the change would be to diminish the number of unemployed. He did not think there was any evidence of that. They would require clearer evidence than they had as to how many men there were unemployed who were willing to work or capable of working. And he should wish to exclude those men who having grey hairs, were not worth to the employer the full Trades Union wages for the district, and who were, therefore, prohibited by their Unions from working. He believed that if the Unions would allow men who had become old, and were, therefore, not as efficient workmen, to work for less than the standard wages, a great deal of wrong would be remedied. With regard to foreign trade, he thought foreign competition was important in this way,—if we were to work less, and consequently to endeavour to make capital content with a lower rate of interest, capital would, so far as possible, and to a very great extent, migrate to other countries. If, however, the reduction were universal, this would be avoided. From that it might be admitted that an international movement would be easier than a national one; but that was nearly all he was prepared to allow in the argument that foreign competition was a bar to a

reduction of hours of labour which was not universal. A change in the hours of labour, which did not disturb the relative values of things would not disturb foreign trade. Looking at the question generally, he should put it in this way,—a reduction of the hours of labour in most trades, not in all, diminish the output. Part of the loss would be thrown upon the capitalist. If the change was introduced spasmodically, it would disorganise labour; but if it was introduced gradually capital would bear a little more diminution of income than labour. If a reduction from ten hours to eight had the effect of diminishing the output by 20 per cent., he thought it probable that the day's wages would fall something less than 10 per cent. if brought about gradually, the rest being borne by capital. The question arose whether it was worth while, and it was one incapable of any universal solution. He could not admit that eight hours was too long for anybody to work. Much of what was called work he should call looking on. As regarded the children, he was of opinion that factory legislation had not gone anything like far enough. Children should not leave school so early as they did at present. Such a tax on the community as would be necessary if children were kept longer at school would diminish the incomes of the present generation but, slightly, and it would increase them in the next generation tenfold.

#### THE MARBLES AND ORNAMENTAL ROCKS OF THE MEDITERRANEAN.\*

WHILE the waters of the Mediterranean Sea are opalescent, abounding with fish of the most exquisite colours and hues, and with sea-weeds equally beautiful, the rocks which surround this basin sea, along with those of its islands, are equally beautiful in colour, and have from the earliest times supplied nearly the whole of the valuable marbles used for the architectural adornment of the cities of Greece and Rome; and if we only include a moderate inland belt of the coast line within the watershed to this sea, we can then call almost every fragment of ancient marble found in Greece and Rome and their colonial cities Mediterranean marbles.

The classic Greeks may be considered the pioneers in the working of marbles, the origin of which is easy to understand. White marble was the stone most easily obtainable in large sizes for architectural purposes, and no doubt this choice material, which was capable of taking and retaining the most delicate chisellings with its ivory-like tinting and semi-transparency, played its part in the refinement of both architecture and sculpture in the ancient world, and it is possible that the outcome of their refined colour-decoration may have been in great measure requisite to subdue its dazzling brightness under an Eastern sun. The Romans, in their turn, endeavoured to obtain lasting colour in their buildings by the introduction of coloured marbles, which the Greeks had all but neglected, the result of which introduction was the magnificent colour-decoration of Rome and Byzantium, the influence of which has continued through all architectural changes and styles down to the present time.

The demand is now so great for varieties of choice coloured marbles, not only for architectural decoration, but for articles of vertu and furniture, that not only has search been made for the various quarries of the ancients (all of which except one have been discovered), but hundreds of new ones have been opened and worked in every part of the explored globe. In the midst of all this modern adventure, the ancient quarries of the Greeks and Romans on the shores of the Mediterranean still retain their pre-eminence.

Greece has her white-marble quarries at Mount Pentelicos; these supplied the material for the Acropolis of Athens and the Greek temple of Jupiter Olympus, and the Pantheon of Rome; those of Paros produced the finest material for sculpture, and also, in my opinion, the marble for Herod's temple at Jerusalem. Several of the islands also produce good white marbles, and in all these white formations are found every variety of greys. The Cipolinos were quarried chiefly at Carystus, from whence were taken the monoliths for the temple of Antoninus and Faustina in Rome. These are the largest marble columns known.

\* By Mr. W. Brindley, F.G.S., F.R.M.S. Read before the Geological Section of the British Association Meeting at Leeds, 1884.

The beautiful Verde Antica green porphyry comes from near Sparta, and the green marbles from the shores of Magnesia, Thessaly, and Tinos.

The Rosso Antico have all been refound on the coast between Cape Matapan and Gythium.

The grand quarries of Porto Santo are still workable at the island of Chios; black marbles are found in several places, and varieties of pavonazzetto at Skyros.

The famous quarries of Synada, in Asia Minor, which supplied Rome with her monoliths of Pavonazzetto marble, were found last year. There are sixteen quarries of immense size, alongside of each other; these are about to be re-worked.

Between Smyrna and Ephesus are white marble quarries, but the most important blocks used for the Temple of Diana, at Ephesus, came from Pentelicus or Paros, although some may have been taken from Samos.

At Tarsus are quarries of ivory white marble, from which the Temple was built. All the white marble used in Egypt came from the Mediterranean.

History tells us little about the old quarries of Greece, but the architectural remains of Greek and Roman cities show plainly that their produce was enormous; eight-tenths of the white marble found in Rome is Greek; and the quantity of worked material recklessly burnt as lime for centuries must have been enormous.

Byzantium was chiefly built with the marbles of the Sea of Marmora; and these quarries are still worked for Constantinople; and most likely this sea takes its name from being really a marble basin.

The produce of the quarries of Egypt brought down the Nile for Roman use may be called Mediterranean, the most valuable of which were those of imperial red Porphyry; these are now being re-worked, the first important consignment of 270 small blocks having this last month arrived in London, the remains of ancient working on some of these blocks being most interesting, showing that they are not only wedged, scabbled, and chiselled, as is now done, but that they were even sawed blocks of this hard material asunder.

The Breche Verde of Egypt, the granites and oriental alabasters, were all extensively worked and floated down the Nile for shipment to Rome and other cities.

Ancient Numidia (now the eastern portion of Algeria and the west of Tunis), produced the Giallo Antico; these quarries are very extensive, the Romans having quarried right through the mountains; from here came the yellow monolith columns of the Pantheon in Rome, and those of the Arch of Trajan, now re-used in that of Constantine.

At a number of places along the Algerian coast are ancient quarries of rich coloured marbles, chiefly reds and yellows; from those of "Cape Chionna," near the ancient Julia Cesarea, the capital of Mauritania, was brought the rich red marble (rouge Etruscan) used for the decoration of the new rooms and staircase at the National Gallery, London. Further west, at Kleber, near Oran, there are the famous quarries of Sig. Del Monto; these marbles are unquestionably the richest (as regards reds and breccias of red, yellow, and browns) that have ever been discovered in any part of the world; they are now largely used in America. The Algerian onyx marbles are found near Oran, and red ones have recently been discovered at Guelma, in the west of Algiers. The Mediterranean coast of Spain for thirty miles inland abounds with marbles of every colour.

There is first the sparkling crystalline statuary of Macael with which the Alhambra was built, the rosy veined of Tarragona, the rich Broccatello and jaspers of Tortosa, the red and orange blended Broccatello and onyx of Malaga, the Griotte deep reds, blue Turquin and fossil of Gevona; also the precious green Serpentine of Granada, which has scarcely a rival in richness of colour and firmness of texture. Many of these were worked by the early Romans and Moors.

On the French Coast are quarried a number of deep and light reds and brecciated yellow.

The ancient quarries of Luni, now Carrara, are at the present day the most renowned in the world, and considered, with the adjoining ones of Massa and Seravezza, to cover an area of 27 square miles. The marble rocks commence a little above the sea-level, and extend up the mountain to an altitude of 7,000 ft., the

whole of the sides and valleys of these mountains being studded with innumerable quarries, giving employment to 15,000 people, the result of whose labour supplies probably 90 per cent. of the white marbles used in the world.

These quarries were known and worked by the Romans, and have been worked continuously since before Christ, but the immense development has taken place within the last fifty years, or we might even say the last thirty years.

Probably no single individual has visited the whole of these quarries, not even interested residents. To see and examine them all would take an entire season.

The most valuable marbles of the Apennine range are those of Mont Altissimo, at Seravezza, situated at an altitude of 7,000 ft.; here the most beautiful and durable statuary is found in immense beds, masses being extracted of the pure quality containing thousands of feet cube, the value per foot being 2*l.*, or even more; single blocks worth 500*l.* each are often obtained, and occasionally up to 1,000*l.* This marvellous mountain of Altissimo produces also a statuary grained marble of blueish tint, nearly the whole of which is sent to France for statuary purposes, as it is extremely durable for exterior work. The famous coloured breccias of grey, red, and purple, the Rhodona, Toir de Perchia, and others, are found here in large masses, also the blue-veined Bardilio and a Cipollino. The promontory of the Gulf of Spezia (Porto Venere) is one massive rock of black and gold marble. Near Genoa are the quarries of Green serpentine limestone; the one containing red spots is called in commerce Egyptian.

Similar marbles are found in Corsica, also the purple-veined (Flor de Persico), and a rich mixed green and amethyst coloured granite used largely in the Medici Chapel at Florence; the orbicular granite (Napoleonite) is also obtained from this island.

Between Sienna and the coast there are the rich quarries of Sienna yellow (this beautiful marble is not found in ancient Rome).

At Volterra, near this coast, is obtained the pure white Italian alabaster; and at Prato, the deep olive-green serpentine used so extensively at Pisa and Florence.

At Mount Rommola, near the coast, are ancient quarries of statuary white.

Sicily contains several good marbles. Near Trappini, on the west, the choice jasper marble is obtained, also the rich coloured silecons jaspers.

At Tauromena are quarries of reds and browns.

The rocks of Brindisi and those of the opposite Adriatic coast, up to Istria, are a fine-grained white limestone; this is the stone with which the Venice palaces are built, the white sort being the Palamino, found in Mosaic pavements. East of Trieste a useful red marble, like the Broccatello of Verona, is worked very extensively.

I hope, in conclusion, this short but very imperfect summary may give some idea of the money wealth in the Mediterranean rocks.

#### ARCHITECTURAL ASSOCIATION

##### VACATION VISITS:

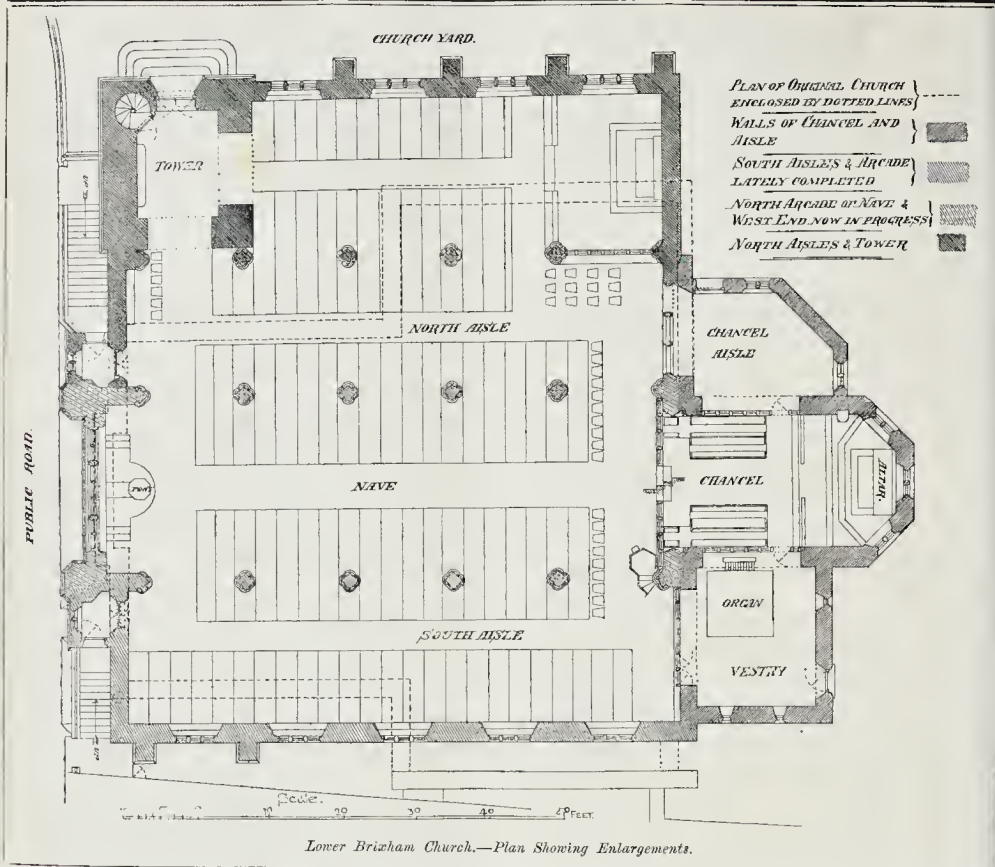

###### KNOLE HOUSE.

THE fifth vacation visit was made on Saturday last to Knole House, the seat of Lord Sackville, when a party of over thirty members visited this remarkably fine and interesting Elizabethan and Jacobean mansion. Knole appears to have been a notable manor-house from very early times, and for a considerable period was associated with the Archbishops of Canterbury, by whom it was used as a country seat, together with their palace at Otford. Knole was bought for 400 marks by Thomas Bouchier, Archbishop of Canterbury, in 1456, from William, Lord Saye and Sele, the son of the Lord Treasurer, who perished in the insurrection of Jack Cade. Archbishop Bouchier rebuilt the house and enclosed the park, and possibly some of the ruins which are situated to the east of the mansion may have formed part of Bouchier's work, besides what remains of it in the present building. Archbishop Morton, successor to Bouchier, enlarged the house and received there as guest King Henry VII. Henry Dean and William Warham, successors to Morton, resided occasionally at Knole, Warham in particular having there several times entertained Henry VIII. In the days of his successor, Cranmer, however, the

spoliation of the Church had been begun by Henry and his courtiers, and the Archbishop was therefore under the necessity of giving up Knole together with other possessions of the See in order to save the remainder. The house and manor belonging to the King, he then bestowed them on John Dndley, Earl of Warwick, afterwards Duke of Northumberland; on his attainder in the first year of Queen Mary the property reverted to the Crown, and she granted it to Cardinal Pole, and at his death, in 1558, it again came into the possession of the Crown. Elizabeth presented the Manor to Sir Robert Dudley, afterwards Earl of Leicester, but he again surrendered it to her and she then bestowed it upon Thomas Sackville, first Earl of Dorset, who came to reside here in 1603, and constantly employed two hundred men upon alterations, and repairs until his death in 1608; it is, therefore, in the highest degree probable that it was during these years that the greater part of the existing features of the house were carried out, and the character of the work would certainly bear out this assumption. For a time, owing to the extravagance of Richard, grandson of the first Earl of Dorset, the property was sold to Henry Smith, Alderman of London, whose benefactions to various parishes in the counties of Kent and Surrey are of a very considerable extent. By his trustees, however, the property was again sold to Richard Sackville, Earl of Dorset, nephew to the former, in 1661, since which time it has continued in the possession of his descendants. The present title of Baron Sackville was revived in 1876 in favour of Mortimer Sackville-West, brother of the present Peer.

Architecturally, the main features of the plan are the two great quadrangles, one behind the other. Entering the first by the carriage entrance, and noting the horn lanterns and silver maces, one receives a foretaste of the distinguishing characteristic of Knole, its richness in old furniture, decorations, and accessories of Jacobean and later periods. In the outer quadrangle are replicas of ancient statues, a gladiator and a Venus, *orta mari*. From the outer to the inner quadrangle the entrance is below a massive tower which forms the central feature of the principal front of the outer court. Fronting us as we enter the inner quadrangle is a colonnade, evidently a later addition to the outer wall, and through this we enter the house and reach the great hall, still the important feature of the interior, whose dimensions are 74 ft. 10 in. in length, 27 ft. in width, and 26 ft. 8 in. in height.

The screen through which we enter, and the minstrel-gallery over, decorated with the arms of the first Earl of Dorset and his Countess, is a good example of the Jacobean treatment of this feature, but loses all charm by reason of its having been "painted four times in good oil colours, grained wainscot, and twice varnished," the wainscoting and other wood-work of the hall having shared the same fate. Even the fireplace has been "grained imitation marble," which, however, throws into stronger relief the high character of the beautiful workmanship of the fire-dogs, which, we are told, were brought from Hever. The principal staircase, one only of the sixty or eighty said to be in the house, has likewise suffered from the attentions of the eighteenth-century painter and decorator, which detracts much from one's enjoyment of the really pleasing design and arrangement of its planning. Remembering the effect of Hatfield, Audley End, and other houses of this period visited lately by the Association, it is pitiable to realise how much charm has been lost by the vagaries and vandalism of vehicle and varnish. In passing through the principal reception rooms, the richness of the house in fine pictures is especially noticed, as when we find, for example, that the Crimson Drawing Room is completely hung with works of Sir Joshua Reynolds, any one of which would make an ordinary man proud. Tapestry, too, of somewhat late date it is true, but exquisite in design, execution, and preservation, meets our view repeatedly, notably in King James' Room, and in the Chapel. The collection of ancient silver also, in King James' room and elsewhere in the house, is remarkable both for its design and its intrinsic value. The number of ebony and other carved cabinets would in themselves signalise many a museum of ordinary size, while ancient Oriental carpets and rugs, hangings and upholstery of costly embroidery, and other rare and valuable bric-à-brac, afforded the visitors a treat which

will not easily be surpassed. Even the attics, to which the party penetrated, proved a mine of wealth in decayed and decrepit specimens of household goods which form a veritable history of domestic furniture for the last three centuries. To the architect, the picture lover, and the enthusiast in bric-à-brac few of the stately homes of England offer greater attractions than Knole House, which through the generosity of the present Baron Sackville is once more open to the inspection of the curious,—at a florin a head.

### Illustrations.

#### THE OLD BRIDGE AT PRAGUE.

**T**HE old bridge at Prague, which has been so seriously (though, we trust, not irreparably) injured by the overflowing of the Moldau is, without doubt, one of the most valuable structures of its date and class in Europe. It is one of the very few, if not the only example, of an important fourteenth-century bridge with its towers and gates complete. In addition to this, this venerable bridge claims our attention upon other grounds. From an architectural point of view it is most valuable as being the work of one of the greatest Medieval architects whose name has been banded down our day.

There appears to be sufficient documentary evidence to establish the fact that when the Emperor Charles IV. commenced this bridge, in the year 1357, he appointed Peter Arler, of Gmünd, as his architect; there were two members of this family, brothers, who have left a great reputation—Peter and Henry. Peter erected the choir-story, transept, and lofty spire of the cathedral at Prague. The spire, which is said to have been the biggest ever erected, was destroyed by lightning in 1541. The Wenzel Chapel, attached to the Cathedral, the

Rath-Haus at Prague, the churches at Kolm, Brun, and Nordligen are also attributed to Peter Arler. Henry became still more famous; he erected the magnificent church of Holy Cross at Gmünd and, under the Italian appellation of "Enrico di Gamodia," furnished the plans for the Cathedral of Milan.

The bridge at Prague appears to have been carried on slowly, even for a Medieval work. The beautiful tower of the Altstadt, called the "Albstädter Brückenturm," which is shown in our view, was not completed until 1451, and the bridge itself was not entirely finished until 1503. There can, however, be no doubt that the bridge was in use long before that time, as John Nepomucine was thrown from the parapet into the water in the year 1383. The great monuments which stand upon the piers of this bridge are, with one exception, comparatively modern; that exception is the so-called "Old Memorial Column" (Alten Denksaule), which is adorned with Gothic panelling and angels holding shields, and on the summit is the statue of a knight in full armour, whose head and shoulders have unfortunately disappeared. A large group, representing the Crucifixion, was erected in 1668, and the bronze statue of St. John Nepomucine, the only really valuable piece of sculpture on the bridge (with the exception of that attached to the Altstadt Tower), in 1683. The bridge itself is 1,572 ft. long, 33 ft. broad between the parapets, and, at its highest point, 42 ft. above the water-mark when the river is in its normal condition. The widest arch is said to be 69 ft. span, but this may be doubted; it certainly does not look anything like so much. As in all ancient bridges, the piers are immense in proportion to the span of the arches. There are sixteen of the latter, though they do not all cross the water, as there is an island which intervenes between the two banks. The bridge is not straight in plan, but makes two deflections—one very slightly to the south just beyond the third arch from the east end, and the other very decidedly

to the north. It is not easy to account for this peculiarity; it may have arisen over some difficulty in the foundations of the piers. The tower, which is shown in the foreground of our view, stands upon a great pier between the first and second arches; it is an exceedingly fine piece of design, and is, in all probability, for the greater part, the work of Peter Arler, because the cognizance of the Emperor Charles IV., the bear, is represented upon the finial of the canopy over the archway, and that emperor himself is portrayed as standing upon a pier between two arches of the bridge.

It is very rarely that one finds a Medieval example of military architecture so elaborate as to its detail. Yet not only was it intended for purposes of defence, but it has borne a very important part in the constant battles of which Prague was the scene during the fifteenth, sixteenth, and seventeenth centuries, and as late as 1648 the Swedish army battered and besieged this gate for six weeks, which accounts for the fact that the front towards the bridge has been deprived of all its decorative features, whereas that towards the Altstadt is, as shown in our view, very rich and elaborate. The gateway leading to the "Kleinsseite," is quite different in design; it consists of an embattled portal, flanked by towers of different height. It is far plainer than the Altstadt Gate, though its bracketed turrets and upper story are adorned with well-designed arcades and niches.

It is not very easy, at present, to say exactly what damage has been done to the bridge by the recent floods. Accounts are contradictory, and until some competent authority has examined it it is impossible to say what repairs are rendered necessary, and how much of the structure will have to be taken down and rebuilt. We trust, however, that the Austrian Government will take such steps as are necessary to save as much of the old bridge as is possible, and will immediately commence such engineering works in connection with the river itself, as will prevent the recurrence of a calamity which

THE BUI

INTERIOR OF THE PARISH CHURCH LOWER BRIXHAM SHEWING NEW NAVE & AISLES.

Mr Somers Clarke & Mr J.T. Nicklethwaite Architects.

has caused so much destruction all over Bohemia.

We should mention that our view, in addition to the bridge, shows the Church of St. Francis, immediately to the right, which, although founded in the thirteenth century, was entirely rebuilt in 1672; in front of this stands the modern statue and monument to the great Bohemian emperor, Charles IV. On the opposite side of the river are seen the part of Prague called the Kleinseite, or "Little side," and rising above it is the "Hradscetin," crowned by the palace of the emperor and the houses of the Austrian and Bohemian nobility. The great dome-crowned church is that of St. Nicholas in the Kleinseite, originally built in 1283; it was rebuilt from 1673 to 1774. To the right of which is seen the thin spire of the Church of St. Thomas,—a thirteenth-century building, but completely modernised; and to the left, over the bridge, rise the stunted towers of the Church of the Knights of Malta, rebuilt in the year 1503. On the top of the hill, to the right, are the spires of the Premonstratensian Priory of Strahow, the church of which is a very plain Romanesque building, commenced in 1140. It contains a fine organ with fifty stops and 3,177 pipes. The library of this monastery,—the most ancient in Prague,—contains 50,000 volumes: attached to it is a large picture gallery and a hospital. Crowning the hill to the left, called "Laurens Berg," are the twin spires of the Church of St. Lawrence; but, as this has been taken possession of by the military authorities, it is closed to the public, and the writer was unable to inspect it, which is to be regretted, because the chapels attached to it are adorned with a series of pictures by Furich, which are said to be fine examples of the modern German school of religious painting. The more interesting old churches of Prague—the cathedral, the "Teln Kirche" (the chief Bohemian Church), and the Benedictine Church of "Kloster Emmaus"—lie out of the range of this view.

H. W. BREWER.

ALL SAINTS' CHURCH, LOWER BRIXHAM.

EARLY in this century the increase of population made it desirable to separate the old parish of Brixham, and to serve the "trawlers," a rectangular box, some 75 ft. long and 40 ft. wide, was constructed in Lower Brixham. This was covered in with a queen-post roof, and celled flat at the level of the ties, about 27 ft. from the floor.

This building was enlarged by transeptal projections, with two stories of galleries, and is shown on the plan by the dotted lines. About twenty years ago, a mean little chancel with aisles was constructed.

The site selected for the church falls so rapidly from the chancel to the end of the nave that, whilst the floor of the latter is 10 ft. above the road outside, the eaves of the former are level with the surface of the hill.

It was determined in 1883 to rebuild the nave, but to retain as far as possible the number of seats given in the old church and galleries. It being impossible to burrow further into the hill-side, or to lengthen the nave by encroaching on the road, the necessary floor space had to be got laterally. The funds in hand did not admit of the work being carried out at one time, and it has consequently been necessary so to plan the work that the old building should be left and used in conjunction with the new. The first work was the construction of the south arcade, and when the roof was supported by it, the old outside wall was pulled down, and a new one built, completing the south aisle of the future church. This aisle is constructed of local blue limestone from Berry Head. The arcade and other internal stonework are of Ham-hill stone, the window tracery and other stone on the exterior are from the Douling quarries. The aisle thus formed is 18 ft. 3 in. wide clear internal measurement, and 75 ft. long and about 27 ft. high. The roof is of iron joists and concrete by Drake & Co., covered with Claridge's asphalt. The concrete is celled underneath with boarding and moulded ribs.

The work now to be undertaken is the construction of the north arcade of the nave, still leaving the old queen-post roof, which will not be removed until later on. The west wall, suited to the pitch of the intended nave roof, is also now to be taken in hand. This contains a seven-light window with flowing Decorated tracery.

The north wall of the old church will still be left standing, as there are not sufficient funds in hand to admit of the aisles being finished at once.

When the nave is roofed the existing chancel arch,—a very lean and unsatisfactory work,—will be masked by a new wall and arch, which will carry the gable end of the nave roof.

The internal width of the church, when finished, will be 84 ft. 9 in. by an average length of 75 ft.

The church is designed by Messrs. Somers Clarke & J. T. Micklethwaite, of Westminster.

PORCH, WEST FRONT, PETERBOROUGH CATHEDRAL.

THE unique design of the Cathedral front is too well known to require much explanation. It is the supposed work of Abbot Alcharius or Zachary, 1200-1210 (prior of St. Alban's during part period of the erection of John de Cella's front there). The plan presents features much akin to those of the foundations Sir George Gilbert Scott laid open at St. Albans'. Peterborough front, when close to completion, underwent both reduction of height and considerable change in design. Its great piers are supplied abundantly with delicate shafts of local "Alwalton marble," obtained from the property of the Monastery, at a village of that name on the south bank of the Nene, in Huntingdonshire. (It is somewhat lighter, but perhaps more durable than Purbeck.) The pillars are triangular in plan, with the point to the front. Of their courses scarcely one can be found to be entirely of a single depth or layer of stone; they are in fact *random ashlar*, differing from all else in the church, and suggesting that the masons were limited to dealing merely with older re-used materials. The natural settlement of such work soon produced that tendency outwards of the upper part of the front, which portends its eventual destruction. So serious had this become at the close of the Decorated period, that the Monastic body procured the original of the design afterwards erected as here drawn, but which the Abbots appear to have delayed as long as they possibly could. Hence the earlier design appears in Perpendicular clothing, though the peculiar gables of the first style are to be discerned on the stair turrets, and the architectural student may otherwise find interesting study of this conflict in the earlier sections of the caps of the vaulting shafts of the inner bay, with those of the outer shafts of the west arch. The top of what is now left of the pinnacle over the apex of the gable, retains part of the hollow prepared for a lamp to be placed in at night.

The following entry appears to refer to the space under the open arches, prior to the erection of the porch:

"In 1347, Simon de Sapcot, executor of the last will of John de Blaketot, of Walcot, in the parish of Bernak, gave his best horse as" (or in payment for) "a mortuary in the place called Galilee (*in loco qui dicitur Galiley*). Reg.: Fraunceys, p. 219.

The very beautiful ironwork filling in the west arch of the porch is not older than about the year 1792, when the following entry in the audit-book of the Chapter occurs, but without any further notice of designer or place of manufacture:—"3rd day July, 1792. It is also agreed that the timber now standing upon our estates at Thorpe, on lease to the Earl Fitz William, he sold in order to pay the expense of the new ironwork in the Minster porch."

G. G. IRVINE.

ANCIENT BRITISH ROADS AND EARTHWORKS.

AT the recent congress of the British Archaeological Association, held at Oxford, Dr. Phéné, F.S.A., read a paper "On some striking Historical and Linguistic Features, belonging to the first 1,000 years of British History, and attaching to the Vicinity of the British Roads and Earthworks." Dr. Phéné pointed out that in all the literary descriptions of the ancient and pre-Roman roads of Britain, there were two important omissions, one as to locality, the other as to language. That he had discovered the absence of such information in long practical researches as well as in the localities, in comparative linguistic derivations.

The description given by Cæsar of the inhabitants of Britain was as true a picture now as it was when he recorded it, viz., that the maritime people were polished, as being well

acquainted with other nations in traffic, and the pastoral people uncultivated.

Though the Anglo-Saxon race now occupied the greater portion of the land, some of the Gallic people (*i.e.*, the pastoral) still occupied the north-western coasts, mountains, and islands.

These latter were just as Cæsar described them, as to their maritime dispositions, and the press, and great men of the North-West, as the Marquis of Lorne, urged their attention to the people of the East coast, (*i.e.*, maritime loving people, as good examples to follow, on many points.

In short, though the numerical proportion now differed widely, the population might be divided into those engaged in some way in or for maritime matters, as manufacture for transport, &c., and the land-loving people of Celtic descent.

He then examined the localities of the great pre-Roman roads of traffic. The Icknield Way from west to east, and the Watling and Ermine Streets from south to north, along the eastern coast.

It was shown that although modern names and meanings had succeeded many of the ancient ones both in English and in Scandinavian, yet that most curious linguistic features still existed along these routes, distinct from other localities, and that a class of words abounding in Cornwall, and found slightly at intervals along these roads, were as abundant in what was once the country of the Iceni,—*i.e.*, on the coast of the North Sea,—as they were on the south-western coast; that not only were they abundant at the two extremities of the ancient Icknield Way, but that where, from the names of the places, there was evidence of any locality having been specially marked, either as a resting-place, or as a place of reverence or worship, there they also abounded, though in a less degree.

Quoting from Cæsar, Strabo, Tacitus, Florus, Quintilian, &c., it was shown that the Continent must have had similar ancient roads—as Cæsar enumerates many bridges over many rivers—and that from the large concourse of merchants he summoned, the commercial feature must have been powerful before Britain was invaded by him, and hence that the British ways must have been in use for traffic; that the names and words referred to showed extensive intercourse throughout these districts, and extended along the east coast up to the Humber, and even farther north; that by a curious mutation of the B and W, letters mutative in ancient and modern Greek, in ancient and modern Welsh, &c., the same names and words, though existing unaltered at these extremities and stations on these roads, abounded also in the same proportion, or nearly so, with the mutative initial changed, and that this appeared to arise not merely from the letters being mutative, but from the custom of the Scandinavians of placing a letter or syllable as a prefix, to indicate their localisation to the east or west, as is prominent in the words Visi or Western Goths, Ostro or Eastern Goths, and that consequently the W, and sometimes the U, was placed less as a mutative letter than as indicative of locality; and that the Iceni, when in the west, were known as the Wiccii, and sometimes as the Uiccii, which latter word was aspirated.

The localities of rest, and also of worship, were found in every case in the vicinity of the great chalk-out figures along these ancient roads, and their intersecting roads, as identified by the names still existing in their localities, and the clustering around them of names and words which only sparsely existed along the more lines of route, as Is-lip, near Oxford, Is-ham, in Leicestershire, Is-ton (though corruptly aspirated), near Cambridge, Is-field, in Sussex, Is-leham, in Essex, Is-lington, in Middlesex and in Norfolk, Is-leworth, &c. This word, always in low-lying districts, was simply the old Norse word, "is" (*ice*), which became an important feature in their winter warfare and their winter traffic, and as recorded, *inter alia*, by the attack on Ely by the Barons opposed to King John was the sole means of their victory.

Again, Ris-borough, near Oxford, was found along these routes, as Ris-ingham (no being Scandinavian for hill), Ris-by, Ris-bury, Ris-ley, Ris-burgh, Ris-hamles, &c. This word Ris is old Norse for hall of hospitality in the word "guest-ris-inn." And the Ris-borough near Oxford, that is at the village of White-Leaf, is further shown to be the place of rest on this route, not only from its being midway in the Icknield road, but from the name itself—"lif"

and "left" spelled by us leaf, being the old Norse for rest, remainder, &c.

Several curious and interesting words were dealt with, as Gamlingay, Warmingay, and Bellingay, all places of worship, around which clustered other words, not British, Roman, or Saxon, but Scandinavian.

It was further shown that the most remarkable events in ancient British history had taken place in the localities indicated by the nomenclature referred to. The first battles which subdued Britain to the Romans, Saxons, and Normans having been fought in the sacred territory of Anderida, a name that occurs solely in Phœnician routes of traffic as Androna Andropolis, Andertium, Andertium, Andros, &c.; that near Hoke-Norton (Hogg-Ormar), close to Oxford, are the Roll-rich stones, where Rollo, conqueror of Normandy, with the Northmen, persistently held the country by obtaining decisive victories over the English; that the Norman conqueror William, when in contest with the Barons, again raised his standard on one of these ancient camps, near Hoggington (Hogg-Ormar, near Cambridge), in the former district of the Iceni, indicating its then still existing importance; that the Romans had to contend with a people from Scandinavia, against whom they established a special guard on the coast, and in Anderida in particular; and that the nomenclature and traffic strongly indicated a pre-Roman-Scandinavian occupation of South and East Britain.

#### ARCHAEOLOGICAL SOCIETIES.

**ESSEX ARCHAEOLOGICAL SOCIETY.**—The annual general meeting of this Society was held at Harwich on the 25th ult., being preceded by a gathering at Ipswich on the previous day, in union with members of the Suffolk Institute of Archaeology. At the conclusion of the general business, the Rev. H. T. Arncliffe, M.A., F.S.A., read an able paper "On some ancient bondlers scattered in the district of the Colnes." In the afternoon an excursion was made to various churches, that of St. Nicholas being first visited. Dover-court Church, and Wix, Ramsey, and Great and Little Oakley were also included in the excursion.

**SOMERSETSHIRE ARCHAEOLOGICAL SOCIETY.**—The forty-second annual meeting of the Somersetshire Archaeological and Natural History Society was held on the 27th ult. at Castle Cary. In the absence of the President, Mr. George Fowkes Luttrell, the chair at the Council meeting, which took place in the Town-hall, was occupied by Mr. Chisholm Batten, who, having briefly opened the meeting, proposed the election of Mr. Henry Hobhouse, M.P., as President for the ensuing year. This was agreed to, and Mr. Hobhouse then took the chair. The Hon. Secretary (the Rev. J. A. Bennett) then read the report of the Council for the year, which stated that the number of members was steadily maintained. The MS. collections of the late Rev. Frederick Brown had been deposited in the museum, and would be known as the Brown collection. The subject of the formation of local branches of the society had been dealt with by a Committee, and rules circulated for the guidance of local societies. One branch, called the Northern, had been established within the district comprised in the petty sessional division of Long Ashton. The report having been adopted, the President delivered his opening address, which was of much interest. On the second day, the 28th, excursions took place to Lyte's Cary, West Camel Church, Queen Camel Church, Sparkford Hill Quarry, Hazelgrove House and Park; and on Friday, South Cadbury and North Cadbury House and Church were visited. The proceedings were reported at considerable length in the *Bristol Times and Mirror* of the 28th, 29th, and 30th of August.

**ROYAL SOCIETY OF ANTIQUARIES OF IRELAND.**—The Ulster quarterly meeting of this Society was held on the 2nd inst. in the Town-hall, Strabane. Among the papers read was one by Mr. S. F. Milligan, on "The Forts of Erin from the Firbolgs to the Normans." A long report appeared in the *Belfast Newsletter* of the 3rd inst.

**NEWBURY DISTRICT FIELD CLUB.**—This Club had recently a pleasant excursion to Aldermaston, Ufton, and Silchester. Aldermaston House was visited by permission of Mr. Higford Higford. The antique carved staircase, removed from the old mansion after the destructive fire forty-seven years ago, attracted much attention, as did some old stained

glass showing the armorial bearings of some of the families which have held the manor. Aldermaston Church was visited, under the guidance of the Rev. J. M. Guilding, who called attention to the Forster Tomb, the Jacobean pulpit, and the old glass. Mr. Walter Money, F.S.A., hon. sec. of the Club, read an interesting paper descriptive of the mansion, and of the descent of the Manor. Ufton Court was next visited, by the permission of Captain and Miss Sharp, and here the party were met by Mr. W. A. Boulnois, who pointed out some of the most noteworthy architectural features. The hall ceiling was, he remarked, a good example of the kind of plaster work introduced into England after the Renaissance in Italy, and subsequent to the reign of Elizabeth. The house as it now stood dated from between 1610 and 1680, but the Gothic of the earlier building was imitated, and a good deal of the material used. Fortunately Ufton Court has fallen into the most appreciative hands. Proceeding to Silchester, the party visited the excavations now in progress there, Mr. G. E. Fox, Mr. Mill Stephenson, and Mr. W. H. St. John Hope acting as ciceroni and explaining the remains recently brought to light. Mr. St. John Hope, in the course of his remarks, said they were dealing not with a camp or a villa, but with a large city, with an area of 100 acres. The wall was as nearly as possible perfect in its ring all round, though the facing was gone, except in a few places. The city was divided into blocks or *insulae*, and one of the questions to be solved was what these blocks contained. Were there shops facing the lines of streets, or did the *insulae* contain the remains of large residences or temples? That question had not been answered either at Silchester or at any Roman site in Britain. Other Roman sites had been built over, but at Silchester there was an opportunity of investigating the whole area. When, however, it was remembered that one *insula* was 400 ft. square, or larger than the site of some of our cathedrals, it became evident that the turning over and trenching was costly work. The Society of Antiquaries had made a handsome grant, and Dr. Freshfield, their treasurer, had undertaken the exploration of one *insula* at his own expense—they hoped others would follow his laudable example. Mr. St. John Hope concluded by describing the work at the *insula*. There were signs that at each corner were large houses with gardens, though the remains were very shattered. In the course of the discussion which followed, Mr. Money said it had always struck him as rather singular what had become of all the materials of such a vast city, but Mr. Guilding had, he believed, discovered that some of the materials had been employed in the construction of Reading Abbey, while he had himself discovered some Roman bonding tiles at Padworth Church. This led to the belief that for centuries the ruined city had been a quarry for materials for building churches and other structures. The party also visited other portions of the remains, including the amphitheatre, and the south and west gates. A long report of the meeting appeared in the *Reading Mercury* of the 6th inst.

#### Books.

*Building Construction and Drawing.* By CHARLES F. MITCHELL, Lecturer on Building Construction at the Polytechnic Institute. Part I., First Stage, or Elementary Course. London: B. T. Batsford, 1889.

THIS is the second and revised edition of a work previously noticed in these pages.\* The author has corrected some of the blocks, and made some additions to the text, which include the examination paper of the Science and Art Department for 1889, with the questions arranged as exercises, in the order of their difficulty in the chapters of the book. The additional matter amounts to some three pages, the body of the work being, with slight exceptions, page for page the same as in the first edition. Without wishing to find fault we must call attention to one or two points that might have claimed Mr. Mitchell's attention while the work of revision was in progress. For example, throughout the chapter on masonry, we find no warning against the practice of working stone to a feather-edge, while feather-edged

springing stones, which could easily have been avoided, are shown in a diagram of a relieving arch at fig. 124, page 49. Further on, in enumerating the various materials of which cramps are made, there is no mention of galvanised iron. In the chapter on girders, there is a section of a fitch girder (fig. 152, page 58) in which the iron fitch is shown of equal depth with the timber, whereas it should, of course be less, in order to avoid the danger of an uneven bearing surface, resulting from the shrinking of the timber. The statement on page 62, that riveted girders are considered more economical than rolled joists for depths exceeding 12 in., is, as it stands, misleading. The pains taken to explain, with a profusion of diagrams, the bonding of brickwork, are deserving of all praise; but in actual work, closers are not treated quite in the manner shown on page 25.

In the chapter on joints in carpentry, descriptions are given of joints for struts and beams, applicable chiefly to the feet of principal rafters abutting upon tie-beams. The descriptions are accompanied by good, practical diagrams, such as abound throughout the work; but it would have been better if more care had been taken to point out why some modes of construction are preferable to others. For instance, at pp. 81, 83, is explained the bridle-joint, in which the heel-strap is formed like a stirrup, with two eyes, and is secured by a bolt passing through the middle of the tie-beam. The bridle is employed, as the author states, to increase the shearing area of the beam; "besides which," he adds, "any defect in fitting is easier to discover." He omits to inform his readers of the disadvantages of such a fixing, such as that any considerable strain upon the bridle tends to enlarge the bolt-hole, and may even cause a split in the beam; or that the bridle cannot be tightened except by wedging behind the foot of the strut. Apparently Mr. Mitchell is somewhat partial to the bridle-joint or he shows it repeatedly in illustrations of roof details, as if it were one of the best means of fixing, instead of being one of the worst. He refers to a diagram showing an excellent form of heel-strap, with ends forged and screwed, which pass through bearing plates to which they are secured by nuts, but he neither shows nor describes the check plate, sometimes employed for preventing the strap from cutting into the underside of the tie-beam. In several cases, also, the foot of the principal, instead of being framed with a tenon in the ordinary way, is left square and let into the tie-beam, a process which necessitates cutting into the latter for its entire width to an unnecessary portion of its depth.

In treating of the lead work on roofs the author figures the width of the part of the lead lining of a gutter turned up under the slates by a measurement on the slope. It would have been better had he laid stress on the fact that the lead must be taken to a sufficient height measured vertically. One of the points most commonly lost sight of by young draughtsmen is that the width required is greater upon a flat pitch than upon a steep one.

Notwithstanding these slight defects, which are pointed out with a sincere desire to assist Mr. Mitchell in perfecting his book, the book is a useful and even valuable one for the student. It would be pleasant reading if what in our schooldays used to be called the definite and indefinite articles were not so frequently omitted; and it would certainly be improved by the expurgation of some grammatical errors, of which the following is perhaps the most glaring—"The cramps put in hot and surrounded by asphalt is recommended by Gwilt as for ever to preserve them from oxidation" (p. 52).

That the book should so soon have reached a second edition is encouraging to its author, and the reduction in price will tend to popularise it still further.

*The Student's Guide to the Practice of Measuring and Valuing Artificers' Work.* Originally edited by EDWARD DOBSON, Architect. Revised, with considerable additions, by E. WYNDHAM TARN, M.A., Architect. Sixth edition. Crosby Lockwood & Son, 1889. It is painful to speak ill of a venerable acquaintance, but candour compels the conclusion that no sufficient reason exists for the production of a sixth edition of this book, at any rate in its present form and with the title it now bears. It might be aptly styled "A Book about Building"; but a guide to the practice of measuring and valuing artificers' work it certainly is not.

\* See *The Builder* for December 29, 1888, Vol. LV., page 475.

As London is said to be full of men who know everything except how to get a living, so these pages contain something that is sound and useful on almost every subject connected with building, but nothing that is thorough and full enough to be of real value to what the preface quaintly calls the "rising student."

Indeed, the fatal fault of the book is that it attempts to do far too many things at once. In no one volume could a writer deal with all the subjects here taken in hand. Squaring dimensions, mensuration, building terms, building construction, dilapidations, ancient lights, contracts, are all treated of in a book of 326 pages, of which some fifty are taken up with a carpenter's or timber merchant's ready reckoner. A half apology is even offered for the absence of an account of the manufacture of building materials as well! At the same time there is some unnecessary detail. Thus we have, "Looks are mechanical contrivances for securing doors when closed" (p. 207). The "rising student" cannot have risen very far who requires to be told this.

Our readers will readily infer from the foregoing that the authors leave themselves but little room in which to play their title rôle and teach the art of preparing quantities, and measuring and valuing builders' works. Oddly enough, too, the attempt to do this is the least satisfactory part of the book. The profession of quantity surveyor, as now understood, has probably come into existence since this book was first written, and the methods of measurement have greatly changed. On page 312 we are told that "the whole of the work of each trade should be taken off before proceeding with the next trade." The authors rightly remark that the rules laid down by London surveyors "are superior to any others that can be adopted," and we venture to state that the practice above described has been abandoned by them for many years. A modern surveyor for taking off a window, for example, would certainly not pay it more than two visits; at the first deducting the brickwork and the facings, and measuring the lintel, arches, stone dressings, and everything else requisite to form the opening, and at the second taking the joiners' work, ironmongery, and glass, and deducting the plastering. It is obvious that, although this method throws more labour on the abstractor, it is both more expeditious and less open to error than the other, possessing in addition the advantage of great convenience in adjusting variations at the end of the works.

Passing from this to the various trades in detail, let us take one example, and consider the rules given for the measurement of masonry, which is the branch of his profession presenting most difficulties to the student, and in which he needs all the help he can get. Here the work before us is hopelessly out of date. "Plain work" is a term not now used as synonymous with labour to beds and joints; nor is "sunk work" the same thing as "sunk joint." The vousoirs of an arch are not usually measured as less than the full size of the smallest stone square every way that each one can be cut out of. Steps are seldom measured except by the foot run. In the rare cases in which they are cubed and the labour taken it would hardly be fair to the builder to measure the length by 4½ in. as sunk work to pay for the front and back rebates (p. 158). Six-inch landings also are given by the foot superficial, not cubed; and solid joggle by the foot run, not as a superficial measurement of sunk work. Similarly, to measure a stone coping feathering from 3 in. to 1½ in. as a cube 2½ in. thick, or to cube up a 6 in. window-sill and take the throat as a superficial of sunk work, would not be in accordance with modern practice. It is difficult to believe there ever was a time when measurements were so taken; but a "rising student" who should take out the quantities of stonework in this way now would speedily find himself in serious trouble with builders. The order of the items in bills of quantities (or what is here termed their "rotation") is, moreover, not correctly given. For example, in the smith and founder's bill it is not usual to mix up the cast with the wrought ironwork. Space will not admit of our entering into further detail: enough, however, has been adduced to show that this book is not a safe guide for the student of the art of measuring.

The instruction in valuation consists of a series of constants of labour expressed in decimal parts of an hour. These are for the

most part good as far as they go, but require amplification.

In conclusion, we are glad to be able to say a word of commendation. The explanations of building terms and the description of building processes are good, and the details of construction given in Appendix II. are excellent.

*Blackie's Modern Encyclopedia of Universal Information.* Edited by CHARLES ANNANDALE, M.A., LL.D. Vol. VII. Blackie & Son, 1890.

THE seventh volume of this dictionary takes us to the middle of the letter S, and we presume another volume will complete the work. The article on Roine is a very good one for the scale of the dictionary. Among the architectural subjects we find "Romanesque architecture" well defined (as far as it can be defined) in a brief article illustrated by an engraving of the Church of Laach, one of the most typical examples which could be selected, and by a characteristic bit of Romanesque ornament. Roman architecture is also illustrated by a well-executed small view of the great hall of Caracalla's Baths, restored. The illustrations to the word "Roof" refer too exclusively to timber roofs, though the writer defines roof as the covering of any building, "irrespective of the materials of which it is composed." Saracenic architecture is briefly described with a notice of some of its principal structures and an illustration. In one of the articles appertaining to building, "Chirked moulding," the description seems at fault, and is rather vague. A quirk may be best described as a nick cut to throw out the form of a moulding which would otherwise die into the wall surface; a profile would have made it intelligible. This is a trifling matter, however; and in general we have been struck with the correctness and ability with which architectural subjects are treated in this dictionary.

*The Timber Merchant and Builder's Trade Measur.* By GEORGE BOUSFIELD. Fifth edition, considerably enlarged and improved. London: William Rider & Son, 1890.

THE fifth issue of this work, useful alike to timber merchant and builder, has been enlarged by additional tables and rules, and carefully revised.

Many of the tables contained in this work are invaluable to those buying and selling timber, for making out accounts and checking them. In table 1 we have scantlings of almost every size, from ¾ by 1, to 14 by 14, with the number of feet required to the Petersburg standard of 120 pieces 12 ft. long by 1½ in. by 11 in., which is almost the only standard now used. In table 2 we have the number of deals, battens, planks, boards, &c., there are in a standard, from 6 ft. up to 25 ft. lengths; and in table 3 the prices per ft. at so much a standard per standard, at so much a foot. Many retail timber merchants sell at perft., especially where they sell in small quantities, and this will be found very useful for this retail trade.

The French and English lineal superficial and cubic measures are given, showing the equivalents in either country, and there is a useful table showing the comparative prices per fathom and standard for fire- and lath-wood buyers. On pages 28 and 29 there is a table giving the price of scantlings (given in superficial inches) at per foot cubic. The table for calculating parts of a standard is one of the most useful in the book, and one that will save a great deal of time to those who use it. The book contains a variety of other useful tables for facilitating calculations of various kinds, as well as general information as to deflection of beams, spans of roofs, &c.; tables of the weights of different timbers, lists of exchanges in foreign countries, schedules of the brands of deals, information as to timbers newly brought into use, &c.

**VALUATION OF THE FORTH BRIDGE FOR RATING PURPOSES.**—The *Scotsman* says that Mr. Munro, the assessor of railways and canals, has valued the Forth Bridges for rating purposes at the net sum of £25,000. Against this valuation the railway company has appealed to the Lord Ordinary in the Bill Chamber. The company maintain that the boundary of each county ends at low-water-mark, and that, therefore, the bridge, so far as it is situated between the low-water-mark on each shore, should be exempt from rating for local purposes. Should the railway company's contention be well founded, the case will rule the valuation of the Tay Bridge, the Solway Viaduct, and similar structures.

## Correspondence.

To the Editor of THE BUILDER.

### AN "EMPLOYERS' UNION."

SIR,—Will you allow us, through your valuable medium, to call the attention of the master builders and contractors, together with those engaged in the furniture, shop-fitting, and other affiliated trades, to the vital importance of organising, while there is yet time, a strong employers' union?

At present masters hold jealously aloof from one another, and trades unions attack them in detail, and often in a most aggressive manner, and no matter how unreasonable their demands, they are often conceded after a week's resistance, because no united stand is made.

A general meeting should take place and a chairman and committee be appointed, together with a thoroughly good paid secretary with clerical assistance, supported either by voluntary contributions, or a levy based on the annual wages paid by each firm. We believe it is the general wish that labour should have an equitable wage, indeed that the position of the working man should be improved as far as possible, due regard being paid to foreign competition, and a fair margin of profit being secured for the masters who take the responsibility and risks of the businesses which provide the opportunities for labour.

But at present the trades unions arbitrarily fix what they consider a proper wage, and, if this is not conceded at once, proceed to withdraw the men, taking care to attack only a limited number of firms at once (in case the strain on their resources should be too great), as witness the action of the French Polishers' Union just now. They then place pickets to "persuade" non-unionists not to "take the bread out of their mouths," and frequently add force to persuasion; or men who try to act independently are "spotted," and it is "made hot" for them wherever they go to work.

Such interference with personal liberty is, we contend, cowardly and immoral, and there is evidence that the law will put it down with a strong hand. It would be more to the purpose if the non-unionists had a little more pluck to carry out their convictions instead of being misled by the agitators who live on their dupes; for dupes they are, and if the present artificial and called-for raising of wages is persisted in (and only employers' amalgamation can successfully check it) the Nemesis must come in the shape of trade driven from the country and much increased importation of goods produced where the new Unionism has not yet found sway.

Will influential men come forward and help an Employers' Union for the Building Trades to take practical shape? CONTRACTORS.

### "A SANITARY NOTE FROM GREENOCK."

SIR,—I notice in your journal of the 6th inst. your correspondent, W. P. Buchan, referring to a "Sanitary Note" that I sent from Greenock, and which appeared in your issue of August 16 last, says that I attacked the Glasgow system of trapping and ventilating house-drains, and found fault with the Greenock officials for recommending drainage to be done in Greenock on the Glasgow plan. He further adds that I do not really find fault with the Glasgow system of trapping, but with the system in which the traps are ventilated. Now, I beg to state that the article referred to was neither intended to find fault with nor hinder sanitary reformers in their good work, but merely to state what is really being done, and to draw attention, particularly of parents, to the fact that the preservation of the health and lives of their children is a far more important consideration than that of any pecuniary gains of a few parties interested in the sale of traps or the repair of defectively-constructed drains. Your correspondent, "W. P. B.," goes on to say that he has no objection to siding with me in a general condemnation of the inlet ventilating grating being put directly over the traps, especially when these traps are on the pavement and close to the hunking, but that the complaint of bad smells from the grating can be easily cured without going to the expense of carrying up ventilating pipes to the roofs—viz., by putting an iron plate over the trap and then having the fresh air inlet a couple of yards or so to one side; that this has been a common practice in Glasgow for years, and if Greenock follow suit the ground for any complaint will vanish, "especially if the work is properly done." It matters little how well the work may be done. I fear the cure suggested would be an aggravation of the complaint by adding two yards more pipe, which would give a

greater volume of gas to eject on to the street every time that a bath or closet were used. The suggestion would no doubt save the pockets of proprietors, but would not lessen the danger to the lives of children. I observe that last month's "Sanitary Journal" still bears out the fact I formerly referred to, viz., that the infant mortality is highest in Glasgow, being 44 per cent. of the total deaths, and that more is being done in the way of sanitary reform than in any other town in Scotland, in view of that fact, it would be dangerous to follow in the wake of Glasgow.

I have no hesitation in asserting that house drains, if properly constructed, would outlast every other part of the building with but little or no repair. The almost imperishable materials now used in their construction make this an absolute certainty.

But instead of that, the drains are generally the most troublesome and expensive part of house property. This is, in a great measure, owing to the fact that the drains of a building are generally included in the mason's contract, and regarded by him as a branch of the work that may be done by the least experienced workman. The contractor generally puts the lowest paid and unskilled of his men to do the work. It is not these men's fault, but rather their misfortune, that they have not had a thorough training to fit them for their task. However, I trust the day is not far distant when no man will be allowed to construct a house-drain unless he has passed a board of qualified examiners, and obtained a certificate that he has sufficient knowledge, both theoretical and practical, how to execute the work without the risk of leaving defects that are certain to produce disease.

Traps on house-drains are in many cases a necessary safeguard against danger resulting from defective construction. It is most desirable that all drains should be so trapped off from the interior of the dwelling that there can be no possibility of gases from them getting admission thereto. But to trap them so as to prevent the escape of sewer-gas above the main roof and make provision for the possibility of its escape on either the pavement or any other part of the street or court is a very questionable practice, particularly in such places as Glasgow or Greenock, situated as they are on a tidal river with a strip of level ground along its bank and rising ground in the rear, the outlet of the sewers being exposed at low tide, while at high tide the sewers in the level streets are filled with water, and there being no provision for the escape of gases at the upper extremities of the main sewers, they get so completely bottled up and compressed between the rising tide and the traps that they force their way through the water in the traps in streets, sinks, and closets in our dwellings. That this is the case I know from experience, having lately had to resist a case where it was proposed to make a connexion between a property and a main sewer in which the tide flows; the sewer being so level that it is practically a long cesspool, the street having at frequent intervals to be opened at every 30 ft., so as to get the deposited contents cleared out. And, strange to say, of late the four-story buildings in the line of that street have had intercepting traps placed at the bottom of conductors which have no connexion with the building beyond the carrying of the rain-water from the roofs to the drains.

The local authority in their wisdom have sanctioned this, and no doubt with good intentions have also authorised the constructing and connecting with this long cesspool a new main sewer into a side street, over which new sewer several open gratings are placed to allow the gases to escape in the centre of the street, in preference to letting them escape above the roofs of the houses.

X. Y.

SIR,—In your issue of the 16th ult., you publish "A Sanitary Note from Greenock." In this there is a very palpable error. Your correspondent says:—"Of the total deaths in Glasgow, 45 per cent. . . . There is certainly some preventable cause at work that requires special attention, and until that cause is discovered and mastered, the fact that nearly half of the human beings born in these cities sicken and die before reaching the fifth year of their age, &c." The 45 per cent. referred to is of the total deaths, not 45 per cent. of the births.

I more particularly wish to enter a plea for what will, no doubt, be considered by many a retrograde movement in sanitary matters, viz., the abolition, except in a few very special cases, of that abominable—the syphon or intercepting trap. I read your articles on house drainage in the "Student's Column," which contained many valuable hints, but all advocate the syphon. In the first place, the syphon is the most fruitful source of stoppages in house-drains; in the second place, it generally contains a certain amount of filth; and, thirdly, it shuts off all means of free ventilation to the sewers. This last is I am well aware, the desideratum of the persons advocating them; what can only be described as a "palimpsest." The stone in question is stated to be considerably decayed, and it is added that "another name can be questioned!" underneath that of the minister in

special attention in the shape of flushing and cleaning by properly qualified sewer-flushers, and I have never come across a private house the drain of which receives periodical attention from any one. In house drains there is only an intermittent flow, whereas in sewers the flow is continuous, gives a decided preference to the air in the sewers over that in house drains,—there should be no such thing as sewer-gas except in cesspools,—therefore it seems self-evident that the best system of house drainage is to have a free access from the sewer through the house drain and up the soil-pipe and ventilator, which should be of the full diameter of the soil pipe, and not a 2 in. pipe as is so often used. The fresh air inlet is very often the foul air outlet placed in a position most dangerous to health; the head of this inlet is frequently fitted with a mica tap, which is mostly out of order; if carried up to the top of the house at the same level as the ventilator, as is also done, the balance of the air in the house drain is equal on each end, and at a complete standstill, instead of a continuous current as it should be, and is where the sewer is ventilated by surface gratings in the middle of the road and the soil-pipes of all houses properly ventilated, the soil-pipes of the house drains.

ERNEST VAN PUTTEN, ASSOC. M. INST. C.E.  
Lewisham, September 4, 1890.

### "THE GREAT TOWER FOR LONDON."

SIR,—Having seen your notice on the book compiled by me on the above subject, I wish to point out the following facts. You say the descriptions are "very incomplete." This must of necessity be the case when the authors of some of the designs either gave no description at all or else very vague ones. It could hardly be expected that I, as compiler of the book, should invent descriptions or supplement those so vaguely given.

The compilation of the book was well considered, and in regard to the inaccuracy of the cost of the design (No. 19), the fact that the author of this design has admitted that the figures given by him in his description were wrong, and which I was guided by, clears me of any blame. Had the author given the figures correctly they would, no doubt, have been correctly published in the Tower book. The figures in reference to Design No. 19 given in the Tower book are, at least, a correct addition of the several items given by the author, and there is nothing in his description to indicate that the sum of these items does not represent the total cost.

FRED. C. LYNDG, A.M. INST. C.E.

\*\* We must of course accept Mr. Lyndg's statement that he did the best with the materials at his command. Indeed, in the last sentence of our notice, we suggested that the authors of the various designs had been "judiciously reticent in their descriptive notes." As to the error in cost of design No. 19, we were at first requested to publish a letter from Mr. Couchman pointing out that the fact is as we stated. Mr. Couchman, it is true, admitted a clerical error, in casting up, of a comparatively small amount (some 20,000, or 30,000, if we recollect aright); but he submitted to us his report sent in with his design, which, as we read it, showed that the amount of his estimate for the tower complete, including of course labour and materials, had been erroneously added by the compiler of the book in question to the amount of a separate estimate for labour and superintendence of construction only, thus adding about 800,000, to Mr. Couchman's estimate. Mr. Couchman's tower, moreover, is (as we might have pointed out before) octagonal on plan, and not circular, as described in the book.—ED.

### CAMBRIDGE UNIVERSITY ASSOCIATION OF BRASS COLLECTORS.

SIR,—As I have already been applied to for information about this Association by people who have seen the paragraph in last week's *Builder*, and as I expect to receive many similar applications, may I ask you kindly to correct in your next issue a mistake which Mr. Beloe unwittingly made in his short notice of the Society?

The subscription formerly was £s., but, owing to the rapid growth of the C.U.A.B.C., it has become inadequate, and therefore was increased to 10s. at the last general meeting in June.

R. W. M. LEWIS.  
Hon. Corr. Sec. C.U.A.B.C.

THE EDINBURGH AND GLASGOW AERATED BRAD COMPANY have erected extensive works at Glasgow, and which are fitted up with all the recent and most improved machinery. The ventilation of these works has been carried out by Messrs. Baird, Thompson, & Co., of London and Glasgow.

A "PALIMPSEST" TOMSTONE.—Archæologists are familiar with "palimpsest" brasses, but if we may believe a writer in the *South London Press*, there is in Norwood Cemetery a tombstone erected to the memory of a Nonconformist minister which can only be described as a "palimpsest." The stone in question is stated to be considerably decayed, and it is added that "another name can be questioned!" underneath that of the minister in

## The Student's Column.

### HOT-WATER SUPPLY.—XII.

#### PIPES AND COCKS: continued.

**H**APS.—There is, as every one knows, an enormous variety of these in the market, but, notwithstanding the many improvements and advanced ideas in this direction, a perfect tap, or a nearly perfect one, still remains to be introduced. There are numbers of these articles to be met with that display excellence of quality and careful workmanship and finish, yet it is doubtful if any maker is prepared to supply a 3-in. bib-tap for hot water, guaranteed to last more than twelve months without leaking, in a large residence where the tap is in fairly constant use—at the scullery sink, for instance. The most usual form of tap to be met with, and one which is found to give fairly good results, is that having a plug through its centre and known as a plug-cock (fig. 21). These are made either with a nut bottom (a nut being screwed on to the plug at its lower end), as illustrated, or with a solid bottom, the plug being secured with a cap screwed on at the top, as fig. 22, this cap forming a stuffing-box; or

FIG. 21.

FIG. 22.

there is another with a solid bottom, the plug being secured by a plate at the top (fig. 23), this being called a "gland" tap. Either of the two latter are preferable to the former, as those secured by a nut at the bottom sometimes leak at that point, which is impossible with the others. These three are the forms of tap alluded to in a former paper as "quick-shutting" (in contradistinction to the slow-shutting screw-down taps), and which cause the concussive noise in the pipe when shut off suddenly where a good pressure of water exists. There is a very simple remedy for this, which will at the same time check the violent outrush of water experienced when a great pressure exists; this is effected by reducing the bore of the tap at what is called the "tail," the screwed portion that enters the pipe, as in fig. 24. This is quite

FIG. 23.

FIG. 24.

understood by the makers, many of whom keep these "checked" taps in stock. Workmen sometimes do this themselves by cutting a circular piece of sheet brass or zinc, and, after making a suitable hole in it, solder it on to the end of the tail.

Where there is a pressure of 15 lbs. to 20 lbs. (cold-water cistern situated 35 ft. or 46 ft. above the tap), the hole in the tail of the tap may be reduced to 1/4 in.; with a 10 lb. pressure a 3/8 in. hole is ample.

Screw-down valves overcome the concussion difficulty, by its being impossible to close them suddenly; but these taps, however well made, require "re-leathering" periodically, that is, the seating or diaphragm, whether rubber, leather, or composition, requires renewing somewhat frequently, and if the tap is not of good quality the thread of the screw-down arrangement wears or strips off quickly. This style of tap is now largely used, but it has an opponent in every servant that has to use it, as it cannot be opened or closed quickly, and in many busy houses a tap is oftentimes applied to a dozen or more times per hour, in which case the unscrewing and screwing usually leads to a loss of temper.

There is a modified form of this tap now being made which can be opened or closed in one turn, or they can be had to open or close with a half turn, which is as quick as a plug-cock; this overcomes the difficulty just referred to, but a new disadvantage is introduced with them, as when the abrupt thread of the screw-

down arrangement wears loose, a fair pressure of water will lift the seating slightly, and permit of leakage, and the thread of a screw-down tap is a troublesome part to repair.

It is now considered best, when purchasing baths or lavatory basins, to choose those that have the hot and cold taps fitted and attached to them, so that the connection of the pipes to the unions provided is all that is needed to complete them. This is a much better and neater arrangement than having the taps projecting from the wall over the basin or bath, and if not infrequently happens, when this is done, that the hot and cold taps will be found of different patterns, as the hot and cold draw-off services are so commonly fitted up by different tradesmen (hot-water fitter and plumber). When the taps are fitted to the bath or basin by the maker they are sometimes placed out of sight, only the handles being visible, these having porcelain discs upon them marked either "HOT" or "COLD," and altogether a very superior result is effected with very little extra cost.

It has been the usual practice with makers, when supplying baths fitted with taps, to place the taps in question on, or nearly on, the rim of the bath, so that the water issuing has to fall about 18 in.; there is no objection to this with the cold-water tap, but with the hot tap it is an objection, as the falling hot water throws clouds of steam into the room, making it very unpleasant, particularly if the room be small. This objection is overcome by having the hot-water inlet situated near the bottom of the bath (not in the bottom itself), so that it is quickly covered with water, which prevents the steam arising; it is as well to have both hot and cold inlets thus situated, as the bath will then fill noiselessly.

This arrangement must not on any account be confounded with the method adopted in the old pattern zinc and copper baths to be met with, into which the hot and cold water issues through the waste grating in the bottom of the bath; the particular objection to this is that, when the bath is emptied after bathing, a certain amount of soapy, objectionable sediment is always left just in the waste outlet beneath the grating, and this substance is washed back into the bath by the inflowing water when the next person makes ready to bathe.

It is very desirable to have fair-sized service pipes carried and connected to a bath, and the taps should be as large as possible, say 1 in., as a slow-filling bath is as much a source of annoyance as one that empties slowly.

The majority of best quality and even many cheap-made baths are now fitted with the taps and with soap and sponge trays, all within the bath; this is an excellent feature, preventing drip water and soapy matter finding its way to the floor, or if the bath is encased it prevents the woodwork being injured from the same cause. When the bath taps are placed on the wood bath rim there is invariably a collection of dirt there, unless they are very carefully cleaned, and in this latter case the cleaning leads to the polish being rubbed off the woodwork and creating an unsightly appearance around the taps.

A very useful and not expensive adjunct to a bath is a shower apparatus; the old form of this appliance was most inconvenient and troublesome thing, as it consisted of a suspended vessel or reservoir which had first to be filled before allowing its contents to be showered down; this, although cumbersome and unsightly,

The more modern form of shower attachment is as fig. 25, consisting of a board of polished wood (to match the bath casing) on which is affixed the hot and cold taps and the shower rose; the method of connecting the pipes is shown at fig. 26, which illustrates the back of the board. It will be seen how simply the temperature can be regulated, so that, if desired, the shower can gradually be made to vary from warm to cold, and the shower can be continued any length of time. A further useful adjunct which can be attached to the shower board inexpensively is a small tap with a nozzle, to which can be secured a piece of india-rubber tube, and this, if fitted with a rose, can be used either for shampooing purposes or for rinsing out the bath after use.

SURVEYORSHIPS.

**CHELMSFORD.**—Mr. Charles Law Green has been appointed Borough Surveyor of Chelmsford, in the room of Mr. Charles Portree, resigned.

**CHELSEA.**—Mr. Joseph Hall, C.E., the newly-appointed Borough Surveyor of Chelsea, was at Torquay a few days ago the recipient of a testimonial, in recognition of the services he had rendered to that town as Surveyor to the Local Board during a period of nine years. The presentation was made by Mr. R. S. Cary, lord of the manor, and consisted of a Beck's first-class binocular microscope, with various powers (eyepieces, polariscope, &c.).

**MARKET BOSWORTH.**—At a meeting of the Market Bosworth Board of Guardians, acting as a Board of Sanitary Authority, on the 10th inst., the Clerk read a letter from Mr. Horton, the Surveyor, stating that he had been appointed Surveyor to the Felixstowe Local Board, and asking that he might be released from his duties on the 26th inst. The Board accepted his resignation.

**YEOVIL.**—Mr. W. K. L. Armitage, Assistant Borough Surveyor of Preston, who is leaving Lancashire to become the Borough Surveyor of Yeovil, was the recipient of a present from the officials of the Preston Corporation a few days since. The presentation was made by the Mayor of Preston, on behalf of the officials, and amongst those present were the Town Clerk, the Borough Surveyor, Borough Treasurer, Medical Officer of Health, and other officers of the Corporation. The gift consists of a silver fruit-dish, embossed in high relief with fruit and flowers, and bearing the inscription:—"From the officials of the Corporation of Preston, to W. K. L. Armitage, Assistant Borough Surveyor, on his leaving Preston to become the Borough Surveyor of Yeovil, September, 1890." Accompanying the gift were several volumes of expensive technical works.

OBITUARY.

**MR. ANDREW M'KELVIE, C.E.**—News has been received in Dundee of the death by drowning of Mr. Andrew M'Kelvie, architect and civil engineer. He was making a trip on board a steamer, when he was washed overboard and drowned during a storm off Cape Hatteras, North Carolina.

**MR. CHARLES POOLEY, F.S.A.**, died on the 3rd inst., in his 74th year. He was a surgeon, but took great interest in antiquarian studies, and wrote a work on the Old Crosses of Gloucestershire and Somersetshire.

GENERAL BUILDING NEWS.

**PROPOSED PUBLIC BATHS FOR STAFFORD.**—At a meeting of the Stafford Town Council on the 12th inst., the Public Baths Committee recommended that for the purpose of obtaining competitive designs for the proposed baths, premiums of 25*l.* and 10*l.* should be offered for the two best plans sent in, and that the accepted plans should become the property of the Corporation. Mr. Matthews proposed the adoption of the report, and Mr. Flammock seconded the resolution. Mr. J. C. Mycock said he was sorry the committee had adopted the course they had in reference to the front elevation for the baths. He thought the competition would be an expensive matter. He took it that at the last meeting the only objection that the Council had to the plans was that the frontage was too plain a character. He thought suitable plans could have been obtained at a small expense, and stated that he had seen a new plan of the front elevation which had been drafted by the Surveyor and which he thought would do. Alderman Goodall asked if the architect whose plan was accepted would expect commission on the amount of the contract, and Alderman Peach pointed out that the terms of the resolution were that the plans should belong to the Corporation. After a great deal of discussion, an amendment was unanimously carried as follows:—"That the recommendation of the Committee be not adopted, and that they be instructed to submit an alternative elevation prepared by the Borough Surveyor, for the approval of the Council at their next meeting."

\* Mr. Mycock, and the Committee too, evidently think that architects can afford to work for nothing.—Ed.

**PROPOSED PEOPLE'S HALL FOR LIVERPOOL.**—For the last year or two a scheme has been maturing for the erection of a much-needed "people's hall" in Liverpool. A Liverpool paper publishes a sketch of the proposed building, as designed by Mr. Edmund Ware, architect, Lord-street. When first proposed, the scheme was warmly taken up by several wealthy gentlemen of the city, who promised to help on the good work by every means in their power. The proposal is as follows:—To secure a piece of land like that at the bottom of William Brown-street for a site. The small concert-room will seat 250 people, and this can be made available for concerts, dramatic performances, public meetings, and all the requirements of our rapidly deepening city life. Then comes the great hall, which is also arranged for in the block which has been planned by Mr. Ware. This will seat 2,500 people, and another thousand could find ample accommodation in the spacious aisles. It is planned to have a very small gallery at one end, with a large platform at the other, and a level floor set with chairs or moveable seats. The entire scheme is estimated to cost 30,000*l.*

**STABLES AT SWANSEA.**—Messrs. B. Evans & Co. have just had completed in Frog-street, Swansea, what are described by the *Western Mail* as a model range of stables. The main front is of Ebbw Vale bricks, with Bridgton stone dressings, and contains a house for the stable manager. Inside the entrance is an open paved yard, and opposite to the doors is a van-shed capable of holding a score of large vans. Over this shed is a large workshop. On the left-hand side on entering the yard from the street is the stable building. A lofty arch admits to a large covered yard, which will be used for cleaning the horses, &c. The stable itself is on two sides of this covered yard, the third side being occupied with the harness-rooms and washing place. The floor is paved throughout with huff adamantine clinkers, laid to proper falls, and draining into a covered gutter which runs along the back of the stalls. The stalls is divided into twelve stalls and two loose-boxes, thus giving accommodation for fourteen horses. The whole of the stall divisions, manger, &c., were supplied by Messrs. Musgrave & Co., of Belfast. An office, weigh-bridge, washing-room (with hot and cold water), a range of lofts, corn-rooms, &c., are also provided in the building. The contractors were Messrs. Jenkin Bros., of Swansea, and the architect was Mr. H. C. Portsmouth, Swansea.

**PROPOSED CENTRAL POLICE STATION AT SWANSEA.**—A special meeting of the Swansea Watch Committee was held at the Town Hall on the 12th inst., to consider a scheme for the provision of a central police-station and the abolition of the stations at High-street, Goat-street, Guildhall, and Oxford-street. Councillor Morgan detailed the scheme, the consideration of which was adjourned.

**WESLEYAN METHODIST SCHOOL AT RUSHOLME, MANCHESTER.**—The foundation-stone of a new Wesleyan Methodist School in Dickinson-road, Rusholme, was laid on Saturday last. Mr. Herbert Turner, of Manchester, is the architect, and the estimated cost is 1,500*l.* Messrs. Smith & Goodwin, of Lower Broughton, are the contractors.

**NEW BISCUIT MANUFACTORY, CARLISLE.**—A large building for Messrs. Carr & Co., biscuit manufacturers, is now in course of erection at Caldowgate, Carlisle. Mr. T. Taylor Scott, of that city, is the architect. The foundations were put in in March last by Messrs. Johnstone Bros., builders, Blencowe-street. Since then the contracts for all the works have been let to the following tradesmen, viz.:—Builders' work, Messrs. Johnstone Bros.; Carlisle; fireproof construction, tanks, and iron-founders' work, Messrs. Homan & Rodgers; carpenter and joiner's work, Mr. Wm. Lattimer; plumber's work, Messrs. W. & R. M. Hill; slater's work, Mr. Thos. Graham; and plasterer's work, Messrs. R. M. Ormerod & Sons, all of Carlisle. The bricks that are being used are from the Birkby brick manufactory. The new buildings include a chimney-shaft 170 ft. high.

**STABLES, &c., MERTON HALL, NORFOLK.**—An extensive range of buildings is now in course of erection at Merton Hall, for the Right Hon. Lord Walsingham, to replace the old stables which were destroyed by fire in April last. The new buildings consist of stables, carriage-houses, harness-room, washing-houses for horses, carriages and harness, coachman's house, men's mess-room, bed-rooms for grooms, hay, straw, and corn-lofts, and the necessary offices. The buildings are being carried out from designs by and under the superintendence of Messrs. Milne & Hall, architects, London, by Mr. William Hubbard, contractor, East Dereham, Norfolk, at an outlay of about 3,000*l.*

**BOARD SCHOOLS, COVENTRY.**—The Coventry School Board on the 11th inst. resolved to accept the tender of Mr. James T. Wingrove, of Northampton, for the erection of new schools in Wheatley-street. Messrs. George & Isaac Stoenes, of Coventry, are the architects. The contract sum is 15,555*l.*

**OTTAGE HOSPITAL, BROMSGROVE.**—The site for the cottage hospital at Bromsgrove is now being cleared. The building will face the New-road, with a side drive approach from Ednal-lane. The builder is Mr. J. Brazier, of Bromsgrove, and the contract sum is 2,673*l.* The *Bromsgrove Messenger* of the 13th inst. gives a long description of the building, but omits to mention the architect's name.

FIG. 25.

FIG. 26.

answered very well with cold water, but if a warm or tepid shower was required there was no way of testing the temperature except by climbing up and testing it with the hand; otherwise the result would be most uncertain, if not risky.

FOREIGN AND COLONIAL.

FRANCE.—The splendid collection of tapestries of the Cathedral of Reims is at present undergoing a process of cleansing and repair. These tapestries date from the sixteenth century and were given to the Cathedral by the Cardinal de Lorraine; they represent the life and death of the Virgin. A copy of the "Venus à la Coquille" of Coysvoix, by M. Suchetet, has just been placed at the end of the "Parterre de Latone" in the park at Versailles, to replace the original which, after repair, has been more safely lodged in the Louvre. The Subscription Committee for the National Monument to Joan of Arc, at its last meeting, appointed three of its members, of whom M. Bailly was one, to select a sculptor to execute the statue of the principal figure, which is to represent her in the costume of a peasant. The monument is commissioned to be ready for inauguration by the spring of 1892.—The town of Châteaudun, which distinguished itself by a spirited defence in the Franco-German war, is about to erect a monument in commemoration of the combat of October 18, 1870.—The death is announced at Bordeaux of the landscape-painter Amélie Baudit, whose works have figured in every salon since 1852.—M. Lambert, the director of the service of maintenance in the court of the Marquis of the Ninth Arrondissement at Paris, has offered to the town of Ferney a reproduction in bronze of the work. M. Lambert is the present owner of the chateau at Ferney in which Voltaire lived.—A French tourist, M. Martel, has made an interesting exploration of the caves of Padirac, near Rocamadour, where he spent twenty-four hours, and discovered eleven lakes or pools, thirty-nine small cascades, and numerous grottoes, besides a great cave or hall 88 metres high. It is suggested that this be taken in hand and made a "show place" of.—A hatchet of cut flint has been found in the Bois de Boulogne, near the alley of Acaulas, apparently of great antiquity. It was found about 5 ft. below the level of the ground, in a layer of flints and sand which formed part of the bed or shore of the Seine in ancient days.

MILAN.—According to the *Courrier de l'Est*, the model of the late Signor Brentano's design for the new facade of Milan Cathedral has been commenced some time back and is now well advanced. According to the original conditions of the competition, the model is to be the large scale of 1/10 of the actual work. It is expected that the model will be exhibited towards the close of the year; but whether or when the actual work will be commenced seems still doubtful.

MISCELLANEOUS.

PARTIAL DESTRUCTION OF THE ALHAMBRA AT GRANADA. Telegrams from Madrid and Granada state that at about 10 o'clock on Monday night an alarming fire broke out in that part of the Alhambra known as the Patio de Albergia, which is situated close to the famous Patio de los Leones, or Court of the Lions, and the Tocador de la Reina, or Queen's dressing-room. The fire was finally extinguished on Tuesday morning, after doing damage which is irreparable, although less extensive than was at first feared. The portion burnt comprises the Sala de la Barca and the right wing of the Arrayanes Court. The remainder of the building was saved. Eight persons were slightly injured. The cause of the accident has not yet been ascertained, but suspicions are entertained that it was the work of an incendiary. The judicial authorities have opened an inquiry.

TECHNICAL CLASSES AT GLASGOW.—We have received the prospectus and time-table of day and evening classes in Civil Engineering, Building Construction and Architecture, and Plumbing and Sanitation, to be held during the coming winter months under the auspices of the Glasgow and West of Scotland Technical College, Glasgow. The syllabus appears to be very full and complete, and the fees are moderate. The Lecturers are:—For Civil Engineering, Mr. Arthur W. Thomson, B.Sc., C.E.; for Building Construction and Architecture, Mr. Charles Goulay, A.R.I.B.A.; for Plumbing, Mr. David Paton, R.P.C.; and for Sanitation, Mr. Gilbert Thomson, M.A., C.E. The classes will commence early in October, in the Andersonian and Science Arts Buildings, George-street and Bute-street. The courses of study, we are informed by Mr. Goulay, are those of the Science and Art Department, and the City and Guilds of London Institute, but the Honorary Class is likely to be especially useful to those who intend to study for the Associate Examination of the Royal Institute of British Architects.

FIREPROOF DOORS.—An interesting proof of the resistance of some simply constructed fireproof doors has been given at Glogatz, in Germany, on August 5, being a large fire at one of the military establishments. According to the *Central-Blätter Bauwesen*, these doors, of 4 cm. thick pine-wood boarding, sheathed on either side with 3 mm. thick iron plating, resisted the intense heat of the fire for more than three hours, thereby saving a wing of the otherwise gutted building. On examining the doors after the fire, the side of the wood nearest the fire was found charcoaled, whilst the further side still showed its natural light colour.

A PROPOSED NEW LINE OF RAILWAY TO LONDON FROM THE NORTH.—Several provincial journals repeat the statement, noticed by us some little time ago, that the Manchester, Sheffield, and Lincolnshire Railway Company intend next Session to bring in a Bill for a new railway, to give them a direct route from Liverpool and Grimsby, via Nottingham, Rugby, and Aylesbury, to London. It will run within half a mile of Lutonwards, the inhabitants of which town have long bewailed the fact that through the folly of their ancestors in opposing railways they have hitherto been without direct communication.

"SKY SIGNS."—It is understood that the question of sky signs is to come before the London County Council at the earliest moment. The point will be raised whether erections of this kind, which are virtually a raising of the house, can be placed in position without the consent of the surveyor acting on behalf of the public authorities. If not, it may be taken as settled that "sky signs" will not only be stopped in their growth, but will be greatly reduced. A correspondent suggests that the Advertising Stations (Rating) Act, 1889, Section 4, seems to apply to such signs, and if ordinary hoardings in outside districts are assessed upon rentals of 6d. per yard superficial per month, the rating of these huge structures in the best positions in the City would bring some consolation to the ratepayers, if it does not offer inducement for the discontinuance of the signs.—*Metropolitan*.

STREET IMPROVEMENTS AT WILLESDEN.—Mr. Arnold Taylor, one of the Local Government Board Inspectors, held an inquiry a few days ago at the offices of the Willesden Local Board relative to the application on behalf of that board to borrow £4,623, for works on private streets improvement. From the statements made by Mr. S. Tilley, Clerk to the Board, and Mr. Robson, the Surveyor, it appeared the loan was to make up eight new streets. Last year no fewer than four new streets were made up. Statistics were given by Mr. Tilley showing that the population of Willesden had risen from 27,397 in 1881 to a present estimated population of 43,900. The development of the neighbourhood was ascribed to the great facilities afforded by the railway and omnibus companies. Mr. Taylor said he had heard that no district in the metropolitan area had developed so rapidly as Willesden. The existing loans were stated to amount to 55,142.

THE PROPOSED VAUXHALL IMPROVEMENT.—At the last meeting of the Lambeth Vestry, a letter was received from the London County Council, intimating that the Council would apply to Parliament in the next session for power to widen the Albert Embankment between Upper Kennington Lane and Vauxhall-walk, provided the Vestry would contribute one-fourth of the net cost of the improvement, which was estimated at 26,600.—Mr. Howlett moved that a letter be sent to the Council declining the proposal. The improvement would be of no use unless it was extended to High-street, Vauxhall, and Nine Elms-lane, and it was no use frittering money away on sections of the work. If ever there was a metropolitan improvement this was one.—Mr. White seconded, and maintained that the work should be carried out by the Council.—Mr. Fritchard disagreed with the remarks of the previous speakers, and contended that the Vestry would recoup themselves the 6,500, they were asked to contribute by the increased value of the frontages.—The motion was supported by Captain Andrew, Messrs. Ayling, Sharpley, Chambers, and Edwards, and agreed to. We think the Lambeth Vestry will do well to reconsider this decision, on the principle that "half a loaf is better than no bread." There is great need of an improvement at the spot in question. If an instalment of the improvement were carried out, its completion would probably follow in due course.

THE ENGLISH IRON TRADE.—There is greater activity in the English iron market. Consumers, both at home and abroad, appear to cognize the fact that prices are not likely to recede again this year, and are consequently anxious to cover their requirements at present rates, which, according to makers, are still too low to profitably cover the cost of manufacture. In pig-iron there is a decided upward tendency. Scotch warrants have been going up all the week, and Scotch makers' fees following the lead, as much as 1s. 6d. per ton more being now quoted for some brands. Middlesbrough pig is 9s. per ton dearer, and pig-iron in other districts is advancing. Makers of Bessemer iron have not yet raised their bottom price, but hematite warrants are nearly 2s. dearer. Together with pig-iron, old materials are taking an upward turn. Finished iron and steel are in a more active position with prices firm. There is a lull in the tin-plate trade, but makers are very stiff. Shipbuilders have not been booking any fresh orders of consequence this week. Engineers continue actively engaged.—*Iron*.

THE NATIONAL ARMADA MEMORIAL AT PLYMOUTH is to be unveiled during the second week in October by H.R.H. the Duke of Edinburgh.

MR. JAMES HILL, of the firm of James Hill & Co., Queen Victoria-street, has just returned to London, after a ten months' tour round the world.

EXCAVATIONS AT CASTLE CARY.—The excavations at Castle Cary, says the *Western Chronicle*, have been steadily pursued, and now the foundations of the keep of Cary Castle are sufficiently exposed to enable an accurate ground-plan to be made. This plan reveals a state of things that was totally unexpected both by archaeologists and the public generally. In the first place, it shows beyond doubt that the castle was not in the position where it was generally supposed to stand, and where its site had been marked on the latest Ordnance map, but about 200 yards to the south-west of it; and it shows that the castle was not an ordinary "shell keep," as described by Clark, but a strongly-built fortress of unusually large dimensions and thickness of walls. The plan of the excavations, as far as they are gone, gives an idea of the size and strength of this stronghold of the Levels. It represents the outer wall to be 15 ft. in thickness, the foundations of which are of "Cary Hill" stone, and the facings of "Doutling" and "Ham Hill." Careful and accurate plans and sections are being prepared for the purpose of preservation among the records of the Archeological Society at Taunton. But there is still a good deal to be done. The keep is nearly complete, but the walls of the inner and outer baileys are yet to be discovered and put upon the plan.

THE ARCHAEOLOGICAL EXCAVATIONS AT KENTWORTH.—The *Coveyent Herald* reports that these excavations are now completed, and that the church-yard has resumed its usual quiet appearance. The nave and north transept of the long-buried church have been cleared, the tiled floor removed, and the surface levelled and turfed over. The removal of the debris has given a sharp pitch of about 5 ft. below the level of the adjoining burial-ground; and almost this difficulty a strongly-built retaining wall has been erected. This answers the double purpose of guarding the nearest row of graves from a landslip, and also gives a pleasing promenade, from which a good view of the excavations may be obtained. The wall extends to the extremity of the north transept, leaving the altars of the Lady Chapel projecting at the top. The two stone officines, found during the progress of the work, have been built into the wall. The largest is that of a Canon (headless) in full vestments, and the smaller (also headless) is a grotesque figure of a monk, seated. The pillars, which originally supported the tower, are left *in situ*, and have been pointed up and raised. The flight of steps leading from the church to the cloisters has been preserved, and the space within the cloisters and the outer monastic buildings has been levelled and turfed over, and with the remainder of the excavated area will now be used for burial purposes. The south transept, chancel, and chapter-house are still untouched, and as these portions are on land which is vested in the Local Board there ought to be no difficulties in the way of further research.

A LARGE MONOLITH.—Vinalhaven, Maine, claims to have produced the largest stone ever brought to light. The Bolwell Granite Company recently quarried a shaft of granite which, it is said, is the largest piece of stone ever quarried anywhere, and, if erected, will be the highest, largest, and heaviest single piece of solid stone standing, or that ever stood, so far as any record can be found. In height it considerably exceeds any of the Egyptian obelisks. It is understood, says *Stone*, that the Company quarried this immense monolith on their own account, not having an order for anything of the kind, and they suggest that it would be a fitting contribution from Maine for the monument to be erected in honour of General Grant.

"AN AMERICAN TECHNICAL JOURNAL ON 'CHINAMANIA.'"—We hope to be forgiven for lack of reverence for things that are ancient, but we must say that there is a precious lot of old brick gathered together by collectors that has neither merit nor history to commend it, and much of it is absolutely ugly,—that is, it is painful to look at it. There are some old things in ceramics that are good and worth gathering together, but the bulk of it is rubbish that is very much like some of the rubbish that is thrown on the market under the guise of novelty. When it first appears, the price is put high enough to impress a possible purchaser with the idea that it is a marvellous bit of pottery. He buys a piece of the line, say a small vase, for 100s., and takes it home to show the innocents of his domestic what a discoverer he is. Six months after he finds a huckster who has picked up the tail end of the "job," and is hawking the selfsame vases on the streets for a quarter. Then he feels real good, like the man in Wall-street a few days ago, who cursed the poor Dago for selling some fancy pottery at rock-bottom prices which corresponded precisely with the expensive pieces of the same line that he had bought last winter. There is a happy mean between old rubbish and new rubbish, and that is solid merit of any age or period whatever.—*Crockery Journal of New York*.

ROBERT BROWNING.—The Society of Arts have erected one of their memorial tablets on the house, No. 19, Warwick-crescent, Malia-hill, where Robert Browning lived from the time of his removal from Italy, after the death of his wife, in 1861, until the summer of 1887, when he removed to 29, De Vere-gardens.

LEGAL.

DAMAGES AGAINST A STATION-MASTER FOR THE DETENTION OF BUILDING MATERIALS.

In the County of London Sheriff's Court on the 11th inst., before Mr. Under-Sheriff Burchell and in the case of Pilbrow v. Ingham & Sons, Holland, and Mansell was heard. It was an action originally before the High Court, and was remitted for the assessment of damages.

Mr. Overend, the counsel for the plaintiff, stated that his client was a builder at Hounslow, and traded under the style of Taylor & Pilbrow. In June last he ordered a quantity of glazed bricks and pipes from Ingham & Sons, a provincial firm, through Mr. Holland, their representative. The goods were duly forwarded by rail to Hounslow, the plaintiff previously receiving an invoice marked "carriage paid. He sent men and carts to the station to remove the goods, but the station-master refused to deliver them up unless the carriage was paid. The invoice, with the endorsement, was shown to him, but he declined to recognise it, remarking that any one might have written in the words. The consequence was that the plaintiff was unable to complete work he had in hand, and, besides, his credit was injured by a rumour being circulated in the district that he had bricks at the station, and could not pay the carriage. It was at first supposed that Messrs. Ingham & Sons and Mr. Holland had failed to carry out their contract, but that turned out to be a mistake, and the claim for damages being made only against Mr. Mansell, the station master.

After a long consultation, the jury gave a verdict for £50 against Mansell.

RECENT PATENTS:

ABSTRACTS OF SPECIFICATIONS.

7,241.—CONSTRUCTION OF WALLS: J. Wilson.—According to this invention layers of corrugated metal plates are placed with their respective concavities opposite to each other, so that the double corrugation forms a tube. These spaces are filled with asphaltine and a wall thus built up, or sheets of metal are placed a short distance apart and strengthened by pipes or equivalent, and thus a wall is formed. Many modifications for different purposes are described in the specification.

13,153.—VENTILATING SEWERS, &c.: F. Barnett.—By this invention, iron, or other pipes of sufficient strength and calibre are fixed with their lowest ends seated in the walls of these sewers, near the crown of their arches, and are brought vertically up the fronts, sides, or backs of houses to about 10 or 15 ft. above the roofs, and fitted with revolving cowls. Short inlet pipes are used, and by reason of the outlet pipes being much longer the sewer gas is carried off. The action of exhaustion is permanent, like that of a syphon with inverted action.

13,483.—BARS FOR FIRE-GRATES: R. Peel.—This patent relates to a new method of attaching the end-pieces of top bars for fire-grates to the top or ornamental plate. This is generally effected by dovetails, but in this improvement lugs or projections are formed on the plate, to which the bars may be secured.

14,007.—LIME-KILNS: A. Bishop.—According to this invention a dome is made to the improved kiln, which is circular on plan, and the centre of the dome is provided with a shaft, and around the central shaft smaller feeding shafts are placed. In burning the fuel in this form of kiln, the fire, being once established, the process is continuous, the chalk being introduced through the central shaft, and a quantity to keep the shaft nearly filled to the top. Fuel is also constantly added in small quantities. As the fuel is consumed and the chalk converted into lime, it passes down the kiln, and is removed at bottom, and the fuel which is introduced through the small feeding-shafts being deposited near the circumference of the burning shaft, the flames from it are drawn onwards towards the centre on their way towards the central shaft, and produce a high temperature with a very moderate amount of fuel.

5,905.—IMPROVEMENT IN JOINERS' SQUARES: H. D. Marples.—The blade has an edge graduated as a measure. The wooden part is fitted with a longitudinal and transverse spirit level, and the upper part of the wood arranged as a mitre.

NEW APPLICATIONS FOR PATENTS.

Sept. 1.—13,707, J. Oll, Roofing and Flooring Tiles.—13,737, S. Washington, Connecting Lead Pipes, &c.

Sept. 2.—13,745, G. Willcock, Fastenings for Windowsashes.—13,764, H. Sutcliffe, Lavatory Wash-basins.

Sept. 3.—13,512, S. Hill, Centre Bearings for Swing Windows, Ventilators, &c.—13,822, R. Whitford, Locks and Fastenings for Doors and Casements.—13,860, G. Gardner, Scaffold-fastenings.

Sept. 4.—13,882, J. Salt, Brick-making Machinery, &c.—13,896, J. Bramley, Ventilation.

Sept. 5.—13,957, J. Legge, Door-latches.—13,972, E. Emanuel and others, Supply-valve for Seat-action Water-closets and Water W.C. preventer combined.

Sept. 6.—14,017, P. Walker, Ventilators.—14,028, G. Hovey Hopper, Ventilators for Windows, &c.—14,057, T. Harris, Water-closets.

PROVISIONAL SPECIFICATIONS ACCEPTED.

10,457, T. Bremner, Connecting Cords to Window-sash Frames, &c.—10,911, J. Birch, Fanlight Openers, &c.—10,950, G. Pearson, Securing Tiles or Panels to their Backings.—11,204, H. Lomax and W. Cotton, Fastening Doors, &c.—11,377, J. Merryweather, Cleaning and Disinfecting Drains, &c.—12,011, G. Rohrbach, Gate-hinges, &c.—12,012, G. Rohrbach, Gate-latches.—12,206, E. Bally and E. Wehrli, Parquetry.—12,579, H. Mott and J. Perry, Decorative Wallpapers.—12,422, H. Kelcey, Caseament Fastener.—12,569, P. Aytton, Bolt fastener for Caseament Windows, &c.—12,655, F. Stanworth, Flushing Tanks.—12,687, G. Challet, Folding Step-ladder.—

12,721, J. Fryer, Bricks.—12,723, J. Bowling, Portland Cement, &c.—12,781, H. Werner, Concrete Pipes, &c.—13,073, T. Faucett, Brick-making and Pressing Machinery.—13,134, C. Abel, Bricks, &c.—13,155, L. John, Firing Pottery.—13,227, C. House, Cement.—13,282, J. Kilderman, Kilns or Ovens for Burning Bricks, Tiles, &c.—13,313, W. Henley and others, Window-sashes, &c.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to Opposition for Two Months. 16,213, M. Rogers, securing Window-sashes in any desired position.—17,443, W. Lindsay, Tiles, and structures in which they are used.—17,666, J. Empson and others, Valves for Gaskets.—17,809, J. Pyle, Water-taps.—18,143, H. Nettelfield and J. Sheldon, Screws.—7,204, W. Thompson, Mortising and Boring Machinery.—9,463, A. Moore and H. Pate, Sheet Metal Roofing.—11,423, F. Smith, Sash Fasteners.—11,446, W. Thompson, Door Bells, &c.

SOME RECENT SALES OF PROPERTY:

ESTATE EXCHANGE REPORT.

SEPTEMBER 9.—By A. G. Thompson & Co.: 11, Hanover-st., Belgravia, u.t. 34 yrs., £7, 7s., 4d.; By W. H. Keer: 11, Garrick-hill, City, u.t. 12 yrs., r. 100s., 100s.

SEPTEMBER 10.—By Hampton & Sons: "Taplow House," Taplow, and 2A, R. 33p. f. and c., 17,000l.; By Wyatt & Son (at Chichester): three f. cottages, Orchard-st., Chichester, r. 23l. 18s., 380s.; two f. houses, r. 23l. 8s., 350s.

SEPTEMBER 11.—By C. C. & T. Moore: 51 and 57, Willow-st., Westminster, u.t. 54 yrs., gr. 104, 10s., £7, 65l., 51s.; 53, Coleridge-row, ditto, f. r. 36l., 87s.; 52, Rochester-row, ditto, r. 55l.; 24 and 26, Collingwood-st., Bethnal-green, c. r. 44l. 4s., 370l.; 2 and 2a, Cottongarden, Shoreditch, l. 95l.; and 8 and 9, Vine-st., Minorie, u.t. 7 yrs., 65l., 600s.; By J. Matthews: 38, 40, 68 to 72 (even), Warwick-rd., West Ham, u.t. 90 yrs., gr. 33l. r. 166l. 6s., 1,020l.; three houses, Sydenham, r. 93 yrs., gr. 23l. 3s., r. 30l., 95l.; "Gayton House," Gayton, r. 40 yrs., r. 100l., 1,650l.; 17 and 19, Handen-rd., Lee, u.t. 77 yrs., gr. 4l. r. 82l., 1,200l.; 13, 14, and 15, South-rd., Erith, u.t. 58 yrs., gr. 13l., r. 1, 600s.; the f. house, Ormsiston, Lesney Park-rd., Erith, r. 60l., 1,000l.

(Contractions used in these lists.—E.g.r. for freehold ground-rent; l.g.r. for leasehold ground-rent; i.g.r. for improved ground-rent; g.r. for ground-rent; r. for rent; f. for freehold; c. for copyhold; l. for leasehold; e.r. for estimated rental; u.t. for unexpired term; p.a. for per annum; y.s. for years; s. for street; rd. for road; sq. for square; pl. for place; ter. for terrace; cres. for crescent; yd. for yard, &c.)

PRICES CURRENT OF MATERIALS.

Table with columns: MATERIALS, £. s. d., and £. s. d. Includes entries for Greenheart, Teak, Sequoia, Ash, Birch, Elm, Fir, Danish, Oak, Pine, Lath, Deals, Riga, St. Petersburg, Swedish, Canada, White Sea, Cedar, Honduras, Mahogany, St. Domingo, Mexican, Tobacco, Box, Bahia, Sao Domingo, Porto Rico, Walnut, Iron, Steel, Copper, Sheets, Gullies, Lead, Siles, Pipe, Zinc, Tin, Australian, English Ingots, Oils, Lined, Coconut, Ceylon, Palm, Lugo.

Table with columns: OILS (continued), £. s. d., and £. s. d. Includes entries for Rapeseed, Cottonseed, Tallow and Oleine, Lubricating, TAR—Stockholm, Archangel.

TENDERS.

(Communications for insertion under this heading must reach us not later than 12 noon on Thursdays.)

ARKLEY (near High Barnet).—For alterations to Eastwood, for Mrs. Barnes. Mr. Hubert A. Gregg, architect, 1a, St. Helen's-place, E.C.4.—James, Barnet (accepted)..... £330 0 0

ARKLEY (near High Barnet).—For rebuilding the vicarage for Mrs. Barnes. Mr. Hubert A. Gregg, architect, 1a, St. Helen's-place, E.C.4.—James, Barnet (accepted)..... £250 0 0

BEDDINGTON (Surrey).—For first portion of new flour mill, at Beddington, Surrey, for Messrs. J. & T. H. Wallis. Mr. Horace T. Bonner, architect, 29, King-street, Chancery, E.C. Quantities supplied:—Chappard..... £2,900 0 0; Spenser & Co..... 1,920 0 0; Holloway..... 1,960 0 0; Page..... 1,895 0 0; Humphries..... 1,810 0 0; Smith & Son..... 1,743 0 0; Taylor..... 1,785 0 0; Trappitt, Beddington (accepted)..... 1,700 0 0

BELFAST.—For works on the Antrim-road, Belfast. Mr. John H. Brett, County Surveyor, County Courthouse, Crumlin-road, Belfast.—John Smith, York-road, Belfast\* £1,600 0 0; Gregg & Gaston..... 1,498 19 0 \* Accepted.

BLACKWOOD (Mon).—For the erection of a new English Baptist Chapel at Blackwood, Mon. Mr. W. L. Griffiths, architect, 63, High-street, Newport, N.S.W. Quantities supplied:—H. Welsh..... £1,650 0 0; J. Linton..... 1,400 0 0; T. Lawrence..... 1,350 0 0; Hughes & Pugh..... 1,245 12 6; Morris & Thomas..... 1,285 0 0; John Hardy, Blackwood (accepted)..... 1,092 0 0

BRAY (Ireland).—For the erection of stabling, &c., at Bray, Ireland, for the Bray Township Commissioners. Mr. F. Comber, Township Surveyor, 8, Anglesea-street, Dublin.—Henry Pemberton..... £379 0 0; Robert O'Connor..... 449 0 0; Bernard Brady & Sons, Bray\*..... 396 8 4 \* Accepted.

BRIMSDOWN (Middlesex).—For the erection of four cottages on the Brimsdown Estate, for Mr. Godfrey A. Baker. Mr. G. Warren Cooper, Bedford Row House, Bedford-row, W.C., architect.—C. J. Price, Beckenham (accepted)..... £760 0 0

BRIMSDOWN (Middlesex).—For the erection of fourteen cottages on the Brimsdown Estate, for Mr. Godfrey A. Baker. Mr. G. Warren Cooper, Bedford Row House, Bedford-row, W.C., architect. No quantities.—F. Voller, Wood Green..... £3,958 0 0; S. Goodall, Stoke Newington (accepted)..... 2,800 0 0

BURNOPFIELD (Co. Durham).—For additions to co-operative Bazaar, Burnopfield, Co. Durham, for the Burnopfield District Co-operative Society. Mr. J. Wm. Rountledge, architect, Blackhill, Co. Durham.—Whole Tenders.—H. Brown & Co., Newcastle-on-Tyne 2700 0 0; R. Mitchison & Co., Newcastle-on-Tyne..... 400 0 0

Mason, Plasterer, Slater, and Plumber. A. & R. Davis, Burnopfield\*..... 278 8 8; John Scott, Burnopfield\*..... 176 14 7 \* Accepted.

Total of accepted tenders..... £455 3 1

[A number of other separate tenders were received.]

CADOXTON (South Wales).—For the execution, completion, and maintenance of works required in the construction of two roads at Cadoxton, South Wales, for the Barry and Cadoxton Local Board. Mr. J. C. Pardee, Surveyor, Local Board Offices, Cadoxton.—Writing and Improving Holton and Weston-road.—Contract No. 1.—W. R. Parker & Co..... £2,354 14 0; Alfred Elliott..... 4,812 16 9; T. Jones Davies, Burnopfield, Co. Durham..... 3,890 0 0; E. J. Ince..... 3,769 18 3; David Love, Cadoxton (accepted)..... 3,615 2 0

CONTRACTS AND PUBLIC APPOINTMENTS.

CONTRACTS.

Table with 3 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer. Includes items like Public Baths and Washhouses, Gasworks, and various construction contracts.

Table with 3 columns: Architect, Surveyor, or Engineer, Tenders to be delivered, and dates. Lists names like K. F. Campbell, H. O. Thomas, and J. O. Lobbey.

CONTRACTS.—Continued.

Table with 4 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, and Tenders to be delivered. Continues the list of construction contracts from the previous section.

PUBLIC APPOINTMENTS.

Table with 4 columns: Nature of Appointment, By whom Advertised, Salary, and Application to be in. Lists appointments for Surveyors and Accountants.

Those marked with an asterisk (\*) are advertised in this Number. Contracts, pp iv., vi., and viii. Public Appointments, p. xviii.

Doncaster.—For erecting Primitive Methodist school, school-rooms, and residence at Hyde-park, Don. Architects: J. J. Simmons, architect (Brundell, Simmons, & Brundell), 1, Princes-street, Doncaster.

Eastleigh (Hants).—For the erection of a shop and residence at Eastleigh, near Southampton, for Mr. J. J. Badd. Mr. Thos. Stophar, architect and surveyor, 57, High-street, Winchester.

Fareham.—For works of rat paving in footpaths, in the District of Fareham, for the Local Board. Mr. Walter Butler, Surveyor.

Foleshill (near Coventry).—For the erection of new Liberal Club, at Lockhurst-lane, Foleshill, near Coventry, for the Foleshill Co-operative Land and Building Society, Limited. Mr. Amos Kandle, architect, 21, Broadgate, Coventry.

Greenwich.—For alterations at the "Royal Briton," Horsesherry-road, Greenwich, S.E., for Mrs. Brookes. Mr. H. T. Bonner, architect, 29, King-street, Chelsea, E.C.

Kendal.—Accepted for building three houses at Kendal, for Mr. Herbert Moser. Mr. John Stalker, architect, Kendal.

Kendley (Surrey).—For additions at Hayes Court, Kendley, Surrey, for Mr. F. Gastle Smith.

Llanhilleth (near Newport, Mon.).—For the erection of cottages for the Llanhilleth Cottage Building Co., Limited. Mr. W. L. Griffiths, architect, 68, High-street, Newport, Mon.

Leeds.—For the erection of thirteen houses at Lindo-ave, Dewbury-road, Leeds, for the Leeds Industrial Co-operative Society (Limited). Mr. W. S. Braithwaite, architect, 8, South Parade, Leeds.

London.—For erecting proposed factory and warehouse in Lever-street, St. Leonards, E.C., for Mr. F. T. Pullivant. Mr. A. Allen, jun., architect, 12, City-road.

London.—For pulling-down and rebuilding No. 47, Great Portland-street, W., for Mr. W. H. France. Mr. Albert E. Fridmore, architect, 2, Broad-street-buildings, E.C.

London.—For works at the "Royal Standard" public-house, Fleming-street, Kingsland-road. Mr. Harvey Dhyall, architect.

London.—For works at the "United States" public-house, Commercial-road, E. Mr. Harvey Dhyall, architect.

London.—Accepted for internal fittings at the "Adolph Stores," Strand. Messrs. Wilson & Long, architects.

London.—For works at 125, Courage-road, Old Kent-road. Mr. Harvey Dhyall, architect.

Market Bosworth.—For the construction of about 740 yards of 9, 12, and 15-in. earthenware and cast-iron socketed pipe sewers, with man-holes, &c., complete, in the parish of Ratby, for the Market Bosworth Rural Sanitary Authority. Mr. G. S. Horton, Surveyor, Market Bosworth.

Morden (Surrey).—For providing and fixing about 600 yards of oak park fencing, on the Hobald's Farm Estate, Morden, Surrey, for the Battersea Baria Board.

Mountain Ash (Glamorganshire).—For building a school-room adjoining the Welsh Calvinistic Methodist Chapel at Mountain Ash, for the Rev. M. D. Jones.

Morden (Surrey).—For providing and fixing about 600 yards of oak park fencing, on the Hobald's Farm Estate, Morden, Surrey, for the Battersea Baria Board.

Mitcham.—For the erection of fire-escape staircases at their Schools, Mitcham, Surrey, for the Guardians of the Poor of the Highborn Union. Mr. H. Saxton Stuel, architect, London.

Morden (Surrey).—For providing and fixing about 600 yards of oak park fencing, on the Hobald's Farm Estate, Morden, Surrey, for the Battersea Baria Board.

Morden (Surrey).—For providing and fixing about 600 yards of oak park fencing, on the Hobald's Farm Estate, Morden, Surrey, for the Battersea Baria Board.

Morden (Surrey).—For providing and fixing about 600 yards of oak park fencing, on the Hobald's Farm Estate, Morden, Surrey, for the Battersea Baria Board.

Morden (Surrey).—For providing and fixing about 600 yards of oak park fencing, on the Hobald's Farm Estate, Morden, Surrey, for the Battersea Baria Board.

Morden (Surrey).—For providing and fixing about 600 yards of oak park fencing, on the Hobald's Farm Estate, Morden, Surrey, for the Battersea Baria Board.

Morden (Surrey).—For providing and fixing about 600 yards of oak park fencing, on the Hobald's Farm Estate, Morden, Surrey, for the Battersea Baria Board.

Morden (Surrey).—For providing and fixing about 600 yards of oak park fencing, on the Hobald's Farm Estate, Morden, Surrey, for the Battersea Baria Board.

Morden (Surrey).—For providing and fixing about 600 yards of oak park fencing, on the Hobald's Farm Estate, Morden, Surrey, for the Battersea Baria Board.

Morden (Surrey).—For providing and fixing about 600 yards of oak park fencing, on the Hobald's Farm Estate, Morden, Surrey, for the Battersea Baria Board.

Morden (Surrey).—For providing and fixing about 600 yards of oak park fencing, on the Hobald's Farm Estate, Morden, Surrey, for the Battersea Baria Board.

NEWCASTLE-ON-TYNE (near).—For leading and laying 5,800 yards of cast-iron pipes and connections between Atkinson-road, Benwell, and Newburn, Northumberland, for the Newcastle and Gateshead Water Company. Mr. J. R. Foster, engineer, Newcastle and Gateshead Water Company, Newcastle-on-Tyne:—

Table with 2 columns: Name and Amount. Includes John T. Simpson (£4,203 0 0), Nicholson & Elliott (2,765 10 0), Smith & Gibbon (2,877 10 0), John & Thomas Young (2,651 10 0), Thomas Bell (2,351 6 0), William Carr, Hexham (accepted) (2,333 12 6), Gustavus Bailey (2,216 10 0).

NEW MALDEN.—For the erection of Baptist Chapel, Kingston-road. Mr. W. H. Woodroffe, architect, 214, Great Dover-street, S.E.:—

Table with 2 columns: Name and Amount. Includes Roffey (£2,050 0 0), Smith & Son (1,938 0 0), Parker (1,943 0 0), Hards (1,838 0 0), Young & Lonsdale (1,764 0 0).

PONTYFRIDD.—For building a workmen's institute and public hall at Ynyshir, near Pontyfridd, for the Ynyshir and Watstown Public Hall Company (Limited). Mr. Charles Taylor, architect, 29, Duke-street, Cardiff:—

Table with 2 columns: Name and Amount. Includes Johnson Bros. (£5,887 10 0), Joseph Thomas (5,572 0 0), Echora of W. Gradwell (4,670 0 0), C. Jenkins & Son, Cardiff (4,600 0 0).

PONTYFRIDD.—For the erection of twenty-two workmen's cottages at Ynyshir, near Pontyfridd, for the Pontyfridd Building Society. Mr. John Bevan, architect, Mountain Ash:—

Table with 2 columns: Name and Amount. Includes Edward Evans, Ynyshir, near Pontyfridd (accepted) (£3,150 10 0).

POTTERS BAR.—For the erection of a new police-station at Potters Bar, for the Receiver for the Metropolitan Police District. Mr. John Butler, architect. Quantities by Mr. W. H. Thurgood:—

Table with 2 columns: Name and Amount. Includes C. Barnes (£1,907 0 0), Patman & Potheringham (1,908 0 0), Hart Bros. (1,909 0 0), J. Smith & Sons (1,897 0 0), Higgs & Hill (1,894 0 0), J. T. Chappell (1,895 0 0), Gwyer & Son (1,892 0 0), Scrivener & Co. (1,877 0 0), Nighthaline (1,852 0 0), Kithley Bros. (1,850 0 0), Willmott & Son, Pottery (1,783 0 0).

SHEFFIELD.—For the erection of lodge at Carbrook Recreation Grounds, Sheffield. Mr. Charles F. Wike, Borough Surveyor:—

Table with 2 columns: Name and Amount. Includes Dutton & Evans (£563 0 0), John Esheley (545 0 0), John Morton (493 0 0), W. L. Smith (491 0 0), T. Cuthbert (467 0 0), J. Chambers & Sons (464 0 0), J. Mason & Son, Sheffield (accepted) (453 0 0).

SHEFFIELD.—For putting work at Lodge Moor Fever Hospital, Sheffield, for the Corporation of Sheffield. Mr. C. F. Wike, Borough Surveyor:—

Table with 2 columns: Name and Amount. Includes Wm. Fuller (£210 0 0), M. A. Topham (200 0 0), G. Smith (197 0 0), A. Jubb (195 15 0), M. H. Thraves (183 10 8), A. Machin (170 0 0), F. Jackson (168 17 0), J. Putterill & Co. (153 0 0), Smith & Snape (150 0 0).

SHEPTON MALLET.—For the erection of a minister's house at Shepton Mallet, for the trustees of the Cumbrian House. Mr. J. Ace Beynon, architect, Coleford, near Bath:—

Table with 2 columns: Name and Amount. Includes Contract A (£290 0 0), Ford (84 0 0), T. Ashman (84 0 0), Jones (76 0 0), E. James, jun. (75 0 0), W. Tovey (73 0 1 5), Doddlehead (71 10 0), J. H. Pullen (accepted) (69 14 0). Contract B, Barnstaple-works, Exeter-works, &c. Pullen (accepted) (£26 0 0).

STAFFORD.—For excavating, paving, kerbing, channelling, &c., roads at Stafford, for the Corporation. Mr. W. Blackshaw, Borough Surveyor, Stafford:—

Table with 2 columns: Name and Amount. Includes Kerby Blue brick channel paving (£447 4 10), Bradshaw & Co. (323 1 11), Burnham & Phillips (49 0 6), W. Moore (479 9 5), H. Newton (507 18 5), C. J. Nevitt, Stafford\* (404 11 2).

STRITON.—For alterations and additions to "Saxbury" St. Mary's-road, Stritton, for Mr. J. E. Bowring. Mr. William Wallace, architect, 27A, Old Bond-street. Quantities by Mr. Walter Herring:—

Table with 2 columns: Name and Amount. Includes Jarvis (£3,714 0 0), Fox & Co. (3,676 0 0), Faulkner (3,663 0 0), Havell (3,458 0 0), Gregory & Co. (3,357 0 0), Marriage (3,203 0 0).

WALTHAMSTOW.—For building new class-room and teachers' rooms at the Gannuel-road (girls) and Infants' Schools, for the Walthamstow School Board. Mr. W. A. Longmore, architect, 7, Great Alie-street:—

Table with 2 columns: Name and Amount. Includes Barrett & Power (£435 0 0), Fuller (585 0 0), Challa (550 0 0), Taylor (540 0 0), Cracknell, Walthamstow (accepted) (455 0 0).

SUBSCRIBERS IN LONDON AND THE SUBURBS by prepaying at the Publishing Office, 19s. per annum (or 4s. 3d. per quarter), can ensure receiving "The Builder" by Friday Morning's post.

TO CORRESPONDENTS.

### The Architectural Education of the Public.

**I**T has become almost a commonplace among those architects who take a serious view of their art, and regard it as something more than a means of making a respectable living, that there can be little hope of a general improvement in the standard of architecture in this country until there is a general public desire for better architecture, grounded on a more cultivated perception as to what architecture really means. It may perhaps be suggested that artists of every class are prone to think lightly of the public appreciation of their own art; and that architecture is no worse off in this respect than painting or sculpture. Admitting this to a certain extent, there is nevertheless some ground for considering architecture as a subject in which the public are specially in need of instruction. There is unquestionably a better general perception as to good and bad in regard to painting and music, for instance, than in regard to architecture, and there is, among well-educated people at all events, a respectable public opinion in regard to those two arts. There is far less in regard to sculpture; and in England at all events this art perhaps fares hardly better than architecture, so far as general comprehension is concerned: and for much the same reason. Sculpture is a much more abstract and less realistic art than painting. Architecture is more abstract than either, and appeals to a more purely intellectual perception. But commissions for sculpture are given commonly by persons who have some love of the art and some idea what they want from it. Architectural commissions are in many cases given by those who have only a utilitarian object in view; or who, if they have any idea of architecture before their eyes, only wish for a building which answers the requirement of being correctly designed according to one of the styles which they have heard of, or which modern custom has accepted as correct. Whether this latter system produces anything better than a mere utilitarian building depends almost entirely on the architect. If he is a man with the feeling of an artist, and who is something of

an enthusiast in his work, he will put into this merely imitative architecture a degree of refinement which will give it interest and value. If he is not, he will merely produce a bald and perhaps coarse imitation which will have no value or interest at all, but which will in all probability satisfy his client as well as anything else.

How are we to influence the public to care for, to demand, something better in architecture than this? For until they do demand it, there is little probability of a general improvement. This consideration forms the subject of two of the papers in the recently issued volume of the Transactions of the National Art Association; the second volume of the series, containing the papers read, and some brief notes of the discussions, at the Congress held at Edinburgh last November. We devoted some space to noticing the proceedings of the Congress at the time, and have no intention of going over old ground again. But the appearance and form of the volume recording the proceedings at that Congress deserve in any case a word of recognition. The volume, printed by the firm of Constable, is got up in such a manner as to render it worthy to be the record of an Art Congress. Not that there is any display about it, or anything elaborately ornate in the binding or decoration; but it is a thoroughly well-printed book, with a good type, a wide margin, and a study to arrange the page so as to produce a generally satisfactory effect to the eye. It is a book which not only contains a great deal that is worth reading, but one which is thoroughly agreeable to the eye, and presents a marked contrast in this respect to the printed page of the ordinary English books of to-day. The Editing Committee have done well thus to make their volume, a record of an Art Congress, in itself a work of art in the manner in which it is got up, thus rendering it a practical exemplification of one minor form of art, and one which is in general greatly neglected in the present day of rapid and voluminous putting forth of books. The whole spirit of the teaching comprised in the papers read at the two Congresses already held is to inculcate the idea that art does not consist in the production of pictures and sculpture only, but that the artistic spirit may be and should be shown in all forms of work; and the Edinburgh volume of Transactions is in

itself a most praiseworthy example of this spirit.

Having done this justice to the form in which the volume is produced, we will devote the rest of our remarks upon it to the papers which deal with the subject which is of the most direct interest to us, the means of developing and improving that general knowledge of architecture in which the English public is at present so deficient. This is dealt with in two papers under the heading "The architectural education of the public," by Mr. Campbell Douglas and Mr. G. S. Aitken respectively. Of these two papers, the latter is the most direct and practical; both to some extent take the same ground, that architecture should be made a portion of general education, but the method of doing this is more practically dealt with by the latter writer.

Accepting the fact that the English public know little of architecture, as one on which all persons are agreed (for the average Englishman, so far from denying his ignorance of architecture, is disposed rather to boast of it), the two questions to be asked are, what is the reason for this exceptional ignorance, and what is the remedy for it. Mr. Douglas suggests, in regard to the first point, that the mere fact that architecture of some kind is one of the daily surroundings of all persons' lives leads them to think that they know all about it. All people are not brought up in the midst of collections of paintings or sculpture; but all dwellers in towns are brought up in the midst of collections of buildings, many of them more or less architectural in character; they are familiar with cornices and pilasters as every-day incidents, and cannot see that there is any mystery in the matter which should make it necessary for them to study it, and "people do not set themselves to learn anything for which they do not see any good reason." The result of this general familiarity with certain every-day forms of architecture is the same kind of acquaintance with it that the man had with literature, who found he had been "talking prose all his life" without knowing it. That man would probably have had little or no perception of refinements of literary style, nor would the man who had seen buildings every day of his life have necessarily any perception of the refinements of detail which make the chief difference between good and

bad architecture. He would recognise a general drawing of a columnar building as representing what he had seen; but if you were to show him drawings of various details, base-mouldings, ornamental details, &c., he would be quite unable to say whether these were correct or not, just as the man who had talked prose by habit would be unable to define correct grammar; or, as Mr. Douglas puts it, just as we might receive a general impression of passion and eloquence from a speech in a foreign language imperfectly understood, but without being able at all to discriminate whether it was good or elegant French, or German, or Italian, that we had been listening to.

That is the position in which average persons stand in regard to architecture; it is a foreign language of which they have only a general impression, without any knowledge of style or of grammatical construction. Mr. Douglas accordingly suggests that they should be taught the grammar of architecture. But is there a grammar of architecture? The phrase sounds well, but it will be rather difficult to tack a precise definition to it. Mr. Douglas puts it in this way:—

“The grammar of architecture consists largely in the intelligent use of such special features of style, arrangement, and shape of mass, as are found in piazzas, domes, minarets, campaniles, towers, spires, &c.; but in those styles with which we have chiefly to do it consists mainly in the judicious use of such mouldings as those who are masters in the style have employed, thereby imparting a certain individuality and mode of architectural thought to that style.”

This is rather vague, especially the term “judicious use,” one of those useful phrases which it is always safe to employ, and which may mean anything. The writer goes on to illustrate his meaning by referring to the distinction between a Classic Corinthian capital and an Early French Gothic one; the man with only a general idea of architecture would regard them as much the same thing; the man who had studied detail at all would see a radical distinction in their mouldings and style of leafage design. But this is a perception as to delicacies of style; it is hardly analogous to grammar. Grammar, in language, is the arrangement and relation of words so as to correctly represent or symbolise processes of thought. To say “there is no houses” is bad grammar because it uses in one part of the sentence a word implying unity, and in the other a word implying plurality of the objects named, and these ideas are mutually exclusive and cannot be entertained together. But it can hardly be said that there is anything in architecture analogous to this intellectual necessity for correct grammar in dealing with mental processes. It has been thought incorrect and bad style, by some critics, to use coupled columns in Classic architecture; but their use does not suggest mental ideas which are mutually exclusive. As has often been pointed out by our ablest writers on architecture, there may be good or bad logic in architectural design,—the use of external features, for instance, so as to imply an interior plan different from the actual one; but this is not the same kind of fault as a grammatical one; bad logic may be expressed in perfectly good grammar. As far as architecture in general is concerned, therefore, it may be said that there is no such thing as a grammar of it to be taught. But there is something like a grammar of separate styles of architecture, or perhaps we should rather say each has its own idiom. The best and most consistent styles of architecture that have existed depend for their consistency and harmony of effect on the observance of a variety of rather minute refinements of detail, of which mouldings are the most important and, it may be added, the least understood of the people.

These elements of refinement and consistency of style are capable of distinct illustration and definition, and can be taught as a branch of knowledge, giving people a correct perception of the characteristics of various styles, taken separately. To give instruction in architecture on this principle is

easy enough, if people are willing to be instructed, and those who know at all accurately the leading features of the principal architectural styles will no doubt develop a better taste and perception in regard to good and bad style in architecture than those who have had no such training; but the teaching of separate styles has the radical defect of confirming the public in the idea, which many architects never emerge from, that architecture means the designing of buildings in some special and pre-ordained “style”; an idea which starts the learner at the outset on a wrong track, leading him to put the secondary before the primary element in architecture.

In any attempt at general or primary instruction in architecture, therefore, a certain general instruction in what may be called elements of architectural design should precede the study of special styles. This is not quite so simple a matter as it appears at first sight, because though there are some broad elementary principles which are felt to be true by all real designers in architecture, they are not altogether susceptible of accurate definition; they cannot, for instance, be formulated into a series of necessary and undeniable axioms such as those which precede the problems of Euclid; their nature is æsthetic rather than scientific; and abstract æsthetic principles form a somewhat thin atmosphere for a beginner to inhale. The best basis for a primary instruction in architecture therefore appears to be, to regard the art from the outset as the expression of construction, and to teach the simple and fundamental principles of building construction in the first instance, as the basis of the whole. A study of the details of the leading styles of architecture, always with reference to their constructive basis, will then insensibly develop in the learner, along with the knowledge of the facts of a style, a perception of the manner in which architecture expresses construction, which the pupil may be afterwards able to apply for himself in a broader and more general sense; while the study of the details of the purest styles of the world forms at the same time a valuable training in the sense of architectural refinement and consistency of expression.

Elements of construction, then, followed by elements of leading styles, seems to be the only practical form which a primary instruction in architecture can take; and when and how can this instruction be conveyed? Mr. Aitken's suggestion, in which we in the main concur, is that “architecture should be recognised as one of the indirect branches of study in the tuition of the young.” We do not know exactly what he means to imply by the term “indirect,” unless it be that architecture should appear as what is called in a school syllabus an “extra.” That perhaps may be unavoidable at the outset, and it may be well to get even that in as the thin end of the wedge, but it is rather of the essence of primary instruction that there should be no “extras,” and that whatever subjects are desirable for laying the foundation of a good education should be a portion of the fixed routine of teaching. The simple kind of elementary teaching which we have advocated need not, in competent hands, take up any disproportionate amount of time and brain-work. Its adoption would probably, in the course of one generation, work a wonderful change for the better in the general level of architectural taste and perception in this country, besides tending to arouse an interest in the subject for its own sake, and putting an end to that “don't-care” attitude on part of the public towards architecture, which is perhaps the greatest of all obstacles to the general improvement of our standard of national architecture.

Mr. Aitken's paper contains some other excellent and practical suggestions for increasing the interest of the young in architecture, during the further progress of their education. He suggests, for example, that in connexion with the study of history, illustrations of the principal buildings of the cities or countries whose history is being read,

should be exhibited to the students, and their origin, uses, materials &c. should be described; we might add, that a word should be given by the teacher, or required from the more advanced classes of students, as to the style of such a building, its position in architectural history, its historical connexion with previous forms of architecture. He suggests that instruction in drawing might be made the opportunity for combining instruction in architecture, by giving the pupil pieces of good architectural detail to copy, with the saving clause (most necessary to bear in mind) that “no copy for imitation should be placed before the pupil which is not in itself a work of art,” an injunction which cannot be too often and too strongly insisted on. And, to sum up the beneficial influences brought to bear on the pupil's architectural perceptions, “With all this systematic reference to the art of architecture in the lessons of the school, it is of course taken for granted that buildings in which that instruction is given are models of high quality in art. The school should not only be well planned, but also ably designed.” This is a good deal to “take for granted;” but, as the writer of the paper admits, a certain number of well-designed schools have been built under recent influences; and we may add that even where the school building is notably deficient in architectural beauty or good taste, it might be possible still to turn it to a melancholy account in an educational sense, by adducing it as an example of deficiency or absurdity in architectural treatment.

In the first of the two papers we are referring to, by Mr. Douglas, something is said as to the value of books on architecture in promoting a more general knowledge of the subject. We fear this has not been hitherto a very important influence. Books on architecture are seldom read except by those who have already developed some interest in the subject; to the ordinary reader they are not attractive. An exception must be made, of course, in regard to the publications of Ruskin, which have the opposite fate; they have attracted general readers by the eloquence of their style, in such as they repel better informed people by the nonsense and clap-trap they contain. It is to be regretted that they should have been recommended at the Art Congress as a means of architectural education. Ruskin's writings in regard to architecture have had the effect of conveying to the popular mind, to a certain extent, the idea that architecture is a subject worth being enthusiastic about, and that is something; but their merit in this respect is more than counter-balanced by the false teaching they contain. A protest was made at the time against the recommendation of them as aids to architectural education, which may be repeated here. The “Seven Lamps” contains a certain amount of truth about architecture expressed in a vague rhapsodical manner, and intermingled with a great deal of idle though eloquent verbiage written purely for effect. “The Stones of Venice” is simply a huge, elaborate, and tumultuous rhapsody, containing isolated passages of splendid literary eloquence, but worse than useless, absolutely mischievous, as a guide to the study of architecture, being crammed with misrepresentations, false rhetoric, accidentals of architecture treated as essentials, corrupt varieties of style represented as central types &c., and marked by absolute ignorance of the constructive basis of architecture. Its value is purely and entirely literary and poetic, and has been a good deal over-estimated even in that respect. From an educational point of view it is one of the most mischievous and misleading hooks on architecture ever written.

TRAMWAY EXTENSION AT Huddersfield.—On Tuesday last Major-General Hutchinson, C.B., one of the Inspectors from the Board of Trade, paid a visit to Huddersfield to inspect an extension of the tram system from Moldgreen to Waterloo, on the Wakefield-road. The extension is a mile and 2½ yards in length, and the line has been constructed under the superintendence of Mr. R. S. Dugdale, C.E., the Borough Surveyor.

## PUBLIC WORKS, IRELAND.

ACCORDING to the last report of the Commissioners of Public Works in Ireland, dated July, 1890, the large sum of 424,800*l.* was appropriated to the construction and maintenance of works for the amelioration of the conditions under which people live in that country, during the year ending March 31 last, consisting of the sum of 69,672*l.* for inland navigation, harbours, and labourers' dwellings under the Acts of 1866 and 1885; of 228,853*l.* for works under the Public Health Acts, Asylum Buildings, Labourers' Acts of 1883 and 1885, dispensary houses, &c.; of 90,582*l.* for river drainage and land improvements; and of 35,693*l.* for miscellaneous works. A larger amount was appropriated in the previous year, viz. 564,850*l.*

These annual amounts are loans from the Treasury. The Commissioners of Works in Ireland divide them into four classes—(1) Loans secured on undertakings, (2) Loans secured on rates, (3) Loans secured on lands, and (4) Miscellaneous loans. The advances on the security of the undertakings have been on a very limited scale during the last year, but they include 3,500*l.* for the Lagan Navigation Company, to enable them, in pursuance of the Act of 1888, with the sum of 7,000*l.* contributed from other sources, to restore the works of the Ulster Canal, and give a depth of 5 ft. of water from end to end, a length of forty-eight miles, which will improve the water communication between Belfast and the Lough Erne. The loans for harbour works comprise 18,000*l.* to the Waterford Harbour Commissioners.

Under the Labourers' Dwellings Act of 1866, the powers of which were enlarged by the Housing of the Working Classes Act of 1885 for a period of three years, and further extended for the three years terminating on December 31, 1891, the sum of 46,319*l.* was appropriated during the last year. In the previous year the sum was 53,753*l.* The loans for the purposes above named are secured on the undertakings. Those made during the last year which are secured on rates, were six advances for road works, one for an industrial-school, forty-eight for sanitary purposes, three for repairing fishery-piers, twelve for improving the accommodation of county lunatic asylums, two hundred and five under the Labourers' Acts of 1883 and 1885, and eleven for building dispensary-houses. The forty-eight loans under the Public Health Act for sanitary purposes amounted to 57,300*l.* In the previous year the amount was 150,384*l.* The 57,300*l.* last year comprised 33,695*l.* for water-works, 8,720*l.* for sewerage, 2,110*l.* for burial-grounds, 4,375*l.* for footpaths, 2,900*l.* for municipal buildings, 4,500*l.* for public parks, and 1,000*l.* for a fever hospital.

In like manner the sum of 89,682*l.*, sanctioned last year under the Labourers' Acts, 1883 and 1885, was very much less than that of either of the two previous years, which was 463,261*l.* in the year ending March 31, 1888, and 188,742*l.* in that ending same date, 1889.

The number of dwellings, upon which the sum of 46,319*l.* was expended, is 603, being an average of 77*l.* each. The Commissioners say:—"To secure that the loans sanctioned shall be applied to the erection of such dwellings as come fairly within the scope of the Acts, and are in every respect suitable to the means and requirements of the labouring classes, it is made a condition with the borrower that the rents to be charged are not to exceed certain specified sums, such rents being fixed on consideration of the locality and the class of labourers for whom accommodation is required. This arrangement has had the effect of limiting the cost of the erection of dwellings built under the loans referred to, and thus securing, as far as practicable, their being permanently available for occupation by the labouring classes."

The sum of 90,582*l.* named as for land improvement, is chiefly for loans to tenants, the owners not now having much interest in the improvements.

Under the head of light railways, the tramways constructed under the authority of the Acts of 1860, 1861, and 1883 are included. The total mileage of projects guaranteed is 307 miles, of which 172 are opened to the public, 61 miles are in course of construction, and 74 are not commenced, although the Orders are still in existence. Under the Light Railways Act of 1889, for the development of fisheries and other industries, sixteen were scheduled in the *Dublin Gazette* in November and December last, but the money voted by Parliament will not be sufficient to construct all the lines scheduled.

## NOTES.

FURTHER contribution\* to the literature on "Building in Earthquake Countries" has recently been furnished by Professor John Milne, F.R.S. It contains much useful information on the subject, not only in respect of the construction of earthquake-proof buildings in Japan, with which the author is especially acquainted, but of the building regulations drawn up for Ischia, Manila, Norica, &c., by their respective Governments. Commencing with the methods of choosing a building site, he shows that this may often be determined by taking the results of experience as a guide. Earthquakes are more often noticed on high- than on low-lying ground; but, in spite of this fact, the low, soft ground is in general conducive to greater destruction. As a rule, hard, high ground is the best to build upon; very wet ground, and notably ground that is marshy, is as insecure against earthquakes as in ordinary cases. Earthquake action is extremely local in character. Amongst other things it was found, as the result of experiment at the late Imperial College of Engineering, at Tôkiô, that of two similar houses in the compound of that establishment, which were situated at a distance of less than 800 ft. apart, one of these houses might be destroyed by a given earthquake, and the other suffer little, if any, damage,—so clearly pronounced was the difference in motion on two sides of that piece of ground. There can be no question, therefore, of the utility of a detailed seismic survey of earthquake-stricken countries, and especially in the cities. One of the results of a general seismic survey of Japan shows that certain parts of that country are comparatively free from earth-movements,—a result of no little importance. Houses, naturally, should not be built near the edges of cliffs or scarps. Dealing with the value of the records of the seismograph, Prof. Milne says he is "of opinion that an earthquake with a 25-millimetre (0.984 in.) amplitude and an ordinary period would wreck the half of London." Great advantages might be gained by giving buildings deep foundations. The Ischian regulations state that buildings should be founded on solid ground; where this is impracticable, however, they provide that a platform of masonry or cement should be formed, the thickness of which varies with the height of the structure to be placed upon it. The author says that loose foundations might possibly be employed for small, light buildings erected on soft ground; but for ordinary dwelling-houses, and especially for heavy structures covering a considerable area, solid continuous foundations in the hardest ground, and, if possible, surrounded by a free area, are preferable. Arched construction, not being suitable to withstand horizontal stresses, is to be dispensed with as much as possible. In regard to the regulations made for Ischia and Norica, which state that doors, windows, or other openings should be placed vertically above each other, Professor Milne remarks that, in his opinion, they "ought not to be above each other, but so arranged that lines of openings when regarded

vertically should be as much broken as possible." Constructors should avoid coupling together two parts of a building having different vibrational periods, or else couple them together so securely that they shall move *en masse*. Chimneys should be made short and thick, and not loaded with heavy coping stones. Naturally, roofs should be made as light as circumstances permit. When a building with a heavy roof is suddenly moved forward, the roof by its inertia tends to remain at rest, and destruction ensues. A case is cited where roofs of considerable span were built so that they rested freely on the supporting walls, and it is shown that, although having experienced many severe shakings, they remain uninjured. Walls ought to be built light and strong, and not loaded in their upper portions with copings and balustrades; whilst it is not desirable to carry any building higher than is absolutely necessary. The Ischian regulations give a limit of height of 32.8 ft. for ordinary buildings, and those of Liguria allow 49.2 ft. "The length of a wall should not exceed twice its height, unless supported by a buttress; its thickness must be one-fifth of its height." Balconies in any form are objectionable features in a house constructed to withstand earthquakes. It is also suggested that buildings should preferably be rectangular in plan, because when they have many wings, &c., the different parts of the structure do not vibrate in unison. The author then describes the construction of floors, ceilings, staircases, materials, &c., all of which might call for special comment. In dealing with types of construction, he says, "One of two systems. . . . can be followed, namely, either to give so much rigidity to a structure that it may be likened to a steel box; or to erect a light building which has so much flexibility that it may be compared to a wicker basket." Prof. Milne is certainly to be congratulated on the production of a paper which cannot fail to be exceedingly useful to all architects or engineers practising in, or designing structures for, countries visited by earthquakes. As a matter of practice it might often be found impossible to comply with all the rules laid down, for, if they were observed in their entirety, the earthquake-proof building of the future would not, apparently, possess much artistic charm. At the same time, the suggestions, founded as they are in the majority of instances on actual experience, and as a result of much painstaking observation, should certainly be borne in mind and applied wherever practicable.

IT is certain that one result of the present epidemic of strikes will be a great increase in labour-saving machinery and in machinery to economise working. There is an untold amount of mechanical ingenuity eagerly seeking after new inventions, and this stream of talent will be now diverted more especially towards discovering inventions by which the extra cost of labour will be minimised. We should be the first to welcome combination for purely legitimate purposes, but where it is used rather for the purpose of crushing capital and making labour supreme, we equally welcome any means which will enable capital to hold its own. The great mistake which the trade union leaders make is to suppose that either unreasonably high wages or arbitrarily shortening the hours of labour will, in the long run, permanently benefit the labouring classes. For example, if the price of coal is raised, then at once means are sought to economise its consumption, whereby the extra cost per ton shall be met by smaller quantities being consumed. When such a general economising becomes established, it is obvious that less coal is required, and that the volume of wages paid to coal-miners is diminished. Hence either wages must fall, or a certain number of men must drop out of that particular class of workers. In either view, the ultimate result of the rise is not more favourable to the workmen. But care must be taken not to

\* Min. Proc. Inst. C.E. vol. C (1890), "Selected Papers," p. 326 *et seq.*

suppose that such effects will result in a moment. As an example of coal-saving which recently came to our knowledge, we may mention the case of a tannery. In order to save the ever-increasing coal-bill, a furnace was devised in which the many tons of tan which had hitherto been practically wasted are now consumed, whereby a great saving in coal is effected. This is typical of what is going on slowly all over England. Mechanical teaching and thought has now brought modern brains to such perfection in this particular intellectual groove that there is hardly any limit to the increase of labour-saving appliances.

THE quinquennial valuation of London is naturally causing much dissatisfaction. The present revaluation was certain to do this. In most parts of the West End of London house property has fallen in value. The Assessment Committees have, however, very generally raised the rateable value of houses. In many cases it is probable that houses have been assessed below their value before, but the householder, when his property is less valuable than it was, is no better pleased at a higher valuation because the valuation was rather below the mark before. In many cases, however, the Assessment Committees have probably trusted to the general disinclination of the average householder to do more than grumble, and have screwed up the valuation beyond what the fall in value of property in West London would warrant. It seems very likely that many appeals will ensue, and we should not be surprised were considerable restrictions made in many valuations. While touching on the point of rates, it may be well to call attention to the ridiculous anachronism which exists under which notices as to valuations, rates, serving on juries, and so forth, are posted on church and chapel doors as the chief place of exhibition. There is no reason why they should not be exhibited there, in case they attract attention, but they should in villages be also placed on the village school, and, primarily, both in towns and villages, on public notice-boards erected for the purpose. Many churchyard gates are locked on week days, and over and over again valuations are raised and not objected to because they have not been seen, and so the time for objecting has lapsed. In France the public notice-board is seen in every village guarded by a wire screen. This is the proper system.

ON Sunday next, Sept. 28, the Turin Architectural Exhibition will be opened to the public. We have reason to believe that this exhibition will be a success, thanks, firstly, to the arduous work of the president of the committee in charge, and secondly, to the valuable assistance rendered by the Italian Government. According to the *Secolo*, of Milan, most of the foreign municipal authorities invited to exhibit have accepted the offer; so that, besides the numerous Italian towns represented (among which we may especially mention Rome, Naples, Milan, and Florence), quite an international collection of examples of municipal work will be on view; capitals such as Vienna, Berlin, Constantinople, Warsaw, Stockholm, Edinburgh, and London taking prominent positions among a host of provincial cities. As to Italy itself, we need only say that a complete collection of plans of the historical buildings of the country will be hung in the central hall of the exhibition buildings, where they have been arranged by order of the Ministry; and that Section IV. shows the plans of the underground ways of the more important towns. Of special interest will be the large number of specimen copies of publications, photographs, and photolithographs sent in from all parts of the world. The Minister of Education, Sig. Roselli, will open the exhibition in person.

IN Italy architectural gatherings, not unlike the biennial congresses held in Germany, have been known for many years, and we

hear that at the last one, held in Venice in 1887, Palermo was selected as a meeting-place for the congress which is to take place in the autumn of 1891. Owing to Palermo having the special attraction of an Italian National Exhibition on a large scale, it was decided to make the coming gathering an "international" one. The International "Congress" of Architects, as it is to be called, is intended as a serious business-like affair, combined, however, with some interesting sight-seeing and official banquets. The congress, which, according to the preliminary "programme," is to last not longer than twelve and not less than eight days, will have its seat in the university buildings of the town, and here the different sections (Architecture proper, Construction pertaining to military, factory, and Civil buildings, Sanitary Engineering, and Civil Engineering) will each have their own series of lectures, debates, &c., the subjects of which, still under consideration, are not only to include theoretical, but also practical items, special explanations (in some cases by the designers personally) being given of the larger monumental erections of the last decade. As to the sight-seeing part of the programme, systematic excursions, under able guidance, will be made inland, and great care will be taken that the visitors shall have easy access not only to the archaeological but to the natural points of interest on the island. Particulars will be published at a later date. The Duca di Verdura has accepted the hon. presidency of the local managing committee.

THE great and picturesque building which has given the name of Christ-Church to a small hamlet in Hampshire has long been in a serious and even dangerous state of decay in many places, and, as we noted recently, is being slowly repaired by little and little as funds can be procured, under the direction of a Bournemouth architect, Mr. Burton, with the concurrent advice of the vicar, Mr. Busb, who is very well acquainted with his church. Few people are probably aware of the great difficulty in the way of carrying out even the degree of repair necessary for the security of the edifice and its fitness for public worship. An edifice on the scale of a second-class cathedral, Christ-Church is worse off than many a small parish church, its permanent endowment representing in fact a *minus* quantity after the first ordinary expenses of carrying on the regular services have been discharged. A local committee has done all it can for a long time towards collecting funds and contributing out of the private means of its richer members, one or two individual members having undertaken each the cost of repairing the most dilapidated piers and giving them the solid concrete foundation necessary for their permanent security. The decayed roof over the north transept and that over the Lady chapel "loft" (the low compartment above the vault) have been replaced by substantial new oak roofs, and the roof of the choir reroled. The most pressing matter now is the nave roof. This was originally an elaborately-decorated open-timber roof, now concealed by the timber and plaster imitation vaulting put up in the early part of the century. The ancient roof principals are in a dangerous state of decay, and are being rendered safe for the time by the insertion of new collars strutted up from a point on the walls below the bearing of the old roof, and by strutting up again from these to the bearing of the purlins. Only a portion of this work, however, is yet done, and any hope of obtaining the funds for reconstructing the roof entirely and removing the timber vaulting seems adjourned *sine die*. The sham vaulting makes a dangerous mass of inflammable timber cradling, and the view between this and roof shows a state of things which ought to be put an end to as soon as possible. There is no desire for "restoration" as such, except for the reconstruction of work that is decayed beyond the possibility of being permanently retained. We recommend the matter to the

interest of any wealthy readers who can afford to contribute something substantial to arrest the threatened decay of a great and most interesting mediæval church.

IN connexion with the operations in constructing the Chambers Memorial Chapel in St. Giles' Cathedral, Edinburgh, the remains of a fine window in the Perpendicular style have been laid bare. The window is in the east wall of the north transept, and overlooks the small gallery above the north doorway. It is to be carefully restored, and will be retained in its position between the Memorial Chapel and the gallery. The jambs of the window have the large shallow mouldings of the style, with moulded bases and carved capitals. There is an elaborate battlemented transom which remains in a remarkably good state of preservation. Above the window, parts of the original corbeling supporting the roof parapet have been found, as also a lion's head and rosette, which are to be preserved and built into the responds of the arch between the Cathedral and the Memorial Chapel. From an archeological point of view, one of the most interesting discoveries is a Norman capital, which is the oldest piece of masonry yet found in the Cathedral.

A SHORT report on an outbreak of fever at Northop Hall, in the Holywell Rural Sanitary District, has been made to the Local Government Board by Mr. Spear. Northop Hall consists of three or four rows of cottages situated at wide intervals by the roadside, and is described by the Medical Officer of Health and Inspector of Nuisances as one of the most troublesome places in the neighbourhood in regard to the maintenance of cleanliness. The report, however, proceeds:—

"The inhabitants have, in fact, little opportunity of acquiring habits of decency and cleanliness. There are no proper means of drainage. Liquid sewage is allowed to flow for the most part into the roadside gutters, or collects in pools outside the dwellings; solid filth is deposited in dilapidated and foul privy-pits, which are rarely emptied, and the oozeings from which are occasionally to be seen even on the surface. Water has often to be fetched by hand from quite unreasonable distances, and is only then procurable from dirt-wells or roadside troughs, doubtless more or less liable to surface contamination."

The fact that water is only to be procured "from quite unreasonable distances" is a frequently recurring cause of evil mentioned in the Local Government Board reports. Unless people have a supply of good water brought within easy reach of them, it is idle to expect cleanliness. The result in this case was typhoid fever.

A CORRESPONDENT sends us an advertisement of the Awre Local Board for a "competent person" for the office of Working Surveyor and Inspector of Nuisances. We read that "the salary as Inspector of Nuisances will be 17*l.* per annum, and as Surveyor 16*l.* per week. The person appointed will be required to labour manually, devoting his whole time to the duties of the offices, which will be those prescribed by the Public Health Acts, the Highway Act, 1835, the Regulations of the Local Government Board, and the by-laws now or hereafter to be in force, and adopted by the Local Board. The population of the district of the Board is 1,179, the acreage 4,093, and the mileage of the roads over which the surveyor will have control is 10½." It is not surprising, when this is the way that such work is provided for, to read such frequent complaints as we do in the Local Government Board Reports as to the inefficient way in which sanitary inspection is carried on in many rural districts.

THE 1st of October will be memorable in railway history, for on that date the hitherto exclusive "Flying Dutchman" will succumb to the levelling influence of the bold policy initiated some eighteen years ago by the Midland Railway Company, and will be available for third-class passengers. The Great

Western management have had to break with the traditions of nearly half a century in thus catering for all sorts and conditions of men, and in taking this action they have no doubt been stimulated by the recent efforts on the part of the London and South-Western to improve their service to Exeter. The fact of the announcement being made a week or two beforehand furnished the *Times* with a text upon which to enlarge upon the unreasonableness of the delays which usually occur in letting the travelling public know of impending changes. A remark to the effect that railway authorities seem to take a delight in stealing a march upon the public by delaying the publication of their time-tables till the last moment brought Mr. Cook, of tourist fame, to the rescue, with an explanation. According to Mr. Cook, their real object is to steal a march upon their competitors, — a railway manager being bound, in the interests of his company, to keep competitive managers in the dark as long as possible when bringing out a fast or improved service. Certainly, this explanation appears a perfectly reasonable one, though it will hardly reconcile the aggrieved section of the travelling public to the late appearance of the time-tables. The shortcomings of railway companies is a proverbially favourite theme of correspondents to the *Times*, and these gentlemen have had a good innings lately, all the old grievances being well ventilated. A writer in last Tuesday's issue pertinently remarks:—"If it is a fraud for me, holding a third-class ticket, to travel in a first-class carriage for my convenience, it is equally a fraud on the part of the company to take my first-class fare and give me third-class companions." This is logical enough, and there is no doubt that the latter fraud is perpetrated systematically on many lines when there is anything like a crush.

A PAPER by Mr. G. N. Hooper, read before the Society of Arts, on "Carriage-building in England and France, and the Traffic of the Streets," has been reprinted. It gives a number of interesting details in regard to the progress of carriage-building, and the comparison between French and English work is especially valuable. Some of the remarks in connexion with the streets of London are, however, of more interest to our readers. It is curious to observe how one system sooner or later affects another. Thus the introduction of wood and asphalt pavement has produced the india-rubber tyre to the wheel,—a method which Mr. Hooper considers likely to increase. Again, too, it is important to bear in mind that had roads mean extra wear and tear of vehicles, and thus when the householder grows too economical in regard to the taxes which are to be spent on roads and streets, he should remember that it is only by having good streets that street-locomotion can be made cheap. Low fares and great wear and tear of vehicles are incompatible. On another point we thoroughly agree with Mr. Hooper,—that there is unnecessary wear of the London streets by market traffic. Much vegetable and other material is carried to Covent Garden and Smithfield, only to be brought back to the suburbs. Several district markets are needed in London.

PROFESSOR ROGER SMITH announces as the subject of the usual public lecture with which he opens his courses at University College, "The Technical Education of Architects." The lecture is fixed for Thursday evening next, October 2, at 7.30 p.m. We understand that in the course of the lecture some remarks on the "Curriculum" now under consideration at the Architectural Association will be made.

A FIRM of tile manufacturers, whom we will not further advertise, are circulating a pattern-sheet of their tiles among architects, with the memorandum scrawled in blue pencil across it—"Fifteen per cent.

commission allowed to architects only." As these manufacturers are evidently very desirous to get their goods under the favourable notice of architects, they ought to be obliged to us for telling them that they have taken the wrong means of doing this by circulating among the profession an offer which the respectable members of it regard as a most improper one. We received on the same day several letters from architects enclosing this circular and requesting us to comment on it. The manufacturers who have sent it had better withdraw and apologise for their offer of a bribe to architects to use their tiles.

WE have received in a pamphlet form an illustration and description of the terracotta bas-relief placed over Mr. Heath's hat shop in Oxford-street. We have before noticed with commendation this work, which is no doubt a form of advertisement, but a form so far superior to most of those employed in the present day that we cannot but hope that it may constitute an example to be followed in other instances. The frieze is modelled by Mr. Benjamin Creswick, of Sutton Coldfield, and commences with a figure of St. Clement, who is said to be the patron saint of hatters. Other panels represent the granting of a Royal Charter by King James to the hat-making industry; the unloading of fur-wool from a ship; the old process of heaver and felt hat-making. After these follows the name of the firm, and the corresponding right-hand portion of the frieze is occupied by representations of the modern processes of hat-making. The groups are spirited in modelling; we do not know that we should have liked the realistic treatment employed had the work been life-size; but on the small scale adopted this passes off better in sculpture than on a life-size scale; and the whole thing is a credit to the tradesman who wished to illustrate his business in an artistic manner, and to the artist who carried out the idea.

IN reference to the view of the interior of Lower Brixham Church, as proposed to be rebuilt and enlarged, which was published in the last number of the *Builder*, the vicar (the Rev. Stewart Sim) writes that the rebuilding of the church was first undertaken as a memorial to the Rev. H. F. Lyte, the author of "Abide with Me," and of other hymns well-known in English churches. Mr. Lyte was the first incumbent of Lower Brixham, and was there for twenty-five years. The parish, the population of which consists almost entirely of fishermen, is a very poor one, and it is exceedingly difficult to collect funds for the completion of the church. The vicar hopes that some of the many thousands to whom Mr. Lyte's hymns have become almost as household words may be willing to contribute something towards the completion of the church in his former parish.

#### EXCAVATIONS AT TEL-EL-HESY.

We have become accustomed as each autumn comes round to look, as to a fixed institution, for an exhibition of ancient relics gathered by Mr. Flinders Petrie in the East. These present to us year after year something eminently worthy of study, and always different. We are sure to find something not hitherto known which indicates how far back must be placed the matured works of human skill and industry. One year we have the results of unearthing an unknown town; another year, a cemetery containing painted portraits of the people interred; another, the discovery of an important Biblical site. These researches, carried on by a single enthusiastic man, are worked out with all the acumen that facile knowledge and love for the work can prompt, while the happy choice of sites to be operated upon is made in a spirit but little short of inspiration.

This year's exhibition, which will continue open at the Oxford Mansion, Oxford-circus, until October 11, is in no way of less interest than any of the previous displays. In some respects it exceeds them, for light at last has been thrown, by Mr. Petrie's excavations, upon the remote past history of one of the cities of

Judea. The collection fills three rooms, the two principal ones containing Egyptian works of great interest, to which we propose again to refer. The third room, of small dimensions, is filled with objects of a very varying class, the greatest bulk of them totally different from the Egyptian articles. They are the first relics that have been brought to light of the early inhabitants of Judea, and, although at first sight their aspect does not arrest attention, yet their importance is only equalled by that of the momentous events of which these feeble articles are mute but eloquent evidences.

It is many years since travellers in the border-land country of Palestine have reported the existence of many artificial-looking mounds, called "tels" by the Arab tribes inhabiting the country, and these have long been supposed with justice to represent the sites of fortresses or habitations of by-gone times. Strange to say, no systematic attempt has hitherto been made to investigate any one of these mounds, although the usual system of erection practised in the East is very encouraging to the explorer—for he knows that the Arab builder, at least of today, seldom or never clears away the remains of the structure which he would rebuild. He constructs his new work upon the old. The site of a town or village thus in time rises above the original level; and the explorer has the happy supposition, to encourage his work of research, that what is being done now, has most probably been done for generations upon almost every Eastern site. He will find old, and still older relics, buried beneath each stratum that he may be able to dig through.

Mr. Flinders Petrie has the credit of being the first systematic explorer of the first of these mounds of Judea, and, although the means placed at his disposal were very limited, both as regards time and expenditure, yet, coupled as these works have been by his usual happy choice of position, the results obtained, shown in the little room by permission of the Palestine Exploration Fund, are extremely encouraging.

One of the principal of the "tels" which dot the plains of Judea is that of Tel-el-Hesy. It is a conspicuous object in the open, rolling country, standing as it does on a range of the low-lying hills of the fertile district, now almost without any settled village, but which at some period must have been very populous. This is sufficiently attested by the existence of the mounds already referred to, and by other sites where ruins (Khürbeh) still exist. The Arabs, to this day, place this word as a prefix to the names of the sites, and they are extremely numerous. Khürbet Tannar, Khürbet Hazzarah, and Khürbet el Wahashiyyeh, are all within sight: while Khürbet 'Ajlan, a large site, is only a mile and three-quarters away from it. The whole of these four places can be visited by a walk of less than three miles from Tel-el-Hesy to Kb. 'Ajlan. Others, apparently sites of importance, are within easy distance, of which Tel-en-Nejjeh must be mentioned, since it is a large mound, the site of a place of consequence, and but three miles and a half away to the south-east. No roads exist, but many trackways meet close to Tel-el-Hesy, and some of these doubtless mark the courses of ancient roadways. A fine Roman road has led northwards through Judea, and is still traceable, the nearest point to our Tel being at Beit Jihân (the ancient Eleutheropolis), which is about eleven miles distant as the crow flies. Two roads branch off westwards in the direction of the Tel, but come to an end four or five miles from it, and are only continued as trackways. One of these, at any rate, if not both, the road two miles to the south of Beit Jihân, is likely to be of Roman construction, since it branches off in a curved line, which appears to be part of the course of the main Roman trunk road from which it separates.

The questions naturally arise, What was the ancient name of the Tel, and if so, has the site played any part in ancient history? There have been many conjectures, but that which may best commend itself to us is briefly stated in the "Survey of Western Palestine," the well-known series of volumes which contain the admirable and painstaking labours of the Palestine Exploration Fund. "The name approaches that of Lachish, with the substitution of a guttural for the Hebrew Caf, as in the case of Michmash." The position, too, of the entering in of Judea would also agree well with the locality in which we might expect to find it. Lachish fell before the children of Israel, and

by Divine decree it was utterly destroyed B.C. 1451. Rehoboam, however, fortified it in as one of his cities of Defence, circa 975 B.C., and it was to Lachish that King Amaziah fled, and where he was killed, circa 825 B.C. It was here that Sennacherib stayed, after its capture, when he received messengers from King Hezekiah at Jerusalem in 713 B.C. This is, in brief, the history recorded in the Old Testament. There is no mention of the site in later times, and we are at a loss to know from recorded history whether or not it continued to exist as a town after the time of the captivity.

The mound, which is 340 ft. above the level of the Mediterranean, measures about 200 ft. square, with a flat plateau on its summit, and it rises to a height of 120 ft. in its highest part above the level of a small stream, which runs along the south and east sides, and which in course of ages has completely undermined and laid bare the whole of the eastern side from base to summit.

Mr. Petrie commenced his researches on a site not far distant, known as Umm el Lagis, which was supposed to contain the elements of the name Lachish, where he soon became aware that but little results would be obtained. Wishing to husband the resources at his command, he turned his attention to Tel-el-Hesi, where he at once happily turned to good account the overthrow of the side of the hill by the action of the stream. It gave him, in fact, a complete section of the mound without the labour of excavating it. Huge fragments of walls were seen projecting from its sides, although, being constructed entirely of sun-dried bricks, and covered with the deposits of similar material washed down the sides of the hill by the rains and storms of generations, it required a critical eye to trace which of the clay masses were constructional, and which was merely deposited, a task rendered all the more difficult by the decay of the facework. Finally, it was discovered that on a natural plateau, about 45 ft. above the existing level of the stream, existed a massive wall still more than 20 ft. high and about 30 ft. thick. This was traced for a considerable distance, and it is assumed, naturally enough, to be the earliest wall of enclosure. Above this wall is a second one, also built of sun-dried bricks and of somewhat less size, still about 10 ft. high. Remarkable to say, above this again, still slightly within the area, thus circumscribing the space enclosed, is a third thick wall.

These indications appear on the whole of the north side. But their continuity is attested by a few other evidences, on the south. But the top wall was traced along the remaining three sides and found to be of irregular figure, terminating in what was probably a tower at the north-west, with an entrance at the south-west, approached by a flight of steps arranged up the slope of the mound, enclosed by a curtain wall built along the slope, the base of which consists of masonry; the stones being worked with a draft around each, the central portions of the face being rough,—merely hammer-dressed, to use our modern term.

The irregular course of the upper wall was made out by Mr. Petrie under no small difficulties, for the crop covered it when it was first known to exist. Fortunately, the harvest was at hand, and as this was gathered trial holes were made from point to point rapidly, as soon as the ground was cleared by the reapers, the angles calculated, and the course of the wall determined.

The interior of the mound proves to consist of the remains of town upon town. Of these the lowest ranges with the top of the lowest wall. Above this there is indication of the partial use of the site by some nomadic population, too ignorant to construct buildings systematically, for there is evidence that their houses were built of small stones gathered from the brook, and they now lie in a well-defined section across the mound. Then must have followed a time of entire abandonment of the site. This is proved in a curious manner. A layer of hush ashes is found covering it. These lay in some places thick enough to be measured, in others they show themselves only by a mere thin line, just as they were blown about hither and thither by the passing breeze. They are the ashes of shrub and plant burning for the extraction of the alkali, just as is practised by the Bedouin at the present day.

But a period of revival took place. This is attested by the existence of a rectangular building, which probably belongs to the period of the second wall, although it stands above it

Sketches of Pottery and other objects from Mr. Flinders Petrie's Exhibition.

in level. Its walls are still about 8 ft. high, completely buried in the accumulated earth of the Tel. But this building itself bears evidences of reconstruction. Old material is found in it re-used. There is a curious scratched figure of an animal on a small slab of limestone. It has been taken from elsewhere, and is turned upside down. Several doorways have been traced, and several of the jambs of these are formed of limestone slabs, on which are worked curious spiral twists, one of which is sketched.

of the third wall. They are still about 14 ft. in height, and are, like the others, constructed of sun-dried bricks, and are adorned with a series of projecting pilasters at irregular intervals, but some of these are probably return walls. From the topmost level, doubtless, to that of the stream exists a well for the use of the garrison: It is placed in the tower-like building.

Such, in brief, are the results of the excavations, and for the first time we know the formation of the mound; and if this example may be taken as a specimen of others, as is probably the case, we are in possession of interesting information likely to be of more general application.

But valuable data are at hand to determine with a certain amount of exactitude the actual periods when the mound was peopled. This is by comparison of the pottery found at various levels, the precaution having been taken to mark all the specimens as they were met with. They are found to vary in style and in texture in the various strata dug through.

At the lowest level the pottery was blackish-brown in colour, fairly smooth and thin in texture, tooled over in some cases before firing to bring the surface to more even surface. It has not hitherto been observed, or certainly not in relation to what was found above it. We illustrate two examples. In no case was this found higher than the level of the first wall. This is succeeded by an entirely different class, but well known to observers as being of Phoenician manufacture.

We give several examples. Similar pottery has been found at Rhodes, by Major di Cesnola in Cyprus, by Mr. Petrie in several sites in Egypt, and, in fact, more or less in every ancient site along the Mediterranean. Its existence in so many places attests the commercial enter-

These form the right-hand sides of the jambs, and mark the thickness of the walls. The left-hand sides are plain, having been covered presumably by the doors themselves when opened against them. Immediately above these ruined walls are others of a larger and more important building, which belong probably to the period

Marks on Handles

Sketches of Pottery and other objects from Mr. Flinders Petrie's Exhibition.

resemblance, as if the forms of the older pottery had been copied by later manufacturers, the workmanship not being so accurate. We illustrate several examples of this fictile ware which are new to observers, and, like the older class, its period seems to be incontestably proved by its position. It may readily be considered as of later date than the Phœnician examples found beneath it.

We have thus, in this interesting mound, distinct traces of at least three active periods of building work, and regarding these in the light of the recorded history there is remarkable agreement. We may assign the lowest wall and its pottery to the time of the Amorites, whose cities, we know, were "great, fenced up to heaven." The period of decay, after the destruction of the city, or of use only by roving herdsmen, is eloquently pointed to by the traces of their bush burnings. The second wall appears to be that erected by Rehoboam, during which time, and later, the Phœnician pottery was used, followed by a re-erection of the walls and the use of the third class of pottery up to a later Jewish time. The upper walls may be, therefore, and most probably are, those of the fortress taken by Sennacherib. Traces of reconstruction and repair are observable in all the walls. A few fragments of painted Greek pottery, about 500 to 330 B.C., and some of Roman times, indicate that the site continued to be occupied until after the Christian era, probably to no great extent.

Be this the site of Lachish or not, it must be borne in mind that what occurred to the former city, ensued equally to at least the most important of its neighbours. All were alike taken by the children of Israel. Rehoboam constructed several strong places in its immediate vicinity, and Sennacherib would doubtless have overcome all the places of strength in the locality of Lachish.

The consideration of these momentous events, connected so intimately as they are with the land and the history of the Chosen People, points in a very practical manner to what should be done further to elucidate them. If a few excavations, skilfully performed, but which have not caused a very great amount of the site to be turned over, have produced such interesting results, what may not be expected from more extensive ones? Surely these discoveries point to what should be the future of Palestine exploration. The pick and the spade will bring to light what is safely hidden until the time comes. Almost every ancient site, it may be presumed, contains town upon town, one built above the other, with all the varying works of each period still remaining. We have already referred to the Eastern practice, and this, in the light of what has been proved at Tel-el-Hesi, should be sufficient to stimulate many an explorer to enter upon this new field of enterprise. The Society which encouraged Mr. Petrie to enter upon his work has many a claim by its years of good service already accomplished, and it may be congratulated upon at last entering upon a new departure. We urge it strongly to continue this work, which has been too long delayed, and to consider that the exploration of the future must be that which the excavator alone can accomplish.

There is a rich harvest to be reaped in these hurried mounds, untold as they are in number, throughout the length and breadth of the Holy Land, and the public will wait with impatience for further indications of the treasures of the past which they contain.

The map which the Palestine Exploration Fund has published is an important addition to human knowledge, since by its aid we can see at a glance the surroundings of every site. But it only raises our anxiety to know the histories of the many important and unknown sites which are shown upon its sheets in such remarkable profusion.

**MOULDING AND PLANING MACHINE.**—Messrs. J. Sagar & Co., of Halifax, have just brought out a new pattern moulding and planing machine, which should prove useful to those who require a single addition to moulding and planing. The machine, in addition to moulding and planing, can be used for tonguing and grooving, both in hard wood and soft. It will cut on all four sides of the work at one time, having top and bottom and also side cutter blocks; the latter being after the top cutter. The bottom rollers adjust vertically, and the bottom cutter block works in a carriage, so that the cutters may be easily withdrawn for sharpening. The table in front of the bottom cutters will adjust vertically to vary the thickness of cut, the space being opened and closed as required. The frame is composed of a single casting, and phosphor bronze is used for bearings.

prise of the remarkable but little known people who produced it. The lowest example found in the mound was at a level of 305 ft. above the Mediterranean, the highest 325 ft., extending thus above the level of the third wall. The date of this pottery can be ascertained with fair certainty from Mr. Petrie's former Egyptian discoveries, where it is known by other articles, the dates of which have been ascertained by

their hieroglyphics, &c., not to be older than about 1,000 B.C. This is important in relation to the history of the mound, since it gives the age of its central portion, leaving us readily to conclude that the articles found at the lower level are earlier, and the upper ones later. The upper ones consist of a different class so far as regards texture of material, and to some extent of form, although there is a certain

View in the Patio Alberca of the Alhambra, Granada: looking towards the Sala de la Barca and the Hall of the Ambassadors.

#### THE ALHAMBRA, GRANADA.

LAST week we gave a short notice concerning the recent unfortunate fire at the Alhambra. To-day we supplement it with a sketch of the interior of the Court of the Alberca, otherwise called the Court of the Myrtles, looking towards the Hall of the Ambassadors, which rises in the background. The view is taken from the south end of the Court, and shows the colonnade and entrance to the Sala de la Barca, which is a long, narrow hall about 70 ft. by 15 ft., and occupies the space between the two small pavilion towers (see sketch). The Torre de

Comares rises immediately behind and contains the Hall of the Ambassadors, 37 ft. square and 75 ft. high, so that the Sala de la Barca really forms an ante-hall to the great hall beyond. The pillars and capitals of the colonnade are of white transparent marble, the upper portion being of very fine stucco work with a surface like ivory. The general tone is a pinky-cream colour. The original colours are only to be found in parts protected from the weather and high up on the ceilings of the halls. Unfortunately the roof of the Sala de la Barca was one of the best-preserved examples of this kind of work, and was in the shape of a boat turned upside down, hence the name Barca (boat).

The courtyard is paved with white marble and the halls with Moorish tiles. The famous Court of the Lions is situated to the right of the sketch. (See sketch-plan on opposite page). We give a detail of one of the columns from the Alberca Court, and also a small sketch-plan, in which the portions burnt are shown black.

The following extract from a letter written on the 18th inst. by Mr. Henry Stanier, the British Vice-Consul at Granada, which appeared in the *Times* of the 23rd inst., may be taken as giving an authentic account of the extent of the damage done:—

"It appears that the fire was discovered about half-past 10 o'clock on the night of Monday, the

MOIR, & C.--MESSRS. CARPENTER & INGELOW, ARCHITECTS.

15th inst., but, being asleep in bed, I did not hear the alarm of fire until nearly twelve o'clock. When I entered the palace the fire was raging furiously, and it seemed the whole of the palace was doomed. It appeared to be on fire in three distinct places, which made one feel certain that

some criminal hand had been the cause of it. By some judicious cutting in the roofs the fire was prevented from extending to the Court of Lions and the Hall of Ambassadors, and was confined to the Court of the Alhambra, and this court, having a large tank of water in the centre, enabled

the fire-engine to have an abundant supply, and everybody who could help with a will, did by two o'clock the fire was localised to the Court of the Alhambra and the Sala de la Barca. The roof of this hall has been entirely burnt, but its walls are intact, although calcined, and the beautiful colouring designed. The gallery at one end of the Court of the Alhambra has also its roof entirely destroyed. This and some rooms extending all on one side of this court form the total of the parts burnt. The Court of the Lions and all the other courts and halls are intact, and have not suffered in the slightest degree. The opinion is that the fire was intentional, but nothing has been found out, and all is a mystery. Inquiries were being made, but I expect it will never be discovered who did it. It is a miracle how anything as escaped, for the fire was most intense, but the immense thickness of the walls of the Tower of Comares prevented the fire extending to the Hall of Ambassadors, and the cutting away of the roof prevented its extending to the Court of Lions. When I left at four o'clock the fire was almost out, merely smouldering a little here and there. I, as well as many others, helped by carrying buckets of water and doing all we could to assist in keeping down the fire. Nothing was heard but lamentations and imprecations on the destitute villain who had been its cause. Granada and the entire world have

to be thankful that one of the most beautiful and wondrous works of art ever made by man is still in existence, and what has been burnt can all be restored, except the ceiling of the Sala de la Barca, and the beautiful colouring on its walls. Men are at work now, day and night, clearing away the rubbish, and the damage will soon be put to rights."

ARCHITECTURAL ASSOCIATION  
VACATION VISITS:

HAM HOUSE.

The seventh and last vacation visit of the year took place on Saturday last, when a large party of members of the Architectural Association visited this extremely interesting seventeenth-century house. By the kindness of Lord Dysart and Lady Huntingtower, who met the party, the visitors were shown over the whole of the house, without restriction, and thus enjoying to the full the many treasures to be found, they felt, one and all, that the last vacation visit was most certainly the best of the year.

Ham House was erected, in 1610, by Sir Thomas Vavasor, and from the fact that he was Marshal of the Household to James I. has probably arisen the tradition recorded by Lysons and Neale that it was intended for the residence of Henry, Prince of Wales; a tradition, however, which appears to lack sufficient foundation, as the Prince does not seem to have resided there, and Sir Thomas certainly did so until he transferred the property to John Ramsay, Earl of Holderness, by whom, or by his heirs, it was sold to William Murray, who was created first Earl of Dysart by Charles I. The first Earl left five daughters but no male issue, and the property thus by marriage came into the possession of the Tollemaches, William Murray's eldest daughter having married Sir Lionel Tollemache, from whom the present Earl and possessor is descended.

Ham House is delightfully situated near the banks of the Thames, and is especially noted for its fine avenues of elms, one of which, Ham Walk, presented itself to the view of some of the visitors, who, however, were unable to pass along it to the house, as the gates have been closed for centuries, and they were, therefore, obliged to take a more circuitous route, after admiring the wrought iron work, erected in the reign of Charles II., by the Duke of Lauderdale, whose arms: quarterly, first and fourth, a fret for Tollemache, second and third, an imperial crown between three mullets, within a double tressure, fretty counter fretty for Murray, surmount the gates.

The house was considerably enlarged in the time of Charles II., the garden front having been then erected by the Duke of Lauderdale, by whom the house was sumptuously furnished, and in whose time Ham was the centre of political activity, the notorious Cabal Ministry in particular meeting there in what is still known as the Cabal room.

Ham House is rich not only in Carolean furniture but also in remarkably fine examples of the work of Vandyck, Sir Peter Lely, Sir Godfrey Kneller, and Sir Joshua Reynolds, among which may be especially mentioned the portraits of James Stuart, Duke of Richmond and Lennox, by Vandyck, of Lady Huntingtower, by Sir Godfrey Kneller, of Charlotte, Countess of Lionel, Fourth Earl of Dysart, by Sir Joshua Reynolds, and of Jane Savage, the first wife of the fifth Marquis of Winchester, who so gallantly defended Basing House against the Parliament on behalf of Charles I. Milton composed the epitaph of the Marchioness, which runs thus:—

"This rich marble doth enter  
The honour'd Wife of Winchester;  
Summers three times eight save one  
She had told; alas! too soon,  
After so short time of health,  
To house with darkness, and with death:  
Yet had the number of her days  
Been as complete as was her praise,  
Nature and Fate had had no strife  
In giving limit to her life."

Other famous and remarkable pictures are found in the great gallery, 92 ft. long, amongst them the portrait of Sir Lionel Tollemache, second Earl of Dysart, by Vandyck, and a portrait of Charles II., specially painted for the Earl of Dysart by Sir Peter Lely.

In addition to the pictures and furniture are some good specimens of tapestry, some of which were possibly worked at Mordlake, where Sir Francis Crane established a factory. That in

the Cabal Chamber, designed by Watteau, well illustrates the feature of fashionable life known as a *fête champêtre*. The elaborate inlaid floor, with the cypher of the Countess Elizabeth, is also worthy of notice in this and the adjoining room.

The restoration of the silk hangings in the miniature room deprived the visitors of the pleasure of seeing the famous collection which has its place on the walls of this apartment, but the elaborate ceiling and cove, painted—as were several others in the house—by Verrio, were fortunately in evidence.

Other features of the house that should be remembered were the central hall, with its open gallery on the first floor; and the remarkably handsome principal staircase, carved in walnut wood to represent warlike trophies.

An especial favour was granted to the visitors by the opportunity of inspecting the famous library, so rich in priceless Caxtons and Court Rolls of the seventeenth century.

Mention should be made of the decoration of the river front, the older portion of the house, by the curious series of busts, cast in lead, although painted stone colour, and ensconced in niches on the wall face.

After revelling among the numerous relics of the historic past, an equally vivid though entirely different interest was experienced by the inspection of the laundry, the first example, we believe, of electrically-driven machinery applied to this purpose in England. The engine and dynamo, supplying the motive-power for this establishment, also furnish the electric lighting for the house.

A glance at the stables and cow-houses completed a most pleasant and enjoyable afternoon in one of the most famous and interesting old mansions in the neighbourhood of London.

Illustrations.

ARMAGH CATHEDRAL.

THE drawing shows the re-arrangement and refitting of the choir with new stallwork, together with the opening-out of the nave for the use of the congregation. These works have now been completed, but since the drawing was prepared canopies and other additions are being made to the chapter-stalls and throne.

Certain structural works have also been carried out, such as a new roof to the south transept, and the careful repair and strengthening of that of the choir, and others yet remain to be done, as the existing roofs of the nave and north transept are but plaster imitations of massive woodwork, and the arcades and walls are thickly encrusted with "compo" and rotten lath and plaster.

Before these alterations, carried out under Mr. R. Herbert Carpenter and Mr. B. Ingelow, the choir and one bay of the nave and the area of the towers were alone used for services, the alterations of 1834, under Cottingham, having been an attempt to squeeze both choir and congregation into this wholly inadequate space, following the precedent then usual in the case of much larger English cathedrals, and cutting off the nave by a solid stone screen, and using it but as a vestibule to the choir.

The history of the Cathedral, though deeply interesting and intimately associated as it is with the religious and civil life of Ireland, is so voluminous that it can only be touched on so far as it relates to some of the changes and alterations in the structure in both ancient and modern times. Founded by St. Patrick, and known in Celtic times as the "Damluag Mor" or "great stone church," the Cathedral of Armagh, though much altered and modernised by Cottingham in 1834, yet retains in some of its details and in its general plan the design of its mediæval rebuilders.

From Cottingham's measurements and drawings (fortunately preserved) we learn that there then existed much of the work of Primate O'Scanlain (1261) and of Primate Swetnam (1395), modified and altered by the repairs and partial rebuildings of the fifteenth, sixteenth, and succeeding centuries; while on the church and around it were the fortifications carried out by the orders of the Earl of Sussex to resist the attack of Shane O'Neill—in effectual, however, as the church was captured and burned by the rebels.

Cottingham's first sketch designs, prepared for Primate Lord J. G. Beresford, show that he was anxious to carry out a "conservative resto-

ration," but, unfortunately, he either changed his mind or was overruled, and the whole of the exterior and much of the interior shows by its modern design how little the spirit of Gothic architecture was then understood, even by so accomplished an architect.

In 1892 the altar had been placed at the west end, the choir dissolved, and, together with the transepts cut off from the nave. Cottingham's task was, therefore, to bring into use again as much as possible of the ancient area of the church. He rebuilt the choir on designs of his own, together with the tower arches, and he reinstated the dilapidated nave, or rather a portion only of it, replaced the whole of the exterior, and refitted the interior.

The choir has now been brought back to its original use, but is adapted to the now reduced number of the Chapter, for whom five stalls on either side are provided. Seats westwards of them accommodate the choir men and boys, while under the eastern arch of the tower are stalls for the vicars choral. The new archiepiscopal throne, a memorial by some of his friends to the late Mr. Beresford Hope, and a gift to the Primate, stands in its proper relative position.

At present the organ, originally erected by Cottingham at the southern end of the south transept, stands in the northern one, immediately under and beyond the lower arch, thus interfering with the proper performance of the services, and rendering the choir almost inaudible; but it is intended, as soon as possible, to remove it to a position, eastward of the singers, in an aisle opening into the choir. A cruciform church, with large central piers, must always be a difficult problem to solve as to the acoustics, and this arrangement is felt to be, on the whole, the best to meet the case.

The throne and stall work have been carried out by Mr. Bowater, of Shrewsbury, aided by Messrs. Colten, of Belfast, the general contractors. The latter firm have reconstructed and adapted Cottingham's oak stalls and seats for the use of the congregation, and have erected the new roof to the transept, and executed the various structural works. The brass and wrought iron gas-fittings are by Messrs. Singer and by Mr. Gawthorpe; the tiles by Messrs. Minton; and the heating by Messrs. Musgrave & Co. Mr. F. E. Smith superintended the completion of the work, after the resignation of the first clerk of works appointed. The drawing of the remodelled in-

terior, from which the principal illustration is taken, was exhibited at the Royal Academy this year. We give also a reproduction of a drawing by Mr. Carpenter, compiled from Cottingham's drawings and other sources, showing the exterior of the cathedral previous to Cottingham's "restoration."

**HATCHFORD PARK, NEAR COBHAM, SURREY.**

THIS house was probably built late in the last century. The principal rooms were to the west, a kitchen wing, with nurseries over, to the east, and beyond the latter were situate the stables. The late owner, some years back, altered the outbuildings, and built a bowling-alley and billiard-room at the back of the stables, but as these were on the basement-floor and approached through the nursery wing, down a staircase and along passages, about 200 ft. away from the dining-room, the present owner decided, on the advice of his architect, to pull down the nursery wing and large range of outbuildings, together with the billiard-room, &c., and to convert the old west wing into a more conveniently-arranged modern residence, re-arranging the whole, and building the billiard-room with retiring-rooms, &c., on the same floor, and immediately adjoining the new dining-room. The old west wing of the house had small entrance and staircase halls, with dining-room behind the former; narrow pas-

sages led to the boudoir, library, drawing and hall rooms on either side. The old dining-room has been turned into a spacious hall, two floors high, with gallery all round same. Stone mullioned hay-windows have been built to the various rooms, and the narrow passages have been built out into spacious ante-rooms and staircase-halls, all as shown on the plan. The first-floor has been heightened throughout and a new second-floor rebuilt and arranged in the wide span main roof with gables running into the latter. The old house had a plain painted stucco front of low elevation, with a parapet concealing the roof all round. Additions have been arranged so that the old house is mostly concealed by the new building, but where it does come to the front it is encased with red brickwork on the outside, on basement and ground-floors, and is tile-hung on first-floor. The roof and gables forming the second-floor are entirely new, and show oak half timbered work and barge boards to gables, and Broseley tile-roofs. The stables adjacent to the house are being altered and added to in character with the house. Messrs. Laign, Wharton, & Down are fitting up the whole of the premises with electric light. Mr. J. Boulting is executing the hot-water heating and sanitary work throughout, and Messrs. Forster & Dicksee, of London and Rugby, are the contractors. The whole is being executed from the designs and under the superintendence of Mr. Rowland Plunbe, architect.

## BABLAKÉ BOYS' SCHOOL, COVENTRY.

THESE Schools, recently completed, afford accommodation for three hundred boys, a hotel for forty boarders, and a head-master's house.

On the ground-floor is the principal entrance in the centre of the south front, leading to ball and staircase; right and left runs a corridor leading to the class-rooms; on the left an under-masters' common room, and the boys' dining-hall, 55 ft. by 23 ft., capable of dining one hundred boys, with sewing-room, pantry, &c., adjoining, attached to the kitchen.

From the entrance-hall the great hall is entered. This hall is 85 ft. by 38 ft., lighted on both sides and end. Beyond this, and approached by corridors on either side, are the workshops, laboratory, and boys' cloak-room and lavatories,—the two latter entered from the playground.

On the upper floor are the boys' dormitories and masters' rooms, &c., approached by a wide stone staircase leading from entrance-hall.

The whole of the buildings are of red brick, with stone dressings, and were carried out by the contractors, Messrs. Thomas & Sons, of Burton-on-Trent, from the designs, and under the superintendence, of Messrs. Giles, Gough, & Trollope, architects, of London.

## CAVENDISH COLLEGE, CAMBRIDGE.

THIS centre portion consists of entrance hall and porter's lodge, communicating with the several blocks by a colonnade of open-pointed arches, with a court to the left, bounded on the other side by the hall. At the end of this, and at right angles to it, runs a passage into which opens, on the left, the hall, on the right, the kitchens, &c. The hall, 81 ft. by 43 ft., is of red brick, interior and exterior. The floor is of wood blocks with a dais at the south end, and the walls to a height of 6 ft. are panelled with American walnut. The roof is an open one, and of pitch-pine, with an open flèche. At the north end, and of the whole width of the hall, is a gallery. Opening out of the hall is the combination-room, which again opens into a court corresponding on the other side to the court on the left of the entrance colonnade. At the rear are the kitchen, buttery, larders, scullery and store-rooms, and servants' hall. The hall will seat 250. The buildings are of red brick with stone dressings, corresponding to the older existing portions, and were, together with the aforesaid older portions, designed and superintended by Messrs. Giles, Gough, & Trollope. The contractors were Messrs. Claridge & Bloxam, of Banbury.

## ARCHITECTURAL COMPETITIONS IN GERMANY.

IN the course of the year we have several times referred to the results of the more important of the architectural competitions held in the German Empire, and as we now have some statistics compiled by Professor Stier (Hanover) for his paper on "Results of the German Competitions of the last Twenty-two Years" read at the recent Congress of Architects and Engineers at Hanover, it may be of interest to give an extract from the somewhat formidable rows of figures contained therein.

According to the learned Professor (who, by the by, intends at a date not far hence to publish a volume on the subject) the number of competitions held in Germany since 1868 (the year of the first five opened in that country) is 258; and for these 258 competitions no less than 11,256 designs have been submitted, showing hence an average of forty-four designs, a number which in some cases is, however, far exceeded; as, for instance, the Houses of Parliament work of 1882 alone attracted 182 candidates. In the 258 competitions, 751 awards (with a total value of 930,000 marks) have been given away, and of these awards one "first prize" has fallen to every forty-nine designs. In 216 out of the 258 cases the final result of the competition has been ascertained, but only in 109 instances has the "First Prizeman" had the erection of the edifice; whilst in thirty-one cases the erection fell to the second or third prizeman. In thirty-one other cases the erection has taken place according to the designs, but not under the superintendence, of a successful candidate; and in forty-three cases no building resulted from the competition. Altogether 171 buildings have been erected for 214 competitions with 9,981 designs, or, in

plainer words, our German friends have been working at their competition designs with a 1½ per cent. chance of an erection,—a percentage far below all reason.

We see how many candidates have, according to Professor Stier's interesting statistics, spent their valuable time on the competitions of the last twenty-two years, and what a small percentage have obtained the much-desired erection according to their ideas; yet if one sifts the matter, the state of these competitive affairs abroad has not been as bad as it looks. Any one who may have visited an exhibition of competition designs in Germany will have noticed the large amount of work absolutely unfit for a place on the walls,—work which has been sent in by young and inexperienced members of the profession, students who, although at the same time not adverse to the possibility of gaining a prize, take advantage of the competition for their own instruction, thereby learning to adapt themselves to fixed requirements; and if we were to subtract the number of these designs from the number of competitive designs proper, the figures throughout would certainly have a far more favourable aspect.

We must take into consideration also that the German competitions, as a rule, are exceedingly well managed, and that this fact certainly encourages candidates to try their strength and hence greatly influences the statistics. When in 1868 the system of having competitions was fairly started, the deputies of the amalgamated architectural societies at once saw that the mode in which these competitions were to be held must be regulated to some extent, and hence we find that at their meeting of the same year, and later again in 1879 and 1883, resolutions were passed and some paragraphs of advice published for the benefit of authorities or private people likely some day to indulge members of the profession in the privilege of competing for the designs of their buildings. On the whole, the advice given in these paragraphs has been followed, and whatever may have been the special faults noticeable at some of the competitions, the candidates but seldom had reason to complain of unfairness in the management. The "appointed assessor" is an unknown personage in Germany; a jury takes his place, and in this jury the majority of members are architects, or, at least, competent judges of the artistic as well as of the practical sides of the question, whilst to the minority belong the laymen, such as mayor, schoolmaster, or museum director, just as the case may be. The possibility of a single person's predilection against or in favour of a certain class of design playing a prominent part in the judgment is hence minimised; the personal opinion of the competent jurymen has the right of making itself heard, but it can be disputed; the vote of the majority decides, and, excepting in one or two stray cases, the decision has found approval both among the unsuccessful competitors and among the public in general. The names of the members of the jury are mostly given on the "competition programme," which has been compiled either under the superintendence, or at least with the sanction, of the jurymen, and hence the competitor not only knows who will judge his design, and can abstain from competing if he does not consider the judgment to be in competent hands, but he has also some guarantee that those who have opened the competition have had some competent advice, and are not likely to ask for what is unreasonable or impossible. The "programme" generally gives the candidate a clear insight into the requirements; it lays stress on the special idea preferable, mentions the material to be used, and often the style to be adopted, gives approximate measurements of the rooms, &c., required, and in most cases a good plan of the site. Only as to one point, *i.e.*, cost, do we continually hear of misunderstandings, as, excepting when very clearly marked, some of the competitors are liable to take the sum as approximate, whilst others take it as the boundary not to be exceeded; the promoters of the competition having been themselves sometimes rather uncertain in their minds as to what they really intended to spend.

As to the draughtsmanship of the designs, the scale (mostly 1/100 or 1/200) for the drawings is always mentioned, the mode of treatment left open; a mounting in a rather decorative fashion is customary. On the whole the competition work shows good line work, done in a sketchy form and touched up with shading in water-colours, mostly monochrome (seldom

hatched); the great thing apparently being to let both elevations and plans appear as "pretty pictures."

It would lead too far to go into the details of the statistics, or to mention all the rules and regulations occurring in the German competition system. The foregoing brief notes may give the reader some idea how these matters are managed in the Fatherland, up to the present time at all events; but in some classes of competitions the previous state of things is likely to be considerably changed under the present régime, when the Emperor has an eye for everything, and has gone so far as to appear at an architectural jury-sitting, and there to hold forth his ideas on the subject under discussion, and has even annulled the decisions given by competent judges by opening a second competition on his own account; so that the competitions for monumental erections are now liable to become the prey of despotism; a change to be deprecated on every ground. If followed on the old lines, and if the larger competitions be left un-influenced by "authorities," the system in Germany is likely to do some good to architecture in general, and is certainly popular, and as usually managed causes the least possible amount of dissatisfaction and petty vexations to unsuccessful candidates.

## Correspondence.

To the Editor of THE BUILDER.

## THE NEW CODE BUILDING REGULATIONS.

SIR,—Your remarks on the above-named touch very lightly on the subject. If the new "rules to be observed in planning Public Elementary Schools" are in the main like former documents from the same source, they deserve much more energetic condemnation than you have meted out to them. The language employed is sometimes obscure, if it have not more academic defects. We are gravely informed, for instance, that the "accommodation of each room depends not merely on its area, but also on its shape"—of which Lord Burghley-like sentence the meaning appears to be simply that the accommodation allotted to depends upon dimensions of length and width suitable for the reception of the necessary furniture. The area is only a complication introduced by the department for the computation of claims for grants, and, although useful as a standard of comparison, the statement of it has only been available for the purpose of examining the space. Again, in describing upon the rules of the department, these are some of the points which decorate the first page (the bottom right-hand corner of which is very quaintly marked "over")—but I will not go beyond this, as the whole thing may be superseded by the last Code.

The Oldham School Board bought copies of these rules at threepence, and generously supplied them to intending or would-be competitors, most of them already in possession of the publication at half-a-crown. As the new Code has come out in the interval,—namely, that between the announcement of the competition and the date for sending in designs,—there is likely to be a curious complication.

F. B. P.

## AN "EMPLOYERS' UNION."

SIR,—I was glad to see the letter in the *Builder* of the current week under title "An Employers' Union."

The course proposed is, in my opinion, the only one that will efficiently check the existing state of affairs, brought about by the agitators in the name of trade unionism.

As an employer, both in the building trade and also brickmaking, I should be glad to help to form an Employers' Union, and to be a member of the same.

In my opinion every member should pay an amount based on the number of men employed, or wages paid; for we want the small as well as the large employers. But all these details must be carefully considered, and the thing must be done well if at all.

J. J.

\* We were guilty of an oversight in referring to these rules in our article as "new"; they have been drawn up and in circulation for some time back, but are now issued afresh as part of the New Code.—Ed.

**"A SANITARY NOTE FROM GREENOCK."**

SIR.—The letter signed "X. Y." in the *Builder* of the 20th clearly shows that the writer does not properly understand the subject of house-drainage. His notion that the side fresh air inlet to a disconnecting trap, two yards from the trap, "would give that much greater volume of sewage air to eject on to the street," is simply the height of absurdity. There is nothing in these two yards of piping to raise a smell. For fifty-five minutes out of every sixty, fresh air will be passing into the drain through them, and should this be stopped for a few seconds by the discharge of a closet, &c., the fresh air that has been entering, and filled the piping, has to be first pushed out at the grating before any badly-smelling air can get out.

By the time the badly-smelling air can get the length of the grating, the closet has ceased running, whereupon the bad air turns back the drain and goes up the soil-pipe and out above the roof. This is especially the case when the soil-pipe is inside of the house, as it is in thousands of cases in Glasgow, &c.

I do not remember of a single complaint of smell from a side grating put in as I have indicated.

"If in some particular case the discharge of a closet, &c., did cause a smell to come out of this grate, it can be easily cured by putting in an automatic valve below it."

If sewage air has anything to do with the high death-rate of Glasgow children it is not from the gratings of proper disconnecting traps, but from leaking drains and soil pipes, which leaks "X. Y.'s" ideas would only make more dangerous.

"If in some particular case the discharge of a closet, &c., did cause a smell to come out of this grate, it can be easily cured by putting in an automatic valve below it." The bad air from the sewers that comes up the gutter gratings at the edge of the pavements to blame for hurting the children. I have for long insisted on these being trapped, as I have often seen the children sitting over them, and have often felt foul sewer air blowing up them.

"I do not believe Mr. van Putten, thinks the houses would be safer by allowing the air from the public sewers to pass into the house-drains and up the soil-pipes. They both forget that this would also be letting in the sewer-rats into our houses, and the majority of people would not look upon this as an improvement."

"I do not believe Mr. van Putten, 'M. Inst. C.E.," when he asserts that the air in our public sewers is less dangerous than that in our house drains. The drainage of many houses has been so much improved of late years, that to do away with their ventilating disconnecting syphon-traps, and let in the sewer-air into their drains and soil-pipes—rats included—would be anything but an improvement."

When fever breaks out in one house or tenement, the disconnecting traps on the other tenements prevent them being contaminated from this fever-house.

Mr. van Putten, as an engineer, ought to know better than to write that, supposing the high-level inlet to a drain is as high, or nearly so, as the outlet, that therefore the air currents "at a complete standstill." He forgets the effects of difference of temperature and of a good cool on one of the ends.

"X. Y.'s" story of bottled-up gases in tide-filled sewers forcing the disconnecting traps of houses and also of the sinks and closets in them, that is drawing the long bow. The rain-pipes and the ventilating-pipe of the soil-pipe should relieve these; and if it be really true that no ventilation has been provided by the public authorities for the sewers he refers to, such should be provided, altogether independent of the house drainage. For people to poll their private drains, and let rats into them, in order to benefit the public sewers, would simply be equivalent to committing suicide.

W. P. BUCHAN.

**"SKY-SIGNS."**

SIR.—As I am sure many of your readers are interested in the above subject, I should like to ask, supposing a sky-sign is erected on premises adjoining my own, and a fire occurs, which causes the sign to topple over and crush my roof, to whom should I look for compensation? If I am insured, I should naturally ask the Insurance Companies to pay; but will they do it? There is nothing in my policy to lead me to believe they will.

J. C. MERRYWEATHER.

**DANGEROUS ADVERTISEMENTS.**

SIR.—While the question of "sky-signs" is before your readers, may I call attention to another form of advertisement which, though not so common, is nevertheless dangerous and objectionable? It consists in covering the walls of a house with boarding, on which paper advertisements are pasted, on a larger scale than can be attained on the ordinary boarding, thus setting the Building Act at defiance, and facilitating the spread of fire in the best possible way.

There is a building in King William-street, near London Bridge, which has been covered in this manner from the first-floor to the parapet, for several years. Last week the boards were all removed, and it looked as if the law had been vindicated; but no—they have all been replaced, and

will, no doubt, be soon covered with pictures more glaring and irritating than ever.

In Mr. Bamister Fletcher's book on the Metropolitan Building Acts, a case is quoted in which this very proceeding was condemned by a magistrate, as clearly contrary to the Act, and rendering it nugatory. One would like to know if this decision has ever been overruled, and, if not, why it is not acted upon.

AN ARCHITECT.

**THE COLONIAL ARCHITECT, NEW SOUTH WALES.**

SIR.—Will you kindly correct an error which exists in the note from New South Wales in your issue of the 13th inst., where my old friend, Mr. W. L. Vernon, is stated to have formerly practised in London and Brighton? For the latter town, Hastings should be substituted. He never practised in Brighton.

RICHARD A. HILL, F.R.I.B.A.

**The Student's Column.**

**HOT-WATER SUPPLY.—XIII.**

**COVERING PIPES AND RESERVOIRS FOR THE CONSERVATION OF HEAT.**

HERE is no branch subject in connexion with hot-water work deserving so much attention as this. It is no exaggeration to say that very shortly no apparatus for hot-water supply will be considered complete or finished if the whole system is not insulated, so to speak, so that almost every particle of heat absorbed by the water in the boiler will be obtainable from the taps, instead of nearly 50 per cent. of it being radiated from exposed surfaces, and worse than wasted.

There are at this moment hundreds, if not thousands, of hot-water systems that, by being carefully covered, would be converted from miserably inefficient to highly satisfactory appliances,—this in particular with the tank-system, when the tank is so commonly fixed in a cold, draughty roof.

An interesting instance of the success attending the covering of pipes occurred quite recently, in which a residence was fitted with a complete system of hot-water supply pipes on a scale sufficiently large for a good boiler in a 3 ft. kitchen range, but owing to a delay experienced in obtaining the range in question, another of a smaller size, 3 ft., was fitted up and connected to the chimney and circulating-pipes for temporary cooking and hot-water supply. It was not supposed that this little range with its boiler would do much in the way of water-heating, but to the astonishment of everyone it gave a really abundant supply of very hot water in every part of the house as quickly in the morning and altogether as satisfactorily as a larger range would be expected to do.

This desirable result was wholly brought about by the pipes and cylinder being everywhere carefully covered with a sufficient thickness of felt, so that however hot the water was within the pipes, no heat could be felt outside the covering, a sure indication that no heat was being dissipated.

It really does seem opposed to all reasonable and workmanlike principles to allow such abundant opportunity for heat to be thrown away, while labour and fuel is being expended in the kitchen apparently for this object. If a fitter or maker of steam-engines and appliances did not attend to the subject of this paper in a thorough and workmanlike manner he would be considered to have hardly mastered the rudiments of his business. The waste of heat is not always the only ill-result experienced, as in many instances the warmed air is very objectionable, and if a hot-water pipe is carried alongside a soil-pipe it is possible for a very unpleasant feature to introduce itself. It is a very customary practice for a hot-water fitter to carry his pipes up in the casing that is bottom to the top of the house, this casing containing all the different pipes of the house, such as the cold service from the main, the cold service down from cistern, the w.-c. cold-water services, and, very commonly, the soil-pipe. There is no objection to his making use of this casing if it is large enough to hold a few more pipes, and it is often used of necessity, as to carry pipes openly through well-decorated rooms is out of the question; but to carry hot-water pipes up this case without felting them is an exceedingly bad practice, as they are not only brought into contact with very cold surfaces (they have frequently been found

wired to cold pipes, four or five pipes in a bundle), but the heat radiated causes a draught or current of air to set in, as we find in a chimney.

When a casing contains pipes that radiate heat, that casing, within a few moments after the heat is felt within it, is converted into a flue, as by applying heat to air it can be made to circulate to all intents and purposes like water. Air that is brought in contact with heated surfaces becomes heated and rarefied, and, being thus made lighter than the surrounding air, rises, and cold particles immediately flow in to take its place, they becoming heated and following the first particles, and so on, so that it resolves itself into a stream of warmed air, flowing out of the upper part of the casing, and cold air flowing in in corresponding volume below. This may be excellent in practice when hot-water pipes are used for effecting ventilation; but it is fatal to hot-water services which are particularly required to keep the heat within them; in many instances they are cooled at about the same speed as they would be if placed outdoors when a strong wind was blowing.

It may be argued, that if the casing is stopped off at its two extremities, the trouble will be obviated, and so it would be if the casing was perfectly air-tight everywhere, and had no cold pipes within it; but this is never the case, there are always numbers of crevices and apertures which permit of a tolerably free ingress and egress of air.

The best material for covering these pipes and also the reservoirs is hair-felt; hair is a natural poor conductor of heat, and nothing surpasses it for this purpose, especially as it is so easy of application. This felt, which is readily obtainable in sheets, is usually cut up in strips for pipe-work; the strips are wound upon the pipe spirally, being secured here and there with cord or wire, but where spiral winding is impossible it can be tied on in lengths, which answers equally well but has not such a good appearance.

The best and most complete arrangement for pipe-work, but which entails a little greater expense, is to have the felt wound on spirally in one direction, say from left to right, and well secured with cord; then cover this with good canvas, also wound on, but in the opposite direction, and this secured with wire.

It is most necessary, to secure the best results, to have the felt thick enough; hair felt is sold in great quantities about  $\frac{3}{8}$  in. thick, but this is not thick enough for good work. If possible have it  $\frac{1}{2}$  in. thick, and a marked benefit will be had by using even thicker than this, or, say, two thicknesses of  $\frac{3}{8}$  in.

In felting cylinders, it is the best plan to take sufficient sheets of felt, and then sew the edges together to form one sheet large enough to go all round the reservoir. This sheet can then best be secured by bands of hoop-iron or brass passed round at top and bottom, and around the middle; these bands being tightened up by having a bolt to draw the two ends together, as fig. 27. After this circular pieces can be cut for top and bottom; these pieces being sewed on to the top and bottom edges of the large sheet. Tanks can be covered in exactly the same way.

Sometimes it is desired to encase the tank or cylinder with woodwork. This makes by far the neatest job, though more expensive, and it causes a little trouble should it be necessary to open the reservoir under some circumstances. If it is decided to have a casing it is very important that the space between the woodwork and the reservoir be well filled-in with some poor conductor of heat, such as cow hair (plasterers' hair), slag wool, or even dry sawdust answers very well when the casing can be filled from the top. If the casing is not "packed" with something it would be much better to be without it, as it would have a current of cold air passing up through it the same as explained with the general pipe casing just referred to.

If the hot-water service-pipes are carried up through the house without entering the general pipe casing mentioned, and it is proposed to encase them for the sake of appearance, this casing must also be packed for the reasons explained, but this is frequently neglected with the worst results, as the casing of pipes is frequently done for appearance sake only, the question of radiation not being considered.

Occasionally it is found practically impossible to carry the pipes up inside the house, in which

case it becomes necessary to carry them outside. This is very objectionable, but where it cannot possibly be avoided the objections do not avail, but they must be guarded against. In the first place, the pipes must be encased, and the casing ought to be of fair size, so that 1½ in. of packing can be filled in between the woodwork and any of the pipes. The packing must fill the case tightly, and it is imperative that the casing be well and tightly secured to the wall, as should it get loose the woodwork and the packing will come away from the pipes, and leave them exposed.

When pipes are carried outside, the packing is not only needed to prevent great waste of heat, but there is a danger to be guarded against in cold weather, when the pipes are liable to be frozen and an explosion possibly ensue, as the only outlet for any steam that may be generated in the boiler is at the upper extremity of the expansion pipe, unless a safety-valve is provided.

#### OBITUARY.

**MR. JOHN MOSSMAN, SCULPTOR.**—The *Glasgow Herald* announces the death of Mr. John Mossman, sculptor, which took place on Monday morning last, at Port-Bannaclayne. Mr. Mossman was in his 74th year. He was born in London in 1817, his father at that time being in the employment of Chantrey. While John was still young his father removed to Scotland, and established himself in business in Leith. Young Mossman assisted his father and became his right-hand man, doing excellent work and much of it. He was, however, anxious to rise in his profession, and, in order to further his art-training, he studied for some time under Baron Marchetti. His progress was steady and thorough, and when thus fairly equipped he came to Glasgow, and, with his brother George, established the monumental works still carried on in Mason-street. Mr. George Mossman died about fifteen years ago. In George-square, Glasgow, were the statues of Sir Robert Peel, Dr. Livingstone, and Thomas Campbell, the poet, were executed by him; and in Cathedral-square, he put up the statues of the late Rev. Dr. Norman Macleod and Mr. Lumsden. Several years ago Mr. Mossman was elected H.R.S.A.

**THE REV. CHARLES ROGERS, D.D., LL.D.**, died at his residence in Edinburgh on the 18th inst., at the age of sixty-five. The deceased was indefatigable in his endeavours to perpetuate the memory of eminent Scotsmen. His work was mainly literary, but his name was most prominently brought before the public in connexion with the movement for the erection of the Wallace Monument on the Abbey Craig, near Stirling. This memorial cost 14,000*l.*, and was inaugurated on September 12, 1869, and is in the form of a peel tower, surmounted by an open crown. The tower contains a "Hall of Heroes," where are the busts of several eminent Scotsmen, which are from time to time being added to. Dr. Rogers also took the leading part in the erection of the statue of Robert the Bruce on the esplanade of Stirling Castle, which was completed in 1877, and he took a similar part in the erection of the statue of Hogg, the Ettrick Shepherd, at St. Mary's Loch.

**MR. THOMAS NELSON.**—The death is announced of Mr. Thomas Nelson, who was for many years engaged in business in Carlisle as a builder and railway contractor. Mr. Nelson made a valuable collection of Burns's manuscripts and other relics.

#### GENERAL BUILDING NEWS.

**THE VICTORIA LAW COURTS, BIRMINGHAM.**—The *Birmingham Gazette* reports that the internal fitting of the new Law Courts in Corporation-street is being pushed forward as rapidly as possible, but it is not expected that, under even the most favourable conditions for the work which yet remains to be done, they will be ready for occupation before the end of March next. The paneling of the three police courts, the coroner's court, and the two assize courts, is now practically finished. The doors in the principal corridors and of the courts are of oak, the remainder in pine. All the oak used has been fumigated, to destroy the tone and preserve the wood, and the whole of the carving has been executed in the workshops of Mr. John Bowen, the contractor for the erection of the courts. Now that the buildings are nearing completion, it is seen (says the *Gazette*) that the plan of the six courts, the three police courts, and the coroner's court, depending on the great hall, and the two assize courts in the rear, is as convenient as it could possibly be, and so far, as at present be judged, the internal accommodation will be both sufficient and satisfactory. The police block fronting to Steelhouse-lane is practically ready for occupation, and the administrative departments in connexion with the courts are ample and convenient. The electric light is ample through the entire block, and the change from the original contemplation, which was to use gas, has caused considerable delay in the completion of the courts. The architects of these buildings are Messrs. Aston Webb and E. Ingress Bell. We gave

a view and plan of their design in the *Builder* for July 31, 1886. We also illustrated the sculptural treatment of one of the gables of the building in our number for Dec. 21, 1889.

**RUARDEAN CHURCH, GLOUCESTERSHIRE.**—Was reopened on the 23rd inst., the work of restoration being nearly complete. This work has been carried out from the designs and under the direction of Messrs. Warr & Sons, Architects, Gloucester, at a cost of 2,000*l.*, the builder being Mr. H. J. Smith, of Wolverley, Kidderminster. The north and south walls of the chancel, the south-east wall of the aisle, and the entire north wall of the nave, have been repaired. The oak roof of the chancel has been repaired. The roofs of the nave and south aisle have been replaced by new roofs of pitch-pine.

**THE NEW MUNICIPAL BUILDINGS, NEWCASTLE-UNDER-LYME.**—On the 23rd inst. a public inquiry was held at the Town Hall by Mr. Thomas Coddington, M.Inst.C.E., as to an application by the Corporation for sanction to a loan of 8,500*l.* for sawdage and street improvement work. There was also conjoined an investigation to the Town Council's expenditure upon the public buildings. A mass of evidence was taken, and the Commissioner will make his report in the usual course.

**MESSRS. HUDSON BROTHERS' NEW PREMISES ON LUDGATE-HILL** have now been completed and opened for business. They have been built from the designs and under the supervision of Messrs. J. W. and R. F. Beaumont, architects, the lower part of the frontage being of grey and red granite, supplied by Messrs. Whitehead & Sons, of Aberdeen. The upper part is faced with Bracknell red bricks and Mansfield stone dressings. The premises, of course, look all the better now that Messrs. Hudson have been so well-advised as to take down their "sky-sign."

**THE PRINTERS' ALMSHOUSES AT WOOD-GREEN.**—A movement is on foot for extending these buildings by covering part of the asylum grounds now vacant, and so providing residences for four additional inmates. It is estimated that 5,000*l.* will be required for the proposed work, and permanently endowing the whole building. To this end liberal contributions are urgently solicited.

**NURSES' HOME, ROYAL INFIRMARY, EDINBURGH.**—On the 22nd inst. a conference took place between the members of the Edinburgh Dean of Guild Court and the Infirmary managers with reference to the nurses' home which the managers propose to build on the grounds. There being no room for accommodation in the Infirmary for the nursing staff, the managers some time ago placed a commission for plans in the hands of Mr. Sydney Mitchell, architect. The site selected was the open space between the two westernmost pavilions

of the surgical and medical sides of the hospital—that is to say, the ground to the north of the westernmost medical wards and south of the westernmost surgical wards. Mr. Sydney Mitchell's plan shows a two-story building occupying a square of about 120 ft. The buildings (according to the *Scotsman*) are grouped on four sides of this square, leaving a square of 50 ft. across in the centre. It provides 140 small bed-rooms for the nurses, and a dining-hall. When the Dean of Guild Court proceeded about three weeks ago to consider the plans, they found that without warrant the managers had put in the foundations of the new building. The Court, however, apart from this, asked time to consider the plans, as the meters were so strongly adverse to seeing the only remaining open space in the Dean of Guild Court grounds built over. They argue, and apparently with justice, that this is a departure from the original pavilion scheme on which the hospital was built, which was specially adopted to secure the maximum of light and air; and objection is also taken to the plan of the building, enclosing, as it does, a hollow square, which is prejudicial to the free circulation of air. For a building which is to be used both day and night for sleeping purposes, it is contended that a plan of this nature is not the best that could be adopted. No decision was come to, but the general feeling appeared to be that the Dean of Guild Court was really powerless in the matter, and that the building would have to proceed.

**ALDBROUGH CHURCH**, in the North Riding of Yorkshire, which has been built at the expense of the Dowager Duchess of Northumberland, at a cost of 1,500*l.*, was consecrated on the 23rd inst., by the Bishop of Ripon. It will seat 120. It is in the Early English style. The architect is Mr. W. T. Hicks, of Newcastle, and the work has been carried out by two deacons of the village, Messrs. Ivison & Brown, who contracted for it.

**PUBLIC BATHS AND CENTRAL POLICE STATION FOR LINCOLN.**—At the meeting of the Lincoln Town Council on the 17th inst., a general combined scheme for the erection of public baths and wash-houses and a new central police station, was adopted. The cost of the scheme is not to exceed 15,000*l.*

**NEW SPINNING MILLS IN THE BOLTON DISTRICT.**—According to the *Leeds Mercury*, several new spinning mills are about to be erected in the Bolton district, besides those now approaching completion, and the spindle power increased by at least half a million spindles, bringing the aggregate to close upon seven millions.

**THE NEW MARKET HALL AT SANDRACH, CHEESHIRE**, built on a site given by Lord Caswe who has also renounced his claims in the future to the market tolls, is rapidly approaching completion. The cost of the building is about 4,500*l.*

**LABOURERS' DWELLINGS, CASTLEFORD, YORKS.**—On Tuesday evening last Colonel John Ord Hasted, R.E., held a Local Government Board meeting at the Local Board offices, Castleford, relative to a proposed scheme for new dwellings for persons of the labouring classes submitted to the Local Government Board, in lieu of those the North-Eastern Railway Company propose to destroy in constructing a new branch of railway in Whitwood Mere. Mr. Gibb, the solicitor to the North-Eastern Railway Company, opened the case on their behalf, and said that the North-Eastern Railway Act of 1859 gave them power to provide a branch line in the parish of Whitwood Mere. They had found it necessary to purchase thirty-three houses, and they required to destroy twenty-six of them. Their scheme to the Local Government Board was to build thirty-six new houses within half a mile of the old ones.

#### SANITARY AND ENGINEERING NEWS.

**HOOLE, NEAR CHESTER.**—On the 12th inst., Mr. T. Coddington, C.E., Local Government Board Inspector, sat at All Saints' Schools, Hoole, Chester, to inquire into the proposal of the Hoole Local Board to borrow 1,000*l.* for the purpose of certain street improvements. The district was the Clerk to the Board (Mr. J. P. Cartwright), in explaining the position of the district, said that a large proportion of the railway men and industrial classes amongst the residents had complained of the bad condition of Philip-street and Walken-trust. The Board considered those streets ought to be sewered, to borrow the 1,000*l.* to the extent of which they had already given notice to the owners and frontagers. Since 1855 the Board had borrowed, with the sanction of the Local Government Board, a total of 6,850*l.*, and 4,000*l.* was repaid of that sum.

**PROPOSED NEW HARBOUR AT WHITEHILLS, BANFERSHIRE.**—The work undertaken by Messrs. D. & T. Stevenson, the civil engineers of the Fishery Board, have finished their marine survey of the bay in which it is proposed to construct a new harbour at Whitehills, about a couple of miles to the west of Banff. At low water the present harbour is entirely dry, and it extends to only 0/35 acre. According to the plan prepared by the engineers, the whole area of the proposed harbour would extend to about 0/60 acre, and at high water to 1/6 acre. The engineers estimate the cost at about 9,000*l.* The depth of water in the new harbour will allow the largest boats to come in practically at all states of the tide and discharge their fish.

**ASTON AND TREETON WATER SUPPLY.**—On the 11th inst., the work undertaken by the Bolton Rural Sanitary Authority in connexion with the supply of water to the districts of Aston, Catcliffe, Osgreave, and Treeton was completed. The cost of the undertaking has been about 5,000*l.*

**WATER SUPPLY AT UTOXETER.**—At the monthly meeting of the Utoxeter Sanitary Authority, on the 10th inst., the Medical Officer of Health reported with reference to the intermittent water supply, that the reservoir at Utoxeter, when built, was possibly large enough to contain a supply sufficient for the bare necessities of the inhabitants, but was now found quite inadequate to meet the demands, and the question must now be grappled with by the Sanitary Authority. The reservoir, when full, held about 50,000 gallons, which, as an ordinary computation would not be considered sufficient for one day's supply. The matter was referred to a committee for consideration.

**THE SANITARY CONDITION OF THIRSK.**—On Monday last, at a meeting of the Local Sanitary Authority, the Vicar of the Parish, Rev. W. Teesdale Mackintosh, appeared, and complained of the unsanitary condition of the town, pointing out that it had not been free from fever for a long time. The Vicar submitted a number of propositions for putting the town into a good sanitary condition, but the Authority seemed to think (judging by the report in the *Leeds Mercury*) that the 10,000*l.* or 15,000*l.* necessary to carry them out was too great a price to pay for the improved health of the town.

#### FOREIGN AND COLONIAL.

**FRANCE.**—The municipal authorities of Calais propose to inaugurate next month a monumental group, designed by M. HOLLIN, to the memory of Eustache de St. Pierre.—In the course of the cutting and embankment works for the new railway line from Mantes to Argenteuil, a well-preserved Gallo-Roman burying-ground has been discovered near Audréry. More than 150 sepulchres have already been found, containing numerous objects, such as coins, jewels, and pottery, which will be preserved in the museum of St. Germain.—The required documents in regard to the scheme for a ship canal between Paris and Rouen have just been deposited at the Hôtel de Ville, Paris. The project has the support of the Minister of Public Works, but is unfavourably regarded by the "Corps des Ponts et Chaussées." The cost is estimated at 135

MISCELLANEOUS.

**THE ALEXANDER THOMSON MEMORIAL.**—At a meeting of the Trustees, held in Glasgow on Thursday, the 18th instant, Mr. John Gordon, President of the Glasgow Institute of Architects, in the chair, the prize (value £50) of the Travelling Studentship for the best set of drawings of a hall with side rooms was awarded to Mr. Chas. B. McIntosh, of Dennistown, Glasgow. The drawings set in competition were exhibited in the Corporation Galleries.

**REQUESTS IN AID OF ARTISTS.**—By the will of the late Mr. Patrick Allan-Fraser, of Hospitalfield, Arbroath, there is to be put in operation a scheme for the assistance and encouragement of young men desirous of following out the professions of painting, sculpture, architecture, carving, or engraving. Funds are also to be bestowed to provide for the comfortable maintenance of aged or infirm professional men, painters, sculptors, or literary men. Various other benevolent bequests, and a large number of legacies and annuities, are also specified. Mr. Allan-Fraser, who was the last of his race, was a painter and an honorary member of the Royal Scottish Academy. He designed and carried out an elaborate and costly mortuary chapel for the reception of the remains of his late wife, and is the author of various publications.

**THE FAN-MAKERS COMPANY.**—The prizes awarded by this Company to the successful competitors in the recent exhibition at the Crystal Palace Hall were on Tuesday afternoon presented by the Lady Mayress, in the Egyptian Hall of the Mansion House. Mr. Homewood Crawford, Senior Past Master of the Company of Fan-Makers, at the request of the Lord Mayor, made a brief statement of the objects and results of the exhibition, remarking that the art and handicraft of fan-making had not been cultivated to any great extent in this country during the present century; but he was happy to say that the efforts of the Company had had the effect of so stimulating the industry that fans of the most beautiful and complex workmanship—hitherto supposed to be incapable of complete production in England—had been manufactured in this country without recourse to foreign aid.

**THE ENGINEER TO THE CITY COMMISSION OF SEWERS.**—We regret to hear of the somewhat serious illness of Colonel Haywood, the Engineer to the City Commission of Sewers. At the meeting of the Commissioners on Tuesday last, the Chairman (Mr. Deputy Green) expressed his deep regret at the receipt of a letter from Colonel Haywood, stating that his health was very far from what he must from necessity desire himself, or that which the members of the Court desired. He had sought the healing influences of Carlsbad, but he had to return home, where he was transacting the business of the Commission which fell to the department, and he was well informed of everything that went on. For the moment, therefore, he asked that he might be excused from attending before the Commission or before the Committees. This request was unanimously granted.

**PROPOSED MEMORIAL TO THE LATE DEAN OF MANCHESTER.**—The *Manchester Courier* says that the committee who have under their consideration the proposal to establish a memorial to the late Dean of Manchester have unanimously decided that the memorial shall take the form of a pulpit in the nave of the cathedral.

**TECHNICAL CLASSES AND LECTURES.**—With the approach of the winter months the many technical classes and courses of lectures are about to commence. The Birkbeck Literary and Scientific Institution, Bream's-buildings, Chancery-lane, commences its sixty-eighth session on Wednesday next. Among the classes and lectures there we may mention those in Quantity Surveying, conducted by Mr. H. Bushell, F.A.S.E.; and on Building Construction, conducted by Mr. W. H. Marsh. At this Institution, also, Mr. G. F. Harris, F.G.S., is commencing a course of lectures on "Applied Geology," with special reference to the requirements of architectural and engineering students.—The Working Men's College, Great Ormond-street, Bloomsbury, founded by the late F. D. Maurice, re-opens for its thirty-seventh session on October 6. The classes announced include as usual, all the subjects which may be regarded as necessary for a liberal education; and at a price which places them within the reach of the poorest working man.—The City of London College, White-street, Moorfields, announces that its forty-third session commences on Wednesday next. The Secretary sends us the syllabus of lectures in the Engineering Department, by Professor Henry Adams.—The winter session of the Carterhouse Science and Art Schools and Art Schools in the United Kingdom, and a school which has trained some thousands of teachers for the offices of science lecturers, commences this Saturday, September 27.—The Bow and Bromley Institute, which is doing very good work, has just commenced its first half of the winter session.

**THE NINETEENTH CENTURY ART SOCIETY.**—Monday, October 6, has been appointed for the reception of Works of Art intended for the Autumn Exhibition (the Twenty-second) of the Nineteenth Century Art Society at the Conduit-street Galleries.

**THE ENGLISH IRON TRADE.**—The English iron market is in a rather disturbed condition, owing to the dispute between the Scotch ironmasters and the blast-furnace men. The Glasgow warrant market has been greatly excited thereby, and prices have been going up all the week, while makers' quotations are rather unsettled, but they are nearly all higher. This condition of affairs has influenced prices in the North of England, Cleveland pig No. 3 having risen 2s. 3d. per ton. The effect of the Scotch dispute has made itself less felt in the southern markets, but prices there are stiffer. There is greater activity in hematites, which have gone up 1s. 6d. per ton. Partly owing to the rise in pig, finished iron and steel have been pushed up; but there is a good demand as well. Ship-builders are more busy in consequence of the orders they have recently booked, and engineers are also doing better.—Iron.

**LABOUR DISPUTES.**—The Dundee Masons' strike has ended by the men accepting the masters' offer of an advance of 1d. an hour. The men came out for 3d. advance. The strike has lasted fully six weeks. The wages to be paid on 23d. to boilermakers, 7d. per hour to hewers, and 73d. to boilermakers. On Tuesday evening last a meeting was held at the Memorial Hall, Farringdon-street, convened by and in support of the National Union of Stove-Grate Workers, which, as the outcome of a strike at Rotherham in the early part of this year, has already, it is said, 2,000 members, and a footing in eight provincial towns.—Mr. Tom Mann, president of the Dock, Wharf, Riverside, and General Labourers' Union, who occupied the chair, remarked that the main object of that meeting was the strengthening of the London branch of the National Union of Stove-Grate Workers. There were 15,000 of these workers in the various branches of the trade in the metropolis, who laboured during excessive hours for too low pay. Mr. Clements moved a resolution pledging the meeting to support the workmen of Messrs. H. & C. Davis, of Camberwell (who are out on strike), by joining the union and by using every legal means to "prevent anyone taking a job there so long as the dispute lasts." The resolution was adopted.

**THE SOUTH WALES ART SOCIETY AND SKETCHING CLUB** announces that their third annual exhibition will be opened in the Public Hall, Queen-street, Cardiff, on or about November 15 next. The Committee announce that they are prepared to receive the following for exhibition:—Recently-executed pictures, drawings and sketches in all mediums, and on all materials ordinarily in use; sculpture and modelling, carving in wood, stone, and other materials efficient for the purpose; metal-work, inlaying and mosaic in panels; and small articles of furniture or fittings, &c., which display artistic design or workmanship. The hon. sec. is Mr. J. A. Sant.

**PROPOSED "PEOPLE'S TEMPLE" FOR LONDON.**—There is a project on foot in London (says the London correspondent of the *Manchester Guardian*) to build a "People's Temple" by covering a space wherein at least 100,000 persons could assemble for the discussion of topics of public interest. The idea is that by roofing an area as large as Russell and Bedford squares there would be an end to such dissatisfaction as has attended the loss of Trafalgar-square for meetings, and that such a temple would be free from the disadvantages of Hyde Park. The People's Temple is to be beautiful, and subdivisible when required, so that discussion on many subjects could be going on at the same time. So far the London correspondent. When the funds and the site for the proposed building have been procured it will be time enough to think of solving the problem which this probably imaginary scheme would involve.

**A CLERGYMAN WORKING AS A MASON.**—What is described as "a novelty in church restoration" affords material for a paragraph in all the newspapers. It is stated that the restoration of the parish church of Marsworth, a village near Tring, has been accomplished under extraordinary circumstances. The Rev. F. W. Rigg, who was appointed to the vicarage in 1880, when, notwithstanding some partial works which had been executed, he found the principal parts of the church—the windows, walls, buttresses, roof, and tower itself—in a very unsound state. About 2000, was subscribed towards the restoration; but, although this was altogether inadequate, Mr. Rigg set to work himself as an ordinary mason, and with the aid of one worker in stone, and a few farm-labourers, who voluntarily assisted, he accomplished all that could under the conditions be done. With this help alone he restored the windows, took down the dangerous buttresses and rebuilt them, set good the south wall, and with the aid of a carpenter raised the roof of the nave. He then had no funds left wherewith to pay the mason and carpenter for further services, but he kept on with the work, completing buttresses and walls, building a parapet, refacing the tower, cutting and erecting a chancel arch, &c. Then an attack of rheumatic fever, due to exposure when working, disabled the energetic clergyman, but on his recovery he put in several windows and completed other work." If our memory serves us, this is not the first instance of the kind during the last fifty years.

million francs, and the probable time of transit for vessels between Rouen and Paris at seventeen hours.

It appears that the new bridge over the Saône, built with the funds left by the late Madame Boucaut, has already shown signs of failure, and the engineers commissioned to report on its condition consider that immediate operations will be necessary to strengthen the foundations.—A new line of railway, entirely strategic in character, is contemplated between Belfort and Les Vosges, on the recommendation of the War Department. It will be carried out by the Compagnie des Chemins-de-fer de l'Est.—The Municipality of Besançon has voted a subvention of 100,000 francs for the erection of a large hydropathic establishment there, to be carried out on the most complete system.—A committee has been formed at Bordeaux to organize an artistic, industrial, and agricultural exhibition in that town in 1891, when it is proposed to repeat or reproduce some of the principal attractions of the Paris exhibition of 1889. The exhibition is to be held on a large estate outside the town and connected with it by a Deauville railway.—In the Department of the Eure the works necessary for carrying the water of the Avre to Paris were commenced some weeks ago. The water will be conveyed by way of St. Cloud, where a large reservoir is to be made. The "Moulin Jacob," on the route from Bergues to Dunkerque, and well known to antiquaries as probably the oldest mill in France, is about to be pulled down.—A group of architects, former pupils of the *Écoles des Beaux Arts*, are endeavouring to establish a professional association at Limoges.—The official inquiry held on the Metropolitan railway scheme for Paris submitted by the Eiffel Company, has resulted in a majority of votes against the concession to that Company.—The City authorities of Paris are about to commence the formation of a new public gymnasium, for which the iron structure has been erected at the Court of the Tuilleries, for the temporary accommodation of the Postal Service, will be utilised.—The Paris "Ceinture" Railway Company has commenced the reconstruction of the Pont de Flandres at the end of the street of that name.—A new bridge is to be proceeded with at Conflans, between Ivry and Chartres. The proposed bridge will run to 200 metres in length, and will be 16 metres in width. The cost is estimated at over a million francs.

**FLORENCE.**—According to *La Construction Moderne*, a museum is to be established at Florence in which will be collected everything relative to the history and design of the Cathedral, under the title of Museum "dell'Opera del Duomo." The same journal states that a number of architectural drawings by Sansovino, Peruzzi, Bramante, and San Gallo, at present hidden away in the Uffizi galleries, are to be framed and exhibited as a portion of the Uffizi collection.

**THE NORTH-SEA AND BALTIC CANAL.**—According to a paper read by Genl. Ober-Baurath Bausch (Berlin), the construction of this canal has been progressing favourably this summer, and the work is likely to be complete by the autumn of 1895, if unforeseen difficulties are not encountered. The canal will have a length of 98·6 kilometres, 62 of which are in a straight line, whilst the rest are on curves, with radii varying between 6,000 and 1,000 metres (1,000 metres being the smallest radius considered advisable for easy passage of modern ironclads or merchant vessels of great tonnage). In working out the sections, the measurement, "22 metres bottom, 53 metres surface, 8½ metres depth" of water was taken as a minimum suitable for most-of-all trading. At every 12 kilometres, extra width has been given for siding purposes, such sidings having 60 metres bottom to a length of 450 metres. The cubic metres of ground to be moved have been calculated at 78,000,000 (see *Builder* of May 17) to 80,000,000, of which 15,000,000 have been moved up to date; and for this enormous piece of work there are employed 6,670 workmen, aided by 27 land- and 24 floating-dredges, 4 elevators, 97 engines, 2,700 trucks, 15 steamers, 51 dredge-boats, and 37 steam-pumps, representing a capital of some 12,000,000 marks, or nearly 600,000. At either end of the canal twin-locks have been planned, each of these four structures having a length of 216 metres; and seawards of these, outer and inner harbours (the latter with some 500 metres quay frontage each) have been designed. Of other structures of importance on the line of the canal, we may mention the lock connecting the new waterway with the old Unter Eider Canal. Land traffic across the new canal will be worked by five swing-bridges, a fixed bridge, and several ferries; the swing-bridges, when open, permitting a free passage of 36 metres width, the fixed bridge permitting the passage of vessels with mast-heads forty-two metres above water.

**MEMORIAL TO THE AUTHRESS OF "JOHN HALIFAX."**—Soon after the death of Dinah Maria Mulock (Mrs. Craik), in 1887, a scheme for the erection of a suitable memorial of her work was started by some of those who prized that work. It was decided that the memorial should take the form of a marble medallion in Tewkesbury Abbey. The memorial has now been placed in the Abbey. It is the work of Mr. H. H. Arnstead, R.A.

COMPETITION, CONTRACTS, AND PUBLIC APPOINTMENTS.

COMPETITION.

Table with 4 columns: Nature of Work, By whom Advertised, Premium, Designs to be delivered.

\*Plans for New Cemetery..... Milton Mowbray L. B. 30 and 10 guineas. Jan. 50 91

CONTRACTS.

Those marked with an Asterisk (\*) are advertised in this Number. Competition, p. iv. Contracts, pp. iv, and vi. Public Appointments, p. xvi, and xvii.

LEGAL.

LIVERPOOL CONSISTORY COURT:

FACILITIES FOR NEW WORKS.

A SITTING of the Consistory Court for the Diocese of Liverpool was held on Tuesday afternoon at St. Nicholas's parish church, before the Rev. Canon Stewart, surrogate to the Chancellor. The following report of the proceedings is from the Liverpool Post.

An application was made by the Rev. Canon McNeil, of St. Paul's Church, Prince's Park, for a faculty to erect a carved oak reredos by the east window of the chancel, having in it a copy of "The Last Supper," of Leonardo da Vinci. The reredos is to be erected at the expense of Mr. and Mrs. W. Nicol, of St. Michael's Hamlet.

The faculty was decreed by the Court, as was also one asked by the Rev. G. Howell, of Christ Church, Everton, for the re-flooring of the chancel with white and red marble, at the expense of Mr. R. G. Dalgleish.

A faculty was granted for the insertion in the east window of the parish church, Fairwater, of stained glass, the central subject of which is to be the Saviour on the Cross. The Rev. J. R. Jones, who made the application, explained that the window—which would cost from 300l. to 400l.—was being erected by Mr. Mess Horsfall in memory of his great grandfather, the Rev. Thomas Moss, who was forty-seven years vicar of the parish, and who died and was buried in the district 100 years ago.

An application by the Ven. Archdeacon Clarke for a faculty to insert in one of the side windows of Christ Church, Southport, a stained-glass window, with the subject, Christ, the Good Shepherd, in memory of the late Mr. Pearman—once curate of the church, but who died last October—was granted.

PARTNERSHIPS.—Mr. W. J. Gant, architect, Hastings, has taken into partnership Mr. C. H. Slatton, of Nottingham. The style of the firm will be "Gant & Slatton." Mr. John H. Fraser (late in partnership with his brother, Mr. G. C. Fraser, as Fraser & Fraser, at Bromley-by-Bow), has now, we understand, taken works at Millwall, which are being fitted with the newest machinery and plant for the production of boilers, bridges, tanks, &c. He has taken into partnership his son, Mr. Harry J. Fraser, who has a practical knowledge of the trade, and the firm will be known as John Fraser & Son.

FAILURES IN THE BUILDING TRADES.—According to Kemp's Mercantile Gazette, the number of failures in the building and timber trades gazetted in England and Wales during the week ending September 20 was only seven, as compared with 13 in the corresponding week of 1889, and 10 in the corresponding week of 1888.

MEETINGS.

SATURDAY, SEPTEMBER 27. Association of Public Sanitary Inspectors of Great Britain.—Visit to the Crematorium at Woking. Train from Waterloo Station at 2.17 p.m.

THURSDAY, OCTOBER 2. University College.—Professor Roger Smith on "The Technical Education of Architects." 7.30 p.m.

FRIDAY, OCTOBER 3. Sanitary Institute (Lectures for Sanitary Officers).—Sir Douglas Galton on "Ventilation, Warming, and Lighting." 8 p.m.

RECENT PATENTS:

ABSTRACTS OF SPECIFICATIONS.

15,713.—VENTILATING ROOFS, &c. T. W. Hollisell.—The object of this invention is to ventilate roof structures in such a manner that, whilst allowing for the entrance and egress of atmospheric air, snow, rain, &c. is prevented from entering. This is claimed to be effected by curving the strips inwardly, and by the use of louvres also curved, so as to overlap each other, keeping out the rain but admitting air.

13,565.—ROUGH-GLAZED AND COLOURED FACINGS.—E. Bond.—According to this invention, the facings-stones are made under pressure in moulds. The stones are rubbed with a scraper, and, where necessary, are coloured with a weather-resisting mixture or facing. Glazing is applied in a manner similar to the water-glass process.

3,827.—GUARD OR SHIELD FOR PAINT-BRUSHES. J. E. Pepper.—By this patent a guard or shield is fitted to the brush. This guard is of tubular shape, with one end closed, and is screwed into the handle of each brush, the open end enclosing the brush so as to have only as much of it projecting as may be required. As the brush wears by use the shield is screwed up the shaft, so as to leave sufficient protection for the brush. The guard or shield may also be enlarged by making a flange on the closed end, which will give it sufficient buoyancy to float in the water.

4,290.—MORTISING MACHINES. T. R. Lees.—The machines which are the subject of this patent have a revolving shaft and a combination of adjustable levers and balance-weight, giving a variable and reciprocating motion to the chisel operating upon the lever.

4,995.—WOOD-BLOCK FLOORING. C. J. Longley.—According to this invention, a tapered groove runs along the side of the blocks to receive the tapered ends of the blocks of the blocks. The upper portions of the blocks are cut square, but the lower portions are a little longer at each end to fit the grooves referred to.

5,878.—WATER-CLOSETS. W. Macenacova.—This invention consists of a box of ancient size to enable a person to sit comfortably, and so constructed as to swing outwards through a frame in the back wall of the closet over the pan when in use, and inwards so as to expose the pan to the air. The inward movement causes a flushing of the closet, and the outward the refilling of a cistern. The door of the closet cannot be opened until the box is drawn inward.

NEW APPLICATIONS FOR PATENTS.

September 8.—14,071, W. Sanday, Hand-planing and Surfacing Apparatus for Wood, &c.  
September 9.—14,139, E. Eadie and J. Tannahill, Joints or Connections for Pipes, &c.—14,129, E. Wilford, Unions or Couplings for Pipes.—14,139, J. Taylor and others,

Fireplaces or Grates.—14,143, P. Koch, Planing-machines.—14,159, J. Macdonald, Ventilating Sash-bars or Astragals.—14,192, J. R. R. Circular Saws.—14,181, J. Sears, Ventilators.—14,188, H. Balban, Pipe Couplings.—14,201, R. Grimaldi, Moulds for the Production of Cast Iron Castings of any Design or Size.  
September 10.—14,218, J. Adams, Door-springs.—14,224, E. Osborne, Paved Streets or Roads.—14,226, J. Bullen and E. Cocks, Raising, Lowering, and Balancing Machinery for Buildings.—14,262, J. Sears, Ventilators.—14,271, C. Reynolds, Door-hanger.  
September 11.—14,289, F. Smith, Ventilating.—14,294, E. Eden and W. Day, Glaziers' Spring-cutters.—14,299, W. Morrison, Wall Ventilators.—14,312, J. Gibbins, Automatic Door-fastening.—14,325.—W. Laycock, Window-lifts and Draught-excluders.—14,328, H. Bonnycastle and T. Rymer-Jones, Refractory and Non-conducting Bricks, Blocks, Tiles, &c.—14,345, E. Oroyd, Warming and Ventilating Hospital Wards, &c.—14,351, J. Bass, Securing Door-handles to their Spindles.—14,353, L. Fargue, Stained or Ceramic Transparent Glass Windows.—14,362, A. Hogan, Machine for Cutting Laths.  
September 12.—14,398, C. Forell, Manufacturing from Roman Cement a Composition similar to Portland Cement.—14,406, J. Jones, Ventilation of Drains.  
September 13.—14,437, K. McKenzie and G. Anderson, Chimney-tops.—14,439, J. and T. Clemenson, Portland Cement, &c.—14,460, E. Edwards, Electric Bells.

PROVISIONAL SPECIFICATIONS ACCEPTED.  
7,342, W. Cox, Ventilators.—11,771, W. Morrison, Door-closing Apparatus.—11,803, S. and J. Filton, Windows.—12,753, E. Urry and G. Farini, Closing of Doors.—13,279, E. Hindle, Drain-pipes.—13,306, G. Farini, Spring-door Hinges.—13,330, A. Cassin, Securing Knobs or Handles to Door-locks, Latches, Door-knob Boxes, &c.—13,399, J. Wilson, Stench-traps.—13,438, C. UNCONTINGENT IMPROVEMENTS AT GOOLE.—At an adjourned meeting of the Local Board at Goole on the 9th inst., Mr. H. B. Thorp presiding, an important report of the Surveyor (Mr. E. C. B. Tudor) was taken into consideration. It was in reference to the expenditure of between 3,000l. and 4,000l. in street improvements, &c., which have been rendered necessary by the growth of the town. The consideration of the matter was adjourned to allow of time for a reply from the Local Government Board as to the conditions of a loan for defraying the cost of the improvement.

### The Sharqi Architecture of Jaunpür.

A finely illustrated volume issued under this title\* forms the first of a new series of reports, begun after the reorganisation of the Archaeological Survey in Upper India in 1885; and if the work is to be continued on the same scale and with the same thoroughness of illustration, we may look to see at last something like an adequate illustration of a considerable portion at least of the immense and multifarious architectural remains of the Indian Peninsula. This volume, with its seventy-four plates, illustrates a small section of this vast object, the architecture of one period of a limited district, which occupies only a chapter of half-a-dozen pages in Fergusson's great work on Indian architecture. According to Dr. Burgess's preface, the former class of archaeological reports consisted "chiefly of cursory notes on places visited on a flying tour, with rough drawings and photographs of the more notable buildings and sculptures met with, and speculations on matters on which the surveyor did not possess the materials for anything better than a mere hypothesis more curious than scientific"; and the result of this hasty though well-intended work has been that while Dr. Burgess had hoped to utilise much of the material in the shape of drawings executed on surveys previous to 1885, it was found that those drawings, though well-executed, were exceedingly inaccurate as to details, which had not been conscientiously measured or drawn with the requisite care, and it was necessary to re-measure and re-draw the whole of the monuments. The object under the new system has been, we are told, to avoid speculative criticism as to history or style, and to make it the main object to give the ascertainable facts correctly in illustration. The illustrative work has been carried out, for

the district under consideration, by Mr. E. W. Smith, in a manner which fully proves his ability and capacity for taking pains. The illustrations have been reproduced at the Survey of India Office in Calcutta, mainly from measured drawings, and in part from photographs, and form a very fine collection of architectural illustrations. Dr. Führer has contributed a short history of the district and of the dynasty of the Mahomedan kings under whom these buildings were carried out.

Anglo-Indian writers are not prone to trouble themselves much about the fact that names and expressions which are familiar to them are as Hebrew to the majority of readers in England; and it is not very easy for the English reader to extract the historical facts from pages bristling with unfamiliar and uncouth-looking words; but we gather that the epithet "Sharqi" applied to the class of monuments treated of here was a kind of dynastic title or affix of the kings who ruled the province, commencing with one Khwaja Jahán, the first independent prince of Jaunpür, and who received the title of "Malik-as-Sharq," the affix of "Sharq" or "Sharqi" reappearing in connexion with the names of sundry of his successors. The architecture produced under these rulers, therefore, is Sharqi architecture in pretty much the same sense that the architecture produced in England under the four Georges is called Georgian architecture.

A map of the district dealt with would have been a convenient addition to the volume, and we may suggest that this should form a feature in future volumes of the archaeological survey. Jaunpür is near the centre of the northern portion of the peninsula, about fifty or sixty miles in a north-westerly direction from Benares, and situated on the river Gómti, a tributary of the Ganges. One of its finest monuments is a grand stone bridge, a view of which, reproduced from a photograph, forms the frontispiece to the volume. This however, is a later work than the monuments which form the main subject of the volume, having been built in 1564-8, under the rule of Akbar, who made Jaunpür and Chunár alternately his headquarters, and by the governor appointed under him, Munim Khán; and therefore does not properly come under the subject of Sharqi architecture. There is an interesting story related as to the origin of this bridge, to the effect that Akbar, who

was fond of water excursions, heard one evening a poor woman lamenting that she could not get ferried across; whereupon he took her across, but subsequently remarked to Munim Khán on the advantage of building a bridge there, and spoke rather contemptuously of the former kings for their preference for building mosques rather than such useful works as bridges. There is a trait of the practical-minded soldier about this which rather reminds one of Napoleon. The advice seems to have been acted on with the readiness which might have been expected from a subordinate governor. The bridge has massive piers, and arches of the peculiar pointed shape characteristic of Saracenic architecture, sharply curved at the springing and nearly straight-lined above, and is decorated with four kiosks, two on each of the pieces flanking the centre arch.

The masjids, which form the most important architectural remains of Jaunpür during the period of the Sharqi rulers, present some architectural characteristics peculiar to themselves. The three special peculiarities are the use of a propylon entrance façade with a large dome immediately in the rear of it; the frequent use of outward slope or batter to the walls; and the combination of Saracenic general idea and style with some Hindú details. The most notable point is the propylon façade to the principal entrances, masking or partially masking a dome in the rear of it. The section through the north gateway of the Atala Masjid, of which we give a reduced reproduction from one of the plates in the book (fig. 1), gives an idea of the combination of dome and propylon, and shows the sloping sides and very Egyptian-like character of the latter. The general arrangement of the front elevation is such as we have indicated in the small sketch (fig. 2), consisting, as will be seen, of a square tower on each side with a screen wall under an arch between the two, and connected together by a horizontal cornice at the crown. In some instances, however, the angle towers rise a few feet above the cornice level and thus assert themselves more distinctly as towers, but always retaining the same arrangement below of a more or less ornamental screen-wall between the towers. The section given in fig. 1, however, though it shows the usual relative proportions of dome and propylon, does not represent the arrangement in the case of the principal

\* "The Sharqi Architecture of Jaunpür"; with notes on Zafarabad, Sahet-Mahet and other places in the north-western provinces and Oudh. By A. Führer, M.B., of the Archaeological Survey. With drawings and architectural descriptions by E. W. Smith, architectural assistant. Edited by Jas. Burgess, LL.D., C.I.E. (General editor of the Archaeological Survey of India.) London: Thacker, Spink, & Co.; Bombay: Thacker & Co.; London: Trueman & Co., and W. H. Allen & Co. 1883.

dome and centre propylon of the principal façade, as in this case the dome is always jammed close up against the rear of the propylon. If the reader imagines the intermediate portion between the propylon and the dome in fig. 1 removed, the propylon pushed back on to the dome, and the scale enlarged about one-third, it will then represent the proportionate arrangement of the principal dome and propylon in the same building and in others of its class. This rather peculiar and (we may add) very clumsy architectural combination, a large dome with a gate façade immediately against it which almost hides it from view externally, is the occasion of some speculation in the notes on the plates, in spite of what we are told in the preface as to the wholesome regulation forbidding the members of the Archeological Survey to "speculate." As the book is, "like Cerberus, three gentlemen at once," we do not know clearly to which of the three authors we are to credit the passage in question:—

"The special characteristic of the Jaunpūr style is the lofty propylon with sloping walls hiding a single dome, and it would be well to have some idea of the cause which led at this place to the adoption of this plan, so original, so quickly perfected and hardly imitated elsewhere.\* Did we know, as we never can hope to know, which was called forth first, the dome or the propylon, we should be able to guess the object each was to answer. For while the dome is undoubtedly the most imposing covering for a single chamber, it seems, at least when seen from without, to overpower a room whose walls are not proportionately lofty, and it is hard to fancy how the effect of any building could be pleasing

Fig. 2.

when a dome covered the centre of a simple oblong. If, for the sake of an imposing internal roof to a central chamber, the founder wished to build a dome, and if with his desire to utilise material existing in abundance at hand, he was somewhat cramped in his choice of the height of his building, no great ingenuity would be wanted to make him think of proportionally elevating the central portion of his façade, turning his minarets, if he had planned any, into abutments, and filling the intervening arch with a rich screen which should conceal the dome. This seems the true theory. For the idea of the dome must surely have come first. The bold façade standing alone can have been satisfactory only when viewed directly in front; from every other point it would have seemed purposeless, from behind worse than purposeless. Yet, though it had been possible to view it only in the most advantageous way, from the direct front, few would dream of building a façade 75 ft. high and only 55 ft. wide at the base. And so we would claim for the Pāthan architects of Jaunpūr the honour of being the first in India to make domes and their adjuncts an imposing part of a range of buildings."

We have given this passage in full as the critical opinion of one of the producers of the book in regard to a peculiar point in the architecture illustrated; at the same time we think it presents a remarkable confirmation of the wisdom of the Indian Surveys Department in forbidding surveyors to "speculate." The result of this piece of speculation is the discovery of a kind of architectural mare's nest, a new combination in regard to which we only require to know whether the dome or the propylon came first, which, says the writer, "we never can know," though a few lines further down he says that the dome "must surely have come first." If he had considered what the plan has to tell him, he might have spared his con-

\* Fergusson gives a rather different impression: observing, "the peculiarities of this style are by no means confined to the capital. They prevail at Gazepore, and as far north as Canouga, while at Benares the examples are frequent."—*Indian and Eastern Architecture*, p. 525.

Fig. 1.—Section through North Gateway, Atala Masjid.

Fig. 3.—Plan of Atala Masjid, Jaunpūr.

jectures, and we should have missed the above-quoted eloquent but hardly convincing passage. True that "few would dream of building a façade 75 ft. high and 55 ft. wide at the base," but the propylon is not a façade in the usual sense, it is a central feature to give dignity to the entrances, a grand gateway in fact. Take the reduced plan of the Atala Masjid (fig. 3); the pylons occur with about the same projection on each façade; where there is no dome, or only a small inner one, opposite the entrance, the dome and propylon do not interfere. On the west side, where it is desired to have a grand central apartment, the dome fills the whole width of the building, and consequently must abut against the propylon. There need be no question of which arose first; the

propylon was the accepted form of gate, the dome the accepted manner of roofing an important apartment; and when the argument to be domed occupied the whole of the plan, it had to be got in as he could, crowding up on the propylon. True that in the Jāmi Masjid the small domes are crowded against the propylon well as the larger ones. But this was hundred years later, and only shows that this as in other cases in architectural history a feature first brought about by accident necessity got repeated and adopted by law. But the origin of it was only a "fluke." Two features have no architectural relation each other, and are merely the result of makeshift. The fine writing about it is therefore all thrown away.

Fig. 4.—Principal doorway, Jami Masjid.

Fig. 5.—Screen-work, Atala Masjid.

Fig. 6.—Masons' Marks, Atala Masjid.

tion on the Lal Darwaza Masjid, "Visadru's son Kamañ, the architect," which seems to settle the matter as to that building at any rate, and suggests every probability of the same cause producing the same result in other cases. The doorway of the central entrance to the Mosque, Jami Masjid\* (fig. 4) is a curious mixture of Saracenic general feeling in the enrichments (though with an admixture of floral forms a little at variance with the pure faith) and Hindû detail in the pilasters and brackets. In some places the Saracenic pointed arch is found, foliated with growths of conventionalised lotus flowers; and in the pierced screen from the Atala Masjid (fig. 5) we see the mingling of Saracenic geometrical tracery with the flower-like ornaments beloved by the Hindû artist, especially in the delicate work in the lower range of ornament below the transverse bar. Among the large and interesting collection of masons' marks from Jaunpur, which fill two plates of the book, we find the same mixture of geometric with more flowing and flower-like designs. We give (fig. 6) a small selection from these. One of them, it will be observed, is a purely natural leaf spray, two others are rude imitations of birds. Neither of these can be supposed to have been used by Saracenic masons.

Nothing perhaps is more striking in this group of buildings than the bold treatment of the outer walls of the Jami Masjid, of which a photograph of one angle is given (plate xlv.). The solid mass of the walls, thickening from the top to the bottom, relieved by occasional lines of delicate surface ornament and a very effective plinth moulding, and strengthened at the angles by the circular turrets also increased in diameter towards the base, combine in a remarkable degree an appearance of fortress-like strength with refined architectural expression. All the details of these buildings, except the diaper or superficial ornament, are however more or less clumsy and barbaric; such details as capitals and columns; and as to mouldings, they do not seem to exist, in our sense of the word; nothing but square sinkings; an infallible mark of architectural incompleteness of style and genius. Among the other buildings illustrated the Lal Darwaza Masjid has considerable interest. It is described as constructed with stone and brick with cement, but principally of stone; externally as well as internally all the walls are of ashlar masonry neatly tooled with fine joints which are so beautifully worked that they hardly exceed a knife-blade in thickness. The writer sarcastically remarks that "churchwardens are the same all the world over," and that the stonework of part of the interior was not long ago treated to a coat of whitewash. He adds another caution which we hope will be attended to in future. Portions of the building, which is in a very dilapidated state, have been repaired, "but in such had form that one almost wishes such restoration had not been attempted. Such work should clearly be conducted only by officers who have received a special training in architecture." Verily; but how many are there of such in the service? It is curious to observe that in reference to this building we are told that "from the evidence of the stones lying about, which have fallen in the lapse of time, it is evident that the stones of this, like all the other masjids of Jaunpur, had been before used in Hindû or Buddhist buildings." We do not know whether the writer of these words is the same who says elsewhere in the volume that the Hindû element in the buildings is the result of the employment of Hindû workmen who were converts to Mahomedanism; but at any rate the two statements are quite contradictory.

The literary part of the volume, in fact, except the historical sketch, is the least valuable; and in future volumes it would be

\* This, it should be explained, is the building hitherto known to students of architecture as the Jumma Masjid. In five years there will probably be another way of spelling it invented. Even in this book it is given in some places "Jami Masjid" and in others "Jami Masjid."

The resemblance of the plan of the surrounding colonnades to Hindû architecture, and the fact that no arches are employed, led Fergusson to half suspect at one time that this was a Buddhist monastery, with the domes and gatepieces inserted by the Mahomedan conqueror; an opinion positively entertained by some other less learned theorists. Fergusson was led on consideration to relinquish this idea, and to

come to the conclusion that at all events the majority of the trabecated architecture in this and other mosques had been made at the time it was required for the places it now occupies. His suggestion that much of it was executed by Hindû converts to Mahomedanism, who could not shake off their old style and manner of working, receives additional confirmation in the present volume, especially in the inscrip-

better to cut the remarks down to the statement of actual facts, and leave theorising out of the question. But the collection of illustrations is of the highest value, and as we presume that the volume, though an official publication, can be purchased through the London publishers named on the title-page, we may recommend it to the attention of all students of architecture as a book worth possessing, containing some of the best illustrations of Indian architecture that have yet appeared. It is to be hoped that similar volumes, illustrating other branches of the architectural remains of India, will appear in due course.

#### THE NORTHERN EXTENSION OF THE METROPOLITAN RAILWAY.

**T**HE extension of the Metropolitan Railway into the country is an interesting piece of railway enterprise. Speaking generally, the period of railway expansion in England has come to an end. The most important works of the present day consist rather in improvements of existing systems than in new and large enterprises. The Forth Bridge and the Severn Tunnel, for example, are simply, though very important works in themselves, improvements in railway systems which are already in existence. But the expansion of the Metropolitan Railway is not a mere improvement, it is the creation of a new system which will add another northern trunk line to the English railway system. When this new work is completed, it will always be regarded as a signal instance of what can be done by a railway magnate whose diplomatic powers are only equalled by his perseverance. The records of many half-yearly meetings of the Metropolitan Railway Company can be produced to show how Sir Edward Watkin, while in his own mind he had fully matured a large scheme of railway extension, was able to persuade his shareholders that he was only going to construct a few miles of line to the north of London for the purpose of feeding the metropolitan line within the metropolis. Now, however, the northern extension has for some time been opened to Chesham, and steady work is in progress on the portion of the system between Chalfont Junction (where the Chesham branch leaves the main line) and Aylesbury. At Aylesbury the Metropolitan unites with that miserable straggling, the Aylesbury and Buckingham railway. There are also intentions of uniting Oxford and London by this line. At the present time, therefore, it is an interesting trip to drive from Rickmansworth to Aylesbury, to see what manner of country it is through which the new line will pass, and to attempt to estimate the probabilities of the future. We take our start, then, from Rickmansworth, where at present the new line does not appear to have produced any kind of development. This is not surprising, for that little town—if town it can be called—which to George Elliot was a kind of permanent curiosity on account of its many public-houses, is handicapped by its situation. On the one side it is shut in by water-meadows which prevent its expansion, and on the other by Rickmansworth Park. It is equally clear, also, that the train service is not yet sufficiently quick to enable Rickmansworth to be the habitation of the clerk class. An excellent road starts from the Metropolitan station along the western brow of a valley of considerable beauty, through which the river Chess may be seen winding down to join the Colne. For a couple of miles Charleywood Common is skirted, where there is a station in a deep bottom, approached by dangerous roads. A few very good houses border the side of the high road, but, practically, the place is yet free from the builder. It is equally clear, however, that Charleywood has, from a speculative builder's point of view, should property come into the market,—large future possibilities. But, on the other hand, it is equally clear that a considerable sum must be spent on making one

or more roads across the common. We very soon come in sight of Chenies,—which it is well for the tourist, if we may call him so, to rest at awhile. There is not a more picturesque spot in England, and the church contains the chapel of the Russells, where most of that memorable family are buried. It is fortunate that it has had its story told by so great a literary master as Mr. Froude, since no inferior writer will be well advised to attempt to say again what he has told us in his essay on "Chenies and the House of Russell." All that we shall remark here is that the chapel is no longer open as of old to any passing person, and that orders to view the monuments must now be obtained from the Bedford Estate Office in London.

Leaving Chenies, the road presently is crossed by the railway, which is now on our right hand. Chalfont-road station is perceived, and almost a mile beyond the Chesham line branches to the right, and the main line bears away to the left towards Amersham and the Misbourne Valley. It keeps along the eastern side of this valley, the station at Amersham being a little distance from this quiet old place. Amersham has an old-world look. It is not difficult to recall the times when Waller, two centuries ago, represented it in Parliament. It is one of those long, broad streets, with an old gable here and a bit of sober red brick there, which take us back into the end of the last century, into the age of stage-coaches. The fine woodlands which thickly clothe the large parts of the valley heights are much more noticeable here, more especially opposite Shardloe, where the railway passes on the verge of Pipers Wood, to which Cobbett, in his "Rural Rides," gives a passing word. The scenery is now somewhat marred by the enormous and unsightly embankment, which will carry the line over the grassy dip at the bottom of this wood. But in due time some of the beauty of the place may be regained by judicious planting, though the converging lines of wood and grass cannot be regained. The line begins to approach nearer to the road, and there are already signs up a lane of what some day will be Little Missenden Station. Before Great Missenden is reached, the line crosses the road, and takes the left or eastern side of the valley. It is in reality, however, running here almost in the bottom of the valley; here the line is in quite an elemental stage. Where it crosses the road the pier of the bridge is erected, but the concrete foundations of the other side are only being laid, and the line itself is nothing more than pieces of unjoined embankments. As we proceed along the road opposite to Missenden Abbey there is nothing to be seen of the line: it is lost behind the houses of Great Missenden, a village in character absolutely similar to Amersham, but distinctly less picturesque. Just at the upper end of the village a conspicuous sign-post informs us that we are still nine miles from Aylesbury, and that the road to the left will bring us in three miles to Hampten. About a hundred yards up this latter road the railway is again observed, but up the broad bit of valley beyond its future track is only marked by the wire fencing which indicates the land which will be taken for the purpose of the line. The wooded summits of the Chilterns around Hampten tempt us for a while from the direct route, and we are able, by a visit to Hampten Church and House, to picture to ourselves the country in which the patriot lived and died. It is as quiet and undisturbed a bit of England as can be found throughout the land, and no one who would clothe the dry bones of history with personal and local interest should neglect to visit Hampten's home.

We regain the bifurcation of these roads in due time, and trot onward to Wendover. The imperceptible rise of the valley has now brought us to the verge of the Chilterns, and on either side headlands of smooth grass rise and protrude into the vale beyond. We feel that almost insensibly we have reached the climax of the valley, which begins to rise from Uxbridge, and this is more apparent when the houses of Wendover are perceived

nested on the hill side below us. The railway will here have to pass through a cutting and as we get beyond the little town the white chalk embankment which will carry it into the vale of Aylesbury pushes its unfinished length into the great vale plain, like a long quay into the sea. It is the last we see of the railway, for we proceed by a gentle and well executed descent more into the valley. A conspicuous house on the right reminds us we are now in the land of Rothschilds, for it is Mr. Alfred de Rothschild's country-house, at Hulton, which stands just on the edge of the plain. If it were clear we should see Waddesdon Manor, in the direction of Bicester and Thame, the chateau of Baron Ferdinand, and most of us have travelled enough on the London and North-Western line to know that the great house of Mentmore lies some ten miles to our right, beyond the wide green pastures, over which the evening haze is hanging.

We have driven some twenty-two miles, and that is sufficient for the day. The county through which we have passed has many charms; it is naturally picturesque, it is as quiet as any part of England, and it has an air of the past about its villages and its secluded homesteads. It is clear that it is a district thoroughly in need of a railway for purposes of convenience,—of that there cannot be a possibility of doubt; but it is equally clear that it is a very naked land from the traffic manager's point of view. By no possibility can either the passenger or the goods traffic be large, and as soon as the line touches Aylesbury, it enters into competition with the two great systems, the London and North-Western and the Great-Western. It lies between these two: will it bear the squeeze of these two flourishing lines? The North-Western Company has already built a new station at Aylesbury, and will be able, it is obvious, to carry goods to or from Aylesbury at less cost than the new and struggling line. New and struggling it must be, for it is a line which only manages to pay three per cent. on its present capital, and to compete as a long-distance line much capital has yet to be expended. Baker-street Station must be converted into a large and roomy terminus, at a great expenditure of money. The line from Harrow to Baker-street must be doubled also, at a large cost, and considerable masses of new rolling-stock must be procured. Sir Edward Watkin's policy in "getting over" his shareholders was clever, but it may be doubted whether a bolder and franker line would not have really been best for the interests of the Company. To make a trunk line without a terminus must hamper its development for a long time, without any corresponding advantage. The line will be a useful and important one for a part of Buckinghamshire, a very poor agricultural county, but one well suited in the future for residential purposes, not too far from London to become thickly populated. But it requires a sanguine mind to believe in the extension being a financial success, so far, at least, as regards the portion of it from Rickmansworth to Buckingham. A poor but picturesque agricultural county is not likely, in this generation, to feed a new line richly, nor can the fine pastures and hayfields between Aylesbury and Buckingham, served as they will be by these lines, be considered a hopeful district.

**BATH.**—In reference to the Bath School Board competition, several architects of Bath have forwarded a letter to the Bath School Board calling attention to certain conditions which are now recognised in the profession for conducting public competitions. 1st, That the architect whose plan is selected shall be employed to carry out the work at the usual charges. 2nd, That certain premiums shall be offered to two or three at least of the unsuccessful competitors. 3rd, That a qualified professional assessor be appointed to adjudicate on the plans, and his award to be final. 4th, That the plans not adopted shall be returned to their authors. The letter was considered in a very respectful manner at the School Board meeting, and further procedure in the matter was adjourned for the fuller consideration of the suggestions comprised in the communication.

## NOTES.

**PRACTICAL** demonstration of the process of cremation as applied to the destruction of animal remains was witnessed at the Crematorium at St. John's, Woking, on Saturday afternoon last, by the Association of Public Sanitary Inspectors of Great Britain, on the invitation of Mr. J. C. Swinburne-Hanham, the Honorary Secretary of the Cremation Society of England. About eighty members of the Association were present, and they were accompanied by Sir Spencer Wells, Dr. Richardson, Captain James, Mr. Swinburne-Hanham, Dr. Tripe, Mr. Perry F. Nurse, Mr. Hugh Alexander, and other gentlemen well known in medical, sanitary, and engineering circles. The body of a ram was cremated on this occasion. The weight of the carcase was stated to be about 200 lb., and the time occupied in the operation was an hour and a half,—this being thirty or forty minutes more than are required for the cremation of an adult human body. The explanation of this delay was, firstly, that the carcase of the ram was considerably heavier than the corpse of an average adult; and, secondly, that the process of combustion was considerably retarded by the fact that nearly all of the eighty or ninety visitors availed themselves of the opportunities afforded by the eight or ten "peep-holes" in the sides of the furnace to watch the process of combustion, which was consequently delayed by the influx of cold air at the apertures in question. In the case of the cremation of a human body, this delay could not take place, as it is the regulation that only one person representative of the family of the deceased can be admitted to the cremation-chamber, and, as a rule, only the furnace-man would use the "peep-holes," and only towards the end of the period usually required for the operation, as the representative of the deceased would usually be content with viewing the body deposited in the furnace and waiting until the ashes, in the form chiefly of calcined bone, were withdrawn at the conclusion of the operation. Saturday's demonstration was regarded by all the visitors as completely successful. There was nothing repulsive about it, and no effluvia of any kind were given off. On previous occasions we have sufficiently described the construction of crematoria. The two at Woking are on the Gorini system. We say "the two," because in addition to the one used for the demonstration on Saturday last, the Duke of Bedford has had a crematorium built for himself closely adjoining, and it is possible that a cluster of four, five, or six will ultimately be built,—all of them, it should be mentioned, being served by one chimney-shaft. At the base of the shaft with which the two crematoria are already connected is a purifying muffle-furnace kept at a very high temperature, through which the gases from the furnaces are made to pass so as to eliminate from them all noxious effluvia before they escape into the atmosphere. The buildings at Woking include a funeral chapel, and a waiting-room for mourners. While the cremation of the ram was in progress, a few speeches were made in the chapel, Sir Spencer Wells expressing his regret at the absence of Sir Henry Thompson, the President of the Cremation Society of England, Dr. Richardson and Captain James (Chairman of the Sanitary Committee of the London County Council) both expressed it as their decided opinion that for large towns cremation was becoming every day more and more necessary on sanitary grounds. Captain James especially referred to the dreadfully overcrowded condition of many of the London cemeteries,—some of them now completely surrounded by densely-populated neighbourhoods. Mr. Hanham stated that cremation seemed now to be making rapid progress in popularity. The Crematorium at Woking had been established thirteen years, but, although up to the end of last year only 100 human bodies had been cremated, this year,

so far as it had gone, thirty-eight human bodies had been cremated there; and crematoria were being erected, or were projected, in such important centres of population as Leicester, Glasgow, and Manchester.

**THE** correspondence in the *Times* on the shortcomings of railway companies is still going on, numerous complaints having been lodged; while some of the letters have been of quite a different tenour, and if written in respect of any other business, might have proved invaluable as testimonials. To our mind, however, the most formidable of the many indictments falls into insignificance in the face of a letter which appeared in the *Globe* of the 1st inst. It is dated from the Temple, and the writer states that he travelled from Gloucester by the Great Western Railway on Monday, and that shortly after leaving Swindon it became apparent that something was seriously wrong with the carriage in which he was seated. He thereupon pulled the communication-cord right into the window, but without any result. After jolting along in a most alarming manner for two or three miles, the train was stopped,—but only through the driver of a train going in the opposite direction calling attention to the mishap by whistling,—when it was found that an axle was broken and the carriage was off the metals. The writer examined the cord, and found that on the driver's side a large knot prevented it from passing over the pulley-wheels, while on the other side it had broken! This certainly appears a most scandalous case, and it is quite clear that the communication-cords are often worse than useless. The law is evidently inefficient in simply compelling the companies to provide means of communication, unless it can enforce their being kept in working order.

**THE** practice of the Great Eastern Railway Company of issuing packets of tickets, available for a week, should be followed by all other Companies. But the tickets should not be confined to third class only, and there is no reason why the tickets should be used within a week from the day on which the packet was issued. More especially should this system be taken up by the Underground Railway Companies. A decorator at Kensington may have a piece of work at Bayswater, which will require his attention for a week. It would be a great convenience if he could take a packet of tickets which would enable him to travel backwards and forwards for one week without having daily to take fresh tickets. The issue of such packets at a small reduction is not only a convenience to passengers, it also increases the traffic of the line, and eases the press of work at the booking-offices. The astonishing thing is that this and many other small improvements have not been long ago taken in hand by the Metropolitan and District Companies, who can never compete effectually against the Omnibus Companies unless they attend to many details which are now unheeded.

**IF** the movement against "tied" public-houses becomes general, it is likely to have some important consequences in regard to the value of house property. For it is obvious that if magistrates refuse licences to the tenants of "tied" public-houses, who are notoriously simply the servants of the brewers, it will be necessary for the brewers to put a good deal of house property in the market. It is too soon yet to be able with certainty to assume that the movement will be general, but there is every appearance of its becoming so, and it is certain that the licensing laws intended that the licensee of a public-house should be the responsible tenant of the house. If the property is put in the market, it is clear that a good deal of it will be depreciated in value, and that many new or proposed buildings, which speculators are hoping may be taken up as public-houses, will not find buyers,

as there will be so much public-house property in the market. It is equally clear, also, that as the ordinary licensee can in many cases not take up a public-house from lack of funds, an impetus will be given to the operations of loan companies and similar institutions, who will have to lend the money to the would-be tenant in order to enable him to buy or fit up the house.

**THE** latest number of the American "Journal of Archaeology" (vol. vi, Nos. 1 and 2), has a good article by Mr. George B. Hussey, of the American School of Classical Studies at Athens, on a subject of considerable interest. Everyone knows the custom that prevailed in antiquity of rewarding public benefactors with a crown, and most people are aware that it was also the custom at certain periods to reproduce these crowns on the grave-reliefs and on monuments connected with the recipients. No systematic treatise on the subject of these crowns has appeared since Paschalius, of Leyden (A.D. 1625) wrote his pamphlet "de Coronis." Mr. Hussey's monograph is illustrated by two plates, showing the various shapes, positions, and inscriptions of these honorary crowns at different dates. We can only state here his main conclusions:—1. In regard to form, it has been shown that the *pendent* crown only belongs to the better periods of Greek art, the *erect* crown, on stone monuments at least, appears first in the time of Trajan or Hadrian. A peculiar ray-like arrangement of leaves is found to indicate a crown of gold. 2. As regards inscriptions, these consist of one, two, or even three terms, placed regularly in the order of giver, cause of the gift, and recipient. A tendency to enlarge and crowd the letters is noticed in the later reliefs. Instances where some of the terms are found outside the crown belong mostly to the second or first century before our era. 3. In the arrangement of crowns on the monuments two positions—extreme left hand or middle—are found to give special emphasis to the crowns so placed.

**I**n a letter to the *Times* Mr. Poynter draws attention to the slow but sure destruction of the remains of Karnac, owing to the eating away of the bases of the great columns by the mineral salts in the soil. He mentions Marris's opinion that if left to itself, the entire ruin of the temple must be only a question of time. Surely some efficient measures should be taken, without further delay, towards the preservation of all the remains still left of this wonderful monument of the most ancient known architectural style of the world.

**I**n the present number we publish reproductions of two fine sepia drawings by Mr. A. Graham showing the existing remains of the Roman arch at Timgad in Algeria, and his restoration of the arch based on those remains. The latter drawing, showing the restoration of the arch, was exhibited in the Royal Academy architectural room this year. In commenting upon it, we expressed surprise that a restoration should have been shown without any drawing of the actual remains on which the restoration was based. It appears that Mr. Graham did send such a drawing, which we have the pleasure of publishing this week, but that the wisdom of the Hanging Committee of the Academy rejected it! This is a new example of the utterly careless and incompetent manner in which the hanging of architectural drawings at the Academy appears to be carried out. An R.A. architect is generally *nominally* responsible for the hanging of this class of exhibits; how much does he really see to it? In a French exhibition it would be considered the height of absurdity to hang a restoration of an ancient building without a drawing of the "état actuel," and if we consider what some few of the drawings were like which were hung, the refusal of this necessary complement to the Timgad restoration drawing, in the shape of a really good and artistic drawing of the actual remains, becomes the more absurd.

WE are glad to receive from Mr. Batsford, the well-known architectural publisher, an announcement of the appearance shortly of the illustrated work which Mr. J. A. Gutch has for some time had in preparation on "The Architecture of the Renaissance in England." The work will be issued in parts at intervals of two or three months, the first part being promised during the present month. All architectural students will look forward with interest to the appearance of a work on so fascinating a subject, by an architect who combines the artistic with the literary faculty in no ordinary degree. Mr. Gutch is assisted in the work by Mr. W. Talbot Brown, A.R.I.B.A. The book will illustrate such essentially English buildings as Hardwick Hall, Hatfield, Kirby, Burchley, Cobham, Blickling, and many others of lesser note. The larger illustrations will be produced by the phototype process, and will comprise general views of the buildings both exterior and interior, with special features to a larger scale, and the text will be interspersed with about a hundred small sketches of other interesting features, such as balustrades, dormer windows, corbels, bosses, &c.

THE project to commemorate, next year, the hundredth anniversary of John Wesley's death (March 2, 1791), has assumed a definite shape. It is proposed to convert his house, near to the Chapel in the City-road, into a museum of relics and curiosities relating to the history of Methodism, to restore the chapel, repair the burial-ground, and to erect a new monument to Wesley there. Wesley laid the foundation stone of the chapel, on a parcel of ground leased by the Corporation, near Bunhill-fields, in 1777; he occupied the house close by, and was buried in an adjoining vault, which he had prepared for himself and for itinerant preachers who should chance to die in London. In 1740 he, with his own followers, left Whitefield, and the tabernacle in Moorfields, commonly styled as "The Foundry," for this site in what was then known as Royal-row. "The Foundry" has been twice rebuilt since. Amongst other buildings in London that are associated with the career of the founder of the Methodists may be cited the meeting-house at Bromley-by-Bow; Count Zinzendorf's Moravian Chapel in Fetter-lane; Lambeth Chapel, opposite to Bethlehem Hospital; and the Wesleyan Chapel in Justice-walk, Chelsea. He preached in the last two named, upon two successive days, within a fortnight of his death.

WE are informed that special efforts have been made to render the Architectural Association soirée, announced for Friday evening this week at the Westminster Town Hall, superior to any of its predecessors in attractiveness. The large hall was to be converted into a large drawing-room hung with decorations, and the whole of the rooms lighted for the occasion with electric light. It would have been better if this information had been given us at an earlier date, but we hope this mention of it may be seen by a good many of our readers before the time appointed for the entertainment.

THE *English Illustrated Magazine* contains an article by Mr. Austin Dobson on "The Vicar of Wakefield" and its illustrators, a subject of considerable interest. Examples of cuts from various illustrated editions are given, some by names little known at present; one by Bewick, one by Stothard, and some outrageous examples from Rowlandson and Cruikshank, neither of whom were worthy to touch Goldsmith's work as illustrators. As Mr. Dobson does not confine himself to prints published in the book, but includes separate illustrative works, such as Stothard's water-colour at South Kensington, it is odd that he should have omitted all mention of two important paintings, among the best illustrations of scenes in "The Vicar" that have ever been painted, and which were both exhibited at different times in the Burlington House

"Old Masters" Exhibitions. One of these, exhibited a good many years ago, was by Newton, and represented the return of Olivia to her family; we remember calling special attention to it at the time, and suggesting a doubt whether there was any painter of the present generation who could have equalled the pathos and delicate perception of character shown in this work, though many might surpass it in technique. The other painting referred to is by the elder Leslie, the father of the present well-known R.A., and occupied a prominent place in the first room at last year's loan exhibition. It represents the scene which provoked Mr. Burchell's famous monosyllabic criticism, "Fudge!" and in it the various characters of the story are realised with a truth and discrimination which we have rarely seen equalled in an illustrative painting of this class; they are the very people as Goldsmith described them. To omit all mention of this work, so recently exhibited in London, in an article on the illustrators of "The Vicar," is an extraordinary oversight.

THE descriptive notices of buildings illustrated in our pages are, naturally, in most cases furnished by the architects of the buildings, who usually and quite properly add the names of the contractors who carried out the work, but unfortunately in many cases do not take the trouble to be accurate in these details. This complaint arrived at (we hope) its climax last week, when we received letters from contractors engaged on three different buildings illustrated, complaining that their names or those of their firms, or what archaeologists call their *provenance*, had been wrongly given. In the description of Bablake schools, "Messrs. Thomas & Sons" should have been "Thomas Lowe & Sons"; in that of Armagh Cathedral restoration "Mr. Bowater" should have been "Mr. Bowdler," and another contractor "of Belfast" should have been "of Portadown" (in this latter case the contractor's name is so illegibly written both by the architect and the correspondent who writes to correct it that we prefer to leave it out); and in the description of Hatfield "Mr. J. Boulting" should have been "Mr. Thos. Boulting." Now, every one of these mistakes are due to the architects who furnished the descriptions, upon whom we are absolutely dependent for such information. One of them was a case of illegible writing, the others were deliberately and clearly written the wrong way in the architect's "copy." We call the attention of architects to this because mistakes of this kind cause a good deal of annoyance and even injury to the tradesmen whose names are given wrong, and a great deal of trouble to us. An architect *must* know the correct name of a firm that has been doing work under him; surely he might take the trouble to write it correctly and legibly.

#### LETTER FROM PARIS.

THERE is not much news at this time of the year that is of architectural or artistic interest. Exhibitions are closed, Parliament in vacation, and the public works in progress mostly partake in the general slackness of the period. Among these latter however may be mentioned with approval the new cut that is to be made into one of the densest and ugliest quarters of Paris by the opening of a new section of the Avenue de la République. In a few days will commence the demolition of the houses between Rue Obuskampf and Rue St. Maur, and the stacks of wretched artisans' dwellings will disappear and their inmates be driven to cheaper quarters in the suburbs. When this long avenue is entirely finished, in about eighteen months, it will form an unbroken communication between the Place de la République and the Faubourg Belleville. A rope tramway is also in hand on the same line of road. These improvements will considerably modify a quarter of Paris which stood in much need of improvement.

Among the new works going on in the eastern quarter of Paris is the enlargement of the Gare de Lyon, on which a large sum is being ex-

pended. One feature in this work is the construction of a steel viaduct carried obliquely over the Boulevard de Bercy and which permits of a division of the traffic from the main line, which it will rejoin in the neighbourhood of Villeneuve St. Georges. This will relieve the pressure of traffic and the delays caused by the frequent crowding of trains at this point.

We may mention in passing a very useless and even dangerous piece of work which has been permitted in the Boulevard St. Marcel, an excavation namely, with the object, it is said, of discovering the remains of Mirabeau originally deposited in the Pantheon! It is matter of complaint with the inhabitants of this quarter that the Administration should have permitted this stirring up of ground which is saturated with human remains; a proceeding quite inconsistent with the regulations which the Municipality is endeavouring in other places to enforce in the interests of sanitation. It is with this object that the mortuary dépôts, now nearly completed, in the cemeteries of Père La Chaise and Montmartre, have been carried out, in order to avoid the necessity of keeping bodies, after dissolution, in the crowded houses of the poorer classes. These mortuaries, designed by M. Formigé, are built in a very simple style and partly masked by shrubs and flowerbeds. That at Montmartre will be opened for use on November 1.

In the same cemetery and at the same time will be inaugurated the graceful monument to the painter Guillaumet, designed by M. Ernest Barrias, sculptor. A model of it in wax was exhibited at the last Salon, under the title "Jeune fille de Bou-Saada." It is now being cast at the foundry. It represents a young African girl seated and throwing flowers on the tomb of the Orientalist painter, whose portrait appears in bronze on a medallion, while the titles of his principal works appear engraved on the granite pedestal along with the simple inscription "Gustave Guillaumet: 1840-1887." The inauguration of the monument to Déla-croix is fixed for October 5. The sculptures have been fixed in position and the decorative effect of the whole can now be judged of. The bust of the painter is admirable in truth of expression. It is placed on a pyramid of white marble in front of which is the fine group in bronze, "à terre perdue," of which we have before spoken, and which, like the bust, represents the best of work of M. Dalou. The whole is in the centre of a small hemicycle in marble, in the avenue of plane-trees which runs by the side of the Luxembourg.

Although not a Parisian monument, we may say a word as to that to Garibaldi which is in course of execution by the sculptor, M. Deloye, and is to be set up at Nice in June 1891: a monument which has already undergone sundry vicissitudes. It was the subject of a public competition in which Antoine Etex obtained the prize. At the death of this aged artist, the Municipality of Nice, after much hesitation, addressed itself to M. Deloye, who found himself embarrassed with numerous difficulties, partly of a political nature, but who has at last completed his model. The statue of the Italian patriot, in white marble, will stand on a stone pedestal, in his well-known and traditional costume which lends itself so well to sculpture: bare boots, and mantle flying in the wind; the right hand rests on the hilt of his sword. Before the pedestal is an allegorical group representing France and Italy clasping hands over the cradle of Garibaldi. The whole will be completed by a bas-relief in bronze representing the "Rendezvous des Nations" at Nice.

There is also to be mentioned among recent artistic works a fine medallion portrait which has been put up in the Church of St. Louis, in the Isle of France, of the last curé of that parish, the Abbé Bossuet, great-nephew of the celebrated Catholic orator, and who devoted all his fortune to beautifying his church. The medallion is the work of M. Coutan. It is surmounted with the arms of the Bossuet family and surrounded by a little architectural framework designed by M. Charles Normand.

The projected French Exhibition at Moscow is already the object of much preparation. Among the committee of organisation is M. J. Alphand. M. de Dramard has been named the delegate for the artistic department on the committee.

Various journals have announced that the *Encyclopédie d'Architecture* is about to establish an annual competition which will offer a certain interest and stimulate the originality of young architects. The object of the competition is to

MR. FLINDERS PETRIE'S DISCOVERIES IN EGYPT.

LAST week we laid before our readers a notice of the discoveries made by Mr. Petrie in the Holy Land where, for the first time, an effort has been made to penetrate into one of the mysterious mounds so common in the country. In continuation, we are now able to publish a section (fig. 1) showing the general formation of the "Tell" which, as we then stated, is most probably the site of the ancient stronghold, Lachish. The diagram, by Mr. Petrie's courtesy, is sketched from the measured drawing prepared to a large scale, and which shows the results of the excavations. Since this drawing has been prepared for publication we have ventured in fairness only to anticipate and not to supersede it by the sketch which we now furnish, which is not to scale, and which will not render the more elaborate drawing unnecessary when published.

It shows at a glance the positions of the successive walls, and of various buildings erected one above another.

The lower construction of the two nearest to the south side is that which contains the slabs of limestone with spiral volutes forming the jamb linings of its doorways, of which there

are two in each of three of its quadrangular sides. The long building above it, of a different age, shows us the pilasters already mentioned.

Its axis is different to that of the building below it, and the interval of time between its erection and that of the abandonment of the lower fabric, must have been of sufficient length to allow not only of the gradual raising of the mound, but of its consolidation sufficiently to admit of the erection of the massive structure now found above it. The small amount of earth that has been excavated, and the large amount of work still remaining for the discoverer, is abundantly shown by the little diagram.

We turn to the Egyptian discoveries which Mr. Petrie has accomplished. In treating these briefly and in the second place, as we do, we are in no way unmindful of their importance in relation to the many items of ancient history, ethnology, and artistic beauty which they render. We do so only by reason of the new page of the history of the Holy Land, which the discoveries at Lachish unfold to us, while those in Egypt are the continuation of the researches of last year.

Mr. Petrie has now entirely cleared the whole

area of the town of Kahun, which, it will be remembered, is situated on the borders of the Fayum, Upper Egypt, and formed, as he supposes, during the XI. Dynasty by a colony of workmen engaged in the erection of the Memorial Temple and Pyramid of Usertes II., and deserted when the work was completed. The plan prepared during the progress of excavation indicates what was the form of an Egyptian town at the period of remote antiquity stated, according to Bunsen's chronology, about 2600 years B.C. It is in form a parallelogram, the two longest sides facing north and south, and closed within a massive wall, constructed, like the houses, of sun-dried brick. The houses to the north, in the more important part, about upon the town wall, and are divided into parallelograms of varying size. Those to the south abut upon a street. Two streets run east and west, connected by another at right angles. Close up to the west wall others perhaps existed, but the site being furrowed by the passage of rain-water, which has washed away a considerable portion, can hardly be accurately examined in this respect.

Adjoining the town on the west is an annex which appears to have been inhabited entirely by workmen. Judging by the way it joins on to the plan of the other portion of the town, we consider that it is of somewhat later date, an addition to the previous work, and this belief is supported by the fact that its south-west angle touches that of the temple enclosure, thus blocking up the separating space which appears to have been previously opened.

We publish a diagram (fig. 2), sketched from the town plan, of one of the principal houses, which will give a fair idea of the whole. Here, for the first time, may be seen what was the arrangement of an important household at a period which is anterior to the usually accepted date of the Flood if we accept Bunsen's chronology; or some few centuries later if we accept Wilkinson's. The curious arrangement of the passages leading to various portions of the mansion are, doubtless, intended for the use either of different sexes or of different grades of occupants. The open courtyards, with their pillars for the support of surrounding coverings, are prominent features of the arrangement, and remind us of the similar planning of the Greek and Roman houses of long posterior date. The workmen's houses were approached from various narrow streets running from the eastward up to the western wall of the town, where they stopped, being thus *culs de sac*. They were of small size, crowded close together, and at right-angles to one another.

The enormous mass of work accomplished on this site by Mr. Petrie may be best estimated by his calculation of the various rooms which the whole of the houses were estimated to contain. These amounted to 2,738, of which the large number of 2,145 were cleared out in a most painstaking manner by our explorer's body of workmen, one by one, and the excavated earth carefully examined.

As the earth from one room was removed it was thrown back into another. By this means no accumulation of earth was ever allowed to remain to impede progress, and the work was all the more easily accomplished. The result of the system adopted was the discovery of many curious items of arrangement, as well as of an enormous number of articles of all kinds and descriptions. One of the most curious is that of the common use of the semi-circular arch. Several cellars were found, which, except where cut in the rock, were found to have arches formed of two rings of headers. This was not the case in merely isolated examples,

aim at the production of a nineteenth-century style. The result will show whether the idea is any more than simply Utopian. All kinds of designs, from a public building to a shop, will be admitted, and are to be sent in by the fifth of November to the office of the *Encyclopédie d'Architecture*. Prizes in money will be given to the designs selected as the best, which will be published in the *Encyclopédie*. A certain number of eminent architects, such as MM. Bailly, de Bandoit, Charles Garnier, Lisch, Moyaux, Vaudremer, &c., have accepted the office of examiners of the drawings sent in.

The "Société Française des habitations à bon marché" has opened a competition of another and more practical kind, for the best study for artisans' dwellings. This new competition will be closed on November 15.

At the École des Beaux-Arts the candidates for the Janvain d'Attainville prize (historical and landscape painting) have just finished their work. The subject for landscape is a shepherd collecting his flock at sunset; that for history, the decoration of a hall with pictures representing Agriculture and Commerce. The decision on these will be given at the end of the month. The classification of pupils for the competitions of the year is as follows:—"Grande médaille d'émulation," M. Bonis, for painting; M. Miserey, for sculpture; M. Chiffolot, for architecture; Abel Blouet prize (architecture), M. Louret; Jay prize (architecture), M. Tavernier; Jean Leclaire prize (architecture), MM. Chiffolot, Jaboutay, and Delassus.

In administrative quarters the question of the admission of women to the course of the École des Beaux-Arts is still under discussion, and is considered to present serious difficulties. Women have already been admitted to the Sorbonne course of study, to that of the École de Droit, and that of the Faculté de Médecine; but it is considered by some that the studies of the École des Beaux-Arts stand on a somewhat different footing in this respect to the more grave and serious studies of the institutions above named. Moreover the students of the École, under pretence of keeping up the classic "Bohemian" traditions, affect too often an exaggerated liberty of speech, dress, and manner, and eccentricities "pen convenables," it is maintained, for feminine association. The Minister of Public Instruction, M. Bourgeois, is said to be in favour of the change, of which Madame Léon Bertaux, president of the "Union des Femmes Peintres et Sculpteurs,"\* is the persevering and eloquent advocate. Nevertheless, there are many who consider that it would be a very questionable expedient, as regards "les convenances," to authorise the joint use by both sexes of the ateliers, as they are at present conducted, and that parents and relations on the ladies' side would probably set their faces against it.

If this is the final conclusion, it would be necessary to establish ateliers for women, in other words to enlarge the establishment altogether, to open new galleries, and proceed in fact to a completely new and costly installation of the whole machinery of the École in duplicate. It would then become a financial question, which the Chambers alone can settle. Nevertheless, M. Bourgeois is so strongly in favour of giving women equal advantages of artistic instruction with men, that in one way or the other it will probably be accomplished.

We have to record the death of one distinguished lady artist, Mlle. Louise Lalande, well known by her contributions to the Salons, and who has died at Paris at the age of fifty-six.

\* "Sculpteurs" would seem more correct.—En.

Sketches of Pottery and other objects from Mr. Flinders Petrie's Exhibition.

but was found to be of constant occurrence, showing that the builders were perfectly familiar with its use, and thus setting back the period of its invention to some long anterior time. The specimen brick exhibited measures 6 3/4 in., by 3 1/4 in., by 1 1/4 in. thick.

Another of the most curious features met with were the traces of the columns to the open courts, of which fig. 6 is an example, of stone. These stood on the flat, widely-projecting circular bases, so common in later work. They appear to have been mostly of wood, so far as regarded those of largest size. A portion of one, octagonal in plan, still existed *in situ*, the upper part being burnt, while in another place a portion of a carved capital, also of wood, was found, fig. 10. There are, however, many remains of small columns of stone, some of which approach an early form of Doric, having slightly hollow or straight-lined flutes, and square blocks instead of capitals, similar to the so-called Doric pillars of the Beni-Hassan tombs. A great many fragments of small, pedestal-like shafts were found, which prove to be hollowed on top, either for the reception of offerings or for the support of lamps.

Figs. 3, 4, 5, 7, and 8, are typical examples of these curious articles of decoration. No. 5 is a capital of a more ornamented shaft, worked like the others, somewhat irregularly, as if the mason had trusted to his eye for his lines. No. 9 is the base of one of these small shafts, imitated from a structural column of larger dimensions.

This being a town of building artificers, our readers will be interested in the sketches of some of the tools used by the workmen of the remote period under consideration. Flint implements are found in great profusion, side by side with others of copper, the principal being cut flint knives (of which fig. 27 is an example), chisels, and scrapers.

Of the copper tools, figs. 28 and 32 are chisels, circular above, flat at the edge—all fair examples. Fig. 29 is a borer, and fig. 30, similar to a modern bradawl, is still contained in its wooden handle. Figs. 31 and 33 are copper knives, of which a large number of all sizes were met with; and 34 is an adze, one of which was found tied with thread to bind it to a handle, similar to the flint knife, fig. 27; but in this case the thread was further secured by a seal.

Some of the houses had evidently been decorated in colour, and a portion of wall-painting is exhibited. This shows a submural red ground lined out with two narrow bands of white separating a broader one of fawn colour from a jet black border.

Traces of occupation, later than the twelfth dynasty, were found; and this points to the possibility of the town having had some separate existence from the sanctuary adjoining it, which we think may have been the case, since the area is so much larger than what any mere band of workmen and their overseers would have required. The better portion of the town is, in fact, of much larger area than that specially devoted to the workmen. One of the papyri found, indeed, affords confirmation of the existence of the town at least into the period of the thirteenth dynasty, since we may fairly accept the town named (Kherp Usertesen) as being the Kahun of to-day. It gives a list of the workmen on the wall of the town, their entries being dated, as rendered by Mr. Petrie, the first, second, and sixth years of Sebekhotep I. Our purpose is but to touch of the more architectural and artistic of the relics found, and reference to the beautiful seals, necklaces, and such-like matters, of which there is abundance, may be omitted as being apart from our object. Still, we are bound to mention, as an example of artistic work, an admirably written papyrus, a hymn to Usertesen III., in which all benefits conferred by Deity are ascribed to him. The writing is beautiful and regular, and in fine general condition, notwithstanding its remote antiquity.

The continuance of occupation of the town, however, does not appear to have been general, for at a later period the vaults of some of the houses were found to be used for burial purposes, and, apparently, at varying periods.

Excavations were also carried on again at Gurob, a site which had been previously investigated by Mr. Petrie, a site of more than a thousand years of later date. Here articles of great beauty and of varying races were found, including many works of greater elegance and finish than the earlier ones, from Kahun. Here was met with a fine lion's head, evi-

lently intended to be used as an architectural decoration, an admirable study for a sculptor, since it is worked to be seen from some little distance, and not a single detail is rendered more than was necessary for proper effect. The implements found are of bronze, instead of copper, and some of the articles, particularly the handle of a mirror worked with the Phœnician Venus with a dove, are very admirably designed and executed. A number of vases, as originally manufactured, used in glazing pottery, and to be ground up as paints, were also found. These are deep blue, the beautiful turquoise green, pistoline iron ore, and samatite, ground up to form red paint, and many others.

Beside these is a case, with examples for comparison which have been prepared by Dr. W. J. Russell, F.R.S., in imitation of the ancient cloths, made of copper salts, and the resemblance is remarkable.

The pottery from the two sites forms a special feature in the exhibition, and, since the existence of Egyptian pottery as a distinctive class has not been in proof for very many years, the present collection forms an admirable opportunity for the comparison of very early and later specimens, together with examples of foreign manufacture imported by the Phœnicians. In addition, there are some few specimens called Egyptian, by Mr. Petrie, of which we illustrate a fragment of curious black ware, fig. 12, the lines of which are filled in with white, similar to examples still made along the borders of the Dead Sea. Another, fig. 13, has white lines on reddish ground, and fig. 16 is a reddish ware, askos.

Of purely Egyptian forms, figs. 11, 14, 15, 17, 8, 19, and 20, may be regarded as typical examples, the first of these being decorated with red and blue lines alternately on a light brown ground. Nos. 21, 22, and 23 are fragments only of moulded and modelled pottery of good design, all highly glazed and decorated in front with purple, blue, and green, in very effective manner, while the interiors are coloured beautifully with turquoise blue. Fig. 3 has green leaves on a black ground. It is a matter of regret that only small fragments of this remarkable ware have been met with. They come from Gurob, as do also the originals of figs. 24 and 25, two beautiful blue jars decorated with patterns of lotus leaves and flowers.

The green-glazed lamp, fig. 26, also comes from Gurob.

The exhibition will remain open to the public, at Oxford-mansion, until October 11.

#### THE COMPETITION FOR THE WORCESTER VICTORIA INSTITUTE.

The Worcester Victoria Institute is at present housed in a most inconvenient building, and it has been proposed to erect a building, at a cost of about 20,000*l.*, providing ample accommodation for a free library, an art gallery, and museum, and in connexion therewith technical, science, and art schools. Mr. Waterhouse, R.A., was retained by the committee to act as assessor, and out of the large number of sixty-eight sketch designs the following six firms were selected and invited to prepare designs in more detail. Messrs. J. W. Simpson & E. J. Milner-Allen, Strand, London; Messrs. Smith, Woodhouse, & Willoughby, Manchester; Messrs. Theo. Moore & W. Henry White, London; Messrs. Salter & Adams, London; Messrs. F. C. Ryde & Bedford, Great George-street, London; Messrs. Walter Cook & G. H. Grocock, Cardiff. These six firms will share the sum of 300*l.* in accordance with the conditions, whilst Mr. Waterhouse has awarded the first place to the designs of Messrs. Simpson & Milner-Allen.

The decision of the assessor we can confidently assert will be fully endorsed by all who will take the trouble to carefully examine the designs.

A short description of the site will explain the difficulties that had to be contended with.

The site, which is fairly level and of oblong shape, adjoins the premises of the Shire Hall, is bounded on the west by Foregate-street, on the east by Sansome-walk, and on the south by Taylor's-lane, which is a footpath with a width of 10 ft. The opposite side of Taylor's-lane is occupied by houses and cottages, whose windows dominate the opposite property to a greater or less degree, but with the intention of minimising this restriction it has been decided to widen Taylor's-lane to 20 ft.

In careful and skilful evasion of these re-

strictions of light, Messrs. Simpson & Milner-Allen far surpass their competitors, and to the cleverness of the plan their success is mainly due, for the elevations are kept very plain in character, with a view to keeping the cost within reasonable bounds.

In every case competitors have placed the library block at the Foregate-street end, and the schools block facing Sansome-walk.

Messrs. Simpson and Milner-Allen plan their library entrance at the corner of Foregate-street and Taylor's-lane, leading through a porch kept low on account of the dominating light; from the vestibule opens the news-room facing Foregate-street, with book-store adjoining. The reference reading-room faces Taylor's-lane, and adjoins the committee-room. The librarian's office is conveniently and centrally placed, adjoining the book-store. A spacious staircase with corridors, overlooking Taylor's-lane, leads from the vestibule to the upper floor, where ladies' and gentlemen's retiring-rooms occupy convenient positions at the head of the stairs. Museum-rooms face Foregate-street, with art-galleries, top-lighted, *en suite*, behind them.

Another staircase, with lift adjacent, is placed in the south-east corner.

The entrance to the schools block has been placed in the centre of the Taylor's-lane frontage, and leads to a corridor parallel to the lane; on either side of entrance ladies' and gentlemen's lavatories have been provided, but these are only carried up to the first floor level to prevent obstruction to the adjoining lights. The lecture theatre faces Sansome-walk, whilst class and other rooms and laboratory occupy the north side of the corridor.

The art school is also conveniently arranged on the first floor. The antique, master's, and modelling rooms all have good north lights, whilst the elementary room has been placed over the lecture theatre, facing Sansome-walk. A good position has been reserved for a conservatory over the entrance, and the south aspect appears to be suitable. Caretaker's rooms occupy a second floor. The basement has been divided between a technical school and the necessary chambers for heating, storage, and other purposes.

The ancient lights of adjoining properties have been most carefully considered and successfully dealt with. There is but one window with which any fault can be found, and that lights the museum and overlooks the Shire Hall Lodge. This will, no doubt, be remedied at an early date.

The remaining designs we must mention in the order in which they hung on the walls.

Messrs. Stephen Salter & Adams, in their design, have placed their entrance to library at the corner of Taylor's-lane and Foregate-street, with news-room facing the latter, and the book-store in the north-east corner, the reference reading-rooms facing Taylor's-lane adjoins the committee-room; but the librarian's room should have occupied a much more central and controlling position; the lavatories are hardly placed in an accessible position, as far as the news-room is concerned. The rooms also are badly proportioned in many respects. The schools block is deficient in method of plan in several instances. Placing the ladies' over the gentlemen's lavatories on a mezzanine floor, for instance, is open to objection; and the entrance in the centre of the Taylor's-lane front would have better utilised the long corridors. The ancient lights have not been completely dealt with.

The designs submitted by Messrs. Smith, Woodhouse, & Willoughby show several original features. The elevations show considerable grace in their treatment of necessities of a somewhat municipal character. The cost of the building would, however, prevent the adoption of this design. The school block has been carefully planned, and it is a pity that the library block is not free from its defects.

An entrance is placed in the Foregate-street front with a large vestibule for statuary, which leads by a staircase to the first floor galleries only. The entrance to the library is kept quite distinct and is reached from Taylor's-lane, with news-room on the left and reference reading-room on the north. The position of the librarian's room in the extreme north-west corner behind the book-store facing Foregate-street is an unfortunate one.

The school block has been provided with entrances in Taylor's-lane and Sansome-walk and a corridor running parallel with the lane. The lecture theatre occupies the north side of

this corridor. The art school on the first floor shows the elementary art room facing Sansome-walk, whilst the antique and painting-rooms have north lights.

Sufficient attention does not appear to have been given to the ancient lights on the south side, whilst small windows appear overlooking the Shire Hall Lodge. The elevations have been carefully designed and, with the exception of the elevation to the school facing the Shire Hall, which is plain, bordering upon ugliness, shows fairly satisfactory Renaissance treatment.

Messrs. F. C. Ryde and Bedford's design differs from the others in several respects. A large and massive tower occupies the north-west corner adjoining the Shire Hall Lodge, and the best portion of the centre of the Foregate-street frontage is devoted to vestibule. The news-room is carried along the north side with book-store opposite the entrance. The reference reading-room is placed with the committee-room facing Taylor's-lane.

The proportions of these rooms are unhappy in several instances, and we consider the tower too massive in its proportions for the rest of the design. Any dignity it might possess in execution would be nullified by the presence of the insignificant lodge of the Shire Hall at its base. With this exception the elevations show a great deal of quiet grace. The plans are capable of considerable improvement in many ways.

The designs of Messrs. Theo. Moore and W. H. White are an interesting study. It is a matter of regret that the really artistic treatment of the elevations should have been coupled with several serious defects of plan and inattention to the dominating lights of adjoining property. The expense of this design also disqualifies it at once.

The elevations to Foregate-street and Sansome-walk specially deserve notice. The Foregate-street entrance is at the base of the tower, and leads to vestibule. A large news-room is placed at south-west angle, with book-store and reference reading-room adjoining. The committee-room occupies the north-east corner.

Little attention has been given to ancient lights in Taylor's-lane, and windows have been opened on the north side which clearly infringe upon the right of the Shire Hall property. The authors of this design would have been well repaid for a little more attention to the practical solution of the problems of the design—viz., cost on improved plan, and closer attention to questions of light. The fate which overtakes the design is to be regretted, as far as the elevations are concerned, though it is thoroughly deserved owing to the defects already mentioned.

Want of space prevents us fully noticing the designs of Messrs. Walter Cook & Grocock, of Cardiff.

There is satisfaction in seeing a competition decided in favour of the architects who most closely and satisfactorily carry out the instructions given, and we are satisfied that Worcester is selecting the most practicable and satisfactory of the six designs submitted, and that the award of Mr. Waterhouse is a right and fair one in every way.

#### ON THE TECHNICAL EDUCATION OF ARCHITECTS.\*

The words in which the title of this lecture is expressed imply obviously that there may be various sorts of education. Education may, in fact, be directed towards the attainment of different results; or, in other words, may have different aims. These different aims form, indeed, a part of the subject which must receive some attention at the outset, and must not be lost sight of through the lecture, since it is the difference in the results aimed at which should suggest differences in the means employed.

I do not think any excuse is necessary for selecting to-day a subject very similar to what I have spoken upon before. The circumstances, if we give them a moment's attention, not only suggest but almost prescribe this subject. This year, for the first time, the examinations established by the Institute of Architects will all be held, so that we now first have a practical and complete demonstration of what those best fitted to judge consider should be the aims of adequate technical education for architects. For the first time also a scheme for an educational curriculum, not drawn up theoretically,

\* Being the opening lecture delivered by Professor Roger Smith to the Architectural Classes of the University of London (Session 1889-91) on October 2, 1890.

but with a view to practical use, has been put forward by the students themselves. That this scheme, embodied in the proposals of the Special Committee of the Architectural Association, has not yet been adopted by that body, leaves one to some extent free here to comment on its provisions. Suggestions, if good ones, can still be considered, and may still be serviceable. Later on, when a scheme had been definitely adopted, I for one should consider it wrong to do more from this chair than wish it well, and watch its working with interest, as I should any other definitely-accepted programme.

Education, such as a cultivated professional man requires, may, if we attempt its analysis, be characterised as *Initial, Liberal, Technical, and Practical*; and while each of these four words refers to a distinct aim and, to a great extent, to a different series of studies and a distinct course of training, all four are so intimately mixed up together that we can only partially disentangle them. We may, however, go so far as to say that the aim of the *Initial* is one of immediate utility, namely, to give ordinary elementary and general instruction, and to develop ordinary powers of learning and remembering. The aim of the *Liberal* is to enlarge, expand, and strengthen the mind and enrich its stores of general knowledge and powers of action; that of the *Technical* is to impart such theoretical or scientific knowledge, or to teach such accomplishments as are necessary or desirable for the pursuit of the profession selected. The aim of *Practical* training is to actually teach the practice of that profession.

The initial training may be dismissed very briefly. We all understand what is meant by a plain English education, though few of us ever stop to think what an enormous stride the child and the boy take while receiving it. I doubt whether any advance afterwards is so great as that made by the child who, during his first five years, more or less masters language. To emerge from the condition of knowing nothing into a state in which you have mastered a vocabulary of several hundred words, and can remember them, can use them correctly, and can understand them when addressed by others to you, is, I think, an advance greater than is ever made in after-life. Nor is the student, youth, or man ever able again to take such a great step, or to enrich his stock of mental possessions with so valuable an addition as when first he has mastered the art of reading, and instead of being dependent for all information and every idea of every sort upon the individuals he is able to talk with, he is made free of that accumulated store of knowledge, wisdom, fancy, or frolic which is the birthright of every one who can read English.

Though this is happily true, and the general effect of brightening and expanding the powers of a youth's mind, which by degrees follows, is of the utmost importance, it is not the main object aimed at. The scholar in this respect is like a man who while digging his field to get in a crop, finds a buried treasure. His aim was potatoes or turnips, or whatever mere food he had sown, and if he got something more precious it was not any part of the expected crop. He had not sown it. That which we may consider a sufficient initial education for an architect may be found described in the programme of the preliminary examination of the Institute of Architects. You will find no subject introduced there which will not be of direct use to the young architect, and no subject carried further than will undoubtedly be required by him.

He is to write from dictation, and is expected to show a legible handwriting, and to mind his stops and capital letters. He is then expected to write something intended as a test of powers of observation and description, which means, I presume, that he will be asked to describe something which has been or is under his notice. Arithmetic, including the rule-of-three and fractions, two books of Euclid, and a very elementary amount of algebra, the geography of Europe, and the history of England, are also required of him, and either one modern language or Latin, with elementary mechanics and physics. These subjects are taught in any good school, and any examination certificate which shows that a candidate has proved to a competent tribunal that he is fairly well educated, is accepted in lieu of going through the paper, and with reason, as, in all probability, the standard will have been higher if the subjects may have differed a little. Lastly, a certain proficiency in drawing is required. This in an ordinary schoolboy may be looked upon as something of an accomplish-

ment, but as any one would be mad to think of making a youth an architect who does not show that he can draw, this in the present programme is only a strictly utilitarian subject; and, speaking generally, it would be easy to show that each one of the attainments named in the programme is important—I think one may say essential—to the intending student of architecture who wants to make progress.

I turn next,—and turn with pleasure,—to that part of education which I have termed *liberal*, and the aims of which I have described as being to enlarge, expand, and strengthen the mind, and enrich its stores of general knowledge, and powers of action. "A liberal education" is not so often spoken of,—nor, let me add, so frequently aimed at,—now as once was the case; but there is no adjective that so truly expresses the best aims of this the best sort of training and teaching. Instead of keeping the boy at school as few years as will just suffice to get a minimum of knowledge, to send him to Oxford or Cambridge for three years more,—instead of limiting his subjects to those most likely to make him get on in the world, to include those which will make him an abler, a better informed, and a more cultivated man; to provide him with resources for leisure, sickness, or old age; to make the best of any powers, faculties, or genius with which nature may have endowed him, and to teach him some accomplishments, and take him at least to the threshold of the temple of learning,—this is to educate a youth liberally. Of course, in many cases, this is out of a father's or a guardian's power from pecuniary reasons; in others, I fear, the student himself fails to understand what a priceless advantage is within his reach, and declines the opportunity; or, what is worse, has it and wastes it. But when it is possible, no greater kindness can be shown to a young man, than, to some extent, and in some way (not necessarily by sending him to an university), to give a liberal character to his education.

Two generations back the classics—that is to say, the languages and literature of Greece and Rome—were invariably the subjects studied by all who were desirous of becoming cultured men, with, in many cases, the addition of pure mathematics.

There can be no doubt that Greek and Latin, well mastered, have produced, as a rule, a remarkable effect upon the mental powers of the student, and if carried far enough to enable him to acquaint himself with the unrivalled literature in those languages, especially that of Greece, they have proved invaluable as educational instruments; and the same, in another way, has been the case with mathematics.

At the present day other studies run the classics hard, so to speak, and are advocated as equally valuable mental discipline, and as more useful in after-life. I am, fortunately, not required to embark on this sea of educational controversy, as the hearers, and most of the readers, of this lecture have passed the time when it is decided how far a man's scholastic education is to go, and on what lines it is to run. Only let me heartily congratulate any who have had the good fortune to receive a classical education, on the circumstance, one which ought to exert a beneficial influence on their whole career. And it may not be amiss to ask why this should be the case.

The study of language is really the study of thought,—words embody thoughts. Grammar consists in the orderly arrangement of thoughts. Literature is a record including the most cultivated, powerful, valuable thoughts of the world. Hence, in studying language you are indirectly studying thought,—learning to think, learning how others think; in studying literature you learn how others have thought. But why a dead language? There are several reasons; but the chief one, no doubt, is that the study, to yield its best fruit, must be more thorough than it can be where the language is spoken, and the learner acquires many phrases, modes of expression, and a host of words in a more or less loose colloquial manner.

I should, however, be the last to assert that the study of the classic tongues is always carried on a little way it is nothing but drudgery. If carried out in the perfunctory spirit which just studies the authors set down for matriculation or B.A., as the case may be, and deems every hour not spent in coaching for an examination sheer waste, that, forsooth, is not a liberal study, or likely to improve the mind.

On the other hand, any study worth calling by the name, given to the acquisition of any important art, science, or literature, if carried on in a liberal spirit and directed to the aim I have pointed out, is improving to the mind,—is *ipso facto* part of a liberal education. It is doubtful how far either art or science, if directed solely to some immediate profit, can bear this character in its effect on the learner. To be really liberal, study must be pursued partly, at least, for its own sake, with a desire to make a knowledge of, or skill in, some subject thorough and complete.

Science is largely now substituted for literature as a subject of study in places of higher education, and, perhaps, rightly, for this is the age of science, and the qualities and temper of mind fostered by scientific study are greatly needed now.

Fine art, though a branch of an architect's technical education, is really what may be called a liberal subject, and I urge you all to pursue it in a liberal spirit. Give attention not solely to architecture, but to the allied arts of painting and sculpture, and to the allied science of archaeology. Study architecture in foreign travel as well as by stay-at-home work. Try to understand the principles of decoration and of applied art; visit and carefully examine good picture-galleries, and widen and deepen your knowledge of the arts as a whole, by every means in your power.

No young man whose actual schooling or college course is over, and who is occupied,—perhaps busily occupied,—in learning his profession, or earning his living, ought to consider that his education, with the exception of professional study, is over. He ought to carry it on for years to come the best way he can. If I am asked how, I would suggest first of all by keeping up, and, if possible, extending what he has got. If you have learned a language, for example, such as Latin, German, French, or Italian, do not let it drop. If you have mastered the rudiments of a science, try to carry it further, and certainly (as already suggested) do your utmost to extend your knowledge of fine art.

One, and that a very accessible and interesting method of cultivating the mind, is the pursuit of English literature. Our best authors' prose and verse, fiction and fact, provide a literature of the greatest possible value, and if there is nothing else that you do for the next few years by way of mental culture apart from all other and more necessary work, at least I pray you to make yourselves acquainted with the writings of Spenser, Chaucer, Shakespeare, Pope, Milton, and Thomson, and of Goldsmith, Addison, Johnson, Swift, Macaulay, Carlyle, Scott, George Eliot, and Thackeray, and in some cases not merely read, but re-read, study, and analyse them.

Technical and practical education, though now to some extent separated, could till lately hardly be thought of as two separate things,—at any rate in our own case, or indeed in the case of several other professions. The apprentice learned practice as he still learns it, by working in it, and if he gained theoretical knowledge, he obtained it at the same time, and as he best could,—partly, I may say, since this class was instituted, in this class-room. Now in all professions an effort is being made to impart technical training of some sort by a machinery created for the purpose. Perhaps it will clear the way for the topics which I chiefly desire to dwell on if the two other observations that ought to be made about practical professional education are made at this first stage, before rather than after we reach the technical.

For no profession is a theoretical or collegiate education, however complete by itself, an adequate preparation. Probably at the present day no system of professional education is so complete as the medical, and apprenticeship is there done away with. But the reason is, that in the hospitals, and outside them, a vast field of practical experience under the most eminent examples and teachers is open to the student, and he, for much of his long and arduous period of studentship, is labouring night and day in the wards of the hospital where he is studying, or among the poor in their own houses in the province which the hospital serves, or at the out-patients' department. Meantime, every sort of disease, and every sort of surgical case, is being so treated by the first men of the day under his notice, that the student not only knows and sees all that is done, but learns the reason why, and, as a dresser or a clinical clerk, and later in higher appointments, takes as

active a part in the work as the progress he has made renders possible. For few professions, again, has a scheme of thorough instruction been so completely elaborated as for mechanical engineers in this college, lately under Professor Kennedy, and now Professor Pearce. Yet let a student go through this whole scientific course, take his degree, and master all that can be taught in this or any college, and the first thing his friends find is that he must now be articled to an engineer for about two years to work in the pattern-shops, the fitting-shops, the forge, and so forth, wearing the dress and doing the work of a mechanic. The same thing is true of any practical profession. The practice can only be learnt by practice.

As a result, I think it is not likely that the practice of apprenticeship, or, to give a more dignified name, pupillage, will cease in our profession. This was hardly my belief years ago, but the more I have seen and experienced of what can and what cannot be learnt under class instruction and under pupillage respectively (and I have had more opportunity than most of comparing the two), the more I am convinced that neither can dispense with the other. True, it is quite possible that changes in form may take place. A radical change did take place when for the old apprenticeship for seven years was substituted the now customary short term of three years, and this alteration, made as it was without the necessary and corresponding provision of means to supplement this brief period by some course of preliminary or concurrent systematic study, has flooded the profession with young practitioners, not a few of whom are, to put it bluntly, lamentably ignorant.

What ought now to become customary, and I hope will be for any young man who is to be an architect, to take a well-arranged course of preliminary technical instruction extending over one year at least, and, when practicable, over two, and then to begin his three years as a pupil, continuing part of his theoretical studies in his evenings and doing the practical work in the day. And I propose, in considering the technical education of an architect, to try to point out what kind of course such a student should take up, and incidentally to show what facilities this college presents for such a course.

Coming now to a closer examination of the technical education of architects, some of us may feel that the phrase "technical education" has been used again and again without any attempt to define, or even to comprehend, what is meant. Of this phrase, now on every one's lips, I have never seen a definition attempted, and I confess to feeling not a little difficulty in understanding one. It might at first sight be thought that "teaching an art" corresponded very closely to the sense of the words; but this is not quite what is meant at the present day, and probably "training for an art" more nearly expresses what is done in those noble institutions where those who are to pursue useful arts are receiving instruction, directed partly to teaching them to understand what they will have to do, and partly to develop such skill, manual or mental, and imparting such knowledge as shall help in the acquisition of practical power. What goes beyond this—like the medical curriculum to which I have alluded—is called, and properly called, practical professional education. As the popular technical education movement for artisans is understood and carried out, it is not to be supposed that the institution will educate pupils into skilled artisans ready to work, but that it will supply them with such theoretical knowledge, and possibly develop in them manual skill in such work, for example, as mechanical drawing, as will enable them to become better artisans than they otherwise could be.

So with architects. The technical education of architects has special reference to their instruction in the science and in the theory of this profession and their training in the skilled arts, such as draughtsmanship, which it is requisite for them to possess.

A statement of what this technical education for members of our profession must consist of, is to be looked for, if anywhere, in the programme of the intermediate and the first examinations established for the Institute of Architects.

The candidate in the intermediate examination is required to do as preliminary work a considerable amount of drawing, and this will of course be looked upon by the examiners, first, from the point of view of draughtsmanship, and then, if sufficiently well drawn, scruti-

nisied to see what evidence it gives of familiarity with the general forms, the details and the ornaments of the orders and of English Gothic architecture, and to some extent with what is known about the buildings from which the examples are taken; and, further, in respect of construction, to see whether it gives evidence of some acquaintance with carpentry and joinery. The written and oral examination on art subjects is to take the same range as the drawings cover. That on construction includes the nature and employment of all the ordinary building materials, the calculations usually made in connexion with the stability of buildings and the principles of construction, and a moderate amount of applied mathematics and physics. This examination it is expected that a student can pass in the course of his pupillage. When his studies have been carried so far with the addition of practical work that he is presumed to be fit for admission to the Institute as an Associate, the programme of the final examinations requires evidence of a good general knowledge of architectural history and an acquaintance with the mouldings and features of the various styles, and of a thorough acquaintance with these in the use of some one style; and it also requires the candidate satisfactorily to prepare a design for a building. The scientific subjects may be summarised as nearly the same as in the intermediate, with some omissions and some additions, that is to say, materials, construction, and the calculations necessary for ascertaining the strength of materials and structures, but with the addition of sanitary science, and the omission of applied physics and mathematics. Of course, however, the student would be expected to know more about the subjects which appear twice in the final examination than in the second, subjects that may be considered as belonging specially to practice, including specifications, estimating, and, to some extent, professional practice, and dealing with unsafe buildings. Though, of course, on the one hand, much of the construction and of the preparation of a design require practical skill as well as theoretical knowledge; and, on the other, professional practice itself is a very suitable subject for class instruction.

This statement is necessarily made in very general terms, and, in some cases, a single word in it, as, for example, construction or drawing, covers a very large and varied range of subjects, though all closely connected together. Still, we are now in a position—putting the three programmes together—to say that the education of the architect ought, in order to conform to the Institute minimum, to include, at least, drawing, elementary mathematics, and physics, and their application to construction. The history and the actual forms, features, and details of architecture, materials and construction, and sanitation, together with reasonable skill in designing and in preparing working drawings and specifications, and in estimates. Professional practice and dealing with dangerous structures are also required.

It is difficult to separate the whole course of the architectural development of the young practitioners into two halves and say this portion is practical and that is technical. What is learned in the class-room must be corrected on the scaffold, and, on the other hand, what is learned in the office must be elucidated in the class-room. But it is at least possible to point out what parts of this complex whole a college may with advantage propose to supply, and if we do as much as this we shall have carried the subject as far as in a single lecture it can be possible to advance it.

The Committee of the Architectural Association, taking these very examination-schedules as the acknowledged guides, have prepared a suggested programme of technical education for architects, to be carried out entirely by means of evening work, and entirely by classes and lectures to be established by the Association, and this, which must be familiar to you, now claims our attention.

It appears to me very doubtful whether the technical part of this programme can be thoroughly and efficiently carried out by evening work alone; and though, of course, the conditions under which the Association works entirely preclude their Committee's shaping its programme otherwise, there can be little doubt that this is a weak point in the proposals contained in the report.

Again, there can be very little doubt that an Institution like the Association, if it is to become the Architectural College for the

Metropolis, must ultimately be prepared to give instruction in all the subjects of study in this programme. But at the outset it appears to be an arduous task for it to collect competent instructors and to start classes in all the branches which are enumerated. There is not the smallest doubt that arrangements could be made to utilise existing institutions, as, for example, this college for the Association students, so that they might take up some of these subjects under existing teachers, while others might be from the first taken at Conduit-street.

It happens to be the intention to go over all the subjects of the Institute's intermediate examination in the first two years of attendance, and those of the final one in the second two years. Students of the first two years standing are to attend classes or studio three evenings a week for three hours each evening, and those of third and fourth years' standing are to attend three evenings one week and four the other. All students would on one evening have two consecutive lectures or classes of one and a half hours each, which seems to put a strain upon them, and once a fortnight the third years' students are to have two such evenings. This, if the scheme is carried out, may, I hope, be considered open to revision; an hour and a half is too long a period for a lecture, though it may not be for a class, and the advantage of two such attendances immediately succeeding each other appears to me very doubtful.

Rightly, perhaps, the Report lays stress upon the fact that the Institute programme does not comprise all that a student of architecture ought to study, but it may be open to doubt whether the subjects outside that programme do not serve to overweight the course, already very arduous, set before the students in the curriculum.

And it seems open to question whether all these should not be more distinctly set aside as *extra subjects*, both as to position in the programme of education and as to their place in the distribution of time. If, for example, the alternate Fridays on which the Association does not hold its ordinary meeting were, throughout the four years for which the course lasts, devoted to lectures and meetings of classes on the extra subjects, there would be as many evenings given to them as are now proposed (studio work excepted), and they would be more distinctly set apart than they are. I am quite aware that considerations can be urged against this proposal, but being thoroughly convinced that the programme as it is is too full, I throw this out as a suggestion, for what it may be worth, as a way to lighten it without entirely removing any subject from the list.

Having now indulged in some criticism, let me turn to the more pleasant task of pointing out that this curriculum is in many ways an admirable statement of the subjects which students ought to become familiar with; that it has arranged them very intelligently, and stated them with much clearness, and that it forms a very good statement of what may be definitely included under technical education for architects. I need not add that it must be supplemented by practical education. It is in its very nature a programme drawn up for the use of students who are every day and all day long practically engaged in professional work, and to such men, if they are resolute enough and in the enjoyment of sufficient vigour and sufficiently good health, to work with a will through the number of hours devoted to study, it offers many advantages.

Of course, the actual success of this or any effort depends mainly on personal considerations—the resolution and abilities of the students; the aptitude and attainments of the teachers; and I know that those who drew out this scheme have not been unmindful of the fact that young men have only a certain amount of learning power left after a day's work,—properly done,—and of that other fact that men of cultivation who are apt to teach and willing to accept what must necessarily be a modest remuneration for teaching are not very easy to find. One other sort of person will, I think, also be required, though no hint of him or his office is included in the report, and that is a kind of general superintending and advising head, who shall be able to give counsel, direction, sympathy, and encouragement to all the students, and to all the instructors.

With very sincere good wishes for the prosperity of this new departure at the Archi-

teetural Association when it actually, after due discussion, gets into working trim, I pass on to consider what those can do who are rather differently circumstanced.

In a very considerable number of cases the men who propose to become architects are in sufficiently easy circumstances, or are fortunate in having friends able and willing to allow them sufficient time and to do for them whatever may be best to procure them an education that will fit them for the higher walks of their proposed career, and incidentally for passing the examinations, with a notice of which this paper opened. Such men, coming either from a good school or from college, are particularly well prepared to benefit by work in a collegiate institution like the one within whose walls we are met; and if they can have one session, or in some cases two, at University College, London, and can occupy their time in receiving technical education here, they will no doubt be far better fitted for taking advantage of the professional training that will follow than they could otherwise be.

We know the subjects. Let us see how a man with a year to devote to them might here take them up. Generally, I should like to say, the student in any classes which he attends here will find the Professors to be men who have been carefully selected as men of high standing and reputation, well acquainted with their subjects, in many cases highly distinguished in them, and in not a few cases, also, their fellow-students will be the men from among whom the eminent practical workers of the next generation will rise, men who come here from institutions where they have had an excellent preliminary training, bringing with them habits of study and good elementary information, and whom it is a great advantage to have as fellow-students. Nor are the fine library and the general organization of the whole place for purposes of study to be overlooked. They form, in fact, elements of great value in estimating the use of such a College as this to the students who frequent it.

The subjects which students with a year at their disposal ought to take up will vary with the progress they have already made, but Elementary Mathematics and Applied Mathematics and Mechanics (especially the graphical methods of calculation), will in almost every case be subjects which should be carried further than ordinary teaching takes them, and the junior course in each of these subjects, as conducted by Professor Hill and Professor Karl Pearson, should, generally speaking, be attended, including in this Professor Pearson's Drawing Class. I have very little doubt, however, that in not a few cases the student may come so modestly equipped with mathematical training, that the lower junior class—which takes up arithmetic, algebra, and geometry, and covers the subjects of the Matriculation Examination of the University of London—will be the one which they should attend. These would cover Mensuration.

Elementary Physics are the subject of a separate course; and land surveying and levelling form the subject of a course of practical instruction given by Professor Vernon Harcourt. This amount of instruction would supply the mathematical knowledge required for passing either of the examinations, and desirable in actual practice.

Sanitary Science, a subject essential for practice and for examination, is taught here by Dr. Corfield, the Professor of Hygiene, a man who deservedly holds a high position as an authority on this subject. It is manifestly wrong that a man whose profession it is to design and erect houses, schools, hospitals, and all other sorts of places where men and women are to reside and work, should be in any respect deficient in acquaintance with the laws of health, and the plans to be followed and the precautions to be observed in rendering buildings safe and salubrious, and in correcting defects in old buildings. The very existence of the distinct profession of a sanitary engineer, is something of a reproach to the architectural profession.

Elementary Chemistry and Geology are subjects intimately connected with the architect's work, and for the study of which in this College provision is well made. These are not set down as examination subjects at the Institute, but they are most desirable to know, and, of course, whenever the honours examination is instituted, they will form some at any rate of the subjects of examination.\*

\* We will give the conclusion of this paper next week.

### A TRIUMPHAL ARCH AT TIMEGAD, ALGERIA.

HERE are few spots in Algeria which possess a greater interest to the architect than the site of the Roman city of Thamugas, better known by its modern name of Timegad. Of its history, like other cities and towns in this great Roman colony, we have but little knowledge, except what can be gathered from the numerous inscribed stones that lie scattered in every direction over a large area of ground. In the Itinerary of Antonine it is called Tamugada, and Ptolemy, the geographer, speaks of it as Thamutuda. In later times it is mentioned as Thamugas, and as it became in the fourth century the seat of a religious agitation the names of several bishops of Thamugas frequently appear in early Christian writings. When Solomon, the Byzantine general, arrived at the gates in 535 he found the city in ruins, so we may assume that, with the fall of the Roman Empire, Thamugas shared the fate of other towns in North Africa, and became a prey to the horde of Vandals who swept across the country early in the fifth century, carrying nothing but fire and destruction, and leaving behind them blackened masses of stone and brick. The ruins cover a large surface of undulating ground, forming the lower northern slopes of the Aurès range, and, owing to the excellence of the building materials, and the use of a good deal of hard blue limestone as well as of marble, decay is little noticeable in many of the overthrown blocks and votive monuments. The Forum, which was partly unearthed a few years ago, still retains its original paving, and the bases of the shafts forming the internal and external colonnades are many of them undisturbed. The Theatre, now buried in 16 ft. of earth, the walls of the Basilica, the overthrown Temple of the time of Valens, dedicated to Jupiter Capitolinus, and of gigantic proportions, are sufficient to give an idea of the rich field for research still awaiting the spade of the explorer.

The most important of the monumental remains is a triumphal arch occupying a prominent position on the north-west side of the town, and visible from the plain below at a distance of several miles. Its present ruined condition is apparently due to an earthquake, evidenced by the position of some of the blocks in the upper part of the structure. The attic, with the dedicatory inscription, has been overthrown, but several fragments restored by M. Leon Renier leave no room for doubt that the arch was dedicated to Trajan by the 3rd Augustan legion, whose headquarters were at Lambœsis, some twelve miles distant from Thamugas in a westerly direction. The mass of the structure is of sandstone, but the columns and all the decorative features are entirely of white marble, and there are indications of the attic having been faced with slabs of the same material. The drawing, which is here reproduced, was made on the south-west side, to avoid the glare of the sun when sitting in an opposite direction; but, by comparing it with a sketch by Bruce in 1765,\* it will be seen that the eastern side is in far better preservation, and the main features of the composition are more easily studied. The podium of the monument is almost buried in sand, but a few apertures between the fallen masses reveal not only the base of the structure, but parts of the original paved roadway. The arch itself, as shown in the restoration here given, had the usual features common to similar memorials that recorded the beneficence of an Emperor or marked the victories of a great people. Exception may be taken to the broken pediments as a debased feature in classic composition, but it must be admitted that picturesqueness is gained by the use of this doubtful expedient. The subsidiary columns, resting on corbels, which flank the two side recesses, are unusual, and are certainly pleasing to the eye. This arrangement imparts a richness to the monument, which in other respects is devoid of ornamentation. It should be mentioned that the volutes of two of the capitals of the principal order are in the form of eagles. The colonnade in the distance, shown on the drawing, is that of the forum already referred to. Portions of the wall, forming the

\* Travels in the Footsteps of Bruce in Algeria and Tunis. By Sir R. Lambert Playfair. C. Kegan Paul & Co., London, 1877.

fronts of a series of shops, are still standing. The bases of the shafts are undisturbed as well as of the piers and columns of the central gateway.

Thamugas of the Romans must have been a pleasant city to dwell in. The configuration of the surrounding country had many charms. The hills, now rugged and bare, were then clothed with timber. The great plain that stretched far and wide in front of the city, now treeless and unpeopled, was then a garden of productiveness and dotted with the farmsteads and villas of successful colonists. The surface of the soil, now scratched here and there with rude implements of husbandry, was then tended and irrigated, and, owing to its wondrous fertility, helped to fill the granaries and storehouses of Rome. It is piteous to observe so fair a land converted into a desert, and to mark the lamentable results of long centuries of ignorance, neglect, and misrule.

"Strange—that where Nature loved to trace,  
As if for gods, a dwelling place,  
There man, enamour'd of distress,  
Should mar it into wilderness."

ALEX. GRAHAM, F.S.A.

### HOGHTON TOWER, LANCASHIRE.

AMONGST the many historic halls of Lancashire, Houghton Tower undoubtedly takes first rank; indeed, with the exception of Haddon Hall, which it somewhat resembles, there are few Elizabethan halls in the country that can compare with it for picturesqueness. Standing on the top of a well-wooded hill, it forms a conspicuous object from the valleys of the Ribble and Darwen. It is built in the form of double courtyards, the outer one being divided by a raised terrace approached by a flight of semi-circular steps; the inner one, which forms the subject of the sketch, has within recent years been made into a garden with excellent effect. The life-size statue of William III. in the centre is of lead, and was brought from the neighbouring hall of Walton-le-Dale, pulled down in 1831.

After becoming dilapidated, and being abandoned as a residence, Houghton Tower has been judiciously restored under the superintendence of Messrs. Paley & Austin, and is now the residence of Sir Charles de Houghton, Bart.

Houghton Tower is the scene of incidents depicted in Harrison Ainsworth's "Lancashire Witches," and it was here that King James I. is said to have knighted the loin of beef.

The following quaint description is by a local historian, Dr. Kuerden, who wrote about 1650. He says:—

"This tower was built in Queen Elizabeth's reign by one Thos. Houghton, who translated this manor-house, formerly placed below the hill here unto the water side. Betwixt the inward square court and the 2d, was a very tall strong tower or gate-house, which in the late and unhappy Civil Wars was accidentally blown up with powder, and some adjacent buildings, after the surrender thereof, and one Captain Starkey with 200 soldiers were killed in that blast most woefully. The outward is defended with two lesser bastions upon the south-west and north-west corners, besides another placed in the midst betwixt them, now serving for an outward gate-house. The stately fabric is inclosed with a most spacious park, which in former time was so full of timber that a man passing through it could scarce have seen the sun shine at middle of day; but of later days most of it has been destroyed. It was much replenished with wild beasts, as with hoars and bulls of a white and spangled colour, and red deer in plenty; the last as yet preserved for game by the lords thereof."

The drawing by Mr. J. Langham, from which the view is taken, was exhibited at this year's Royal Academy.

### BULLERS WOOD, CHISLEHURST.

THIS house is an old one remodelled entirely. The old house was a fair sized villa, built about thirty years ago. The outside was "Italian," with a uniform covering of grey stucco, relieved by bands, bays, quoins, strings, &c., of painted cement. The roof was of very flat pitch, and covered with blue slates; it was also much cut up.

Where the old walls have been left they have been faced with red brick. The hall, staircase, library, and drawing-room are new, and a new tiled roof and wooden cornice has replaced the old. The new rooms are panelled, and have pattern ceilings and oak floors.

Outside there is a large forecourt on the south, a small one on the north, and a long

terrace on the east, with brick walls and stone steps and balustrades.

The house is lighted throughout by electricity. This is generated on the spot, engines and dynamos being in duplicate. The chief electric fittings are designed by the architect, and made by Messrs. Shirley & Spence, of Rathbone-place.

The builders are Messrs. Arnand & Son, of Bromley; electrician, Mr. Drake (working under Messrs. Lea & Thornbury, of Birmingham); the plumbing was done by Messrs. Mathew Hall & Co.; the windows and casements by Messrs. Wenham & Waters; the hot-water supply by Messrs. Longden & Co.; the ceilings by Messrs. Jackson; floors by Messrs. Arrowsmith; and the wood-carving by Mr. Knox. Mr. Thomas Spooner was clerk of works.

The architect was Mr. Ernest Newton. The drawing from which the illustration is taken was exhibited in the Royal Academy of this year.

**COMPETITION DESIGN FOR SHEFFIELD MUNICIPAL BUILDINGS.**

THE perspective drawing of this picturesque design, by Mr. B. Woodard, was exhibited in the architectural room at the Royal Academy this year.

The designer has not been able to furnish us with a plan, and we give the drawing merely as a specimen of architectural design for a special site.

**DESIGN FOR A COUNTRY HOUSE.**

We do not usually publish designs which, as we take this to be, are for imaginary buildings only; but the geometrical elevation of this was accepted at the last Royal Academy Exhibition as an example of domestic architecture, and we therefore give it a place in our plates, accompanied by the perspective view which further illustrates the design.

Without exhibiting anything strikingly original, the design has the merit of simplicity and suitability for its purpose, and a certain amount of character and expression is given to the exterior by the arrangement of the windows in reference to the apartments they give light to. The placing of the hall and staircase windows shown in the perspective view is especially a good point in the design.

The author is Mr. L. Ambler, architect, of London and Brentford.

**COMPETITIONS.**

**NEW BUILDINGS, SUNDERLAND.**—We are informed that the plans of Mr. T. R. Milburn, A.R.I.B.A., have been chosen by the Sunderland Corporation, in an open competition, for restaurants, shelters, cafés, shops, concert hall, and public cloak-rooms, to be built on the Lower Promenade at Roker.

**WHITEFIELD'S TABERNACLE.**—Professor Roger Smith has issued his report on the designs submitted for the rebuilding of Whitefield's Tabernacle in Tottenham-court-road. The report recommends the design signed "Winged Heart" for the first premium, and that signed "Lux Mundi" for the second. The former is by Mr. F. Boreham, the latter by Mr. J. M. Brydon. Ten designs were sent in.

**ASSOCIATION OF MUNICIPAL AND SANITARY ENGINEERS: VISIT TO EDINBURGH.**

THE Association of Municipal and Sanitary Engineers and Surveyors held a two-days' meeting at Edinburgh on Friday and Saturday of last week, under the chairmanship of their President, Mr. H. P. Boulouis, City Engineer of Liverpool.

On Friday forenoon a meeting was held in the hall, 117, George-street, when two papers were read,—one by the Burgh Engineer of Edinburgh (Mr. Cooper) on "Municipal Work in Edinburgh," and the other by Mr. W. N. Colam on "The Cable Tramways of Edinburgh."

In his paper Mr. Cooper first welcomed the Association to the city, and pointed out how by the formation of County Councils an opportunity was presented for the inauguration of a new era of sanitary work. Passing on to deal with municipal work in Edinburgh, he called attention to several facts to show that the city itself was about to begin a new history. These facts were the completion of the Forth Bridge, by which the city had become an emporium of traffic, and increased railway accommodation had been made necessary; the acquisition of the gas supply, and the intended increase of the horse tramways, the proposed increase of the water supply, and the application to Parliament for powers to better deal with various local matters. As to the municipal work of the recent past and the present, Mr. Cooper explained first the Chambers Improvement scheme, and the system of sanitary administration in relation to infectious disease. On the authority of the Medical Officer of Health it was known, he said, that the zymotic death-rate had decreased from 3.33 per thousand of the population in the period 1870-79 to 1.82 per thousand of the population in the period 1880-89. The Public Health Committee, he also said, had for several years maintained a spirited oversight of the poorer districts of the city, although the mortality and infectious disease statistics showed that there was much yet to be done before all sources of physical, if not moral, deterioration were rooted out. The following particulars would give an idea of the amount of work done in this direction:—Number of uninhabitable houses dealt with during the last five years, 2,000; number of houses closed as being uninhabitable, 1,006; number of tenements of houses where water-closets have been introduced by order of the authorities, 1,100; number of sinks introduced by order of the authorities, 650; number of tenements where the drains and sanitary appliances have been overhauled and put into good order, 3,400; all the work at a cost to the owners of 57,000. He was strongly of opinion that the condition of the slums and poorer districts of a city was a very fair measure of the extent to which its civic rulers and officials were conscientiously alive to their duty. The lines of action followed by Edinburgh, to which he had referred, might not have been pursued so actively as was desirable, but the plan of her action was intelligible, and the results had been so far satisfactory. An experiment had been made with one small

scheme of model dwellings for the very poor, containing some thirty-three houses, with rentals from 6*l.* 10*s.* to 9*l.* It was situated in the West Port, a district where such accommodation was much required, but the cost of acquiring the site had handicapped the scheme itself, and entirely prohibited any further effort in the same direction. On the question of the duty of a local authority to provide suitable dwellings for the poor, there was in Edinburgh considerable diversity of opinion, and serious opposition by the Magistrates and Council themselves. The Society would confer a boon upon the citizens should they shed light upon this subject. Mr. Cooper next called attention to the system of inspection of the drainage and sanitary appliances of houses and buildings, and paid a tribute to the Dean of Guild Court work of the late Sir James Gowan, whose memory, he said, inspired them still. He then explained the sewerage system of Edinburgh, mentioning also the new scheme for the purification of the Water of Leith. He afterwards alluded in succession to the roads, streets, pavements, and footpaths, quoting from information supplied by the City Road Surveyor (Mr. Proudfoot), and also to the cleaning of the city. Regarding Princes-street, he said it was likely the whole of that street would be shortly repaved in wood—either beech or red-wood. A stretch of heech-wood paving properly seasoned and cross-cut, 250 yards by 8 yards in width, was laid down last year, and with the exception that it became very slippery during wet, frosty, or muggy weather, and required to be kept exceptionally clean, and occasionally sprinkled with sand or fine gravel, it was giving satisfaction. As to the re-paving of the street, of course the old concrete foundation remained good, reducing the cost of re-paving to that extent; the cost of the beech-wood paving, not including the concrete bottom, was 10*s.* 4*d.* per superficial yard. As regarded wood paving otherwise, he confessed that Edinburgh had never given this kind of paving fair play. At the present time they had only two or three short streets, where noiselessness was of first importance, paved with it. At the beginning of the era of wood paving they did try it on one or two of the busy thoroughfares, but as the wood blocks were simply laid on the original cross-cross wooden boarding, a seven years' trial was deemed sufficient, and they again fell back on the whinstone sets. Mr. Cooper closed by giving a short résumé of the powers as to the formation of streets and the erection of houses which the Corporation proposed to submit for the sanction of Parliament next session.

Mr. Colam, in his paper, first spoke generally of the development of the cable tramway system, and then in detail described the Edinburgh system. He mentioned a number of the facts which were contained in his paper recently read before the British Association.\* Alluding to the question of speed, he said an application had been made to increase the speed from six to eight miles per hour. It seemed manifestly unfair they should not be allowed to increase the speed, because steam tramways were now worked with loads of twenty tons behind them down inclines of 1 in 14, with really practically nothing like the control that the cable car had. The cable car had two complete and distinct sets of brakes in case it was entirely disconnected with the cable. But, assuming that all the brakes were done away with by some extraordinary mishap, the cable itself would act as a brake for the car, and would prevent the car going at a greater speed than the cable. So that if everything were to go, the car could always return to the speed of the cable, which was limited.

A discussion took place on the papers. The speakers were, the Chairman, Mr. de Courcy Meade (Hornsey), Mr. Edward Pritchard (London and Birmingham), Mr. Charles Jones (Ealing), and Mr. Loble (Hanley). Mr. Pritchard, in his remarks, said, with regard to paving, he had read in the *Scottsman*, in a statement from a special correspondent, the announcement that one of the ablest Town Councillors of Edinburgh was devoting his time inquiring into the best means of paving; and he (Mr. Pritchard) noticed some remarkable information in that announcement—information which he before certainly was not in possession of, and he rather hesitated now regarding it. He wished to point out, however, that wood-paving in its best form was a luxurious

paving, but it had not the life that the writer of the *Scotsman* told them it had.

On the motion of the Chairman, seconded by Mr. Meade, a cordial vote of thanks was passed to Mr. Cooper and Mr. Colam for their papers. The vote was suitably acknowledged.

The members afterwards, under the guidance of Mr. Colam, inspected the cable tramways system and depot. They lunched with the Town Council, and in the afternoon visited the Exhibition. In the evening they dined in the Royal Hotel.

On Saturday the party visited the Forth Bridge, and inspected the Craiginny Meadows and the Water of Leith works.

DWELLINGS FOR THE POOR.

THE Rev. Arthur Robins, of Windsor, who has taken such a deep interest in the great question of the better housing of the poor, read a paper on this subject, by the invitation of the Archbishop of York, at the Hull Church Congress on the 30th ult. He proposed to show that "human homes" for the poor can be built so as to pay, and to this end he produced a practical design for working-class dwellings, by Messrs. Knill Freeman & Denison Robins, architects, Newcastle-upon-Tyne. It has always been urged as an excuse for doing nothing that it will never pay to build decent dwellings for the poor. By means of the plans which we publish in our issue of to-day, the Rev. Arthur Robins undertakes to demonstrate that not only is it a Christian duty to give "human homes" to all our poor, but that the duty can be so discharged as to become a remunerative transaction, and that such dwellings can be built so as to produce, at a moderate rental, a very fair return upon the outlay.

THE LONDON COUNTY COUNCIL.

THE London County Council held its first meeting since the Autumn recess on Tuesday last, the Chairman, Sir John Lubbock, presiding.

**Open Spaces in St. Pancras.**—Paragraph 8 of the Parks' Committee's report of July 29, which was adjourned over the recess, was as follows:—"On June 24 last we reported that the Vestry of St. Pancras had asked that a sum of 1,500l. might be voted to them out of the 12,000l. paid by the Midland Railway Company for the acquisition of new or the improvement of existing open spaces in the parish. This sum of 12,000l. was paid by the Railway Company as compensation for a portion of the recreation-ground on the improvement of which the Vestry desire to expend the 1,500l. The improvements consist in the building of a keeper's lodge; the draining of the ground, and the sloping of it towards the adjoining roadway; and providing a greenhouse, urinals, iron gates, new railings, stone steps, &c. We considered that the Council might properly, under the circumstances, make the contribution asked for, and we so reported, but the recommendation was subsequently withdrawn in order that the wording of it might be amended. We now recommend,—

"That the Council, subject to an estimate being submitted to it by the Finance Committee, as required by the statute, do contribute a sum not exceeding 1,500l. towards works of improvement at the recreation-ground in St. Pancras-road, such money to be taken, not out of the rates, but out of the 12,000l. recently received by the Council from the Midland Railway Company, and to be paid to the Vestry on a certificate by the Comptroller and the architect respectively, as to the expenditure of the money and the carrying out of the works."

After a long discussion on an amendment by Councillor Dickinson, who wished to see the money applied to the acquisition of new spaces rather than to the improvement of existing ones, the recommendation was adopted.

**The London Water Supply.**—The consideration of the following report of the Special Committee on the Water Supply had also been deferred from July 29. Councillor Beal now brought up the report, which was as follows:—

"It will be within the recollection of the Council that the General Powers Bill contains a clause for authorising the Council to prosecute and conduct inquiries and negotiations relative to the supply of water, or to companies supplying water, and relative to markets in or near London. The Bill has passed the Commons, and is now in Committee in the Lords. Should it become law, it will be desirable for many reasons to enter upon the inquiries with the least possible delay, and it may even be necessary to commence them before the meeting of the Council after the recess. To enable us to do this it will be necessary for the Council to pass a resolution authorising us to undertake the inquiries, and we therefore submit the following recommendation:—

"That, in the event of the necessary power being given by Parliament, the special Committee on Water Supply and Markets be authorised to prosecute and conduct enquiries and negotiations relative to the supply of water, or to companies supplying water, or relative to markets in or near London, provided that the cost of such enquiries do not exceed the limits imposed by the section authorising such enquiries and negotiations."

Before entering upon the inquiry relating to water, referred to in the preceding paragraph, we think it will be desirable to approach the water companies with a view to ascertaining whether it would be possible for the companies and the Council to make some provisional agreement as to the terms upon which the companies' water undertakings should be transferred to the Council if Parliament gives the necessary authority. If some such arrangement as this were made, it would save great delay and expense, and we think that the Council should endeavour to provisionally agree upon terms with the water companies. We therefore recommend—

"That the Committee be authorised to enter into tentative negotiations with the water companies for the purpose of ascertaining upon what terms the companies will be prepared to dispose of their undertakings to the Council in the event of Parliament empowering the Council to acquire such undertakings."

These recommendations led to a long discussion, but they were eventually adopted, with certain verbal amendments, by 58 votes for to 37 against; majority for, 21.

**The Sewage Question.**—The Main Drainage Committee presented the following report:—  
"Your Committee regret that the report of Sir Benjamin Baker and the Chief Engineer cannot be presented to the Council before the end of the year. Sir Benjamin Baker has been called by other pressing engagements to America, and will not return until early in November. Meanwhile your Committee have received from the Chief Engineer a report stating, on behalf of Sir Benjamin Baker and himself, that it would tend greatly to a more perfect understanding of the case, and greatly to the certainty and accuracy of our recommendations, and to any future action on the part of the Council, if some reliable tidal float experiments could be made in Sea Reach, below the Mucking Light, in the direction of Canvey Island, the Chapman Light, and the Nore, recommending the employment of Mr. C. J. Woods, M.I.C.E., and expressing the opinion that the cost for the required two months' observations would amount in all to about 3000. Your Committee therefore recommend—

"That, subject to an estimate to be submitted to the Council by the Finance Committee as required by the statute, an expenditure not exceeding 3000 be sanctioned for all costs in connexion with making the proposed tidal float experiments in the lower part of the Thames."

"With reference to the new 4-in. cast-iron water main pipes ordered by the Council on June 21 to be laid from the Manor-road, East Ham, to the Barking outfall, an error was made in the Engineer's department in the estimate of length, and your Committee are now informed that an additional sum of 3000, will be necessary to complete the main pipes required. They recommend—

"That, subject to an estimate to be submitted to the Council by the Finance Committee as required by the statute, an expenditure not exceeding 3000 be sanctioned for all costs in connexion with making the proposed tidal float experiments in the lower part of the Thames."

"The resolution, as now moved and adopted, contains the words 'the necessary powers having been,' in lieu of those italicised."

statute, an additional sum of £300 be sanctioned in respect of the cost of the new 4-in. cast-iron main to be laid from the Manor-road, East Ham, to the Barking outfall, for the purpose of conveying a proper supply of water to the works, the work being carried out under the general contract."

"Your Committee have received from several parts of the County of London various complaints of recent flooding, to which in all directions they are giving their best attention. Measures of relief have been already sanctioned by the Council for the repair and enlargement of the Abbey-mills Pumping-station, for the construction of an important relief sewer in Hackney, for new works in connexion with the Isle of Dogs Pumping-station, &c. Among the cases of complaint on the south side of the river is one as to works near the 'White Horse,' in Brixton-road, where some very complicated trough-weirs were built by the Metropolitan Board of Works, with a view of carrying off storm-water from the Effra sewer. Your Committee, upon a report from the Engineer, recommend—

"That, subject to an estimate to be submitted to the Council by the Finance Committee as required by the statute, the expenditure of a sum not exceeding £150 be sanctioned for the proposed alteration, including the removal of these cast-iron troughs and the building of a brickwork weir 35 ft. in length."

"The attention of your Committee has been directed to the necessity of reconstructing the Council's 5 ft. by 4 ft. sewer in Upper North-street, Poplar. The Engineer reports that this sewer, which is about sixty years old, has holes in its invert from 50 ft. to 100 ft. in length, which are about 12 in. below the proper level, and that its bad gradient has, he is informed, long been the cause of much trouble and expense in clearing out the deposit. He states that if the sewer were reconstructed, a fall of about 20 ft. from Northumberland-street, where floodings have been of frequent occurrence, could be obtained, and that considerable relief would doubtless be afforded to the whole district (about 1½ square miles) draining into the sewer. As a remedy, the Engineer reports it would be requisite to construct a new 4 ft. by 2 ft. 8 in. brick sewer in substitution for the existing one in Upper North-street, Poplar, from the Limehouse Canal to the sewer in High-street, Poplar, a distance of about 800 yards, at an estimated cost of about 6,000. Your Committee has considered these reports, and recommend—

"That, subject to an estimate to be submitted to the Council by the Finance Committee, as required by the statute, the execution of the above-mentioned work be sanctioned; that the specification be printed, and that an advertisement be issued inviting tenders for the construction of the proposed sewer."

These recommendations were all agreed to, and after the transaction of a great deal of other business, the Council adjourned.

THE "LITTLE FOUNTAIN" FILTER.

THIS is a form of filter patented by an architect, Mr. Fogarty, the working of which is sufficiently explained by the section. The

The "Little Fountain" Filter.

object is to provide a filter for drinking-water connected with the house service, which requires no filling by hand, the water percolating

upwards under the pressure from the service-pipe, and being always ready for use. The patentee writes:—

"It is a domestic filter, intended for the pantry, and is fixed between two shelves at about 18 in. apart. It is connected to the main water-supply, or to the supply-tank, and gives a constant flow of water. It is intended to obviate the trouble and inconvenience of having to fill the ordinary type of filter, and as the water is kept constantly running, no stagnant water accumulates or remains in the filter,—a too common complaint in other filters. As the filtering media are composed of ordinary wood charcoal and clean silver-sand, it is a simple matter to renew them when required, thus materially lessening the expense, as it is found in practical working that the carbon blocks used in some filters become clogged, and require to be constantly renewed."

Correspondence.

To the Editor of THE BUILDER.

AN "EMPLOYERS' UNION."

SIR,—Referring to a letter in your issue of the 20th ult., signed "Contractors," will you allow me to state that this Association fulfils, as regards builders and contractors, all the requirements of your correspondents?

With reference to the ancillary trades I may mention that since this Association was originally founded, in 1872, the members of these trades, with some few exceptions, have always refused to render us any assistance in times of trial.

I have no doubt that, if proper representations were made to my Committee, they would consider the advisability of admitting the allied trades.

I may also mention that this Association is affiliated to the National Association of Master Builders of Great Britain, as well as some other local Associations in between forty and fifty of the principal towns in the country.

E. S. HENSHAW, Secretary.  
Central Association of Master Builders,  
31 and 32, Bedford-street, Strand,  
London, October 1, 1890.

SIR,—I have been away, so did not before see your number of September 20.

I observe there is no date to the letter signed "Contractors."

Surely, it must be an old letter, written twenty years ago and crept into your columns by mistake.

If your correspondents are English contractors, what could they be about or where do they come from not to have heard of the Central Association of Builders, which was established in 1872 for the purpose proposed by them.

I suppose "Contractors" never heard of the 1872 and 1877 strikes?

October 1, 1890. STANLEY G. BIRD.  
\*\* We read the letter in question with some surprise, but we presumed that the writers, a large and well-known firm, had their own reasons for wishing for a new departure.—E.D.

TRADES UNIONS AND THE BUILDING TRADES.

SIR,—Seeing that considerable prominence has been lately given in the columns of the *Builder* to the sayings and doings of the late Congress of the Trades Union delegates, I am constrained to ask what on earth has the congress, or the unions either, to do with the hulling trades? or, rather, what right have they to assume the authority to speak for those trades when by the utmost stretch of imagination it cannot be said they are in any sense of the word representative of any one particular branch?

Talks, for example, the "Carpenters and Joiners" one of the most important, I should say, as to numbers. I take their own words for it, when I state the union does not represent a tenth part of the whole body.

At a meeting which took place a few Sundays ago on Clapham Common, one of the speakers is reported to have said, when calling upon those present to join the union, "that in London alone there are 30,000 of this class of workmen. Yet there are only 3,000 out of the whole lot that were unionists."

Again, in regard to the bricklayers, of whom it was said many years ago the metropolis contained upwards of thirty thousand, a number which by this time must be considerably augmented, I was informed only a few days ago that, taking all England together, about six thousand were members of the union. Now, without going further, I think it must be admitted that, in relation to the unions,

these two branches may be taken as fairly typical of the remainder.

It may perhaps be said that, if not in point of numbers, the Union is representative in the same way that its members are the élite of the several trades. This I flatly deny, for the proportion of mediocrity, as against superior skill, is, I know, as great inside as outside the Union.

Now, Sir, taking the foregoing statement to be in the main correct, which I maintain it is, I ask am I not justified in my contention, that whatever may be the case with other industries, in so far as concerns the building trades, the union is not representative, and, therefore, has not the slightest claim to arrogate to itself the right to dictate the terms, either as to hours, wages, or methods, by which those trades are to be regulated?

One word more: Mr. Burns himself at the Congress acknowledged that to a million and a half of Unionists, meaning all classes combined, there are seven millions unorganised (*vide Daily Telegraph*, September 5).

Now, while granting to the million and half the full right to combine, to which they are, undoubtedly, entitled—surely, the seven millions have an equal right, if they choose, not to combine. Herein lies the pith of the whole question.

A LOVER OF FAIR PLAY.

#### THE CONVERSION OF TIMBER BY MACHINERY.

SIR,—I agree with the remarks of Mr. S. Worsam in your issue of Sept. 20, that the merits of the band-saw for converting heavy logs are not properly appreciated in your country. Circular saws for breaking down heavy timber, when compared with band-saws used for the same purpose, possess the advantages of a greater out-put, a somewhat lower first cost, and are perhaps a little easier managed. On the other hand, a well-designed and managed band-sawing machine uses much less power and wastes less wood at the same time the cut is cleaner. In converting valuable woods, this waste is a matter of great importance, and even if mill-saws are used, unless it be a single one, the band-saw possesses the advantage of enabling the operator to examine the figure of the wood as the sawing progresses, and, should soundness be detected, the log may be cut into scantling, or be otherwise more usefully converted.

In America, where inserted teeth are largely used, the saws are of much thicker gauge than ours, consequently the saving in power and wood through using a band-saw is correspondingly greater. It may be of interest to your readers to compare the output of circular and band-saws as used in America. The average output of a first-rate circular-saw, cutting pine, may be set down at about 40,000 ft. per day of ten hours, whilst a band-saw in the same time would produce about 30,000 ft. An American authority, in comparing circular and band-saws, says "that the kerf of circular saws averages 5-10 in., and in sawing 1,000 ft. of such boards, 90 lbs. of lumber is lost in dust. The average kerf of the band saw is about 1-12 in., and in sawing the same amount of boards it turns 83 ft. into sawdust. This shows a clear saving of 229 ft. in favour of the band-saw on every 1,000 ft., and on every 1,000,000 ft. of 29,000 ft."—an enormous saving, to say the least. The figures given must, however, be very considerably discounted when applied to this country, as the saws in use here are of much thinner gauge, but supposing a reduction of 50 per cent., and the saving is still very great.

I take it three of the chief reasons for large band-saws falling are the employment of blades of too thick a gauge, and allowing them to run over saw-wheels of small diameter, consequently the arc of contact of the saw and wheel is too acute, and cracks are set up at the roots of the teeth which end in fractures. Another reason is that sufficient attention is not given to guiding and supporting the blade as it enters and leaves the cut, and so enabling it to saw in a true vertical line. The writer has overcome this difficulty in a simple manner, and would have no objection to communicate the plan to anyone especially interested. On a well-constructed machine, good saw-blades may with safety be run considerably quicker than the speed given by Mr. Worsam; but it should be regulated by the diameter of the saw-wheel and the nature of the wood being cut. A short saw running over medium-sized wheels cannot, with safety, be run so fast as a long saw running over large ones by several thousand feet per minute. The diameter of the wheels should be in proportion to the thickness of the log sawn, varying from 6 ft. to 12 ft. diameter, the speed of the saw varying in ratio 5,000 ft. to 10,000 ft. per minute. I have found for all kinds of hand-sawing a thin gauge saw will stand better than a thick one.

M. POWIS BALE,  
Author of "Wood-working Machinery,"  
"Saw-mills," &c.  
Appold street, E.C., September 22, 1890.

#### "A SANITARY NOTE FROM GREENOCK."

SIR,—I shall be obliged if you will permit me a little space to answer Mr. Buchan's letter in your last issue, wherein he criticises some remarks in my former letter to you.

Mr. Buchan seems to consider the chief object of a syphon to be to exclude rats from a house drain. If this be so I agree with him that its answer to his purpose is fairly well, but I fail to see that this is a matter of importance, because rats cannot do any harm to the drain, and from one which is properly constructed they cannot get out into the house. Rats do not much frequent pipes where they can get into a brick sewer.

I am sorry that Mr. Buchan should not believe that the air in sewers is less impure than in house-drains in most cases, but as a matter of fact it is so. The flow in sewers is continuous, as I pointed out in my previous letter, consequently the soil is always covered with water and moving forward; in a house-drain it seldom happens that one discharge of a closet will put the solid matter into the sewer, the water runs away, leaving the soil in the drain, the next discharge taking it a little further, and, if the drain be a short one, perhaps into the sewer; if not, it may wait for a third or fourth flush of water, but suppose no sink or bath water to have been used between these times there will be several deposits of soil left uncovered by water in the house-drain. This is principally due to the use of water-waives, preventing the soil from being washed down.

As to Mr. Buchan's idea of fever being communicated from one house to another, I see no fear of this, the quantity of water used in a sewer being sufficient to keep fever germs under; moreover, when there is no intercepting trap or syphon between the house drain and sewer, the sewer having a proper trap, and all stack pipes discharging on trapped open receivers, and the soil-pipe being ventilated, there would be no danger of fever germs entering the house from the drain.

I am still of opinion that the air in a house-drain—disconnected from the sewer by a syphon and with the fresh air in it carefully excluded from the house—is practically at a standstill. What effect does temperature have on this drain? It is like the letter U, both extremities being brought up to the same level, they are in the same temperature and pressure of atmosphere. Many people who, to use Mr. Buchan's words, "ought to know better," entertain the most ridiculous theories as to the question of sewer ventilation. No doubt many of these theories are mathematically correct, but unfortunately they do not obtain in practice, and it is no use basing a system of drainage on theory without practical knowledge. Regarding cows, I have no faith in them. As they are dependent on wind for their action they are worse than useless when the wind is not sufficient to work them, and when there is much wind they are least wanted, as the current of air in sewers is always greatest when the wind is high.

ERNEST VAN PUTEN,  
Assoc. Memb. Inst. C.E.

Levisham, September 27, 1890.

#### "DANGEROUS ADVERTISEMENTS."

SIR,—The question raised by your correspondent, "An Architect," is a very important one both for the architectural profession and the public.

An architect often feels aggrieved when he is ordered to set back his window-frames, or to do a small moulding, with, perhaps, a 2 in. projection, because it is within 4½ in. of the face of the wall; but, on reflection, he knows that in making such a requisition the District Surveyor is only doing his duty. It is a matter for surprise, however, when he finds his next door neighbour is allowed to cover his whole house with match-boarding, and then proceed to deface it with advertisements, which are both hideous and dangerous, or perhaps, which is nearly as bad, to cover the space from the head of one window to the sill of the next with wooden notice boards, the whole width of his front, setting forth in huge letters his name and the merits of his various wares.

Surely there must be something wrong either in the Act or its application to allow such a state of things as this to continue.

I have heard district surveyors urge that on attempting to deal with this class of advertisement they are at once met with the reply that "they are only temporary erections," or that "they are not a part of the building, and consequently exempt"; but I would not be surprised if, in some cases even, had been carried to the superior courts, and, if not, should not the district surveyors combine together to do so, for the purpose of having a definite pronouncement from the judges on the question?

Surely it cannot be maintained that boardings such as your correspondent speaks of, which are put up and maintained for the purpose of producing a yearly rental,—and do produce a very large rental,—are temporary erections! A notice that a house is to let or a hoarding round a new building are clearly temporary by the very nature of things; but such boardings as one now sees on the face of buildings in or near important thoroughfares all over the metropolis are in quite a different category.

Then, again, to contend that notice-boards, which are so freely plastered over the fronts of buildings in all directions, are not part of the building when they are fixed to it by iron holdfasts is manifestly absurd. A tenant erects some fitting for his own convenience inside his house and fixes it to the walls; this is held to be part of the house and

becomes his landlord's property at the termination of his lease, unless otherwise agreed. In what respect does a fitting fixed outside the house, also for the tenant's convenience, differ from that inside? Surely this must also be part of the building.

The matter resolves itself into this:—Are these notice boards and advertisement boardings infringements of the fourteenth section of the Building Act or are they not? If they are, why is the law not enforced? If they are not, should not representations on the subject be made to the County Council to induce them to take steps to amend the Act?

"ANOTHER ARCHITECT."  
London, September 27, 1890.

#### WHITEFIELD TABERNACLE COMPETITION.

SIR,—From the report of Professor Smith, the assessor in this case, he appears to have given the first premium to a design, "Winged Heart," which has exceeded the frontage to Tottenham Court-road by some 6 ft. above what was shown by figures on the site plan issued to competitors. As one who kept strictly to those figures I should like to know by what authority "Winged Heart" adopted a greater frontage. The assessor also states that "Lux Mundi" has done the same thing, which he notices "with regret, but thinks it does not infringe the spirit of the instructions;" and, in commenting on "Hearing and Seeing," he speaks of it as having encroached upon the site land for steps and areas. This seems contradictory, as he sanctions it in the two designs referred to.

Every one knows that where figured dimensions are given they are to be adhered to, unless competitors are told to check them, of which nothing was said in these instructions; and we all know, in a restricted site, how an extra 6 ft. makes all the difference in planning; and in this case it was assumed that in fixing the dimensions the Committee had some special reason for not giving what may, or may not, be the actual available frontage. I therefore protest against the award, solely on the above grounds, and maintain that "Winged Heart" was disqualified, and that the premiums should have been awarded to the two best designs which had adhered to the instructions.

A COMPETITOR.

#### SCALE RULES FOR ORDNANCE MAPS.

SIR,—The use of Ordnance maps has now become so general that it would be a great boon if the mathematical instrument-makers made a pocket rule, on the inside bevelled edges of which were 1 in. and 2 in. to a mile, and the also some other. This arrangement would occupy one side of the rule, and the other could be utilised by the most commonly used scales—viz., 1, 1/2, 2, 3, and 1 in.

Should chain scales be needed, they could be placed on the flat part of the rule, or on the edge at the back of the bevelled ones.

The great need, however, is the handy reference to the "Ordnance scales" in the pocket rule.

JAMES JERMAN, F.R.I.B.A.

#### The Student's Column.

##### HOT-WATER SUPPLY.—XIV.

COVERING PIPES AND RESERVOIRS FOR THE CONSERVATION OF HEAT (continued).

**METHOD** sometimes adopted for covering outside pipes is to run them within a larger pipe, such as is used for rain water, filling in the intervening space with sand or some other material. This plan is neat and convenient in the first instance, but it is very disadvantageous should a leakage occur, when it becomes necessary to displace most of the large pipes, or to break out one of the lengths.

There are various materials in the market prepared and sold expressly for covering heated surfaces to prevent radiation and loss of heat; these generally take the form of a cement, and are largely used for coating steam-boilers and tubes in which conservation of heat is so very necessary; but these materials have not been taken to at all favourably by hot-water engineers. No doubt the chief reason is that they are a little difficult of application compared with felt and some other substances, and with these latter there is less trouble occasioned should it be necessary to expose and afterwards re-cover the pipes.

There is a material deserving of special mention on account of its excellent qualities, and which is used alike by steam and hot-water engineers. This is "slag wool," a material obtained as a waste product from blast furnaces; it is a fine, soft, woolly substance, and an ex-

Our correspondent is mistaken; the words quoted from the report refer to the design signed "Red Cross."

cellent non-conductor of heat, as it is wholly composed of glass (silica). For packing pipe cases it equals hair, and its cost is very reasonable, being about 12s. per cwt.

Asbestos is, of course, a suitable material for the purpose under discussion, but it is little used in hot-water work, probably on account of its cost.

Sand, where it can be used, is also a poor conductor of heat, as this is chiefly composed of silica, the same as slag wool; but it is not so easy of application as this latter material, which is a woolly glass.

CONVERSION OF A TANK APPARATUS TO THE CYLINDER SYSTEM.

It very frequently happens that when any extensive repair is being carried out, or from some other such cause, it is thought desirable to convert an old apparatus to a more modern system, and the change can usually be effected without very great expense, that is to say, at considerably less expense than erecting a new apparatus.

FIG. 28.

The most usual method, when circumstances will allow, is to utilise the existing flow and return pipes of the tank system for the rising main and cold supply to the cylinder, respectively. Fig. 28 shows a small, ordinary style of tank apparatus, and fig. 29 shows the same

FIG. 29.

apparatus converted. It will be seen that the conversion requires the removal of the tank entirely by this method. The flow-pipe which entered the tank has to be continued up to above the level of the cold-water cistern; the cold supply service which was carried into the tank must be connected on to what was the return pipe, and this completes the alteration at the top of the house. In or near the kitchen the original flow and return services have to be cut, and the cylinder inserted as shown, the flow and return from the boiler being connected

into the cylinder in the usual way, the continuation of the flow-pipe has to be connected into the cylinder at the top to form the rising main service, and, lastly, the lower extremity of the cut return pipe (which is now connected with the cold-water cistern at the top of the house) has to be carried into the bottom of the cylinder, forming the cold supply. The stop cock in this service, which we have left at the top of the house, can, of course, remain there, but it is much better to bring it down close to the cylinder, so that when a workman has to use it there is no occasion for him to traverse the house three or four times, certainly twice.

The alteration at the top of the house can be lessened if desired by the non-removal of the tank, this article being left to increase the cold water supply; in this case the only change to be effected at the top of the house is to convert the flow-pipe into a rising main carried to above the level of the cold cistern, as Fig. 30.

FIG. 30.

It will be noticed that the conversion described (Fig. 29) does not provide for the rising main being returned; this, if it is necessary, must be a distinct and new service, and it becomes a necessity should there be any draw-off services that were "returned"; as otherwise there will be no service-pipe to return them into. This brings to notice the only disadvantage of the cylinder system, which is that a good and complete apparatus has to have three pipes down the house, whereas the tank system needs only two; but after all the difference is not so very great, as the pipes above the cylinder

FIG. 31.

do not require to be so large as the flow and return of a tank apparatus.

Sometimes the conversion can be effected without interfering with the tank at all, but the circumstances have to be rather special. As an instance, let it be supposed that the existing tank system which is to be converted has a tank, say 25 or 30 gallons, which has proved to be rather insufficient for the demand;

or supposing the demand for hot water has increased and a larger kitchen range or a larger boiler is being introduced, then in either of these instances, instead of taking away the tank, it can be allowed to remain and a small-sized cylinder inserted below, as Fig. 31, it being arranged for the contents of tank and cylinder together to be, say, 55 to 60 gallons, if the range is of fair size, or according to the general requirements.

This arrangement can be but seldom resorted to, as most usually the tank will be found of ample size, and capable of fulfilling the demand, in which case to insert an additional reservoir would in all probability be more than the boiler could heat successfully, and a limited success in this work may be considered a failure.

The illustration shows exactly what is necessary in a conversion of this character. There is no alteration whatever needed in the upper part of the house, except that it must be seen that the flow-pipe in the tank terminates in a high position, say, within 3 in. or 4 in. of the top, and not on any account near the bottom of it. The insertion of the cylinder below differs a little from the arrangement last explained, as will be seen by comparing the two illustrations, as the original return-pipe still remains a return-pipe, and instead of being connected high up into the side of the cylinder, it must be brought in at or near the bottom, as we cannot look for much hot water in this pipe, and it must be kept away from the draw-off services accordingly.

The following diagram, fig. 27, was inadvertently omitted from its proper place in the last of these articles (p. 251 ante).

FIG. 27.

GENERAL BUILDING NEWS.

NEW MISSION CHURCH AT LANDORE.—On the 26th ult., Lady Vivian laid the foundation stone of a new mission church at Landore. The building is to be of native stone, rough cast on the outside and plastered to a smooth surface inside, with the chancel arch window and doors of red brick quoins. The nave is to be 60 ft. by 24 ft. 6 in., and is to be entered by a porch. Accommodation is provided for 300, and the contract is for about 6000. The work is to be carried out from the designs and under the superintendence of Messrs. J. Buckley Wilson, F.R.I.B.A., and Glendinning Moxham, architects, Swansea. Messrs. Gustavus Bros. are the builders.

NEW BUILDINGS AT THE MAIDSTONE MUSEUM.—The formal opening of the new Bentlif wing at the Maidstone Museum took place last Monday. The new building has a frontage to the street of 45 ft., and measures 56 ft. from back to front. On the ground-floor are a reference library 31 ft. by 32 ft. and a room 54 ft. by 20 ft., while the floor above contains two galleries for the exhibition of pictures. The floors throughout are fireproof, and are laid with solid oak blocks. The heating is by hot water, supplemented by fire-places. The work has been carried out by Mr. James Clements and Mr. Henry Brennan, under the direction of the architect, Mr. Hubert Bensted, F.R.I.B.A.

NEW SCHOOL HALL, CHINGFORD.—On the 25th ult., a new congregational school hall at Chingford was formally opened. The building has a frontage of 100 ft. to the Buxton-road, and 45 ft. to the Drive, and consists on the ground-floor of a hall 56 ft. long and 29 ft. wide, capable of seating 300 people; two large class-rooms, entrance-hall, and a completely fitted kitchen. The building is faced outside with red bricks and Bath stone dressings, with tiled roofs, and has pointed windows, glazed with lead lights. The hall is warmed by means of Grudy's warm air apparatus. The buildings have been erected from the designs and under the superintendence of Mr. Rowland Plumble, F.R.I.B.A., of London, by Mr. J. F. Sargeant, of Hackney.

ST. THOMAS'S CHURCH, STOURBRIDGE, was opened last week after additional alterations. The architects were Messrs. Cotton & Bidlake, of Birmingham.

**NEW R.C. CHURCH FOR PAISLEY.**—On the 27th ult. the memorial-stone of the new Roman Catholic church being erected at the west end of George street, Paisley, was formally laid by Archbishop Eyre, of Glasgow. The church is in the Gothic style of architecture, and consists internally of nave with aisles, the nave being divided into six bays, separated from the aisles by octagonal pillars. These pillars are of stone from the Giffnock quarries. There are seven three-light windows in the clear-story, and a similar number of windows in each of the aisles. The organ gallery is being erected at the north end of the church, where also will be the baptistry and the confessionals, whilst the vestry-rooms are on the south side, close to the church. The main window of the nave will consist of five lights 30 ft. in height. The church is being built of red stone from Lochartbriggs quarry. Accommodation will be provided for about 300 worshippers, and the cost of the building will be fully 5,000l. The architects are Messrs. Pugin & Pugin, of London.

**RE-OPENING OF ST. MICHAEL'S CHURCH, SOMERTON.**—The ancient parish church of Somerton, after complete restoration, was re-opened on Monday last by the Right Rev. Lord Arthur Charles Hervey, Bishop of the diocese. The whole of the roofs of the nave and aisles have been replaced, the decayed timbers removed, and new wood substituted. The roof of the south aisle has been almost wholly re-tilled; but the major portion of the magnificently-carved nave roof has been retained. The arcades on the sides of the nave and the piers supporting the arches have been rebuilt, and the whole floor of the walls has been thoroughly repaired. The church has been raised to nearly its original height, and covered throughout with a bed of concrete, while upon this solid wood blocks have taken the place of the decayed boards and joists which originally rested on the earth. The old memorial stones in the aisles have been relaid, the gallery has been entirely removed, and an apparatus for heating the church with hot air has been fixed. The ancient ends of the seats in the nave have, as far as possible, been retained; but the seats in the aisles have been modernised. A painted window is placed at the east end of the church at the cost of Colonel Pinney. The chancel has been restored, at a cost of about 700l., by the key rectar (the Earl of Rochester), who employed his own architect and builder, and had the work carried out entirely according to his own ideas. The work of restoration has been carried out at a cost of some 3,500l. by Messrs. Merrick & Sons, of Glastonbury, from the plans of Mr. George Vials.

**RESIDENTIAL FLATS AT KENSINGTON.**—The Commissioners of the Exhibition of 1881 having sold the ground immediately in the rear of the Royal Albert Hall to Messrs. Geo. Newman & Co., of Billiter-street, and Deptford, this firm is now carrying on the site, covering an area of four acres, blocks of residential family flats. The plans for these buildings have been prepared by Mr. F. Hemmings, A.R.I.B.A., of 7, Finchurch-street, E.C. Messrs. Mark Fawcett & Co.'s system of fireproof construction has been adopted for all floors.

**CHURCH RESTORATION AT LYDFORD.**—On the 24th ult., the Church of St. Petrock, Lydford, was re-opened for Divine service by the Lord Bishop of Exeter, after having undergone enlargement and restoration. The church is of the thirteenth century, and the present work of restoration and enlargement was commenced in the year 1888, when the chancel was restored. A vestry has since been built, and also a new north aisle. The roof of the church has been restored, new oak timbers having been used. Under the tower arch a new oak screen has been placed. All the flooring of the church has been laid with solid wood blocks, and the plastering has been removed from the walls, which have been re-pointed internally and externally. The windows have been re-glazed, and new stonework inserted where required. The porch has also been restored and paved with granite. The architect is Mr. S. Hooper, of Hatherleigh, and the contractor Mr. William Petherick, also of Hatherleigh. The general carving in the interior of the church has been effected by Mr. Harry Hems, of Exeter. The cost of the work is 850l.

**NEW WING, SUFFOLK CONVALESCENT HOME, FELIXSTOWE.**—A new wing to this institution has recently been opened. The new erection, which is for women, occupies the western side of the building, and will accommodate thirty patients. The south front on the ground floor is devoted to the sitting-rooms, and the entire north front is occupied by a common dining-room, capable of dining seventy persons. On the north side and in a separate block are the lavatories, sea bath-rooms, &c. The bath-rooms have the inside walls lined in white glazed tiles, with wood block floors. The baths are in porcelain, with hot and cold sea water laid on thereto. On the first and second floors are dormitories, three on either floor, bath-room, lavatory, &c. The facings of the building are in red brick up to the first floor; above this it is weather tiled. The roofs are covered with Broseley tiles. The total cost of the building will be about 3,250l. The work has been executed from Mr. E. F. Bishop's designs and under his supervision, by Mr. Thomas Ward, of Felixstowe.

**NEW R.C. CHURCH AT FORT-AUGUSTUS, N.B.**—The foundation-stone of a new church which is to be erected at the Benedictine Monastery, Fort-Augustus, was recently laid by Archbishop Smith of St. Andrews and Edinburgh. The new building will occupy a commanding site immediately adjoining the monastery, and overlooking Lochness and the river Tarff. Designed in the Early English style of architecture, the new church will be about 500 feet in length, and will be connected with the monastery and college by three cloisters. The Abbey Church will provide accommodation for the celebration of the full services of the church, there being, in addition to the main building, the Lady Chapel, the Chapel of the Blessed Sacrament, twelve small chapels, chapter-room, baptistry, and three sacristies. The pile of buildings will be surmounted by a tower rising to a height of 260 feet. The church will be built of grey granite, with freestone dressings, and the interior throughout, including the groined roof, will be built of Rosebrae stone. The new church is being erected from designs by Messrs. Pugin & Pugin, of London, and is estimated to cost over 60,000l.

**NEW CHURCH FOR PENARTH.**—The foundation-stone of the new All Saints' Church was laid by Lady Windsor some days ago. The site stands in Victoria-road, was presented by Lord Windsor. The new church will be of the Early English style of architecture, providing sitting accommodation for 600 persons, and will consist of a chancel, nave, two side aisles, organ chamber, and vestry. The cost of the structure is estimated at 6,000l. The architect is Mr. Coates Carter, of Cardiff, Mr. Furnell, of Penarth, being the builder.

**CRADLEY CHURCH, WORCESTER.**—It is reported that Cradley Church has been seriously injured by mining operations, and the Mr. J. M. Gibson, architect, of Kidderminster, has been called in to report thereon. It has been found necessary to rebuild vestries and make other alterations.

## SANITARY AND ENGINEERING NEWS.

**CLECKHATON SEWERAGE.**—We are informed that the Local Board of Cleckhaton have called in Mr. W. H. Radford, of Nottingham, as consulting engineer, to report on a scheme of sewerage and sewage-disposal prepared for the Board by Mr. J. C. Haller, of Rotherham. The estimated cost of the scheme is 29,000l.

**WHITCHURCH (SOMERSETSHIRE) SEWERAGE.**—We hear that the Keynsham Rural Sanitary Authority have instructed Mr. A. P. J. Cottorell, C.E., of Bristol, to report upon a scheme of sewerage to the village of Whitchurch, within their district.

**COVENTRY WATER SUPPLY.**—The meeting of the Coventry City Council, on the 23rd ult., was largely occupied with the consideration of the Waterworks Committee's recommendation that Mr. Hawksley, C.E., be instructed to prepare plans and specifications for waterworks at Whitely. The adoption of the report was moved by Mr. Read, who said that while the population of Coventry was increasing, and a water supply of 1,100,000 gallons per day was required, the available quantity fell below the needs. They had Mr. Hawksley's word that in the Whitely Valley was to be found a sufficient supply of good water, and he urged the Council to adopt that eminent engineer's plan and make ample provision for a population of 80,000 or 100,000 persons.—Alderman Maycock seconded the adoption of the report, which was adopted, on a division, by 24 votes to 11.

**PROGRESS OF THE NEW ARTESIAN WELL IN THE CITY OF LONDON.**—With reference to the progress of the work of sinking the artesian well in Petticoat-lane, the acting engineer, on the 23rd ult., reported to the Commissioners of Sewers that during the recess the contractors had not succeeded in removing the substratum of hard stone which was not with, and which was 4 ft. thick. A large staff of men had been employed night and day, and gun-cotton and dynamite had been used, but not efficaciously. The contractors, however, were about to free the well entirely of water, and remove the rock by working on the surface. The depth of well was at present 172 ft., and there was 67 ft. of water in the well. Considering the difficulties of the work, reasonable progress was being made.

**DOCK EXTENSION AT LEITH.**—The Leith Dock Commissioners have, it is reported, been considering proposals for increasing the harbour accommodation at Leith. The schemes suggested involve (1) the reclamation of the shallow foreshores on the east side of the East Pier, and the construction of a dock to the north of the Edinburgh Dock, and (2) the construction of a dock on the west side of the west pier and north of the marine parade, involving the removal from that quarter of the ship-building yards. A modification of the first scheme has been prepared, and is at present under consideration. It involves the deepening of the fairway, and under it there might be made available more dry dock accommodation, which it seems is urgently required. Half a million sterling is mentioned as the probable cost of the new scheme.

**PROPOSED WORKS NEAR BOLTON.**—At the Public Law Offices, Maudslayi-street, Bolton, on Tuesday, Mr. Arnold Taylor, one of the Inspectors for the Local Government Board, held an inquiry into applications by the Rural Sanitary Authority of Bolton Union for sanction to borrow a sum of 4,860l. for defraying the cost of carrying out private street improvements in Great Lever (part of the No. 1 Special Drainage District of the No. 1 Sanitary District of Bolton), and another sum of 400l. for works of sewerage in the rural portion of Ramsbottom, Atherton, the Surveyor to the Authority, in evidence as to the details of the schemes.

**SHIPLEY AND WINDHILL SEWERAGE.**—At a meeting of the Windhill Local Board, on the 21st inst., a letter was read from the Local Government Board, in answer to the application made joint with the Shipley Local Board for the issue of a provisional order constituting Shipley and Windhill two districts, and their reply to the Local Government Board refer to the proposed amalgamation or incorporation of Shipley and Windhill for local government purposes, and state that they defer their decision as to the provisional order pending further information as to the amalgamation question.

**CONTEMPLATED NEW PORT ON THE SOUTH COAST.**—At a meeting of the New Romney Local Commissioners, last week, the subject of the assessment of the railway-station at Littlestone-on-sea was discussed. This railway is worked by the South-Eastern Company, but it was stated that still belongs to the company to whom the Act making the line was originally granted, namely the Appledore, Lydd, and New Romney Railway Company. The Clerk to the Commissioners stated that the South-Eastern Company have decided to acquire the branch railway by purchase, inasmuch as it is in contemplation to run a line of steamboats from Littlestone, which is in the estate of Dungeness. A line of steamers in connection with the Appledore, Lydd, and New Romney Railway Company will be outside the agreement between the South-Eastern and London, Chatham and Dover Companies. Not only does the *South-Eastern Gazette* state that the construction of a large landing-pier has been prepared for the Littlestone Estate Company, who are virtually the proprietors of the branch railway, but the spot where it is to be commenced is marked out, and the proprietors of the Littlestone estate say the pier will be proceeded with next year.

**LECTURES FOR SANITARY OFFICERS.**—Under the auspices of the Sanitary Institute, a course of lectures has been arranged for the special instruction of those desirous of obtaining knowledge of the duties of sanitary officers. The various subjects will be dealt with in a course of sixteen lectures given by well-known authorities, and will be illustrated with diagrams, drawings, and models. The lectures are a continuation of the courses previously held by the Parkes Museum, and it is proposed to repeat the course twice each year, to suit the requirements of persons preparing for the examinations of the Institute. The lectures will comprise the subjects scheduled for these Examination. The first lecture was announced to be delivered by Sir Douglas Galton on Friday, Oct. 3, subject "Ventilation, Warning, and Lighting."

**SEWAGE DISPOSAL.**—We are informed that the Local Board of West Derby have asked Messrs. Bailey, Dantou, & Co., of Palace-chambers, Westminster, to advise them on the question of sewage disposal.

## STAINED GLASS AND DECORATION.

**THE NORTH WINDOW OF DODDINGTON CHURCH** has just been filled with stained glass. The subject selected is the wise man presenting their offerings to the infant Saviour. The window is the work of Messrs. Joseph Bell & Sons, of Collogreen, Bristol.

**MEMORIAL WINDOWS IN CALTON PARISH CHURCH.**—On the 6th ult. were unveiled in Calton Church four stained-glass windows, the gifts of Sir John Neilson Cuthbertson, in memory of his grandfather and grandmother, who, with their family, were members of Calton Church for many years; of the late Mr. David Brown, jun., in memory of his wife and daughter; of Rev. John Murray, minister of the parish, in memory of his father and mother; and of Mr. David Brown, jun., in memory of his mother. The windows were all executed by Mr. Edwards, Hooper & Edwards, Bothwell-street, Glasgow.

**MEMORIAL WINDOW AT ST. GILES'S CATHEDRAL, EDINBURGH.**—A stained-glass window to the memory of the late Mrs. Cameron Lees has just been placed in the nave of St. Giles's Cathedral. The memorial window is that above the session house on the west side of the north transept. It is a three-light one—its division by a transom into an upper and lower half, the compartments of which are filled with figures symbolical of the Christian virtues. In the upper half the figures are those of "Faith," "Hope," and "Charity," and in the lower half of "Truth," "Justice," and "Mercy." The window is stated by the *Scottish* to be by Cottier, of London.

LEWISHAM.—A stained glass window has just been placed in St. Mark's Church, Lewisham. The window consists of three lights, and illustrates the Sermon on the Mount, with architectural canopy work. In the tracery are figures of angels with scrolls. The work was executed by Messrs. Warrington & Co.

BROCKLEY.—Messrs. British & Gilson have in hand a new window for the Lewisham High-road Congregational Church at Brockley, of which they have sent us a lithograph. The design is rather unusual in effect, consisting entirely of conventional foliage design in panels—one long panel with foliated ends in the centre of each light, and a half-panel above and below; in the long panel a scroll is intertwined for the inscription. The lower portion of each light is left plain, with diamond panes, except the border which runs round the whole.

SOUTH KELSEY CHURCH, LINCOLNSHIRE, has just been supplied with two memorial stained-glass windows on either side of the chancel, the gift of Mrs. A. E. Bower, of Nottingham. The designs were designed and executed by Mr. Jno. Duff, London.

WINDOW, HOLY INNOCENTS' CHURCH, FALLOWFIELD.—A new memorial window, which has been placed in Holy Innocents' Church, Fallowfield, to the memory of the late Mr. G. H. Gilliat, was unveiled and dedicated on the 27th ult. The window contains four pictures, illustrative of scenes in the Saviour's life, subsequent to the Resurrection, and completes the series of subjects selected for the windows in the apse of the church. The window has been erected by Messrs. Lavers & Westlake, of London.

NEW BEREDES, ST. MICHAEL'S CHURCH, MAIDSTONE.—On the 27th ult. a new carved oak reredos and fresco painting was unveiled in St. Michael's Church, Maidstone. The design comprises a central recess for the metal cross, and on either side two of the four Evangelists. Over these figures are canopies with delicate traceries and carved crockets, and along the top runs a carved frieze with emblematic designs. In addition to the reredos itself, the remainder of the east wall below the window has been panelled in oak and carved. The reredos was designed by Sir Arthur Blomfield, and executed, as regards the oak carving, by Messrs. Pryer, of West Borough, and as regards the figured panels by Messrs. Heaton, Butler, & Bayne, of London.

FOREIGN AND COLONIAL.

FRANCE.—An exhibition has been organised at Valenciennes, in the rooms of the Hôtel de Ville, of the works of artists born, educated, or residing and working in that arrondissement. It includes more than six hundred works, some of them of remarkable merit.—The Société des Amis des Arts of Valenciennes has opened its thirty-seventh annual exhibition, consisting of over seven hundred works of various classes.—At Royat (Puy de Dôme) a new centre is being built, in keeping with the general arrangement of appointment of this much-frequented southern town.—In the south of France have produced numerous disasters. Among these may be mentioned the wrecking of the railway bridge at Beauchastel, on the Lyons and Nîmes line, and the overthrow of the viaduct of Pont St. Esprit by the flooding of the fine Rhodan.—The partial destruction of the fine viaduct at Lagny, on the same line, and the viaduct, of twenty-nine arches and 48 metres in height, was built in 1843, on the road between Paris and Nîmes.—At Bastelia, Corsica, the statue of the national hero, Sampiero Corso, has been inaugurated. The statue is the work of M. Vital Dubray.—An inhabitant of the town of Hilaire has the singular idea of constructing, in the cemetery at that place, a representation of the Eiffel Tower as a monument over the tomb of his parents. It is 17 metres high and surmounted by a cross! On the first platform is a statue of St. Joseph, and on a marble tablet fitted between the four main piers are engraved the names of the persons who have suffered the misfortune to repose under this novel and absurd monument.—At Rambouillet (Seine-et-Oise) the funeral of an eminent French contractor, M. Dallongne, has just taken place. He was well known as one of the ablest and most devoted coadjutors of many eminent Parisian architects. He worked on a great many of the principal buildings erected from 1850 to 1870, notably at the Palais de Justice, the Halles Centrales, the Châtelet Theatre, the National Library, the new Morgue, &c. He was a man of remarkable ability in his business.—It is announced that the Military Engineering Department has decided to pull down the "Porte de France" constructed by Vanban at Belport, and one of the principal curiosities of that town. The people of Belport are strenuously opposing its demolition, rightly valuing it as a most interesting record of the past.—At Saint Servan, near St. Malo, it is stated that the remains of the ancient cathedral of Aleth have been discovered, which was the episcopal seat of Saint Malo, first bishop of that ancient town. The foundations of the building have been discovered, and some of the walls contiguous to the existing chapel of St. Pierre.

BERLIN.—We hear that the greater number of the artists invited by the Chancellor (or, rather, by the Emperor) of Germany to compete in the new "National Monument Competition," before mentioned in our columns, intend to send in a protest about the non-mention of the names of the assessing body (it being feared that William II. wishes to decide the matter according to his own and Professor Begg's ideas), and, if it comes to extremes, to send in refusals to the invitation.

PALERMO.—The provisional buildings to be erected on the extensive grounds which will be occupied by the Italian National Exhibition in the winter of 1891 have been taken in hand. On a corner position of the grounds (situated near the Porta Maqueda) there will soon rise the main building, which will contain the large central hall, machinery hall, and manufactured goods section. This building will have a main frontage of 258 metres, with a depth of 80 metres. The style chosen is the so-called "Norman-Sicilian." The cost has been estimated at 521,000 lire, the construction being of iron and wood. The "Fine-arts Pavilion" will soon be commenced, this erection measuring 130 metres by 70 metres, and being in a light Italian Renaissance style. The architect in charge is Professor Ernesto Basile. The opening of the exhibition is to take place on November 1, 1891.

NATURAL GAS GETTING SHORT IN AMERICA.—"Industries" says that at the recent meeting of the Indianapolis Association for the Advancement of Science, Professor Orton, the Ohio geologist, in discussing the probability of exhaustion of the supply of natural gas, said that the supply is not only exhaustible, but is rapidly and surely vanishing. He stresses the imperative necessity of cities and states taking action to restrict wasteful use of gas, but even the strictest regulations, he says, cannot prevent the exhaustion of the supply in a few years. Within a week comes the report of a shortage of gas more general than any previous one. At Jones & Laughlin's American Iron Works, at Pittsburgh, the men are not making full time, and at the Republic Iron Works the gas supply is short. People using their own wells are also feeling the shortage. Officials of the gas companies will not admit that the supply is in danger of exhaustion, but it is the opinion of many competent judges that Pittsburgh manufacturers will soon have to use manufactured gas, or return to the use of coal.

MISCELLANEOUS.

ECCLESIASTICAL ART EXHIBITION AT HULL.—In connexion with the Church Congress, which is being held this week at Hull, an ecclesiastical art exhibition has been held, including a loan collection of nearly 600 exhibits. Church plates, which have for many years past formed a prominent object at these exhibitions, was represented by the communion vessels from Holy Trinity and St. Mary's, Hull; St. Mary's, Beverley; Preston-in-Holderess; Burton Agnes; St. Michael-the-Belfry, York; Swine; Gaisborough; Mr. Franks lent a collection of rubbings of monumental brasses, and Mr. Peck also contributed ancient examples from their collections. Local ecclesiology was represented by a number of drawings, engravings, and books, having reference to the churches and monastic remains of the neighbourhood, which abounds in interesting antiquarian associations. Mr. Franks lent a collection of rubbings of monumental brasses, and Mr. Peck also contributed examples of the same kind.

ROYAL VICTORIA HALL, WATERLOO BRIDGE-ROAD, S.E.—The autumn series of lectures at the above Hall commenced with the first of two "People's Lectures" (under the auspices of the London Society for the Extension of University Teaching), by Mr. J. D. McClure, on "Nebulæ," on Tuesday last. Next Tuesday Mr. McClure will lecture on "The Sun." The arrangements for lectures during the rest of the month are as follows:—Oct. 14, "Bees as Florists and Fruit-producers," by the Rev. Prof. Cheshire. Oct. 21, "The Colours of Animals and their uses," by Dr. W. D. Halliburton. Oct. 28, "Mountaineering," by Mr. H. G. Willink.

THE SURVEYORS' INSTITUTION has just announced that the next Preliminary Examination for the admission of students will be held on Wednesday and Thursday, January 21 and 22, 1891. It is proposed to examine candidates from the counties of Lancashire, Cheshire, Yorkshire, Durham, Cumberland, Westmorland, and Northumberland, at Manchester. Candidates from other parts in England and Wales will be examined in London. Notice is also given that the next Annual Professional Examinations for Land Agents, Valuers, and Building Surveyors (held under the provisions of the Charter and qualifying for the Fellowship and Associateship of the Institution) will commence on March 16, 1891. Candidates for the Professional Examinations will be examined in London only. All particulars as to days, subjects, course of examination, prizes, and scholarships can be obtained of the Secretary. Notice is also given that the next Special-Certificate Examinations (for members) in Forestry, Sanitary Science, and Land Surveying and Levelling, will be held on Tuesday, Wednesday, and Thursday, June 16, 17, and 18, 1891.

ARCHITECTURE AT UNIVERSITY COLLEGE, LONDON.—We have received the programme of the classes for the study of Architecture, Construction, and Modern Practice, conducted by Professor H. Roger Smith, F.R.I.B.A., at University College, for session 1890-91. Three courses of lectures are given. Course A, on Architecture as a Fine Art, treated historically, consists of thirty lectures, delivered every Tuesday evening from 6 to 7.10; first lecture, Tuesday, October 7. Course B, on Architecture as a Science or Constructive Art, consists of thirty lectures, divided into three terms of ten lectures each, delivered every Wednesday evening from 6 to 7.10; first lecture, Wednesday, October 8. Course C, on Modern Practice, consists of eight or ten lectures in the first or Christmas term, delivered every Monday evening from 6 to 7.15; first lecture, Monday, October 6. Examinations will take place, and at the end of the session the following prizes and certificates will be awarded should the work done by the students at the final examination be of sufficient merit. For the best answers in either A or B, the Domitian Silver Medal; for the second best, a prize of books. For the best set of sketches, illustrative of the work of either course, a prize of books. For the best answers to questions in Modern Practice, a prize of books. Certificates of first, second, and third-class rank will also be given to those students who may merit them by the general excellence of their answers to questions set in the examination.

BUILDING TRADE WAGES IN JAMAICA.—According to a recent report by the United States Consul at Kingston, Jamaica, on the condition of that island, the working hours in the neighbourhood of Kingston are from 6 a.m. to 5 p.m.; with one hour for breakfast between 11 and 12; on Saturdays from 6 to 11 a.m. In the country this hours vary considerably, but, as a rule, they are from 7 a.m. to 4 p.m., with one hour for breakfast, and the people seldom turn out to work on Saturdays. The average rates of wages paid about Kingston under ordinary circumstances are:—

Table with 2 columns: Trade and daily/weekly rates. Trades include Bricklayers, Carpenters, Joiners, Masons, Painters, Labourers, Hire of mule and cart, Hire of two mules and cart.

Table with 2 columns: Trade and rates per cubic yard or per square. Trades include Breaking road-material, Bricks making and burning, Brickwork (ordinary), Drilling and blasting rock, Excavating and throwing out earth, Excavating and throwing out earth and removing to a distance, Excavating rocks, Painting per coat, Shingling, Walling dry stone, Walling rubble in mortar.

Day labour rates are lower in the country districts, but, after making allowance for shorter hours, the rates remain practically the same for both country and town. In some parts artisans are very scarce, and are getting scarcer every year, and inferior men have to be employed at town prices. Wages have an upward tendency. The foregoing prices do not refer to work on estates, which is paid for at somewhat lower rates.

THE PLUMBERS' COMPANY.—At the Guildhall, on Monday, the officers of the Worshipful Company of Plumbers for the year ensuing were sworn in as follows:—Mr. W. H. Bishop, Master; Mr. Chas. Hudson, Warden; and Mr. Philip Wilkinson, Rentor Warden. Mr. G. C. Sherrin, architect, was elected a Liveryman of the Company. The Court was subsequently entertained at dinner a number of guests, including the Master of the Worshipful Company of Glaziers, and Mr. H. D. Davis, Architect of the City of London School. Sir Philip Magnus, in responding to the toast "Industrial Education," referred to the large increase in the number of students attending the plumbing classes in connexion with the City and Guilds Institute, stating that 569 students presented themselves at the last examinations held by the Institute. He said the Institute welcomed the graded scheme formulated by the Plumbers' Company for the training of plumbers, commencing at the period of their apprenticeship, and providing for examinations at three stages, preliminary, intermediate, and final,—the last entitling successful candidates to enrolment under the rules of the National Registration of Plumbers.

HAMBLETT'S "MARBLE-PORCELAIN" TILES.—This is the name given to a method of preparing floor-tiling shown in a pattern-book sent to us by Mr. J. Hamblett, of Bromwich, which consists in laying surfaces or panels with small tiles about 2 in. square, each tile worked with a mottled face in two or more colours, so that the total effect is that of a random mosaic, the joints being little noticeable amid the irregular colouring. It is not, as the patentee claims, superior to mosaic, but it gives somewhat of the same effect at a probably lower cost.

COMPETITION, CONTRACTS, AND PUBLIC APPOINTMENTS.

Table with columns for Competition and Contracts. Competition section includes 'Plans for New Cemetery' by Melton Mowbray L. B. Contracts section lists various building projects like 'Boardsley Well, &c.', 'York Pavilion', 'Swedish Timber', etc., with columns for nature of work, by whom required, architect/engineer, and tenders to be delivered.

Those marked with an Asterisk (\*) are advertised in this Number. Competition, p. iv. Contracts, pp. iv, vi, and viii. Public Appointments, p. xvi.

LORD HILL'S ESTATES.—The Stanton Estate of Lord Hill of Hawkstone, comprising 1,217 acres, was offered for sale at Shrewsbury, on the 27th ult., in 27 lots. Stanton Farm, 181 acres, with a rental of 3,191l., was withdrawn at 5,000l., and another farm of 135 acres, rent, 2,311l. 16s., met with no bidder. A water corn-mill, having a rental of 65l. 10s., was withdrawn at 1,075l. The freehold estate, the Hazels, comprising 463 acres, was withdrawn at 9,500l., after keen bidding, which rose from 4,000l. The Coolmore Estate of 83 acres was bought by Mr. Corser, of Shrewsbury, for 3,000l. A freehold and fully-licensed house the New Inn, was bought by Mr. W. Hall, brewer, of Wren, for 1,200l. Hilcop Bank Estate, a freehold farm, was withdrawn at 5,000l. Os. 11d.

THE ENGLISH IRON TRADE.—There is no doubt that the crude iron market is still seriously disturbed by the dispute between the Scotch iron masters and their men, but the general market is steady, and there is a considerable business in finished iron and steel. The Glasgow warrant market has been greatly excited, but its tendency, on the whole, has been upwards. Scotch makers' iron is higher in price, but irregular. Middle-borough pig has been somewhat similarly affected, but there is no increase in price compared with last week. The other pig-iron markets are also unsettled, hematite pig being the least disturbed. The demand for finished iron is well maintained, and prices are strong. The enquiry for steel rails and shipbuilding material being better there has been a further stiffening up of values. Many factors both of iron and steel, however, are rather backward in taking orders. Shipbuilders have secured more orders. Engineers continue well employed.—Iron.

SOME PLUMBING NOTES.—The County Council for the West Riding of Yorkshire have passed a resolution to the effect that "No plumbers be engaged on work in connexion with county buildings, except persons daily registered as suggested by the Worshipful Company of Plumbers." At the opening of the winter session of the Manchester Technical School, Mr. John Smeaton, of the Worshipful Company of Plumbers, gave an address in the Lecture-hall on "Plumbing and Sanitary Science." Mr. Smeaton said the Plumbers' Company felt that all plumbers ought to pass a proper period in the workshop, and should pass a certain time in schools such as that at Manchester. The teaching of plumbing should include the arithmetic of the workshop and some knowledge of geometry and drawing. A knowledge of mechanics, of hydraulics in relation to syphons and water gauges, of the properties of heat and the expansion and contraction of metals, of chemistry, the action of the various waters and gases upon his materials, and of machine drawing, was necessary for the plumber, and he should have some slight knowledge of electricity, as well as be thoroughly acquainted with the practical details of his work.—On the 24th ult., in the Domestic Technical Institute, Mr. J. Radcliffe, R.P., member of the Sanitary Institute of Great Britain, and principal teacher of plumbers' work and sanitary engineering at the Manchester Technical School, delivered the opening lecture in the plumbers' classes connected with the Institute. Mr. Radcliffe maintained that a scientific education was necessary for a plumber. He ought to be acquainted with the sciences, especially chemistry, and he ought also to be thoroughly up in mechanics, mathematics, and geometry. Heat was another important science for the plumber. They all knew that water expanded or contracted according to the application of heat or cold respectively, and it was well that the plumber should be acquainted with what would take place in lead work from heat or cold.

CLOCK, TOWN HALL, LOCKERBIE.—The new clock at the Town Hall, Lockerbie, is the gift of Mr. Andrew J. S. Johnston, of Haleshead, and is by Mr. V. W. Hanson, of London. The clock shows the time upon four illuminated dials, 5ft. in diameter.

OXFORD MUSIC-HALL.—An order has been made in Mr. Justice Sterling's Court, Chancery Division, for the sale, under provisions of the late Mr. Morris Robert Syers's will, of the Oxford Music-hall. The property consists of one lot, comprising the music-hall, with the adjoining Nos. 18 and 20, Oxford-street, and the fully-licensed premises known as the "Boar and Castle." The vendors hold these upon a fifty years' lease, of which twenty years, reckoning from last Lady-day, are still unexpired, at ground-rents amounting to 925l. per annum. The hall, with its gallery and boxes, has a total capacity for nearly 1,200 persons. It is said to be one of the first, *au gascon*, to have been established in London. If we remember aright, the premises have been twice destroyed by fire. The "Boar and Castle" tavern represents a posting-house and inn which flourished during the seventeenth century.

LONDON MECHANICAL STUDIO.—At No. 45, Wilson-street, Finsbury-square, E.C., an amateur class-room has been started, where are taught (practically) carpentry, cabinet-making, wood-carving, wood and metal turning, &c. The room is fitted with benches, lathes, and all the necessary tools required. Mr. T. J. Syer is the principal.

SILICHER.—A correspondent of the Times writes:—"A discovery of the greatest interest has just rewarded Mr. St. John Hope and his fellow explorers at Silchester. In one of the houses, the foundations of which have been laid bare, the excavators came across a dry well, which, on being explored, proved quite a little museum of antiquities. Some 15 ft. down the shaft were found a number of shaped pottery vase, about 1 ft. high, quite intact, and, curiously enough, protected by lumps of chalk built around it. The vase, which probably originally contained some precious substance, was, however, quite empty. Above it were deposited a great number of iron implements, most of which were in a wonderful state of preservation. They seem to have been the tools of a carpenter and a cooper-smith or silversmith, with some miscellaneous objects of blacksmith's work thrown in. The principal specimen is a carpenter's plane of quite modern type, although unquestionably more than 1,500 years old, three or four axes, retaining their fine cutting edges and still quite serviceable, a number of chisels and gouges of all shapes and sizes, hammers, adzes, saws, files, &c. In the smith's department may be specified a brazier for burning charcoal, quite complete, two or three anvils of different sizes and shapes, a fine pair of tongs adapted for lifting crucibles, a curious tripod candlestick lamp, or candlestick, and several other curious objects of the precise uses of which have not yet been determined."

MEETINGS.

FRIDAY, OCTOBER 4. Association of Public Sanitary Inspectors.—Annual General Meeting to receive the annual report, &c. (p.m.)

MONDAY, OCTOBER 6. Society of Engineers.—Mr. W. Santo Crisp on "Sewer Ventilation." 7.30 p.m. Clerks of Works' Association (Carpenters' Hall).—Paper by Mr. W. Baker. 8 p.m. Liverpool Architectural Society.—Opening address by the President, Mr. T. Mellard Reade. 7 p.m.

TUESDAY, OCTOBER 7. Sanitary Institute (Lectures for Sanitary Officers).—Mr. H. Law on "Principles of Calculating Areas, Cubic

Space, &c.; Interpretations of Plans and Section. Scale 8 p.m. Institution of Architectural Association.—Mr. H. Milsom on "Greek Architecture." 8 p.m.

FRIDAY, OCTOBER 10. Sanitary Institute (Lectures for Sanitary Officers).—Dr. Gault on "Water Supply, Drinking Water, and Pollution of Water." 8 p.m.

RECENT PATENTS:

ABSTRACTS OF SPECIFICATIONS. 12,737.—WINDOW WEDGES: R. Batey.—The window wedge clamps which are the subject of this invention are made with a wedge-shaped hook; one of these clamps are fixed on each side the window-sash, so that on coming together in shutting at the meeting rails the wedges, by the clamps locking each other. 12,847.—ORNAMENTS AND DECORATING CEILINGS AND WALLS: J. A. Wilson and Another.—For ceilings or walls of buildings, shop fronts, verandahs, &c., gilded or otherwise ornamented, is used in section a contracted iron within an eighth of an inch. This is to allow the water to flush basin, and in the middle the front part of the basin is a flush-hole, which allows the water to enter halfway down the basin and catch the soil away with force. 8,977.—PAYMENT LIGHTS, GLAZED GRATINGS, &c. J. Jacobs.—By this invention lenses are formed in the glass by their peculiar shape; they are used either with or without concave films. 30,809.—VENTILATORS: J. Jones.—This invention relates to that class of ventilators, chimney cowls, &c., which revolve by the wind, and have wings, fans, or sails, inside, to increase the draught up the shaft or chimney. A collecting space is arranged, and the wings are caused to revolve close to the circumference of the tubular shaft. 15,414.—VENTILATORS: P. Whitehead.—It is claimed with regard to these ventilators that the exit air space being greater than usual, and the curbs being specially arranged so as to offer less resistance, the vital air is permitted to escape from the place ventilated with greater facility. NEW APPLICATIONS FOR PATENTS. September 15.—14,535, T. Cooley and W. Elm, Manufacture of White Lead.—14,532, E. Hill, Importing Window Sashes. September 16.—14,597, T. Carr, Window Sashes. 14,622, W. & C. Martin, Convertible Window Sashes. September 18.—14,739, E. Hugh, Disinfecting Closets. Draughts, &c.—14,765, A. Hird and J. Ford, Cassment Sash Windows, &c.—14,766, R. Haddon, Windows with Horizontal Sliding-sashes, and Lock or Fastener, &c.—14,775, A. Glover, Paving Composition. September 19.—14,799, S. Hills, Adjusting the position of Swing Mirrors, Windows, Ventilators, &c.—14,1 J. Sears, Ventilators.—14,830, F. Walton, Accommodating Electric Wires in Buildings. September 20.—14,850, W. Edwards & W. Hibbel, Spring Hinges.—14,853, A. Pomfret, Current Regulator for Ventilation.—14,877, L. & S. Swale, Syphon Clusters for Water-closets, &c.—14,900, B. Brown, Substitute Decorative Tiles for Furniture, &c. PROVISIONAL SPECIFICATIONS ACCEPTED. 3,402, A. von Solemacher-Antweiler, Bricks, Tiles, &c.—7,312, E. Baudry-Diot, Bridges.—10,610, E. Stal, Preventing the Steaming of Shop Windows.—10,9 J. Baker, Locks.—11,568, J. Bircham, Hinged and Movable Ornamental Iron Railings.—11,927, W. Morrison, Door-knob Attachments.—12,107, W. Worsam, Scraper-driver.—12,478, S. Bromhead, Flexible Covering for Water-closets, &c.—12,530, J. H. Brown, Window Fastener.—12,765, L. Gregory, Blocks for Flooring.—12,922, G. Helmore, Window-sash Fasteners.—13, W. Sturmev, Door Locks and Latches.—13, J. T. Hartley, Locks for Doors.—15,661, J. W. Hancock, Clough, Closets, &c.—13,699, F. Perry, Electric Bell Gongs.—13,745, G. Willcock, Fastening for Window-sashes.—13,764, H. Sutcliffe, Lavatory Wash-basins.—13,806, J. Bramley, Ventilating Windows, Latches.—14,133, J. Macdonald, Ventilating Sash Joints or Astragals.

**LUTON.**—For constructing a service water-tank, and providing and laying two cast-iron water mains, at Luton, Bishopscote, Devon, for the Newton Abbot Union Rural Sanitary Authority. Mr. Saml. Segar, surveyor, Union-street, Newton Abbot.—

### The Architectural Exhibition, Turin.

THE first general exhibition of architecture held in Italy was opened at Turin on September 28 last, as incidentally mentioned in our columns. Among the Italian architects a great deal of interest and enthusiasm seems to have been aroused in regard to this exhibition, which has been planned on a very extensive scale, and is regarded in Italy as a demonstration of the achievements and powers of modern Italian architecture; and we might before this have had in our hands more than one account of the exhibition, "written in very choice Italian" and inspired with the glow of patriotic fervour. English readers, however, will be more interested to know how the exhibition appears from an English than from an Italian point of view; and we preferred, therefore, to postpone any detailed comment on the collection till it could be specially visited from England.

Considerable pains have been taken to make the exhibition thoroughly representative of the artistic side, at least, of Italian architecture, both mediæval and modern. The more ancient work of classic times is but slightly shown, with the exception of that of Pompeii. The building in which the exhibition is located is that erected some few years since for the exhibition of Italian painting and sculpture, but the façade has been decorated to make the building especially expressive of its immediate purpose. In the centre of the façade is an Ionic tetrastyle portico, with pediment over, the detail and colouring being Roman, or, more strictly, Pompeian, rather than Greek. The columns, which are without flutes, are painted dusky red for the lower third of their height and yellow above, the capitals being principally white, picked out with red, yellow, and blue; the bases are painted dark green, and the entablature is white with two lines of red on the frieze, and one cyma below it, painted blue. The egg and tongue enrichment and fret on the soffit of the corona are painted only, not carved, the whole of the façade being executed in stucco. Above the pediment rises, slightly in the rear, an attic inscribed in painted letters with the

word "Architettura." The walls flanking the portico are painted dark red, and are quite plain, except the cornice, which continues that of the portico and is similarly treated. At the angles are the words "Ars" and "Labor," one on each side, and a certain amount of decoration is given by two ornamental sockets to support the flag poles; these have as part of their design female winged figures of heroic size, with laurel wreaths and palms of victory. The sockets and figures are boldly and somewhat roughly modelled in stucco, and coloured to imitate bronze.

The plan of the building is simple, and well adapted for the purposes of an art exhibition. Passing through the tetrastyle portico we enter the first of a series of eleven top-lighted galleries; on the right of these, and occasionally communicating, are ten more top-lighted rooms, while on the left are two side-lighted galleries, separated by a central pavilion, which forms the entrance to the grounds, and affords space for a café and restaurant. The exhibition building is in the public gardens on the banks of the Po, in a picturesque situation, and is easily reached by tramcar.

The general arrangement of the exhibition to a considerable extent lacks system and order, the original scheme of the grouping having apparently been interfered with by irregularity in the reception of the various objects exhibited; in fact, some important additions were made during the stay of our special correspondent at Turin. The catalogue, too, is not yet ready; and though advertised to be held for the months of September, October, and November, the opening of the exhibition was only at the end of September, as already mentioned, and it therefore suffers somewhat from the general tardiness.

The original idea of arrangement seems to have been to locate modern Italian architecture in the central range of galleries, excepting the middle one (No. 6), which is devoted to the exhibition of old work, grouped according to the various districts of Italy, and the two end galleries, which were evidently intended to receive examples of internal decoration. The right-hand galleries are mainly devoted to sketches, photographs, and publications; and the left-hand galleries to municipal exhibitions, both native and foreign. The original idea has, however, not been

strictly adhered to, various departments have overflowed into the space of others, while late arrivals have been utilised to fill up gaps, independent of their proper place. Thus, for example, while several of the competition drawings for the Houses of Parliament at Rome are hung together, others are found singly in various parts of the exhibition, rendering comparison naturally somewhat difficult. The galleries are subdivided by screens, to give increased wall space, which is, of course, of the highest importance in an architectural exhibition, and particularly in Italy, where it is the custom to make competition drawings to the large scale of  $\frac{3}{16}$ , even for large monumental buildings, with details to  $\frac{1}{32}$ . The drawings are certainly not spread out, but are, on the contrary, rather crowded, so that many that are hung considerably above the line are not seen to advantage.

After an examination of the works of modern Italian architects, from the drawings and photographs of executed designs, we very forcibly realise the importance attached in Italy to the calling of an engineer and to the scientific side of the profession. An *architetto* is one who has not sufficiently advanced his education to enable him to earn the more honoured title of *ingegnere ed architetto*, which is borne by all leading members of the architectural profession in Italy, and is the aspiration of the architectural student. Hence we see that, in competition designs, the drawings of the foremost men show carefully the ironwork, especially of the construction. This exaltation of the engineer probably accounts in a considerable degree for one of the predominant characteristics of much of modern Italian architecture; the estimation of architectural design as merely the clothing, more or less well fitting as the case may be, of the building, and not, as it should be, the vital essence of the whole structure. The engineering construction is not simply the articulation of the body, but the body itself.

This characteristic is, possibly, also largely developed by two other important factors in the history of modern Italian architecture; first, the extensive use of stucco for the formation of architectural features and decoration, and, second, the intensely eclectic character of modern Italian architectural design. The use of stucco,—in which, it must

he granted, the Italian workmen are experts, both as regards the durability of their workmanship, and their skill in modelling wet plaster *in situ*, naturally leads to dislocation in the construction of the building; first the *ingegnere* designs and superintends the erection of the framework, the walls, floors, and roof; then the *stuccatore*, with the design and superintendence of the *architetto*, clothes the framework with its architectural adornment. Nor does the union of the *ingegnere* and the *architetto* in the same man compensate sufficiently for the mischievous tendency to separate construction and design, which appears so prominent in this exhibition. We must, however, not omit to notice that there is among some of the younger men, especially the students of the Milan School of Architecture, like Sommaruga (whose design, in conjunction with Luigi Broggi, for the new Houses of Parliament in Rome, was illustrated in the *Builder* of the 20th ult.), a manifestation of a more healthy spirit of architectural design. Some of these men are evidently architects, in the best and fullest meaning of the title, and uniting thorough knowledge of construction with that of the vital principles of architecture, produce designs which have that essential unity of conception that can alone be accepted as true architecture. The exceedingly eclectic character of modern Italian architecture surpasses even that of contemporary English work. Not only are different styles adopted by different designers, but in the work of each individual, there is seen, very frequently, an attempt at the expression of architectural ideas in widely dissimilar dialects. Thus, for example, among the drawings exhibited by Gaetano Moretti, of Milan, whose premediated design for the new House of Parliament was also illustrated in the *Builder* of the 20th ult., we find, besides the originals of the design just referred to, a photograph of an executed design for a church façade in the Rococo development of Renaissance usual, known as the Jesuit style, a design for a cemetery in a Byzantine manner, sketches for altars in late Italian Gothic of florid, ornate, and restless character, though exhibiting a great wealth of invention; several sketches for the façade of Milan Cathedral, with photographs of the completed designs, which are, of course, designed to harmonise with the Germano-Italian Gothic of the existing building; several sketches for tombs and mortuary chapels, some Greek, some Renaissance, one in French fourteenth-century Gothic, others in sculpturesque treatment. Moretti also sends designs and photographs of furniture, chiefly in Rococo and Baroco style, but excellent designs for the style, sketches for ewers and paten, showing an ability and versatility of idea that mark the genuine artistic impulse of the man.

Unfortunately, the eclecticism of which we are speaking is not confined to the adoption of various styles for separate designs, but occasionally in the same design we find an attempt to unite features borrowed from various periods, especially of the Renaissance, which too often leads to incongruities that detract from artistic effect. Without yielding entirely to the views of straitlaced and puritanical or academical architectural purists, it is sufficiently obvious that an attempt to combine detail of varied forms of architectural expression requires, if failure is to be avoided, a very nice sense of judgment and fitness in the selection of the component parts,—a sense that, in spite of the inheritance of good taste to which we might suppose the modern Italians were heirs, is occasionally absent in their architectural design. This demerit, however, it is but fair to say, is not universally, or even generally, found in the work of modern Italian architects, especially in that of men of the calibre of Moretti and Sommaruga. Eclecticism of style in Italy appears to be, to a certain extent, limited by a somewhat conventional appropriation of various styles to particular uses; thus, without any rigidity of selection, Greek, Romanesque, or Byzantine appear to be the

favourite styles for cemeteries; Italian Gothic and Romanesque for churches; some form of Mohammedan art for Jewish synagogues; and various phases of Renaissance, according to the individual caprice of the designer, for public buildings, residential and business premises.

Together with eclecticism of design, there are among the modern Italians many varied forms of expression in drawing; the pencil, the pen, and the brush all finding their use in different hands. As compared with modern English draughtsmanship, there is nothing to equal the work of our best men with pen or pencil; the brush, on the other hand, is far more generally and more skillfully used. We may safely say that there is not a single drawing in pen or pencil in the whole exhibition which would give the draughtsman the faintest possible chance in the annual competition for the Soane Medallion or the Association Travelling Studentship; with the brush, however, there are very few of our students who could successfully compete with those of the Milanese school. In competition drawings, perspectives, though occasionally used, are rare; highly and realistically coloured elevations, with shadows accurately projected in the French manner, skies, back-grounds, and accessories taking their place. As compared with French draughtsmanship, the Italian work lacks refinement and delicacy of shading, but has instead very frequently a power and vigour of effect gained by strong contrast and the skilful use of accidental shadow. The varied methods of draughtsmanship in elevations may be thus described:—Drawings in pen-and-ink line entirely, including the shadows and window-openings; this is, to an English eye, very inferior in effect, and is particularly liable to degenerate into scratchiness, or what is, in our student argot, called "flick and dot"; various depths of tone are obtained by the use of ink of varying strength and blackness, but the method can hardly be considered a success, and usually accompanies second-rate design; then pencil-drawings in line, with faint tints of colour for the general surfaces, shadows, and voids; this is usually refined in effect, but frequently looks weak in competition work when opposed to more strongly-executed drawings; this method is often found as the expression of an academical character of design. More strongly-tinted drawings, either over pencil or ink lines, come next; these are finished either in monochrome or polychrome, and form the large majority of competition drawings; those in monochrome are frequently carefully finished, while the polychromatic examples aim rather at a picturesque effect. Lastly, we have the strong forcible methods of the younger men, especially of the Milanese students, in which monochrome or polychrome are handled with an extreme vigour of effect, which might readily descend to vulgarity if used by less consummate artists than Moretti and Sommaruga, and others of their fellow students, whose work we shall have occasion to notice in speaking of students' work. Sketch-designs are usually made in pen and ink or pencil, and never omit to give some indication of the shadows; they are usually made, it appears, with extreme rapidity, aiming at general effect rather than at detail, which is vague and indistinct. By students and the representatives of the older style, sketches are made in elevation for the most part; by many of what we may call the new school, of which the Milanese students are the great examples, sketch designs are made frequently in perspective, though not entirely so. Drawings of old work, made for the purpose of study, by students, are but poorly represented. The careful and thoroughly worked-out measured drawings, which we are accustomed to see in England, are absent. Measured drawings are few and far between, and appear chiefly to have been prepared for the purposes of book-illustration or for official records of historic monuments. Nor are free-hand sketches much more numerous, save for some few instances, such as the excellent

collection by Professor F. Mazzanti, of Rome, chiefly of detail and "bits;" these are mostly in pencil, some in ink slightly tinted, except the examples of coloured decoration, which are, of course, of full strength. Even this example suggests the collection of a professor rather than the studies of a practitioner. Sketching old work must, naturally, appear somewhat of a waste of time to the student, who is deluged with the productions of the enterprising publishers and skilful photographers, who, both native and German, cater so largely for the continental student. That this is the cause of general lack of sketching study of old work is strongly emphasised by the fact that, what the men who do sketch mostly fancy is the early ecclesiastical work, which has been less fully illustrated by publications of phototype and other methods than the Renaissance work of civil and domestic character; hence sketching is the resource of the young church architect, or else is mainly a study of colour, either in decoration or as the accidental effect of time and weather.

Having thus summarised the chief points that command our attention in modern Italian architecture, we shall notice how these are especially exemplified in some of the most important work exhibited, and we shall call attention to the methods of solving some of the various problems daily presented to the profession by our Italian confrères in dealing with the design of edifices for particular purposes.

In an exhibition of professional work of the extent now gathered together at Turin, it must be sufficiently evident that the weaker as well as the stronger side of Italian modern architecture is presented, and we should therefore be careful to select for consideration and criticism, in any attempt to fairly gauge the position of Italy in art, the work of the leading and most prominent men.

As an example of the work of a leading man we may take the design for the new Law Courts at Rome, by Guglielmo Calderini, Professor of Architecture and Construction at the University of Pisa, which is shown in a series of elaborate drawings to the scale of  $\frac{1}{16}$ , which nearly corresponds to our scale of 4 feet to an inch. The principal façade has for its ordonnance three orders, Tuscan, Doric, and Ionic, in successive stages, treated with single columns engaged and planted on the face of wide plasters except to the angle pavilions, where the columns are coupled. At the orders, with their horizontal lines, are continued round the flank and re-elevations, where they enclose two floors, the upper being a mezzanine, the windows of which are omitted on the front, it results that, in the principal front, the windows, which range with those on the flanks and are of similar detail, have above them a blank wall space which appears to crush the openings. In the centre of the composition of the principal front a great arch entirely fills the height of the upper order, and under this are coupled columns, capped with a broken pediment crowned with figures. This use of a gigantic arch for the central feature of a design seems to be a favourite device of modern Italian architects and frequently, indeed usually, spoils the scale of the remainder of the design. An example of the abuse of this feature may be seen in the design of Broggi and Sommaruga for the Houses of Parliament (*Builder*, September 20 last). The detail of the design we are considering shows a good acquaintance with the work of the past, being largely based on the style of Michelangelo and his contemporaries. The side elevations, which embrace two orders only, are decidedly the most pleasing, as here the lower order, which is rusticated throughout, assimilates with the basement, which is also rusticated, to form a substantial substructure for the upper order, which rightly is made the principal in richness and grace of design, without crushing the lower portion of the façade, which holds its own by virtue of its superior height and strength. In the principal front there appears to be no dominant part, and the rusticated portion looks too weak for the

superstructure, an impression which is intensified by the fact that the entablature of the lowest order is cut through to provide the relief given to the large semicircular-headed openings of the entrances, the cornice only being a continuous horizontal line. The rusticated ground-floor assimilates with the basement, and thus looks too high for a subsidiary portion of the design, while at the same time it is too low for a principal story. The angle pavilions, which as before mentioned have coupled columns, are crowned with a blank attic, but neither this nor the blank wall space, owing to the manner of its disposition, are able to give repose to the design, a quality which is lacking throughout, although it should, doubtless, be an essential point in the design of a monumental building of this character. There is also a certain amount of incongruity in the combination of the Late Renaissance detail with the rigid classicism of the orders employed. The elevations are shown in heavily-shaded monochrome of cold brown tint, which, however, does not give the necessary dignity to the drawing. The whole design shows a knowledge of the detail of the past united with a lack of the true principles of design which is, we fear, but too characteristic of much of the work of modern Italian architects.

Another design by Calderini, for the national monument to Victor Emmanuel II, although not submitted in the actual competition, is nevertheless one of the happiest conceptions for this work illustrated in the exhibition. Too many of the designs place the statue of the monarch in an isolated position, with an architectural background too far in the rear; that by Calderini emphasises the statue, and at the same time brings it into connexion with the remainder of the design by setting it in a semicircular-domed apse, treated with a colonnade, which is continued to segmental bays on either side, the whole standing upon an acclivity approached by an imposing flight of steps. The design is spoilt by the introduction of a meaningless range of Corinthian columns, carrying nothing, connected by a band of masonry at about two-thirds the height of the shafts, carved with a weakly-designed ornament of festoons. These columns are intended to mask the exterior of the roof of the semidome, but are evidence of an impatience which did not permit the designer to grapple carefully and successfully with what, it must be granted, is a somewhat difficult problem to solve. Almost any other solution would have been preferable, even to leaving the roof of the dome in its bare simplicity. This design is shown in drawings finished in a warm sepia tint that is highly satisfactory.

The design by Professor Gherardo Rega for the same subject shows the statue in the open with a semicircular colonnade in the rear, reminding us of the colonnade of old Burlington House. The composition is placed upon high ground, approached by numerous steps, and the design is best described by the term "academic."

Another design for the Victor Emmanuel monument, and one which received a silver medal in the competition, is that by Pietro Berti, of Florence. This in the centre has a Roman triumphal arch, closely resembling that those of Constantine and Septimius Severus would be if the side arches were filled with masonry, having statues in front. The centre of the composition is flanked by straight colonnades, with a straight-lined attic over, and stopped by solid pedestals. The attic is sculptured, but is too high for the colonnade on which it is supported. The approach is made by a series of winding and returned steps, and the whole design is less overdone with figures, and is far more satisfactory than the majority, being much quieter and more restful in character. The statue, however, is too much isolated in position. It is remarkable that, among a people so attached to the theatre as the Italians, the designers should have failed to recognise the necessity for an intimate connexion between the scenery and the actor, between the statue of the King and the architectural background.

There are many other designs for this competition exhibited, but the majority follow closely the lines of those by Rega and Berti just described, and a full description of all would be tedious and a waste of space.

We may, however, mention that by L. Boffi, which differs entirely in *motif* from those already mentioned, and is besides one of the best examples of pen and ink drawing in the exhibition. Here the design takes the form of a square central tower, surmounted by a figure of Victory with laurel wreaths, and flanked by wings at a much lower level, decorated with sculptured subjects, the import of which is denoted by the superscription, "Sant. Martino," the famous battle, and "Unita Nazionale," the ever-memorable scene, to Italians, in the Parliament House. The figure of Victor Emmanuel is in the foreground, an equestrian statue, somewhat eclipsed by the monument, which is rather too important to form an appropriate setting or background to the central figure; this latter, indeed, is hardly more than a decorative accessory to the composition, of slightly greater weight than many of the other sculptured emblematical figures. The draughtsmanship is admirable, especially the way in which the sculpture is indicated, and the effective shading, which is free from rigidity and stiffness. These particular drawings show one strong point of many modern Italian architects,—the design of detail and accessories, especially in the free style of the Late Renaissance,—a point on which we shall have occasion to touch still further in continuing the subject in a future article.

NOTES.

WE observe with much interest that our Australian relatives are exhibiting in that quarter of the world the passion for exploration which may be said to be an hereditary quality of the English race. From a communication in the *Times* of Tuesday, we learn that the wealthy and large-minded colonist Sir Thomas Elder (whose portrait bust by Mr. Woolner we illustrated a short time since) has offered to furnish all the money necessary for a great exploration expedition into the centre of the Australian continent, on condition that he is satisfied with the scheme of such expedition, to be submitted to him beforehand. In a letter addressed to Baron von Müller, and read before the Royal Geographical Society of Australasia, at their meeting on August 22, he says in regard to the enterprise:—

"I have already referred to the importance of finding a thoroughly competent leader, as upon that much of the success of the expedition will depend. He ought to be a man not merely of pluck, courage, energy, influence over his men, but possess all the required physical qualities, and of such scientific attainments as will enable him to report advantageously on the topographical, geographical, botanical, geological, and other features of the tracts of land which he may travel over. But I need not expatiate at length on this branch of the subject, as no one knows better than yourself the special qualifications required by the conducting of such an expedition, if it is to be thoroughly successful. What I would like you to do is this,—viz., to intimate to the Melbourne exploration and geographical societies, and to the kindred societies in the Australian colonies, that I am willing to bear the entire cost." Let a scheme be carefully prepared in concert with the best experts for the final important work of Australian land exploration, and transmitted to me, when, if approved, I shall immediately take steps to have the scheme realised at my own expense."

That Australians would not allow themselves to be beaten by the difficulties of inland exploration, or allow the interior of their continent to remain for ever a trackless desert, we have always felt sure. But what perhaps is of even more interest is the effort which is being made in connexion with the same Society for further Antarctic exploration. Baron A. E. Nordenskjöld, an Arctic explorer of note, has consented to take the command of an Antarctic expedition if the Australian colonies contribute a sum of 5,000*l.* towards the expenses. We could

have wished that the Australians could have found a leader among themselves. England led the way under Cook in Antarctic exploration; it would be a fitting thing that it should be resumed by those of English race who are now so much more conveniently situated, geographically, for getting at the Antarctic region. But we wish success to the expedition, when formed, under whatever command.

WE print in another column an appeal from Mr. Penrose for funds to enable the architectural students of the British School at Athens, Mr. Schultz and Mr. Barnsley, to carry out the examination they are commissioned to make of the Byzantine buildings recently destroyed by fire at Salonika. We hope Mr. Penrose will obtain some substantial response to this appeal. It is of the greatest importance that trustworthy details should be obtained of the work before it is further destroyed, for all archaeological purposes, by restoration.

THE latest phase of the strike in the shipbuilding trade (to which we have before alluded) is the acceptance by the Mayor of Newcastle of the position of mediator. Although a comparatively small affair at the commencement, this strike caused a great deal of friction in the trade, which has kept on extending, and it is still far from certain that a general strike of shipbuilders will not take place before the questions in dispute are settled. A large number of men have gone from Plymouth and elsewhere to take the place of the Tyneside strikers, and this importation of strangers has intensified the irritation among the disaffected. The plan proposed by the Mayor of Newcastle is that a Board of Conciliation should be formed, representative of all the trades engaged in the shipbuilding yards, with full power to deal with the present dispute. The success of this scheme depends upon whether both the shipwrights (who accepted the original award made by Mr. Burt) and the joiners, who struck against it, will agree to the proposal. It is stated that Mr. Burt was occupied for some months in taking evidence as to the practice of the trade, &c., so that his award was not given without good grounds; but it is certainly possible that a Board constituted in the manner proposed may arrive at a more equitable decision than a single individual. A necessity seems to have arisen for permanent Conciliation Boards to be established in all large industries, together with a central body to whom matters may be referred which the local Boards fail to adjust.

THE Architectural Association *soirée*, held in the Westminster Town Hall on Friday, October 3, to which we called attention in our last issue, certainly put all its predecessors into the shade. An energetic Entertainments Sub-Committee, with the help of a courteous band of willing exhibitors, transformed the large hall into a luxurious reception-room, where the guests were received by the President, Mr. Leonard Stokes, and the Committee, and where refreshments and the band of the Coldstream Guards contributed to the entertainment. The large hall and staircases were fitted up with electric light by Messrs. Rashleigh, Phipps & Dawson, the current being obtained from the Westminster Electric Supply Corporation. The Association ask us to express their acknowledgments to the following firms, who contributed greatly to the general effect by exhibiting choice specimens of their manufactures, exemplifying the arts and crafts connected with architecture:—

- |                       |                        |
|-----------------------|------------------------|
| T. Bonsor & Co.       | Hayward & Son          |
| Collinson & Lock      | Hindley & Sons         |
| Duckrell & Co.        | Jeffrey & Co.          |
| D'Oyly & Co., Limited | Morr's & Co.           |
| Felix & Wayman        | Pitman & Son           |
| Fisher & Co.          | Rottman, Strome, & Co. |
| Gillow & Co.          | Thomas Wardle          |
| Graham & Biddle       | Woolmans & Co.         |
| Gregory & Co.         |                        |

An interesting collection of Class prizes and other drawings was exhibited on the first-

floor. The illustrations of Hypnotism in the Council-chamber, by Dr. George André, excited great interest and large audiences. The professional value of Hypnotism soon became apparent to all, for might not its influence be utilised in smoothing the anxieties of an architect's existence in convincing a client at the right moment that the plans before him really were what was best for the purpose, and the tenders received rather below than above the sum originally mentioned? There is yet time for "Hypnotism as applied to Clients" to take its place beside Professional Practice in the new Scheme of the Association, and we place the suggestion entirely at the Committee's disposal. The evening seems to have been a great success.

MR. ST. JOHN HOPE contributes to the October number of the *Antiquary* a short account of the recent excavations at Silchester. In one portion of the site have been found two large detached rectangular pieces of building filled in with clay and sand as if to form raised platforms for large buildings. There are indications of wall veneers of polished Purbeck marble, and the external walls were plastered and painted. Of the various small objects found, pottery and bronze and iron implements, the more important will probably be exhibited at the Society of Antiquaries' rooms when it resumes its meetings in November. Mr. Hope observes that such work cannot be carried on without money, and hopes that everyone interested in Romano-British archaeology will send some contribution, however small, to the Treasurer of the Silchester Excavation Fund, Mr. F. G. Hilton Price, 1 Fleet-street. He adds that visitors to the site may depend on finding some of the Executive Committee on the spot, who will give them every information.

THE Dean and Chapter of Ely Cathedral set a good example to similar bodies by supplying visitors to the choir with a leaflet, on one side of which is a ground-plan of the choir, with numerals to indicate the monuments, and on the other the explanation of the figures, and a few brief notes as to the architecture of this part of the building. Such leaflets should be obtainable at all our cathedrals, for visitors do not want to be turning over the pages of a guide-book or architectural hand-book, as they move from one part of the building to the other, but such a leaflet indicates in a convenient way for the moment the features of the building. It is doubtful, in some respects, how far the natural curiosity to know to whom this monument was erected, and by whom that was placed in the building, should be gratified in a short account of this kind. The attention to often immaterial details tends to take away the thoughts from the main features and characteristics of a building, which are sufficient for the mind of most visitors. But, on the other hand, this same body should provide some seats outside this vast building. There is not one single seat on which a person can rest. It is essential that the external part of a building such as Ely Cathedral should be studied without haste, and it is most fatiguing not to be able to take a rest in the course of one or two hours' inspection of the building. There are many places perfectly suitable for such seats, and it is surprising that this want has not been before this supplied.

WE have received a circular from Mr. Haysman, President of the Working Men's Home Union, in regard to the proposed operations of that Society. The vagueness of the above appellation certainly needs some gloss. We understand from the circular that the two main objects of the Union are to obtain fair rents for working men's dwellings, and, secondly, to take care that such dwellings are kept in a proper sanitary state. We cannot but think that it would have been better to have aimed only at the latter object. We have no sympathy with landlords who charge exorbitant rents for premises which

they let to working men, but it is perfectly clear that the two objects are entirely different, and that one would be quite enough for any association to attain. The first matter is one which is a good deal regulated by purely economic laws, for unless there is a great demand for house-room by artisans, it is obvious that the landlords could not obtain an exorbitant rent. Again, it is difficult to see how a society like this can make a landlord take a lower rent, except by some kind of business competition. But it is well within the power of such a society to bring pressure to bear on the Sanitary Authorities and on landlords, so that sanitary defects may be remedied. No one can fail to sympathise or to support such endeavours, and we would strongly urge on the Working Men's Home Union to confine their efforts to the making the homes of working men healthy. They will find that steady work in this direction will be fully as much as they can accomplish.

THE White Lead Company, Limited, was, as probably a good many of our readers know, brought out in May of last year with a good deal of *éclat*, and its shares were applied for many times over. Since that time it seems to have been under a cloud, and the promise of great dividends has not yet been fulfilled. From a circular recently issued by the Board, it would appear, however, to be now emerging from the recent gloom. That its promise should be fulfilled is a matter in some respects of public interest, since it is claimed for the method of manufacture adopted by the Company that it is quite harmless to those engaged in the process. Anything also which cheapens and yet keeps efficient materials of any kind is also useful. It is immaterial to us whether its shareholders find it a satisfactory concern, but for the two reasons just given we hope that the Board is correct, and that the enlarged works will enable the Company to carry out its original programme. At the same time it is well to point out that those who bring out industrial companies might as well state a little more frankly when their works are inadequate for the purposes of the business, for we take it that no one who joined this company expected to see October, 1890, without having received a dividend, and that so many months were to be occupied in putting the works into a satisfactory state.

IT is satisfactory to see that District Surveyors are turning their attention in a practical manner to the subject of sky-signs, and that the Bovril Company have been summoned by the Surveyor to the St. Luke's Vestry for projecting a gigantic "B" over the street so as to constitute a danger to the public and an infringement of the Local Metropolis Act. The magistrate took the same view, and fined the company 40s. We fear that the law as at present existing cannot interfere with letters that do not project beyond the frontage; but it is something to get as much check on sky-signs as this. Perhaps some District Surveyor will next take up one of the cases of affixing huge boardings for advertisements in front of buildings, as alluded to in our correspondence columns of the last two weeks, and see if a conviction cannot be obtained on that score also.

IN a letter printed in this number Mr. W. P. Buchan refers to one point to which we have often thought attention should be directed, viz.: the inadequate quantity of water frequently allowed for the flush of waterclosets. Considering how important it is, in a sanitary point of view, that there should be an adequate flush of water to carry matter quickly to the sewer and to prevent the chances of stoppage in the house drain, especially in crowded cities, the restriction which water companies often endeavour (not always successfully) to place on the amount of water allowed to

pass at each discharge, by means of what are called "waste-preventing supply cisterns," is a dangerous one, and a very false economy as far as the interests of the public are concerned, though it is no doubt an excellent one in the interests of the water companies. This is particularly the case in London. We have known cases in London houses (and no doubt there are many such) where the water admitted by the waste-preventer was absolutely insufficient to cleanse out the pan, with consequences which may be imagined: and the matter is rendered still worse by the slow filling which is allowed to the waste-preventer, which is not ready for use again till perhaps ten minutes after the first discharge. No doubt many pans are so unscientifically constructed that the full power of the flush would not be obtained in any case; it is not only a question of how much water, but how it is introduced. But it is far better to allow a wide margin in the supply of water and allow the possibility of a certain amount of waste, than to risk the clogging of the drain, with all its disagreeable and insanitary consequences. Some London water companies endeavour to enforce, as far as they can, the employment of a supply cistern admitting only two gallons at each flush, a quantity which is most inadequate. Such a restriction ought not to be countenanced by the sanitary authorities of any city. Mr. Buchan, one of the most experienced of sanitary experts, considers three gallons too little, and advocates four, an error on the right side at any rate. But the two gallon "waste-preventer" is an enemy of public health, and should be put down.

THE report in last Saturday's *Times* on the "Arts and Crafts Exhibition" is a characteristic example of the "Philistine" point of view in these matters, of which the leading journal is so faithful an exponent. As our readers know, the Arts and Crafts Exhibition was set on foot with the express object of doing away with the wholesale production of what is called art by large firms, behind whose name-plate the real artists, where such existed, were hid in obscurity, and of bringing forward the personal work and personal credit of the individual artist in such things as furniture and wall-hangings. Visitors to this year's Exhibition, as noted in another column, have already felt disappointed to find that the shop element was invading this Exhibition also, and that we have collections of furniture, with the names of well-known *entrepreneurs* of art-workmanship placarded above them, just as we may see them in every ordinary "International" or "Industrial" Exhibition. But to the daily press intellect this is the great point in the present Exhibition. "Regarded as a whole, the present Exhibition is an improvement upon its predecessors, especially as the names of some important firms who have hitherto held aloof from the Society are to be found in the catalogue"; and the reporter ("critic" one cannot call him) goes on to pick out costly pieces of furniture which are labelled with the names of "important firms," but which are in fact among the common-places of the Exhibition, and represent only the kind of thing which money can always purchase. In one instance the *Times* pitches on an original piece of work, the "mahogany settee with canopy," which is designed by Mr. Mackmurdo; but not a word is said as to the designer, it is only referred to Messrs. Wilkinson & Co., one of the "important firms," for whom it was designed by Mr. Mackmurdo. To the daily press intellect and its public the question is not, who designed and made an excellent piece of work, but, "who sells it?" And if it bears a well-known selling name it is worth mention; otherwise not. There are in the same room with the exhibits of the "important firms" about half-a-dozen pieces of furniture showing the thought and the work of an original artist; but the reporter cannot see these; they are not labelled with any name known on the shop-fronts of Oxford-street or Bond-street.

IT is much to be regretted that *Punch* should have committed itself to the ridiculous misrepresentation of facts implied in a contribution to the last number under the heading "How it is done," in which a "Surveyor" (official) is represented as "taking drinks" with a jerry builder whom he has had to warn about some unsound and illegal construction, and squaring the matter under the influence of drink and good fellowship, and a consideration in money, "as a little addition to his salary." *Punch* being a journal published and no doubt mostly written in London, there can be little doubt that the satirist imagines himself to be representing the possible corruption of a London District Surveyor. If he had taken any trouble to ascertain facts before posing as a reformer of abuses, he would have discovered that the District Surveyor is not a salaried official, but usually an architect in good position and practice on his own account, and deriving his Surveyor's income, in addition to that arising out of his private practice, from fees in cases reported and dealt with, and that (supposing him capable of putting himself in the position represented) he would be probably acting against his own pecuniary interests in consenting to overlook a case of illegal construction. Perhaps, however, *Punch* was only speaking in a prophetic mood, with an eye to the time when the County Council shall have abolished the high-class architect from the ranks of its District Surveyors, and reduced them to the position of small-salaried officials forbidden to undertake any other work. Then perhaps the scene depicted in *Punch* might be within the bounds of possibility—but not till then.

THE nursery-gardens of London,—bright, fragrant, little spots, laid out here and there in the now predominant desert of houses,—have not as yet, so far as we can at this moment recall, inspired the recording voice of their own *vates sacre*. Perhaps they have been deemed to be too insignificant; yet they owned a certain charm of their own, nevertheless. A garden, said Charles Lamb, is always a garden, and doubly so in London. Thus, too, writes Gray: "And so you have a garden of your own; and you plant and transplant, and are dirty and amused. Why, I have no such thing, you monster; nor ever shall be either dirty or amused as long as I live. My gardens are in my windows, like those of a lodger up three pair of stairs in Petticoat-lane or Camomile-street, and they go to bed regularly under the same roof that I do."\* They flourished chiefly in Old Brompton, Paddington, and St. John's Wood. Many of these have gradually disappeared within our memory. In the last one or two years the nursery-garden in the Wellington-road, St. John's Wood, has been taken for the practice wickets and covered tennis-court of the M.C.C. at Lord's cricket-ground. Smith's nursery, at the higher end of Richmond-road, by Thornhill-road, Barnsbury, was to have been covered with houses. But the Islington Vestry bought the land for 2,000*l.* (of which sum the late Metropolitan Board of Works agreed to contribute one-half), and opened it last summer as a public recreation-ground, by name of Thornhill-gardens. A different fate overtakes the Pine Apple Nursery, Maida-vale, Messrs. Hooper & Co. (Limited), having acquired a ninety-nine years' building lease of that site.

MR. CARBONELL, the Vicar of Fairford, in Gloucestershire, has, we observe, been obliged to make a further appeal for funds to pay for the preservation of the church, and more especially of the stained-glass windows. It is to be hoped that his appeal will be generously met, and we can only suppose that abundant funds for the purpose were not before forthcoming because the great beauty and inestimable value of the Fairford windows is not sufficiently known. As a matter of fact, they are

priceless; no such series exists anywhere else in England, and no money could replace them. Many years ago—1826—Cobbett, in one of his "Rural Rides," thus writes of them: "Its windows of beautiful stained-glass had the luck to escape not only the fangs of the ferocious good Queen Bess, not only the unsparing plundering minions of James I., but even the devastating ruffians of Cromwell." There is no reason why, with proper care, these unique windows should not still last for many generations; but if they are to do so, each generation must take care that they are handed down intact, and it now rests with the present generation to do their duty.

WHAT is called "the Vyrnwy Hotel Scandal" at Liverpool seems to have furnished an unusually apt illustration of the folly of entrusting house planning and designing to men, however otherwise clever, who have made no special study of it. It appears from the report in the *Liverpool Daily Post* of the Council meeting held last week, that it had been decided to build a small hotel at Vyrnwy, where the new Liverpool reservoir has been made, at a cost of 5,000*l.*, and with the mistaken idea of economy, they put the matter into the hands of their very able water engineer, Mr. Deacon. The economical result appears to have been that the hotel which was to have cost 5,000*l.* has cost from 11,000*l.* to 12,000*l.*; the architectural result has been that the landlord, who was to take the hotel over on lease from the Corporation, refuses to sign the agreement on account of the bad planning and arrangement of the house. In a letter which was read at the Council meeting he complains that the cesspool for drainage, which would have to be cleared out from time to time, is within forty yards of and in sight of the drawing-room window, and abuts on what would be the favourite walk of the hotel grounds; that the cottages in connexion with the hotel contain no sleeping rooms except attics in the roof, and are therefore practically uninhabitable; that the heating apparatus, "from its ill-judged and awkward situation, close to the dining-room door and bar, causes a great nuisance by emitting such noxious fumes when it is opened for filling, as to annoy many of the guests who have stayed here, besides the ash and dust which often cover the hall furniture and bar-fittings;" and, to crown all, that the cellar for the heating apparatus is placed between the wine and beer cellars! It may be doubted if even Lord Grimthorpe could have beaten that. We should advise the Liverpool Water Engineer to retire from practice in house-planning, and the Town Council to make a memorandum that when next they want a house built for letting purposes it may be cheaper in the end to employ an architect who has some knowledge of the subject.

SIR E. WATKIN has been lecturing at Wrexham on the Channel Tunnel, and concluded with the remark that "they had reason to believe that there was no country in Europe except our own where any party was to be found that would not approve and welcome the construction of such a communication." Precisely so: he could not have stated the case against it a more terse and pithy manner.

THE PUBLIC LIGHTING OF LEWES.—On the 1st inst. a meeting of ratepayers was held at the Corn Exchange, Lewes, to consider the question of the lighting of the borough. The Mayor, Alderman White, presided. For some time past, it is stated, there has been a general feeling of dissatisfaction both with the quality of the gas supplied to the public lamps and with the price charged for the same, and the discontent has found expression in a demand either for a better and cheaper service of gas, or for the introduction of a superior system of illumination. Speeches were made by Alderman Farncombe (who explained the position of affairs), the Hon. A. Braud, Mr. T. de Castro (Chairman of the Giltcher Electric Light Company), and others. The introduction of the electric light was strongly advocated by some of the speakers, but some fears were expressed as to its successful maintenance. The meeting was ultimately adjourned for a fortnight.

## THE ARTS AND CRAFTS EXHIBITION.

THE third exhibition of the Arts and Crafts Society, which has opened this week in the New Gallery, is hardly equal to the two which preceded it, and we fear there is evidence of some departure from its original lines. In the first two exhibitions we had the satisfaction of seeing designs for furniture and decoration exhibited purely as designs, and on the same footing as pictures in a high-class exhibition. This year we find that the "furniture firm" has invaded the exhibition; we have a partitioned-off room of furniture devoted to a special firm, just as we see at industrial exhibitions, like the recent ones of Glasgow and Edinburgh, &c. Other furniture shops are prominent on the various labels; there is a profession of giving the name of the actual maker and designer (not always carried out), but this is in subordination to the name of the seller. If this system is allowed to invade the Arts and Crafts Exhibition, there is an end of all its real motive and function. What have these names of furniture-shops to do with art? It is just as if, at a picture exhibition, a picture-dealer's name were put centrally in the catalogue, and the painter's name as a sub-heading under it. We observe also that one exhibitor (who is a member of the committee too) has tacked price-cards on to his exhibits! Unless this kind of thing is stopped with a strong hand, the Arts and Crafts Exhibition will degenerate into a mere aesthetic bazaar, of which we have plenty already, and will lose its distinctively artistic character and its very reason for existence.

The present exhibition is arranged somewhat differently from the preceding ones. The cartoons for mural decoration and windows are collected in the South Gallery (where the catalogue numbers begin); the West Gallery is mostly given up to textiles, and the largest room, the North Gallery, to furniture. In the South Gallery a cartoon by Mr. Burne Jones (8) for a series of nine lights for a window of Jesus College Cambridge, occupies a central position; this and some other designs of his are again all catalogued under the head of "Morris & Co." who executed the work; an entire inversion of the proper order of things. The window represents the ninefold hierarchy of angels according to mediæval classification, one figure to each light, and is very similar to the same artist's painting of the "Days of Creation"; mild-looking figures all with the same rather melancholy expression of face. A fine colour effect will no doubt be obtained by the wings and drapery, in the executed windows, but there is something very feeble intellectually in this conception of angels; how different from the powerful beings whom Raphael produced as angels. The first figure in the row holds a drawn sword which he looks as if he would never have strength to use. There is a weak mannerism in this style of art, for all the grace of pose and drapery, which will cause a future generation to marvel at the sentimental taste which was satisfied to admire it. Mr. Madox Brown's cartoon for one of the Manchester Town Hall paintings, "The Baptism of Eadwine" (22), is a far more robust piece of work, distinguished by excellent draughtsmanship, though some of the figures, notably the queen and her children on the right, look too much like modern people arrayed in ancient garb. The grouping of the figures so as to give all the incidents of the scene and at the same time preserve the fitness of composition proper to mural decoration, a point in which the artist is a master, is admirably carried out. Mr. C. W. Whall occupies the centre of the west wall with a cartoon for a three-light cemetery chapel window, flanked by two other designs for part of a memorial window, of which the one representing St. Christopher is a fine design, the principal figure very good, and the attempt to convey the effect of water in a manner suitable to stained glass work is very successful. There is a danger, in the decorative treatment of sacred subjects in somewhat rebellious materials, of reducing them to mere experiments in conventionalising, which is certainly not avoided in Mr. Heywood Sumner's sgraffito design for Clane Church, Kildare (2), representing the Baptism of Christ. The principal figure is stiff and expressionless, the water is indicated by concentric dark and white rings drawn in perspective round the feet of the figure, the palm trees above are conventionalised into shapes that are not beautiful, and one is chiefly im-

\* Letter to the Rev. Norton Nicholls, dated from Pembroke College, June 24, 1769.

pressed by the cleverness of the designer in this kind of translation of nature into ornamental patterns. The companion work (54), "The Resurrection," or rather the two Marys and the angel at the sepulchre, is much more successful, as the decorative lines are finer and the figures freer in line.

Among minor works in the same room is a cartoon for a wall-paper by Mr. Walter Crane, called "Corona vite," consisting of a large repeating pattern partly composed of figures, and a grandly-designed frieze of angels whose wings are in a decorative sense splendidly treated, and in a manner exactly suited to the material. The paper itself (by Messrs. Jeffrey & Co.) is hung in the north gallery, where the frieze loses its effect through being treated in flat tints in ordinary colouring, while the lower part of the paper is resplendent in gold; if this is intended to be the finished effect of the paper, it rather kills the frieze, which is the finest portion. We observe that against Mr. Walter Crane's designs his name always appears in the central position on the page, though we presume Mr. Crane does not make wall-papers, any more than Mr. Burne Jones makes stained-glass; the catalogue is very inconsistent in these matters. Mr. Frank Murray, again takes the central place as the artist of the two decorative cartoons for a Marine Insurance Office (21, 28), Salvatori's name appearing modestly in small letters as the executant. Why are not "Morris & Co." content with the same arrangement in similar case? The cartoons represent "Ancient and Modern Shipping," not a very good subject for decorative mosaic, but this is a praiseworthy attempt to give a little meaning as well as colour to the decoration of a business building; the design for the building was exhibited in the architectural room at the Royal Academy. Among other exhibits in this room may be mentioned Mr. Dressler's bas-relief from a design for the centre of an altar-piece by Mr. J. D. Sedding "The Nativity" (75); the same sculptor's little design for the back of a hair-brush to be executed in silver, showing a figure of a mermaid in bas-relief; Mr. A. Silver's design for cretonne in three colours (31); Mr. Bladen's design in water-colour for stained glass (42), a profile of a fine female head with the flowing hair partially filling up the background; and Mr. Selwyn Image's design for a stained window for a drawing-room (23), in charcoal and chalk, a very bad medium for conveying the idea of stained glass effect; we happen to have seen the design in execution, where the colour effect is very rich and the detail very original, but the design is ungraceful in its general lines, or rather it has no general lines, it is a set of patches of colour, decorative only as colour and not as form. The case of bindings by Mr. Cobden Sanderson contains some exquisite work (88), especially the rich little copy of "In Memoriam," but we should fear that such bindings can only be produced at a cost almost prohibitive to most owners of libraries.

The textile exhibits in the West Gallery illustrate the divided feeling which exists at present between the partially realistic and the purely conventional and symmetrical treatment of foliage forms in embroidery. The gallery contains two very fine examples of these two apparently opposed systems. One is a curtain embroidered on blue linen (subject, "Fruit Tree") designed by Miss May Morris and executed by her in conjunction with Miss Yeates and Mrs. Emery. This is a sumptuous rendering of a fruit tree with the flowers and fruit treated in irregular masses, with spaces between; a more conventional type of acanthus-like foliage worked in outline runs through the whole as if to bind it together. The more purely conventional method is shown in Mr. W. Morris's design for wall hanging (151), coloured and darned by Miss (?) Catherine Holliday. This is a symmetrical flowing design in immense acanthus-like leaves which dispart from a centre and curl round either way; it is a grand-looking design, though it may be just a question whether this scale of leaf is not rather too large and tends to dwarf the scale of a room of ordinary size. This tendency to large and too pronounced detail in work of this kind is illustrated here and there in other pieces of work in the room, as in the embroidered "greenscreen or cushion" (115) designed by Mrs. Hallward, which is powerful but far too "loud" in effect. Among the larger textile works is a fine piece of silk embroidery by the Leek Embroidery Society, one of the numbers 96, 97, and 98; the catalogue does not distinguish

Mrs. Thursfield exhibits a bed cover embroidered in Tassar silk, of a pattern taken from the ceiling of a room in the house of Orchemonos, Boeotia; the early Greek spiral ornament used as a diaper, with a border of circular paterae. This is effective and pleasing, though it is not exactly the kind of detail to select for textile work, being too architectural in character. The wall hanging designed by Mr. Heywood Sumner and executed by Miss Mary Augusta Smith, representing "Earth, Air, Fire, and Water" (127) is curious and clever, but has the objection that we find in the same designer's sgraffito of the Baptism of Christ; the forms and lines are not pleasing in a decorative sense. Mrs. Thackeray Turner's "Embroidered curtain, worked on hand-woven Assam silk in Morris & Co.'s crewels" (166), is an example of the style of foliage design which approaches nearly to realistic work and avoids all symmetry or conventionality of arrangement, except in spacing the design so as to distribute it equally over the ground, which is very little covered, the design meandering over it in open lines. The tone of the ground is very pleasing, and the whole effect quite as decorative as in some of the very richly worked examples in which the whole ground is covered. Miss Humphrey's dinner-table centre "worked in silks on white brocaded satin" (124) is an example of the charming effect which may be produced by working a design on a ground which makes a subordinate design beneath the principal one; the effect is very pretty, and the foliage of the border design, in colour silks outlined with *clavons* of gold thread, is a beautiful bit of work. Miss Gattson's coverlet in appliqué work designed by Mr. H. Home (143), has a border of conventionalised poppies, with the central part ornamented by the repetition of the words "Quid est somnus gelidus nisi mortis imago," arranged in squares of decorative letters with blank spaces of ground between. There is a curious and original fancy in this, but the sentence is not a very comfortable one to place on a bed-cover; and why repeat a facsimile of it over and over again, when each repetition is a separate piece of hand work? Among smaller things may be mentioned a bit of silk embroidery by Miss Clara Day from Mr. Lewis F. Day's design (118), a collection of cretonnes (100), exhibited by Mr. T. Wardle, some of them reproduced ancient designs, others by various designers who are mentioned (they vary much in merit, but some are very good); some dessert doyleys embroidered in silk with small conventional flower designs (135) by Miss May Field, and three side-board cloths in different Norwegian styles (182a) by Miss Julie Nøregard.

The West Gallery contains also a few pieces of furniture of some individuality. The chimney-piece designed by Mr. Lethaby and exhibited by Messrs. Farmer & Brindley looks rather as if it were intended to exhibit specimens of marble, but the refinement of the thin shelf at the top, with its delicate curves and small moulding, should be noted. A "Presidential Chair" designed by Mr. Ashbee and executed at his School of Handicraft, we give a sketch of (see lithograph); the characteristic portion of it is the embossed leather back, laced on to the framework so as to give play to it and leave an open *joint* between the leather and the woodwork. The lower portion of the chair is somewhat too ostentatiously simple, and thereby is out of keeping with the ornate character of the leather work. Otherwise it is of interest to see well-designed plain furniture, in regard to which we give a sketch of Mr. Spooner's sycamore sideboard (238), a good workman-like example of a "cottage" sideboard, with a very pretty hand of slightly-sunk floral ornament running across it (too small to be shown in the sketch). Interesting for the same reason is Mr. F. Madox Brown's "Chest of drawers for workmen or cottager" (307) in the North Gallery, of which also we give a sketch. The handles for pulling the drawers open are sunk in the drawer fronts, the rounded back of the sinking being gilt; on opening a drawer we perceive that this necessitates a covering-piece being fixed inside, producing a couple of excrescences in the interior of drawer which looks awkward; but as all events the pull in opening the drawer comes on the solid front, and not on an affixed handle; and we all know what a tendency the handles of ordinary sets of drawers have to come off. In the West Gallery is also a very

characteristic table (236) designed by Mr. Lethaby for a piece of green porphyry which forms the table surface, the design being made to fit the shape of the porphyry slab: we give a sketch of this (see lithograph).

The North Gallery, as observed, is devoted to furniture, and there are some very rich and elaborate pieces of work shown out of the stock of some large dealers. In Messrs. Galton & Lock's exhibit all the articles are designed by Mr. G. T. S. Lock, and the exponents' names are given; the execution is all admirable and the design unimpeachable in a general way, but it just wants that individuality which an artist turning his attention to furniture can put into such work, and it is for this that we come to the Arts and Crafts, not to see cabinet-makers' art, however good of its kind. The same remark applies to the sideboard exhibited by Messrs. Gregory & Co. (359), with the names of four workers appended to it; it is satisfactory that the movement initiated by the Arts and Crafts Society has led to some large furniture dealers admitting the propriety of giving the names of the actual designers and workers; but this sideboard still has the air of the furniture shop about it; it is only like many other such things that one sees, furniture worked up to a certain degree of richness of effect and costliness, but a mere repetition of old ideas and old details that form a cabinet-makers' stock-in-trade.

Some few things may be mentioned which illustrate the difference between artists' and cabinet-makers' design in furniture. Mr. R. T. Blomfield's mahogany corner cupboard, inlaid with snake-wood and ebony (311), is one of these; essentially an architect's design in its general form and the treatment of details; it is executed by Mr. John Finch. Another is the mahogany writing cabinet designed by Mr. Ernest W. Gimson (313), a charmingly original bit of work, very simple in its lines, and with one bit of inlay ornament forming a circle of enrichment in the middle of the otherwise plain front. Artistic effect is not necessarily produced by covering a thing all over with ornament, as cabinet-makers imagine. The cabinet designed by Mr. Lethaby and executed by Mr. A. Bowen and Mr. T. Ward (316), is another example of work thoroughly artistic in feeling though entirely without ornament properly so called; it produces its superior effect by superior workmanship and the care with which all its lines are set out. The "Bachelor's Sideboard" (319), designed by Mr. G. Jack, is very well planned for its purpose and in excellent taste in regard to design. It is exhibited under the name of "Morris & Co.," as is the very different-looking oak cabinet standing by it (323), and designed also by Mr. Jack. This is a highly picturesque-looking piece of furniture, consisting of a chest of drawers below, a table-top with a small plain cabinet at the back, which latter forms a kind of pedestal for a great over-sailing coffer at the top, the front of which is enriched with a carved frieze. There is a very fine effect about this; it impresses one as if it came out of an old picture; but the coffer at the top does look rather top-heavy. The large mahogany settle with a canopy over, designed by Mr. Mackmurdo (280), is noticeable for the treatment of the posts or colonettes which form the supports at each end, with their solid plinths with partially rounded faces; the manner in which the legs under the framework of the settle are set back so as to be out of the way is another little practical point worth notice. A large mantle fitting of teak (333) is exhibited under the name of Liberty & Co., but with no name of either designer or workman; this is an attempt to work in the details of Egyptian architecture, the overmantle being treated with miniature columns and lotus capitals, while above is a cornice with the usual section of Egyptian cornice, but immensely magnified as compared with the columns. To the architectural eye this is an absurdity; the best portion of the design is the repoussé copper work forming the face of the fire opening. Two chairs which go with it are copied from a well-known example in the British Museum. We should not omit to notice also the very characteristic little "Billiard" screen by Messrs. H. & J. Cooper, with painted panels by Mrs. Jopling, and the inlaid walnut coffer and hench designed by Mr. Lethaby (417), a piece of work with the feeling of the Renaissance in it, and with some beautiful floral inlay work on the sides. We notice also in the same gallery an effective frieze panel

in plaster by Mr. T. R. Spence (371), of which a sketch is subjoined.

Frieze panel in plaster by T. R. Spence (371).

We omitted to mention in the West Gallery the great fireplace at one end of the room, the joint design of Mr. Wilson and Mr. Pomeroy. This consists of stumpy marble columns carrying a ponderous overmantel in aluminium, decorated in relief with a figure of Undine rising amid a mass of conventional foliage; the side portions are differently toned and treated, and suggest water and fishes. The central portion is very boldly modelled; the capitals and columns unfortunately have rather a clumsy appearance. In the entrance hall there are some good things, some of which we give sketches (see lithograph). A piece of frieze designed by Mr. R. T. Blomfield, and in which no less than four artists have collaborated, hangs on the gallery railing, of which we give an illustration; also by a very boldly-modelled heraldic panel (477) by Mr. W. Aumonier, of which we give a sketch, and which is intended for that fine house of "Rhinefield," Hants, which was illustrated in the 1889 Royal Academy in a drawing published in our pages on August 17 of that year. Another heraldic sketch is a lion designed by Mr. J. D. Sedding (see illustration). Mr. J. D. Hunt exhibits a cast and wrought lead wall cistern (472) of which we give a sketch, designed by Mr. R. T. Blomfield, an altogether novel and peculiar bit of work, decorated with gilt dolphins in low relief meandering over the lead ground. We give also a sketch of Messrs. R. A. Belland G. Frazer's "Panels for an Altar-piece" (478), in which the kneeling figures in the upper panels, on either side of sacramental cup, are very graceful in pose and sentiment; we are not sorry however to read the note that these panels are executed in a church near Liverpool "differently coloured," for the colours here are sickly and ineffective. Among other objects in the hall is a marble chimney-piece (466) rather remarkable for neatness of execution than originality; a lion in mosaic by Mr. T. R. Spence (480) shown in the subjoined sketch; a powerfully modelled

The balcony contains a number of small but pretty and interesting things; book illustrations and ornaments by Mr. Walter Crane, among others a selection of original drawings for "The Book of Wedding Days," a very pretty variation on the old-fashioned "Birthday Book" idea. Mr. Whall exhibits a frame of designs showing what can be done in decorative effect by lead-light glazing (for Bank screens &c.) without any colour (576); it is a new idea of which something may be made. In the table-cases in the gallery are some admirable examples of printed books, notably those from the Chiswick press; books which it is a pleasure to look at for the mere neatness and finish of their pages.

There are plenty of things that are interesting and pleasant to look at, but we fear there is some falling off in the success of these exhibitions both in regard to the contents and the attendance. The introduction of anything like the shop class of exhibits is, as we have already observed, a mistake which will prove fatal if not corrected; we can get that kind of exhibition anywhere; but simultaneously with this there seems to have been a falling off in interest on the part of fickle and changeable London society; the private view was by no means crowded, and the rooms have been but very sparsely attended since. Both facts are disappointing, for when the first of these exhibitions was started we regarded it as a new and most interesting form of art exhibition, filling a real want and which, from the great interest it aroused, seemed likely to have a most prosperous career and to be a very good influence on art-handicraft. It has given a stimulus to this class of art already, but there should be a rally round it of those who are real artists in design; it cannot be kept up by drawing on furnishing firms, of whatever reputation and wealth.

ON THE TECHNICAL EDUCATION OF ARCHITECTS.\*

ANOTHER branch of study, not included among the Institute subjects of examination, but of no small value to the student of architecture, is archaeology. In fact, the architect has to study the buildings of the past, much in the same way as the archaeologist studies the whole life and work of past times. To those who have the time for it, the study of archaeology can be warmly commended, and we have in this college special facilities, as you all know, for the pursuit of that study under Professor Poole, whose lectures and demonstrations take a wide range.

We now approach a group of subjects where the instruction received in any college cannot of itself suffice, but must be supplemented by practical experience, but where the technical study for the most part forms the subject of the work of class B. for the study of construction which I conduct. In that class all the more important building materials, such as wood, stone, slate, marble, brick, terra-cotta, lime, cement, and iron are taken up in succession, their strength, weight, durability, and other properties described, and the defects and excellences of bad and good specimens are pointed out, and the part they play in building construction is explained. The general principles of construction, trussing, walling, arching, vaults, domes, and so on are also taken up in succession, and are passed in review, and thus the whole of the subjects named in that part of the programme for the examinations which deals with materials and construction are in turn dealt with. No examination papers have been yet published to show exactly what the scope of the intermediate examination is to be, but, judging from the published programme, it appears to me that a student going through this course, and doing a proper amount of preparation work at home, ought to be well able to pass that part of that examination, and the lectures will be adapted to secure that aim. No academic course alone is to be relied on to impart that practical knowledge of construction which the final examination requires, but the course here will suffice if supplemented by home work, and by diligent use of the opportunities which are enjoyed during three or four years in an office, with access to works in progress, to prepare the

student for passing that examination, so far as the building subjects go.

At the same time that I give this statement of the work of one Construction class, I am bound to add that it is impossible in a single course of lectures, and difficult for a single Professor, to pursue the study of all the numerous and very various known building materials as far as it is desirable, in some cases at least, to push it. Accordingly, that part of the course of Engineering and Mechanical Technology can with advantage be taken by architectural students, in which the manufacture of iron and steel, and the strength of materials and structures, forms the subject; and also that part of the course of Chemical Technology which covers the technology of building materials. I have already alluded to geology, but ought to add here that those students who are acquainted with that science in its main outlines will yet do well to take the course of lectures on Economic Geology, for the sake of the information they will afford on the geology of building stones.

Passing now to the subjects connected with architecture as an art, the instruction given in the Architectural A or Art class takes up the subjects required for the art side of the examinations, but, as in the case of the science subjects, they must be supplemented by drawing and measuring existing buildings, and by other study. In order to enter for the Intermediate Examination, the student has to do an amount of preliminary work which will be of great value in making him familiar with the forms, features, and ornaments of Classic and of Gothic art, and it will usually be best for him to do that in the office where he is a pupil. Here, in the class-room, the history of the art is pursued, beginning with Greek and the styles on which Greek is founded, and then taking up successively Roman, Basilican, Byzantine, Romanesque, Gothic, Renaissance, and modern art, and, in addition to the history, pointing out the distinctive qualities and features of each, and some of the principles of design which were dominant in the successive periods. It has been my custom, and I intend to follow it in the coming session, to take Greek architecture more in detail than any other part of the course, partly on account of the great importance of the subject, as at the root of almost all architecture since, and partly from the circumstance that it lies in smaller compass, and it better admits of a somewhat thorough examination than any other style.

Drawing, though left to a late part of the lecture, is a subject of which the importance cannot be overrated. As I have often pointed out before, drawing in three ways is the servant of the architect. He first learns to know all the forms, features, and details of buildings by drawing them, and learns how buildings are planned and contrived by making plans and working-drawings; in short, it is through the use of the pencil that he fills his mind, hand, and eye with the material out of which any designs of his own must be made. Secondly, the pencil is the instrument which assists,—may enable,—the architect to design his buildings and their details. The most original mind could not go far if prohibited from working pencil in hand, and required to think out the entire idea of a proposed building before putting a line on paper. Thirdly, the pencil enables the architect to prescribe what to do to the workmen who will be engaged erecting his building, or preparing portions of the fittings of it so precisely that they fall into their place exactly, and to make clear to his clients what the proposed buildings will be like. Without good, exact, and complete drawings, the modern rapid method of erecting buildings would be simply impossible; and though small and plain structures can be built,—as probably English parish churches were previous to the fifteenth century,—practically without drawings, the mode of procedure and the nature of the buildings were quite different from what we have to deal with.

In order to be a good architectural draughtsman, with cultivated eye and hand, a man must learn something of what is called freehand drawing, and it is best that he should begin with it. He who, when he commences his acquaintance with drawing, has a square and rule and compasses put into his hands, is never likely to go alone without them, and is never likely to learn to use them as an artist should. A good draughtsman is made by mastering the drawing of the human figure from the flat and the round, and where practicable from the life

wrought-iron newel and panel for a staircase designed by Mr. W. A. Fenn—a bit of classic wrought iron, free and powerful in treatment; a small wrought-iron music-stand adapted from an old design (485) by Mr. A. W. Battershall; the Ellison challenge cup (511) in cast silver chased and repoussé, by Mr. F. Erai Harrison, of which we give a sketch, it is very good in general form, but the details of modelling seem a little wanting in crispness; and cases of their respective wares exhibited by Messrs. Powell, the Murano Glass Company, and Mr. de Morgan. The collection of the latter contains some very fine work in pottery, both as to colour and design. The Cantagalli firm of Florence also have a case of their pottery, which is admirable enough both in colour and design, but then it is a sheer imitation of Renaissance work, and nothing more.

\* Being the concluding portion of the opening lecture delivered by Professor Roger Smith to the Architectural Classes of the University of London (Session 1890-91) on October 2. (See p. 285, ante.)

and by then being introduced to the use of drawing instruments; and he deserves the name of "good" when he can work with the instruments in his hand as freely and as unfettered as if he were simply using chalk, or pencil, or etching-pen. In laying out the course for a student acquiring technical education at a college preparatory to becoming the pupil of a practising architect, to pursue the wisest plan, in many cases, would be to devote whatever time can be spared from other subjects to figure-drawing, and to postpone all geometrical drawing and the study of architectural features,—such, for example, as the orders,—till his pupilage. I hardly need say that for this work there are facilities in the Slade school, forming part of this college, inferior to no art school in London. Where the pupil is already a good draughtsman, or, in some cases, where he has not the facilities in the office where he is articulated for pursuing the kind of work, I believe a school of architectural drawing here would be of service, and I do not doubt the feasibility of establishing one as soon as a sufficient field of usefulness seems open for it.

This additional consideration must, however, be borne in mind: that the study of drawing is calculated not merely to make a man a draughtsman, but to promote his becoming an artist. Some small spark at least, of artist's knowledge, feeling, and skill must be part of the architect's composition, or he will be but a poor sort of an architect, however elaborately trained; and it is to work in the Art School that we must partly look for rousing any germs of artistic enthusiasm there may be, for opening a man's eyes so that he may know how to see the beauties of nature, and how to appreciate the art of good pictures, statues, or buildings. And among auxiliaries for helping to learn the nature of art let me include the lectures given here by our newly-appointed lecturer on applied art, Mr. Stannus. No architectural student will regret attending them, and I doubt if any more interesting and stimulating instruction can be obtained by a student anxious not merely to make himself familiar with ornament as used in architecture, but to understand the reason why good ornament is good, and bad is bad; in short, the principles which underlie all successful applications of art to industry,—among which applications architecture holds the foremost place. In speaking earlier of a liberal education, I spoke of fine-art training as calculated to give that liberal quality to an architect's education which it must not be without. Here I refer to it as an essential. Any other kind of accomplishment is desirable, but something of the artist he must be if he is not to be a failure. Here, then, time and attention may be wisely bestowed, otherwise the scientific and practical training may outweigh or smother the artistic sense, which often is not at first at all vigorous, and in many respects needs careful fostering.

I ought not to omit, and at this point ought to take up the subject of design in architecture, did time permit; but a few sessions ago I devoted a lecture similar to this to an examination of the question, covered by the following subject, "Learning to Design Buildings," and as that was printed in the professional journals of the time, I must refer you to them if you wish to see in detail what I have to say on that subject, and I will ask any who may feel interested by this lecture to be good enough to turn up the reports of that one and read them. Briefly I may point out here, however, that designs can only be made by persons who have in their possession the material out of which they are made, and know how to use it.

To put this truism into other words, the first essential in designing buildings is knowledge of buildings,—of their plan, of their structure, of their intention, uses, and qualities. The next is a knowledge of the architectural features which are put together in forming a design,—a knowledge to be only gained by drawing them, and to a considerable extent only by drawing them from actual existing examples. Thirdly, some familiarity with the principles of design or composition to be detected in good buildings; and lastly, repeated and persevering effort. If there is any branch of knowledge and of skill in which it is more true than usual that practice makes perfect, I think it is in the designing of buildings. If you compare the early-executed works of Sir Charles Barry with his latest masterpieces you will see how far he was when he began from meriting the distinction which has often been accorded to him of being the foremost architect in Europe of his

time; and his great genius was only brought out by unwearied practice in using the vast store of architectural knowledge, which during his long period of pupilage and of study abroad he had accumulated.

There remains one branch of architectural technology to consider, a branch of which much can be learnt in the lecture-room, though the nature of it is essentially practical. I allude to professional practice. This topic forms the subject of examination at the Institute, and it is one on which it is peculiarly advantageous for a practitioner to be forewarned, quite apart from examinations. A course of lectures on "Professional practice" is given by me in this College. I do not recommend students who are going through such a preliminary technical course as I have suggested may with advantage be taken before entering an office, to include this subject. The course is intended rather for men who have had some practical training and are preparing for the final Institute examination, or desire to qualify as District Surveyors, or, at least, wish to understand what is going on in the practice of the office where they are, or to prepare themselves for entering practice on their own account. The entire routine of the professional conduct of building operations from the architect's point of view, and those points in which law comes most into play, such as the Acts of Parliament regulating buildings, and rights of light and air, form the subjects of these lectures, which also include a notice of dangerous and ruinous structures, and the precautions to take in dealing with them. These lectures, I hope, may enable some of my students to profit by other men's experience, instead of having to win the whole of their experimental knowledge of practice for themselves.

It is now time briefly to recapitulate the course on which we have travelled, preparatory to drawing this lecture to a close. After referring to the now-completed series of Institute Examinations as pointing out to us the subject of technical education for architects, we divided a professional man's education, and looked at its initial, liberal, technical, and practical sides; and, after glancing at the initial and its hearing upon the Preliminary Examination, we considered at some length the nature of a liberal education, and how a man who originally has not enjoyed many advantages, may improve and expand his mind by suitable studies. A notice of practical education led to a few words on the subject of pupilage in the architectural profession, and we were then left to consider technical education in connexion with the tests involved in the Intermediate and Final Examinations at the Institute. The scheme for technical education now under the consideration of the Architectural Association appeared here to claim special notice, and if, as an old member and former officer of the Association, I ventured on some remarks that were critical in their nature, I trust it will be understood that they were not dictated by any desire to find fault,—far less to oppose,—but as a contribution to the discussion of a scheme which must be very thoroughly sifted.

I then considered the course which a different class of candidates for success in these examinations, especially in the intermediate, can follow, and I pointed out the large provision of skilled instruction in the subjects on which the technical studies of an architectural student must chiefly turn, which exists at this College, and of which a student whose friends can send him here for a session before he is articulated,—or, let me add, his master after he is articulated,—cannot do better than avail himself. This includes, of course, a brief *résumé* of the work which those who go through with me the courses that begin next week will take up, for a fuller statement of which work I must refer you to the printed prospectus; and I beg here to remind you that the first lectures of each course are open to you free, so that those who desire to do so can attend one or two lectures to see if the sort of information given is what they desire. I have, however, very little doubt that most of the students who go through the courses this session will not be in the position of the imaginary student whose course of study I have sketched; they will rather be pupils or assistants in architects' offices desirous of making the most of their time. I can only say that any or all of you will be welcome in that character. It has hitherto been almost entirely from architects' pupils that these classes have been recruited, and the hour of meeting has been fixed

and is still retained at six, as being likely to suit the majority of such pupils. I have in this paper sketched what I believe would be the most useful programme for the education of an architect; but it is not the programme so much as the quality of the teaching, and, let me add, the quality of the learning, which makes education of any sort a success. You gentlemen, have arrived at a period when, to a large extent, a man's future is in his own hands more than in those of any other persons in any way concerned. And do not let this evening's engagement lead you to put too high a value on any system of education *per se*. A good system is a good thing, as it affords a good teacher and a good learner the best scope for their respective shares in the great work of education, but that is all. A resolute, intelligent, and persevering student can manage to extract a vast amount of knowledge if only he can get at any person, any class, or any book where the knowledge exists, even if proceeding according to a very imperfect method; and a good teacher is to a very large extent independent of any exact scheme, for he involuntarily steps over the boundaries of a cramped one and straightens the irregularities of an ill-considered one. I do not, however, wish so be understood as apologising for the programme here as either cramped or ill-considered; on the contrary, no pains have been spared to make it comprehensive; and a great deal of consideration has been bestowed upon the question what to include, and in what order and by what methods to take up the different subjects. Of the Professor it is not for me to say anything except to claim that he has had a long experience in his share of the work, and to assure you that he has a very genuine sympathy with you in your share, and a hearty desire to be of as much service to you as possible. What you gentlemen, may be as students, time only will show; but I can assure you that your predecessors in years gone by have been uniformly such students as it was a pleasure to lecture to, and that among them not a few have shown a diligence, an intelligence, and an artistic feeling worthy of the highest praise; and I not only hope, but expect, to have students of the same calibre in the session which commences to-day.

#### CITY ARCHITECTURE IN WESTERN AMERICA.

UNDER the title of "The City House in the West," *Scribner's Magazine* for October publishes a very interesting and admirably written article from the architect's point of view, by Mr. J. W. Root. For the details of the subject and the numerous plans and illustrations we must refer the reader to the magazine, but the following extracts in regard to the general position of architecture in Western America will be of interest to our readers:

"The conditions attending the development of architecture in the West have been, in almost every respect, without precedent. At no time in the history of the world has a community covering such vast and yet homogeneous territory developed with such amazing rapidity, and under conditions of civilisation so far advanced. Few times in history have ever presented so impressive a sight as this resistless wave of progress, its farthestmost verge crashing down primal obstacles in nature and desperate resistance from the inhabitants; its deeper and calmer waters teeming with life and full of promise more significant than has ever yet been known. Between the period of conquest and the period of realisation there is for art in this great development a distinct hiatus. It is a long time full of deadness, except of physical force, then a sudden hursting of art into exuberant flower. Up to a time twenty years ago every energy of the hardy pioneers who were opening the vast district now called 'the West' was expended in the most rudimentary work—that demanded by self-protection and self-support. Even now, in remoter districts, still sounds the Indian's war-whoop, and still exists something of those wild and barbaric conditions so recently conquered farther East.

During the period of this ceaseless struggle architecture, as we understand it, was not thought of; and the most primitive log-hut served for shelter. But as cities began to spring up, the 'balloon-framed' wood house was evolved. This early type of dwelling has made

the growth of the West possible. Frail as its structure seems to be, it has been the very fortress of civilisation, withstanding all assaults of heat and cold, and often baffling the deadly cyclone where massive structures of masonry succumbed. Nothing could be more simple than its skeleton. Unlike the early dwellings of wood erected in the East, no expert carpenter was needed,—not mortise nor tenon nor other mysteries of carpentry interfered with the swiftness of its growth. A keg of nails, some two by four inch studs, a few cedar posts for foundations, and a lot of clapboards, with two strong arms to wield the hammer and saw,—these only were needed, and these were always to be had. For no sooner did the yell of the Indian grow distant upon the verge of the prairie, or over the slope of the hill, even if but for a few days, than its fierce sound was followed by the drowsy buzz of the saw-mill. Even to-day many Western cities, not only like Chicago, whose earliest growth dates back fifty years, but like Duluth, Minneapolis, Omaha, and others of later growth, are more than half made up of these frame houses. In Chicago the great West Side contains thousands of them. Their life, however, is now nearly finished; for in nearly every Western city of more than one hundred thousand inhabitants the law is passed that within city limits no wood house may be built; so that the next five years will see their total disappearance in favour of more or less substantial structures of masonry.

Thus these hardy pioneers of architecture, in their very disappearance, do architecture some service, for because of them every old Western city must be almost entirely rebuilt, and this under modern and enlightened auspices, as if it had been devastated by a great fire or cyclone. This is clearly an advantage to architecture and to civilisation; that is, it may be a great advantage to architecture and to civilisation. It certainly presents possibilities to the architects of the West such as have never been given to any other group of men. . . .

Chicago possessed a few interesting souvenirs of its early history; but these, alas! went with the great fire of 1871; and scarcely a remnant remains; and of these few not one has been spared by the irreverent hand of progress.

From the early and meagre architectural development of this and other Western cities, the present state is vastly removed. Indeed, modern Western dwellings seem to have scarcely a visible trace of relationship to these earlier types. First, let it be noted that there is in Western cities a notable absence, compared with cities in the East, of houses built in blocks. The reason for this is obvious. Eastern cities, being older, were begun, and their traditions established at a time when their citizens were more interdependent, and facilities of transportation were less complete than now. For this reason they are not only more compactly built, but ground has become dearer than in the West. The reverse is true of Western cities, and the result is that residences much more frequently occupy considerable space, being entirely detached from other houses and surrounded by their own trees and lawns. It will frequently happen that a citizen imbued with characteristic and full confidence in the future growth of his city will purchase a large tract slightly removed from the business centre, upon which he will build his home, knowing that but a short time will elapse before it will be embraced by the city itself. When this occurs, he subdivides and sells what he does not need, reserving an acre or two for his own purposes. The frequency of this kind of thing gives Western dwellings a general suburban aspect, removing them from the class of city houses to which we may have become accustomed. This suburban effect is also enhanced by the extraordinary increase in the variety of building materials, which, coupled with the characteristic Western love of novelty, often leads to the erection of houses of different material, colour, and treatment as is possible to conceive, different dwellings in the same street being as independent of each other,—often as apparently hostile, as if separated by wide stretches of open country.

Nevertheless, many streets thus built up present a superb air of space, comfort, and even luxury. In driving through these streets the eye is at no time wearied with the monotony which is so tiresome in Fifth Avenue or other similar streets in Eastern cities, but is everywhere delighted with constant change, constant appeal to new sentiment, and that delightful

sense of the picturesque which, to the stranger, is so inspiring. Notable among such streets are Euclid-avenue in Cleveland, where the splendid residences which line it are often set back as much as two or three hundred feet from the street; Michigan Boulevard and the Lake Shore Drive in Chicago, superbly paved streets with great variety of interesting outlook; Prospect and Grand Avenues in Milwaukee, the first overlooking the lake from a bluff 100 ft. high, the second a magnificently-wooded avenue 200 ft. wide; and several avenues in St. Paul, Minneapolis, and other cities. Occasionally these streets are laid out park-wise, still further accenting this suburban aspect. . . .

San Francisco has had a very unusual architectural experience; it has been more isolated from the rest of the country than almost any other of our cities; its development, therefore, has been more peculiarly its own, and has been less modified by contemporaneous work in Eastern cities. It is only of very late years that work being done in the East has strongly modified the feeling of San Francisco architects. The fear of earthquakes has caused nearly every dwelling-house to be constructed

Modern House, Prairie Avenue, Chicago. (From Scribner's Magazine.)

of wood. In spite of this fact, little seems to have been done, as might have been expected, toward developing an architecture of wood. All sorts of architectural styles, originating in stone, have been adopted bodily in wood, with scarcely a change in the original stone expression except such as is absolutely necessary for the jointing of a different material. California and other parts of the Pacific coast are blessed, in so far as their wood houses are concerned, in their beautiful red-wood. This is a lovely colour for interior, as well as exterior work. Its effect, when used outside in shingles and otherwise, and treated with spar varnish, is singularly fine, presenting to the eye a fine leathery texture. This wood is not difficult to work, and when used with intelligence and discretion should be made to contribute, in a great degree, to the development of new forms of design in wood.

The houses mentioned above, like all typical Western dwellings, are better finished within than their exterior would seem to indicate. The reverse of this is seldom true, and this is a good deal to say for the certain honesty in Western cities, where the occupant of the house is less interested in making a specious display to his neighbours than in acquiring a solid and enduring comfort for himself. Native hard woods are freely used, especially white and red

oak, both quartered and plain. These woods have been especially popular; their beautiful grain and open texture lend themselves to so many effects of colour that they have taken the place of other wood, the colour required being imparted to them by filling and staining; indeed, their use has become so general that the supply threatens to be exhausted, and their market value has increased during the last few years nearly double. From California come several beautiful,—if rather showy,—woods, in yellows and reds. The manilla-wood from the coast has much of the beauty of mahogany, with its deep red tones and waving grain. Curiously enough, when we have practically abandoned in the West the use of American black walnut, which at one time was employed far more than any other native hard wood, and are now beginning to use so freely the English oak, the very 'swell thing' in England seems to be to abandon the use of their beautiful oak and substitute instead our American black walnut.

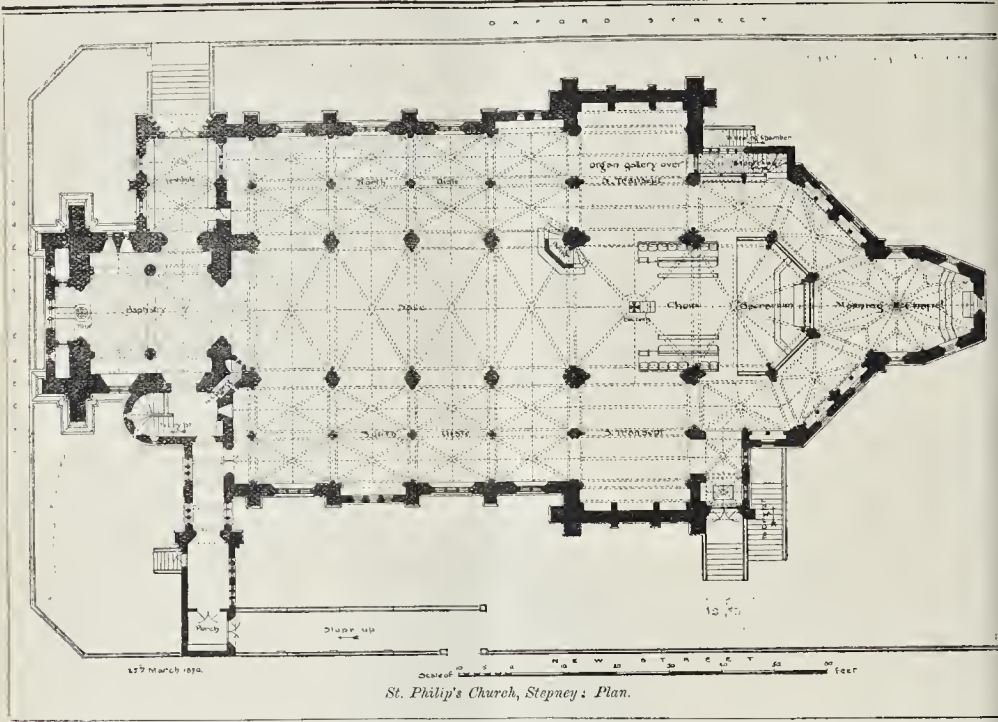

Much more may be said of the interior aspect of these Western dwellings, which is as varied as their exterior designs, or as the temperament and social position and disposition of the occupant.

Again let me say, that between the character of the occupant and the general expression of the dwelling there is much greater similarity than in any other part of the country. The one is much less governed by artificial conditions than his brother in the East, and very much more freely expresses himself.

A few years back, and contemporaneous with the reign of, first, the 'Victorian Gothic' and afterward the 'Queen Anne', was the reign of marvellous wall-paper, portières, *bric-a-brac*, and 'Eastlake' furniture. To all of these the West gave swift obedience. Houses may still be found in abundance where each of these sovereigns holds divided sway; but in the main common-sense has won the day, or at least other and less artificial fads now rule. First the embroidered, carved, painted, cast and wrought iron crane, who so long stood on one leg amid surrounding cat-tails, has died; the death was prolonged and painful, but seems finally to have occurred. After this, the famous, honestly-constructed, glued-on, mortise-and-tenon furniture fell to pieces and went to the cellar; then, as intelligence increased, the people began to purchase pictures of interest and beauty, and ceased to paste pictures of no interest and beauty on their walls and ceilings. After this came a yearning for more sunlight and fresh air, and heavy stuffs were largely removed from doorways and windows, and lighter materials substituted. Last of all, the indiscriminate vase and plaque, the ubiquitous display of cups and saucers, have given way to temperateness in this as in other things. Even stained glass, which in the West has for many years run a most shameful career, has grown less wild and uncivilised, exchanging its barbaric hues for gentler whites and opals.

Take it altogether, the outlook for Western city houses seems most promising. Western people themselves are becoming, and will still more become, almost ideal clients. It is true that, as in the East, Western city dwellings have not escaped the deadly touch of the 'know-it-all' client, nor of the man who is 'building the house to suit himself', nor of him who 'is going to live inside the house, not outside', and who is, therefore, loftily indifferent to the street aspect of his house; but each, even the last person, is becoming infrequent. In the past, and to some degree at present, Western cities have been and are influenced by men whose lives have been absorbed by things too material to leave them much leisure for art; but even in the case of such men there is a marked disposition to dictate in directions where their knowledge is incomplete. They have a large openness and unbiased attitude of mind, and a genuine and earnest desire to 'get the best.' In the West is less often found than in the East the 'aesthetic crank,' and it is also true that life in the West is less conventional, freer, less restrained by artificial restrictions than in older communities, and the true nature of people and things is, perhaps, more frankly expressed.

All of these conditions are helps to the architect, for while they free him from such artificialities as might tend to hamper him, or to make his work more formal, they give wholesome impetus to honest and earnest endeavour.

St. Philip's Church, Stepney. Plan.

Circumstances are also such that the architect may act with great catholicity. Architectural tradition in the West there is none. Even from such practices as may exist in the East, the West will often hesitate to borrow; and among the various Western cities, marked tendencies towards divergence, not only from the East, but among themselves, may be noted. This contemporaneous work in St. Paul and Minneapolis will differ in marked degree from similar work in Omaha or Denver; and the dwelling-houses now erected in Chicago have marked peculiarities not to be found in other cities. These variations are due to great differences of climate and customs, as well as to differences of temperament among both clients and architects, for the enormous size of 'the West' must be borne in mind when considering this great architectural development. Among these various rival cities dominant 'fads' in architecture are likely to become less common, and problems will be more generally determined by the nature of the case."

Illustrations.

"THE DANAIDES": DESIGN FOR MURAL DECORATION.

THIS design, by Miss May Bowley, occupied a central place in the Architectural Room at the last Royal Academy exhibition. The drawing is an illustration of the ancient legend of the Danaides, the princesses who were condemned for ever to draw water in vessels with holes in the bottom. It was intended by the artist, however, to express a further meaning, as symbolising "Labour," but that kind of labour which is hopeless and ends in no useful result.

ST. PHILIP'S CHURCH, STEPNEY.

This church, at the back of the London Hospital, Whitechapel, is now being built from the designs of Mr. Arthur Cawston.

The western half, including the western transept piers, has been finished about a year, and is used for services, as shown by our illustrations. The eastern portion is now being built, and the contract time for completion is August, 1891.

Mr. T. Higgs, who superintended the erection of the western portion, is again the clerk of works, and Messrs. A. Bush & Sons are the builders.

Our interior views are printed from photographs taken by Mr. Charles Latham.

The instructions given to the architect when he was first called upon to design this building, were that it was not to be a strictly utilitarian building, crowded with seats everywhere, like a meeting-house, a concert-hall, or even an ordinary modern parish church, but it was to be, if possible, a building worthy of the great purpose to which it is put; an interesting place for the parishioners to rest and hide themselves for a time from their neighbours, and a permanent protest in this practical age against the everlasting question, "Will it pay?"

It is for these reasons that in this small parish this church has double aisles, but a narrow nave, and short choir; for these reasons that the windows are kept small, and their light dimmed; that the north-west door is not in ordinary use, but that the entrance is by a cloister, which, when completed, will probably run the whole length of the south side.

It is to give interest to the building that the Morning Chapel is hidden away as much as possible in the east end, so that it cannot be immediately seen by any one who enters the church. In fact, by whichever door the church is entered, it was intended that there should always be one thing of interest which required a walk right into the building before it could be seen.

The building, as originally designed, had one bay more length in the choir; but when the east end was being commenced the size had to be curtailed, and a visit to St. Denis, near Paris, where the chancel and many handsome steps up to it project boldly out beyond the transept piers, suggested this arrangement, which is also found in some few of our English Cathedrals.

No steps are shown on the plan between the choir and the nave, but this, to some minds, is an advantage.

A glance at the plan of Wells Cathedral will dispel the fear that the shape of the Morning Chapel is original. The centre pier here is to be polished Hopton Wood stone, to support the many irregular ribs of vaulting that will spring from it, and the walls of the chapel will be faced with Sussex stone from Mr. Whitehead's quarry, near Three Bridges, a stone which has often been used with success by the architect.

The surface will be rock-faced, and, of course, the stones will be kept small in size.

The remainder of the church internally is faced with common stock bricks, freely relieved with Bath stone, as in Mr. Pearson's church in Red Lion-square. Externally the materials are red brick and Ancaster stone; but, in view of the surroundings and for other reasons, it was not thought desirable to ornament the exterior.

Should any of our readers visit the neighbourhood we would call their attention particularly to the wonderful transformation recently made just at the east end of the building. What was once a dust-heap is now a miniature garden, with its artificial lake, rivulet, and bridges, its menageries and its grottoes. It is surrounded by a high paling to ensure quiet, and is reserved for the old people of the parish.

SKETCHES AT THE ARTS AND CRAFTS EXHIBITION.

The sketches given in this plate, representing various objects in the Arts and Crafts Exhibition, are referred to and commented on in the article on the exhibition in another column.

THE CASE OR SHRINE OF ST. PATRICK'S BELL.

THE ancient Celtic Church had the peculiarity, not shared by other Churches, of possessing various small bells which appear to have belonged to the earliest of her ecclesiastics. Much respect was afterwards shown to these objects, as is evidenced by the care with which they were preserved, in many cases shrines of great beauty and value being provided for their reception, while special keepers, generation after generation, had charge of the sacred objects.

The greatest number of these bells are found in Ireland, but many are preserved in Scotland, a few in Wales, but only two are known to exist in England. They are always of small size, being clearly hand or portable bells, resembling in their general form those of ancient Roman date, examples of which are not uncommon, and from which they were most probably derived.

What may reasonably be considered as the earliest examples are formed of sheets of thin iron, the edges of which are lapped and riveted together after having been bent to the intended

Shrine of St. Patrick's Bell.

Detail of Head of Shrine.

form. The joints were then filled in with bronze, and the bell itself dipped into liquid bronze, and thus coated with that material, after the manner practised in the manufacture of sheep-bells in Wiltshire. Another variety, probably of later date, is of cast bronze. An approximately dated example of this latter class,—the bell of Armagh,—was fabricated before A.D. 904.

Our illustration represents the celebrated case of the bell of St. Patrick, which, for the extreme beauty and minuteness of its workmanship, is the finest and most worthy of study of all the bell-shrines remaining in the kingdom. It is formed of bronze, the corners being secured by copper flutings. On this groundwork are riveted the gold and silver panels which contain the mass of decoration, of which the more salient features only are possible to be shown by the engravings. The precious stones and glass remind us of the bindings of some of the earliest MSS.

The upper portion, shown more in detail, is of elaborate work in silver and gold. The sides consist of similar work, of different design on each side, of great elaboration and beauty, which has to be seen to be fully appreciated, the minute and intricate nature of the entwined spirals being difficult to follow. Some of these have heads, the eyes of which are filled in with minute specks of green glass. Rings for suspension exist on both sides springing from crosses; the back consists of a diaper of Greek crosses; while around the margin is an inscription in Irish, asking for a prayer for the maker of the bell, for Donald, the successor of St. Patrick, for whom it was made, for the keeper of the bell and others. From the occurrence of some of the names in the annals of the Four Masters, the date of the shrine has been assigned to between 1091 and 1105, but it will be noticed that many of the patterns are of early form. The history of the descent of the bell and its case from one generation of custodians to another is remarkable and curious, but it need not be repeated here. Both are now among the most precious of the contents of the Museum of the Royal Irish Academy, Dublin.

The bell contained within this beautiful case is perhaps the most ancient of its class now existing in Ireland. It is formed of plates of iron, dipped in bronze as already described, and is of small dimensions, the height being only 7½ in., including its flat bow handle. The width at the mouth is 4½ by 3½ in., and the total weight is 3 lb. 11 oz. There is nothing whatever on the bell itself to connect it with St. Patrick; but the reverence which has been shown to it by the preparation of the costly case which enshrines it, the careful keeping which it has received through so many hundreds of years, and the name given to it by tradition

during all this period, are important elements in support of its title to be considered, indeed, as a personal relic of Ireland's Apostle. A charming monograph of the bell and its case, with full-sized plates printed in colours, has been published by Marcus Ward & Co., with a description by Dr. Reeves.

THE COMPETITION FOR THE WHITEFIELD MEMORIAL CHAPEL AND TOPYLADY HALL, TOTTENHAM COURT-ROAD.

The old building, which was once a landmark in the Tottenham Court-road, has been lately removed and the site cleared for the erection of a new building. The Committee decided upon a limited competition, in which the assessor, Prof. T. Roger Smith, has recently published his award, the drawings being exhibited in the temporary school-room in the Tottenham Court-road.

Ten firms of architects were invited to compete, and the instructions were supplied together with a plan. The plan, however, has given rise to a good deal of comment and a letter in our last issue from a "Competitor."

The site is rectangular in shape, with a rectangular addition at one corner. The breadth, however, in Tottenham Court-road is wrongly figured to the extent of 6 ft.; 102 ft. is figured, whilst the existing dimension is 108 ft.

We cannot too severely condemn the carelessness of the Committee in furnishing a plan which is misleading in such an important point; we also sympathise with the competitors who, having followed these faulty instructions, now find themselves at a disadvantage.

On the other hand, we cannot refrain from pointing out to all the competitors that this error is apparent on a cursory examination of the plan, and without measurement of the site itself, for by comparing the dimension in Whitefield-street, 133 ft., less the break, figured 25 ft., the result is 108 ft.; whereas 102 ft. is figured, and all the angles are drawn as right-angles. How, then, is it that in plotting the site, every competitor did not immediately ask for the Committee's explanation? We are surprised that only two competitors took advantage of the extra 6 ft.

The requirements of the instructions included the provision of a chapel to seat 1,500, a school-room beneath it to accommodate 1,000 scholars, and other rooms. These, with a caretaker's residence, were to be placed at the back of the site, abutting on Whitefield-street, whilst the front portion, facing Tottenham Court-road, was to be provided with offices for letting, a church-parlour, ladies' cloak-room, secretary's office, and class-rooms. The first-floor of the front portion was to contain a hall with galleries

to accommodate 1,500. For all the accommodation asked for the cost was not to exceed 15,000*l.*, which will probably prove to be an altogether inadequate sum.

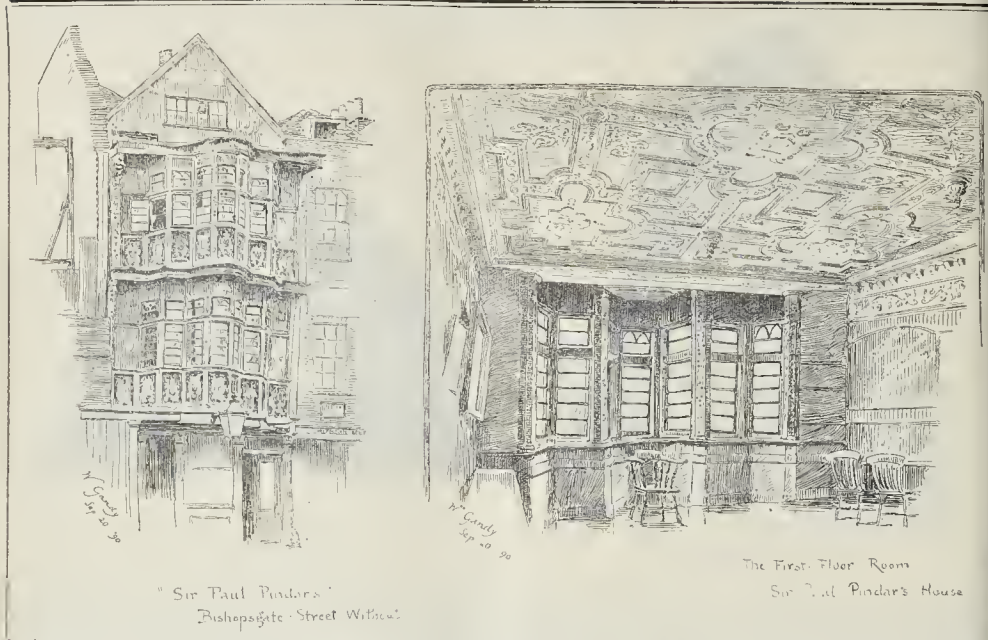

The plans to which the first place has been awarded were prepared by Mr. F. Forham, of Finsbury-pavement, under the device of a "winged heart," and he took advantage of the additional 6 ft. already mentioned.

A spacious entrance in the centre of the Tottenham Court-road front, which is flanked on either side by three offices, leads into a hall which has two class-rooms on the south and a church parlour on the right, also secretary's office and ladies' cloak-room. Areas are provided between the two blocks, and on each side of the passage, which leads direct into the chapel, are placed staircases leading to the Topylady Hall. The chapel lies north and south, with the pulpit, organ, and choir at the north end. The entrances at the south, which appear to be very narrow, are flanked by staircases leading to the gallery above, but no means appears to have been provided at this end for getting from the ground-floor to the galleries without going outside the building. The pastor's and other vestries are placed in a convenient position on the ground-floor of the caretaker's house, but lavatory accommodation is conspicuous by its absence. The hall on the first floor is spacious and well lighted.

The plan of these buildings is decidedly the most creditable part of the design. The elevations are not pleasing, designed as they are in that singular style, too often met with in dissenting places of worship, which abounds in semicircles and circles. The building is not one which will cover the art of architecture with glory, and we doubt whether it will give continual joy to any Committee, though art, worthy of the name, be to it a closed book.

It is with relief and satisfaction that the attention is directed to the design which has had the misfortune to be placed second in this competition, and which has been carefully prepared by Mr. J. M. Brydon, under the motto "Lux Mundi." The plan shows a central entrance from Tottenham Court-road, with two offices in each side. The corners of the front are occupied by circular staircases leading to Topylady Hall. The hall is continued through to the chapel and has staircases on each side, which serve both the hall and gallery of chapel.

It is the interior of the chapel that is particularly charming in its treatment. Almost square in plan, the centre is carried up on columns at the angles of a hexagon to form a dome, which is treated with much grace and refinement. The pulpit has been placed on one side of the hexagon, the aisles radiate from this point, and the seating is arranged amphitheatrically. The first floor is occupied in front by the hall, with exit stairs at each corner of

"Sir Paul Pindar's"  
Bishopsgate Street Without.

The First-Floor Room  
Sir Paul Pindar's House

the front wall already mentioned. Two doors open on to the landing of a spacious staircase between the two hooks.

The elevations are very refined in the treatment of the English Seventeenth Century style accepted. It is presumed that terra-cotta would have been used in conjunction with a quiet tone of red brick. The building, had it been erected from this design, would have graced the important position of the site.

The names of the owners of the remaining drawings exhibited not having transpired, we are obliged to refer to them by motto. They are—Saxis, Arcanus, Forward, Hearing and Seeing, Lux, Red Cross, Spero, Wisdom Strength and Beauty.

The design submitted by "Saxis" is an interesting study, and certainly ranks high amongst any of those sent in.

The question of cost is, however, unfortunately always to the fore, and though the author proposes to omit the tower, the design would be too costly for the funds available. We certainly think the perspective most pleasing, and the position allotted to the tower a good one.

We do not feel disposed to take notice of any of the remaining designs, some are better than others, and some are very poor.

It is, perhaps, not to be expected in this prosaic age that an effort would be made, or extra expense incurred, by a Committee to erect a building worthy of an important position. It should be remembered, however, that the site is an important one, occupying a large frontage in a wide thoroughfare, and with large open spaces on each side, which greatly enhance its value, and it is to be regretted that this opportunity of erecting a building which would be a bright feature in one of the dreariest streets in the metropolis should be thrown away.

The Committee is endeavouring to obtain too much accommodation for its money, and we sympathise with the assessor in being driven to place economical mediocrity in front of artistic merit.

**PLANE TREES IN LONDON THOROUGHFARES.**—The Metropolitan Public Gardens Association has offered 100l. each to twenty Metropolitan Vestries and District Boards, to be expended in planting plane trees in suitable public thoroughfares in each district, on condition that the local authorities agree to maintain the trees when planted, replacing such as may die. The Association is willing to do the planting itself should any Vestry so prefer. The chief requisites for success are thoroughfares of sufficient width (say not less than 40 ft.), plenty of good soil to such trees, and the avoidance of gas mains as far as possible.

#### THE "SIR PAUL PINDAR" TAVERN, BISHOPSGATE-STREET.

As we mentioned in a "Note" in our issue of the 13th ult., the picturesque old house in Bishopsgate-street-without, known as the "Sir Paul Pindar" tavern, has been doomed to destruction by the extension eastward of the Liverpool-street terminus of the Great Eastern Railway,—a work, by the way, which necessitates the pulling-down of nearly the whole of the western side of Bishopsgate-street-without. The tavern is stated to be the remnant of the house of Sir Paul Pindar, a contemporary of Sir Thomas Gresham. One of the two sketches by Mr. W. Gandy, which we append, faithfully shows the appearance of the front of the house as it has been of late years; the second sketch gives a view of the interior of the first-floor room. The old house-front, with its greatly-projecting bow-windows, was one of the most picturesque bits of old London.

#### THE LONDON COUNTY COUNCIL.

The usual weekly meeting of the London County Council was held on Tuesday at Spring-gardens, Sir John Lubbock in the chair.

**Finance and Technical Education.**—Lord Lingen, Chairman of the Finance Committee, presented a revised estimate of the contributions required to be levied for the year ending March 31, 1891, explaining at considerable length the reason for the revised estimates. It appeared that a revision of the estimates, approved by the Council in April last, had become necessary as certain charges in respect of pauper lunatics, industrial schools, coroners, &c., which it was estimated would fall upon the General County Account had, by arrangement with the Guardians of the City of London Union and the Corporation of the City of London, been transferred to the Special County Account. This alteration reduced the amount required from parishes within the City. There had been an increase of the Exchequer Contribution through the legislation of last session, by which a proportion of the new taxes on beer and spirits become payable to the County. The whole sum expected to be thus received within the financial year 1890-91 was 140,000l. As a set off against this increased receipt there was the sum of 74,532l. portion of Probate and Licence Duties estimated for in April, but not now expected to be received till after the close of the financial year; 10,250l. estimated decrease of such duties and increased charge thereon; and 10,847l. increased working balances carried

forward to next year. The remainder was accounted for by differences of estimated receipts and expenditure and reduction in the amount to be levied by rate in the City parishes. Of the total Exchequer contribution for 1890-91 there would be receivable after the close of the year the sum of 130,124l. The result of the revision of the estimates was that as regards the parishes outside the City, the contribution required for the second six months would be at the same rate in the pound as for the first six months of the financial year, viz., 6-625d., and as regards the parishes within the City, the contribution would be equivalent to a rate of 4-875d. in the pound, as compared with 6-25d. for the first six months.

The Committee recommended that the amount required to be raised in the second six months should be for the General County account 641,569l., and for the Special County account 202,073l., and "that the Council do appoint Tuesday, October 14, to pass an order for the making of a County rate of 4½d. in the pound for General County purposes, and 1¼d. in the pound for Special County purposes."

The Committee referred to the Act which enables the Council to contribute the whole or part of the grant arising from the new taxes on beer and spirits for the purposes of technical education, within the meaning of the Technical Instruction Act, 1889. The amount expected to be realised within the present financial year was 140,000l. This sum had been included in the receipts on which the estimated rate for the second half of the current year was based. But the ultimate application of any such receipts, if renewed in the present or any equivalent form, required careful inquiry and consideration, and the Committee recommended—

"That a Special Committee be appointed to consider the subject, with express reference to the question whether any, and, if any, what proportion of such further amount as may be received pursuant to the said Act, should be applied to technical education."

With reference to the second recommendation of the Committee, which was taken first, Lord Lingen referred to an amendment which was to be moved by Mr. Spicer in favour of devoting the money, or a portion of it, to the promotion of technical education. He (Lord Lingen) was against applying any portion of those funds to a suspense account. Mr. Spicer had selected one of the most urgent subjects with which they could have to deal; but there were other matters which loomed before them in the near future. There was the water question; then again, they had not laid the ghost of the Thames Tunnel; there would be further expenses, at no very distant date, at Barking

outfall, where the sewage was creating a bar and poisoning the water; there was the question of the dwellings of the working classes, and also that of open spaces. The function of the County Council was to look to the health and convenience of the people of London rather than to that of education, to deal with which there was the London School Board.

Colonel Hughes remarked that if the 140,000 had not come to their aid, the rates would have gone up one penny in the pound, and he objected to the money, which it was the obvious intention of Parliament should be devoted to some special object, being applied to the reduction of the rates in general.

Mr. Campbell said that the money should be kept separate from the rates. He thought they would be untrue to the welfare of the people at large if they applied it to reduce the rates.

Mr. Evan Spicer then moved—

"That a special committee be appointed to consider the subject of technical education, and that until such a committee has reported, the sum of 50,000, part of the estimated proceeds of the new beer and spirit tax, be carried to a suspense account, and the balance of 123,000, standing to the general county account, be reduced by that amount."

He had, he said, originally intended to propose that the whole sum should be set aside, and he was still of opinion that the Finance Committee ought not to have appropriated it to relieve the rates; but as that had been done, and an extra penny would have to be levied as an alternative, he compromised the matter for fear that it would go forth that the increase in the rates was owing to technical education. What had he in London at the present time in the way of technical education? Beyond the efforts of a few philanthropic gentlemen, conspicuous among whom was Mr. Quintin Hogg, the Technical College at Finsbury, and one or two other smaller institutions, no provision was made for affording technical education. If the sum were applied to the purpose suggested it would be paid to them every year, and if used in a proper manner the Government would no more think of stopping his grant than the South Kensington grant.

Mr. Donbleday seconded the amendment. Mr. Burns said that technical education was not a local question for that Council to consider, but an Imperial question, which the State, through the various school boards, ought to see to; and anything short of 20,000,000, towards such an object would be tampering with the question as he understood it.

After a long discussion, during which Lordingen admitted that an extra rate of a penny would be necessary if the 140,000, were not used in the manner suggested by the Committee, the amendment was lost by a large majority. Two other amendments were also lost, after which the recommendations of the Finance Committee were approved.

*London street Advertisements.*—On the motion of Mr. Marks the following resolution was carried:—

"That it be referred to the Local Government and Sanitation Committee to consider and report how the Council can best acquire the power to control and regulate the business of advertising on hoardings in London, by the granting of licences, the proceeds of which should go in relief of the County rates."

The Council soon after adjourned.

## Books.

*Encyclopédie de l'Architecture et de Construction*; Vol. IV. Premier fascicule. Directeur, P. PLANAT. Paris; Dujardin et Cie.

THE fourth volume of the Encyclopédie opens with a long article on "Contrefort," tracing the transmission of the column into the buttress, with numerous illustrations. "Corniche" is the subject of a fairly illustrative article, hardly so complete as so large and important architectural feature seems to demand. This mark applies more strongly to the article on "Couples," signed by M. Alphonse Gosset. By such a subject should be dismissed with scarcely any illustrations it is not easy to understand, except that in dictionary work generally an author is necessarily a good deal dependent on the good will and convenience of his contributor, dictionary writing being usually a very unskilful class of work to undertake. "Crypte" is a very largely illustrated article; the illustrations, as usual, drawn almost entirely from French monuments, which is the defect of

the work throughout; it is a dictionary of French architecture rather than a dictionary of architecture. "Distribution d'Eau" is well treated by M. L. Borne. The article on "Egine" is very well illustrated, with a restoration of the temple of Egina by M. Charles Garnier. "Eglise" would seem a subject rather for a book than a dictionary article; the writer states that he limits himself to marking, in a more precise manner than in the article "Cathédrale," and by some new examples, the origin and first developments of religious architecture "sur notre sol," in this case avowedly limiting it to French work. This exclusive nationality of feeling in such a book is to be regretted, because it limits the scope and usefulness of what is nevertheless a very remarkable publication of its kind, which we are glad to see is fast progressing.

*Guns and Gun Material.* By GEORGE EDE. London: E. & F. N. Spon. 1889.

THIS is an interesting little book, and not the least interesting part of it is its introduction, in which the author, who has been engaged all his life in forging weapons of war, laments the necessity for their manufacture, but, whilst advocating the advantages to be derived from international courts of arbitration, still holds that "in the present state of the majority of the human race, and while it remains the custom to fight first and reason afterwards, war will be best prevented by nations appealing to the fears of each other; such as by continuing in their present course of endeavouring to thoroughly equip themselves with the most destructive weapons."

Mr. Ede has worked for many years in the Royal Arsenal at Woolwich, and is already known as the author of a little work of some repute on "The Management of Steel." He is therefore a competent person to treat on a subject with which he has so long been practically connected. Let us see what he has to tell us, for he has "come to the conclusion that the science of gun-making, even in our own country, is considerably behind other sections of science," and he very truly remarks that "finality has not been reached." He demonstrates that steel is the only possible material which, with our present knowledge, could justifiably be used for guns, and the present work is in some respects supplementary to that above quoted. The object of the work is apparently to induce the Government of this country to conduct experiments which shall, in the opinion of the author, be more satisfactory than those hitherto carried out for testing the nature and properties of the steel supplied for gun manufacture, for he considers that we are so much in the dark on those points that no one can draw up a specification for steel for guns which is based on anything much exceeding guesswork. He recommends the supply and testing of 147 barrels of all sizes, divided into batches of 21, supplied by seven different steel manufacturers, and he enters into as much detail as is possible in a work of seventy-four small octavo pages (of a comfortable-sized type) in respect to the subsequent treatment and mode of completion of each sub-division of each batch of this rather considerable stock of ordnance, which is to be provided for testing purposes only, and with the sole object of enabling a reliable specification for gun steel to be prepared. He is not to be deterred by the question of cost, though he anticipates opposition from some quarters, but he dismisses this with the observation that "if it be conceded that the really expensive experiments are those from which nothing valuable can be obtained, and that those which I have suggested are proper, and under present circumstances necessary, then I think, considering how much they promise in the interest of all, they should be carried out."

This is, of course, the crux of the matter, and, whether M. Ede be successful or not in his tournament, we commend the terseness of the style and the simplicity of the language with which he pleads his case.

*Hamburg und Seine Bauten.* Edited by the Architekten-und-Ingenieur-Verein zu Hamburg. 1890. Publishers' Agents: O. Meissner, Hamburg.

SINCE 1864 we hear of descriptions of German cities being published on occasion of their being selected as meeting-places of the biennial gatherings of the architectural and civil engineering societies (see p. 205, ante), and these descriptions, although commenced in the

modest form of a guide-book, have gradually attained such dimensions that we now find every two years bulky volumes in relation to Berlin, Dresden, Cologne, Frankfurt, and their buildings, of 600 to 800 pages each, before us, containing no more the superficial sketch, but a professional and technical description which even goes into important detail.

This year Hamburg has had its turn (or rather second turn, as in 1868 it had a book of 160 pages). We find the "description" of this most agreeable of all North-Germans cities in the shape of a 730 page volume, edited by a committee of sixteen members of the Hamburg Arch. and Ing. Verein, adorned with no less than 1,377 illustrations. The book, as the introduction says, has been written by members unused to literary labour, in German characters (yet with many a French phrase not admired under the present regime) for Germans, and not for international criticism. It has been divided into the three main sections:—1, history; 2, public work; 3, private work; and each of these three groups has been very fully treated. The historical introduction, written in one chapter, shows us the gradual progress made from the year 811 up to date, and, besides having a good supply of old maps and views reproduced, also has a paragraph of statistical matter. The second section, public work, has been divided into thirty-four sub-divisions, each treating of some distinct subject, pertaining to public works in civil engineering or architecture. The third and last section embraces all private work, the business premises in the city, the stores, hotels and mansions, the residences and villas of the suburbs, and the factories and labourers' dwellings outside the town. We can recommend this book, as well as its predecessors dealing with other cities, as a valuable addition to any reference library.

## Correspondence.

To the Editor of THE BUILDER.

### THE FIRE AT SALONIKA.

SIR,—Three or four months ago you were good enough to insert, and, still more, to recommend by an editorial note, a letter from me calling the attention of architects and archaeologists to the work which was being done by the British School at Athens in the investigation of the Byzantine antiquities of Greece, and inviting subscriptions in aid of that effort.

Although that particular invitation has not met with the response I had ventured to hope for, I am encouraged to renew the appeal under present circumstances. Our architectural students have just been directed to proceed to Salonika for the purpose of carefully examining the ruins and recovering as much as possible from the buildings there, which, it is well known, take the very highest rank in Byzantine architecture, and which are now subjected to a double danger, namely, that of utter destruction if neglected for even a short time on the one hand, and from the great perils incident to restoration on the other. The work already done by the two artists referred to (Messrs. Schultz and Barnsley) has earned the highest possible praise from those who have seen what they have done; but funds are sadly needed to enable them to devote a sufficient time to this very interesting expedition. I need scarcely say that, for their own sake, the School Committee will be anxious to make the results they may arrive at as public as possible. Subscriptions will be received either by Walter Leaf Esq., Old Change, E.C., or by your obedient servant, F. C. PENROSE.

### "AN EMPLOYERS' UNION"

SIR,—It does not say very much for the vitality or scope of the Central Association of Master Builders that, although employing from 400 to 500 hands, comprising largely joiners, polishers, smiths, labourers, &c., and being as you state, Sir, a well-known firm, not the least invitation to join its ranks, not even a circular, has ever reached us from that body, so far as we can remember, since its inception.

The sooner the auxiliary trades receive an invitation to join this Association, if it is the best existent, the better for them and also for the Association itself, which cannot be too strong. Large cabinet-making firms, furniture makers, and shop-fitters employ amongst them a very large number of joiners, polishers, &c., but in the event of a strike, however unreasonable, they would pro-

bably he heaten in detail through utter unpreparedness—witness the late strike of French polishers—a body of men considerably overpaid at \$d. per hour, at least by comparison with skilled joiners at 9d., who have to serve a longer apprenticeship and maintain a kit of tools. It is, therefore, highly important either that these allied trades form a union of their own, or that they join the Central Association of Master Builders, if the latter can adapt its regulations to the slightly varied classes and rates of labour prevalent amongst the branches we mention. CONTRACTORS.

#### "A SANITARY NOTE FROM GREENOCK."

SIR,—In reply to the letter from Mr. Ernest van Putten, on p. 272 of to-day's issue, I beg to say that I did not state that the chief object of a disconnecting syphon was to keep out rats, but that this was one of its important uses. Mr. van Putten thinks that allowing the rats free access into the house drains would do no harm. I think he is wrong, for they could eat through any lead pipes they could get at, and they can sometimes run up inside of the pipes and so get into the house. The plumbers and masons sometimes when working at houses leave pipes open, or partly so, when both sewer smells and rats might get into the house if there was no disconnecting on the drain.

Mr. van Putten is wrong in supposing the "continuous" flow in the sewers is such as to prevent smells, for after six p.m., or somewhat later, the flow of the water in the sewers will be much less than during the day, whereupon smells, &c., rise from the sewage exposed to the air between the high and low-water marks.

Mr. van Putten does well to mention that the unsanitary two-gallon closet flushings are unable to wash the soil properly along the drain; but this is no argument for adding the bad smells from the soil to the drain smells, but goes to show that four-gallon flushes for the closets should be the rule, and that all closet cisterns should have capacity for several two-gallon flushes without waiting till the cistern fills.

Mr. van Putten is wrong in supposing there would be no extra danger incurred by dispensing with the disconnecting trap on the drain, for earthenware closets are easily broken, and many have too little water-lock, while there is danger of sewer air conveying fever germs. Dr. J. B. Russell, Medical Officer of Health, Glasgow, is of the same opinion with me as to this, and could quote instances of fever so produced.

Mr. van Putten seems to me to have had very little experience in house drainage and plumbers' work when he reiterates that "the air in a house drain—disconnected from the sewer by a syphon and with the fresh-air inlet carried up to the top of the house—is practically at a standstill."

With the air inlet at the front of the house and the outlet at the back, there would be pressure of the wind to send a current to the point of least resistance. Then, the sun shining on one of the pipes and not on the other, or one pipe inside of the house and the other outside, all cause differences which produce currents of air through the pipes, and we do not need these currents to be great or very quick.

If Mr. van Putten expects me to be a plumber to sacrifice my house-drains and soil-pipes, &c., for the benefit of his sewers he is quite mistaken. If, as a civil engineer, cannot ventilate his sewers satisfactorily, independent of the house-drains, then I fear he is behind the age. Various plans of doing so have been concocted, and are in practice.

I see one "C. E." has just patented one of the high-level styles similar to what is advocated by me in the "Transactions" of the Sanitary Institute of Great Britain for 1883. I fear he is rather late to claim this as a new idea in 1890.—I am, &c.,

W. P. BUCHAN.

Glasgow, October 4, 1890.

SIR,—In the *Builder* of the 27th ult. your correspondent, Mr. Buchan, in criticising a former communication of mine to your journal, says that my notion that two yards additional length of pipe to a side fresh air inlet of a disconnecting trap would give a greater volume of sewage air to eject to the street shows that I do not understand the subject of house drainage.

I admit that I have not the large experience and scientific knowledge of your able correspondent, still I take credit for having as much commonsense as to see that he is wrong in some of his assertions. However, when he says that there is nothing in those two yards of pipe to raise a smell, I quite agree with him, for the smell comes either from the contents of the closet that is being discharged, or from the deposit in the intercepting trap, or it may be partly from both.

Again, he says that fifty-five minutes out of every sixty fresh air is passing into the drain, and that though this should be stopped for a few seconds by the discharge of a closet, &c., the fresh air that has been entering has to be first pushed out at the grating before any badly-smelling air can get out, and by the time the badly-smelling air can get the length of the grating the closet has ceased running, whereupon the bad air turns back in the drain and goes up the soil-pipe, and out above the roof. That to a great extent concedes the point I have been

contending for—viz., that the air in the pipes is ejected out to the street through the grating, which ought not to be; but that the badly-smelling air, when it gets down to the trap, should turn back and go up the soil-pipe and out above the roof is a novel idea. Suppose a closet or bath is discharged at the top flat of a four-story tenement, where there are eight tenants. The discharge acts like a plug, or piston, driving before it the greater part of the air in the pipe between the point of discharge and the trap, while at the same time, above the roof, there is a rush of fresh air into the soil-pipe following close on to the discharge, and by the time it reaches the trap it has acquired such a velocity that, instead of merely glancing into the trap and turning back and going out at the roof, as stated by Mr. Buchan, the impetus it has acquired in its descent continues for a little after the discharge has reached the trap. The result is that it moves on towards the fresh-air inlet and on to the street. But admitting Mr. Buchan's view of the matter to be correct, that the foul air has turned back and is ascending the pipe, while the other part is in the top flat being discharged, in that case the foul air from the previous discharge must be ejected on to the street. X. Y.

#### FONTS.

SIR,—I have lately been staying at Penmaenmawr, in North Wales, and while there I was struck with the unusual character of the font at St. Seiriol's Church. It is a modern one, about twenty years old. The bowl is large, and prettily ornamented with a bold carving of water-lilies, but the peculiarity consists of a small column standing on the west side of it, which supports a stone reading-desk which rests on the edge of the basin of the font.

Fonts having such appendages are not often seen, and as I have been for some years collecting instances of them it may interest your readers to hear of some. The other modern one with which I am acquainted is at Wraxall, Somersetshire. This has a stone hook-rest attached to the pillar against which the font is placed. It is, I believe, about sixty years old.

At Beckley Church, Oxfordshire, is a massive plain tub-shaped font, and close beside it is a small column of Perpendicular work supporting a stone desk. This is figured in the "Guide to the Architectural Antiquities in the Neighbourhood of Oxford." At Pitsford, Northamptonshire, is a fourteenth-century font of octagonal shape, and to one of the eight sides is attached a species of bracket perforated with four holes. The use of this has not been satisfactorily ascertained, but it was possibly the support of a book desk.

At Heyford, Northamptonshire, is a font, the plain, round basin of which is oolite, resting on a stem of red sand-stone, and attached to this stem where it joins the basin is a stone bracket, for what purpose is not apparent. At Faxton, in Northamptonshire, is a font with a plain bowl, and in the interior of this basin a rudely cut recess has been made, 4½ in. high, 5 in. wide, and 2½ in. recess. This was probably to hold some of the things enjoined in early baptismal ceremonies—such as the holy oil or salt. A circular font at Rainham, Essex, has a small bracket attached to its upper edge.

A font at St. Martin's, Exeter, has a pocket-like receptacle attached to it for moulding, where the octagonal basin joins the pillar which supports it. A fourteenth-century font at Odiham, Hants, has a curious projection on one side. This has, however, not been added to the font, but has been cut out of the same piece of stone as the font. It has been hollowed out into a sort of trough, 5½ in. in length, 2½ in. in width, and 1½ in. in depth, and at each end of this trough is a hole pierced. The font is further interesting by having the text, "Auxiliu meum a dno qui fecit celum et tñ," in raised characters, about 6 in. high, round the bowl. This text is preceded by a pretty lily-like flower.

A font at Youlgrove, Derbyshire, of circular form has a small basin-like appendage attached to one of its sides, a winged dragon lying with twisted tail on its back is carved on the bowl of the font, and apparently holds the smaller basin in its mouth. At Princes Town, Jersey, is an old font now lying disused in a public tea-garden. This font has a small basin fastened to the inside edge of the larger bowl.

At Nun Monkton, Yorkshire, is a round font standing on an octagonal stem and step, and in one of the angles of this step is sunk a rounded hollow, 7½ in. in diameter and 3 in. deep. A wooden font found in a hog at Dinas Mawddwy, Merionethshire, has a large round basin hollowed in it, and by the side of this a second much smaller basin has been cut. A font of stone with a similar arrangement of a large and small basin, side by side, is at Cossenil, near Grenoble.

Several fonts on the Continent have appendages attached to their sides resembling a smaller font standing beside the larger one. The small one is used as a piscina to receive the surplus water which falls from the head of the baptised person so that it shall not run into the font, and be mixed with the consecrated water. Of these, I may mention fonts at Quimper, Guingamp, St. Pol de Leon, Clisson, Chirens, St. Nicolas de Macherin,

Bilvès Villers, Canvoct (Falaise), and Roche Mahille.

Two Swedish fonts,—those of Bjälland and Säfve,—have an arrangement very similar to the one at Nun Monkton, in Yorkshire, having small round receptacles sunk in the lowest step.

EMMA SWANN.  
Wallon Manor, Oxford, October 4, 1890.

#### ILLUSTRATIONS OF THE "VICAR OF WAKEFIELD."

SIR,—With regard to what you describe [p. 252, ante] as "an extraordinary oversight" in my paper on "The Vicar of Wakefield and its Illustrators," I permit me to refer you to the statement (in the first paragraph) that it gives an account of the story "exclusively in its aspect as an illustrated book." If I mention Stothard's drawing, it is because it is exactly like the other drawings he prepared for the engravers of his designs for books; if I mention Mulready's pictures, it is because they were elaborated from his book illustrations. I am perfectly aware that, besides those you name, many artists, e.g., Ward, Maclean, Woodward, have sought in the "Vicar" the subjects for paintings, but to have enumerated those works would have been beside my purpose. AUSTIN DOBSON.  
Ealing, W., October 6, 1890.

#### The Student's Column.

##### HOT-WATER SUPPLY.—XV.

REFERENCE to the conversion of a tank to a cylinder system, treated of in our issue of the 27th ult., last, it remains to be added that whenever a conversion is effected, and it is found that a draw-off service is connected to the flow pipe below the cylinder, this service must be cut off and reconnected to the rising main above the cylinder, as it will now be understood that the chief advantage, the safety, of this system is effected by omitting all means of emptying the cylinder, except by the special cock with loose key that is provided for workmen's use and emergency. If, in the conversion last explained, anything would be gained by leaving the original return pipe untouched, this may be done, as no particular benefit will be effected by cutting this pipe and connecting the two ends into the cylinder; it can be left as it existed before, running from the tank to the boiler, the cylinder being inserted into the flow pipe only.

##### TWIN BOILERS AND SERVICES.

There are at this moment hundreds, if not thousands, of houses, particularly in the West-end of London, that have the old-fashioned open ranges in their kitchens, these ranges having two boilers fitted in them. These are not exactly "twin" boilers, but they serve to illustrate the use and occasional necessity of these articles.

The object of having two boilers in these old ranges was twofold; firstly, one boiler was considered and generally found to be incapable of providing sufficient hot water for the whole house, and it became necessary to put in two boilers with a proportionate increase in the size (width) of the fire, so that one could be used and kept distinct for kitchen supply, and the other for baths and the other taps in the house. This arrangement was so customary that makers of modern ranges are continually being asked if they are sure the one boiler in their ranges is sufficient for all purposes, and the enquirer is often incredulous if answered in the affirmative, as the boiler in a modern range may only be half the size of one of the boilers in their existing range.

The only argument in favour of the two boilers in the open range was that the demand for hot-water in the servants' offices need not exhaust the bath supply, or *vice versa*, but this argument cannot hold good with a modern range, provided it has a good boiler. The arrangement of two boilers, however, became so customary that great numbers of houses will be found to have a cistern at the top and another below, one for upstairs use, and one for kitchen supply (for both hot and cold water, but this is now quite unnecessary so far as hot water is concerned).

Sometimes instead of two boilers a single boiler of large size was used, this boiler supplying the kitchen under low pressure, and within this boiler was fitted a coil of pipes which acted as a heating medium for a hot-water circulating apparatus, that was in connexion with the bath supply, &c.; this is a wretched arrangement, as, in the first place, hot-water is a po-

medium to heat water with, and secondly, every time a drop of hot-water was drawn in the tub the coil was cooled to some extent by the cold water flowing in. The two boilers were better than this, but neither could possibly be recommended now.

An occasion that arises for the use of twin boilers is when the cistern at the top of the house is insufficiently large for all purposes, and the cistern which we must suppose exists above is of necessity to be relied upon. It will be obvious that the two cisterns cannot now be made to supply one apparatus (if any part of the apparatus extends up above the water cistern), and it becomes necessary to have two boilers in the fire, each doing distinct work with a distinct supply. This, fortunately, rarely happens, as it is an unsatisfactory arrangement, and an effort is always made to overcome the difficulty by adding to the storage capacity of the cistern at the house-top, so that it can meet all demands, and so need only one boiler. It is hardly necessary to mention that the arrangement of two boilers is much the more costly, and as it necessitates an increase in the width of the fire the consumption of fuel is greater, and the range has to be strengthened to withstand the greater wear and tear caused by the greater heat evolved, &c.

FIG. 32.

Fig. 32 illustrates a pair of boilers to go at the back of a kitchen range, but to get a separate pipe to each it becomes necessary to have the range of a most extravagant width, especially if both boilers are not required all day. The difficulty is, therefore, overcome to some extent by

FIG. 33.

making the boilers as fig. 33, but here a disadvantage presents itself in the fact that no means can well be devised to work one boiler independently of the other.

When a pair of boilers are really necessary, it is practically impossible to make them each of an exactly suitable size for the work each is to do. The consequence of this is that in all probability one boiler will overdo its work, and the other fail, and under any circumstances some annoyance will be felt by the boilers working unequally. A very marked instance of this is when one boiler is used for circulation, and the other for steam cooking. The circulating boiler must, of course, be capable of good work, and the steam boiler has to be powerful. Yet its latter boiler may be only in use for two or three hours in the morning, and for the rest of the day the increased size of fire is a mere waste of fuel, and the water boiling furiously and for no purpose. If it is at all possible to avoid using two boilers in one fire, it is much the best to do so.

Coming within this subject is an arrangement for connecting and using two distinct boilers (say, in two different rooms) attached to one circulating apparatus; this is often resorted to, and is frequently of great convenience, particularly where the demand for hot water varies to any great extent during the day or in different seasons. In some institutions,—col-

leges, for instance,—the quantity of warm water required for early bathing is frequently very large, and complaints then occur of the kitchen-range boiler being quite unequal to meet this excessive demand, although quite able to supply sufficient at other times in the day. The remedy, in this instance, would be to introduce an independent boiler; but on this occasion it would be best to still retain the services of the range boiler, as it will not only aid the other materially, but it will permit of the independent boiler fire being let out when the demand has slackened; or there are cases where a second range of smaller size exists in the kitchen or scullery, and if fitted with a circulating boiler it can be connected on to the apparatus which is worked by the large range, so that whichever is in use (or if both are at work) the supply of hot water does not cease.

The usual way of connecting up the two

FIG. 34.

boilers is as shown at fig. 34, the flow-pipe from each being joined at the nearest point, and the return pipes in a similar manner; if it is the cylinder system the pipes can be made to enter the cylinder from each side, or they can be joined at the nearest point as just explained.

It is sometimes recommended under this arrangement to have a stop-cock inserted in each flow and return pipe (four in all), so that when one boiler is undergoing any repair or being cleaned, the stop-cocks in that pair of pipes can be closed, and so permit of the other fire being used, and providing the customary hot-water and cooking conveniences. This is certainly very convenient, but the introduction of stop-cocks into the main (primary) flow and return pipes is a most objectionable and sometimes disastrous practice; the least forgetfulness, or any conscious or unconscious trifling with the cocks, may lead to an accident, which is invariably fatal to any one who may be near.\*

Sometimes twin boilers can be avoided by carrying two distinct sets of pipes from one boiler, but it will be clearly understood that these two systems must be fed by one cistern (or two cisterns on the same level), with the expansion pipes both carried to an equal height, otherwise one will, of course, overflow the other the instant they are charged (unless an arrangement of stop cocks is introduced, which, however, would not permit of the two systems being worked at one and the same time). An arrangement of this kind is of use when one or two small coils are to be heated, say, for an entrance-hall, from the kitchen boiler. It is then best, if it can be possibly managed, to take a flow and return service from the boiler, independent of the ordinary flow and return; this coil service may have stop cocks, provided none are inserted in the other pair of pipes, and this will permit of shutting off the coils when the tank or cylinder is to be heated up quickly, or when the heat from the coils is not needed. This subject of coils in connexion with kitchen range boilers will be treated fully in a later paper.

There is no objection to carrying more than one rising main (secondary flow) service from the top of the cylinder, if hot water is wanted at a distance in different directions, these various services being either brought back into the return or each having its own return to the cylinder. At one of the Hôtels Métropole just erected there are four 1½ in. secondary flow-

\* It is but a short time ago that a plumber—a practical man—lost his life through omitting to open these stop-cocks when testing a boiler, after having done some work which necessitated their being closed. He was killed instantaneously.

pipes, as water is wanted in great quantity in different parts of the building; the cylinder however is heated by steam, being made of copper and much like a multitubular boiler, but of course an independent boiler would heat it equally well if there was not steam to spare.

GENERAL BUILDING NEWS.

THE NEW SPANISH CHURCH, MANCHESTER-SQUARE.—The new Roman Catholic church which replaces the old chapel of the Spanish Embassy in Spanish-place, Manchester-square, was opened on September 29. The first stone of the building was laid on June 17, 1889. The architects of the new building are Messrs. Goldie, Child, & Goldie. It is a large and massive structure in the Early Gothic style. Externally it is of Portland stone, and internally the whole building is faced with Bath stone. The columns are constructed of Hopton Wood stone and Derbyshire marble. There are double aisles to every part of the building, and the whole is vaulted in stone. The builders are Messrs. Doves Brothers. The length of the church is at present about 160 ft., and the height to the vaulting over 60 ft. The exterior is very unfinished, but it is proposed to lengthen it considerably, to construct a tower and spire upwards of 200 ft. high, and add gabled roofs and turrets to the transepts. A good idea, however, of the fine proportions of the church may be gained by the view from South-street. The internal fittings, altars, &c., are all temporary, and have been removed from the old chapel. We have published the following illustrations of this church in the *Builder*, viz., Exterior Views, August 1, 1885, and June 4, 1887; Interior Views, August 1, 1885, and June 11, 1887.

NEW CHURCH, ST. ANNE'S, STANLEY.—On the 27th ult. the new memorial church of St. Anne's, Stanley, Lancashire, was consecrated by the Bishop of the diocese. The building consists of nave, 27 ft. wide, 87 ft. long, in six bays; north and south aisles; baptistery at the west end; chancel, 42 ft. long by 27 ft. wide, with chapel on the south side, and organ-chamber, choir, and clergy vestries, with lavatories, &c., on the north. The principal features of the exterior are the tower over the chapel, the main porch, and the west five-light window. The walls of the church are of stone, that for the exterior being from Woolton and the interior from Rancorn, of variegated colour. The wood-work of roofs and seating is of pitch-pine, the stalls and other furniture being of oak and teak. The roofs are covered with grey Welsh slates, except that of the tower, the covering of which is green Westmorland slate. The flooring of the nave, aisles, &c., is of pitch-pine block paving, laid by Messrs. Roger L. Lowe, & Co., of Farnworth; the flooring of the chancel and sacristy is of marble and glass mosaic. The altar steps are of white marble. The stalls have carved ends, and the screens enclosing them are traceried and carved. The screen on the north side is divided into five bays, and has a central doorway. The screen on the south side has six bays. The reredos is composed of Derbyshire alabaster, with Devonshire marble retails. The subject of the carving is the Last Supper, a composition by Mr. Walter Lonsdale, of London, who was also the designer of the stained glass. The pulpit is of Ancaster stone, with red stone plinth and base, supported by five shafts of Devonshire marble. The font is of Ancaster stone, supported on Devonshire marble shafts. The heating is heated with hot water. The windows and floorings are glazed with glass in lead quarries. The general contractors for the building are Messrs. Jones & Sons, of Liverpool. The reredos, pulpit, and font, by Messrs. Earp & Hobbs, of London and Manchester; the screen and choir stalls by Mr. Harry Hems, of Exeter; the beating by Messrs. J. R. Cooper & Sons; the mosaic flooring by Mr. George Swift. The stained glass of the east window has been executed by Messrs. Heaton, Butler, & Bayne, of London. Mr. Thomas Hallam acted as clerk of the works. The architects are Messrs. Aldridge & Deacon, of Liverpool.

NEW MEAT MARKET FOR EDINBURGH.—On the 2nd inst. the Edinburgh Central Meat Market Company's new premises in Ponton-street were formally opened for business. The market, which is built of brick, with facings of Corncockle stone, measures 80 ft. by 80 ft. The side walls are 18 ft. high. The premises are suitably lighted and ventilated. The total cost of ground and buildings is about 4,500l. The contractors were Messrs. James Duncan & Son, and the architect Mr. W. H. Gray, of Edinburgh.

PROPOSED NEW CHURCH FOR BARRY.—We are informed that a gentleman holding important local interests has placed 500l. in the hands of the Bishop of the diocese towards the erection of a new church at Barry. A grant of 400l. has also been voted by the committee of the Bishop of Llandaff's Fund, and a site in a good central position has been given by Mrs. Jenner, of Wotton Castle. Plans for the building are being prepared by Messrs. Kempton & Fowler, architects, Llandaff. It is proposed to build, in the first instance, only one portion of the fabric (nave, chancel, and one aisle), estimated to hold 600 persons. The cost of the first portion of the fabric is estimated at from 3,000l. to 4,000l.

FOREIGN AND COLONIAL.

FRANCE.—The committee for inquiring into the project for a maritime canal between Paris and Rouen has been officially constituted, under the presidency of M. Alphonse. The Chamber of deputies will have shortly placed before it for consideration a project for the demolition of the fortifications of the city of Saint Omer. The estate of the late Comte de Bardi, which has only been in the possession of the Duke of Parma and the Comte de Bardi, to whom the Comte de Chambord has left this historic domain and château. A committee has been formed at Chignon (Indre et Loire) for the erection of a statue of Jeanne d'Arc and the hippodrome at Bourdeaux, only recently opened, has been completely destroyed by fire. At Lyons a hitherto unknown painting of Karl du Jardin has been discovered. The competition for the construction, at Melun, of a building for storing the departmental archives of Seine-et-Oise, has just been decided. The first premium has been awarded to M. Léon Majoix of Paris; the second to M. Prosper Bulot of Melun; the third to M. Léon Beaubourg of Paris. The decision on the competition held at Epinal (Vosges) for a new Lycée, has been decided, with the following results:—First premium, MM. Clusquin and Guillet; second premium, MM. Guillet and Dulaire, of Nancy; third premium, M. Jasson, of Nancy. Innumerable mentions were given to MM. Guillet and Berger, of Nancy, and to M. Guillet, of Paris. The building will cost about 300,000 francs.—The excavations near Bourges, in connection with the construction of a bridge over the Auron, have led to an interesting archaeological discovery, in connection with the course of the river a series of sculptured steles has been found; and in their rear considerable number of coins, pieces of pottery, hand-mill and several grindstones.—The inauguration of the monument to Flaubert at Rouen, has taken place in November, has been put off indefinitely to give time to M. Chapu to finish the medallion portrait, with which he is not satisfied.—There is to be inaugurated at Angers, shortly, a monument to the memory of the members of the "Gardes Nationales mobiles" of Dordogne who fell in the Franco-German war.—The works going on for the repair of the cathedral at Cahors have led to the discovery, on removing some coats of whitewash, of some large frescoes in an excellent state of preservation, and with richly decorative designs. They are representations of eight prophets. In the centre of the cupola there is also a fresco of St. Stephen, of the thirteenth century. There is to be "restored" this year, M. Aimé Morot has completed his decorative paintings for the Salon d'Honneur of the Hôtel de Ville at Nancy, which will be shortly fixed in their place.—The workmen occupied in digging the foundations for the new Hôtel de Ville at Evreux have come upon a quantity of Roman coins of the first and second centuries.—The scaffolding has been removed from the ceiling of the Salle des États at the Louvre, and M. Duran's painting of the Triumph of Marie de Medicis is now exposed to view. The moulded framework surrounding the painting is now being completed.

ENMARK.—The East Street of Copenhagen, the chief thoroughfare in the Danish capital, has been improved during the summer at a cost of 500,000. The improvements in Copenhagen are of a high order. It has now been definitely decided to build a large industrial museum in Copenhagen at a cost of about 30,000. It is to contain complete samples of the past and present Danish industries. The so-called Prince's Palace in Copenhagen, where are the national Norse and ethnographical collections, is to be re-modelled and greatly enlarged, so that the building is to be isolated, so as to render it safe from external fire. Prof. Storch has been entrusted with the work. The building is one of the most imposing in Copenhagen, and is of the last century. The excavation of the remains of the Amtvorskov Cloister is now taking place, a great portion having been laid bare. The chief interest is of being the only cloister in Denmark in the Romanesque style. It was built in the twelfth century for the Order of St. John by Waldemar the Great.

RUSSIAN HARBOUR.—The Russian Government is constructing a great new harbour at Treuf, four versts north-east of Lihau. At first it was suggested to make the harbour in the latter bay, the cost being estimated at 60,000,000 roubles, but this idea was abandoned. The new harbour will cost 13,000,000 roubles, and will be completed in five years. There are to be two tidal locks, with separate entrances, protected by a breakwater.

THE NEW OPERA HOUSE IN STOCKHOLM.—The Minister of Public Works has now under consideration the plans of the new Opera House to be built in Stockholm. Afterwards the local authorities will consider them. An expert has been attached to study the interior arrangements in leading theatres abroad, but it seems decided that the process of impragoration of decorations,

curtains, &c., will not be adopted, it having been found in several foreign theatres that the process only protects against fire for a short while, and that, moreover, it is injurious to the atmosphere on the stage.

THE NEW SWEDISH HOUSES OF PARLIAMENT.—A member of the jury for adjudicating upon the plans of the new Swedish Houses of Parliament has caused the designs of Herr Helgo Zetterval, the Government Architect, and which have been accepted in their main features, to be published at his own expense. There are sixteen plates in half the size of the original drawings, handsomely reproduced by the Lithographic Institute of the General Staff in Stockholm. Borings have shown that the site of the new buildings is satisfactory, of which some doubt was entertained.

MISCELLANEOUS.

EXTENSION OF DOVER HARBOUR.—The Dover Harbour Board have just decided upon some very extensive harbour works. It has been decided to apply next session for a Bill to authorise the Board to spend 300,000 upon the extension works, and to raise the money by means of a small passenger tax. It is proposed to enclose a large area of water between the Admiralty Pier and a point to the eastward opposite the Esplanade, where a structure similar to the Admiralty Pier will be run out. The enclosed area will be utilised as deep-water docks, while one portion of it will be devoted to covered water stations, with accommodation for trains on either side of the vessels. It is estimated that the whole work can be completed in three years.

SANITARY ASSOCIATION OF SCOTLAND.—The Board of Examiners in Sanitary Science held an examination in Mansel College, Aberdeen, on the 1st inst., when nine candidates presented themselves. Certificates of competency in Sanitary Science were granted to five candidates, namely:—Mr. James J. Little, Assistant Sanitary Inspector, Pollockshaws; Alex. Knowles, Assistant Sanitary Inspector, Aberdeen, with commendations; James Mackintosh, Assistant Sanitary Inspector, Aberdeen; George Horne, Surveyor, Milton of Campsie; David A. Duncan, Water Inspector, Shirling.

HONEYSETT'S PATENT HYDRAULIC CALCULATING RULE.—An instrument, resembling an ordinary slide-rule, has been devised and patented by Mr. Honeysett, by the use of which time and labour may be saved when such calculations in hydraulic engineering as the velocities and discharge of pipes and conduits have to be frequently made. The rule, which is based on Bazin's formula, contains eight scales, four of which correspond to the different nature of the channels under consideration, which may vary between smooth pipes and ordinary river courses. The velocities in feet per second and the quantity discharged for any of these channels, according to the hydraulic mean depth and such inclinations as occur in practice, can be read off the rule with great ease. The instrument is also capable of showing the diameter of a pipe to discharge any given quantity. On the back of the rule, tables will be found for facilitating the calculations of the area and hydraulic mean depth of segments of circular and various oval conduits, for use when ascertaining the discharge of a conduit flowing only partly full. Mr. W. F. Stanley is the maker of the instrument, and great care appears to have been taken in its construction.

THE ENGLISH IRON TRADE.—The English iron market is still unsettled, owing to the strike in Scotland, and although there are reports of its early collapse, which should be received with due reserve, its present effect tends, to a certain extent, to paralyse trade and to disorganise prices. This has been especially the case in the Glasgow market and the Middlebrough iron markets. Scotch warrants have vacillated a great deal, while makers in Scotland do not quote at all. The fluctuations in the North of England pig-iron market have not been great, but they show that speculative influences are at work. In the Lancashire and other markets business in pig-iron is almost stopped. A fair inquiry continues in the hematite iron trade of the north-west, with prices tending upwards. The trade doing in finished iron is from moderate to fair, but prices are well maintained, which, under present conditions, could not well be otherwise. The improved tone in the steel market has not been impaired. Ship-builders and engineers continue busy.—Iron.

DOCK EXTENSION AT GLOUCESTER.—The Canal Company have for some time had under consideration proposals for the extension of dock accommodation in Gloucester. The property proposed to be developed lies at the side of the canal just outside Gloucester, and is thirty-seven acres in extent, and by the construction of a dock here much greater facilities will be offered for the discharge of vessels and the storage of cargoes than hitherto. Messrs. Thomas Adams & Son, Limited, timber merchants, of Gloucester and Birmingham, have secured seven acres of land adjoining the proposed new dock, which will give them a frontage of 1,500 ft. to deep water, and enable them to discharge six or seven vessels at one time. In this connection the

probability is mooted of important changes by the Midland Railway Company which, if carried out, would enable the company to do away with its present connexion between the dock system and the main line and its many inconvenient level crossings. —Birmingham Gazette.

TECHNICAL EDUCATION FOR PLUMBERS.—The Newcastle Chronicle announces that Mr. G. E. Bland, lately of Leeds, has been invited by the committee of the Plumbers' Technical Class Association, acting in conjunction with the Durham College of Science, to assist in the teaching of the technical class held in that college. Mr. Bland will give a short course of lectures during the present term. The Worsbipful Company of Plumbers has undertaken to conduct an elementary examination in May next, and to give certificates to junior apprentices. The same company will, in subsequent years, conduct examinations of a more advanced character in accordance with the graded syllabus of instruction drawn up by them, and intended to occupy at least three sessions.

INLET SAFETY GAS REGULATOR.—This is a very useful and simple invention by Messrs. Slatter & Watkins, the object of which is to enable the master of a house or of a large establishment to check and regulate the inlet of gas from the main before it enters the meter, and to prevent any one turning on the gas fuller than experience has proved to be necessary for the sufficient illumination of the building. This is done by means

of a stud on the ordinary regulator wheel, which enters a slot on a spur wheel which is called the "stop wheel." The shaded hand on the dial, shown in the cut, marks at what point the supply is to be checked; when the shaded hand is at that point, the gas inlet cannot be turned on further than will bring the black indicator hand level with the "stop" hand. The stop action is worked by the rack wheel on the left below the dial, the dial-hand indicating the result of the movement. The door can of course be kept locked after setting the regulator, so as to prevent its being interfered with. In large houses or places of business this would form a most useful check on the waste of gas.

ARCHEOLOGICAL DISCOVERIES AT ATHENS.—One of the representatives of the German Government, watching the excavations at Athens, writes to us:—In the quarter north-east of the Acropolis an extensive Roman gymnasium is being excavated on behalf of the Greek Archeological Society. The site is close to the well-known Tower of the Winds, or the Horologion of Andronicos, and as evidently of the same importance for the leisure and recreation of the Athenian public in Imperial times as is the splendid Stoa of Hadrian in the next street, together with which and the Attalos Stoa, the gymnasium, when entirely excavated, will become a special feature of this part of the town. The excavations show a double row of Roman columns with ionic capitals, surrounding a large yard, beautifully laid out with well-preserved marble slabs. The underground water-pipes, visible through the round opening of a well, remind them that every new excavation shows how much better the Athens of ancient times was watered than is the city of the present day. Some funds, consisting of tombs with reliefs, have been made in the classic cemetery near the Dipylon.—Pall Mall Gazette.

THE PROPOSED BRIDGE ACROSS THE CHANNEL.—A paragraph which has appeared in all the daily papers says that the soundings made by the French engineers on their side of the English Channel, in connexion with the proposed Channel-bridge, have now been completed. The results of the survey are, it is stated, not so satisfactory as was hoped, and the bed of the Channel between Folkestone and the Varne being somewhat unfavourable to the scheme. In this case another route will have to be found, probably between the nearest land points—namely, Cape Grisnez and Dover.

THE BOROUGH SURVEYOR OF DEVONPORT.—The Devonport Town Council has increased the salary of the Borough Surveyor (Mr. J. K. Burns) from 2500. to 3000. per annum.

COMPETITION, CONTRACTS, AND PUBLIC APPOINTMENTS.

Table with columns: Nature of Work, By whom Advertised, Premium, Dates to be delivered, Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, and Tenders to be delivered. Includes sections for COMPETITION, CONTRACTS, and PUBLIC APPOINTMENTS.

Those marked with an Asterisk (\*) are advertised in this Number. Competition, p. iv. Contracts, pp. iv. and vi. Public Appointments, p. xviii.

WOOD-CARVING.—A new studio will be opened at King's College on Monday, the 13th inst., under the auspices of the Worshipful Company of Carpenters, for wood-carving classes.

ASSOCIATION OF MUNICIPAL AND SANITARY ENGINEERS AND SURVEYORS.—The tenth examination held under the auspices of this Association was held at 11, Victoria-street, Westminster, on Friday and Saturday, October 3 and 4, when eight candidates entered.

PYROGRANITE.—This is the title of a new material formed by a combination of a fusible with an infusible clay, by which a very hard material can be formed from very common clays, which can more over be mixed in such a manner as to take (after polish) the appearance of various marbles.

THE ASSOCIATION OF PUBLIC SANITARY INSPECTORS.—The annual meeting of the Association of Sanitary Inspectors of Great Britain was held on Saturday evening in Carpenters' Hall, London-wall, Mr. Hugh Alexander, Chairman of Council, presiding.

paid to the memory of the late Sir Edwin Chadwick, ex-President of the Association, and reference was made to the block of business during the late Parliamentary session, excluding measures of sanitary reform recognised as necessary to make sanitary inspection more beneficial to the public health.

LEGAL.

THE DANGERS OF SKY-SIGNS.

On the 3rd inst. at the Clerkenwell Police Court, the Bovril Company (Limited) were summoned by Mr. C. Mealy, surveyor to St. Luke's Vestry, for that at 63, Bath-street, St. Luke's, they did unlawfully erect a sign projecting over the public way of Lever-street, St. Luke's, and that they did not within fourteen days after notice to them remove so much of the sign as projected over the public way of Lever-street, contrary to the 18 and 19 Vic. cap. 120, section 119.

A CLAIM FOR PROFESSIONAL FEES.

IN the Westminster County-court, on the 2nd inst., the case of Tylor v. Newstead came on for

hearing before Judge Bayley. The plaintiff, an architect and surveyor, sought to recover 26s. for fees due to him for work done for the defendant. The case for the plaintiff was that the defendant was going to erect a building at the French Exhibition for a panorama of Tel-el-Kobir. Mr. Tylor drew plans (which were submitted to the London County Council) of a wooden building, but that the Council refused to pass. Fresh plans of a larger building were eventually agreed to, and the Council passed the plans of the building on the condition that corrugated iron was substituted for wood. A tonard was received from Messrs. Chappell, of Pimlico, for 2,600l., the price for erecting the iron building, but by this time the site had been let to some one else.

The defendant said he had wanted the plaintiff because he knew he had erected the buildings for other panoramas, including "Niagara" and "Waterloo." The arrangement was that as the matter was all speculation, and he agreed that if the plans were not passed that he should only receive 10l. 10s. that he had paid into court. He could not erect the building as the Exhibition opened on May 1, and the plans were not passed before that month.

Plaintiff did not press for the item of 2l. for a second lot of plans, and his Honour gave judgment for 24l., with costs.

MEETINGS.

- TUESDAY, OCTOBER 14. Sanitary Institute (Lectures for Sanitary Officers). Professor H. Robinson on "Drainage." 8 p.m.
FRIDAY, OCTOBER 17. Architectural Association.—Annual General Meeting when an address will be given by the President, Mr. G. G. Scott, at 8 p.m.
Sanitary Institute (Lectures for Sanitary Officers).—A Lecture will be given on "Sanitary Building Construction." 8 p.m.

RECENT PATENTS:

- ABSTRACTS OF SPECIFICATIONS.
15,140.—DOOR HANDLES: J. Kaye.—By means of this patent the handle is fixed in a frame the shape of the letter B, the straight part being the handle. There is projection at the back of this frame into which a push and pull spindle is screwed. In the door plate is a hole or socket near its centre for the projection of the handle frame to slide in, so shaped as to prevent the handle being turned after having been fixed for use.
15,093.—SASH FASTENERS: J. H. Austin.—According to this invention, the object is, first, the automatic locking of the sash when closed; and, secondly, the prevention of the fastening from being undone from outside the sash. Two plates are used, one having a tongue and the other a groove. The tongue and groove are lapped, so that, while there is ample space to insure their engaging with one another when they come together, they draw the two parts of the sash together and prevent their rattle. This tongue is kept forward by a spring, and its engaging end is bevelled or chamfered off, so that it is pushed back against the spring, as the sash is closed, and automatically springs forward to engage with the recess in the other plate when the sash is closed. A handle is provided, so that the tongue can be drawn back to free the fastening and open the sash.
15,115.—SINK OR PEDESTAL AND SIPHON TRAP COMBINED: J. T. Bolding.—A pedestal or stand for a closet pan, which is the subject of this patent, is made in the form of and acts as a siphon trap. Being made in lead, it can be fitted direct to the soil or waste-pipe, or, 8,966.—CHIMNEY TOPS: G. Tweedy.—In order to better fix the chimney pots or cowls upon the brick work, a cover and flange and socket, which the cowls or pots may slip over into, is made and fixed into the brickwork of the chimney at the top.

11,185.-INLET VENTILATORS FOR DRAINAGE: S. Jennings... According to this patent, the air-ripeners hang under pipes...

NEW APPLICATIONS FOR PATENTS. September 22.-14,963, H. Dickinson, Sky-aligner... September 23.-15,043, J. Lewis, Filling or Securing...

PROVISIONAL SPECIFICATIONS ACCEPTED. 8,203, J. Empton and others, Siphon. Flushing terms... 13,371, H. Harris and W. Power, Electric lights and indicators...

OME RECENT SALES OF PROPERTY: ESTATE EXCHANGE REPORT.

SEPTEMBER 29.-By P. Hodson: 37 and 53, Carlton-Kentish Town, n.t. 6 yrs. gr. 111 12s. 4d., 4,300... SEPTEMBER 30.-By T. B. Westcott: 11, Crogland-Haverock-hill, u.t. 76 yrs. gr. 82, r. 482 p.a. 6s. 6d. 44, 402, 2, Goldharter, Hampstead...

ICES CURRENT OF MATERIALS.

Table with columns: Material, Price per unit, etc. Includes items like Timber, Sheet Iron, and various types of wood.

Table with columns: Location, Price per unit, etc. Includes items like Deal, Timber, and various types of wood.

Table with columns: Location, Price per unit, etc. Includes items like Iron, Steel, and various types of metal.

Table with columns: Location, Price per unit, etc. Includes items like Lined, Coconut, and various types of goods.

TENDERS.

(Communications for insertion under this heading must reach us not later than 12 noon on Thursdays.) ABERDEEN.-For new cottage at Park Gwyn and a cottaged and other works at Great Trinity Park near Abernethy...

ASHBURTON.-For the erection of two detached villas residences at Ashburton, Devon, for the Ashburton Building Company (limited). Mr. W. Borell, architect, Newbury Abbott...

BARNET.-For the construction of 12-in. pipe sewers, &c. Park Road, Barnet, for the Barnet Local Board. Mr. Mansbridge, Surveyor, Local Board Offices, 14, High Street, Barnet...

BISHOPS WALTHAM.-For building new stable and coachhouse, at the Kings' Head Inn, Bishops Waltham, Hants, for Mr. T. Young, Mr. H. B. Waltham, architect, Bishops Waltham...

BRANDON PARK (Suffolk).-For carting iron work to hold 25,000 gallons... on brick tower, for the Baron de Harrelle. Mr. Edward S. Mansbridge, surveyor, 25, Mount Street, Grosvenor Square, W. Mr. J. Mowlem & Co., 11, Victoria Street, Westminster, London, W. 1, 11,225 0 0...

CRUYDON.-For five years of houses, Brighton Road, Cruydon, for Mr. J. Peiton. Mr. R. W. Price, architect, 12, Buckingham Street, Strand...

DARLINGTON (Kent).-For painting work at the asylum and schools for the Metropolitan Asylum Board. Messrs. A. & C. Harston, architects, 15, Leadenhall Street, E.C. 3...

DEBROUROUGH.-For the enlargement of Board Schools at Debrough, for the Debrough School Board. Messrs. Golch & Souders, architects, Kettering...

EDINBURGH.-For about 400 tons of dry-ash cast-iron pipes and special castings for the Edinburgh and District Water Trustees. Messrs. J. & A. Leslie & Reid, engineers, 72a, George Street, Edinburgh...

EXMINSTER.-For extension of gasworks, new gasometer, reservoir, &c., at the County of Devon Engineering. Mr. Archibald D. Davern, engineer, Exminster...

HALIFAX.-For the erection of eighteen scullery houses, the formation of a new street on the Edge Estate, Halifax, for the Halifax Industrial Society (limited). Messrs. Jackson & Fox, architects and surveyors, 23, George Street, Halifax...

MANLEY.-For sewers at Trent Hay, Swan-Parage, &c., Main Drainage Works, Manley, Staffs, for the Borough authorities. Mr. Joseph Lobley, Borough Engineer, Manley, Staffs...

LONDON.-For taking down and rebuilding the Mansfield Tavern, Gospel Park, for Mr. Richard Daver, exclusive of all bar fittings and gas. Quoties by Mr. A. Griggs, Mr. Albert E. Taverner, architect, 2, Broad Street Buildings...

LONDON.-For rebuilding Nos. 8, 10, 12, Tottenham-hill and 22, Whitefield Street, Tottenham-court-road. Mr. H. H. Barden, architect, Quoties by Mr. Rockwood & Bywaters...

LONDON.-For the extension of the Governor's buildings, for the St. George's, Hanover-square, Workmen's Dwellings Association. Mr. G. E. Barchus, architect, Quoties by Mr. Rockwood & Bywaters...

LONDON.-For the erection of a house at Streatham Park. Mr. William Hunt, architect, 5, York Buildings, Adelphi, W.C. 1...

MANCHESTER.-For the erection of four buildings on the unmodernized site, each to contain a room for the teaching of manual instruction and a room for the use of clerk of works for repairs, for the School Board for London. Mr. T. J. Bailey, Architect...

MANCHESTER.-For the erection of a Village-hall at Crawley Down, Sussex. Mr. Paul H. Chambers, architect, Ship-street, Crawley, Brighton...

MANCHESTER.-For the erection of a Village-hall at Crawley Down, Sussex. Mr. Paul H. Chambers, architect, Ship-street, Crawley, Brighton...

MANCHESTER.-For the erection of a Village-hall at Crawley Down, Sussex. Mr. Paul H. Chambers, architect, Ship-street, Crawley, Brighton...

LONDON.—For providing heating apparatus on the low-pressure hot-water system for the new portion of the Bloomfield-road School, Plumstead, and for providing a new boiler for the School Board for London. Mr. T. J. Bailey, Architect, 21, Abchurch-lane, E.C.4. £1,021 0 0  
 Fraser & Frost ..... £1,021 0 0  
 W. G. Cannon ..... 783  
 J. & C. Bowyer ..... 693  
 \* Exclusive of an additional sum of £103 if School Board pattern boiler and Russell's patent radiators are used.  
 Accepted by the Works Committee.

LONDON.—For rebuilding the "North Pole" Tavern, Greenwich-road, for Mr. H. B. Towers. Messrs. John Giles, Gough, & Trullisp, Architects, 28, Craven-street, W.C. Quantities by Mr. C. H. Goods, Clerk to Messrs. Giles, Gough, & Trullisp, Architects, 28, Craven-street, W.C. £2,783 0 0  
 J. & C. Bowyer ..... £2,783 0 0  
 Holliday & Greenwood ..... 2,540  
 W. & H. Carter ..... 693  
 \* Accepted.

LONDON.—For laying out the Tench-street recreation ground, Wapping, for the London County Council. Mr. A. R. Binnie, Engineer.—  
 J. Biggs ..... £2,294 9 0  
 J. F. Metton ..... £1,760 0 0  
 S. Kavanagh ..... 1,859 4 0  
 J. F. Bowles ..... 879 16 6

LONDON.—For alterations to Cottages, Hill-street, Peckham, S.E., for Mr. F. J. Farford. Mr. R. Cray, Architect, Brighton-road, S.W.1.—  
 Cooper ..... £500  
 Garrett & Son ..... £355  
 Haydon ..... 339  
 Layton ..... 283  
 \* Accepted.

LONDON.—For alterations and additions to the "Rum Punchon" public-house, Whitecross-street, E.C., for Mr. Palling. Mr. C. J. C. Fowler, Architect, 2, Prince's-Manacles, Victoria-street, S.W.1.—  
 F. Gill, 27, Minories (accepted) ..... £490 0 0  
 [No competition.]

LONDON.—For shop front and shop fittings for Mr. Philgo, at New Stores, High-street, Plumstead.—  
 Emsberg (accepted) ..... £789 6 0

LONDON.—For building a garrison-house at Chamberwell, for the Salvation Army. Mr. Gillies Scott, Architect.—  
 D. Odling & Co. .... £291 19 0  
 J. C. Nicolls ..... £330 10 0

 R. Hindle ..... £125  
 J. & S. Dowyer (accepted) ..... £105

LONDON.—For alterations and additions to No. 8, Albion-buildings, Albion-street, for Mr. A. Solomon. Mr. Walter Graves, Architect, Winchester House, E.C.—  
 R. Hindle (accepted) ..... £345

MANOR PARK (Essex).—For building the United Methodist Free Church in Romford-road. Messrs. Polls, Sulman, & Hennings, Architects, Quantities by Mr. A. Fickwood.—  
 Holloway Bros. .... £4,296 (tentative) ..... 3,135  
 Watson ..... 3,228  
 Willmet & Son ..... 3,070  
 Dodd ..... 2,225  
 Allen & Son ..... 1,982  
 North Brothers ..... 3,223  
 Carter, Grays, Essex ..... 2,973  
 Cheston & Sons ..... 3,200  
 \* Accepted.

NEWBY.—For the covering in of about 150 ft. of the Newry River, at Newry, Ireland, for the Town Commissioners. Mr. J. L. Derentin Meares, C.E., Town Surveyor, Newry.—  
 Alex. Whelan ..... £1,380 15 0  
 J. Dwyer, N. A. Ireland ..... £1,011 4 6  
 John O'Hare ..... 3,255 0 0  
 \* Accepted.

PAIGNTON.—For masonry work, &c., at 15, Victoria-street, Paignton, for Mr. H. Waycott. Mr. Geo. Simons Bridgman, Architect.—  
 Westlake ..... £392 0 0  
 Fabbish & Brown ..... £123 0 0  
 \* Accepted.

SHIRLEY.—For kerbing, channelling, &c., Winchester-road, Shirley, for the Shirley and Plesnaunt Local Board. Mr. H. J. Weston, C.E., Surveyor to the Board, 178, Shirley-road, Shirley.—  
 J. W. Roe & Co., Southampton (accepted) ..... £105 0 0  
 [Surveyor's protecting tender, £10.]

SOUTHAMPTON.—For pulling down and rebuilding No. 23, High-street, Southampton, for Mr. H. H. Emanuel. Mr. A. W. Edmunds, C.E., Architect, 23, High-street, Southampton.—  
 Foxalls ..... £2,530  
 Morgan, Isted & Morgan ..... £2,886  
 Crook & Son ..... 2,647  
 Lewis, Southampton ..... 2,900  
 \* Accepted conditionally upon making certain reductions.

WANSTEAD.—For building residence on Grove Estate, Wanstead, Means Estate, Sulman, & Hennings Architects. Quantities by Mr. G. Fleetwood.—  
 Fleetwood ..... £2,386  
 Morley ..... £2,234  
 Reed ..... 2,195  
 Willmet ..... 2,076  
 Holloway ..... 2,282  
 Richardson Bros. .... 2,076  
 Gattley ..... 2,270  
 Chesson, Haggerston ..... 2,012  
 \* Accepted.

WEDNESBURY.—For the supply of blue-queened paving bricks at Wednesbury, for the Corporation. Mr. E. Martin Scott, Borough Surveyor, Town Hall, Wednesbury.—  
 Per thousand delivered.  
 Wood & Ivory, West Bromwich (accepted) ..... 68.  
 F. & S. Wood, West Bromwich ..... 68.  
 The Tipton Collieries and Brickworks, Limited, Tipton ..... 68.  
 \* Accepted.

SUBSCRIBERS IN LONDON AND THE SUBURBS, by prepaying at the Publishing Office, 10s. per annum (or 4s. 9d. per quarter), can ensure receiving "The Builder" by Friday Morning's post.

### The Architectural Exhibition, Turin.—II.

THE important competition for the new Houses of Parliament at Rome is well represented in the exhibition by a collection of several of the designs submitted. In addition to the designs by Moretti and by Broggi and Sommaruga, illustrated in the *Builder* of September 13 last, several others are worthy of notice. That by Enrico Ristori, which received one of the premiums of 5,000 francs, is shown in a set of drawings of which the elevations are delicately drawn in pencil fixed with a light wash of colour, the windows being marked by a flat tint. The drawings thus look somewhat faint for competition purposes, but the general effect is most refined, and the character of the design accords with the refinement of the drawings. The central feature of the design both in plan and elevation is a large dome of pleasing form, which however does not, as in some of the designs, overpower the remainder of the building, but is well proportioned to the whole mass. The proportions, indeed, throughout this design are excellent, and stamp it as the work of a thoroughly skilful artist. The scheme of the elevations is well conceived, a rusticated order with pilasters on the ground-floor is supported by an astylar rusticated basement, and carries a great Corinthian order which embraces the first-floor and a mezzanine; above is a blank attic with figures in front. The centre and angle pavilions have coupled columns, the remainder of the façade single shafts. The whole design is quiet, dignified, refined, and eminently artistic. The drawings illustrating the design of Signori Enrico Deserti & Co., hanging in close proximity to that just described, are as great a contrast as could well be imagined. Apparently reproductions by the ferro-prussiate, or some similar process, and printed in purplish colour, the drawings are decidedly unattractive. Nor is the design one whit more pleasing; the façades, consisting of a long range of pilasters of a single order, running through two stories, with a commonplace pediment and portico in the centre. A blank attic, with figures at intervals over the pilasters, runs the length of

the façade and at each angle forms the base to a quadriga. A heavily-designed dome of truncated, pointed form, with a square cupola over it, terminated by a horizontal line, forms the crowning unpleasantness to a most unpleasing design.

Next in order comes the design of Broggi and Sommaruga, which is shown in cleverly-shaded Indian-ink drawings, and, in addition to those illustrated in our pages, a large detailed drawing, to a scale of  $\frac{1}{16}$ , shows the ornamentation of the interior of the centre hall. This drawing is strongly coloured, and evidently the handiwork of Sommaruga.

The design by Vittorio Evanes is one of the less satisfactory of those exhibited, and suggests a theatre rather than the home of legislation,—an effect mainly produced by the adoption, for the chief features of the principal façade, of three large arches over triple openings divided by detached columns. The drawings are an example of the method of execution in ink line, bold and rough in draughtsmanship, with paler ink used occasionally to give an idea of difference of plane. Both drawing and design agree together in leading to an impression of something approaching vulgarity of effect. A rusticated basement carries an order which extends wholly round the building, and comprises the ground-floor and mezzanine over. Above this is a second order, containing no visible floor, and whose purpose is merely to contain the great arches already mentioned and a medley of features which enhance the tendency to vulgarity noticeable in the design. The side elevations are somewhat more pleasing, being restricted to the single order and rustic basement. This design is evidence of the difficulty felt by many of the competitors in giving the necessary dignity to a building which in its main features is virtually of one story only. We need scarcely add that in this case the difficulty has not been successfully met. The design by Vittorio Moschini is apparently an attempt,—and that not a happy one,—to outvie the entirely successful design of Baron von Hanseus in the Houses of Parliament at Vienna. The author has evidently a sincere admiration for the form of hexastyle peripteral temples, and the design consists of a large collection of these, no less than seven being visible from one point of view, as shown in the perspective, connected by colonnades of the Corinthian order, or by astylar walls with simple rectangular openings for win-

dows, surmounted by a carved frieze of considerable height, the whole standing on an astylar rusticated basement, with simple openings. The elevations are drawn in ink, and tinted in greys more or less greenish in hue, the shading being in cold grey, with the windows partly coloured of similar tint. The detail is coloured to represent marble and granite.

Moretti's design, which we have illustrated, is shown in some well-executed ink-drawings, tinted in cold sepia and grey. The detail drawings are in sepia, with the bronze sculpture in a dark grey tint. The next set of drawings is by Professor Giovanni Ugolini, and, by their proximity to those of Moretti, the difference between the older and younger generations of modern Italian architects is emphatically defined. Professor Ugolini's design we can but characterise as extremely feeble, lacking in sense of proportion and in coherence of idea. The feature of the great arch is once more in evidence, and serves but to suggest a railway station instead of giving the dignity to the design that the author probably intended. The next design we come to, that by Giuseppe Brunetta, is an example of what may be found in most open competitions, the "vaulting ambition that o'erleaps itself and falls on t'other side," the work of one who has yet to learn to walk before he can run in architectural design; the drawings, too, are unfinished, and suggest the "after office hours" style of preparation.

The design by Professor Calderini is cold correct, and commonplace, drawn in pencil and black lined, the windows left white. A great order on a rusticated ground story embraces the first floor and mezzanine; the windows have for their dressing the Roman Renaissance order treatment with pediments triangular and segmental alternately, and the whole design is tame and uninteresting. A nicely-executed set of drawings in ink, shaded in Indian ink and grey, illustrates the design of Signor Ciampietri, which was one of those that obtained honourable mention and a premium of 3,000 francs. The chief façade is composed of three well-designed pavilions, connected by colonnades standing on a rusticated basement and extending as wings beyond the outer pavilions. Behind the colonnade are two stories of windows, and above it a blank attic.

Over the central pavilion is a well-proportioned dome, the cupola of which, how-

ever, is a complete sphere supported by a circular colonade, and apparently resting upon the point of an obtuse conical roof, a feature that is, perhaps, rather a *tour de force* than legitimate design. Besides those we have described there are some three or four others exhibited from this competition out of the forty-nine designs sent in, and, assuming that the drawings in the Exhibition are a fair sample of the whole, as they certainly appear to be, since designs of superior, mediocre, and inferior quality are all impartially shown, we can with confidence express our opinion that the award of the premiums has been just and equitable; the best designs, although by younger men, take the highest place, while the prestige and position of the professors does not enable their inferiority of design to oust their more artistic rivals from the premier positions.

Some few designs submitted in the competition for the Courts of Justice at Rome, as far back as 1886, are hung in the Exhibition, and serve rather to show the advance that is being made in modern architecture. Besides the design by Professor Calderini, noticed in our last issue, that by Camillo Pistrucci, of Rome, may be instanced. This is of very classic character, and has a ground-floor with simple rectangular windows, with architrave around, surmounted by a cornice carried by consoles. This storey is astylar and forms the basement for a colonnade of the Ionic order, enclosing commonplace pedimented windows on the first-floor and a mezzanine over of very feeble design. The central pavilion has the favourite feature of a great arch and under it a projecting tetrastyle Ionic portico. This design, which is of commonplace character, does not convey to us a very exalted idea of the abilities of modern Italian architects, although submitted for the second competition. The design by L. Caselli, of Carrara, also does not rise above the commonplace, suggesting rather a simple wall pierced with holes and decorated with applied orders, each comprising a story and mezzanine.

Another important competition which has been recently decided, the drawings having been sent in on March 31 last, is that for the proposed new Jewish Synagogue at Rome, with college and school adjoining. The plan is in almost all cases identical in its main features, a large central square open space of considerable height, covered with some form of dome; around this on three sides aisles with galleries in two tiers over, and on the fourth side the rostrum, and behind it the tabernacle or Holy of Holies. The galleries are reached by staircases enclosed in turrets at the front angles. The drawings are executed to the scale of  $\frac{1}{16}$  with details to  $\frac{1}{32}$ . The style adopted is almost universally some version of Mohammedan architecture, more or less freely treated. The first premiated design, by Attilio Muggia, of Bologna, well merits its position, and is shown in an excellently-prepared set of drawings, drawn in ink and tinted, the elevations being coloured a light greenish yellow with greenish-grey bands; the interior shown in the sections is tinted in a light greenish-grey, with deep shadows in warm sepia, the sections of walls being blocked in with madder brown. The iron construction is carefully shown, and clever and original in design. The detail drawings show an elaborate scheme of colour-decoration in keeping with the Granada Moorish style adopted. The central dome is well raised, of rather steep pitch, and surmounted by a pointed cupola and lantern. In close proximity to these designs are other drawings by the same architect, for a chalet restaurant in Swiss style, and a design for some flats, the façade of which is indeed very flat, and hardly gives promise of the excellent design for the synagogue. Signor Muggia also exhibits a student design for a theatre, based very palpably on the published illustrations of the Vienna Opera House, both in plan and detail, even to the section of the basement below the auditorium.

A very striking design for the synagogue is

that by Ed. Collamarini and Gustavo Tognetti, of Rome. This at first sight reminds us of an Indian temple; on closer examination the detail is seen to be a combination of Neo-Grec, Byzantine, and Moorish. The central area is larger than in the design just noticed, with narrower aisles around for the galleries, and is surmounted by a cupola of irregular decagonal form, carried on pendentives from the great semi-circular arches, enclosing the central area. The elevations are lightly tinted over a pencil drawing to represent white stone, with bands of blue, and are strongly shaded in sepia. A projecting portico forms the entrance in the centre of the principal façade. The design by Tito Carassa and Professor Francesco Fasi is in a Moorish style, with a Byzantine cupola; the entrance is marked by a group of three arches of moderate dimensions; the drawings are executed in ink, faintly tinted in sepia, and a coloured perspective is also submitted. Dante Viriani has adopted an Arabesque type of design, with horse-hoof arches, a triple arrangement of which forms the entrance under a great arch springing from the staircase turrets at each angle, which are carried up and completed with small domes. The principal dome over the central area is of circular plan and flattish section, lit by windows in the lower part of the shell in a Byzantine manner. The elevations are tinted in warm buff, with bands of deeper tone, and shaded in a purplish tint. The design by A. Lasciere is in a Moorish style, with a very flat dome over the central area, not visible externally. The chief façade has a great arch over a triple arcaded entrance, and the towers at the side are carried up to a considerable height with small pointed circular domes of Turkish outline. Giuseppe Guastalla, of Turin, also adopts a Moorish style, but the detail is very thin and flat, and, like several others, the design has a great semi-circular arch over the front, surmounted by a straight cornice. The central area is covered by a flat internal dome, not shown externally, and the interior is intended to be elaborately decorated in a Hispano-Moresque manner.

Of Christian ecclesiastical buildings there are several examples in the Exhibition, showing the work of modern Italian architects in this direction. The most usually adopted style is the Romanesque of Northern Italy, but, as a general rule, this particularly difficult style is not treated with satisfactory results, and there is in particular a noticeable lack of coherence in very many of the designs. One of the greatest masters of Italian Medieval work, as far as we can gather from this Exhibition, was the late Conte Edoardo Athorio Mella, whose numerous works show a thorough knowledge of the Lombardic Romanesque period, and an ability in the use of that style for modern building, which appears to be wanting in the designs of many of his successors. The Conte Mella was a voluminous writer on the Medieval ecclesiastical architecture of Northern Italy, and his work entitled "Elementi dell' Architettura Romano-Bizantina detta Lombarda" is a most careful and painstaking account of the architecture of the Lombardic Romanesque period. Conte Mella's work on the Gothic of North Italy is also highly interesting, and in it he takes considerable pains to elucidate the system of triangulation, which he believes was adopted by the Medieval designers in determining the proportions of their buildings. The premiated designs for the façade of S. Petronio, Bologna, submitted in 1887 by Edoardo Collamarini and by Giuseppe Ceri, are very interesting, and either would make a satisfactory frontispiece to the church. The main point of difference between the two is that the design by Collamarini shows flat-pitched roofs, while that of Ceri has high-pointed gables. The interest attaching to these designs is heightened by the exhibition of earlier attempts at the same problem; the original drawings of Maestro Domenico di Jani, date 1512-1514; of Francesco Terribilia, 1572; of Enrico Brunetti Rodati, 1857; and of Giuseppe Modonesi, 1846, being hung in close proximity. The design by

Maestro Domenico has a central gable of ogee form, with pointed gables of moderate pitch, over the side aisles. The wall surface is divided up into parallelograms, and in the centre over the chief doorway is a two-light pointed window, with geometrical tracery, flanked on either side by a square-headed single-light window. The design of Terribilia has a central pointed gable of about 55 deg. pitch, with steeper gables over the side aisles. A similar treatment of the wall surface is adopted, but the central fenestration is changed to a three-light pointed tracered window. Without undue partiality for modern work, we can fairly say that the designs of 1887 are far more satisfactory works of architecture than those of the sixteenth century.

The modern Church of S. Antonio da Padova, erected at Turin in 1883-87 from the designs of Alberta Porta, is illustrated by a well-executed model of the façade, the main feature of which is a great semi-circular arch spanning the width of the nave, with a fresco in the tympanum. The principal doorway stands in the centre of the façade, under the great arch, but entirely lacks connexion with the remainder of the composition. Thus the design, which is in detail based upon the Lombardic Romanesque style, well illustrates the usual failing of the modern Italian church architect, who simply collects details, not always of the most pleasing or refined character, from the work of the past, but fails to weld them successfully into a homogenous design. Another modern church by the same architect—that of S. Pietro in Vincoli, at Bagnolo, Piedmont—similarly illustrates the tendency of modern ecclesiastical architecture in Italy. A design for a church at Castino, by Frizini, showing a very lofty aisle-less nave, and another at Pesinno, by the same architect, a basilican church with aisles, the nave arcade consisting of two bays only, show a lack of proportion which the use of features of abnormal dimensions leads us to believe is a common failing in modern Italy.

Another notable instance of unfortunate proportion is seen in the parish church design by F. Scarpini di Villanuova and Rivetti, where the interior, shown by photographs, although scaling some 60 ft. to the crown of the vaulting, looks quite depressingly low,—an effect largely due to the size of the bays of the nave, which, in the usual Romanesque manner, is vaulted in square compartments with semi-circular arches, each bay of the nave comprising two of the aisles. The scale of the building internally is still further dwarfed by the large size of the blocks in the alternating bands of light and dark stone employed in the piers and arches. The photographs of the interior show some excellently executed coloured decoration, the work of G. Rollini, which, while thoroughly Byzantine in scheme and general treatment, shows a correctness of figure drawing which it would be mere pedantry to ignore in modern work. Externally, the design is an extremely poor version of Lombardic Romanesque, lacking in cohesion to a supreme degree.

In connexion with the execution of the new façade to the Cathedral at Florence, carried out from the designs of Professor Emilio de Fabris, and completed after his death by Professor del Moro, there are exhibited large size photographs of Professor de Fabris' alternative designs for the façade, showing the difference of effect, according as pointed gables or low-pitched roofs were adopted for the culminating features over the nave and aisles.

In a competition design for a parochial church, exhibited by Camillo Pistrucci, is seen an attempt at a somewhat original plan, consisting of a long nave and chancel with transepts, but without aisles, or rather the aisles are external to the church, and form loggias. The crossing of nave and transepts is covered by a dome, which is circular internally, and is terminated externally by an octagonal lantern. Beyond the crossing is the high altar, also with a dome over it, which, how-

ever, does not show externally, being wholly contained in the roof. Flanking the high altar on plan are transeptal projections, in which the sacristies are located. The choir is eastward of the high altar, the seats being returned in semi-circular form at the extreme east. The church is terminated by an octagonal apse, with chapels of similar form on the diagonal sides. At the west end there is on the north side an octagonal baptistery, with a chapel of corresponding plan to balance it on the south side. Between these are three western entrances, and there are besides no less than five separate and distinct entrances on each side of the church. The style adopted is Italian-Romanesque, the prominent features being the octagonal lantern over the crossing, and a tower at the west end, surmounted by a spire resting most uncomfortably on flat pediments terminating the tower walls,—a feature which shows the tendency of modern Italian church architects to follow closely the lines of Mediaeval detail without too carefully considering the nature of the effect produced. Perhaps, however, to an Italian there may be some charm about such a piece of composition, though to Northern eyes the result is most uncomfortable. Apart from this, the tower and spire look too thin for the design of the building, which generally looks long and low, and, mainly from its number of features, lacks repose and dignity, without, however, obtaining picturesqueness.

A somewhat special and interesting example of ecclesiastical work is seen in the design by Giovanni Ferrogio, for the extension and completion of the Hospice di Oropa, a famous pilgrimage church some sixty miles from Turin, which is situated on rising ground, lending itself to a fine architectural and scenic effect. In this case it is proposed to extend the buildings further up the hill, forming an avenue to the new church intended to be erected on the highest point of the hospice. The design for the church is adopted from that prepared by Galletti, but not carried out. This is to be enlarged, however, in the proportion of 4 to 3, by simply modifying the scale of the original drawings. The regulation of the levels and gradients is elaborately shown by contour lines on the plans, which evidence once again the engineering knowledge of the Italian architect.

Competitions for the laying out of cemeteries seem to be as attractive to the Italian competing architect as to the English, and several good designs of elaborate character are exhibited. These usually show a rectangular arrangement of the ground with a cloister round, an imposing entrance, and a chapel at the opposite side. In Moretti's design for the cemetery at Musocco, near Milan, Greek Doric, with somewhat of the French Neo-Grec feeling, is adopted, and shown in an exquisitely-shaded set of drawings. The cemetery at Pavia has been carried out from the designs of Angelo Tavolo, in Italian Romanesque, which style is here somewhat successfully treated.

Some few examples of school planning are exhibited, and show careful attention to the special requirements of educational science. Dual desks are usually adopted, and the rooms are made deep rather than long, the desks being arranged in rows of four or five and ten to twelve rows deep. The windows are then placed down one side, so that left-hand lighting is obtained, a point to which considerable attention is paid. A design for the Communal School at Ampezzo, by G. Falconi, of Udine, is a good example. Here, on the ground-floor, are three class-rooms for 100, 96, and 64 children respectively, the larger numbers being those of the lowest grades. There is no hall for general assembly, but a gymnasium, about 24 ft. by 50 ft., is provided, this being a feature found in the majority of school plans. On the first floor are three more class-rooms and rooms for mistresses, apparently residential.

In the design for a new school in the Via Galiari, Turin, by C. Boito, each class-room has its separate cloak-room, and is lit on both

sides, a wide corridor running along on one side of the class-rooms; all the rooms are carefully arranged to have a south-west aspect, and, in addition to the gymnasium, four rooms for manual work are provided.

In the planning of hospitals, a modern example is the design for a large hospital at Turin, prepared by Dr. G. Spantigati and Engineer A. Perincioli. The hospital is arranged on the pavilion system, but the plan of the pavilions is not all that can be desired. The ward kitchen, lavatory, and bath-room open immediately into the ward, and, being placed against the side walls, absorb some of the space which might with advantage be occupied by windows, of which there are too few, one only being allowed for every two beds. The whole of the pavilions are in one storey and basement under, with fireproof ceiling, and are connected by open galleries, with subway under for tramways from the administration block. Considerations of aspect do not appear to have been strictly regarded, as the wards have every possible variety of aspect, a result partly due to the disposition of the pavilions upon the irregular shaped site. Certain pavilions in proximity to the operating theatre are especially allotted to the clinical school, while separate blocks are provided for ophthalmic, skin, and other special diseases, and for contagious diseases. The scheme also includes an anatomical and pathological school.

In the design for a hospital for contagious diseases at Milan, by Giovanni Giochi, isolated blocks connected by a light, open gallery and subway from the kitchen, are employed, and special care is taken to provide ample ventilation, both by placing a window between each bed, and by forcing in fresh air by a fan from a central ventilator. A well-arranged and fitted steam laundry is placed in a separate block.

As an example of lunatic asylums we have the plans of one at Florence for 600 patients. Here the system adopted has been to divide the patients into different classes and to locate these in separate blocks, rendered to a large degree independent and self contained, no common dining-hall being provided. The divisions of classes made are, Quiet, Infirm and Paralytic, Suicidal, Epileptic, and Chronic and Acute. Comparatively few single rooms are provided, except to the block appropriated to acute patients, which is wholly detached from the remainder of the asylum, and is largely made up of single rooms.

In domestic architecture there are two distinct types of residence which the modern Italian architect is called upon to design; the one, the detached private residence standing in its own grounds, the other, the suite of rooms forming part of an immense block let out in separate flats and usually called a palace, in distinction to the villa. Some of the designs for villas, as represented in photographs from the executed buildings, are among the happiest efforts of modern Italian architectural art. An admirable instance of this is the design of the Villa Maggia, in Sordevolo, Turin, by C. Gilodi. The main house is a rectangular block; on one face is a projecting porch of Ionic columns, not uniformly spaced, on another face is a one-storey circular bay, also ornamented with engaged Ionic columns. The first-floor windows are treated with the conventional order and pediment dressings, and above a richly-carved frieze of amorini and scroll work, embracing circular windows, leads to a bold cornice, the whole forming a charming composition, the effect of which is to no slight extent enhanced by the rapid falling away of the ground and the boldly rusticated part-basement necessitated.

Another pleasing example of the villa is the Villino Romanelli, erected in the Corso Loreto, at Milan, and designed by Romeo Bottelli. This, again, is a square block, with a loggia brought forward on the ground-floor, formed of three arched bays divided by rusticated Doric columns. The central feature of the façade on the first-floor is a two-light arched window opening, surmounted by a segmental pediment carried by two rich

Corinthian columns. The blemish on the design is that at the sides of the central feature are square-headed windows, with a heavy cornice on consoles, which both in size and detail appear quite incongruous with the central part of the design. Signori Musso & Copperi, of Turin, exhibit several designs for villas, one for Copperi himself. Their plans are usually less formal than those just described, and advantage is taken of breaks in the plan to provide niches for galleries and loggia that add largely to the pleasing effect of the designs, which are mainly Italian Renaissance of the Farnesina type. Occasionally what may be called fancy styles are adopted for country houses or seaside residences, as in the designs for the Villa Marsaglia, at San Remo, by Rivetti, which is an attempt at a Moresco treatment, with alternating bands of brick and stone. Other designers have based their work on the chalet of Switzerland and the Italian Alps, these naturally being carried out in wood.

The residences in flats form, of course, by far the larger number of the town buildings of modern Italy, and it would be impossible almost for us to give a detailed account of the numerous examples illustrated in the exhibition. Few plans are shown, but the general idea is to group the various suites around a central courtyard. In each suite the rooms are intercommunicating, but corridors are also in more modern instances provided to facilitate ingress to any particular room without passing through two or three others. In their external treatment uniformity of plane is the predominant characteristic. The various methods in which the openings are decorated differ, of course, largely. Some of the most successful have been those in which the later phases of the Renaissance have been taken as models. The abandon and fertility of invention that characterise the Rococo and Baroque styles appear to be particularly suited to the temperament of the modern Italian designer. One universally adopted means of enlivening the dullness of these façades is the use of balconies, and efforts are made to group balconies and to vary them in design, sometimes even in material, stone and iron. In Turin itself the favourite loggia is extensively used, and assists in giving considerable dignity to some of the otherwise monotonous façades.

Shops are for the most part merely the ground-story of the palazzo devoted to flats, but there are one or two attempts to follow the Magasins du Louvre and au Printemps of Paris, as models for business premises for the Bocconi, the Whiteleys of Italy. These in their mad desire for plate-glass lead to the perpetration of some very unfortunate pieces of design; the establishment at Rome having, for example, no less than three floors to one arched opening filled with plate-glass from top to bottom. Where the shop-front retires behind an arcaded loggia, as in the Milanese example, the opportunity for good design is more favourable. Between the flats and the shops the street architecture of modern Italy tends to become intensely monotonous and uninteresting.

#### THE LABOUR MOVEMENT IN AMERICA.

THE labour movement, as it is commonly but perhaps not very happily termed, will certainly occupy very many pages of the historian who will some day write the history of the last half of the nineteenth century. The very fact that it is in some form or another constantly present to the attention of the most casual of the observers of contemporary events tends considerably to deaden its importance in the mind. But it is not only the labour question in Great Britain which is of importance to the people of this country; commerce is of so international a character that the labour movement in other countries must be watched in order that its effects may be observed on our own labour

market. Hence the work\* the title of which stands at the head of this article is especially welcome at the present time. It will give readers in this country an opportunity of becoming acquainted with the history and characteristics of the movement in America, which has certainly had some marked effects on the same movement in Great Britain. The work itself contains such a large mass of facts that it would be impossible in our space to give anything like a comprehensive sketch of the entire book. There are chapters, for example, on "Early American Communism," on the "Economic Value of Labour Organisations," on the "Socialistic Labour Party," and so on, all of which are full of interest to any one who has given the least thought to this most momentous question. But we shall restrict ourselves to the chapter on "The Growth and Present Condition of Labour Organisations in America," since it is the one which best indicates the characteristics and the progress of the labour movement beyond the Atlantic.

The beginnings of trades unionism are visible in a crude form in the very first years of the century, and the modern machinery of strikes is visible also at the same time. There is evidence of this in the year 1802. "The sailors in New York received 10 dollars a month, but wished an increase of 4 dollars, and endeavoured to enforce their demands by quitting work." They marched about the city with a band, and compelled other seamen employed at the old wages to leave their ships, but "the constables arrested the leader, lodged him in gaol, and so ended the earliest of labour strikes." We mention this incident because there is a popular impression that strikes are features of very recent growth: on the contrary, a rule of the constitution of a body called "The General Trades Unions of the City of New York," which was in existence in the year 1833, states that "no trade or art shall strike for higher wages than they at present receive without the sanction of the Convention." Thus it is obvious that in the Eastern States of the Union strikes were a well-recognised means of obtaining higher wages at the end of the first quarter of the present century. But the power to strike implies more or less of cohesion and combination among working men, and therefore it is equally clear that by this time the system of trades unions was already in existence. In the earlier years of the growth of unionism the chief centres of the movement were Boston and New York. The General Trades Union which we have just mentioned was a New York union, and was a combination of subordinate unions of the various trades and arts in New York city and in its vicinity, and in Dr. Ely's opinion "is the earliest example in the United States of those central labour unions which attempt to unite all the working men in one locality in one body, and which have now become so common among us." Again, a pamphlet is quoted by the author containing an address before a working men's society in Massachusetts in 1831 in which the speaker congratulates his audience on the working men's associations as being, though comparatively new, yet growing in number and importance. We must, however, wait for a good many years before we can find trades unions in great numbers. They are essentially the results of large populations, of keen competition, and of an aggregate of capital. These conditions, it goes without saying, are far more characteristic of the later years of the United States, and therefore it is not a matter of surprise that trades unionism has shown a marvellous growth in the last thirty years. Thus we find it is the year 1865 when the Bricklayers' and Masons' International Union of America was formed. The establishing of such a union as this shows at once the comparative paucity of labour organisations in the earlier years of the century, and indicates with clearness the historical period of their development. In the year

\* "The Labour Movement in America." By Richard T. Ely. London: William Heinemann, 1890.

1869 the society, now one of the most powerful and remarkable labour organisations in the world, "The Knights of Labour," was formed. The founder was one Uriah S. Stevens, a tailor of Philadelphia, who called together eight friends, who were the nucleus of a body now numbering many thousand members.

Having reached the formation of this society, it would be useless to enumerate others which have since been formed. It is of greater interest to turn to the constitution of these bodies. The original unions were chiefly, in fact, entirely, for the purpose of organising the workmen in separate trades, to obtain better wages and shorter hours. These, of course, have still been continued, but there has followed on the union of individuals a union of unions. Thus the Journeymen Bricklayers' Protective Association of Philadelphia was formed in 1880, and now contains two thousand members. The resolution at the end of the preamble states that this body is established "to maintain a fair rate of wages, encourage members to advance themselves in their trade, to fraternise in a spirit of harmony, and use every means which may tend to the elevation of bricklayers in the social scale of life." Here we have a purely selfish trade organisation, that is to say, one which is concerned only with the interests of a particular trade. But there have also sprung into existence such combinations as the Federation of Organised Trades and Labour Unions, which "aims to promote the common interest of all trades unions and labour organisations, and to watch the course of legislation in order to promote that which is considered beneficial and to express that which is regarded as injurious." But central labour unions such as the "General Trades Union of the City of Cincinnati" now exist all over the United States, and at the present time we find unions of individuals, and what we have called unions of unions, so that labour across the Atlantic is thoroughly organised from top to bottom. In this country the size and vastness of the organisation is not easy of realisation, because we can scarcely properly picture the numerous and great cities spread throughout the equally great territory of the Union. It places labour in a most powerful position, since it enables it to be in a comparatively stronger position than organised capital which, in a much smaller country like England, is capable of much greater combination, and is thus *pro tanto* more powerful than in the United States. For this reason the frequent success of labour over capital in the United States, when contests have arisen between them, does not necessarily forbode the same amount of success in this country.

But there have also come into existence associations of workmen which, in principle, are antagonistic to the older union. Of these, that to which we have already alluded,—the Knights of Labour,—appears to be the most powerful. These associations are antagonistic, in a sense, to the more restricted trades unions, because they are formed to benefit the working-man generally, without distinction of trade or of capacity, or, it appears, of sex. For the twenty-second article of its constitution states that the object of this Association is "to secure for both sexes equal pay for equal work," by which, we presume, is meant a fair day's pay for a fair day's work. But an Association which does not discriminate between trades, or between skilled and unskilled workmen, is one which, though it may, and does, contain members of trades unions in the strict sense, can hardly fail, some day, to come into active opposition with the older form of union, and may even, in spite of its present power and strength, degenerate into an association of quite unskilled labourers. Again, the constitution of the Knights of Labour shows that this body, the numbers of which are sometimes reckoned by millions, has set before itself a much more ambitious programme than does the ordinary union; one of its objects, for example, is "the removal of unjust technicalities, delays, and

discriminations in the administration of justice," and another "that a graduated income-tax be levied." In other words, the object of this Association is to obtain, by legislation from the State, or by compulsion through its powers from employers, anything which will benefit the working class generally, or, to use the vague phraseology of the constitution of the Association, it seeks to enable workers "to share in the gains and honours of advancing civilisation." While most men will smile at the grandiloquent language of this document, it would be foolish to underestimate the strength of this body or its capacity for good or ill. It brings out clearly a remarkable feature of the labour movements of the day, the vague, half-socialistic desires of large bodies of working men, to some extent the results and to some extent the moving forces of modern trades unionism. To consider these in all their bearings would be to embark on the consideration of trades unionism throughout the world. We must content ourselves with having indicated briefly the general character of the growth of trades unionism in the United States, with having noticed its appearance in the first twenty-five years of the century, its growth towards the middle of it, its rapid increases in the last twenty years, together with its three broad phases: the combination of individuals belonging to a particular trade, then the organisation into associations of these simple trades unions, and lastly the creation of societies of workers, without regard to trade, capacity, or sex, somewhat socialistic in tendency, and with the largest and most vague aims.

## NOTES.

THE current number\* of the "Geological Magazine" contains an interesting article by Mr. J. G. Goodchild, F.G.S., on the "Weathering of Limestones." He commences by referring to a previous article on the same subject, written by him in that magazine in 1875, in which he gave some data upon the rate of weathering of certain limestones, deduced from the observed extent of waste that had affected some tombstones in the churchyard of Kirkby Stephen. The mean of several observations gave as the rate of solution about one inch in five hundred years for stones that were standing erect; the author was unable to find any dated tombstones there lying flat, but is of opinion that disintegration on similar stones in that position would be much accelerated. The estimate above given did not take into account the fact that after being subjected to atmospheric erosion for several years the rate of waste is materially increased by the multiplication of the surfaces presented to the denuding agents. Denudation may take place (1) along the original planes of deposition of the rock, or (2) follow those obscure planes of separation along which the stone will most readily dress, or (3) along planes parallel to the dressed surface. After the lapse of a few years limestone may, and often does, weather by the detachment of flake after flake from its exposed surface. Taking these things into consideration, the author concludes that we may "safely assign to this rock a rate of destruction treble or quadruple that given in the estimate above." From further observations on limestones generally, he says that those which contain an unusual percentage of clayey matter appear to waste at the highest rate, whilst the compact, well-bedded limestones, that include much bituminous matter in their composition, stand at the other extremity. He gives an instance, however, where stone of the latter description, having lain on a disused and very wet road for about twenty-five years, weathered at a considerable rate. On examining several pieces, he states that "it was perfectly evident that since the road had ceased to be used as a cart-road, the surface"

\* Geol. Mag. N. S. Dec. III, vol. VII, Oct. 1890, p. 463, et seq.

waters had etched away the limestone to a depth of at least one-sixth of an inch, leaving the sharp edges of the fossils standing out to that extent in relief, to testify to the quantity of the surrounding matrix that had been dissolved and carried away in the meantime." Another case is given where an exposure to the weather for ten years, in a railway-cutting near Penrith, lowered the general surface of a limestone about one-third of an inch; whilst a limestone quarried in Millgill, and used hard by in the construction of the railway station at Askrigg, in Wensleydale, was similarly reduced by about one-twentieth of an inch in twelve years, as exhibited by the fossil remains carved in relief. Scrutinising the results arrived at, the methods by which they were obtained, and bearing in mind the large problems which they are intended to partially elucidate, we are at the outset struck by the great want of detailed description of the materials referred to in the article, by which alone we could hope to fully grasp the import of the communication. Reviewing the general scope of the observations, however, we deny that it is possible to get even a slight approximation of the rate of weathering of limestones over long periods from an examination of the effects of a few years only. The author has to a certain extent felt this himself, for, after calculating the rate per inch as indicated by each of the above-mentioned cases (one of which, by the bye, is worked out erroneously), he draws up an average rate of disintegration, and then, in making allowance for accelerated action as the weathering proceeds, he finally states that he believes that "we shall not err greatly in assigning at least double the rate of erosion to limestone generally." To us this appears to be rather a loose method of computation, and conveys the impression that the known rates of weathering as given in the article must be supplemented by a certain amount of guesswork before anything approaching a satisfactory solution of the problem can be hoped for. We hold that the number of observations made as to the rate of weathering of stone, is at present much too limited to enable anyone to judge of the matter; the few additional instances quoted by the author are useful as a further instalment to our knowledge of the subject, and they have a considerable practical bearing in regard to the durability of the particular kinds of stone referred to, and herein consists the chief value of his communication. In other words, the author's scientific facts may be accepted, but not his inferences. It is perfectly possible to arrive at the approximate and comparative rate of waste of a given limestone from observation on old buildings and otherwise, but the general question of the rate of disintegration of limestones as a class must still remain *sub judice*.

THE President of the Local Government Board has issued a circular to the various local authorities throughout the country, and also to the County Councils, calling their attention to the Housing of the Working Classes Act, 1890, and the necessity of putting its provisions as to the sanitary state of workmen's dwellings into force. Mr. Ritchie urges on local authorities "a strenuous and judicious exercise" of the powers of this Act, which is not only a Consolidation Act, but contains some new provisions. His object in addressing County Councils, is because these bodies can make use of the powers of the Act in cases of default by the Rural Sanitary Authorities. These circulars are admirable, but they have the fatal weakness of being simply good advice. Mr. Ritchie has no power to enforce the law,—it rests with the local authorities to do this. The consequence is that careless local authorities will simply let the circular lie on the table, and the County Council, of course, cannot do anything until representations have been made to them that the local authorities are in default. Moreover, it remains to be seen whether when such representations have been made to the County Councils they will take up these new duties with energy. The fact

is, it is impossible to unite two antagonistic principles,—viz., local self-government and central governmental control. In this country we have adopted the former principle, and we must take it for better or worse. Circulars such as Mr. Ritchie has just issued are full of good intentions, but are practically worthless.

THE London Society for the Extension of University Teaching may count itself fortunate to have secured a course of lectures on Homeric Greece from the well-known scholar, Mr. Walter Leaf. The first lecture was given on Wednesday (October 15), at the Obelsea Town Hall, Sir Charles Newton taking the chair. Mr. Leaf distinctly stated that he approached the subject from its archaeological, not from its literary, side,—his object being to illustrate the Iliad and Odyssey by reconstructing as far as possible the surroundings among which they were produced in the light of recent excavations. Twenty years ago we had simply no material with which to answer the question, has Homer a historic basis or not,—how far is the world he paints merely the realm of a poet's fancy. Now, thanks to Dr. Schliemann's spade and the logic of his co-operator, an answer, definite, if not complete, can be given. In the present lecture, Mr. Leaf dealt with the geography of the catalogue of the ships, and then passed to the excavations at Hisarlik. He wisely wasted no time in detailing the errors into which Dr. Schliemann at first not unaturally fell, but dwelt on the ground-plan (illustrated by the lantern) of the buildings, palace, citadel walls, and the two successive Propylæa now on all hands acknowledged to be associated with the Homeric Troy. Passing to Ithaca he showed that the topography of the Odyssey, unlike that of the Iliad, though in places clear and accurate, showed no consistent first-hand knowledge of the places dealt with, hence he concluded that the poem was compiled from more than one source,—a conclusion now widely accepted. Sir Charles Newton, in acknowledging a vote of thanks at the conclusion of the lecture, paid the lecturer a high compliment, saying that in his long and varied experience he had never heard the perplexed Homeric question so clearly stated. Subjects to follow are the Heroic fortresses and architecture, Homeric dress and armour, Homeric art.

THE problem of the restoration and significance of the "Venus of Milo" will possibly never be solved with certainty, but till it is solved it will not cease to exercise the ingenuity of archaeologists. Mr. Ravaissou, at the recent meetings of the "Académie des Inscriptions" at Paris, has brought forward a theory which is in one respect satisfactory, that it makes the Venus one of a group, and thereby gives a motive to the at present unmeaning pose. Mr. Ravaissou believes not only that the statue was one of a group, but that he can lay his finger on the other statue that actually completed the group. This, he believes, is the well-known "Achilles" of the Louvre, which he holds to be an Ares. The group represented, according to him, the Love-goddess either disarming,—or, at least, quieting,—the War-god by laying her left hand on his shoulder. Mr. Ravaissou exhibited to the meeting casts of the two statues in this juxtaposition. So far, so good; but Mr. Ravaissou goes on to associate the original of the group with Alkamenes and Pheidias, and believes that this type of Venus was the famous "Venus of the Gardens." Here we cannot follow him, and still less when he places the district of the gardens near the Kerameikos, and hence apparently deduces the conclusion that the group was a sepulchral monument representing the heroized dead.

WE drew attention at the time of their discovery to the remarkable Vaphio cups, with their realistic representations of the catching and taming of wild hulls. Much has been written and spoken about the

curiosities of their "barbaric" style, but till just now no one has undertaken to give a name to the race who made them. Herr Trendelenburg is, indeed, a bold man. In his paper (reported in a recent issue of the *Berliner Philologische Wochenschrift*, 1890, No. 39) he dares to utter the name *Pelasgians*. As the *Wochenschrift* observes, the Pelasgians have long been under a cloud. To every sound "archæologist" they have been of late inscribed with *noli me tangere*. But the tide is turning in their favour now, and it seems just possible that they may have to become responsible for the art, architecture, and civilisation generally that we group under the name Mycenaean. The Cyclopean fortifications of the Acropolis at Athens were attributed by tradition to the Pelasgians; the very counterpart of these fortifications have been discovered at Mycenæ and Tiryns. The Pelasgians were a people accounted to pay honour to the dead and the chthonic gods; just such a worship is presupposed by the "bee-hive" tombs at Mycenæ, Spata, Orchomenos, and the like. It was the characteristic attainment of the Pelasgians that they tamed oxen to bear the yoke. This is the very work in which they are engaged on the Vaphio cups and on the curious mural painting at Tiryns. Certainly the theory is worth consideration.

WE read in the *Daily News* that the Principal and dons of Brasenose College, Oxford, accorded last week a high and ceremonious welcome to the arrival in their midst of the "brazen nose" from Stamford, Lincolnshire. A. à Wood describes this relic as being a face or head of old cast brass, with a ring through the nose thereof, fixed to the gate-wicket of the "Brazen Nose" in that town. Some doubt appears to still remain whether it was carried to Stamford on the wether, for three months in 1334, of students from Brasenose, Oxford; or whether, finding it there, they adopted the sign for their own style and name. At the end of the thirteenth century Stamford University so called,—though never, we take it, a *Universitas* in the common acceptance of the term,—comprised certain colleges and halls. Amongst these were reckoned Robert Luttrell's Sempringham Hall, founded in 1292, for Gilbertine students, and named after the birthplace of the founder of that monastic order; Henry de Hana's Carmelite College; the St. Leonard's Priory, attached to Durham; Peterborough Hall; Black Hall; Vauldrey Hall, for students from the Cistercian Abbey of Vauldrey (*de valle Dei*), near to Grimsthorpe; and Brasenose College,\* Royal authority suppressed Stamford in 1335; the gate of its Brasenose, in St. Paul's-street, has remained to our own day. The King's Hall and College under that name at Oxford was founded in the interval 1509-12 by William Smyth, Bishop of Lincoln, and Sir Richard Sutton, Knt., of Prestbury, Cheshire. They obtained from Oriel and University Colleges, respectively, leases of Salisbury and St. Mary's Entry Hostels, and of Brasenose and Little University Halls. The site also included those of the Staple, Black, Haberdashers, and Little Edmund Halls; together with that, reputedly, of the *brassium* (brew-house, or brasserie) appertaining to King Alfred's Palace in that city. Polydore Vergil, though did he stand alone we should scarcely take his authority, thus refers to the nose:—

"Per id quoque tempus Gulielmus Smyth, Episcopus Lincolnienis, Margarite exemplo ductus, Oxonii scholasticorum collegium collocavit in aula quam vulgo vocant Brasyn Nose, hoc est osium nasum, quod ex loco imago ærea facie admodum immani pro fortibus extat."

An inquiry of date 1278, quoted by à Wood, and cited in Ingram's "Memorials of Oxford," mentions Brasenose Hall there. The name is also traced farther back, to Henry III.'s reign. A nose, fashioned of metal, over one of the college gates which faces the Radcliffe, has been familiar to several generations since. We have lately illustrated and described Mr. T.

\* For this list we are indebted to a paper, *ad hoc*, read by the Rev. E. G. Wood, at a meeting of the Cambridge Antiquarian Society, on October 29, 1885.

G. Jackson's plans and designs\* for the new quadrangle at Brasenose, between St. Mary's and Lincoln College and All Saints'. For these buildings a clearance was made of some tenements in the adjoining Amsterdam-court, which has perpetuated, in name and site, the memory of the ancient Amsterdam or Broad-gates Mall.

IT may be of interest, not only to those members of the profession who have had their work hung at this year's Munich Art Exhibition, but also to our readers in general, to hear that the Scotch and English work exhibited in the Bavarian capital has been viewed throughout the summer with great interest both by artist and layman, and that very complete criticisms on it have appeared in the local press. These criticisms are, on the whole, very favourable ones; they treat the draughtsmanship with special admiration, and the designs themselves for the most part very fairly. The German critics are, however, somewhat sarcastic as to the want of plans, and express their surprise that members of a practical nation should neglect to send in any kind of plan to explain designs, even in a miniature form. There would have been plenty of room for plans, and it is the custom to hang even large-size plans in a German architectural exhibition, as in a French one. The English architects are the only ones who regard an architectural exhibition as a mere collection of pictures. We have commented on this over and over again, and both French and German critics will take the same view. If our countrymen had paid more attention to this in their *envois* to Munich they would have done themselves more justice.

THE present "tightness" of the Money Market will, it is to be hoped, pass away without causing serious loss to persons engaged in building operations and building transactions generally. But there is no doubt that the present is a time of difficulty, financially speaking, and it is scarcely possible for such a period to pass away without leaving financial trouble in its track. For it is obvious that when city and business men are realising securities at a loss, the market for buildings must be very prejudicially affected, and sales, which in more easy times would be arranged, do not take place. Again, those who have borrowed money on building securities which they have hoped to see turned without undue delay into cash, cannot but be anxious, for banks and lenders of money have now to charge a high rate of interest, and are averse to keeping their money out of reach. But just as the present period is doing good in the City by stopping wild speculation, and breaking up rotten firms, so it does good in the same way in the building world. It checks the current of building speculations, it puts sound business firms on a better footing, and gives them a better chance against men who trade on credit. Such a period, indeed, as the present is certain to recur from time to time, and it is well that it should, for it acts as a kind of financial purge, checking improper business and leaving financial affairs in a sounder state when it has passed away, even though to some it is a period of ruin.

WE have frequently to point to the laxness of sanitary inspectors in rural districts. One reason no doubt is that if they carry out their duties properly, they necessarily make themselves disagreeable to many of their neighbours, and they dread to be considered "unneighborly." The result is that they often neglect their duties. This hesitation to enforce the law is natural, but that is all the more reason why landowners and persons of influence should, to the utmost of their power, assist the sanitary authorities. From the following paragraph, which we extract from the *Buckinghamshire Advertiser*, it would appear that Lord Chesham does not bear this wholesome principle in mind: "In regard to

the water supply at Londams Cottages, the authority resolved to do the work themselves, and to charge the work to Lord Chesham if it was not at once done." This, from the same report, appears to be the sequel to a number of ineffectual attempts to induce Lord Chesham to remedy a sanitary defect. When landowners in a high social position thus set a sanitary authority at defiance, it largely increases the difficulties, always great, which exist in the way of keeping a community in a proper state of sanitation.

THE case of the Bristol Trams and Carriage Company v. The Mayor and Corporation of Bristol, which is reported in the current number of the Law Reports, is one of much importance to tramway companies. The Bristol Trams Company was a company using the streets of Bristol for the purposes of its business, under the provisions of the Tramways Act, 1870. The Corporation of Bristol decided to lay down wood pavement in two of the streets used by the Trams Company; they proposed to do so not only outside the rails of the tramway, but between them. To this alteration the company very naturally objected, as the alteration would have caused much extra expense. Indeed, in many respects such an alteration would appear to be altogether inconsistent with tramway traffic, since there is so much stopping and starting in this kind of traffic. They demanded that the dispute should be referred to the Board of Trade for decision under the thirty-third Section of the Tramways Act, 1870. The Court of Appeal decided, however, that this section did not apply, since the power of the road authority to do the work objected to by the Company, was preserved by Section 60, which provides that nothing in the Act shall take away or affect any power which any road authority may have to widen, alter, divert, or improve any road. This decision is obviously correct, but still it is clear that it is one which may be very detrimental to the interests of Tramway Companies, who have thus no control over the material of which the streets are made.

THE churchyard of St. Mary the Virgin, Aldermanbury, has just been laid out for public resort, and is opened, from 10 to 4, except during the hours of service. The Metropolitan Public Gardens Association have provided some seats, and Mr. Deputy Rogers will present a drinking-fountain. This church, standing within Cripplegate Ward, of which the watchhouse formerly stood at its north-eastern corner, was built in 1677, after Wren's designs, at a cost of 5,237*l.* 3*s.* 6*d.* The tower has raised coigns and a high balustrade like that above the aisle walls. On the tower stands a lofty square turret, of which the upper stage has large railed openings, with a concave roof, and vane. The tower windows, as also those of the aisles, have been filled in with heavy tracery in the Byzantine or Lombardic style. Into a vault on the northern side of the altar the remains of Judge Jeffreys were removed (1692) from the Tower, there to lie by those of his son, Lord Wren. Here, too, are buried Shakespeare's brother actors, Condell and Heminge. A cloister surrounded the graveyard of the earlier church, whereof mention is made by Ralph de Diceto, who was dean of St. Paul's towards the end of the twelfth century. Subsequently, it passed to the hospital or priory of St. Mary the Virgin, founded by William Elsing, by London-wall, and now represented by St. Alphage church. The name of Aldermanbury is commonly attributed to the fact that in this street stood the aldermen's hury or court; and Stow says, "I myself have seen the ruins of the old court hall in Aldermanbury-street, which of late hath been employed as a carpenter's yard." But the late George Godwin reminds us, in his "Churches of London," that at the end of the twelfth century the presentation to this church vested in one Aldermanbir, and that

in 16 Henry III. Gervas alleges that his father Allen had presented one William, who died in 1202. Each of these worthies had for surname "de Aldermanbir"; yet it is possible they were so styled from the locality, and did not, on their own account, give their surname to the church.

THE uppermost floor of the recently-completed west wing of the Edinburgh Science and Art Museum has been utilised for the systematic display of the fine collection of Scottish minerals for which the Museum has been indebted to various donors. These donations are representative not only of the mineralogy but the geology of Scotland, and consist of three sections—(1) A collection of rock specimens; (2) a series of geological maps, sections, &c., published by the Geological Survey under the direction of Professor Geikie; (3) a series of fossils mostly from the Palaeozoic Rocks. The specimens have been arranged, as far as possible, on a chronological basis, so that by a reference to the maps which they illustrate a student may be enabled to trace the tracts where the examples have been found. The collection forms probably the best of its kind ever brought together. To the general visitor the most attractive portion will be the fine specimens of Scottish gold and gems, comprising a series of polished agates, jaspers, cornelians, and serpentine. The portion of the museum where these exhibits are placed is remarkably well lighted, and the building, which is now completed, will, as a whole, bear favourable comparison with any other institution of the kind, whether in Britain or on the Continent.

THE London County Council acted for the best in confirming at their last meeting the order for a new sludge steamer for removing the London sewage out to sea. It is true that this can be only a temporary expedient, and that the cost of it is very great; but as it must be some years before any better scheme for disposing of the sewage can be carried out, even when resolved upon, it is necessary in the meantime that the river should be protected from the serious accumulation of foul mud which must go on increasing at or below the outfalls as long as the sewage is allowed to go into the river.

IN the course of a correspondence which has appeared for the last few weeks in our columns apropos of "A Sanitary Note from Greenock" it has been urged that the syphon trap disconnecting the house drain from the sewer should be discontinued, on the ground that it is a frequent cause of stoppage in drains and is of no sanitary value, inasmuch as, according to our correspondent Mr. E. Van Putten, the sewer, if properly laid and looked after, is less liable to contain offensive and dangerous emanations than the house drain itself. As the subject is of great importance and all the correspondents engaged in the argument seemed to be in earnest in their wish to recommend the best sanitary methods, we have given some space to their letters, but we fear that they have not led to anything very conclusive so far. Mr. Van Putten seems to forget that below the syphon there is often a considerable length of house-drain before the sewer with its "continuous flow" is reached, and that therefore by removing the lower syphon he is taking away the means of protecting the house from that portion of the drain, which, on his own theory, is liable to contain offensive matter that has not yet been fairly driven to the sewer by the closet flushing; nor can we accept his theory that the sewer is likely to be less charged with insidious emanations than the house-drain. In a letter which he has forwarded to us in further reply to Mr. Buchan (but which we do not think it will serve any useful purpose to print as a continuation of a correspondence which has already occupied a good deal of space), he admits that the flow in the sewer varies very much at different times of the day, but urges that it is "con-

\* The *Builder*, June 4 and August 27, 1887; May 26, June 9, and August 4, 1888; and June 7, 1890.

tinuous" in the sense opposite to "intermittent." That however seems rather a verbal than a real distinction: there are times of the day when the flow is too small to operate as a cleansing influence. He was right in calling attention to the inadequate amount of water often used for water-closet flushing, or which we have already commented, and on which point Mr. Buchan supports him. No doubt with an insufficient flush the syphon affords chances of stoppage which would not exist otherwise; but its advantages more than counterbalance this drawback, which with an ample flush from the closet is reduced to a minimum. With only one syphon under the closet-pan a communication with the sewer is opened, more or less, every time the pan is discharged: some of the air displaced in the pipe by the flush is likely to be driven up past it as well as down before it, especially where there is any upward pressure from the sewer, as often happens in elevated situations. Since it has been discovered that syphons do not do all they were supposed to do in cutting off foul air, there has been a counter-theory set up that they are of no value at all, which is an error on the other side. Nor does it by any means follow that they shut off free ventilation from the sewer and the length of drain immediately connected with it. Ventilation can be taken from immediately below the syphon and carried up to above the roof, if that method is desired. The most important point in the controversy is the long-debated one whether sewers are best and most safely ventilated into the roadways, or by upcast pipes carried up the houses; and this question is still far from being finally settled. We quite agree with Mr. Van Putten in having little faith in extract cowls, which depend on the action of wind, and are therefore useless in a perfectly still condition of the air, which is just when ventilation is most wanted. It would need a more extended series of experiments than have yet been carried out, to determine whether ventilating extracts carried to the tops of the houses are really free from danger of bringing foul air into the upper windows: and a more certain method of insuring the efficient action of such extracts must be found than cowls or reliance on opposition of currents formed by natural causes, the steady operation of which cannot be depended upon. Probably a ventilating upcast at intervals, operated by artificial heat, would be the most certain means of securing regular action; but for a large city this is a very large order to carry out completely. In the meantime our judgment is that the syphon between the soil pipe and the drain is not a thing to be lightly given up, and that greater evils would follow from doing so than any which can be shown to result from its use.

THE ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD.

THE "Nineteenth Annual Report of the Local Government Board, 1889-90," just issued,\* is, as usual, an elaborate account of the complex details of the local administration of the country. It is of additional interest this year as containing some account of the first year's working of the Local Government Act, 1888,—the Act which created the County Councils. Details are given of the various proceedings which were taken for the purpose of bringing that Act into full operation on or before "the appointed day," April 1, 1889, at which date every County Council had to come into office, the date being, however, anticipated by some ten days in the case of London, owing to circumstances which will be in the recollection of our readers.

The "Report" itself, signed by Mr. Ritchie, the President of the Local Government Board, covers 186 pages, which are supplemented by 600 pages of appendices. The first section of the Report deals with the Local Government Act, 1888, and the County Councils. With regard to the financial aspect of this subject, the Report expresses satisfaction that the Im-

perial revenues which were ceded by the Act to the Councils of the Administrative Counties and County Boroughs of England and Wales, in substitution for local grants, had slightly exceeded the estimates which were formed concerning them. Into the details of this statement we need not enter; but before leaving this section of the Report we may quote one paragraph which is worth bearing in mind, viz.:—

"By the Technical Instruction Act, 1889, County Councils have been authorised to make payments out of the County Fund for the purpose of supplying or adding the supply of technical or manual instruction as defined by the Act, to such extent and on such terms as they think expedient, subject to the conditions imposed by the Act. One of these conditions is that the amount of the rate to be raised in any one year by a County Council for the purposes of the Act shall not exceed one penny in the pound. Money may, however, be borrowed for the purposes of the Act, subject to the provisions of the Local Government Act, 1888. County Councils may appoint Committees consisting either wholly or partly of members of their body to exercise any of their powers under the Act, except the raising of rates or the borrowing of money. Provision is also made in the Act for a County Council being represented on the governing body of a school or institution receiving aid from them under the Act. The Town Councils of County Boroughs and other Municipal Boroughs have the same powers under the Act as County Councils."

The second section of the Report deals with "Relief of the Poor and the Poor-rate." We learn that on January 1, 1890, the total number of paupers of all classes in England and Wales in receipt of relief was 793,246, of whom 200,263 were indoor and 592,764 outdoor paupers, while 219 received both indoor and outdoor relief. As compared with January 1, 1889, these figures show a decrease of 4,493 indoor and 19,623 outdoor paupers, and an increase of 74 in the number of those receiving both indoor and outdoor relief. The decrease on the total number of paupers was 23,944, or 2.9 per cent. The population of England and Wales, as estimated by the Registrar-General, was 28,028,804 in the middle of the year 1888, and 29,015,613 in the middle of 1889. Taking these figures as the basis of calculation for the purpose of ascertaining the proportion to the population of the paupers relieved on the 1st of January of the two years 1889 and 1890 respectively, it appears, according to the Report, that the total number of paupers amounted approximately in the former year to 1 in every 37 persons, and in the latter year to 1 in every 37 persons. The cost of the relief of the poor, which was 8,440,821*l.* during the year ended at Lady Day, 1888, fell to 8,366,477*l.* during the year ended at Lady Day, 1889:—

"The latter amount represented an average charge of 5*s.* 10*d.* per head of the estimated population, being 1*3*d.** per head less than in the preceding year, and an average rate of 1*s.* 14*d.* in the pound on the rateable value of the property liable to contribute to the poor-rate. In thirty-nine out of the forty-six preceding years, the average charge per head of the expenditure on the estimated population has been higher than in 1888-89, and in every previous year for which we have statistics of pauperism, with the exception of the year 1887, the average rate in the pound on the rateable value has also been higher."

These statements, taken in conjunction with others contained in the Reports of the Poor-law General Inspectors, printed among the appendices, are somewhat reassuring. For instance, Mr. R. Hedley, Inspector of the district comprising the Metropolis, refers to the satisfactory state of trade in London, and he points out that the strikes which occurred, though greatly to be regretted, indicated that there was a ready demand for able-bodied labour, and accordingly there had been very little able-bodied pauperism during the year in London. With respect to the arrangements for the relief of the indoor poor of the Metropolis, the Board during the year approved of plans for the reconstruction of the St. Pancras Workhouse; for an extension of the Hackney Workhouse and the St. Saviour's Workhouse at Newington; and for the erection of an auxiliary workhouse, with casual wards, for the Strand Union. Plans were also approved for married couples' quarters at the Fulham-road workhouse of the St. George's Union and the Holborn Union Workhouse at Mitcham, and for certain improvements in the administrative buildings at the Chelsea Workhouse. The Board also approved of plans for the extension of the St. Olave's Union Infirmary at Rotherhithe, and sanctioned certain additions to the lunatic

wards at the Lambeth Infirmary. Plans for many new Poor-Law buildings outside the Metropolis were sanctioned by the Board; they are too numerous for mention here. The totals of expenditure sanctioned during the year for new Poor-Law buildings and the purchase of sites therefor were: For workhouses, 392,652*l.*; Metropolitan District Asylums, 19,028*l.*; District Schools, 27,114*l.*

"Public Health and Local Administration" is dealt with in the third section of the Report, which begins by giving statistics as to the extent to which the borrowing of money by Sanitary Authorities has been sanctioned by the Central Departments which have successively been entrusted with the administration of our sanitary laws. It appears that the total amount of the loans which were sanctioned by the old General Board of Health under the Public Health Act, 1848, up to September 1, 1858, when the Local Government Act, 1858, came into force, was 2,956,178*l.* The sanctions granted by the Secretary of State under the latter Act and the Sewage Utilisation Act, 1865, prior to August 19, 1871, amounted to 7,363,366*l.* Since its constitution on the date before named, August 19, 1871, the present Local Government Board has sanctioned the borrowing by Urban and Rural Sanitary Authorities of sums amounting in the aggregate, up to last year, to no less than 43,938,757*l.* The grand total of these figures, extending over forty-two years, is upwards of 54,000,000*l.* sterling, or upwards of a million and a quarter per annum. This money, as we now know, has not all been profitably spent, for sanitary engineering has been progressive, and mistakes which were committed thirty or forty years ago are not likely to be repeated in the present day. It is interesting to note that of the 43,000,000*l.* odd of loans sanctioned by the Local Government Board during its existence, by far the larger proportion, viz., 37,816,821*l.*, has been borrowed for sanitary purposes in Urban Districts. In respect of sanitary improvements in Rural Districts loans to the amount of 2,914,997*l.* were sanctioned during the same period. Under the Artisans' and Labourers' Dwellings Improvement Act, 1875, loans to the amount of 2,813,353*l.* have been sanctioned, and Joint Sewerage Boards have borrowed 1,153,358*l.*

Although the Report says that the number of defaulting Sanitary Authorities under Section 299 of the Public Health Act has perhaps never been so small since the passing of that Act as it was during the past year, the reports of the Engineering and Medical Inspectors of the Board afford melancholy evidence that many Sanitary Authorities are only not in default, technically or officially, simply because they have never been called to account for their shortcomings. It is only when some serious outbreak of illness has occurred that the inhabitants of rural villages and hamlets throw off their supineness and begin to regard the preservation of their health as a matter of more importance than "keeping down the rates." The extracts which we give almost weekly from the reports of Inspectors of the Local Government Board show that much,—very much,—remains to be done for the sanitation of rural districts. Of many a picturesque village whose situation in the midst of delightful country reminds the traveller of the poet's description of "Sweet Auburn," it can no longer be said that there "health" cheers "the labouring swain"; on the contrary, it is too often the lurking-place of typhoid and diphtheria.

It is satisfactory to note that the Board confirmed during the year no fewer than 370 series of by-laws made by Sanitary Authorities under the Public Health Act, 1875, the Public Health (Interments) Act, 1879, and the Acts incorporated with the first-mentioned Act. This number was considerably larger than the number of series of these by-laws confirmed in the previous year. The greatest increase was in the series relating to the regulation of offensive trades.

We can only mention in passing the record of much other useful work contained in the Report, such as the steps taken with regard to the enforcement of the provisions of the Rivers Pollution Prevention Act, 1876, and the Artisans' Dwellings Acts. We are glad to see that the Board is endeavouring to keep Sanitary Authorities up to the mark with regard to their powers in making regulations under the Dairies, Cowsheds, and Milk-shops Order of 1885. Milk is a very facile medium for the conveyance of infectious disease from country to town, and too much vigilance cannot be exercised in re-

\* London: Printed for Her Majesty's Stationery Office by Eyre & Spottiswoode.

The Tower Bridge Works: Sketch Showing the Present State of the Middlesex Pier.

gard to the sanitary conditions of its supply. A safe and harmless precaution on the part of the consumer is to boil it before using it. The administration of the Canal Boats Act and the Sale of Food and Drugs Act form the subject of other interesting paragraphs in the Report. Good work is also, we are glad to find, being done under the Alkali, &c., Works Regulation Act. Mr. A. E. Fletcher, the Board's Chief Inspector under that Act, reports that steady progress is being made in diminishing the amount of noxious vapours discharged into the outer air from chemical factories. The new process for the recovery of sulphur from alkali waste is being largely adopted, and promises to materially diminish the nuisance arising from that waste, while adding to the profits of the manufacturers.

One of the most interesting and important subjects treated of in the Report is that of the London water supply. The reports of the Examiner under the Metropolis Water Act, 1871 (Major-General A. de C. Scott, F.R.S.), and of the Analyst (Professor Frankland, F.R.S.) on the water supplied by the eight metropolitan companies in 1889, are given as appendices to the Report. As to the quality of the water, Professor Frankland reports very favourably. According to his analyses, the mean proportion of organic impurity in the water delivered in London by the five companies deriving the chief part of their supply from the Thames was less than in any year since 1868, when the present system of analyses was begun, and was not much more than half the proportion in 1880, since which year the improvement had progressed pretty steadily. The water delivered by the two companies which chiefly depend on the River Lea for their supply was still better. These results, we are told, are due mainly to improvements in filtration, but partly to the fact that 1889 was, on the whole, a fine year in point of weather, there being, to quote Mr. Ritchie's words, "few floods to carry into the rivers the filth from cesspools, farms and ditches, and manured fields." These words alone should be sufficient to warn Londoners as to the possible dangers of their present water-supply. General Scott points out, as regards the river waters, that there is a marked augmentation of impurity, both suspended and in solution, in times of flood, and he calls atten-

tion to the serious fact that the rapid increase of population in the valley of the Thames and Lea tends to increase the difficulties connected with the diversion of sewage and refuse matters from the waters. To quote Mr. Ritchie's summary of General Scott's report:—

"He remarks that in both valleys there are towns, villages, and detached houses the drainage from which reaches the water-courses in an imperfectly purified condition, and that the washings from manure spread over the fields are also apt to find their way into the stream. There is, therefore, necessarily for constant vigilance both in securing the removal of all preventible sources of pollution, and in requiring that the methods of filtration adopted shall be as thorough and effective as possible."

This is all very well as far as it goes, but it does not go very far. Efficient filtration may be depended upon to remove the suspended impurities, but impurities in solution cannot be thus mechanically intercepted, and according to some authorities it is in these impurities in solution that the greatest danger of contagion lies. In view of the growth of the population of London and of the annually increasing amount of water taken out of the Upper Thames and the Lea by the water companies, it is clearly time that this question was grappled with on sanitary grounds, apart altogether from considerations arising out of the exactions made by the companies under cover of a laxly-worded Act of Parliament. The London County Council is now considering the question of acquiring the water companies. If those undertakings are acquired for the public, the price to be paid for them should, in equity to the ratepayers, be fixed with due regard both to the limited volume and the possible dangers of existing sources of supply.

According to General Scott, the average daily discharge of the Thames at Hampton, taking one day with another throughout the year, is 1,100 million gallons, and the dry-weather flow rarely falls below 300 million gallons daily. Now although the quantity of water daily abstracted from the Thames for the use of the metropolis (which is limited to a maximum of 130 million gallons in twenty-four hours) is but a small fraction of the average discharge, the question of real importance is, as General Scott points out, "the relation between the volume of discharge of the river

and that necessarily abstracted, during exceptional droughts in the summer, when the first is at or near its minimum and the second simultaneously approaches to a maximum. This question derives its importance mainly from the fact that the metropolitan water companies collectively cannot impound more than seven days' supply of water at the present summer rate of consumption,\* and practically they must take from the rivers and other sources day by day the quantity required by the population."

It is satisfactory to learn that the constant service supply is becoming every year more general in London.

The fourth and concluding section of the Report deals with "Local Taxation and Valuation." From the masses of figures in this part of the Report we pick out two items of interest. In the year 1888 the gross estimated rental value of property assessed to the poor-rates was 178,589,584*l.* and the rateable value was 149,696,812*l.*,—showing increases over the previous year of 631,709*l.* and 362,188*l.* respectively. The amount of the outstanding loans of Local Authorities at the end of the financial year 1887-8 was no less than 192,222,099*l.*

#### THE TOWER BRIDGE.

WE give a sketch this week showing the state of the work now being carried out at the new bridge which is being erected at the cost of the Corporation of London over the Thames at the Tower. Our view, which is taken from the west end of the north pier looking east, shows the large central well in the pier, into which the short arm of the moving leaf descends when the central span is open for the river traffic. The bases of the four steel columns, which will be inside the four corners of the large towers, are now practically completed, and it is anticipated that before the end of the year the steelwork on this pier will be built up to its full height.

The erection of the steelwork on the south pier is proceeding, but it is not so far advanced, however, as that on the north pier. Messrs. William Arrol & Co. are the contractors for the

\* The East London Company is excepted from this statement.

steelwork, and Messrs. Perry & Co. for the masonry.

We gave a general view of the bridge, showing it as it will appear when completed, in our issue of July 3, 1886.

The architectural portion of the bridge was designed by the late Sir Horace Jones, City Architect. Mr. J. Wolfe Barry is the engineer-in-chief; Mr. E. W. Cruttwell is the resident engineer; and Mr. J. E. Tait the engineer for Messrs. Wm. Arrol & Co.

We may mention that the Bridge House Estates Committee of the Corporation of London paid a visit of inspection to the works on the 30th ult., and the temporary platform on which to lay the permanent superstructure of the two spans being now completed on both sides of the river, the Committee were able to traverse the whole distance to the centre abutments.

#### NIAGARA FALLS FOR MOTIVE POWER.

The oft-proposed scheme for the industrial utilisation of Niagara Falls seems at last likely to become a fact. Of course, a small portion of the mighty body of falling water,—a mere dribble by comparison,—has for long been used as a means of supplying power on the United States side; the tall water of certain mills on the cliffs above the Rapids being a familiar feature in the landscape. The scheme which is at present on the point of being carried out is a very big thing, even in this land of big things. According to our American contemporary, *Engineering News*, work is to be commenced at once by the contractors, Messrs. Rogers & Clement, on behalf of the Cataract Construction Company, the corporation that has been formed to exploit the concession; and the Engineer to the company is now on this side to consult Sir William Thomson, who is interested in the matter. The proposed plan is to take from the Falls 120,000 horse-power, and about 1,400 acres of land have been secured for carrying out the operations. A water tunnel of 6,700 ft. in length, and 490 square feet in section, will have its intake at some point in the Niagara River above the Falls, and will deliver at a spot a short distance below the Falls,—probably near the upper Suspension Bridge. This vast conduit will, therefore, pass under the town of Niagara, and, at a suitable point, a central station will be constructed. The tunnel will be simply a tail-race, and mills or factories requiring power will be situated along its course; it being a part of the scheme to develop a large manufacturing centre in the neighbourhood of the Falls. Poets, painters, and all lovers of the grand works of nature may well be alarmed when they hear the details of this portentous scheme; but there is really less cause for fear than would at first sight appear. Niagara has been for generations handed over to the great army of sightseers, in no country more Philistine than in the United States, so that if a man's impressions are of so delicate a nature as to be marred by a commonplace crowd, Niagara can have no more charm for him now than if there were a thousand factories within reach. Exactly opposite the American fall there is a large hotel, with no more pretension to beauty than is possessed by the average American hotel; right on the brink of the Horse-shoe Fall there is a common-place building; and the whole place swarms with photographers, flymen, guides, vendors of Drummagen curiosities, and touts of various descriptions. Within the last few years the two Governments have made a laudable endeavour to improve Niagara,—“to make our unparalleled cataract more attractive,” as was said by an enthusiastic citizen of local fame. The land immediately contiguous to the Falls is now public property, whilst an effort has been made to clip and curl the surroundings into a genteel suburban aspect, which is strangely in contrast with the savage “Thunder of Waters.” But nothing can vulgarise Niagara so long as it exists; even a “sky-sign” on its crest would not quite destroy its sublimity. The vital question, therefore, is whether the Cataract Construction Company will falsify its title by using up all the water, and becoming the Cataract Destruction Company. A single fact may set our minds at rest, for the present, in this respect. The company proposes, as we have said, to abstract water equal to 120,000 horse-power. If we allow 2 lb. of coal per horse-power per hour, this would give an equivalent

of 5,760,000 lb. per day of twenty-four hours. That is a great deal of coal; but Sir William Siemens once calculated that if all the coal mined daily in the whole world were utilised for driving machinery to pump back Niagara it would be barely sufficient for the work. We have not the details of Sir William's calculation before us, and doubtless our readers will excuse us looking up statistics in order to form an estimate of what the world's output of coal amounts to. Certainly it is more than 2,571 tons, which is the amount of coal the new company proposes to save, expressed in the larger and more compact unit of weight.

#### THE GATE TOWER, ST. AUGUSTINE'S COLLEGE, CANTERBURY.

At the recent meeting of the Kent Archaeological Society an interesting report by Dr. Maclean, the Warden of the College, was read, detailing the method of dealing with this valuable but rather dilapidated relic of Edwardian architecture which has been adopted by Mr. Herbert Carpenter in the repair and partial restoration which has been necessary. This report is of interest both in regard to the method of dealing with the work, and also in the additional light it throws on the curiously careless manner in which the practical question of constructive security was often neglected by Mediaeval architects.

In regard to the peculiar design of the angle turrets of the gateway it is observed in the report—

“Usually the turrets of gateway towers, as can be seen in the case of the ‘Cemetery Gateway,’ were continued of the same diameter up to their parapets. But it is probable that this Abbot, or his architect, felt that the turrets of the great Gateway would not thus be sufficiently important and dignified. By using, therefore, the full projection of the main cornice of the structure, which is continued round the turrets, they were able to increase the diameter, and therefore the height, of these important features, and thus gain the desired effect, although the overhanging and ‘top heavy’ appearance of this upper story is not altogether satisfactory.

At the same time, there is reason to believe that the parapet on the west side of the Gatehouse itself was of necessity raised and adapted to the altered turrets, by the introduction of the rich triangular tracery between them, above which were then erected the battlements and rich parapet work of Abbot de Fyndon, adapted by cutting at each end, so as to accommodate the battlements to the wider turrets.

The whole of this parapet and tracery work is very rich and refined in its details, which are of the type peculiar to Kent and Eastern Sussex, while on the central battlements there yet remains the lower part of the figure of St. Augustine, represented as sitting on its moulded coping.

The upper parts of the turrets, though beautiful in design, yet, as examples of good masonry, are full of faults, and in some places of a very serious nature. There was some risk in overhanging this lofty superstructure beyond its base, all possible care in bonding the masonry should have been used by the builders, but, on examination, the bonding was found in places to be seriously defective; so much so, that it was evident that while the work was in course of building, the vibration of the wind, and the consequent swaying of the mass, had dislocated the masonry, and opened some of the joints, which, therefore, had been filled in with thin slices of stone. Moreover, it seemed, too, as if at the close of the works some inferior stone had been used, mixed with the other, which is of an exceedingly hard texture. It is probably Aubigny, or from a bed of Caen stone long since worked out.

To this want of care the dilapidation of the turrets was mainly due, and on examination the decay of the stone was found to be very unequal, for while much of the hard stone is almost perfect, very much of the soft stone had perished, from 1 in. to nearly 3 in. inwards, while the projecting mouldings had crumbled away, or were but slightly attached to the mass behind.

It will be remembered that the general effect of age on these turrets, and on the upper part of the gateway was due to the dark, and, in some places, black appearance of the stonework, with here and there grey and almost white portions. It was found, however, that this darkened stone was the result of the decay and flaking off of the surface, and the induration of the flakes with modern coal soot crumbling at the least touch into powder, while the grey tone was the original surface of the ancient stones, many of which are as sound as when first erected.

Various portions of the mouldings having thus become separated, fell to the ground, and after some severe gales it was found much damage had been done. The College therefore instructed Mr. R. Herbert Carpenter (of the firm of Messrs. Carpenter & Ingelow) to make a careful inspection from scaffold-

ing erected for the purpose of enabling him to note each stone.

It then became evident that the vibration and swaying forward during heavy gales had become most dangerous, and that the upper stages of the turrets, especially the weaker north-western one, were inclining outwards to a very serious extent. The removal of the ancient timber lead-covered roof had contributed to bring about the settlements, together with the use, in modern times, of the upper part of the turret, as pigeon houses.

Much of the masonry had seriously suffered through neglect, and many of the upper steps which had tied the structure together had perished, and in some instances altogether broken away. The window openings had been originally filled by oak shutters hung to iron staples; but they had been removed for the convenience of the pigeons; in one sense, however, most fortunately, for by thus allowing the wind to pass freely through them, the upper parts of the turrets have been preserved to our time.

On the treatment of the upper portion of the turret, in an architectural sense, Dr. Maclean makes no comment; and indeed in regard to the work of Mediaeval architects it is too much the custom for modern critics to assume that “whatever is, is right”; a reverential attitude which is often carried much too far. Mediaeval architects were after all mortal, and like other mortal men made mistakes at times; and it is not serving the cause of architectural truth to ignore this. To corbel out those turrets when they had reached a little above half their contemplated height, and then continue them with those thicker proportions has a most awkward effect architecturally, and so far from doing away with the thin effect of the lower portion, was just the way to exaggerate it, and to give the whole a clumsy top-heavy appearance. It is quite a different thing from corbelling merely for a cornice and parapet, and it would certainly be condemned as a blunder if done by a modern architect. The defective bonding of this heavy upper length of the turret is a mistake of another kind which has become only too obvious in its results.

As to the means already taken, and the further steps proposed to be taken to render the whole work solid and secure, and at the same time to preserve as far as possible all the record of the former work, the report continues:—

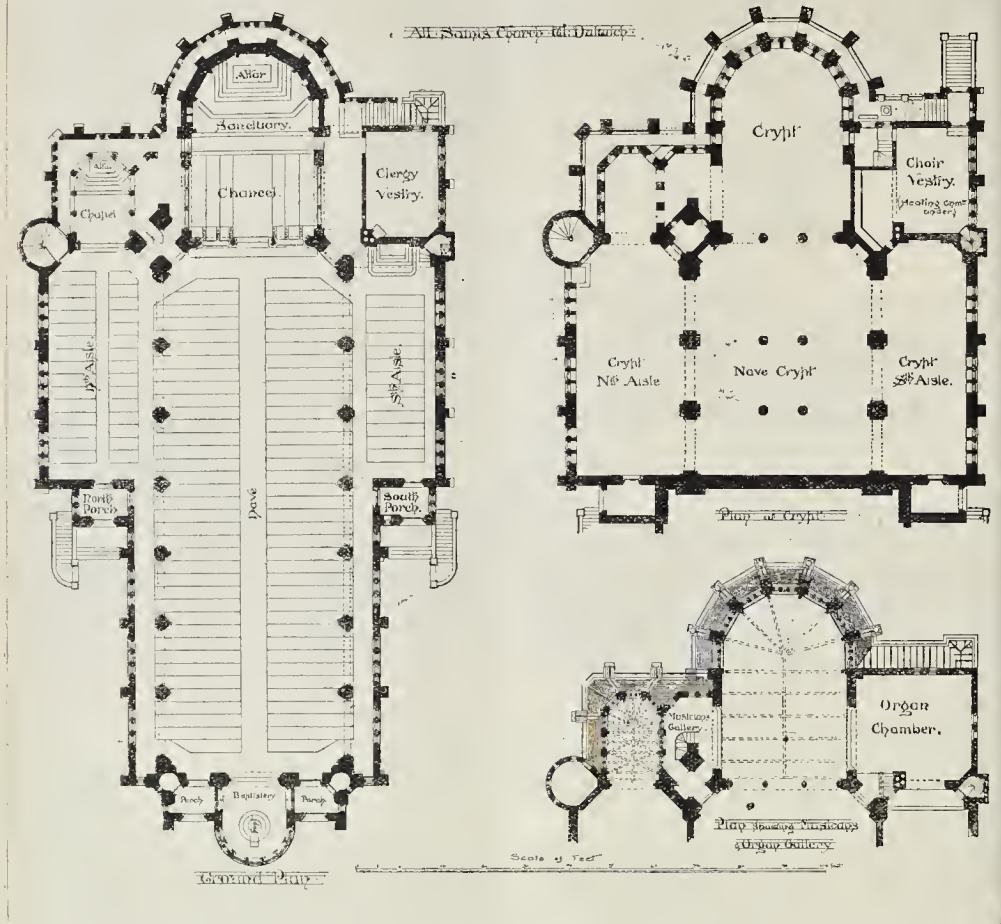

“Mr. Carpenter was of opinion that these defective upper stories of the turrets must be rebuilt from the corbelled-out cornice-line; and this is the work recently brought to completion. It was, however, of the utmost importance to preserve every stone which could wholly, or in part, be reused, exactly in its ancient position. Mr. Carpenter, therefore, by means of many stages of scaffolding, fixed in the ancient putlog holes, was able to make careful measured drawings, showing each stone on each face of the turrets, noting them one by one, and indicating by tints on drawings (a) those which could be replaced; (b) those which could be repaired or pieced; and (c) those so utterly perished as to require renewal. These drawings have been followed in carrying out the work; and it is proposed to deposit copies of them, both at the College and in the Library of the Society of Antiquaries at Burlington House, as a part of the collection of drawings of ancient buildings before restoration, now being arranged by a committee, of which Mr. Carpenter, F.S.A., is a member.

In the rebuilding it was felt that some better provision than formerly should be made for bonding the whole together, and this most important consideration has been attended to, and is carried out by forming the roof of each turret of a solid slab of Portland stone, built into the surrounding masonry, while a similar slab is built across the hollow circles of the stairs, at the level of the cells of the small openings before alluded to.

It has been a matter for consideration, whether or not these openings should be closed with wooden shutters, as originally intended; but for the present they are left open for the free passage of the wind.

The question as to the best stone to be used was a most important one. It was felt to be injudicious to trust to Caen stone, and it was, moreover, thought that the use of another kind of stone in conjunction with the ancient stone would serve to mark the modern masonry. Weldon stone was suggested, but the delicate sections of some of the mouldings could not be executed in it. It was therefore decided to use the Douling stone of the ‘Chelych bed’ for all the new masonry, backed up with solid brickwork instead of flint, thus also showing the nineteenth-century work.

We learn that it is now proposed also to cut out and repair some of the defective and decayed stones in the parapets and in the lower part of the turret; and each stone has again been noted in the manner before described. This appears to be an example of “restoration” carried out in a very commend-

able spirit. The only point about which we feel in doubt is that we are informed it is the intention to have a new figure of St. Augustine executed in place of the shattered lower portion of the original figure. The latter, as well as other pieces of the ancient work which will have to be cut out, is to be placed in the Coleridge Museum in the crypt of the library. That is a commendable course to take. But we may suggest, as to the proposed new St. Augustine, that no piece of modern-Medieval carving can possibly harmonise with the old work, or appear otherwise than an intruder. Why not leave the portion of the ancient figure in its place, and put the new one "in the Coleridge Museum?" We should prefer that course of the two.

**Illustrations.**

**ALL SAINTS' CHURCH, WEST DULWICH.**

THIS lithograph is from the original sketch design made for the above-named church by Mr. George H. Fellowes Frynne, A.R.I.B.A., London, in 1887, by whom complete and more elaborated designs were made during the following year for the Rev. James Beebey, vicar-designate.

Tenders for the whole work were obtained. The funds being inadequate, it was determined to build the church in sections. The first contract included the foundations at the east end, which were carried out by Messrs. Kynoch & Co., the foundation-stone being laid on All Saints' day, 1888. The second contract in-

cludes crypt, chancel, chapel, vestries, north and south transepts, and four out of seven bays of the nave, the flèche and tower being, for want of funds, temporarily cut off at roof level. The present contract is being carried to completion by the firm of Messrs. J. & C. Bowyer, of Upper Norwood, who have undertaken to complete the work by next May. The salient points of the design are as follows:—

The site has a fall of 28 ft. from west to east. The nave floor taking the western level, space is obtained for a spacious crypt for parochial, heating, and other purposes.

The main scheme of the church shows a lofty nave 58 ft. high and 40 ft. wide and 128 ft. in length, divided into seven double-arched bays, the piers being built of red brick and stone. Panels for decoration are formed over lower arches, and a clearstory in spandrels above.

Three eastern bays open into the north and south transepts. The chancel and sanctuary are the same height as nave, 28 ft. wide, 41 ft. in length. The altar is placed twelve steps above the nave floor level, and a good effect obtained both externally and internally by seven lofty windows at eastern end. The dividing arch between the chancel and nave is enriched with tracery supported by two slender columns rising from the lower screen. A wrought-iron roof screen is to span the spaces between columns.

The northern transept forms the nave of a chapel, the sanctuary of which is placed on the northern side of the chancel; clergy and choir vestries and organ chamber are placed on the south side of chancel. An ambulatory runs entirely around the east end of chapel and

chancel, connecting the northern turret with the vestries. Space is obtained for a musicians' gallery between chancel and chapel, both of which it faces. As the means at the disposal of the architect were wholly inadequate to admit of a tower or spire of large dimensions, he has designed a kind of minaret tower, which, while it is in accordance with the feeling of the design generally, is sufficiently large to admit of a peal of bells. The tower is placed angle-wise to the building, the arches at the base by this means forming a double squint for high and chapel altars.

An apsidal baptistery is placed at the west end.

The present portion of the church will accommodate some 950 persons, and, when complete, about 1,400. The church will be heated by Mr. De Ridder.

The present outlay is about £12,500. The design illustrated was exhibited in this year's Royal Academy.

**APPLETON THORN CHURCH, CHESHIRE.**

The view of this building was exhibited in this year's Royal Academy Exhibition.

It is a country church, about six miles from Warrington, and was erected at the cost of Mr. R. E. Egerton Warburton, of Arley Hall. The plan is that of a small transeptal church with a single aisle to the nave.

The positions of pulpit and tower-stairs give a quaint finish to the east end of the nave, and a baptistery, at its west end, makes a fitting receptacle for the font at the entrance of the church.

The dedication is to St. Cross, which influ-

anced the design in the disposition of the cross-like shape of the plan.

Care has been exercised in laying out the churchyard, and due regard paid to the proper disposal of its drainage before any interments took place.

Besides the church, the donor has added to it commodions vicarage, with outbuildings.

The contractor was Mr. William Winnard, of Vigan. Mr. T. C. Edwards's roofing, and Messrs. Maw & Co.'s flooring tiles, were used. Mr. John Grundy supplied the heating apparatus. The architect is Mr. Edmund Kirby, F.R.I.B.A., Liverpool.

**BOISTERS, CANTERBURY CATHEDRAL.**

At the end of the fourteenth century, the nave and cloisters of Canterbury Cathedral were rebuilt from the designs of Prior Chillenden. Of the cloister, we give two sketches by Mr. F. Wilkinson. The smaller sketch shows a portion of the East Walk, and the larger one the door at the south-east angle of the cloister, which is the principal entrance from the church from the west wall of the north transept, or transept of the Martyrdom, as it is sometimes called. Architecturally, it is an interesting example, of which so many exist, of additions made in the Perpendicular times, grafted on the Old Norman and Early English walls, and designed without any regard for the earlier work. The vaulting, very elaborate and beautiful of its kind, partially hides the arches of the earlier arcade and doorway, and even at the cost of reduction in the size of the doorway, the earlier arch has been filled in round the square-headed doorway of later times. This doorway derives additional interest historically, as standing on the site, and, perhaps, built into the wall, of the structure which witnessed the murder of Becket in 1170, and through which he passed on his flight from the palace to the church.

**CROOKSBURY, FARNHAM.**

THIS house is now being erected on the south side of Crooksbury, near Farnham, from the designs of Mr. Edwin L. Lutyens. It is intended as a summer residence, and is built of red brick with old tiles on roof and for the clanging. The house is planned following the natural levels of the site. There are nine bedrooms, and bath-room, &c., on first floor. There are attics in the roof, lighted by dormers on the north side. The floors in hall and living-room are wood-block with red brick margins.

Messrs. Mitchen Bros., builders, of Shalford, are the contractors.

The drawing from which the illustration is taken was exhibited in this year's Royal Academy.

**BORWICK HALL, LANCASHIRE.**

**BORWICK HALL**, situate about three miles from Carnforth, was built by the Bindloss family in the year 1559. The various wings and apartments seem to have been added on three sides of an older "Peel," or fortified tower, the walls of the latter being of immense thickness. Among other "Peels" in this neighbourhood, more or less ruinous, are Arnside and Vraysholme Towers, the latter of perpendicular date, and once in possession of the Harington family. [There is a fine but mutilated tomb and canopy in Cartmel Priory Church to the memory of Sir John Harrington.]

One floor of the original Peel at Borwick was used as the chapel, two sides of which were decorated with tapestry previous to the fall passing out of the hands of the Strickland family, of Sizergh Castle, to whom it descended by marriage. Adjoining the chapel is the priests'-room, under the floor of which was a "priest-hole," access to which was gained by a ramp in the floor. Through alterations to some of these this is now made up.

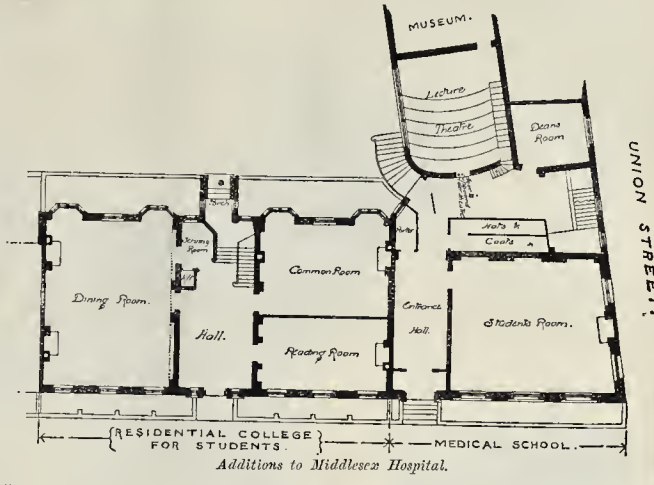

Some good oak panelling remains in the great hall and other rooms.

The archway through the gate-house still shows the masons' marks, indicating the order in which the stones were to be set.

The face of nearly all the external walls is rough cast, which finishes in a line a few inches from external angles and openings, showing the joints of quoins and dressings.

The backing of this picturesque pile and the gate-house are the only portions now inhabited.

E. HARTLEY.

**NEW BATHS, ST. GEORGE'S-IN-THE-EAST.**

THESE baths were erected, and presented as a free gift to the parish, through the instrumentality of the Rector and private friends. They comprise a swimming-bath, 73 ft. by 30 ft., and forty-three private or slipper baths, a wash-house for towels, &c., and a residence for the superintendent.

The builder's work was carried out by Mr. S. J. Jerrard, of Lewisham, and the engineer's work by Messrs. Slater & Co., of 251, Holborn, from the designs of Mr. Keith D. Young.

**NEW BUILDINGS, MIDDLESEX HOSPITAL.**

THE additions recently made to the hospital buildings comprise a home for trained nurses, a residential college for students, and additions to the medical school. In the perspective view only the two latter are shown.

The garden front of the college, which forms the central feature in the view, is faced with red brick and terra-cotta from the Burmantofts Co., Leeds. Accommodation is provided for thirty-three students.

The new school buildings comprise a luncheon room in the basement, with lavatory accommodation, common room for students, Dean's room, and small lecture theatre on ground-floor; library on first floor, and physiological class-room and laboratory on second floor. The whole of the buildings were carried out by Messrs. Holland & Hannen, from the designs of Mr. Keith D. Young (hon. architect to the hospital) and Mr. Henry Hall.

**INFLUENCE OF EXTERNAL CONDITIONS ON ARCHITECTURE.**

THIS formed the main subject of the first of a series of lectures on the History of Architecture, delivered at the Heriot-Watt College at Edinburgh on Monday last, by Mr. G. S. Aitken. The following is a brief outline of the main points of the lecture:—

The lecturer referred to the various possible sources of the origin of architecture, such as the *tent*, the *cave*, and the *burial-place*, and mentioned seven conditions which had determined its various forms. These were: 1. Climate; 2. Scenery; 3. Location; 4. Material; 5. Tools; 6. Race; 7. Religion.

"A country may have the most genial climate upon earth, but if it be such that the land brings forth spontaneously, and people have only to sit under their vine and fig-trees, the ripe fruit dropping into their mouth, so to say, the mental faculties will in such too favourable circumstances remain languid; with no inducement to physical exertion there will be little or no art culture. It is quite true, on the other hand, that the labour required to maintain a race may be so excessive as to crush out all liking for art. We do not expect to find it fostered in the sweating dens of any of our great cities,—indeed, we hardly look for it where toil is more moderate in its demands, as in the instance in Gray's elegy of the "Ploughman

homeward plodding his weary way." Mental exertion is not possible to the physically weary man. If he wishes to find satisfaction in art, it must be through the medium of others, who may be able to act as interpreters to him. All other things being equal, an equable climate is most conducive to the progress of art. Labour under propitious skies is necessarily less arduous for the body than toil in fitful climes. Man under such conditions has a due amount of leisure for art pursuits, and is physically in a condition to follow them with pleasure.

But what if he have no stimulus to mental activity from the scenery around him? Suppose the country to be as flat as a plain or as dreary as a desert. Though the climate be agreeable, yet if the scenery be unimpressive, we cannot expect to find in such a region the highest developments in architecture. It may be good, but at the same time unimaginative and ponderous.

Egypt will furnish us with an apt illustration of the truth of this,—a fine rainless climate, no scenery such as we understand it, but the bare syenite and limestone cliffs of the Arabian desert to the East and the African watershed to the West; no clouds to suggest the grand forms of peak and dome; the sun rising into the intense cloudless blue, and setting as he rose in a ruddy haze which makes him like a ball of fire. What is there in these physical conditions to produce the highest forms of art?

A third element is *Location*. A centre of civilisation may be in the heart of an inland country, its influence not extending beyond that country; or it may be on the sea-coast, where by maritime intercourse it may be in touch with many lands. In the one case, the art resulting may be expected to be essentially provincial; in the other, generous and eclectic, displaying variety, energy, and character. As illustrating this, Indian architecture, as it was before the irruption of Islam, may be taken. Gorgeous and laboured, it is an exotic in art, which could thrive in no other land, because there is nothing within it with which the people of any other country can feel sympathy.

How different with the lands on the northern shores of the Mediterranean. Take which country on that coast we may, there is always something in its architecture which can bear transplanting to other lands, because its roots are down in the soil of common principle, and in this way its foliage may, in a figure, be said to be for the art healing of the nations.

*Material* is the next matter we take into account. We can imagine the Desert of Sahara becoming by irrigation fertile enough for occupation, but we cannot see what prospect of building there could be even if the dwellers there had all the ambition and energy of a Nimrod. Tent-dwellers they must perforce be, for in so tropical a clime, and without a "boundless contiguity of shade," they could not afford to lose a single palm-tree to help in erecting so much as a solitary hut.

We see how much material had to do in the development of Pointed architecture. If it had been a style depending upon large cubes of

17<sup>th</sup> Cent<sup>y</sup>.  
Corner Post

Old Corner-post, Ipswich.

Post and Bracket, Ipswich.

stone it would soon have reached the end of its journey, but as the principles of its construction permit, indeed, encourage, the use of blocks of moderate size, its progress was assured wherever stone and brick were available.

An abundance of material without tools to shape and weld it would avail nothing for the formation of a style of architecture. For just as the invention of type printing has developed literature so the invention of tools has loosened the bonds of the genius of architecture. With hammer and chisel the mason can make the rough stone shapely, can revel in all the intricacies of moulded work, forming here a mystic hollow and there a living line of light, he can garnish a frieze with a reminiscence of the flowers he saw in some woodland nook or on mountain side; or he can crown the shaft with the semblance of leaf and flower with "Ibthic" birds embowered herein. All this and much else can be done because of tools.

A more important and determining factor in architecture is that of *race*. But, who can explain how it is that the art of one race shall be of a higher type than that of another, that the works of the Greeks should stand head and shoulders above, say, the art of the Hebrew race? An attempt to solve this would be like an effort to discover the principle of life in plant or man.

Our seventh formative condition is *Religion*. Turn to what land we may, and survey in imagination its architectural works, its religious buildings occupy the first place, whether in point of scale, dignity, or elaboration, so that it may truly be said that the history of architecture is mainly the history of the shrines of religion.

And we find the noblest works of this depart-

ment of art associated with those forms of religion which are the most spiritual. The Greek temple is a masterpiece of intellect, but it clings to the earth, and is, as its horizontal lines suggest, of the earth—earthly; on the other hand, the Medieval cathedral soars heavenward, as if it would claim kindred with worlds beyond, and is undoubtedly the realisation of all that goes to make truly good architecture."

OLD CORNER-POSTS, IPSWICH.

THE adjoining sketches of two of the numerous quaint features of this kind to be found in Ipswich are taken from a book of illustrations of them by Mr. J. S. Corder, of which some notice will be found under the heading of "Books," in another column. The drawings are considerably reduced in size from the originals.

THE PRIOR'S DOOR, ELY.

THE Prior's Door, on the south side of Ely Cathedral, is well known as one of the richest and most elaborate of the many rich and elaborate doors of similar date which are to be found scattered about in various parts of this country. The work belongs to the latter part of the twelfth century, and, as was usual at this period, the whole doorway is overlaid with a wealth of ornament which was not surpassed at any later time. The carvings are in a very fair state of preservation, except, perhaps, close to the ground-level, where they are partly obliterated; they represent in the tympanum our Lord in glory, with attendant angels, the

shafts and piers being covered with grotesque figures, including the signs of the Zodiac.

The jointing is noteworthy, more especially in the outer arch, and the method in which the design of the tympanum sculptures has been arranged to work in harmoniously with the stones and their joints is interesting. Seen by the light of the afternoon sun, this doorway is a very beautiful object.

THE LONDON COUNTY COUNCIL.

THE ordinary weekly meeting of the London County Council was held on Tuesday afternoon last at Spring-gardens, the Chairman, Sir John Lubbock, presiding.

**Jobbing Contracts.**—The Standing Committee brought up the following report, dated October 8:—

"In a report that was before the Council on April 22 last, we recommended that with a view to avoiding the possibility of error in the settlement of the accounts under jobbing contracts the measurements of work done should be made by the contractor and checked by the officials of the Council. A suggestion, however, having been made that there might be an improvement arrangement with respect to contracts generally, the matter was referred back to us for reconsideration. We have now to report the result of our further deliberations, in which we have been aided by a sub-committee composed of some of our own members, with the addition of Colonel Edis and Mr. Brereton, whose professional knowledge and experience enabled them to offer valuable suggestions. Having considered the report of the sub-committee in conference with the Chief Engineer and the Architect of the

The Prior's Door, Ely.

...ncil, we have arrived at certain conclusions which we now submit to the Council, and which, adopted, we believe will be productive of considerable economy in the carrying out of the Council's works. Before stating them, however, we may mention that it appeared to us in the course of our investigation that some of the works hitherto done under the jobbing contracts might be carried out more economically if tenders were obtained for them. This being the case, we are of opinion that, where practicable, tenders should be obtained, the recommendations which we now make it may be observed that we distinguish between the Engineer's and the Architect's departments, as regards the course to be followed in large contracts, the different circumstances of the two cases appearing to require a different procedure. Our recommendations are:—

- (a) That a quantity surveyor be employed by the Council (whenever required) to prepare bills of quantities for all large works, the Council accepting responsibility for such bills of quantities.
- (b) That copies of the bills of quantities be supplied, with the specifications, drawings, &c., to persons who wish to tender, and that each person invited to tender on the bills of quantities thus supplied.
- (c) That, in the case of large works carried out under the direction of the Chief Engineer, the arrangements be made as the work proceeds by an assistant in his department, who should be placed in direct charge of the works in progress, and that payments to the contractor for the amount of work executed be calculated according to the prices on the bills.
- (d) That, as regards the smaller works carried out under the direction of the Chief Engineer, a quantity surveyor having experience in civil engineering work be appointed in the first class at the commencing salary of 200*l.* a year, and that he be required to abstract and bill his own measurements.
- (e) That, in the case of works carried out under the direction of the Architect for which bills of

quantities have been prepared, the extras and omissions be measured by the surveyor who has taken out the quantities, and valued by him in accordance with the priced and signed bills of quantities.

(f) That for all other works in the Architect's and Valuer's departments the following appointments be made under the Architect, viz.,—

A measuring surveyor in the first class at the commencing salary of 200*l.* a year.

A clerk for abstracting and billing dimensions in the third class at the commencing salary of 100*l.* a year.

(g) That, whenever practicable, instead of having works executed under the jobbing contracts, tenders be obtained.

We may add that, if the Council adopts our first recommendation for the appointment of a quantity surveyor, we propose to invite by public advertisement applications for the appointment.

The report and its recommendations were agreed to without discussion.

*Vauxhall-bridge.*—The Bridges Committee reported that they had given consideration to a petition which had been received from the Vestry of Lambeth praying that Vauxhall-bridge might be superseded by a modern structure. The Committee, after hearing a deputation in support of the petition, had come to the conclusion that, although the bridge was narrow, the gradient steep, and the number of piers tended to obstruct the river traffic, the matter was not urgent, and might be delayed till the other works which the Council had in hand had been completed, and they recommended that the Lambeth Vestry should be so informed.

Mr. Myer moved that the matter be referred back to the Committee for further consideration, on the ground that the matter was of real urgency. He said that the Engineer of the Council had reported that, with regard to some of the piers of the bridge, viz., Nos. 3, 4, and 5 from the Middlesex end, it had been found that

the bed of the river adjoining them had been scoured away by the tide to a level below the bottom of the timber cradles, and in the case of pier No. 3 it was ascertained that the current had actually undercut the pier for several feet upwards, and to a depth of 9 in. below the bottom of the cradle. The Engineer had also reported that the ebb-tide passing under the bridge had been calculated to flow through the central arch with a velocity of  $\frac{7}{8}$  miles per hour, and had been a fruitful source of accidents.

The amendment having been seconded, Mr. Osborn, the Chairman of the Bridges Committee, said that the Committee were fully cognisant of the Engineer's report, but Mr. Myer had omitted to state that the hollows caused by the scour of the river under the piers of the bridge had been filled up with slag and cement concrete, and the bridge was now in a safe condition, and the question of its rebuilding could very well wait until three or four years later, when the work would no doubt have to be taken in hand.

The amendment was negatived by a large majority, and the report of the Committee was adopted.

*The Sewage Question.*—The Main Drainage Committee brought up a report recommending that the tender of Messrs. Schlesinger, Davis, & Co., amounting to 28,000*l.*, for the construction of a new sludge-ship, be accepted.

Mr. Aneas Smith moved that the matter be referred back to the Committee, on the ground that the Council would not be justified in making such an expenditure until the report of Sir Benjamin Baker, who had been paid 500 guineas to advise them in conjunction with their Chief Engineer on the whole subject, had been received.

Mr. Lidgett seconded, and Mr. McDougall and Mr. Benn supported the amendment.

On the other side, Mr. Burns urged that whatever the recommendations of Sir Benjamin Baker might be, it would be impossible to carry them out in less than four or five years, and they must continue their efforts to keep the river as clean as possible in the meantime.

Mr. Arthur Arnold, the Chairman of the Committee, said the vessel would be required because it would be almost criminal not to utilise to the utmost extent the works at Crossness, on which three-quarters of a million sterling had been spent, and which would come into operation about the beginning of July next.

On a division, the recommendation of the Committee was approved by a large majority.

*Sky-Signs.*—The Building Act Committee reported that their attention had been called to the erection of "sky-signs" upon various premises in the metropolis without the licence of the Council having been either applied for or obtained. As the Committee considered the erection of "sky-signs" most objectionable and dangerous, they recommended that the Solicitor be instructed to take the necessary proceedings in a test case.

As an amendment to the recommendation of the Committee, Mr. Beachcroft moved, "That it be referred back to the Committee to frame By-laws for the consideration of the Council either under Section 56 or 57 of the Metropolitan Building Act, 1865, or under the 16th section of the Local Government Act, 1888, as the Solicitor may advise, for the purpose of controlling the structures known as sky-signs." He maintained that by taking a test case to the police-court, where they were pretty sure to fail, they would abandon all the rights they possessed, and as the Council had large powers to frame regulations, rules might be framed which would meet the case.

On the other hand it was argued that if a test case, which could be brought in a police-court at very little expense, proved successful, the Council would be able to deal with the nuisance, and, if successful, they would be in a strong position in going to Parliament to ask for authority over sky-signs.

On a division the recommendation of the Committee was agreed to.

*Parks and Open Spaces.*—On the recommendation of the Parks and Open Spaces Committee, the necessary steps were taken to complete the purchase of Brockwell-park, Herne-hill. The consideration of proposal to negotiate for the purchase of 74 acres of pine forest adjoining Bostall-leath was adjourned for a week.

*Alleged Nuisances from Brick-burning, &c.*—The Sanitary and Special Purposes Committee brought up the following report:—

"Our attention has been directed from time to time to the serious nuisances arising from brick-burning, ballast-burning, and kindred trades. These nuisances mainly arise from the evolution of large volumes of offensive effluvia and smoke in the burning of bricks in clamps and in the burning of ballast, and also from the burning of the refuse-matter or soft core which is not suitable for use. On account of the peculiarly offensive nature of the vapours, and the distance to which they are at times carried, the nuisance extends over considerable areas, which are often thickly-populated districts. We are satisfied that the discomfort experienced in London from these sources is more considerable and widespread than perhaps from any other source. The 16th section of the Local Government Act enables the Council to exercise the power given by the 23rd section of the Municipal Corporations Act, 1882, of making by-laws for the good rule and government of the County, and for the prevention and suppression of nuisances not already punishable in a summary manner, and we consider it most desirable that by-laws dealing with the nuisances referred to should be made by the Council under this section without delay. We have prepared and now submit the following by-laws for this purpose—

4. By-laws for the prevention of nuisance in brick-burning, ballast-burning, brick-making, tile-making, pipe-making, and the burning of soft core, made in pursuance of Section 16 of the Local Government Act, 1888, and Section 23 of the Municipal Corporations Act, 1882.—

1. Every person who carries on within the county of London any of the following processes,—that is to say, brick-burning, or ballast-burning, or brick-making, or tile-making, or pipe-making, or the burning of soft core, or any other like process, shall cause every such process in which any offensive effluvia, vapours, or gases are generated, to be carried on in such manner that no offensive effluvia, vapours, or gases shall escape into the external atmosphere, and shall cause all such offensive effluvia, vapours, or gases to be effectually arrested or destroyed.

2. Every person who shall offend against the foregoing by-law shall be liable for every such offence to a penalty of five pounds.

Provided nevertheless, that the justices or court before whom any complaint may be made, or any proceedings may be taken in respect of any such offence may, if they think fit, adjudge the payment as a penalty of any sum less than the full amount of the penalty imposed by this by-law.

We recommend—

"That such by-laws be made, and the necessary steps taken for obtaining the confirmation of the Local Government Board thereto."

The report and recommendations were agreed to without discussion, and, after the transaction of other business, the Council adjourned.

#### SHEFFIELD SOCIETY OF ARCHITECTS AND SURVEYORS.

THE opening meeting of the new session of the above Society was held at the Montgomery Hall on Tuesday night, and there was a large attendance of members, including the President (Mr. F. Fowler), Messrs. C. J. Innocent, J. B. Mitchell-Withers, E. M. Gibbs, W. F. Hensoll, W. H. Lancashire, C. Hadfield, J. F. Wightman, E. Winder, jun., J. Winder, H. W. Lockwood, J. Smith, and others. Letters expressing regret at non-attendance were read from Mr. J. F. Massie (Wakefield) and Mr. T. J. Plockton. The members on keeping up their numbers, and on the fact that the Society had a good balance to its credit. The main object of this Society was to look after the interests of their profession, and to stand by one another. He trusted they would all continue to take an interest in the well-being of the Society, and do their best to enlarge its sphere of usefulness. The proceedings terminated with a vote of thanks to the President.

GIFT BY LORD DERBY TO THE LIVERPOOL FREE MUSEUM.—It is announced that Lord Derby has just presented to the Liverpool Free Museum a valuable collection of prehistoric implements illustrating the stone and bronze periods of Europe and America. The collection has arrived safely at Liverpool, and is now being prepared for exhibition by Mr. T. J. Moore, the curator of the Free Museum.

#### Books.

*A Manual of Wood-carving.* By C. G. LE-LAND, F.R.L.S., M.A. Revised by JOHN J. HOLTZTAPFEL. London: Whitaker & Co., and Holtzapfel & Co. 1890.

THIS is an admirable little book, combining artistic feeling for wood-carving as an art with useful practical information. We have occasionally had to notice books on wood-carving in which, while the practical information given as to the handling of the tools was useful and well arranged, the illustrations were in such wretched taste as to be injurious rather than helpful to the student who wished to become anything better than a wood-chopper. In Mr. Lealand's book there is not only much good critical teaching from the artistic point of view, but the illustrations are quite above the average of such small manuals, and many of them show a great deal of artistic feeling and fancy.

The book commences, as every such work must commence, with a description of the tools required, and the method of using them, and then proceeds to describe and give illustrations of various classes of work, commencing with the simplest, indenting and stamping, going on to cutting grooves, cutting simple leaves, and the "sweep-cut" or freehand carving, to which the author rightly attaches much importance, as being that which really separates carving proper from mere cutting. "Amateurs who have taught themselves," it is observed, "can generally cut or chip only straightforwards, they cannot turn or carve a leaf with a sweep"; and the student is recommended to practise the freehand cut on waste wood, so as to master the action, before seriously attempting to carve out a subject. He also strongly recommends the student to model a difficult bit of detail, or at least to draw and shade it carefully before beginning: "the reason is this, that having its principal points in the memory, it is much easier to reproduce them when cutting in wood; we know when and where to turn the hand or the tool." We are quite in agreement with the author in his advice not to undercut leaves to the extent of trying to make them look thin and natural, till they are as fragile as paper ("much more fragile," in fact). "This is greatly admired as indicating 'skill,' and it certainly demands skill of a common order to effect. But it requires a much higher and nobler kind of art and will to make the leaves strong and firm, even if we conventionalise them, so that their curves are really beautiful." The object in carving foliage being in fact not to imitate it, but to imitate its beauty in such a form as can be best represented in wood.

Many a person will consider the author heretical in saying that polishing and finishing with sandpaper is not necessarily a fault. He should no doubt learn to carve clean and well without glass or sandpaper, "but there is no law why he should go no further." This is a little bit of re-action against the contempt which has been poured of late years upon sandpapered work; but we hope it will not be taken by students as a kind of licence to offend in this way. Another suggestion in the book we do consider decidedly heretical, that of appliqué carving (of an animal in low relief for instance) fixed to a previously-carved diaper ground. No doubt "effects" are to be produced in this way; but they are not legitimate effects, and one always feels a sense of dissatisfaction from the knowledge that the thing is not a solid whole, and is likely to separate some day. Another point we take exception to is the three-legged stool which forms the tail-piece at the end of the last chapter, and which is vile. It is true, as the author implies, that it is a mistake to carve such stools on the seat, if they are to be used as seats at all, and ornament is better applied on the legs; but to encrust the legs with realistic foliage twining irregularly round them is an utter misapplication of carving, and entirely at variance with the quasi-architectural methods which ought to preside over furniture design. But in the main this is one of the best small books of its kind that we have seen, and should be looked after by those who desire to try their hands at the fascinating art of wood-carving.

*Structural Mechanics.* By R. M. PARKINSON, A.M.I.C.E. London: George Bell & Sons, 1890. Whitaker & Co.

MR. PARKINSON'S little handbook on "Structural Mechanics" is an addition to the litera-

ture of a branch of engineering which I already been so ably treated by many eminent men that it is somewhat surprising to find anyone who cares to occupy his time in travelling over such old ground again.

The author deals with the usual subjects—strength of beams, columns, and arches—explaining the methods of calculating the stresses upon them under various conditions of loading. It is to be regretted that throughout the work the word *strain* is used where *stress* should be written. *Strain* is the deformation or change of shape resulting from *stress*, and should not be used in any other sense. We also think it a mistake, when dealing with the effects of heat, to measure the temperature by the centigrade rather than the Fahrenheit scale; for, although this may be desirable in some scientific works, it is likely to be appreciated by the class for which this book is written.

At the end of each chapter will be found a set of examples which cannot fail to be of much service to the student, as they are in most cases questions which occur in every day practice, and the author has certainly added very much to the value of his book by a judicious selection of these problems, the solutions of which he has given in all cases.

*The Old Corner-Posts of Ipswich,* with illustrations in photo-lithography from original sketches. By JOHN S. CORDER, architect Ipswich; S. H. COWELL, 1890.

THIS literary portion of this work was an essay read before the Ipswich Fine Art Club during the present year, by Mr. John S. Corder, whose name our readers will remember as the author of some interesting collections of small sketches published from time to time in *The Builder* under the title of "Wayside Notes East Anglia." The essay consists of a sketch of the history of Mediaeval woodwork with some remarks on the special features illustrated, the corner-posts of the timber houses. These massive posts came necessary where a half-timbered house with an overhanging upper story happened to be the corner house of a street, and the oversailing story had to be carried round the angle instead of being merely a projection in one plane. These posts were very massive; they not only had to carry a considerable weight, but to resist the effect of the accidental collision of any vehicle turning the corner carelessly.

There seems to have been in ancient Ipswich a special love for carving these posts, so as to render them rich and decorative objects. The author has no doubt that in olden times Ipswich abounded with them, but they have all disappeared except nine, and of these the last figured in the book have been removed from their original situations and taken away from the town.

The author has done an excellent piece of work, and produced a series of very interesting drawings, in preserving a record of objects picturesque in themselves, and the life of which is naturally so very precarious. The drawings are large and carefully executed, and the subjects are arranged as nearly as can be judged in order of date. The first is a fifteenth-century one from the junction of St. Andrew and St. Nicolas-street. This is a rich of panel and tracery work, but has not the force of design or force of execution of some of the others. The five following examples are of late Mediaeval, all of the surface tracery style of design except No. 6, which is a plain panel with a carving of birds and griffins between two mouldings at the top, with a cresting of the whole forming a kind of impost for a heavy carved corbel which carries the arch. No. 8 is a seventeenth-century example with a demon figure squatted under the angle, and a boldly-carved horizontal cornice over. No. 9 is a much more ornate example, very florid taste, but interesting as an example of spirited execution; Renaissance ornament executed in the rough manner of country carver. The plate showing this and the highly-picturesque group of houses which it forms a part, is reproduced to a scale on page 310. In the extraordinary example from Gooding's coffee house (plate) the decorative treatment is carried up through both stories of the house, the oversailing of each story being carried by a grotesque, drooping-looking figure stooping with his knees and appearing to carry

fit on his bent shoulders; each of these figures stands on a pedestal carried on the ends of a group of three figures, the lower group appearing to represent Christian and upper one pagan personages. This is one of those now removed; a more curious piece of work of its kind could hardly be found, though it is more grotesque than graceful. The nineteenth plate in the collection is a bracketed post from a house in Carr-street, not a corner-post; a demon figure interlaced with rap work, and carried on a column with a deeply-carved Corinthian capital. Of this also I give a reduced facsimile on page 310. Mr. Corder's thin folio should be of interest to those who like to secure illustrations of ancient carved work before it is removed in the course of the rebuilding which is now invading our old towns more or less.

Correspondence.

To the Editor of THE BUILDER.

BAND-SAWS AND OTHER SAWS.

The following is the translation of a communication received from MM. F. Arhey et Fils, of Paris, reference to the article by Mr. Worssam on "The Conversion of Timber by Machinery," which appeared in the *Builder* of September 20:

Sir,—In reference to the article by Mr. Worssam on the conversion of timber by machinery which appeared recently in the *Builder*, perhaps our readers may be interested in knowing the result of our long experience in regard to one class of machines referred to, those called band-saws.

In the first place large hand-saws cannot be used except for straight cuts. We wish to call attention to the numerous drawbacks which we have found in our experience, in the employment of this class of saw.

In the first place, the difficulty of sharpening is very great. It is a question of sharpening a long ribbon of steel, sometimes up to fifteen metres in length. There are no doubt machines for sharpening them, but it is not easy to get good results by these means. It is in fact impossible mechanically to obtain a perfect and regular set in these long bands, which are often not of the same temper throughout. It is necessary therefore to give or to complete the set by hand, and to employ a skilled workman for this purpose.

Another drawback with hand-saws, which often escapes the notice even of practical men, is this: to obtain a perfectly straight cut it is necessary to give the saw at the greatest tension it will bear, causing very heavy friction on the pulley bearings, and consequent loss of some of the power expended in driving the saw. If the saw is not in sufficient tension, what happens? It deviates a little from the straight line, and at once begins to heat from friction in the working, and with this heating the blade sensibly lengthens.

As the saw being very thin, frequently breaks; it then becomes necessary to solder them, perhaps in two or three places. Each of these points causes a jar in the working of the saw, and one cannot obtain the same tension as before; hence a great source of imperfection in the work.

If it is answered, why not have larger and heavier saws, we reply that in that case the friction for working must be still greater, the pulleys heavier, and the proportionate cost of working increased, not to speak of the increased cost of the blade itself.

All these causes tend to vitiate the results of hand-sawing. In fact, the planks or panels cut by hand-saws never are, and never can be, of completely uniform thickness throughout, and do not have a good sale, good wood being spoiled by bad sawing, and in countries where wood is dear this is serious matter. In England we believe fine cutting is more sought for than in this country; and fine cutting depends mainly on the regularity of the cutting in curves, and the marking of the wood results from some of the teeth not being cleanly set, and where there are such a number of teeth as in these long hand-saws it is most difficult to avoid this.

The band-saw has its own special application, and within that limit is a splendid tool—that is, for cutting in curves, and the marking of the wood results from some of the teeth not being cleanly set, and where there are such a number of teeth as in these long hand-saws it is most difficult to avoid this.

The one characteristic merit of the band-saw is the continuity of its cut. Vertical saws, say the sawyers, cut only in descending, the instrument, in rising, it makes a little noise, and it has come into fashion (and in France there are fashions in machinos as well as in ladies' dresses), and it has been pushed by the makers of this class of saw in their own interest.

ever surmounted this difficulty by making a vertical saw with teeth to cut both ways (*denture alternee*). The arrangement of the teeth is such as to allow of the free escape of the sawdust; and owing to the great speed of the saw the cuttings is virtually continuous. This saw is working in the French, Portuguese, and Brazilian Government dockyards, and is reported to have very satisfactory results. The sharpening is done very quickly, and can be done while the saw is working, and the change of the blade demands only three or four minutes. The length of the saw is not more than 2 metres at the most. The power employed is completely independent of the tension of the blade, which is stretched in a frame that bears all the strain. Soldering for breakages is never required.

The blade is in high tension, preventing an inconvenience familiar to all sawyers with the use of band-saws, and which is called in France *tirage à cœur*. The flexible band-saw has a tendency to sverve towards the heart of the wood, interfering with the true vertical direction of the cut. Consequently, in France, the wood sawn by the vertical saw above described commands 15 to 20 per cent. better price than that sawn with the band-saw.

The vertical saw blade lasts much longer than the band-saw, and the blade is only one-fourth the cost to begin with. It will saw 150 superficial metres of wood per minute. It has also been applied to machines with several blades for sawing up square blocks. Both machines, the single and the multiple blade, were at work continuously at the Paris Exhibition of last year. P. ARHEY, Ingénieur des Arts et Manufactures (Maison F. Arhey et Fils.)

SKY-SIGNS AND ADVERTISEMENT BOARDS.

Sir,—As the matter of sky-signs and advertisement boardings and boardings has been made the subject of special comment in your last issue, I may be allowed to observe—in response to your remark, "perhaps some district surveyor will next take up the subject"—that the subject has already been taken up by myself; and the ruling of the Bow-street Magistrates, obtained in the following case (only one out of several of those which I have brought before them), has been so distinct and clear that the matter may be considered as, so far, settled in this district, I hope:—

First: D. S. St. Giles and St. George v. Willing (reported fully in *Bannister Fletcher's* edition of *Building Act*, 1852, pages 20-21, &c.). As regards boarding affixed to walls of houses in Little St. Andrew-street, for advertisement purposes. This kind of boarding is considered as especially dangerous in case of fire, as it covers all windows and openings and prevents their use for light or air. Notice was required for the "work" as done "in, to, and upon" a building, and its removal was required, as being woodwork irregularly fixed thereon. Since then Messrs. Partridge and others have several times been required to remove similar woodwork from face of various buildings, and have done so, the placards being now fixed to the brick face without any woodwork, and so without covering up any windows or openings.

Secondly, as to *sky-signs*. The District Surveyor v. Sage, Bow-street, 1888: summoned for want of notice, and to take down sign as a dangerous structure. It was decided at Bow-street that notice must be given to the District Surveyor for this as work done "in, to, and upon" a building, and that as a dangerous structure it must be made safe, &c.

Oxford-street.—This case against owner of No. 51, New Oxford-street, was peculiar, and shows how easily the best intentions are frustrated by interests of a different kind springing up in opposition (in this case that of Crown property). At the end of Shaftesbury-avenue, where it enters Holborn, was the rough flank wall of the building No. 51, exposed by the pulling down of the adjoining house to form sufficient width for this entry to the new street. This rough wall was made into a cemented architectural front, with panels, &c., at the cost of the ratepayers, through the Metropolitan Board of Works. These panels were supposed to be simply architectural decoration, and being a very poor kind of finish for such thoroughfare as Shaftesbury-avenue, and standing in such a commanding position, it was suggested by some good citizen that it would be just the position for a good fountain, and an offer was made to erect one entirely at private cost. But this was opposed, because for one thing the Crown had leased these panels for advertisements, and had required a sham shop front to be erected for the same purpose. These panels are now filled in with staring enamelled iron advertisements, but the sham shop front has been prevented by the application of the Building Act. Surely it would only be a grateful thing for the Crown to forego any extra rent it may receive for these panels being filled with advertisements and allow the Local Authority—the District Board—to arrange with the worthy citizen who would bear the expense himself to erect his fountain, and so take away the reproach attaching to this particular spot at present through the inconsistent action of the Crown agents or the Officer Works. C. F. HAYWARD.

October 11, 1890.

R.C. CHURCH OF ST. JAMES', SPANISH-PLACE, W.

SIR,—With reference to a paragraph in your issue of the 11th inst., I beg to say not only are the dressings of the exterior of Portland stone, but the whole of the rock-faced ashlar as well. As this is the first building in London where this has been used, I thought, perhaps, you might care to mention the fact in your next issue. This rock-faced ashlar was supplied by myself. F. J. BARNES. Portland.

The Student's Column.

HOT-WATER SUPPLY.—XVI.

IMPROVED AND OTHER SYSTEMS; PECULIARITIES NOTICED FROM EXPERIMENTS, AND THEIR RESULTS IN PRACTICE.

PERHAPS one of the most interesting, as well as instructive, things that it is worth anyone's while to erect, is a model hot-water apparatus; its construction is simplicity itself and to those who are at all interested it well repays the trouble. It would prove a most expensive undertaking to have the pipes especially made of iron, and the joints in themselves would possibly deter the most ardent, and what would prove most fatal to this arrangement is that, when erected, results could only be tested by feeling the different parts of the structure and judging by the temperature outside, the same as in an ordinary house system.

If we make the reservoir of glass, and use a small-sized glass tube (say  $\frac{1}{4}$  in.) for the pipes, we then have an apparatus that will permit of its interior phenomena being thoroughly investigated, every peculiarity, however trivial its action, being instantly noticeable; and, provided the proportions are about true, every reliance can be placed on it as a model of the actual working of a system. Amber dust, obtained by filing up a piece of broken pipe mouthpiece (provided it is amber), will render the movements of the water easily perceptible, as it is a material the particles of which will be found to remain perfectly still in still water, and only

FIG. 35.

move as the particles of water propel them. The glass tube can be jointed with rubber tubing.

Perhaps one of the most useful results noticed in an apparatus of this kind, and which has proved to be a result of almost every day utility to many who have noticed it, is that water proceeds both up and down a flow-pipe in equal volume when a draw-off tap connected to that pipe is opened; this is a perfectly natural result, as any work on hydrostatics shows us that in an apparatus of this kind the water cannot very well proceed from one way only, yet if a number of intelligent hot-water fitters were asked from whence does the water come that flows out of a tap when it is opened, whether up the flow-pipe from the boiler or down the flow-pipe from the tank (on the tank system), the chances are that not one will say that the water proceeds equally half each way, and the consequence is that numberless mistakes occur, some of them very perplexing to the uninitiated.

To more clearly explain the phenomenon in question, if we erect a double tube, as at fig. 35, and insert a draw-off tap in it at any point, as shown, and we then open the tap, what takes place? The water that issues from the tap does not wholly proceed from the pipe above the tap, neither does it wholly proceed from that portion of the pipe below, for it will be

found that as the water flows so will the level of water in the pipes be lowered exactly equal in each pipe, and this is a sure indication that the pressure both down and up is exactly equal, the same as if the lower part of the tube were taken away, as in fig. 36. This will make it

FIG. 36.

clear that we must expect water from both directions when a tap is opened anywhere in the circulating pipes of a hot-water apparatus, as we have only to place a boiler at the lower end of the pipes (fig. 35) and a reservoir at the top extremity to have a tank apparatus almost complete.

The commonest fault arising from an ignorance of this fact is the "returning" of a draw-off service on a tank apparatus. The draw-off service, of course, proceeds from the flow-pipe, and is carried back and connected into the return, and the effect is that the water does not lie stagnant, as it does in a single pipe, and the hot water is brought right up to the tap, or nearly so; everything is satisfactory up to this point, but immediately the tap is opened a partial failure manifests itself, for water will instantly proceed in equal quantities from both flow- and return-pipes, and as it is the exception rather than the rule for the return-pipe to be hot the water that issues from the tap will not always be of a satisfactory temperature, certainly not as hot as it might or should be. Should the whole apparatus be full of hot water so that the contents of the return-pipe are nearly as hot as the flow, then, of course, the water drawn off will be of a satisfactory heat, but even this satisfaction would be short lived, for the instant water commences to flow from the tap a corresponding volume of cold water enters the tank and quickly finds its way down the return-pipe.

An observance of this action of water proceeding from all directions to an open tap has led to the rising main of the cylinder system being returned and connected into the cylinder at a high point (as already explained), so that although the water makes its way up both pipes when a tap is turned on, yet as both proceed from the upper part of the cylinder no ill result whatever ensues. It was but a short time ago, and is very often now, the practice to return the rising main into the bottom of the cylinder or into the primary return, and many an apparatus has been cured of its inefficiency or been greatly improved by the mere alteration of this detail.

The discussion of this particular action may not strike everyone as being worthy of the importance that is being attached to it, but in practice it will be found that there is no effect which requires to be so continually under consideration when a problem in this work presents itself, and a knowledge of it is of the utmost value in a practical sense.

It should be mentioned that the question of the friction or resistance that water experiences in flowing through pipes has not been overlooked, but it makes such a trifling difference to this particular subject that it is scarcely worth consideration, yet, of course, if a tap were so situated that in one direction the water had only to flow a few feet, and in the other direction a hundred feet, a marked difference would be noted, but so great an inequality seldom occurs.

#### SURVEYORSHIPS.

WITCHINGTON.—The Withington Local Board (near Manchester) have increased the salary of their Surveyor, Mr. A. H. Mountain, from 200*l.* to 230*l.* per annum.

DIOCESAN SURVEYORSHIPS.—Mr. F. W. Waller, architect, of Gloucester, has been reappointed as Surveyor of Ecclesiastical Dilapidations in the Archdeaconries of Gloucester and Cirencester; and Mr. C. E. Pouting, of Lockeridge, Wilts, has been reappointed to a similar office in the Archdeaconry of Bristol.

#### GENERAL BUILDING NEWS.

RE-OPENING OF PETERBOROUGH CATHEDRAL.—After a restoration which has been in progress since the beginning of 1883, as chronicled and illustrated in our columns from time to time, Peterborough Cathedral was on Tuesday reopened. The work which has been done has been of a most extensive character. The great central tower was at the end of 1882 found to be in so insecure a state as to necessitate its being entirely taken down and rebuilt. This has been done, the tower being now rebuilt on solid foundations. In addition, the pillars of the choir and the north and south transept roofs have been repaired, and both transepts have been underpinned. These works, which were essentially necessary for the security of the fabric, have absorbed the greater portion of the expenditure. The other works which have been done include the cleaning of the internal masonry of the nave, aisles, and western transepts, the placing of a cement floor in the triforium, and new bell frames in the north-west tower. The total cost of these works has been 31,639*l.* 17*s.* 7*d.* The works on hand, or which have been provided for by special donations, consist of a choir pulpit, Bishop's throne, and marble floor for choir, exclusive of aisles and transept crossings. The choir has a seating-gallery with the funds in hand; but there are other works certified by the architect, Mr. Pearson, as urgently needed, which are estimated to cost 4,000*l.* The work in question consists in making good the masonry of the north and south transepts, and in underpinning and repairing the north-east angle of the eastern chapel. It is also proposed when the choir is forthcoming, to complete the stalls with bookboards and seats, at a cost, with canopies, of 3,176*l.*, to re-arrange the east end of the choir, and to reconstruct the organ in another position.

MODEL DWELLINGS FOR ARTISANS, BIRMINGHAM.—At a meeting of the Improvement Committee of the Birmingham City Council, on the 10th inst., the Clerk (Mr. A. E. Davis) reported that the model houses erected by the Corporation in Ryder-street had been completed and occupied. There are twenty-two houses, and they have been built at a cost of 4,000*l.*, Messrs. Martin & Chamberlain, of Birmingham, being the architects, and Mr. John Wood, of Handsworth, the contractor. Each house consists of a sitting-room, scullery (fitted with boiler and other necessary conveniences), two bedrooms, and an attic. At the back there is a large asphalted yard for the use of all the tenants. Water is laid on.

THE ARTISANS', LABOURERS', AND GENERAL DWELLINGS COMPANY, LIMITED.—This company has resolved upon an extensive extension of its operations. Another extensive suburban estate has been secured for the purposes of the company. Although the attention of the board has for the last few years been chiefly directed towards block buildings in central London, the work of the company in the suburbs has not been left sight of, and the directors have acquired a large plot in Streatham-hill, a freehold estate of 60 acres, upon which it is proposed to build about 1,600 houses and shops of the same kind as those on its Shaftesbury Park, Queen's Park, and Noel Park estates.

NEW TECHNICAL SCHOOL, COATBRIDGE, N.B.—The foundation stone of Coatsbridge Technical School was laid Saturday, the 14th inst., by Sir Archibald Campbell, Bart., M.P. The new building will form a part of the Coatsbridge School, the main entrance is from Kildoman-street. Internally the school embraces on the ground-floor three lecture-rooms, a mechanical laboratory, and a large mechanical and architectural drawing-room about 50 ft. by 33 ft. On the upper floor there are three large art-rooms for elementary and advanced art, including painting; also a chemical laboratory about 52 ft. by 32 ft. with chemical lecture-room and a preparation-room. The chemical laboratory when finished will be fitted up for sixty students doing practical work. There are also a sufficient number of sitting-rooms, lavatories, and other conveniences for such a building. The buildings are being ventilated by Robert Boyle & Son's patent system, and heated by hot water at low pressure. The whole buildings have been erected from plans by Mr. James Davidson, architect, Coatbridge, and the work is being carried out under his supervision.

A NEW ROMAN CATHOLIC CHURCH FOR HULL.—On the 7th inst., the foundation-stone of the new Roman Catholic Church of St. Mary's, Wilton-street, Hull, was laid by the Bishop of Middlebrough. The building has been designed in the Early English style of architecture, and is dedicated to the Sacred Heart and St. Joseph. The accommodation is for 500 adults, and the contract price is 18,500*l.* It is being carried out by the Messrs. Smith and Brodric and Mr. A. Lowther joint architects.

NEW WESLEYAN CHAPEL, SALTSAY.—On Tuesday last were laid the memorial stones of a new Wesleyan Chapel for Saltsay. The new chapel is to cost 3,500*l.* It will stand at the top of Fore-street, and seat about 100 persons. There will also be a school-room on the ground-floor, and vestry and infant class-rooms on the first-floor. Mr. Finch, of Plymouth, is the contractor, and Mr. H. J. Snell, of Plymouth, the architect.

A NEW BOARD SCHOOL FOR BENWELL.—The foundation stone has just been laid of a new Board School at Benwell, Northumberland. The rooms of the school are all on the ground-floor. The building is of stone, with slated roof, the insides of the roof being open timbered, stained, and varnished. The school is for boys and girls, 59 ft. by 22 ft. Connected with this school are five class-rooms, 25 ft. by 24 ft., each capable of accommodating sixty children. There is also a cooking-room fitted up with the latest improvements. The infant school is 36 ft. by 22 ft., and connected with this are two class-rooms, 24 ft. by 20 ft. The school has been designed by Mr. J. W. Thompson, architect, Newcastle, whose plans were selected in competition. The contract has been let to Messrs. T. & V. Common, of Horsley, for 4,630*l.*

A NEW HOSPITAL FOR BIRMINGHAM.—The Governors of the Birmingham Hospital have just decided to erect new buildings on a more convenient site, at a cost of considerably over 100,000*l.* The present buildings are antiquated and inconvenient.

SCHOOLS, CADBURY HEATH.—The designs of Messrs. W. S. Bernard, F.R.I.B.A., and R. I. Drake, of Bristol, have been selected in open competition for a new Board School for 300 children, to be erected at Cadbury Heath for the Oldland School Board.

#### SANITARY AND ENGINEERING NEWS.

TECHNICAL EDUCATION OF PLUMBERS.—BRIGHTON.—At the Brighton Technical and Manual Instruction School, York-place, an evening class of practical plumbers has just been opened. The instruction given will be in accordance with the syllabus of the City and Guilds of London Institute, the examination in this subject including Mechanics and Chemistry allied to plumbers' work as required by the Institute. The practical teacher is a registered plumber under the Plumbers' Company. ST. LEONARDS PIER.—The Mayor of Hastings performed the ceremony on the 9th inst. of screwing the last of the 22,500 bolts in the ironwork of the St. Leonards pier.

HARBOUR IMPROVEMENT AT WEYMOUTH.—On the 9th inst., Mr. Alfred Dennis, the Mayor of Weymouth, laid the final stone of the new quay which has just been completed in connection with an important widening of the quay at a cost of about 12,000*l.*

DUFFIELD WATERWORKS.—At the request of theelper Rural Sanitary Authority, Mr. W. I. Radford, C.E., of Nottingham, has sent in alternative schemes for waterworks at Duffield, and they are now under consideration. In one scheme Mr. Radford proposes to take the water from the Hazlewood spring, and store it in a service reservoir and supply by gravitation, any future deficiency being made good by putting down the pumping station mentioned below. In the alternative scheme Mr. Radford proposes to pump river water from the alluvial deposit, after natural filtration through sand and gravel, the water being pumped into a service reservoir to command the district.

NEW PIER FOR BLACKPOOL.—It is proposed to construct a third pier at Blackpool, and a meeting was held on Monday night in furtherance of the scheme. The new structure will jut out from the promenade at the South Shore, and a special feature in connection with it will be a large pavilion for the use of the public. PROPOSED BIRMINGHAM AND LIVERPOOL SEACANAL.—A meeting was held on Tuesday at 61 Dudley Town Council and the Dudley Chamber of Commerce to consider the proposed Birmingham and Liverpool Ship Canal Scheme. To commence at Birmingham the canal, it was suggested, should pass through Black Country towns towards Wolverhampton. Mr. Brian Shephard, the originator of the scheme, addressed the meeting giving details as to route, method, cost of working, &c. He said the canal was estimated to cost 2,800,000*l.*, without the land, which was 1.2 acres, and the work could be done within three years. After some discussion, a resolution was moved and unanimously carried, expressing approval of the scheme, and declaring it to be worthy of support.

#### FOREIGN AND COLONIAL.

FRANCE.—The works for the consolidation of the Pont-Neuf, commenced in May last, are now completed.—The works have been commenced for the derivation of water for Paris from the source of the Avey, the Vigne and the Verneuil. The works comprise three distinct sections; first, the construction of a grand aqueduct in the department of the Eure and Loire; second, the carrying of the water through the department of Seine-et-Oise where the high ground of Marly and St. Cloud will have to be tunneled, and thirdly the conduits to take the water into Paris, and the construction of a three-story reservoir at Montretout of 60,000 cubic metres capacity, representing three days supply for Paris. The water will be distributed in Paris through the department of Seine-et-Oise by a railway line from Melun to Paris. The Ministry of Public Works has under consideration a project for a bridge between the two hills of Croix-Rouge and Fourvières at Lyons, crossing the Saône.

a height of 107 metres above the river. Lifts will be established on each bank to raise passengers to the hill level.—At the Columbar barracks at Cannes a lead coffin has been discovered containing an embalmed body clad in monastic vestments. The barracks were built on the foundations of old convents, and the memory of the Marquis de Desmoulins is to be erected at Cannes.

Bourgeois, the Minister of Public Instruction, is proceeding to Maacon to inaugurate the statue of maritime in his native town. The ceremony is to take place on the 20th.—M. Mascart is about to install at the Eiffel Tower a bronze thread of pendulum 5 metres long, finishing 2 metres from the ground, and attached to the centre of the second platform, carries a steel sphere of 96 kilogrammes weight, and is intended to observe some interesting scientific experiments.—The tower of the church of vest des Brosses, in the Arrondissement of Forquier, has been struck by lightning, and the fall also injured the works of art and paintings in a sacristy.—The death is announced, at rival-surmer, of M. Léopold Dizon, architect of the Arrondissement of Abbeville, and former pill of Leulid. His career was a short but an honorable one, he obtained many premiums in his competitions and was a corresponding member of the Académie Centrale des Architectes.

The new Marais at Gagny (Seine-et-Oise) has been opened.

DRESDEN.—On the "Brühlsche Terrasse," and opposite to the New Ministry of Finance in course of erection, on the other side of the river, a block of buildings is being erected to contain the offices, and the works of art and paintings in the Saxony. This very extensive block (the river front of which measures 170 metres) has been erected under the superintendence of Professor Paus, and will show Renaissance façades carried to a good Saxon frontage.

BRIDGE.—The still remaining piers of the old bridge, which were examined by order of the municipal authorities of the city. We hear at besides the piers dismantled during the recent floods two others, No. 5 and 8, will have to be rebuilt, flaws having been found in their foundations. As the thorough repair of the old monument will take many years, a provisional wooden bridge is to be erected alongside the damaged one.

CHARLOTTENBURG.—The first part of the extensive sewerage system for this town, commenced 1887, and so far already costing 7,500,000 marks, or nearly 375,000*l.*, was opened on the 6th inst., an official ceremony taking place in honour of the occasion. Up to date, 30,000 metres' length of pipes and sewers have been laid, the largest section measures 2-30 by 2-70 metres.

ASIA.—According to a German contemporary, a Russian engineer, Herr Bethge, has been commissioned by the Siamese Government to construct a proposed Bangkok Canal railroad, in spite of a British competition.

NORTH SEA AND BALTIC CANAL.—For those interested in canal-building, we take note of a map of the above canal which has been lately published in order of the authorities under the special permission of Reg. Baumeister Brennecke, of the Netherlands. It is published by Fatsch, of Rotterdam.

FRENCH EXHIBITION IN MOSCOW.—Between May 10 and October next a French Industrial Exhibition is to take place in Moscow, but the idea is greatly opposed by native and German manufacturers in Russia. The exhibition will be held in the buildings of the Moscow Exhibition of 1882.

THE TASHKENT INDUSTRIAL EXHIBITION.—An industrial exhibition is being held this season at Tashkent, in order to show the progress of industry in Central Asia. It has been a great success, having been visited by some 35,000 persons, including many visitors, who have been greatly impressed with a show.

SWEDEN.—During the summer, granite to the value of 6,000*l.* has been exported from the west of Sweden, chiefly to Germany.—Up to the end of the year 1889, there have been expended in the restoration of the old Upsala Cathedral, and there still in hand 15,000*l.* The stained windows are still made in Sweden for the first time.—The district Council of Grisholm, near Stockholm, the first celebrated in Swedish history, is to be restored its appearance about the year 1500, according to plans of Herr Liljekvist, architect, which have been approved by King Oscar.

RAILWAYS.—The new railway-station has just been completed, and was handed over for public use last week. The new station buildings, although below the present standard of the large modern stations, are an improvement as regards architectural merit, and deserve mention on account of the clear and practical planning shown in them. Among the new buildings—those which are worth notice are those erected in connection with the University; the new end group of hospital buildings and the new medical Institute deserve to be specially taken notice of; whilst those belonging to other bodies in the new Provincial Law Courts and the premises of the Mining Board ought not to be passed over. It is probable, however, that the above erections, which occupy a prominent position among the most modern buildings in Germany, may be deemed the new theatre,

a model one of latest date, containing 1,200 seats, erected according to the designs and under the superintendence of Herr Selig, of Berlin, at a cost of 1,200,000 marks (the original estimate, by the way, was 400,000). Among the buildings at present in course of erection is a new lunatic asylum for university purposes, a municipal poor and workhouse of large dimensions, an archaeological museum, and a building for the newly-formed town fire-brigade. The horse tramway is to be turned into an electric one, the concession for this purpose having been given to a Berlin company.

MISCELLANEOUS.

BRADFORD HISTORICAL AND ANTIQUARIAN SOCIETY.—The annual meeting of the above society was held in the Alexandra Hotel, on Monday evening last. The chair was taken by the President, Mr. T. T. Empall, who called upon the Hon. Cor. Secretary, Mr. J. A. Clapham, to read the annual report. The society is in a very flourishing condition, numbering 224 members. The papers given during the winter session had been very valuable, and the excursions in the summer to various places of historical interest much enjoyed. The election of officers and council then took place. The following were elected officers and council of the society:—President, Mr. T. T. Empall; Vice Presidents, Messrs. John Lister, M.A., and Wm. Thackray; Treasurer, Mr. Wm. Glossop; Editorial Secretary, Mr. Wm. Cadworth; Corresponding Secretary, Mr. J. A. Clapham; Librarian, Mr. Peter Sothell; Council, Messrs. J. Bottomley, W. M. Brookes, C. A. Federer, Thos. Lord, Richard Poles, Wm. Suddards, and Butler Wood; Auditors, Messrs. Thos. Howard and J. W. Turner. Five new members were admitted. The study of architecture was strongly recommended, and it was said that Parker's "Introduction to the Study of Gothic Architecture" was a very valuable work published at a very reasonable price.

CABLE TRAMWAY IN NEW YORK.—New York is much behind most of the large American cities in its tramway system. Horse traction, with all its horrors and inconveniences, is the rule; but there is now to be a cable railway up Broadway, and work is, according to our American contemporary, *Engineering News*, to be begun at once, and a section of the line will be finished by the beginning of the winter. There is a feature in connexion with this enterprise which we commend to the notice of our "local authorities." The street will be paved at the same time that the line is laid, and "all companies having mains in the streets will be required to put the same in order before the new pavement is laid." New York is notoriously the most ill-paved city in Christendom, and "all companies having mains in the streets" have hitherto seemed to work their wicked will unchecked by authorities of any kind whatsoever. If we are to gather that there is to be a new departure in this respect it will be a more welcome change than even that of substituting a steam-engine for the unhappy horses that now supply motive power for street locomotion.

THE UNHOUSING AND HOUSING OF THE POOR.—Perhaps no sanitary measure is more desirable as such than the demolition of the London "rookeries." Tenanted for many years by the very poorest of our poor, haunted continually by filth, disease, and vice, their existence is a constant menace to more wholesome neighbourhoods, and the space they stand on constitutes their sole value. In spite of these facts, however, the work of renovation has had to proceed without any basis for an evident reason. The housing of their inmates is a matter of concern, and occasionally also of some difficulty. The occupant of a slum cannot always find a more suitable home. Model buildings, often excellent in design, though let at the most moderate rents, are still too costly for his precarious means. The less pretentious tenements of an older type are occupied by others like himself, but often also by workmen of a better class, attracted either by a prospect of economy or a dislike to the model buildings. These latter, indeed, do not seem to be duly appreciated. Airy, clean, commodious, economical, they are still to some extent unpopular. According to Dr. Yarrow, the medical officer of St. Luke's parish, skilled workmen do not appreciate the advantages of such homes. He mentions the case of two locks, in each of which many sets of rooms are still vacant. Unless it depend upon an objection to the collective life of the flat system, we are at a loss to account for this apparent oversight. It is possible that the noise of the work may have exercised some influence, and it would be of interest to learn whether other buildings of like type are similarly populated as those above mentioned. Meanwhile we may remark that their construction as a rule affords reliable guarantees for sound sanitary condition, a consideration which should never be disregarded. The housing of the poor will be a question of the time for many years to come, and it may well occupy the attention of divisional sanitary authorities.—*The Lancet.*

THE ENGLISH IRON TRADE.—The unsettled state of the English iron market has been further complicated by a partial cessation of all business, both buyers and sellers being much perplexed by the present abnormal conditions of the trade, and

consequently reluctant to operate to any large extent. There has been a decline in pig-iron prices, but the finished products display a steadiness which shows that there is a large reserve of work in hand, and that manufacturers believe in an early recovery of the crude iron market. Scotch warrants have gone down about 2s. 6*d.* per ton since the commencement of the blast-furnace men's strike, which appears to be farther off from settlement than last week. It is impossible to say what Scotch makers would sell such iron for as they happen to have yet in stock, for they still abstain from quoting. Although hematite iron has declined 2*s.* 4*d.* per ton on the week in the north-west, the stability of the market seems to be greater, makers continuing to book large parcels. The triple market keeps very strong, and a further advance is announced. Shipbuilders have been able to add to their orders, and continue active, and engineers likewise find ample work.—*Iron.*

ARCHITECTURAL ASSOCIATION CONVERSAZIONE.—Messrs. W. Woollams & Co. ask us to notify the fact that the name of their firm should have been given in the list of firms contributing to the "Conversazione" as "W. Woollams & Co.," not "Woollams & Co." simply. This is not an idle correction, as it appears, rather curiously, that there is a firm of John Woollams & Co., also paper-stainers and in the same neighbourhood, and also descended from the founders of the original firm, now divided into two which have no business connexion with each other. The invitation to contribute to the Conversazione was delivered by mistake to Messrs. John Woollams & Co., who declined, and the Committee at first thought the refusal came from the firm of W. Woollams, whom they had intended to invite.

MODERNISING VENICE.—The modernising of Venice, says the *Wiener Bauindustriezeitung*, is proceeding apace. Canals are being filled in, and streets made instead, whilst the handsome, light gondolas are fast disappearing and replaced by steamers. Of late a large number of the magnificent ancient palaces, with the characteristic loggias, have been pulled down, and ugly barack-like structures with tasteless façades erected in their place. However, up to the present this "vandal campaign" against the old structures has been carried on without any settled plan, but if a proposal now before the corporation of the city be accepted, it is to be feared that the appearance of the famous town will be entirely changed. The plan suggests the pulling down of the old buildings en masse and the building of modern ones, as well as the filling-in of canals and the making of streets on a large scale.

AGRICULTURAL HALL.—The Fourth Printers, Stationers, and Kindred Traders' International Exhibition, and Market is appointed to take place at the Royal Agricultural Hall, London, on March 16 to 30, 1891. Considering the number of type-setting machines and other wonderful inventions that have been introduced during the last eight years, this Exhibition should prove interesting.

FUEL GAS.—In the United States is being carried out the often proposed plan of having separate mains for the supply of fuel gas. It is needless to say that the ordinary illuminating gas is an unnecessarily costly product when used for heating purposes. The introduction of the cheaper fuel gas, with its higher calorific value, would cause a great revolution in domestic economy, both in the matter of cooking and heating in our homes, and application for power purposes in gas engines. The Boston (Massachusetts) Gas Light Company announce that after November 1 they will be in a position to supply to houses in certain streets a fuel gas with a calorific value of about 400 heat units per cubic foot, at 60 cents per 1,000 ft.<sup>3</sup> Chicago is still further in advance; for there, we are informed by an American technical journal, the Mutual Fuel Gas Company has established works with a capacity of over 2,000,000 ft.<sup>3</sup> per day. About forty-two miles of mains are owned or controlled by the Company, and 3,000 customers are on its books. The charge here is 50 cents per 1,000 ft.<sup>3</sup>, with a probable discount to large consumers. Water-gas has for some time been used in the United States for calorific purposes, but these two enterprises seem a fresh departure, and may inaugurate quite a new era in the history of Gas Companies.

FLUSHING CISTERN DISINFECTOR.—We have had the opportunity of seeing in action, at the office of the Sanitation Company, Limited, Victoria-street, Westminster, a working model of Taylor's patented contrivance for mingling liquid disinfectant with the water at each discharge of the cistern, or urinal flushing cistern. The invention is a very simple one, consisting merely of an ordinary bottle of disinfecting fluid, fitted with a special but simple discharging arrangement in the form of a small glass siphon tube inserted through the cork of the bottle. The bottle is placed neck downwards in the flushing-cistern, and by reason of the operation of certain natural laws a teaspoonful of the fluid is automatically discharged into every charge of flushing-water at the time it is used. There is no leakage of the fluid between the times of the using of the flushing-water. If flushing takes place twenty times a day there will be twenty discharges from the bottle, and if only once flushing there will only one discharge. There are no mechanical details.

COMPETITION, CONTRACTS, AND PUBLIC APPOINTMENTS.

COMPETITION.

Table with 4 columns: Nature of Work, By whom Advertised, Premium, Design to be delivered. Entry for Club House and Premises by E. Gristland Club Co. Ltd.

CONTRACTS.—Continued.

Table with 6 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, Tender to be delivered, Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, Tender to be delivered. Includes entries for York Stone, Making-up Roads, Alterations to Pier Rooms, etc.

PUBLIC APPOINTMENTS.

Table with 4 columns: Nature of Appointment, By whom Advertised, Salary, and Date. Includes appointments for Surveyor, Inspector of Nuisances, and Building Inspector.

Those marked with an Asterisk (\*) are advertised in this Number. Competition, p. iv. Contracts, pp. iv, v, vi, and viii. Public Appointments, p. xviii.

GOVERNMENT GRANT TO SCOTLAND FOR PICTURES.—The Board of Manufactures has just received a communication from Lord Lochlain, Secretary for Scotland, announcing that the Government propose to give a grant of 1,000*l.* a year for five years for the purchase of pictures for the Scottish National Gallery.

an outline similar to an oak sill; but the ends of the sill are formed into raised slots or sockets to receive the end of the pulley-stiles, casings, or side-pieces, so that the point of junction between the sill and the side-pieces, instead of exposing a joint presents a solid metallic surface, and a retention of moisture. A wood casing is fixed at the back of the sill, which may be raised to form an additional weathering, if required.

MANCHESTER SHIP CANAL.—As will be seen by an advertisement in our columns, the directors of the Manchester Ship Canal Company are inviting subscriptions for 600,000*l.* mortgage debentures at par. The directors hope to be able to open the lower section of the canal (Eastham to Weston Point) early in 1891, and the higher sections by the time fixed by the contracts.

MEETINGS.

- TUESDAY, OCTOBER 21. Sanitary Institute (Lectures for Sanitary Officers).—Professor W. H. Corfield, M.A., on "Sanitary Appliances." 8 p.m. Manchester Architectural Association.—Conversation to be held in the Athenaeum Lecture Hall. 7.30 p.m. Glasgow Architectural Association.—Mr. W. P. Buchanan on "The Ventilation of Buildings." 8 p.m. FRIDAY, OCTOBER 24. Sanitary Institute (Lectures for Sanitary Officers).—Mr. J. Wright Clarke on "Details of Plumbers Work." 8 p.m.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

15,406.—PLASTER OF PARIS: W. J. Oswald and others.—According to this invention, plaster is made from old waste plaster moulds or casts or of specially prepared hydrated sulphate of lime. Enormous quantities of this material is at present thrown away as useless, or used for whitening floors, &c.; but it is proposed to utilize it by grinding to powder, burning in kilns or in revolving furnaces, pounding the burnt material, and mixing with water. The plaster then hardens to the required degree in a few minutes.

NEW APPLICATIONS FOR LETTERS PATENT.

- September 30.—15,415, J. Dalnati, Folding Ladders.—15,416, W. Kimberley, Combined Plane and Oilstone.—15,435, H. Lake, Hinge Mortising Machines.—15,431, W. Telf, Woodworking Machine.—15,432, J. TENDERS.

Communications for insertion under this heading reach us not later than 12 noon on Thursdays.

BERMINGHAM.—For the erection of a new building at the corner of the Birmingham Exhibition Hall and Winter Gardens, and County Hotel Company, Limited. Messrs. J. P. Sharp & Co., architects, Manchester-street.

BERMINGHAM.—For the erection of a warehouse, at Station-street, for Messrs. G. F. Marlow & Co. Messrs. J. P. Sharp & Co., architects, Manchester-street.

BLOEMFONTEIN (South Africa).—For carrying out certain works of addition and alterations to the premises of the National Bank of the Orange Free State, for the Directors. Mr. Herbert J. C. Conleux, architect, St. Andrew's-street, Bloemfontein.

BROMLEY (Kent).—For the completion of two villa residences at South Hill Park, Bromley, Kent, for Mr. J. Bramson, Messrs. Rector, Payne & Lepp, King William-street, E.C. 4.

BROMLEY (Kent).—For erecting and finishing an addition to "Glenview," Bromley Park, Bromley, Kent, for Mr. Daniel Graham, Messrs. Wadmore, Wadmore, & Mallist, architects, 35, Great St. Helen's.

CARDIFF.—For the erection of three houses in Rappoch-street, Cardiff, for the trustees of the Welsh Presbyterian Church, Mr. Charles Egan, architect, 24, High-street, Cardiff.

DAREMOUTH.—For the establishment of telephone communication between the School and Pavilions for Industries at Darem, near Darford, for the Metropolitan Asylums Board. Messrs. A. & C. H. B. Parsons, architects, 10, Abchurch-lane, London.

DURHAM.—For supplying and laying 1,600 lineal yards of 2 1/2 and 3 in. water main, with valves, stand pipes, and a second-hand boiler for storage tank in concrete tierewith, at Gosport Colliery, for the Durham Rural Sanitary Authority. Mr. Geo. Gregson, engineer and surveyor, 10, Victoria-street, Durham.

EAST FINCHLEY.—For the nave, south side, and narthex of All Saints Church, Messrs. J. E. K. & J. P. Cutts, architects, 28, Southampton-street, Strand, W.C. 2.

EGHAM.—For levelling, installing, and making good by roads at Egham, for the Windsor Rural Sanitary Authority. Mr. W. M. Munnis, surveyor, English Green, near Egham, Surrey.

GATEHEAD.—For the erection of rooms for cookery at Gatehead, for the Gateshead School Board. Mr. Chas. Kempton, C.E., architect, West-street, Gateshead.

HAIN COMMON (Surrey).—For providing and laying about 2,000 ft. of Lametrite kerbing at Hain Common, Surrey, for the Hain Common Local Board. Mr. Warner, Surveyor.

HAMPTON WICK.—For additions to bathhouse, "The Elms," Hampton Wick, Middlesex, for Mr. F. Jacob, Mr. Ernest H. Abbott, architect, 6, Warwick-court, High Holborn.

HELEBRON (South Africa).—For carrying out certain works of addition and alterations to the premises of the National Bank of the Orange Free State, for the Directors. Mr. Herbert J. C. Conleux, architect, St. Andrew's-street, Bloemfontein.

HOVE (Sussex).—For providing materials and repairing three timber gables at Hove, Hove, Sussex, for Mr. H. H. Scott, Hove Surveyor, Hove Hill, Hove.

LEAMINGTON.—For alterations and repairs to the Aylesford Well House, for the Leamington Corporation. Mr. W. de Vereaux, engineer, Broughborough.

LEICESTER.—For erecting St. Paul's Methodist New Connexion Church and School, Malvern-road, Leicester. Mr. H. Goodhill, architect, Nottingham.

LLANDYSSILL (Carmarthenshire).—For additions, alterations, and repairs to Llandyssill Mansion, near Llandyssill, Carmarthenshire, for Col. W. L. Lewis, Mr. D. Jenkins, architect, Llandilo.

LONDON.—For the erection of a stable at Peuilfachog, for Colonel Lewis. Mr. D. Jenkins, architect, Llandilo.

LONDON.—For the erection of a new police station at Kilburn, for the Receiver for the Metropolitan Police District. Mr. John Butler, architect, Quantities by Mr. W. H. Thurston.

LONDON.—For the erection of model dairy and dwelling houses South Grove, Highgate, N., for Mr. Chas. Davies, Messrs. Bray, Young & Co., architects, 6, Warwick-court, High Holborn.

LONDON.—For the rebuilding of Nos. 231, 232, 235, and 237, Walworth-road, E.S.E., for Messrs. Lawless & Liddle. Mr. Albert L. Guy, architect, 78, High-street, Lewisham, S.E.

LONDON.—For additions and alterations to No. 27, Camden-road, and No. 128, Camden-street, N.W., for Messrs. Walkworth & Roberts, Mr. Theo. Newell, architect, Quantities by Messrs. Young & Brown.

LONDON.—Accepted for decorative, sanitary, and engineering work at No. 18, Phillimore-garden, Kensington. Mr. Joseph, architect, 18, Basinghall-street, E.C. 4.

LONDON.—For alterations and additions to "The Dover Castle" public-house, Plumstead, for Mr. Llanux. Mr. H. H. Church, Fletcher & Wigzell, architects.

LONDON.—For general internal fittings at the King's Cross Restaurant, 1 and 3, Roston-row, for Messrs. Reggiori Bros. Mr. Robert Willey, architect, 65, Langley-street, E.C. 4.

LONDON.—For pulling down and rebuilding the "Blue Posts" public-house, 28, Old Bonmarket, for Mrs. Rebecca King. Mr. J. Ashby Brose, architect, 65, Langley-street, E.C. 4.

LONDON.—For alterations and additions to the "Lord Napier" public-house, Abbey-road, Stratford, E., for Mr. J. Sull. Messrs. Fletcher & Wigzell, architects.

LONDON.—For alterations to shop at No. 15, High-street, Kensington, for Sister, Limited. Mr. Chas. R. Guy Hill, architect.

LONDON.—For alterations and extension of offices for Messrs. Mason, Scott, & Brittain, engineers, Battersea.

LONDON.—For alterations and repairs at the Ravensbourne Club and Institute, Lewisham, Kent, Mr. Albert L. Gray, architect and surveyor, 73, High-street, Lewisham.— £120  
 T. H. Court ..... £220 R. Super. .... 40  
 R. Hoare ..... 200 Chas. Robson, Lewisham ..... 169

 \* Accepted.

WIMBORNE.—For the sewerage, draining, paving, &c., of Lansdown-street, South-street, Wimborne, for the Wimborne Local Board, Mr. A. H. Mountain, Surveyor, Town-hall, Wimborne, Hampshire.— £454 19 4  
 B. Linton ..... £231 15 0 W. Sains & Sons ..... £454 19 4  
 G. Clarke ..... 473 19 8 Wm. Clarke ..... 457 8 11  
 M. Naylor ..... 467 17 8 Wm. Lambart, Ashburton .....  
 Worthington & Pownall 465 16 1 on Mersey (accepted) 418 8 2

*The Truck-road between the ground.*—Mr. James Howles asks us to note that the amount of his tender for this work should have been £276, 15s. 6d., and not £76, 15s. 6d. The mistake was due to a clerical error on his own part.

*A Correction.*—In the lists of tenders for works at Tuttenham-courts-road and Grosvenor buildings (see col. 3 of page 297 of our last issue), the architect's name was mis-spelled. The architect concerned for those works is Mr. R. H. Barden, not "Barden."

SUBSCRIBERS IN LONDON and the SUBURBS, by prepaying at the Publishing Office, 10s. per annum (of 4s. 9d. per quarter), can ensure receiving "The Builder" by Friday Morning's post.

TERMS OF SUBSCRIPTION.  
 "THE BUILDER" is supplied gratis from the Office to readers in any part of the United Kingdom at the rate of 12s. per annum. **EXTRAID.** To all parts of Europe, America, Australia, and New Zealand, 25s. per annum. To India, China, Ceylon, &c. 30s. per annum. Remittances payable to DOUGLAS FOURDRINER, Publisher, No. 46, Catherine-street, W.C.

TO CORRESPONDENTS.

C. M., E. V. P., J. R. (not suitable).—O. H. M. (received).—G. P. H., "Plumber" (we cannot undertake advising correspondents on their studies; see heading notice to that effect below). All statements of facts, lists of tenders, &c. must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline pointing out books and giving addresses. **NOTE.**—The responsibility of signed notices, and papers read at public meetings, parts of contracts, &c. with the authors. We cannot undertake to return rejected communications. Letters or communications (except mere news items) which have been duplicated for other journals, are NOT DESIRED. All communications regarding literary or artistic articles should be addressed to THE EDITOR. All communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHERS, and not to the Editor.

PUBLISHER'S NOTICES.

### Old Newcastle.

It is a curious kind of unintentional play upon words that the buildings and sites called "old" in this connexion are all more modern than the erection which originally gave rise to the name of

"New Castle," which the city on the Tyne still bears. The new is the old now, and the buildings which we call old Newcastle were once new and comparatively gimcrack erections in comparison with the massive Norman building which frowned down upon them from the top of the hill. And now these too in their turn are old, while the most prominent object in the minds of most of those who pass by or through Newcastle-on-Tyne is the lofty double-storied bridge, with the railway above and the roadway below, which connects the two quarters of the town, and from the height of which the traveller in the nineteenth century steam-driven conveyance looks down on the river which is older than all, though a very different sort of stream now from what it was when the Norman soldier looked down from the heights of the New Castle, probably over wooded banks, climbing from the water-side, on a clear and freshly-flowing river. The sun still shines on Tyne stream, and on bright days gives a glimpse of splendour on the river and the wreathed smoke as the train passes over the bridge; but the glitter on the water is only a superficial glamour on a stream which has long lost its purity and become tainted with all kinds of offscourings. For all that, Newcastle is a picturesque place to the passer by, both in regard to appearance and association. The castle and the bridge seem to vie with each other as the representatives of two epochs of great building activity, the castle-building of the Norman race and the bridge-building of the modern engineer, and it is a remarkable testimony to the power of the ancient builders that after all these centuries the castle keep still stands as the predominant object amid the town which has grown up around it, its only rival being the high-level bridge. Whether the bridge will last as long as the castle has lasted may be questioned.

Next to the castle and the bridge, St. Nicholas Church, with its picturesque and unusual lantern, is one of the notable structures of the town; and it is with these three buildings that its name is chiefly connected by the architectural traveller, and perhaps by most others. But there is a great deal more of picturesque and historical interest, hidden from the casual visitor in some out-of-the-way portions of the town; enough to furnish matter for a goodly and most interesting quarto volume of records and illustrations.\* It is true that Mr. Boyle does not by any means

Fig. 1.

pretend to present his readers here with a history of Newcastle; such a history, he observes, in any finally satisfactory way, is yet unwritten, and its writer probably unborn. But the book is full of curious information on the past records of the town, which, while interesting the reader of the present generation, may help to prepare the way for the future more complete history, the possibility of which is pointed to. The illustrative portion, we learn from the artist's preface,

\* "Vestiges of Old Newcastle and Gateshead." Illustrated by W. H. Knowles, architect; text by T. R. Boyle, F.S.A. Newcastle; Andrew Reid Sons & Co., London, Elliot Stock.

originated in the possession of a number of sketches, made during leisure hours many years ago, and not intended for publication. The drawings necessary to complete the series have been made in spare moments of professional labour, and under these circumstances are highly creditable to their author. They serve to convey an idea of the number of interesting old buildings and street houses existing in Newcastle, and may prove valuable also as records when the originals have been removed. Some of the buildings depicted, we are told, have already disappeared.

All towns which lie partially on steep declivities contain in that very fact the elements of picturesque effect in street architecture; and the first thing the author has to speak about is accordingly "The Side," a name which in itself carries one back to the formation of the town, for "the side" was originally the side of the hill on which the castle stands. No one would think of coining such a name now for a single street among a congeries of streets; but when the name arose no doubt "the side" was the one street that straggled up the side of the hill. "The Head of the Side" disappeared when the high-level bridge was made, as other old and quaint corners will ere long disappear under the march of improvement; but the lower portions of The Side still contain various quaint and picturesque old houses, one of which is figured in our first cut, slightly reduced from the vignette to the book. The lower part of the street, the Foot of the Side, is shown in another drawing, and contains some of the same curious corbelled out-houses, with their picturesquely grouped large windows with small panes. The higher part of The Side is steep and narrow, though we are told not nearly so narrow as formerly; and as this was the fashion of constructing the houses, it is not surprising that the upper stories nearly met in the middle; picturesque, no doubt, but like too many other picturesque things, sadly at variance with the conditions of healthy life. Indeed, one can hardly imagine a more dingy existence than must have been led by those who kept shops at the base of these toppling piles of houses, shutting out all the light and air. Other equally picturesque bits of street architecture are figured in the plates, one of the best being Cosyn's House on Quayside, in which the heavy projecting square bay is carried on columns standing free on each side

Fig. 2.

of the entrance, and connected with the door-jambs by a low balustrade on each side. The support given to the superstructure is probably rather apparent than real, the columns being merely ornaments; but the whole "hit" is one of the most piquant and sketchable incidents of old-town architecture that could be found. Other picturesque bits of building are taken sometimes from back courts and alleys, others from irregular groups of houses by the river side. In the older examples we find constantly that method of treating the windows in continuous horizontal bands or rows, the picturesque effect of which has been re-discovered by some architects of the present day. In the curiously plain and prim building called the Keelmen's Hospital, with its little clock-tower in the middle, dating from about 1700, we can study the opposite effect produced by very small windows dotted along a plain expanse of wall.

What is to be found inside of Cosyn's house is shown in our second cut, reduced direct from Mr. Knowles's original drawing. This is on the Quayside, once protected by a fortified wall, part of which was first removed in 1765, as being "a very great obstacle to carriages, and a hindrance to the despatch of business," as it no doubt must have been. The precise date of the house is not given. The room illustrated, the only one which retains its old aspect, and which is stated to be "the most charming old room in Newcastle," may have been fitted up subsequently to the erection of the front, which, picturesque as it is, gives no token of such richness within; and indeed we should be strongly inclined to suggest that the columns and balustrades flanking the entrance door, before mentioned, were not part of the original house, but added under the corbelling to give greater importance to the entrance, perhaps by Cosyn himself, who inhabited the house during part of his life, and died in 1661. The carved work over the fireplace of the room is very rich and bold in

design: of the three panels, the middle one bears the arms of Cosyn, the left-hand one that of the Drapers' Company of which he was a member, and the right-hand one the arms of the town. This decoration certainly also suggests the idea that the room was fitted up by Cosyn in accordance with his own taste and wealth. He was apparently a man of some power and influence in his day, so much so as to have had an information laid against him in Parliament as a political offender who was "endeavouring to bring the Scots into this nation." He left the town one hundred volumes of books, to be taken out of his library, sixty folios and forty quartos, and various charitable bequests in money.

Among the churches illustrated and described are St. Nicholas (which is now called the cathedral); St. John's; St. Mary's, Gateshead; St. Andrew's, and All Saints'. The cathedral, though as it stands mostly of rather late date, is a church of some interest independently of its well-known lantern. This latter, it appears, has not been always an object of admiration, having been alluded to in contemptuous terms by one Dibdin, an ancient chronicler, besides incurring the more serious visitation of the displeasure of Mr. E. A. Freeman, who speaks of it as a "strange anomaly," and adds, "the heauty or propriety of such a grotesque arrangement it is indeed hard to understand"; a criticism very characteristic of an amateur critic who judges Mediæval architecture by its conformity to an orthodox type. On the other hand we cannot see in it "weird grandeur," which, *pace* Mr. Boyle, is also a very amateurish expression and a great deal too large for the occasion; but we concur in considering that Newcastle lantern is a very admirable and withal graceful piece of work both in regard to design and construction. Whether Rickman is right as to its having given the original suggestion for St. Giles', Edinburgh, the College Tower at Aberdeen, and St. Dunstan's-in-the-East, London, may

be matter of opinion; in regard to the latter suggestion, we should be much more disposed to see Wren's imitation of it in the lantern of Bow steeple, a kind of translation of the Newcastle lantern from Gothic into Classic. A thin and wiry imitation of it in a Batty Langley sort of Gothic was also produced, we know not precisely at what date, in one of the original parish churches of Liverpool, also dedicated to St. Nicholas. Mr. Boyle states that "no part of the church founded early in the twelfth century exists now. Such fragments of Norman work as I have seen are of late date, and cannot be ascribed to a period earlier than the year 1150." Then what does he call the small crypt, figured on page 107, with its segmental barrel vault ("elliptical" the author calls it, but it was never deliberately set out as elliptical) carried by flat transverse groins. We have not seen this crypt, and cannot say how far the sketch accurately represents the details; but it is very unlike a late Gothic crypt, and very like the Early Norman one at Christ Church, except that there the flat groins are rounded off and not chamfered. The circular traceried window at the end might of course be a later insertion. On the face of the illustration given we do not feel at all clear about this crypt. Nor is it made quite clear how much of the present exterior represents the ancient design, except that it is remarked that the present traceried windows are taken as probably following the lines of the old tracery. The church was restored in 1873 "at a cost of 21,400*l.*," a very formidable charge of restoration powder, and it would be interesting to know what it brought down. An engraving by Hollar of the church in his time is reproduced, with the south transept window represented with a circular or segmental head. In Mr. Knowles's drawing of the south transept and tower the window is a pointed Mediæval one; is this a restoration, or was the round-headed window in the old print only one of Hollar's little eccentricities, like

he enormous projecting buttresses, which most certainly never existed?

The interior of it is spacious in effect, but weak in detail. Some of the monuments are really curious and characteristic, notably the Madison monument, a picturesque Renaissance erection carried on a base with great sculptured leaves and scrolls, a kind of rude reminiscence of a Corinthian capital, bold enough in its way, but completely out of keeping with the scale of the other details.\* St. Mary's Church, Gateshead, with an ancient history, has little of architectural interest left over. It possesses however some characteristic carved bench ends and a very fine Renaissance chair. We give the illustration of the interesting communion-cup and

Fig. 3.

over, with its decoration formed by the arms of the donor engraved on the plain metal; ineffective artistically, but how out of place and bow curiously at variance with the Medieval (we may say also with the modern) feeling as to the sacred rite. The cup is inscribed also, "The free gift of James Cole to St. Marijes Church in the parish of Gateshead." This last bit of spelling points to what the author suggests as the undoubted origin of the name of "Gateshead," from the monastery "Ad Capræ Caput." "At the head of the Goat," referred to several times in old documents which are quoted. One would have thought "Gateshead" a name so naturally arising out of topography, the head of the gate or entrance-street, as to need no further investigation; but when we find in a Latin chronicle the sentence "in loco ubi dicitur Gotesheved, id est, ad Caput Capræ," it seems impossible to doubt this curious derivation.

St. John's is a Gothic church of interest in quiet way. All-Saints was originally a Medieval church of apparently some interest and importance, which in the eighteenth century had become very ruinous, and the reports of three architects were called in as to its state, one of whom contemplated the repair of the ancient building, while two others counselled its entire removal, and the building of a new church. Their advice prevailed, though we are told that when it was actually taken down, "the firm manner in which several parts of the tower were cemented, rendered it necessary to have recourse to the operation of blasting with gunpowder." We have heard something like that in more recent times. All-Saints now stands as the Renaissance church of the town, of which it is not a bad example in its way; it was completed in 1796, at a cost of about

\* It may be worth while to mention in passing that a new literary interest attaches to the old Newcastle church since the publication of Browning's "Parleyings with certain People"; one of the "certain people" being Avison, once organist of the church in the early days of music, and who appears to have been a kind of reformer in music in his day, and wrote essays indicating what were then thought very "advanced views" on the art. His name is found occasionally in old collections of music, but was forgotten till Browning resurrected him as

"Thou, whilom of Newcastle organist."

Mr. Boyle, who indulges much in old social and artistic records, seems to know nothing of Avison.

Fig. 4.

27,000. One of the most characteristic bits of church architecture which is given in the volume, next to the Cathedral lantern, is however the massively buttressed old tower of St. Andrews, of which we give a reproduction from the author's drawing; there is not much of architecture about it in one sense, but it is a kind of thing every artist would feel irresistibly impelled to stop and sketch.

St. Mary's Chapel, Jesmond (*quasi* "Jesus' Mount") appears to be a very interesting relic of Transitional work. But some of the secular buildings of more modern days are apparently as interesting and characteristic as any of the Medieval work, perhaps more so. Among those figured and described in the volume none is of more interest than the Jesus Hospital, founded and endowed by the Corporation of Newcastle in 1681. Of its simple but truly architectural front with its arched loggia on the ground story, we give an illustration from Mr. Knowles's drawing. There is a lesson to be learned from this as to the really dignified effect to be obtained by this simple and broad treatment of a long building with regular lines of windows. It is of course the arcade which really makes the building, architecturally; without that it would be nothing; but that avails to give it architectural character and interest without any further enrichment of ornament or detail. In this respect it reminds one

of Queen's College quadrangle at Cambridge, with its plain brick arcade. There is a good balustraded staircase with a heraldic lion on one of the newels, and a sea horse on another, of which a drawing is given. A more detailed sketch of a portion of the front, given on another page, increases one's respect for it as an excellent example of the architecture of its date. It is a pleasure to come across a building so totally unaffected in style, and in which the architectural effect arises so naturally out of the conditions of the building.

We have purposely avoided touching on the Castle, which is fairly well illustrated in the book, but which is a subject rather for a separate monograph in itself, and at all events can merely be alluded to in a short article. Besides, it is a well-known monument, while we have thought it more to the point to draw attention to the information and illustration given in the book in regard to less known buildings of Newcastle, as indicating how much more there is to see there than the passing visitor probably imagines. We have really said little or nothing as to the fund of curious historical information to be found in the volume, in regard to the former social and municipal history of the city; but we can assure those who wish to know more of this that they will find Mr. Boyle's pages full of interesting and amusing reading; and probably most architects who see the sketches of

Fig. 5.

the old streets and corners will be disposed to arrange to give a little time to Newcastle-on-Tyne when next they go that way.

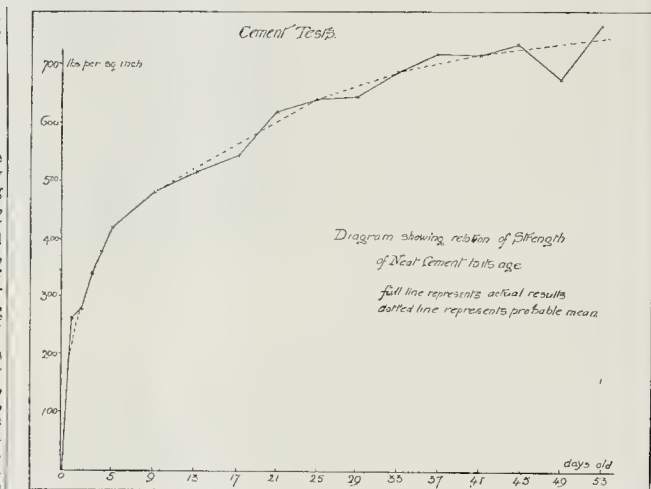

#### CEMENT TESTS.

BY PROFESSOR T. HUDSON BEARE.

**T**HE tests, the results of which are given in this article, were made by the author in his engineering laboratory, University College, London. They were made chiefly with the object of ascertaining if the method of gauging the briquettes by dry pressure, and then allowing them to suck up water for a given time, gave more reliable and trustworthy results than ordinary hand-gauging, and also to determine the rate of gain of strength of such briquettes with age.

This method, devised by Mr. Arnold, is as follows:—The moulds are of the ordinary form and cross-section, but for briquettes, which, when finished, are to be 1 in. thick, they are 2 in. deep; the moulds are placed on a stout, flat tray, with a shallow rim all round it, and are filled with dry cement, a weighed quantity (0.3 lb.) being placed in each; a brass die the exact shape and size of a finished briquette is then placed on the top of the cement in each mould, compressing the contents; this compression is completed under a small hand screw press, and the dry cement is so compacted that it occupies only half of the mould; the die is then flush with the top. We have thus a briquette of exceedingly closely-compacted dry cement exactly 1 in. thick; water is then poured into the tray, and the cement absorbs this by capillary attraction,—this goes on for twenty minutes; the briquettes are then removed from the tray and placed on a table, die down, to set for twenty-four hours. The after-procedure is precisely the same as in the ordinary method; the briquettes are taken out of the moulds at the end of the above twenty-four hours, and at once placed in water, where they are left for the intended time, then taken out, and immediately tested.

Since in this method it is rather difficult, owing, perhaps, to a slight recovery of the die on releasing from the press, to insure that the briquettes are exactly one square inch in

section, they were all measured; the areas, however, varied but little from the inch, the smallest being 0.96, and the biggest 1.04 square inches. In all cases, however, the total breaking load was corrected for the real area.

The machine used in the tests was made by Kuhlman; it is the standard German form, an ordinary double-lever one with a leverage of 50 to 1. It is an excellent little machine for use. There was no automatic arrangement, the shot being poured by hand. Extreme care was taken to keep the flow constant. The rate was about 400 lbs. a minute on the test piece, so that the weaker specimens were broken in about a minute, the stronger in one minute and a-half. For these the initial loads were 5 lbs., i.e., 250 lbs. on square inch, against only 1 lb., or 50 lbs. per square inch, for the weaker ones.

The briquettes were all in fracture exceedingly compact and close grained. This

is a result of the fact, that while an ordinary hand-gauged one of this size contains about 0.26 of a pound of cement, these had 0.3 of a pound, or about 15 per cent. more; the compactness must, therefore, have been much greater than in the ordinary method. They were all made from one barrel of cement (supplied to the author by the London Portland Cement Company) kept carefully dry when not in use. The experiments lasted over a period of three months; it is quite certain, however, that the cement was just as good at the end as at the start. It was originally intended to have three briquettes in each set, but it was afterwards decided to have five. The first set was tested immediately after removal from the mould, the second after one day in water, the third after two days, the fourth after three days, the fifth after four days, and then each succeeding set was four days longer in the water than the one before. In a few instances,

where a briquette was a good deal weaker or stronger than the average of the set, a fresh series of five were made; in the table, however, all the results are given; it was only necessary to discard two out of the 114 made, in both cases because some impurity had got mixed up in the dry cement in gauging them. The table gives the mean of each set, and the range of strength above and below the mean, the notes appended to it explaining any peculiarities. A diagram showing the results graphically is also given; from this it is quite clear that the rate of increase beyond fifty-two days would be small. A curve approximating closely to the actual results is also shown.

In conclusion, the author would like to draw attention to the necessity of engineers and architects adopting some standard tests for cement, as is done in Germany. It is a much more difficult matter to secure satisfactory tests of cement than of such materials as iron and steel; there are so many things likely to affect the results. There is always a certain amount of uncertainty in briquettes gauged by hand, the personal equation of the operator becomes so important; if, therefore, some such apparatus as the one used in the above were adopted, one element of uncertainty would be eliminated. It is not denied that a clever manipulator might, over a series of experiments like this, obtain results quite as uniform, but the chances are against it. Then, too, a standard rate of test should be adopted, and also the number of briquettes needed for a test. At the same time, the other tests, such as fineness and weight, might also be standardised. It seems hopeless to expect a general agreement about ordinary iron and steel tests, but surely it would be an easy matter to come to an agreement in the case of cement.

It is certain that this form of gauging gives higher results with neat cement than hand-gauging, so that a new minimum strength would need to be fixed. This could easily be done by a series of comparative tests with the same qualities of cements, gauged by hand and by pressure. This question of standard tests has been frequently urged by Mr. Grant, Mr. Fajja, and many others.

T. H. B.

TABLE SHOWING STRENGTHS AND AGES OF CEMENT BRIQUETTES.

Number of briquettes in set.	Number of days setting in water.	Breaking load in lbs. per square inch.	Departure from mean values in set.	
			Over mean, per cent.	Under mean, per cent.
5	0	267	18.3	18.3
5	1	281	18.5	14.6
5	2	342	19.0	19.6
5	3	384	7.3	6.3
10	4	422	16.1	6.6*
20	8	484	14.6	16.4†
5	12	519	5.8	4.1
15	16	549	22.0	24.0‡
5	20	624	7.0	7.4
5	24	645	6.0	4.0
5	28	650	5.7	13.7§
5	32	694	10.1	7.1
5	36	725	5.5	4.0
4‡	40	723	10.2	6.4
4‡	44	742	5.3	6.3
5	48	684¶	5.1	6.6
4**	52	773	9.5	7.0

\* Mean of first set, 438; of second set, 405 lbs. second set extremely regular; first varied 11.9 per cent. above, and 10 per cent. below mean.

† Mean of first set, 480; of second, 450; of third, 496; of fourth, 511; the variations were respectively, 17.1 per cent. above; 15.6 per cent. below; 26.0 per cent. above; 13.1 per cent. below; 8.9 per cent. above; 12.4 per cent. below; 7.0 per cent. above; 3.7 per cent. below. The strongest was thus much the most uniform, while the weakest set had the strongest (567 lbs.), and the weakest (301 lbs.) briquette.

‡ Mean of first set, 627; of second, 636; of third, 599 lbs. Variations: 11.2 per cent. above; 24.4 per cent. below; 13.4 per cent. above; 10.4 per cent. below; 19.8 per cent. above; 17.1 per cent. below. The sets were thus all irregular; but eliminating the very

NOTES.

AT the meeting of the Hellenic Society on Monday last some interest was excited by the paper read by Mr. A. H. Smith as to the subject of the sculpture on the well-known drum of one of the columns of the temple at Ephesus, which forms the most precious of the late Mr. Wood's excavated treasures, and of which the first published illustration was given in this journal shortly after its discovery. The accompanying small

cut of the principal portion of the sculpture, reduced from a diagram handed round at the meeting, will serve to explain the point of the paper. The sculpture has been accepted as representing the release of Alcestis from Hades, the central female figure being Alcestis, that on the left Thanatos (Death) and that on the right Hermes, about whom at all events there is no doubt. Some traces of a figure on the left (not shown in the cut) are supposed to indicate Herakles, who conquered Death and brought back Alcestis. This theory does not account for the action of the female figure on the right, with something like a necklace in her hands. Mr. Smith's theory is that it is the birth of Pandora, who was decked with gifts by the gods, and conducted to earth by Eros and Hermes, and he gave an unpublished archaic scene from a vase-painting in which Pandora formed the central figure, and a wreath is being offered to her, while other figures stand round on either side. The objection at once to this theory, however ingenious, is that the central figure is not stationary or in receipt of gifts, but moving away to the left. The theory partially explains the action of the other female figure, but that is all it has to go upon; the rest of the figures seem quite at variance with it. The Alcestis theory is much more nearly in keeping with the general aspect and action of the group, though it does not explain either the necklace in the hands of Persephone (as the other female must be in that case), or the peculiar sad and languid expression of Hermes, with head thrown back and parted lips, which is what probably most strikes every one who looks at the sculpture. Still, we think Alcestis is the best suggestion that has been made. On the same occasion, Mr. Theodore Bent gave a very interesting account of his recent explorations in Cilicia, a locality which seems to promise fresh pastures for the architectural archaeologist.

WE published on October 11 a letter from Mr. Penrose asking for subscriptions towards the cost of getting drawings and records made of the remains of the Byzantine buildings destroyed by fire at Salonika, before they were "restored" so as to obliterate their original history, as seems likely to be the case. The following letter from Mr. Penrose shows that his appeal has met with a liberal response from one reader at least, and we publish it here *pour encourager les autres*—

"SIR.—The letter you were so good as to publish inviting subscriptions in aid of the work of the British Archaeological School at Athens in the examination of the ruins caused by the recent fire at

strong one of set 1, and the very weak one of set 2, the grand mean is 551,—very close indeed to 549.

§ Eliminating a very weak one, the other four being very regular; this mean would be 671 lbs.

\* One in each set rejected because of flaws.

† No explanation can be given of this anomaly; two were gauged at one time, three at a later time; the tests were, therefore, on different days; the results are all fairly uniform one with another, and were carefully checked.

\*\* Only four were made in this set.

Salonika, has already produced one most encouraging response in a subscription, which heads the list with 20l., received from Miss A. F. Yule.

It is hoped that it will be well followed up, as a report from our students who have gone to Salonika shows that it will demand several months' hard work to do justice to the occasion.—Your obedient servant,  
F. C. PENROSE.  
65, St. Paul's-churchyard."

We shall be glad to announce in our columns the receipt of any further subscriptions for the same object.

ON the afternoon of Friday, the 17th, a large gathering of archeologists, artists, and classical scholars met to celebrate the opening of the New Cast Museum at Oxford. There was no formal ceremony, but the guests invited to meet the Vice-Chancellor were received at the galleries by the Curators. Among those present were Sir Charles Newton, Mr. W. Richmond, Sir Frederick Pollock; and Cambridge was represented by Professor Middleton and Dr. C. Waldstein. The Oxford Museum naturally suggests comparison with Cambridge, and must inevitably, to some extent, suffer by such comparison. Cambridge erected a building specially for the purpose of housing its casts, and expended on it 9,740l. Oxford had little more than 4,000l. with which to provide casts and books and other apparatus of archeology, together with new rooms for their accommodation. It was further hampered by the possession of a large number of indifferent and cumbersome casts, not only of second-rate Roman statues but of modern benefactors. In compensation it had, however, a rich treasure of inscribed marbles. The inscription room is, indeed, a notable feature in the new arrangement; the room is in the basement, but admirably lighted, and the inscribed slabs are well set up on a level with the eye, not, as too frequently, lying on the floor where they can only be examined in a painfully prone position. The collection of casts,—a large one,—is amply supplemented by drawings, photographs, and plates. The illustrations of such works as the Monumenti, Gerhard's Vase publications, and Brunn's collection of photographs, are exposed on screens in a profusion almost perplexing to the eye. Certainly Professor Gardner,—to whom, as Lincoln and Merton Professor of Classical Archeology, the arrangement is largely due,—has every reason to say that "the notion which seems in some quarters to prevail that archeology can only be learned at Berlin or Athens, is quite unjustified." The bulk of the German archeologists enjoy, in their preliminary training, no greater material advantages than those which are now available at Oxford.

READERS of the *Builder* who may be planning a winter's journey to Rome or Athens may be interested to know in advance the official programme for the public meetings, lectures, &c., of the German Archaeological Institute at both places. Dr. Petersen, the head of the Roman Institute, will, besides conducting the regular meetings, hold from December 9 to April 21 a series of classes in the various Roman Museums, for demonstration and for archaeological practice in the examination of monuments. The sub-secretary, Dr. Hülsen, will give three times a week, from November 15 to December 20, demonstrations *in situ* on Roman topography, and, if the course is well supported, he will repeat it in April and May of the following spring. Besides this, he will hold practice classes in epigraphy from January till the beginning of April. In the summer Herr Mau will give an eight days' course of lectures at Pompeii.

AT Athens the fortnightly meetings of the Institute will begin on December 10, and continue as usual till Easter. During the same period Dr. Dörpfeld will give his usual *in situ* demonstrations on the buildings and topography of Athens, adding Petraea and Eleusis. The second secretary, Herr

Wolters, will give practice classes in the examination of antiquities in the museum at Athens. In the month of April, an expedition through the Peloponnese will be organised under the personal supervision of Dr. Dörpfeld, and a further journey, which will surely attract many students, for the examination of the site of Pergamos, Troy, and some other places to be fixed later.

WE have received a circular from the Secretary of the National Society for the Exemption of Machinery from Rating (why, by the way, are secretaries so enamoured of the much-misused word "National?"), the object of which is to answer an attack made on the Society by the Guardians of the Chard Union in reference to the rateability of some machinery in their district. We cannot say much for the logical character of this circular; a considerable part is taken up with an extract from a consular report as to the effect of the bounty system on French ship-building, which is what lawyers call very irrelevant to the main issue. But it is obvious, from the tenor of the circular and from the way in which an Austro-Hungarian law exempting factories from taxation for fifteen years is cited with approval, that the practical object of the Society is to obtain the exemption of factories from taxation. It is obvious that the valuable and really rateable element in factories is the machinery. The rateable value of a factory without machinery is comparatively small. We then naturally ask ourselves, Are British manufacturers poor struggling men who require relief from taxation? On the contrary, the manufacturers are one of the richest classes in the community, and factory hands are some of the best paid artisans in the kingdom. That being so, why should an alteration be made in the existing law? From a business point of view manufacturers do well to try and obtain the exemption of machinery from rateability, but we do not anticipate success for the effort. That local authorities are inclined to make more out of factories and railways than is perfectly just is, no doubt, in some cases the fact, and an association to assist them in prosecuting rating appeals is legitimate enough. We cannot, however, agree with the views of the "National" Society above-mentioned.

WE hear that at the last sitting of the Prussian Royal Academy the majority of the members were in favour of not holding the usual annual exhibition next year, on account of the severe competition against it by the new Munich institution, which has attracted most of the best artists, and leaves but an insignificant show of North German work for the capital. It is certainly high time that Germany should have its one annual Salon, like other nations, instead of the competition of several exhibitions in different cities (Düsseldorf, Berlin, Munich), and that this Salon should be a recognised institution. Although it may be considered a pity that Berlin should have to give way to the Bavarian capital on such a point, this is only natural, considering, firstly, that Munich is the art centre of the Empire; and secondly, that the Berlin Exhibition has of late years been badly managed, remarkable more for the quantity than quality of pictures hung, and mostly held at the worst time of the year, when all Berlin is out of town.

AMONG the important statutes passed last session, and which are now printed, one of the first is the Companies Winding-up Act, 1890. The provisions of this Act are of too technical a character to be referred to at length. We may point out, however, that where "the capital of a company paid up or credited as paid up does not exceed ten thousand pounds, and the registered office of the company is situate within the jurisdiction of a County-court," it may be wound-up in such County-court. This will save a good deal of trouble and expense in the case of small industrial and similar companies, more

especially in the North of England, where small companies are more numerous than in the South. There is also a noticeable section, of which the substance is thus stated in the marginal note, "power of Court to assess damages against delinquent directors, officers, and promoters." The sums so obtained are to go to the assets of the company. While the provision is likely to make officials more careful, it is possible that it may be used by irritated but not very prudent shareholders as an engine to punish directors who have been unfortunate rather than wrong in their management. It is evidence, however, of the popular feeling against many of the existing malpractices of those who have charge of limited companies.

THE Bath stone firms have asked our attention to a method of chemically treating Bath stone for preservation against weather, by the exterior application of a liquid entitled "Fluate," which it is claimed renders the stone practically imperishable without altering its colour. At our request they have sent us two cubes of the stone, one in its natural state the other treated with "Fluate." The latter does affect the colour, giving the stone a light grey tint darker than its natural tint; but as the whiteness of new Bath stone is rather a defect as regards architectural appearance, the dulling of the colour is not a matter of consequence. The result of an examination of the Fluated stone is satisfactory, if it does not promise quite the imperishable quality that is expected from it. The two cubes were analysed first as to general composition; the following is the result, No. 2 being the Fluated specimen:—

	No. 1.	No. 2 F.
Water (lost at 212 deg. F.) ...	.14	.28
Loss on ignition .....	1.60	1.68
Oxide of Iron .....	.79	.84
Alumina .....	.26	.31
Lime .....	55.13	54.34
Magnesia .....	.36	.55
Potash and soda .....	.47	.60
Carbonic acid, &c. ....	40.72	40.68
Sulphuric acid .....	trace	trace
Chlorine .....	.03	.03
Silica .....	.50	.49
	100.00	100.00
Alkalinity of the ground stone	.012	.017
" " outside surface	.012	.081

The analytical results do not present much difference, showing that the general composition of the whole blocks has not been much affected by the surface application of the solution, which does not appear to have penetrated more than one-sixteenth of an inch, but has undoubtedly hardened the surface very much, and rendered it much less liable to the effects of acid corrosion or of atmospheric action through frost. The following are results of special tests for acid and frosts:—

Ratio of solubility in a 1 per cent. solution of muriatic acid:—	
No. 1 Stone = .....	1.00
No. 2 Stone (Fluated) = .....	.89
Ratio of solubility in a solution of (1 in 1,000) muriatic acid:—	
No. 1 Stone = .....	1.00
No. 2 Stone (Fluated) = .....	.73
Loss of weight by artificial frosting in three days:—	
No. 1 Stone = .....	.56
No. 2 Stone (Fluated) = .....	.16
Ratio as 100 to 28.	

The action of the acid on the natural stone is the same over the whole surface, whereas in the "Fluated" specimen only the softer portions, the chalky cement between the Foraminifera and Globigerina, appear to have dissolved. We certainly consider that the "Fluated" stone has been practically improved and rendered more durable and impervious to the weather by the treatment of the surface.

At a meeting of the Local Committee of the National Association for the Advancement of Art, held in Edinburgh last week, the schemes of the North British and Caledonian Railways, and their effect upon the city, were

considered. Dr. Rowand Anderson startled the meeting by saying that "he would be delighted to see most of the trees in the Princes-street Gardens removed. He thought the view of the old town and the Castle, and the whole aspect of the place was spoiled by these trees. If the great central valley went, however, Edinburgh would lose its most lovely and its greatest charm." Mr. Birnie Rhind, sculptor; Mr. D. W. Stevenson, sculptor; Mr. W. D. Mackay, R.S.A., and others differed from the opinion expressed by Dr. Rowand Anderson. Mr. Mackay said that "of course they could not expect Dr. Anderson to withdraw his statement for fear of its going abroad, but they could do all they could to neutralise the effect of it." It is true, as Dr. Anderson said, that he was not singular in the view he had expressed, for we have a distinct recollection of a grandiose design for a terrace adorned with sculpture and architectural monuments, which was exhibited by Mr. Dick Peddie at one of the annual exhibitions of the Royal Scottish Academy. At this time of the year, when the trees are denuded of their foliage, there is little obstruction to the view, and we are decidedly of the opinion of Mr. Stevenson, "that the view of the Castle through the trees might be more charming than if they could see it in a bold way from one end of the street to the other, without any such foreground." In fact, the proposal to assist in the beautifying of the valley between the Castle Hill and Princes-street by removing the trees seems to us one of the most extraordinary propositions we have ever heard, and we cannot understand how any Edinburgh architect anxious to preserve the beauty of the city could propose such a step.

WE regret to find that diphtheria has broken out at Marlborough College, admittedly one of the healthiest public schools in England. Fortunately, the disease seems to be of a mild character. The sanitary arrangements and the water of the College are believed to be excellent, but a rigid inspection is to be made of the whole premises, in order to leave no uncertainty about the matter. But the authorities of the public schools are now so alive to the necessity of first-rate sanitary conditions that we do not anticipate that there will be anything found to be wrong with the general sanitary arrangements of the school. The fact is, that illnesses of this kind cannot always be avoided in great schools; once, by some mischance, an epidemic or contagious disease is introduced, it is most difficult to prevent it from spreading. We have been informed that diphtheria has been in existence at the village of Manton, a mile or so from Marlborough. If this is so, it has probably, in spite of precautions, been carried into the College. Of the sanitary condition of this village, and of the efforts of the Rural Sanitary Authority to stamp out the disease at Manton, we have, at present, no information. Possibly this outbreak, the cause of which it should not be difficult to arrive at, may throw more light on the way in which diphtheria is propagated in places where buildings and sanitary arrangements are carefully looked after.

IN an article printed in the *Antiquary* for this current month, Mrs. Chaworth Musters gives an account of Leicester Castle. Directing attention to its imminent destruction, she writes:—

"The proposed new line of the Manchester, Sheffield, and Lincolnshire Railway Company is projected to run through the great hall diagonally, just shaving St. Mary's Church by a few yards, levelling the grassy mound on which stood the keep, and whether entirely destroying or only running close past the wall of the Trinity Hospital I am not aware; but, of course, the scheme, if carried out, means the utter destruction of this little group of historic buildings."

The buildings in question include the lately-restored church, two gateways, one of which is called "John of Gaunt's," the castle hall now serving as a court of justice, and Trinity

hospital. This last-named was founded, to the Annunciation, in 1330 by Henry, Earl of Leicester and Lancaster, son to Edmond Crouchback; liberally endowed by his descendants, and known for a while as St. Mary's the Greater, it was refounded by the Corporation, and it has now an annual income of about 2,700*l.* The hospital stands in the Newark, or *Novum Opus*, which formerly constituted an outwork of the castle. It is said that William I. built the latter, on an earlier foundation, and making this ancient Mercian town into a royal demesne, gave the Wardenship to Hugh de Gentemaisnel. Having been razed to the ground by William Rufus, it was rebuilt by Henry I., and fortified by Simon de Montfort. Here Henry V. held a Parliament in 1414, and in 1425 one was held by the young King's uncles, the Dukes of Bedford and Gloucester, as "protectors" of the realm. Henry, Earl of Lancaster, and his two successors in that title, largely restored the fabric. But it was so allowed to fall into decay that on the eve of the battle of Bosworth Field Richard III., with his suite, was fain to lie at the Blue Boar Inn.\* In 1633 a royal order was issued to the Sheriff "to take down the old pieces of our castle at Leicester to repair the castle-house wherein our records of the honour of Leicester do remain." Upon Henry IV.'s accession, the Duchy and Earldom of Leicester merged in the Crown; in 1744 Sir Thomas Coke (Lord Lovel) was advanced to the earldom, which was revived in 1837 in favour of his great-nephew, Thomas William Coke, of Holkham Hall, Norfolk.

ANOTHER exhibition of bird studies by Mr. H. S. Marks is to be seen at the galleries of the Fine Art Society, and has proved equally attractive with the former one. The greatest successes of these studies appear to us to be among the parrots and eagles, the former especially (including cockatoos and macaws among the general tribal appellation of "parrots"). None are better than the studies numbered 2 and 4, in which both colour and texture are so admirably conveyed without any minute working up of detail. Other very good examples are 7, 40, 49, 60, 99 and 101. Among the eagle subjects is a very fine head of the Bateleur eagle (28) well known to all visitors at Regent's-park, and a large and grand drawing of the vulturine eagle (89). Again in this collection we find was the weak point: there is only one drawing of them, and the swans in that seem heavy and wanting in swan-like grace and purity of colour; the painter does not seem to sympathise with them. Nor should we accept the portrait of the "Demoiselle Cranes" (44) as doing justice to those singularly graceful and delicate looking birds. The grotesque penguin is a bird after Mr. Marks's own heart apparently, and its capacity for the expression of humorous situations is done full justice to in "Romeo and Juliet" (5) and "The Peacemaker" (85). Naturalists and sportsmen will be interested alike in the careful drawing of "Pallas's Sand Grouse" (48), the reappearance of which in England raised a correspondence in the *Field* which spread over some months. Mr. Marks's preface to the catalogue is worth reading, and is full of humorous hits, especially against the visitors at the Gardens, who offer the eagles sponge-cake to eat (Mr. Marks thinks natural history is neglected in our schools), and who expect an artist painting in the Gardens to be a complete guide "not only to each house or cage in the gardens, but to every railway station or cah-rank out of them.

THE more one looks at exhibitions of photographs the higher becomes one's estimate of painters. For securing portraits of one's friends photography is a fairly ade-

quate and remarkably cheap expedient, and as such is a boon to humanity, though it usually fails in cases where the features of the sitter are very marked or characteristic, as it almost always exaggerates the special character. But look at the composed groups under different titles in the exhibition of the Photographic Society (now open at the Society of Water-Colour's rooms); at the rustic pair reading at their cottage-door, for instance, under the title "In the evening there is light;" this is intended for an idyllic picture such as we frequently find in the Society's galleries in water-colour time; but look at the hopeless vulgarity and inexpressiveness of this old couple set to pose for an idyll. That is realistic art, of which the camera is the true exponent; and what is it worth? A painter would have taken the same two figures, perhaps just as models for costume and position, but would have put the light of feeling and sentiment into the faces; not such as could not exist in nature, but such as we do not find in the average man and woman, which is the material photography has mostly to deal with. There are various other scenes in which real figures play a part, but they all point the same moral. Take the absolute realism of ordinary men and women, and there is little to make a picture of; it is the artist who makes the picture, the living figures are only the raw material. Landscape is equally a failure in pure photography. Look at the two large Goupil-gravures exhibited by Messrs. Bousod Valadon & Co.; they are worth more as pictures than any of the pure photographs. There is one branch of work only in which photography has a value beyond that of any other process, viz., in the representation of architecture, and it is just this which is neglected. There are hardly more than half-a-dozen architectural subjects in the whole collection. The photographs of racing yachts are interesting, as recording the actual movement of the vessels and set of the sails. The photographs of clouds are interesting and valuable. But the bulk of the exhibition strikes those who are accustomed to go to that room to look at pictures, as an illustration of what photography cannot do. It can not produce landscapes, and it can not make figure pictures. It only gives the prose of human life; we have to go to the artist for the poetry.

THE disastrous fire at Siena Cathedral, which has gone near to deprive the world of art treasures that could never be replaced, is again the work of plumbers, bringing their melting-pots and braziers in close proximity with timber in a more than usually dry and inflammable condition. Why do not those who are responsible for the safety of great architectural monuments exercise more control and supervision over this class of incendiary artisans? It is scandalous that the safety of buildings and works of art which nothing can ever replace should be left at the mercy of plumbers' journeymen.

PUTTING together the evidence of those letter-writers in the *Times* who seem to be most fully in possession of their reasoning faculties, we have little doubt that the smells complained of in the Paddington district, in the course of the sensational correspondence which has been recently going on, are due to the burning of refuse under brick-kilns in the west and north-west districts of London. This is a nuisance which ought to be put a stop to, but we have little doubt that it is very much exaggerated in the correspondence referred to. People who are allowed to write to a paper to air a grievance of this kind seem to lose their heads entirely, and deal in superlatives of the most tragic kind, which every reasonable person must know to be exaggerations. In fact, if the matter were as bad as is represented by some of the correspondents, the portion of London affected would have been deserted long ago. As one definite example of the exaggerations indulged in we may mention the letter signed "A Householder," in which it was stated that

"There is a large, open, iron grating just as you cross Bayswater-road to go in the gate into Kensington-gardens, at the fountains, from which there is a horrible smell, so strong that you can perceive it twenty yards away. This shows the state of the drains in Paddington district." We went to the spot, found the grating in question, stood on every side of it, and stood over it, and there was not the faintest perceptible smell from it. So much for the reliance to be placed in anonymous correspondents.

#### THE ARCHITECTURAL ASSOCIATION.

THE first ordinary meeting of this Association for the present session was held on Friday, the 17th inst., at 9, Conduit-street, Mr. Leonard Stokes, President, in the chair.

The minutes of two previous meetings having been read and confirmed, the following gentlemen were duly elected:—Messrs. P. E. Newton, J. M. Sharman, J. M. Crean, S. Reddy, E. A. Sharp, A. Harston, E. A. Tombs, and L. Gough. The Chairman proposed a vote of thanks to the Entertainments Committee for the trouble they had taken in connection with the recent *conversations*; and in particular to Mr. Burrell, Mr. H. O. Cresswell, and Mr. A. W. Earle. This was carried unanimously, as also was a vote of thanks to the various firms who had come forward as exhibitors and who had lent objects with which to decorate the hall.

The discussion of the rules and the report of the Committee was deferred.

Mr. P. B. Farrow (Senior Hon. Sec.) announced that, in accordance with the will of the late Mr. Ernest C. Ayton-Lee, past President of the Association, twenty-seven books had been handed over to the Association. He wished to move a formal vote of thanks to Mr. Lee's executors, Mr. H. W. Lonsdale and Mr. C. Henman, for their kindness in handing over the books to them.

It was also announced that the session 1890-1 of the Lyric Club would commence on the 28th inst. with a smoking-concert at the Mona Hotel.

The Chairman then presented the prizes gained during the last session. The following is the list:—

*A. A. Travelling Studentship*.—Awarded to Percy D Smith; second, Sydney Tugwell.  
*Cotes Prize*.—F. M. Simpson.  
*The A. A. Medal*.—Wm. Pywell.  
*The Essay Prize*.—Henry G. Gamble.  
*The Architectural Union Company's Prize*.—First, W Wounacott; second, not awarded.  
*Lectures on History*.—First, A. T. Walmesley; second and third, S. W. Cranfield, J. W. Hall, W. B. Hopkins (equal). Hon. Mentions:—C. Wymouth, J. Murray, C. J. Shaw.  
*Lectures on Construction*.—First, A. T. Walmesley; second and third, Victor T. Jones, G. H. M. Trew (equal).  
*Elementary Class of Design Sec. I.*—First, C. O. Law; second, H. C. Lander. Hon. Mention, F. G. Hicks.  
*Elementary Class of Design Sec. II.*—First, Kotaro Sakurai; second, H. C. Lander.  
*Elementary Class of Construction*.—First, H. C. Lander; second, W. B. Hopkins.  
*Elementary Colour Decoration Class*.—First, C. O. Law. Class Prize, F. B. Gould Willis. Hon. Mentions, H. G. Lidstone and A. T. Griffith.  
*Class of Design*.—First, E. C. Fetch; second, Alfred Cox; third, J. Hutchings.  
*Colour Decoration Class*.—First (Time Sketch Prize), F. C. Christmas.  
*Class of Construction*.—First, H. J. Leaning; second, J. W. Hall. Hon. Mention, E. Penfold.  
*Advanced Class of Construction*.—Not awarded.  
*Lectures on Quantity Surveying*.—First, T. Murray; second, H. Emrich; third, not awarded.

The Chairman next delivered his Presidential Address as follows:—

#### Mr. Stokes's Presidential Address.

GENTLEMEN,—In the address which I delivered you from this chair just a year ago, I endeavoured to show you, as far as I was able, what perhaps you were all perfectly aware of,—that it was no easy thing to be a good architect, the qualifications, special knowledge, and other requirements being not only numerous but also such as are not generally met with in everyday life. I told you that before entering our profession a young man should make himself thoroughly acquainted with its special requirements and his particular capability to meet such requirements. I also insisted upon the fact that special or technical education was necessary after entering our profession beyond that which is usually imparted to a pupil in an architect's office; stating that which might be termed the "picking up" system now almost universally in

\* Pulled down about sixty years ago. See the woodcut in Charles Knight's "Pictorial Shakespeare," iv. 314. The site of Grey Friars, where the King was buried, has lately been covered by an elastic web factory. His bedstead was preserved, and found to contain a large sum of money.

vogue was a defective and delusive one, unfair alike to the pupils and to their parents or guardians; I did not, however, suggest any alteration in the system, beyond advocating some systematic course of study to be taken in conjunction with the work done in an architect's office, as I felt that, supplemented in this way, the system might perhaps be as good a way of training a young architect as any other. I also ventured to criticise the work of our Association, making sundry suggestions as to possible improvements in our methods, dwelling at some length upon the advisability of a joint action between this Association and the Royal Institute of British Architects with regard to the question of education. Reading through my address again I am surprised to find that I had the courage to say as much as I did upon this subject,—which I am afraid is not a popular one,—and disappointed to think that all I did say practically ended with the miniature storm which I myself created in my own little teapot.

The President of the Institute, in his address delivered shortly after mine, certainly did say,—“I commend Mr. Stokes's utterances on this point to the attention of every member of the Institute and the Association, believing as I do that the senior and representative body of the architectural profession will do wisely, if the way can be made clear, to give substantial help to those who, during a long and prosperous period, have shown an earnest determination to help themselves.” But from that day to this, no further words of encouragement or offers of help have reached us from the Institute.

I alluded last year to the fact of a Special Committee having been appointed to consider and report upon the whole working of the Association, and it is now a matter of history that that Committee did report to the General Committee, who adopted the Report, and in their turn presented it to you for your adoption. What happened after that is a little complicated, and as we shall shortly have to decide what course we really intend to take with regard to the carrying into effect of the recommendations contained in the report, I think I had better try and clear the ground a little by stating the exact position of affairs. Briefly, then, we stand thus:—The recommendations contained in the Report of your Committee,—for the Education Committee's Report has now become the General Committee's Report,—having been embodied in a series of resolutions, these were put one by one to a special business meeting held in June and carried, instructions at the same time being given to the Committee to take the necessary steps to carry these resolutions into effect. The first step the Committee took, however,—viz., proposing some alterations in the rules to make them accord with the resolutions passed,—was met, in a perfectly straightforward manner, by the presentation of a requisition, signed by a considerable number of well-known names, asking for a change in the method of voting. The presentation of this requisition somewhat complicated matters, and disclosed the fact that our rules were not as consistent as they might be in some respects; this, taken with the fact that the session was really over, led to the adjournment of the whole question of the proposed alterations in the rules until the present session. In order, however, to save as much time as possible, a Committee was appointed to consider and report upon the whole question of our rules at as early a date as possible this session.

Our present position is therefore simply this, that we, as an Association, have passed a series of resolutions stating that certain changes in our methods, &c., are desirable, but have not as yet made any alterations in our rules.

Having gone so far in stating our position with regard to this matter, I should like, with your permission, to go a little further, not that I wish to advise you one way or another on this subject, as I shall in all human probability shortly have to sit in this chair, and endeavour to conduct impartially the meeting at which your decision will be come to; at the same time, I believe there is no reason why I should not lay the whole question before you, so that you may perhaps be better prepared to vote when the time comes.

In the first place, I take it that everyone in this Association is proud of his profession, and wishes to see it take its proper position before the world. Architecture, as we all know, is a fine art, and an architect an artist. Architecture is also essentially a useful art, and an architect a utilitarian. Architecture is, again,

a constructive art, and an architect a constructor. Now, a man may be born an artist, and unless he, at any rate, is endowed with artistic instincts, he will never make an architect; but I doubt if many men are born utilitarians or constructors; but, even if they are, technical education will develop their powers in the same way that artistic surroundings and sympathetic associations will stimulate an artistic temperament. From this we gather, I think, conclusively, that an architect requires a special education or training, and the only point that there can be any difference of opinion upon is as to the amount and nature of such education or training.

One form, and a certain amount of training, has hitherto been obtainable at this Association, and if you think it is the right form, and of proper quantity to meet the case, don't be persuaded to change; but if, on the other hand, you agree with your Committee's Report on education, and think the form capable of improvement and the quantity somewhat scanty, then why not go in for an improvement as proposed, at the expense even of old associations and traditions? This Association is not even now carried on in the way it was originally intended, and I venture to assert that a body like ours cannot remain stationary; it must move with the times, otherwise it will be deserted. Here I think we might ask ourselves, how it is that, with hardly an exception, all our classes show a falling off in popularity during last session, and for the matter of that during the last two or three sessions? Is it because the classes are not so good as they were? I think not, for I believe myself that they have been more ably conducted than ever; but perhaps it is that something more is now required than is supplied by our classes, something more in touch with the times, and less haphazard than some of our instruction is. If this is so, and as we have already broken tradition once, why not do so again if there is good cause? I confess that personally I admire and agree with the originators of the mutual system, and I can conceive few things more interesting and instructive for men of a certain standing than meeting with their fellows on an equal footing, and forming classes, where good-natured criticism and debate formed the method of gaining and imparting information. This, however, is almost a thing of the past; neither is it suited to the younger men, but it is to be hoped that what little remains of the old system will be jealously preserved. The great majority of our classes, however, are not worked on this principle. The blind leading the blind is perhaps too strong an expression to use in our case, but exaggerations often illustrate a meaning better than an exact simile. The very short-sighted, however, often find themselves being led by the short-sighted, and not only this, but by fresh short-sighted guides at every crossing. A dog is a very effectual guide when properly trained, but a series of young dogs new to the work would try the temper of the best of blind men in a journey across London.

There is an art in imparting knowledge which is not possessed by everyone; but everyone who has that art should be pounced upon by this Association, and encouraged to work in forwarding the cause of architectural education; and when I say encouraged I mean encouraged, and that substantially too. For although a man may be able to find out for himself all that he may require in a given time, yet if a qualified instructor can impart that knowledge to him in half the time, surely something is gained, for time is everything in this go-ahead age. I don't say that much can be done for your heaven-born genius, but for the average man a great deal may be done; and as of necessity we have rather more average men than we have geniuses, I think we shall not be doing a bad work if we can improve these average men, until, perhaps, if we are fortunate, they are almost as good architects as the more fortunate genius. Surely this is worth working for; for who is it that we meet at every street-corner? the average man. Who is it we meet when we go into a church? the average man,—as a rule. Who is it we meet when we attend public meetings, stop at an hotel, or visit a friend in the country? the average man. Your genius is rarely met with; and, although I do not wish to disparage him, I think he is quite able to take care of himself, and, as a rule, will not be interfered with. But these are the exceptions, and, as I have said before, our friend the average man is the one we want to improve.

There are some, I know, who think that fees that were named in the Education Report as fair remuneration to the instructors and lecturers were quite inadequate for their purposes, and I am inclined to agree with them. At the same time it must not be forgotten, in the first place, that these figures were only suggested *average* amounts; some subjects being so much more simple than others that quite a small staff would be adequate for the purpose, thus leaving more for the more difficult and advanced ones, and, in the second place, that at first the supply of good teachers might be so small that his fees would be out of place, at any rate until the teachers had proved themselves efficient; for cannot help feeling that this is the one great difficulty to contend with,—the want of men really suited for teachers; but it is to be hoped that the demand will produce the supply in this case, as it almost invariably has in others.

If I am stating the case too strongly in favour of change it is only because I cannot find arguments to produce on the other side. If the Association does not supply proper teaching, other societies must and will. Of course, there is a reason why they should not; but, if they do, the Association must be prepared to go to the wall. At King's College already fresh help is apparent, and, together with the Carpenter Company, great things are to be done. In Edinburgh the architects there have presented a memorial to Her Majesty's Commissioners for the Scotch Universities, asking for the establishment in the University of Edinburgh of a curriculum of architecture. In their memorial they refer to the Architectural Association, stating that students in London have the advantage of attending classes at this Association held with a view of preparing students for the Institute examinations. I am afraid the architects at Edinburgh do us too much honour, as I do not fancy that a student who confined himself to attending classes at this Association would stand much chance of passing the Institute examinations.

Professor Roger Smith, in his opening lecture at University College the other day, called attention to our proposed curriculum, and while criticising some details, spoke not unfavourably, I think, of the scheme as a whole, and we all know that Professor Roger Smith's opinion is as well worth having as that of any man in London. The professional press, too, has, I think, without exception spoken favourably of our proposals, devoting a considerable space to leading articles and reports of our meetings.

On the other hand, we are told that we are tending too much towards academic courses and that the individuality of our future members will be lost, and thus the “glorious freedom” of our national architecture impaired. I am a great believer in individuality myself, but I fail to see how a little more system in the training of our students will lessen their individuality. We cannot send each of them to a desert island to work out a “style of architecture” for himself; but what we can do is to deliver him from the individuality (!) of Bayly, Water or Brixton by laying before him other influences which will open his eyes to the reasonable, and I hope to the beautiful, in architecture. I have looked carefully through our curriculum with a view to finding, if possible, where our scheme was likely to absorb the individuality of our members, but I fail to find any such possibility, the scheme being so elastic that the individual tastes and tendencies of students will be encouraged and developed,—as they are at the Academy schools at the present moment,—and not compressed into one mould as in some of the foreign schools. The individuality of the painter and sculptor is not endangered by the study of the old masters, neither is the work of an author or poet less the work of a genius because an apt quotation or allusion to the work of another is introduced into his writings. But I think we are all agreed by this time that a liberal education, if not absolutely necessary to an architect, will at any rate be found of the greatest help to ninety-nine out of every hundred.

This is felt so strongly by some that they have already offered us the help of their purses, Mr. Florence, through an invisible friend, offering us a hundred guineas to improve our library, and Mr. Seth Smith a guarantee of 50*l.* a year for three years if we will start our new curriculum, and I have little doubt but that many others will come forward when they see that we really have made a beginning, or are, at least,

*Royal Academy Exhibition, 1890.*

COMPETITION DESIGN FOR COURTS OF J

—MR. HENRY T. HARK, A.R.I.B.A., ARCHITECT.

determined to make one. The present system of pupilage remains quite unaltered in our proposed course; all we ask for is that pupils and improvers may be allowed proper time to attend the classes at the Association. For this class of members we are anxious to establish a course of day classes, so as to relieve, as far as possible, pupils from any large amount of evening work.

It now come to the point in our proposals of last year that I consider of the least real importance, yet it is almost the only one which met with any serious opposition. I refer to the proposal to raise our annual subscription. It would almost seem as though this question of half a guinea, more or less, was going to set us at each others' throats to do or die, on the particular side we may have happened to response. This is a thousand pities, and I trust we shall be led by our common sense and not by feeling, for the question is really a very simple matter of £. s. d. If you think certain changes in the working of the Association,—e.g., the opening of the library in the daytime, and the employment of a paid assistant secretary,—desirable, are you prepared to put your hands in your pockets and produce the necessary funds? If not, you cannot have them, i.e., unless you are ready to forego some of the other advantages you now enjoy, such as the *conversations* or the *soirée*, or both.

Another way out of the difficulty was proposed at the time by Mr. Cole Adams, I think, viz., that the subscription to all incoming members should be raised, that of existing members remaining as at present. I regret now that this suggestion was not adopted, as I believe, with a little care, that the money thus produced would prove enough for us to introduce what we want by degrees, instead of all at once as was intended. It is not even now too late to adopt this course, which has some advantages, and I think it not improbable that this course may be laid before you, by your Committee, when the proper time comes.

One more point and I have done with our present troubles: I refer to the proposal that we should vote by means of voting papers, and not by show of hands, as hitherto, on subjects affecting the rules, &c., of this Association. There is something to be said in favour of the proposal, but at best it is a lazy way of voting; and if this Association is to go on with spirit as it hitherto has, I think the old-fashioned way of coming to the meeting and hearing the arguments on both sides of the question, and then holding up your hand either for or against it, is far more suited to our ways than voting in cold blood, perhaps without being properly alive to the question at issue.

I take it that no President ever read an opening address to any body or association without feeling it his duty to make at least one suggestion, and I feel that I have now come to the point in my address when such a suggestion should be made,—not in the present case, however, simply for the sake of making it, but because I feel that if the suggestion I am about to make were adopted, we should be in a much stronger position than we now occupy, and if we are to do much in this matter of education the stronger our position is the better.

I would, then, suggest that we follow the example of the architects of Edinburgh, and memorialise some one. I am afraid it is no use our going to the University of London, as they probably would not listen to us,—at any rate, at present; therefore I think we had better go to the Institute and boldly ask it to either establish some course of architectural training itself, or to help us to amend and strengthen our methods so as to meet the requirements of the case. The Institute is practically pledged to do something more for education than it at present does, for, in the words of its charter, "the Council may, subject to such limitations or restrictions as by laws may from time to time prescribe, apply the funds of the Royal Institute in furthering professional education and in conducting all examinations which the Royal Institute may hold under the authority of this our charter," &c. Observe, the funds may be applied to furthering education and conducting examinations, two distinct objects; but if the Institute will not help us, then I think we might summon a general conference of architects, and get their support if possible, or at any rate hear what was to be said by them with regard to our proposed curriculum.\*

\* We will give the conclusion of the President's address, and the discussion which followed it, next week.

THE LONDON COUNTY COUNCIL.

The usual weekly meeting of the London County Council took place on Tuesday, at Spring-garden, Sir John Lubbock, M.P., presiding.

**Wood Paving at Fulham.**—The report of the Finance Committee stated that the committee had considered the application of the Vestry of Fulham for sanction to borrow, and also for the loan of £12,360, repayable in six years, to defray the cost of wood-paving works. The Vestry proposed to take up, to a depth of 1 ft., the existing macadam over an area of about 20,059 yards in the carriage-way of the Fulham-road, from the "George" public-house to Putney-bridge, and to lay down about 20,059 square yards of cross-bedded deal blocks, 9 in. by 5 in. by 3 in. upon a bed of cement concrete 6 in. in thickness, and to reset the kerb and footway paving where necessary between the points referred to, a distance of about two miles, at an estimated cost of 20,360*l.* (including 588*l.* 11*s.* for contingencies and supervision). The Committee saw no objection to the advance if limited to 12,300*l.* and repaid in five years, and they recommended that the application be granted.

This was agreed to without discussion.

**Withdrawn Tenders.**—In the report of the Standing Committee the following recommendation was brought forward and agreed to without discussion:—

"The Council will not accept the tender of any person or firm who shall on any previous occasion have withdrawn a tender after the same has been accepted by the Council, unless the reasons for the withdrawal were such as to appear satisfactory to the Council."

**Open Spaces.**—The Parks and Open Spaces Committee reported that their attention had been drawn to an opportunity which had arisen for purchasing Bostall Woods, a pine forest of about 74 acres adjoining Bostall Heath, an open space of about 55 acres already under the control of the Council. It was true that Bostall Heath was at the extreme verge of the county, and that the land adjoining thereto was unbuil upon to a great extent. Owing, however, to the development of the tramway system and other causes, houses were rapidly being built, and it was a mere matter of time for the last portion of vacant land in this part of the county to be disposed of. In these circumstances, the acquirement of the freehold of Bostall Woods at the moderate sum of 200*l.* per acre, only half of which the Council would be required to pay, the District Board providing the remainder, was an opportunity not to be lost. The Committee had visited the woods, and found that practically no expenditure upon them was necessary. The Committee had had before them a deputation from the Plumstead District Board, urging the acquirement of the woods. The Committee recommended:—

"That, subject to the Plumstead District Board agreeing to contribute 100*l.* an acre towards the purchase of Bostall Woods, and to pay such amount to the Council when called upon, and also subject to an estimate being submitted to it by the Finance Committee, as required by the statute, the Council do agree to purchase from Sir Julian Goldsmid an area not exceeding 74 acres, at 200*l.* an acre, under the powers given to it by the Open Spaces Acts, 1877 to 1890."

A long discussion followed this recommendation, several of the speakers thinking it better that the Council should confine itself to acquiring open spaces within the metropolitan area.

Mr. Lloyd opposed the recommendation on the ground that the land was not worth £200 per acre.

Mr. John Burns supported the proposal of the Committee. In the interests of the thousands of artisans and their families employed at Woolwich Arsenal, the Committee was right in asking the Council to vote the money.

After two amendments had been defeated, the recommendation of the Committee was approved.

**Vauxhall Park.**—The Parks Committee also reported that they had reconsidered their recommendation that the Council should not undertake the maintenance of Vauxhall Park. The late Metropolitan Board of Works had contributed 1,500*l.* per acre; but the duty of maintaining the park had been vested in the hands of the Vestry of Lambeth. The Council maintained many smaller places, and the Committee recommended that it should undertake the future maintenance of Vauxhall Park.

Mr. Corbett moved an amendment, which was carried, to the effect that, considering that Mr. Beaufoy, M.P., had guaranteed the maintenance

of the park for two years, the recommendation be disagreed with.

**Proposed New Lunatic Asylum.**—The Asylums Committee reported that they had had from time to time under consideration a letter from the Commissioners in Lunacy, on the question of the provision of proper accommodation for the insane poor of the county of London, which they pointed out was woefully insufficient. The Commissioners had ascertained from the returns that on Jan. 1, 1890, the number of insane patients chargeable to unions or parishes in the county of London and to the county itself, who were placed in out-county asylums or in licensed houses, was 3,419. For the patients so placed accommodation should properly be found in asylums belonging to the county. To supply this accommodation, the Asylum at Claybury for 2,000 patients, and the extensions at Cane-hill for 800, were in course of erection. It was not probable, however, that either would be complete within two years from that time. Taking account of the annual increase of pauper lunatics in the county of London, who had to be provided for, it was certain that the new accommodation, when ready, would be at once fully absorbed by existing patients, and that none would be left for freshly occurring cases.

The Commissioners urged the importance of a careful forecast of the probable prospective requirements of the county of London in the matter of asylum accommodation, and of timely action towards providing what might be found to be necessary. Judging from the past, the Commissioners could not hope that the accumulation of lunatics in the future would be materially lessened, and they did not suppose that the need of public provision for their care in asylums would be removed. It would, therefore, they thought, be prudent in the County Council at once to initiate preliminaries for the erection of another large asylum, or, which no doubt would be better, of two of moderate size. The Committee felt that it would not be wise to postpone action in this matter any longer, and recommended:—

"That they be authorised to take such preliminary steps as they think best for promptly providing further asylum accommodation for 2,000 lunatics, provided no engagement or liability be entered into without the sanction of the Council."

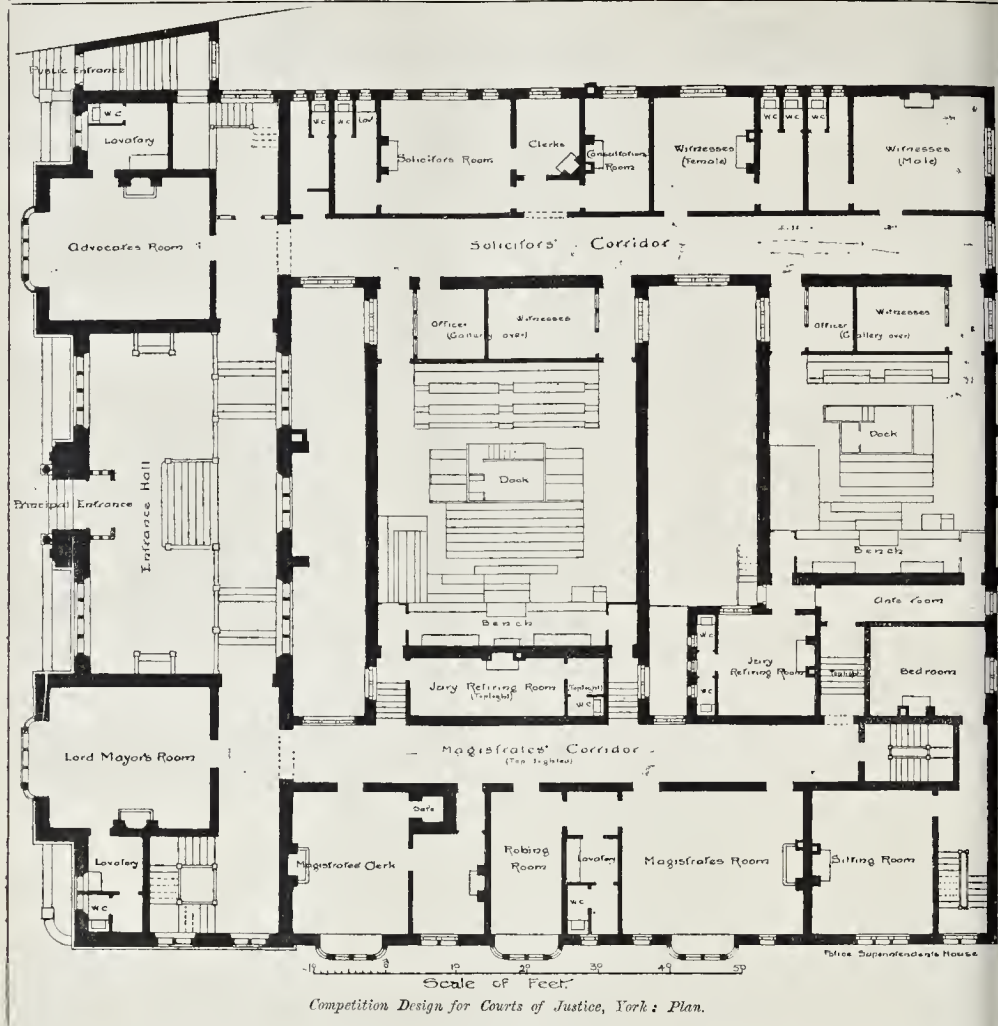

Mr. Boulnois, M.P., moved that the consideration of the matter be postponed for six months.

Mr. Young said there were at present 3,419 of the lunatics of the Metropolis boarded out by the Council, each one of whom cost from 3*s.* to 4*s.* more per week than the lunatics in their own asylums.

After the amendment had been lost, the recommendation was agreed to.

**Condition of the Thames.**—The Main Drainage Committee submitted a report of the chemist on the condition of the Thames. While the rainfall from January to September, inclusive, had been the same as the average for the corresponding period during the past seventy-five years, that during September was 2.4 in. below the average. The total flushing power of the upland water was nevertheless less than the average in consequence of the ever-increasing intake of the water companies in the upper parts of the river. The five water companies, whose supply was drawn solely from the river Thames, supplied to their consumers in 1869 a daily average of 51,591,000 gallons. In 1879 they supplied 68,139,000 gallons, whilst in 1889 the quantity amounted to 83,468,000 gallons. Thus 32 millions of gallons more water were abstracted daily from the river than during 1869, or nearly 19 thousand millions of gallons per annum. On the 6th inst., accompanied by the Medical Officer, he made an inspection of the river from Charing-cross to Wandsworth at low water, when the foreshores were exposed, and from the result of that inspection, and the analyses of samples of water, he was of opinion that no injury to health could accrue from the character of the river at that time. The Council soon after adjourned.

**THE ELECTRIC LIGHT AT GODALMING.**—The town of Godalming, Surrey, has decided to adopt the electric light for public lighting purposes. The light was in use in Godalming some years ago, and it is claimed that this town was the first in England lighted by the new illuminant. The motive power was water, but this not proving satisfactory, the light was discontinued for a time. It is probable that the Charterhouse School, which has its own gasworks, will be included in the scheme for electric lighting.

Competition Design for Courts of Justice, York: Plan.

### Illustrations.

#### COMPETITION DESIGN FOR COURTS OF JUSTICE, YORK.

THIS design, by Mr. H. T. Hare, was exhibited in the Architectural Room at the last Royal Academy Exhibition.

The materials proposed to be used were Tadcaster stone for the principal elevations, and Westmoreland green slates for roofs. The entrance-hall was designed with an open-timbered roof in oak. We append a plan of one floor with which the architect has kindly supplied us.

#### HARROW SCHOOL MUSIC-ROOMS.

THESE are essentially utilitarian buildings, the design being moulded by the peculiar necessities of the accommodation. The purpose has been to provide a series of small chambers, in which separate single music lessons could be given,—side by side, and yet so that each should not be disturbed by sounds from its neighbour. Also a room sufficient for the teaching of a brass band, placed so that the bray of the cornet and oboe might be inaudible, not only to the rest of the building, but also to the occupants of the neighbouring houses. Finally, a large hall was needed, not for concert purposes, but for the teaching of an orchestra, with sufficient air-space to give their full value to the instruments. A large

floor had to be provided to accommodate the large "house-choirs" which are a feature of Harrow School music.

Each of the rooms had to be thoroughly ventilated without fireplaces, and so that there was no chance of the sound penetrating from one to the other through the ventilation-shafts.

In the small music-rooms, shown on each side of the small plan on the lithograph, doors and windows are double, as are also the floors and ceilings. An in-draught of nearly two square feet area is provided for each small room, and an out-draught of about three square feet.

It is proposed to change the air of each room four times an hour. The contract for the building is 4,410*l.*, the cost being defrayed by the subscriptions of old Harrovians and others interested in the school.

The drawing from which the lithograph is taken was exhibited at the last Royal Academy Exhibition.

#### HYMERS' COLLEGE, HULL.

THE drawings illustrated in this issue are from those prepared by Messrs. Chorley and Connon, of Leeds, and which were awarded the third premium. The Assessor, Mr. E. C. Rohins, reported on the design as being "one of the most original and interesting of the artistic designs."

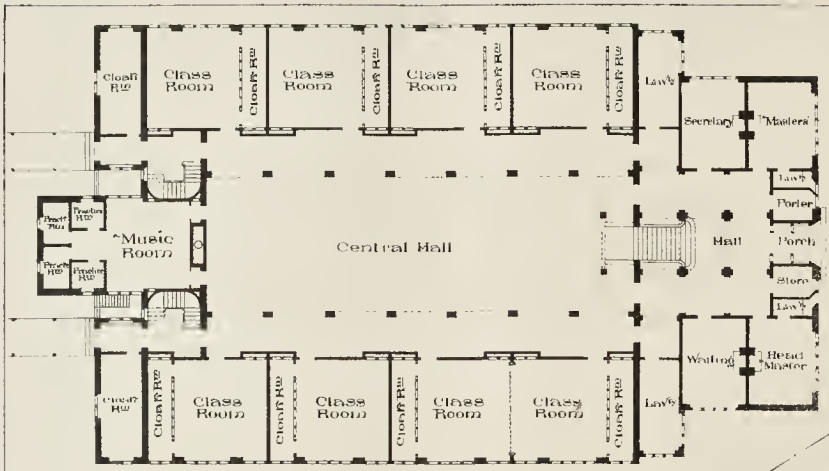

The plan appended shows the general arrangement. We commented on the premiated designs in some detail at the time the drawings were exhibited.

#### OLD WORK AT LEICESTER.

THERE are several remnants of bygone times still standing in the oldest thoroughfare of this ancient town, those of which sketches are given (page 329) being amongst the most interesting, and of which I have been able to gather a few particulars. The Tower in High Street is a prominent feature, projecting, as it does, several feet on to the footway. The following inscription is attached to the structure, viz., "This turret is part of a building in which, in the reign of Queen Elizabeth resided Henry, the third Earl of Huntingdon, in which Mary Queen of Scots lodged for a night in the year 1586; in which also King James I. lodged in 1612, and his son, Charles I. in 1642." The old brick gabled shop standing exactly opposite forms a striking contrast in height. The old house in St. Nicholas-street is interesting from the facts mentioned on the inscription-plate attached to the building, of which the following is a copy, viz.,—"In this house John Dunyan was once lodged; also John Wesley, on his first visit to this place, in 1770." The half timbered houses formerly standing in Highcross-street, were pulled down some five or six years ago to make way for an extension of the adjoining coffee-house, &c. This old structure was one of the few remaining buildings standing in the thoroughfare of the old Cross Market, and stood near the site of the old Market Cross, which was removed to another part of the town many years ago. The old Town-hall, in Town-hall-lane, "was," says

Correspondence.

To the Editor of THE BUILDER.

THE COMPETITION FOR WHITEFIELDS TABERNACLE.

SIR,—A good deal has been written with reference to my award of the premiums in this competition, to the general effect that the first premium ought to have been given to "Lux Mundi," and that no premium ought to have been given to "Winged Heart."

I sincerely admired the artistic and practical merits of Mr. Brydon's design, "Lux Mundi," but its cost and its acoustic qualities stood in its way. Of every design which on other grounds it seemed might possibly deserve a premium, a careful approximate estimate was made; and, though I could recognise that Mr. Brydon had striven to keep down cost, I could not see my way to report that his design could be carried out within, or even very near, the limit of cost fixed.

Further, I did not consider that a dome of the size and height proposed was a suitable or safe ceiling for a large public place where clear hearing and easy speaking were of the first importance.

The objection to "Winged Heart" has been raised that it occupies a longer frontage to Tottenham-court-road than is figured on the lithographed plan issued to competitors; and when I discovered this fact I had to consider the position of this design and another which was similarly drawn carefully. The lithographed plan, on the face of it, proclaims itself incorrect; for, as you were good enough yourself to point out, the dimensions figured on the east frontage and those figured on the west frontage differ by 6 ft. though there is no indication of any oblique boundary north or south. These two competitors appeared to be the only two who had cleared up the difficulty, and it did not seem reasonable, or required by any principle of equity, to exclude them for fitting their design to the site it was intended to occupy. Further, looking at the nature of the considerations which the decision would have to turn upon, it did not appear to me that either of them gained any advantage over the other competitors by reason of the difference in dimension of the east frontage, and there was nothing to suggest any suspicion of bad faith. I do not think that any one of my critics, under the circum-

stances, would have felt it right to act differently.

T. ROGER SMITH.

THE ARTS AND CRAFTS EXHIBITION.

SIR,—I have read with great interest your article on the "Arts and Crafts" Exhibition, and your warning as to the introduction of the "shop element" is one the committee might certainly take to heart if they wish to make their society a success.

May I offer a suggestion which I think would increase the attendance of visitors, which you say is rather small? I understand the Society wish to bring about a closer union between workman and artist. If so, why not give the former a chance of viewing the works of art exhibited? But that cannot be if they close at six. I know several workmen who, like myself, would be glad to go and learn something, but we cannot afford to lose five hours even for the sake of learning a little. If it were open till eight, or even later, on Saturday, I am sure hundreds would come who cannot get away before six. I would guarantee to bring half a dozen men myself. And why not open it on Sunday? Surely Mr. Morris or Mr. Crane would not object to that.

A YOUNG CABINETMAKER.  
\* We understood that the Committee of the Arts and Crafts Exhibition intended to open the Exhibition on Monday evenings for free admission by tickets which would be allotted on application. Our correspondent had better address a note to the Secretary on the subject.

PYROGRANITE.

SIR,—I thank you for your comment in the *Builder* for the 11th inst. It has had the effect of directing public attention to this new system of dealing with the clays of the United Kingdom. As I am asked to exhibit these products longer than I did at Westminster Town Hall last week, so that more architects and builders may have the opportunity of seeing them, permit me to inform your readers that a room has been appropriated for this purpose at Charing-cross Hotel, and I shall be most pleased to give my earl to view these specimens on application here; or they can be seen on application to Mr. C. Burke, at the Charing-cross Hotel.

T. FREEMAN.

Lane End Works, 200, Phoenix-street, N.W.

TRADE DINNER.—The workpeople and clerical staff of Mr. Andrew Potter, waterproof and sacking manufacturer, Melbourne Works, Wolverhampton, numbering between 400 and 500 persons, recently took their annual "beanfeast" to Bridgenorth. Various places of interest in the neighbourhood were visited.

Thompson, "partly erected in 1586," and was used for the transaction of the business of the police department prior to the erection of the new municipal buildings. It is still in the hands of the Corporation, and is now used as the old Town Library and for meetings of charitable and other societies, and contains many interesting books and relics of different kinds.

The Chimney-piece in the Mayor's parlour (see lithograph plate) is a fine specimen of the woodwork of its time, the carved date on the right-hand side being 1637. The scroll work is much painted and gilded, and is in a good state of repair.

A. DALE.

SWISS HOTEL, OLD COMPTON-STREET, W.

THIS ancient house, lately pulled down and now rebuilt for Mr. C. Giattli, was one of the oldest and best known "inns" in the west of London.

The new hotel is built with ordinary stocks, except the front elevation, which is of Leicester pressed red bricks and flesh-coloured terracotta, Schutte's patent lime being used throughout.

The elevation of the ground-floor is entirely of glazed faience ware in five tints.

The whole of the brick and wood carving, modelling, tile dados, &c., were executed by Messrs. Reid & Co., of Berners-street, W.

The builder is Mr. E. A. Roome, of Clapton, E., and the cost, including fittings, is 5,170l.

A novel and somewhat interesting feature in the rebuilding arose from the fact that the whole of the eastern party-wall comes over the centre of the passage leading to the churchyard in the rear, and had to be carried on specially-designed girders.

The drawing from which the illustration is taken was exhibited at the Royal Academy this year.

The architects are Messrs. W. A. Williams & Hopton, of London and Bromley, Kent.

COMPETITIONS.

BATHS AND WASH-HOUSES FOR ISLINGTON.—We are informed that the competition for the baths and wash-houses for St. Mary's parish, Islington, has been settled by the arbitrators awarding the first premium to Mr. A. Hessel Tiltman, of Torrington-square, W.C.

The Improved "Kenon" Trap.

SOME SANITARY SPECIALTIES.

Messrs. THOMAS CRAPPER & Co., of Chelsea, send us their new catalogue of sanitary specialties, some of which we have had the opportunity of inspecting. Their patent disconnecting "Kenon" trap, for use in deep inspection-chambers, we noticed on a previous occasion. They have now brought out an improved form of the same trap, in which, as will be seen by the accompanying illustration, the flow of sewage is quickened by the conduit or passage of the trap being made egg-shaped in section, instead of circular.

The catalogue includes examples of some improved air-tight frames and covers for man-holes and inspection chambers, and covers and frames to allow of the ready inspection of drain-channels in situations where large inspection-chambers are not required. No. 510 in the catalogue shows a very effective form of automatic flush-tank, judging from experiments with it which we have witnessed. Nos. 511, 512, 513, and 514 illustrate different forms of a new grease-trap, which is automatically flushed at desired intervals. Grosse passing into the trap becomes congealed by the cold water, and is retained until the flush-tank discharges and carries away the floating film of fat. This arrangement, no doubt, prevents the necessity for periodical cleaning-out which exists with most grease-traps; but, on the other hand, objections may be urged against sending fat into the sewers.

No. 510 in the catalogue shows a new form of siphon water-waste preventer for water-closets, which requires no brackets for fixing, and no unions or sockets are left in sight, although they can be easily got at when necessary. It consists essentially, in fact, of a segmental-shaped, moulded, cast-iron tank and cover, in lieu of the usual unsightly square-shaped affair.

The catalogue also includes some very good forms of water-closet, and an improved self-rising closet-seat, weighted with fixed leaden weights, which are concealed from view.

OBITUARY.

MR. THOMAS URMSON.—It is announced that Mr. Thomas Urmsou, builder and contractor, died on the 15th inst., in his sixty-seventh year, at his residence in Cressington-park, Liverpool. The deceased gentleman for many years past was in an extensive way of business. He was born at Hatton, near Darabury, and after having served his time as a joiner he worked at his trade in the locality. While still a young man he went to Liverpool, and obtained employment with several firms. Some thirty-five years ago he commenced business as a builder, and took a yard near Mansfield-street, in St. Anne-street, Liverpool, after which he removed to more extensive premises in Sobers-street, where the business has been carried on ever since.

MR. A. B. MULLETT.—A Dalsiel cable message to the *Californian Messenger* states that Mr. A. B. Mullett, formerly Supervising Architect of the U.S. Treasury Department, shot himself in Washington on Monday afternoon, during a temporary aberration of mind, and he died the same evening. He was the designer of a large number of the Government buildings in the leading cities of the States, and also of the War, State, and Navy buildings in Washington. In consequence of the stereotyped character of his work, the buildings he designed are said to be in the "Mullett" style (according to the telegram).

SURVEYORSHIPS.

MARKET BOSWORTH RURAL SANITARY AUTHORITY.—We learn that Mr. Harry W. Taylor, of Birmingham, has been appointed Sanitary Inspector and Surveyor to the Market Bosworth Rural Sanitary Authority. He is at present Engineer to the Sewerage Works at Rathy, for the Bosworth Board.

The Student's Column.

HOT-WATER SUPPLY.—XVII.

IMPROVED AND OTHER SYSTEMS (continued).

ANOTHER question intimately connected with this subject is whether the cold supply service of the cylinder system could by any means be shortened by taking it into the secondary return or elsewhere, and the study of the results made visible in a glass apparatus has gone far towards settling the question.

There has always been the objection of having to provide three pipes (rising main, return, and cold supply) in a complete cylinder apparatus, against the customary two of the tank system, and this has led to various attempts being made to make one pipe answer the double purpose of secondary return and cold supply to the cylinder, but the majority of these attempts have been failures, or else so limited in their success as to be held in suspicion as unreliable.

If we take the cold supply direct into the secondary return, as fig. 37, we shall have the

FIG. 37

worst possible results, especially with the taps at the top of the house, as, immediately the taps are opened, a flow of cold water will set in direct from the cistern to the tap, as indicated by the arrows, and in this instance the friction element will be against the good results, as considerably less resistance of this character will be felt by the water that passes, as just explained, than by the proportion of the water that comes up the rising main, as this latter quantity has to pass right down the house and through the cylinder before it reaches the tap. An attempt was made to prevent the cold water passing to the tap by putting a deep dip in the pipe where marked \* on the illustration, but this had no good effect; in fact, the suggestion was somewhat absurd.

The only means at present known of overcoming the difficulty that is worthy of recommendation, is to insert a "stop-back" valve in the circulation. These valves are made expressly to regulate a flow of water so that it may travel freely in one direction, but should it from any cause attempt to travel the opposite way it is instantly checked. This valve is by no means a modern idea, as it is used in various forms for different purposes, particularly in sewerage work, &c., but its application to hot-water work is somewhat recent and by no means general yet.

Fig. 38 shows in section a valve of this sort, of simple construction, and the only particular care needed in its manufacture is to have the

FIG. 38

flap A loosely hinged or jointed. In action the flow of water in one direction lifts the flap readily, but in the other direction it tends to close the flap tight. (The flap shuts on to a turned surface so that it is nearly watertight.)

In fixing one of these valves it should be placed anywhere in a horizontal position between the point where the cold supply enters the return pipe and the point where the return is branched from the rising main, as fig. 39, so that when

FIG. 39.

the water is circulating it passes the valve, as indicated by the arrows, but when a tap is opened the valve is closed by the approach of the cold water from the direction of the cold-water cistern, and the whole of the water drawn has, therefore, to come up the rising main from the cylinder, while the corresponding volume of cold water passes down the secondary return.

This arrangement answers very well, and under ordinary circumstances is reliable, as the valve has had a fair trial and no failures have been recorded; they have the advantage, too, of causing little trouble should they get out of order; as, supposing the valve got stuck shut, it would only convert the apparatus into one that has a single rising main not returned, and provided a "connector" is inserted next to the valve, it could be easily taken out for inspection if needed. There are three of these valves that have been in constant use and under the

FIG. 40.

writer's notice the last four years, and none of these have ever required the least attention, for the only thing that could very well interfere with their free working is "fur," which, however, shows itself but little up in this high position; and the constant flapping of the valve (for it keeps up a perpetual movement while the water is circulating) prevents its becoming fixed from this cause.

When the secondary return is made to answer this twofold purpose, it should not be connected

gh up in the cylinder, hut near or into the bottom as a cold supply. It has been shown in some of the preceding illustrations that the primary flow-pipe from the boiler is connected into the cylinder about six inches up, and that there is a piece of pipe (attached by an elbow) carried up inside so that it flows freely terminates about half the way up, as fig. 40. This may appear to many to be a rather unnecessary and peculiar arrangement, which it really is, as the same purpose will be attained by letting the flow enter the top of the cylinder half the way up, and so make the stand-pipe inside unnecessary, as fig. 41.

FIG 41

The cost of fitting in either instance is about the same, but by the latter method a benefit is perceived by lessened trouble, as should the boiler have a removable top and no manlid, will be found a most difficult task to attach an elbow and pipe inside, particularly if the boiler is a high one. It matters not where the cylinder is purchased, if flanges for flow and return are ordered they will be put both within and without. Yet the poorest of boiler fitters know that a primary flow-pipe should always terminate at least half way up a reservoir of either description. Therefore, if it is taken to order sufficient flanges to be fixed to the cylinder in their proper places, a saving in cost may be effected also, as there then no need for a manlid or removable top, and this makes an average difference of about eight shillings net (in the price of the reservoir), an economy worth practising for the little trouble it entails.

There can occasionally be found an apparatus to the cylinder connected up, as at fig. 42, a

FIG 42

method that can by no means be condemned, it answers a useful purpose in giving hot water in the upper part of the apparatus a little quicker after first lighting the fire, as there is (as will be seen) a clear way for some of the water to circulate from the primary to the secondary flow without passing through the boiler. In practice it is found that by this method one-half passes each way, but, of course, the half that passes into the cylinder loses its heat almost instantly until the apparatus (or the part of the cylinder) is charged with hot water, consequently water of a high temperature will be obtained in the upper pipes quicker than this arrangement, but it will only be in all quantity.

**ELECTRIC LIGHTING AT LEWES.**—At a largely attended meeting of Lewes ratepayers, held on the 18th inst., under the presidency of the Mayor, it was decided by an overwhelming majority to adopt electricity for street lighting.

GENERAL BUILDING NEWS.

**THE NEW CALEDONIAN RAILWAY STATION AT EDINBURGH.**—An Edinburgh evening paper (the *Dispatch*) of the 10th inst. published a view and description of the elevations to Princes-street and the Lothian-road of the new station which the Caledonian Railway have commenced to build at the west end of Princes-street, to take the place of the present wooden sheds. In consequence of the necessity for a great increase in the length of the station, the entrance front has been brought out to the line of the present gate pillars, so that the space in front of the present station will be enclosed within the new building. The entrance to the station is by three large archways towards Princes-street. The one next Lothian-road is for cabs, and the other two for foot passengers. On entering the station cabs will pass along an arcade parallel to the Lothian-road—there being a length of 105 ft. for setting down passengers. The station platform is separated from this arcade by an inner wall pierced by four arches. After setting down their passengers, the cabs will proceed southwards along a continuation of the arcade and debouch upon Lothian-road at a point almost opposite Castle-terrace. As regards the elevation, owing to the shape of the ground which the station will occupy, the enclosing walls will be slightly curved, and, the distance along being greater, a more graceful elevation than at another, there was no alternative but to adopt a series of transverse roofs with the gable-ends showing towards Lothian-road. As seen from the Castle, or other elevated standpoint, the series of parallel girder roofs will be much less obtrusive than would one great semi-circular roof of glass and iron. From above the roof also the one now adopted will be much less conspicuous, and will be masked by a pavilion or mansard roof over the principal entrance. The architects are Messrs. Kinneair & Peddie.

**ST. ADAM'S CHURCH, HARTLEPOOL.**—The Bishop of Durham, on the 11th inst., consecrated the new church of St. Adam, Hartlepool, a fine and generally architectural character of the fabric is Early English, and on plan comprises nave, aisles, and chancel, with organ-chamber on the north, and choir and clergy vestries on the south side of the chancel. A tower with spire is to be built over the organ-chamber at some future date; this portion is at present covered with a temporary roof. The nave arcade consists of five bays, with arches springing from circular piers; the clerestory above is lighted by a range of three-light windows. The west end is pierced by a large traceried window, with single lights on either side. The chancel is divided from the nave by a low parapet wall, with a moulded arch above springing from corbels. The east end is lighted by three lofty windows, with deeply splayed jambs and richly-moulded arches. The chancel fittings have been designed on a very complete scale; on either side are the canopied choir and priests' stalls, with the organ-case rising above on the north side. The total length of the church is 113 ft., and width 52 ft. The walls of the internal fittings and roofs are of unvarnished pitch pine; the walls, both inside and out, are faced with red brick, with dressings of Whitby stone. The church is heated by a hot-water apparatus, supplied by Messrs. Dimming & Cooke, of Newcastle. The contractors for the mason and bricklayers' work were Messrs. W. Scott & Son, of Sunderland, and for the carpenter and joiners' work Messrs. G. Clark & Co., of West Hartlepool. Mr. T. Adamson, of Sunderland, acted as clerk of the works. The church has been designed by Mr. J. H. Morton, F.R.I.B.A., of South Shields.

**NEW COAL HOIST AT THE ALEXANDRA DOCK, HULL.**—Contemporaneously with the great increase which has taken place in the coal trade of this port with continental and more distant centres, the directors of the Hull and Barnsley Railway and Dock Company have just had completed for them at their Alexandra Dock a new coal hoist, which commenced working for the first time on the 13th inst. This addition (says the *Hull Daily News*) constitutes the third hoist now studding the north quay of the dock, and it is certainly not exaggerating to state that Hull never before possessed such facilities for the prompt shipment of coal. The coal trade at the Alexandra Dock has increased so rapidly that a third hoist was felt to be absolutely necessary; but to erect the new one on the quay between the two already in use would have negated its utility, as there would not have been sufficient space between each to enable three large steamers to take in coal simultaneously. To get over this difficulty it was decided to construct a timber jetty, projecting from the dock wall in the shape of a T, to which a third vessel could be moored, and the new hoist erected thereon. The length of this new jetty was to be 150 ft., and its width 24 ft. 6 in., with dolphins at each end. Messrs. Turner & Sangwin, contractors, were entrusted with this difficult portion of the undertaking, and likewise the erection of the timber viaduct leading therefrom. As is well known, the Alexandra Dock is of great depth, and to get a substantial foundation for the new structure piles of an extraordinary length have had to be obtained specially for the work. No fewer than 130 piles were 62 ft. long, and from 15 in. to 16 in. square,

and very great care had to be exercised in driving these high timbers into their beds. Altogether about 250 piles have been used in the structure, Menol timber and American elm being principally brought into requisition. A very strong and substantial jetty was thus obtained for the hoist. The height of the iron frame-work of this new hoist is 62 ft. above the quay, the lift of the cradle being 45 ft. above quay level. This high lift will enable the largest steamships to take coals direct into their bunkers. The hoist is actuated by hydraulic pressure from the existing hydraulic mains, and in order to supplement the power an additional set of engines has been provided by Sir Wm. Armstrong & Co., of Newcastle. The plans for the jetty and general work connected with the hoist were designed by Mr. R. Pawley, the Company's engineer, who has also superintended the work. The hydraulic portion has been under the supervision of Mr. Stirling, the locomotive engineer of the company. The contract for the jetty and the elevated timber viaduct leading from it was let to Messrs. Turner & Sangwin; the iron framing and hydraulic work to Sir W. Armstrong & Co., Newcastle; and the girder work of the high level line to Messrs. John Butler & Co., of Stanningley, Leeds.

**NEW ROMAN CATHOLIC CHURCH AT CAMBRIDGE.**—The new Church of Our Lady and the English Martyrs, Cambridge, was consecrated on the 16th inst. The first stone of the church was laid on June 30, 1887, by the R.C. Bishop of Northampton. The architects are Messrs. Dunn, Hansom, & Dunn, of Newcastle-on-Tyne, and the contractors have been Messrs. Rattee & Kett, of Cambridge, the clerk of the works being Mr. Joshua Bowdler, of Cambridge. The glass has been executed by the firm of Messrs. Lavers and Westlake, and Messrs. Hardman & Co. The woodwork is the work of various artists. The sanctuary screens and pulpit are the work of Mr. Ralph Hedley, of Newcastle. The baldachino is by Mr. Boulton, of Cheltenham; the benches are by Messrs. Rattee & Kett; the organ-case by Mr. Lewis, of Bristol. The organ itself has been built by Messrs. Abbott & Smith, of Leeds. The church from the foundation to the plinth is of Caisteron stone; the plinth is of Ancaster stone; and the rest is from Combedown. The stone used for the interior is Farleighdown. The shafts are of Plymouth marble, with the exception of those in the arch-chapel, which are of Newbiggin stone. The Bath-stone work was executed in Bath, by Mr. Joseph Bladwell, and sent to Cambridge ready for fixing. The carving on the exterior of the buildings is by Mr. James Owens, of Preston. The statues at the tower and west entrances and in the interior are by Mr. Boulton, also the altars and the font.

**MISSION CHURCH, BRAMALL, NEAR STOCKPORT.**—On the 4th inst. the Bishop of Chester consecrated the new mission church of St. Michael and All Angels at Bramall, in the parish of St. Thomas's, Stockport. The building, which is simple in its architectural character, has cost about 1,000*l.* towards which a large proportion has already been realised. It has been constructed from the designs of Mr. J. Stevens, F.R.I.B.A., of Manchester. In the recessed niche that occurs near the apex of the gable, a boldly carved statue, in the round, about 5 ft. high, has been placed. This represents St. Michael the Archangel, and is carved in hard heart of English oak. This is by Mr. Harry Homs, of Exeter.

**NEW MEAT MARKET FOR GLASGOW.**—A new dead meat market, erected by the Glasgow Meat Market Company at a cost of fully 2,500*l.* has just been opened. The market is constructed externally in courses of polished ashlar, and the whole interior is faced with white enamelled bricks. What is thought to be thorough provision has been made for ventilation, and there is hanging space for 100 bullocks, 300 sheep, and 140 quarters of meat. The architects of the building are Messrs. F. Burnet & Boston, Glasgow.

**NEW HEBREW CLUB AT BIRMINGHAM.**—Plans, &c., have been prepared for a new Hebrew Club-house which it is contemplated to erect in Holloway-head. The building will be four stories in height, and will consist of care-taker's premises, wine cellars, refreshment bars, large and lofty assembly-room, billiard-room, card-rooms, and necessary lavatories, &c. The style adopted is described as a free treatment of English Gothic, ornamental brick-work, stone, terra-cotta, Milton's tiles, and other decorative features being introduced into the front elevation. Mr. J. Statham Davis, of Birmingham, is the architect.

SANITARY AND ENGINEERING NEWS.

**THE WAKEFIELD UNION RURAL SANITARY AUTHORITY** has resolved to petition the Local Government Board for powers to borrow on loan the following sums—viz., 1,850*l.* for the carrying out of a scheme of water-supply to the township of Crofton, 1,600*l.* for water-supply to the township of Walton, 1,500*l.* for the improvement of the existing water-supply to the township of Shillington, and 1,650*l.* for the construction of a main outfall sewer for the drainage of the Common-lane district, in the township of East Ardsley. The plans and estimates for these works have been prepared by their engineer, Mr. Frank Massie, Assoc. M. Inst.-C.E.

**INSTITUTION OF MECHANICAL ENGINEERS.**—An ordinary general meeting of this Institution will be held on Wednesday evening, October 29, and Thursday evening, October 30, at 25, Great George-street, Westminster, by kind permission of the Council of the Institution of Civil Engineers. Among the papers to be read is one on "The Frame Goods Wagons of light weight and large capacity, and their effect upon the Working Expenses of Railways," by Mr. M. R. Jeffers, of London. In connexion with this paper the members are invited to inspect one of the wagons which will be on view at any time during daylight for October 29 and 30, at the Victoria Passenger Station of the London, Chatham, and Dover Railway, where it will be standing in the siding behind the main arrival platform, by kind permission of the Railway Company. We mention this because we have on one or two occasions referred in "Notes" to these wagons.

**CAMBRIDGE SEWERAGE WORKS.**—Mr. Mansergh, M. Inst. C.E., who was invited in by the Urban Sanitary Authority of Cambridge to advise them on the respective merits of two schemes which have been submitted to them for the sewerage of the town, viz., one by Mr. Anson, and the other by Mr. Wood, has issued his report. After describing the salient features of the two schemes, Mr. Mansergh proceeds to reply to a series of questions put to him, and in the course of doing so criticises in the schemes, especially Mr. Anson's. He says that Mr. Wood's scheme is laid down generally upon the right line, but it would not be correct to say that they have been strictly adhered to. As, however, by some alterations in detail the general design can be elaborated to a satisfactory and thorough efficiency, he approves it rather than the other. With regard to the correctness of the estimates, Mr. Mansergh says he should increase Mr. Anson's estimate from 83,500*l.* to 106,400*l.* Mr. Wood's 82,515*l.* 14*s.* 7*d.* he should make 97,681*l.* 12*s.* Neither of these totals includes anything for the purchase and preparation of land. Mr. Mansergh says he has no hesitation in stating his preference for the general ideas embodied in Mr. Wood's scheme over Mr. Anson's. As to the treatment of the sewage, Mr. Mansergh observes that in the two schemes submitted to him two different methods of treatment are recommended. Mr. Anson proposes the precipitation of the solids by chemical means in tanks, and the further purification of the clarified liquid in the process of downward intermittent filtration upon fifty acres of land. This combined process, if judiciously and honestly worked, would insure satisfactory results in the production of an effluent good enough to go into the Cam. The sludge difficultly would also be reduced to a minimum by the use of filter-presses; but he is of opinion that it is not desirable to establish works of this character within the town and so close to an important public road. Mr. Wood recommends the utilisation of the sewage upon the land by the well-known method of broad irrigation, and Mr. Mansergh was quite disposed to agree with him. It was thirty years since he (Mr. Mansergh) laid out the first sewage-farm in England, in conjunction with Mr. McKie, and since then he had been connected with over a score of others, and he had no reason to alter his opinion that the process of broad irrigation on suitable land was the most satisfactory.

**RICHMOND SEWERAGE WORKS.**—On the 4th inst., Mr. Charles Hart, Chairman of the Richmond Main Sewerage Board, laid the memorial stone of the sewerage works at Mortlake, which are now approaching completion. Mr. J. C. Mellis is the engineer. Messrs. Webster, and Messrs. Nowell & Robson, are the contractors. The total cost of the works will be upwards of 100,000*l.*

**THE SEWERAGE OF GRAYS.**—The Local Board of Grays Thurrock, in Essex, lately advertised an open competition for the best scheme for the sewerage and sewage disposal of the town. The present population is 12,000, and it is rapidly increasing. The Local Board have selected a scheme prepared by Mr. W. H. Radford, C.E., of Nottingham. The pumping-station will be placed on the east side of the Marsh-road, and the whole of the sewage will be brought down to the site by gravitation through 8½ miles of pipe-sewers. There will only be one pumping-station; and with a storage-tank for the reception of the night sewage, the pumps will only be required to be worked by day, unless there is an exceptional storm. The pumping-machinery is to be duplicate, and it will raise 120,000 gallons per hour. The sewage will be pumped a lift of 97 ft. to the Lodge Farm, where it will be purified by broad irrigation on 83 acres of light, dry land. Ten acres will be laid out as a special intermittent filtration area. All surplus storm-waters will flow into the Thames by gravitation at low water, and will be pumped into the Thames at high water, and will be automatic flushing arrangements are provided. A road surface-water is proposed, which will be stored in open hach-waters during high water, and turned into the Thames by gravitation at low water. The total cost of the engineering works will be 19,400*l.*

**THE MAIN ROADS OF CARLISLE.**—On the 13th and 14th inst., Mr. T. Coddington, M. Inst. C.E., one of the Inspectors of the Local Government Board,

held an inquiry at Carlisle with reference to the application of the Carlisle Town Council to the County Council to have certain roads within the city declared main roads within the meaning of the Highway Act, 1878, and the Local Government Act, 1885, in order that the County Council of Cumberland may be called upon to contribute towards the cost of the maintenance, repair, and reasonable improvement of such roads and streets as may already be main roads by operation of law, and such others as may be comprised in the declaration which the Local Government Board have been called upon to make. The case for the Corporation was heard, evidence being given by the City Surveyor, Mr. Howard Smith, and others. Mr. Martinson opened the case for the County Council, and the evidence of the County Road Surveyor and members of the Highway Committee having been heard, the inquiry closed.

**PUBLIC IMPROVEMENTS AT SOUTHPORT.**—Colonel W. Marlon Ducat, R.E., one of the Local Government Inspectors, attended at Southport Town-hall, on the 15th inst., for the purpose of holding an inquiry into an application by the Corporation for power to borrow the sum of 54,924*l.* for works of public improvement, namely, 37,074*l.* for improvement of marsh lands and foreshore, 9,500*l.* for completion of the Municipal Offices, 4,500*l.* towards cost of the erection of Barton-street bridge, 1,500*l.* for fire-engine purposes, 1,100*l.* for purposes in connection with museum, schools of science and art, and art gallery, 500*l.* for market purposes, and 800*l.* for laying parks. No opposition was raised to the application.

**PROPOSED TUNNEL BETWEEN IRELAND AND SCOTLAND.**—A public meeting, specially convened by the Mayor to consider a scheme for constructing a tunnel between Ireland and Scotland, was held in Belfast on the 17th inst. Sir Barton, C.E. (Great Northern Railway), submitted a scheme in which he proposed a tunnel, thirty-three miles long, between Island Magee (co. Antrim) and Wigtonshire, the greatest depth being 500 ft., and the steepest gradient 1 in 75. Mr. Barton, continuing, said the scheme had the support of Sir Douglas Fox, engineer of the Severn Tunnel; Sir Benjamin Baker, the Forth Bridge engineer; and Sir John Hawkshaw of London. He estimated the total cost at 8,000,000*l.*, and the tunnel could be completed in ten or twelve years. The meeting passed resolutions recognising the great national importance of the scheme, urging the Government to render financial assistance, and appointing the Duke of Abercorn, Lord Belmont, Lord Arthur Hill, and twelve other gentlemen, a committee to consider and report upon the whole question.

**DEEPENING OF THE RIVER DEE.**—At the Chester Town Hall on the 6th inst. a quarterly meeting of the River Dee Conservancy Board was held, when the report of the acting conservator (Mr. H. E. Taylor, C.E.) was read. It stated that the new training walls from the north and south sides, below Connal's Quay, had been built, the former to a length of 135 yards and the latter 225 yards. The result had exceeded his expectations. The channel was so much improved in the short time that the statutory depth was established to the wharves of the Wrexham, Mold, and Connal's Quay Railway Company. For maintaining and furthering that state of things he recommended that the north wall be extended 100 yards, and that the south one be pushed on north parallel to the old Causeway, with the channel gradually opening as it proceeded seaward. These works, the extension of the main training walls towards Flint, and the walls in the upper river, will be proceeded with tentatively, and at a cost not exceeding an outlay of 50*l.* per week. To seize the opportunity, now presenting itself, of deepening the upper river at a minimum of cost, he would advise the provision of three crabs, fitted with steam power, for dredging works. He estimated the cost of the whole at 2,300*l.*, and of working them at 18*l.* 18*s.* per week. A motion to adopt the report of the Works Committee was carried.

**NEW CANAL FOR SOUTH YORKSHIRE.**—The Aire and Calder Navigation proprietors are promoting, in the next session of Parliament, a Bill authorising the construction of a new canal. The proposed canal, to be known as the Goole and South Yorkshire Junction Canal, will be a connecting link between the Aire and Calder Navigation and the South Yorkshire Navigation from Sheffield to the Trent, for the deepening of which an Act was obtained in 1859. It will start from the South Yorkshire Canal at Kirk Bramwith Locks, about eight miles from Doncaster, to Sykehouse Bridge on the Aire and Calder Navigation, seven miles above Goole. It will cross by an aqueduct the River Don and the River Went, but the intervening country is flat and entirely agricultural, and it is calculated the work can be completed in two years. The canal is to have a breadth of 75 ft. and a depth of 10 ft., and it will be five and a-half miles long, with only one lock.

**MATLOCK BRIDGE WATERWORKS.**—We understand that the Waterworks Company at Matlock Bridge have called in Mr. W. H. Radford, C.E., of Nottingham, to report as to what is advisable to increase the present supply of water, and as to which of the springs in the neighbourhood would form the best source of additional supply.

## FOREIGN AND COLONIAL.

**FRANCE.**—The work of restoration of the Tour de la Grosse Horloge at Rouen has been commenced. The cost of the work, 58,000 francs, is to be borne partly by the town and partly by the State. It is to be hoped the 58,000 francs, no very large sum, fortunately will be applied with moderation and for necessary repair only.—The town of Laval is about to build a museum for which the Minister of Public Instruction has promised to give a certain number of the paintings and sculptures purchased by the State.—At Niederbrunn, in Alsace-Lorraine, a monument is to be erected to commemorate the first French soldier who fell in the Franco-German war.—The Société des Amis de l'Art, of Bordeaux, has organised a retrospective exhibition of illustrated advertisements. The collection extends over forty years, and shows the great progress which has been made in the artistic character of such work during this period.—The Parisian journals have been occupying themselves not without reason, about the lamentable state of dilapidation of the Chateau de Chameaucé, and its former owner, M. de Pelouze, was obliged to put it up for sale. The park is completely neglected and allowed to run to waste, the chateau containing a valuable collection of paintings, and the chambers of Diana of Poitiers and Catharine de Medicis, as well as the grand gallery restored by M. Touché some years ago, are going to ruin. The papers, in denouncing this neglect, demand that the State should purchase and preserve this fine example of Renaissance architecture.—A decisive ecclesiastical has discovered in Tunisia, on the plateau of the Beni-Hassan, a number of Carthaginian tombs, enclosing a great number of ornaments, &c.; among them painted vases, gold diadems, pointed ostrich eggs (i), statuettes, and other objects in silver and bronze.—A narrow gauge line is to be established between the railway station at Rimogne (Ardennes) and the town of Rimogne, and the station at Rimogne, which was too far from the town, is shortly to be carried out by the company of the Chemin-de-fer de l'Ouest.—The company of the Chemin-de-fer de l'Ouest has in hand some new works intended to connect the lines to Versailles and St. Germain, and to relieve the traffic, which is at present much congested at the junction between the lines of the Amiens and Combevoie, which will be known as "Bécon-les-Bruyères."—In the Commune of Mureaux, near Meulan (Seine-et-Oise) some important remains of ancient building have been discovered, including a small square building with remains of coloured decoration in red, yellow, and blue, and a large one which has also been found. The excavations are under the conduct of Dr. Verneau, and are to be the subject of a report to the Académie des Inscriptions et Belles Lettres.

**BURNING OF AN HOTEL, SYRACUSE, NEW YORK.**—The Leland Hotel, at Syracuse, New York, a large building six stories high, was destroyed by fire on the 15th inst. Over 200 people were taken to the hospital. The kitchen was the first to be found. The excavations are under the conduct of Dr. Verneau, and are to be the subject of a report to the Académie des Inscriptions et Belles Lettres.

**BERLIN.**—The Leaning statue recently unveiled by Professor Otto Lessing (a descendant of the critic), is in fine white marble, and placed on a pedestal of red Swedish granite. It is local much admired, and regarded as a masterpiece of art. As usual, the erection of a new monument in the precincts of the damp Tiergarten again gives rise to animated technical discussions in the papers as to the best means of preserving statues from the inclemency of the winters. At present one finds the marbles of the capital enclosed in a mass of straw for the winter, which is highly and only marked by their ugly coverings.—In order of the Emperor, a two-leaved wrought-iron gate, having the enormous dimensions of 8 metres width, to 9 metres height, has been hung in the larger opening of the great portal leading in the old Schloss. This gate, which is said to be the largest in Germany, has been so constructed as to be able to swing round on cast-iron wheels, with any extra support from rollers.—The municipal authorities have voted 500,000 marks, or near

000, towards the erection of a new museum building for the provincial collections of Brabant.

**OSTDAM.**—The mausoleum of the deceased peror Frederik (see page 225, ante) is now complete. The ceremony of placing the coffin of the deceased in its final position took place last week.

**NORWAY.**—The large new lunatic asylum at Ager, upon which work has been progressing for 18 years, is now nearly completed. It consists of six large and two small buildings, and affords room for 200 patients. The cost has been 35,000, stone used is granite, the style being modern. The architect is Herr Ebbel.—King Oscar, who has great interest in, and has given large sums towards, the restoration of the Cathedral of Aundjand, paid a visit to it the other day, and is greatly struck with the beauty of the work executed. Nearly the entire interior had at a later period been whitewashed, according to the opinion which seems to have prevailed at one time in a great part of the world. All this has now been removed, and the original design restored. The interior is so far finished that at Christmas, probably, service will be held in the main structure, which has not been the case for four centuries. The floor is being laid with Norwegian marble. However, much work still remains upon the exterior, particularly the building of the great organ tower and several smaller ones.—A cement factory of its kind in the district of Ager, was started on the Christiania fjord, where excellent raw material has been found, and 600 men are employed, and the works are capable of turning out 80,000 barrels of cement a year. In addition, yellow and red bricks and tiles, of fine clay being found in the neighbourhood. The out-turn is 4,000,000 bricks a year.

**ROME.**—The late Minister of Public Works, and now President of the Amalgamated Societies of Italian Architects and Civil Engineers, Alfredo Cesarini, died at his country-seat, near Ravenna, on the 14th inst. Highly respected as an able and efficient engineer, his death is a loss to the country, he had not yet been forgotten by fellow-countrymen.

**MOSCOW.**—A national monument to the deceased peror Alexander II. is to find place inside the Kremlin, and according to a contemporary the erection will be in accordance with the design of Messrs. Shukowski & Sulzner, whose model has not been approved by the authorities, and is now exhibited for public view. The statue of the deceased monarch, enclosed on three sides by a system of colonnades, is to be placed on a gigantic pedestal, the interior of which is to be made accessible, and to be used as a museum of relics of the Emperor. The treatment of the monument is to be chromatic; the pediment and colonnades being designed in various coloured marbles and granites, the statue in bronze, the roofs of the colonnades gilded, and the interior surfaces of the vaulting painted with mosaics.

**PARIS.**—The grand new Central Railway Station has now been seriously taken in hand by the Messrs. Saxton & Ministry, and the evil of having six dozen separate stations in a town so much crowded in continental traffic, has some chance of being done away with. If the somewhat cramped work fall into Saxon hands, a decade is to elapse before its completion.

**EGYPT.**—According to the correspondence in the press the other day, the pyramids of Gizeh being used as a quarry for building-stone by the Arabs, who are carrying away large blocks from the lower courses of the two large pyramids. It is reported that this is being done with the sanction of the Egyptian Government; but this seems hardly probable.

**BUILDING MATERIALS IN TANGIER.**—The British Consul at Tangier, in a recent report on the trade of that district, observes:—The increasing population of Tangier as a place of residence, and the consequent rapid growth of the European population, has given rise to a proportionately increased demand for building materials, of which 12,000,000 worth were imported during last year, principally consisting of bricks, cement, deals, gypsum, iron wires, tiles, &c. The main walls of the houses are still of rough stones, but bricks are used in considerable quantities for inner walls, &c. In addition to those imported, which come chiefly from the quantities of bricks of fairly good quality were used out from the kilns lately established here. Cement comes almost entirely from France, being generally preferred to the English, on account of its water cheapness; but in the contract for the supply of this article to the Government works at Rabat, the stone which is well known British mark used to be furnished. Iron joists are of Belgian manufacture.

**AN OPENING FOR BRICKMAKING AT BAGDAD.**—According to a recent report of the British Consul at Bagdad on the trade of that district for 1889, there exists a good opening for brickmaking by some simple but scientific method. All Bagdad (population 116,000) is built of mud-dried bricks. Stone is little used here, as it is in Mosul in house-building, and although the tenacious clay of the givens good material, its use is chiefly confined to huts and agricultural wallings along the

Tigris banks. There are about twenty-five kilns of various sizes, and kiln-tracks, dotted over the desert outside the city, but the out-turn is far short of the demand, half-built houses sometimes remaining so for long periods through want of bricks, and often in spring, owing to the inundations of the Euphrates and Tigris, brickmaking has to be suspended. Another great promoter of the demand for bricks is the absorption of water every winter by both bricks and mortar, owing to porosity. There is hardly a brick pathway, house, or wall in all Bagdad which does not call constantly for patching or rebuilding. The best bricks, of a chrome yellow, though good to look at, are very brittle, and many are broken in conveyance from the kilns on small donkeys, carrying not more than ten large bricks, 12 in. square, or twenty-five small bricks, 7 in. square. The usual prices at the kiln are:—Large bricks, 1/2 1/6s. per 1,000; small bricks, 18s. per 1,000. Unskilled labour can be engaged to any extent at 9d. a day for men and 5d. for boys. Fuel is abundant; excellent wood (there not being coal) costs 1s. 6d. per cord, and the thorny desert scrub burnt in the kilns, is delivered at a little more than 6d. per ass-load.

MISCELLANEOUS.

**PISTON PUMPS vs. CENTRIFUGAL PUMPS.**—Some comparative tests have been made recently in Germany which give interesting information as to the relative efficiencies of centrifugal pumps and piston pumps at fairly high lifts. The firm of Schaeffer, L'vance, & Co., of Pfaffatt, use in their manufactory from 8,000 to 10,000 cubic metres of water every day. They draw 20 to 45 gallons per second from a well by means of two conjugated centrifugal pumps supplied by a Continental firm of engineers. The supply proving insufficient, piston pumping-engines were obtained from Messrs. Hathorn & Davey, of Leeds. These consisted of a horizontal compound receiver steam-engine, cylinders 19 in. by 33 in. by 3 ft. stroke, and a working four pumps in the well by bell-crank levers. The capacity of the pumps was about 90 gallons per second. As the two types of pumps were working under parallel conditions the opportunity was taken of making these tests. The water in both cases was drawn from the same source, and was raised to the same height and delivered by the same discharge-pipe. The centrifugal pumps had been erected in 1870, and are said to have worked until May, 1888, without needing repairs. The suction-pipe was 12 in. in diameter, and the delivery 10 in. The two conjugated pumps could deliver thirty-seven gallons per second through an average height of 39 ft. 6 in. at 220 revolutions per minute. The engine driving these pumps had a 21 1/2 in. cylinder with a stroke of 39 1/4 in. The pumps were geared about ten to one. With the centrifugal pumps the best result obtained was when running at 470 revolutions per minute, the lift being 35 1/2 ft. The efficiency then was 48 1/4, that being the percentage of engine-power available as useful work. With the plunger-pumps the best result was obtained with a speed of engine of 13 1/2 revolutions per minute, the lift being 36 1/2 ft., when the efficiency was 73 1/2 per cent. The lowest duty obtained from the centrifugal pumps was on a trial, when 611 revolutions per minute were made, the lift being 35 1/2 ft. The lowest efficiency for the plunger pumps was when running at 26 1/2 revolutions of the engines per minute, the lift being 36 1/2 ft., and the duty being 64 1/2 per cent. of the engine-power. In both types of pump the efficiency fell off as the speed of working was increased. The moral of the trials, of course, is not to use centrifugal pumps in positions for which they are unsuited. If the lift is sufficiently high to require pumps to be conjugated, so as to divide the lift, placing one above the other, the better practice for permanent work is to use other types. Fuller particulars of these trials may be found in the *Bulletin de la Société Industrielle de Mulhouse*, 1888, p. 691.

**THE ENGLISH IRON TRADE.**—The English iron market preserves the features of the previous week. It is still unsettled, and there is not much trade doing, the little buying that is going on being mostly confined to immediate wants. In those branches, however, where requirements must be met, such as shipping material, for instance, Middlesex-rough pig-iron and steel is not very heavy, prices are steady character. Contrary to all expectations, Scotch warrants are still declining, although the difference since last week is not much, while makers do not sell any iron, for the simple reason that they have none to sell. Should the strike continue there will be a serious inroad into Connal's stores, and this will be a mitigated blessing. Middlesex-rough pig has lost a, too, and hematite iron in the North-west has gone back to a like extent. Elsewhere it cannot be said that pig-iron has given way much, the tone of the market being characterised by greater steadiness than could be expected under present circumstances. Although the demand for finished iron and steel is not very heavy, prices are firm. Tipples have been very active this week, and values are still rising. Shipbuilders and engineers keep busy, but not touch fresh work has been booked this week.—Iron.

**AUTOMATIC BRAKE FOR LIFTING JACK.**—Accidents are not by any means infrequent through workmen leaving go of the handle of a lifting-jack, when the load is on, either through carelessness or being overpowered by the weight being lifted; although it may be said that the man is always to blame for not putting the pawl in gear. It is, however, always disastrous to average human nature to take precautions, and for this reason a device invented by the Company of the Alesian Society of Mechanical Construction, Grafenstaden, will be acceptable to those who have to do with the lifting of heavy weights. This is a simple automatic brake to be applied to rack-jacks, which is described as follows in a communication to the Institution of Civil Engineers:—A circular mass of cast-iron is mounted as a sleeve on a short steel shaft, the end of which is formed as a pinion, which gears with a hand is driven by the first wheel of the rack. The part of the shaft within the circular mass is out as a screw of long pitch, with several threads, and engages the interior of the circular mass, which is carried round with it. Under ordinary circumstances the mass is held in its proper place by means of a helical spring, but when the machine accidentally commences to run down at quick speed, the circular mass is induced by the screw overpowering the spring to slide onwise on the screw and come into frictional contact with a fixed conical surface. The descent is thereby almost instantaneously arrested. In lowering at low speeds the spring is sufficiently stiff to maintain the circular mass out of contact with the friction surface in all positions of the rack.

**PROPOSED CLASS IN PLUMBING AT ABERDEEN.**—Under the auspices of the National Registration of Plumbers' District Council, a meeting was held on the 17th inst. in the High School, Airthwaik, for the purpose of considering the formation of a class under the programme of the City and Guilds of London Institute. Provost Keith presided, and introduced Mr. A. L. Pascock, teacher of plumbing in the Technical Institute, Dundee, who gave his introductory lecture on "Lead: its various properties, methods of preparation, qualities, sizes, weights, applications, and behaviour when exposed to action of gases," instancing the galvanic action set up by lead in proximity to zinc immersed in water, and concluding by referring to the importance of a knowledge of electricity to plumbers, both as a branch of business and as enabling them to avoid mistakes in their more ordinary work.

**ARCHAEOLOGICAL DISCOVERY IN NORTH WALES.**—An interesting archaeological discovery has just been reported from the Vale of Llangollen, where the Rev. Trevor Owen, Vicar of Trevor, is conducting a series of excavations at Valle Crucis Abbey. Whilst excavating along the north of the tomb, Mr. Owen discovered the tombstone of a Knight-Templar, bearing a clear impression of the knight's sword scapular at the base, beneath which were a few decayed bones. In completing the excavations along the west front of the abbey, the base of a spiral staircase was also discovered. Seven pieces of molten lead and iron and charred wood and stone have been discovered, clearly demonstrating that the original abbey was destroyed by fire, and it is now believed that the monastery was suppressed, during reconstruction, by Henry VIII.

**LEIGHAM COURT ESTATE.**—We advertised last week to a scheme of the Artisans', Labourers', and General Dwellings Company for building over the site of Leigham Court Estate. That property was sold in July at auction, for 90,000. Having a frontage of 825 ft. along the eastern side of the main road from Brixton, it lies between the Streatham Hill and Tulse Hill railway-stations. The house, in the Classic style, and standing in a finely-timbered park, was for some years occupied by the late Mr. J. Fredwell, railway contractor. His widow preserved here a pick and a shovel which her husband had himself used when a navy, during the first stage of his career. To enable them to begin operations speedily, the directors ask for a present subscription by the proprietors and their nominees of 100,000, in ordinary and preference 10l. shares, and for a like subscription a few months hence. The neighbouring house (built in 1829, and since enlarged) and grounds having been vacated by the St. Ann's Asylum, was purchased rather more than two years ago by the St. Pancras Board of Guardians. The new sanitary and other alterations were carried out by Mr. H. H. Bridgman, architect.

**THE CARPENTERS' COMPANY.**—The annual dinner given by this Company to their friends and others interested in technical education took place on the 21st inst. in the hall of the Company, London-wal. Professor Banister Fletcher occupied the chair. Mr. A. Preston proposed "The Examiners and the Teachers of Technical Instruction." At their schools, he said, at Stratford, wood-carving was given up with as great success as in Belgium. Sir J. Coope, President of the Society of Civil Engineers, and Mr. T. F. Rider, President of the Builders' Institute, responded, and eulogised the work done by the Company in furthering technical education. The Rev. J. R. Diggle, in responding for "The London School Board," said they had great difficulties to overcome when they first began to teach lads the use of tools; but he was glad to acknowledge the help received from the Carpenters' Company and other Companies.

CONTRACTS AND PUBLIC APPOINTMENTS.

CONTRACTS.

Table with 4 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, and Tenders to be delivered. Includes entries for Drains, Sewerage, Repairs to Church, Waterworks, etc.

CONTRACTS.—Continued.

Continuation of the Contracts table with 4 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, and Tenders to be delivered. Includes entries for Waterworks, Pipe Sewers, etc.

PUBLIC APPOINTMENTS.

Table with 4 columns: Nature of Appointment, By whom Advertised, Salary, and Application to be in. Includes entries for Clerk of the Works, Chief of Works, etc.

Those marked with an Asterisk (\*) are advertised in this Number. Contracts, pp. iv, and vi. Public Appointments, p. xvi.

LONDON WATER SUPPLY.—On Tuesday last a special meeting of the Court of Common Council was held at the Guildhall to consider the report of the County Purposes Committee in relation to the water supply and the public inquiry held thereon. Prior to the discussion of the report a letter was read from the London County Council asking the court to enter into communication with them with a view to the promotion jointly of a Bill for revising the amount of charges of the water companies, and for power, if necessary, to establish an independent supply, and stating, also, that the Council were entering into negotiations with the companies to ascertain whether they were prepared to dispose of their undertakings to the court of Parliament name their acquisition by the County Council. The letter was referred to the County Purposes Committee.—Mr. Rose-Innes then moved the adoption of the report. It was not proposed to urge the establishment of a Royal Commission, he said, but to bring in a Bill for the creation of a Water Commission, who should have the control of the supply in their own hands in the interests of the public, and in the event of companies not disposing of their undertakings, to give them power to establish an alternative supply. It was not proposed to buy out the companies for 35 millions, but to give power to the Commission to settle with the companies the terms of acquisition.—Mr. Price moved an amendment that the consideration of the report should be adjourned until the Corporation and the London County Council had had a conference on the subject as proposed by the latter body.—Mr. Deputy Hors said he hoped the Court would not make the mistake it did twenty years ago, when it was disposing of the necessary supply to the water companies. It then delayed to do so, and in consequence the price would now be 15 or 20 millions dearer than then.—Mr. G. N. Johnson contended that the present sources of the water supply were showing signs of exhaustion and decay, and that they were not likely to continue to be large enough to supply the increasing requirements of the metropolis. He therefore argued that to obtain a new and independent supply would be far less costly and more satisfactory than the buying up of a failing supply.—Mr. Malleson thought that the Bill should give power for obtaining an independent water supply provided that the interests of the existing companies could not be bought on equitable terms. He believed that for a third or fourth of the amount proposed to be given for the present undertakings a most abundant supply could be obtained from the Bala Lake in Wales.—After the amendment had been withdrawn, the report was unanimously adopted.

EDINBURGH UNIVERSITY BUILDINGS.—Notwithstanding the addition of an extensive range of new medical class-rooms made to the Edinburgh University buildings a few years ago, the accommodation is found to be inadequate to the yearly increase in the number of students, and the class-rooms are this year already crowded to their utmost capacity. At the opening last week the matriculation reached 1,120, being an increase of 159 of the number at the same time last year. There may be many more entries yet, and should this state of matters continue, it will be absolutely necessary to procure additional accommodation if the prosperity of the University is to be maintained. The building of the new college hall has been completed to the height of the main cornice. It takes the form of an amphitheatre, and will be lighted from the roof.

The walls follow the semicircular lines of the seats, and from the circumstance of there being few openings, and those of comparatively small dimensions, the effect of the elevations is very dignified. Dr. Rowand Anderson, the architect, has made provision for the introduction of sculpture by the formation of niches, which, when filled, will impart life to the facade. The pedestal attached to the hall will be the highest structure in Edinburgh, and will form an effective feature in the skyline of the city, as seen from various points of view. The probable cost of the hall and tower when completed will be 80,000l. or 100,000l.

STREET SWEEPINGS.—According to Indian Engineering, the city of Bombay is situated in a difficulty in regard to the disposal of its street sweepings. The sweepings are now conveyed in carts and emptied on what are known as the Flats, but all available space at this locality, which is being gradually dotted with dwelling-houses, will be exhausted in a few years more. The Bombay municipal authorities have under consideration a proposal to construct a steam tramway to convey the street sweepings from a spot on the Flats to the municipal tidal lands at Kuria, at the northern extremity of the island, with a branch line to the slaughter-house at Bandra for the conveyance of the daily meat supply of the city. The project, which was prepared and submitted in October last by Mr. P. H. White, deputy Executive Engineer in charge of the Tansa Waterworks, provides for a 2 ft. 6 in. gauge steam tramway, to be laid partly in connexion with the Tansa Water Duct line. The quantity of sweepings now taken to the Flats at Tardeo is about 800 tons daily; the quantity estimated for in the tramway project is 1,000 tons per day. The present difficulty is to establish a higher order of plumbing work in general, for it would be necessary hereafter for candidates to pass an examination in the principles as well as in the practice of their trade in order to obtain registration.

REGISTRATION OF PLUMBERS.—A meeting has just been held in the Public Hall, Preston, under the auspices of the Local Committee for Preston and District of the National Registration of Plumbers (in connexion with the Worshipful Company of Plumbers, London). The President, in opening the meeting, said the object of registration was to enable the public to distinguish between qualified and unqualified men. The advantages of registration were that the introduction of the system would gradually tend to establish a higher order of plumbing work in general, for it would be necessary hereafter for candidates to pass an examination in the principles as well as in the practice of their trade in order to obtain registration.

MEETINGS.

- TUESDAY, OCTOBER 23. Sanitary Institute (Lectures for Sanitary Officers).—Mr. Charles Jones on "Scavenging, Disposal of Refuse and Sewage." 8 p.m. WEDNESDAY, OCTOBER 23. Institution of Mechanical Engineers.—General Meeting, when three papers will be read. 7.30 p.m. Liverpool Engineering Society.—The President (Mr. Ferdinand Hatfield) will deliver his inaugural Address. 8 p.m. THURSDAY, OCTOBER 30. Institution of Mechanical Engineers.—General Meeting (continued). 7.30 p.m. FRIDAY, OCTOBER 31. Architectural Association.—Messrs. Walter Millard, A. Beresford Pitt, Needham Wilson, and Owen Fleming

on "The Present, Past, and Future of the Architectural Association." 7.30 p.m. Sanitary Institute (Lectures for Sanitary Officers).—Mr. Murphy on "Murphy on Infectious Diseases and Methods of Disinfection." 8 p.m.

RECENT PATENTS:

- ABSTRACTS OF SPECIFICATIONS. 14,018.—RAIN-RESISTING PIPES; J. Z. Brown.—This patent has for its object to secure rain-water pipes to walls of buildings by means of a hinged collar or band which, when closed, will lock the pipe in any position and which admits any portion of the pipe, or a new pipe, can be taken from its place—at any height—and a new pipe inserted without risk of damaging the adjoining connections. The fastening or lock is made so that when it is desired to remove the pipe or to unfasten it the collar the pipe is to be turned round, either to the left or right, until the projecting lug is clear of the groove of the pipe is then drawn  $\frac{1}{4}$  in. into the lower socket, when it can be drawn out. When the collar or plate is fixed it need not be removed, which prevents the wall being damaged, and easily admits of the pipes being taken down and refixed quickly. 17,443.—TILES, &c.; W. Lindsey.—The tiles which form the subject of this patent have their two opposite faces dovetailed grooves or recesses to receive plaster, &c. Another pair of opposite faces are notched to receive iron supports, and of the remaining opposite faces one is furnished with a recess and the other with a projection fitting the corresponding recesses and projections on the adjacent tile. 6,904.—GLAZING SKYLIGHTS, &c.; G. Martin.—This invention consists mainly of a slotted sash bar and slotted sash bar in combination with sheets of glass for roofing. 11,446.—DOOR BELLS, &c.; F. Sauterson (U.S.A.).—The object of this patent is to give the mechanism for operating a hammer striking on a bell by the means of simple elbow levers, and a further object is "to connect the push-button and the lever which operates the hammer that the connection will be in alignment by the introduction of a bifurcated pitman, which permits the hammer to vibrate vertically within the space between the two arms of the said pitman." NEW APPOINTMENTS FOR LEADERS PATENT. October 6.—15,782, J. and W. Chivers, Imitation Stone, Slate, Marble, &c.—15,793, D. Campbell and G. Schultz, Construction of Bridges.—15,811, H. Hardy, Stays and Fasteners for Casement Windows. October 7.—15,870, G. Redfern, Fire-grates.—15,901, J. Sears, Ventilators. October 8.—15,929, E. Orford, Flues and Barrel Bolts.—15,976, G. Davis and E. Jones, Coverings for Cisterns &c.—16,985, L. Kern, Support for Builders' and Decorators' Platforms or Stagings.—15,900, F. Trier, Machine for Unloading Ship Casks. October 9.—16,019, J. Brooks, Water-taps.—16,059, W. McLachlan, Mould for the Production of Inlaid Designs on Tiles. October 10.—16,067, F. Lynde, Water-closet Traps, &c.—16,071, H. Enoch, Spreader for Water-closets and Urinals.—16,083, F. Scholer, Automatically Flushed and Disinfecting Water-closets, Drains, &c.—October 11.—16,131, J. W. B. Kilm for Tiles, &c.—16,132, C. Mitchell, Capping for Use as a Chimney Top Ventilating Cowl, or Exhauster.—16,147, C. Gabriel, Flushing Cistern.

PROVISIONAL SPECIFICATIONS ACCEPTED.

6,613 J. Dart, Self-acting Door Fastener, 11,705, W. Jay, Screw Appliance for the Fast Movement of Irons...

TIMBER (continued).

Table listing timber types and prices: Cedar, Cuba; Honduras; St. Domingo, cargo average; Mexican; Honduras; Box, Turkey; Rio, Rio; Bahia; Satin, St. Domingo; Porto Rico; Walnut, Italian.

METALS.

Table listing metal types and prices: IRON-Bar, Welsh; COPPER-British, cake and ingots; LEAD-Pig, Spanish; TIN-Straits; AUSTRALIAN.

OILS.

Table listing oil types and prices: Lard; Coconut, Cochin; Palm, Lagos; Rape-seed, English; Cottonseed, refined; Tallow and Oleine; Lubricating; TAR-Swedish; Archangel.

TENDERS.

[Communications for insertion under this heading must reach us not later than 12 noon on Thursdays.]

BLACKBURN.—Work for covering the river Blackwater at Cobh Wall, Blackburn. Mr. J. McMillan, Engineer, Blackburn.

BRANLEY.—Accepted for the erection of sixteen houses and two shops at Branley, Leeds, for Mr. John Town, Mr. John Ross, architect, Spring-garage, Branley, Leeds.

BRENTWOOD.—For the erection of house and shop, at Station-road, Brentwood, for Mr. Henry Owen, J.P. Mr. W. G. Shoobridge, 138, Strand, W.C., architect.

CREWKERNE.—For erecting tanks and buildings for carrying out the "Amias" process of sewage treatment at Crewkerne, Richard Draper, 25, Abchurch-lane, London, E.C. 4, 41,450 0 0.

EASTVILLE.—For sawing, levelling, paving, installing, etc. streets at Eastville, near Bristol, for the Stapleton Urban Sanitary Authority. Mr. A. J. Sains, Surveyor, Local Board Offices, Philipson's, Bristol.

FULL.—For the erection of college buildings (including the addition of dining hall to existing house), Hymers' College, Kingston-upon-Hull. Messrs. Metford, Son, & Wilson, architects, 23, Parliam. street, Hull. Quantities by the architects.

FWSVICH.—For the supply of wood blocks (65,000 for street paving, Spanish, for the Corporation, Mr. E. Backham, Borough Surveyor, Town Hall, Ipswich).

### Architecture in Birmingham.

EXT week the National Association for the Advancement of Art is to hold in Birmingham its third annual Congress, and in the course of the proceedings a good deal will be said about architecture, wherein it consists and how the architect should be educated, or not educated but evolved, according to the various views prevalent with various speakers. It is to be hoped that the ground on which this seed is to be sown will not prove as hard and unfruitful in the future as the outer aspect of Birmingham, architecturally considered, might seem to threaten. There is no doubt that up to the present time Birmingham is one of the most architecturally depressing of all our large towns; and that if there is anything to be taught as to the true nature of architectural art from those who will speak on the subject at the Congress, such teaching could hardly be brought anywhere where it is more required. There is something about the architectural barrenness of Birmingham which seems to require some special explanation. The two or three good buildings there, one of them barely completed, are all the work of outsiders; and our own experience, which we give rather in sorrow than in anger, is that we are scarcely able to accept for publication in this Journal any architectural drawing sent from Birmingham. There is a peculiar and defiant absence of beauty or refinement in its local architecture which is not so conspicuously noticeable in any other English town that we can call to mind. Mere commonplace and absence of all pretence at architectural design of course is to be found in all quarters; but this is not a complaint special to Birmingham. On the contrary, there seems a great inclination there to be both ambitious in design and costly in execution, but the results are not of the right kind. People used satirically to speak of a certain type of architecture as "Manchester Gothic," but while Manchester has somewhat improved her old reputation in this respect, it is to be feared that Birmingham

Gothic must be placed in much the same category.

This phase of Birmingham architecture is of course comparatively recent birth. The building which marks the architectural centre of Birmingham is Classic of the most pronounced type. It is a little more than half a century since the old and now we fear not much respected Town-hall was erected, a building the offspring of the same Classic creed which produced St. George's Hall in Liverpool. It is far inferior in size as well as in general effect to that structure, being a mere hall, whereas the Liverpool building is a hall and law-courts combined; and what is more important to notice, there is no such attempt in it at any new treatment of Greek features as there is in parts of St. George's Hall. It is frankly and purely a Classic temple with a peripteral Corinthian order, mounted upon an abnormally lofty rusticated podium. The *motif* of the podium was in part, no doubt, a practical one; it was intended to utilise this portion for offices, making a utilitarian story, in fact, below the state story on the upper level. The worst point about it architecturally is that there is no external suggestion of the means of access from the ground story level to that of the hall; but that was the way with the modern Classic building of the temple type. Staircases did not exist in temples, and could not therefore be recognised in modern imitations of them. A grand external flight of steps in the front would have had a fine effect, and would have added immensely to the architectural value of the building, but the practical inconvenience, in this climate, for the intended uses of the hall, would have been so great as to be prohibitive. Another defect is that the imposing effect of monumental solidity which might have been obtained by the lofty podium is seriously interfered with by the cutting of an arcade into it at the lower end of the site, with a return arch at each end, absolutely necessary of course for passage, but which takes away all the solidity of effect from this end of the building, especially when viewed from one side, where the return arch seems to weaken materially the foundation on which the superstructure stands.

With all these defects of treatment, coupled with the fact that the style imitated is peculiarly unsuited to the atmosphere of a manufacturing town, it is impossible not to feel a

certain respect for the old Classic Town-hall, more especially when comparing it with some of the structures in its vicinity. It stands well on its site; there is a breadth and repose about it which is in strong and advantageous contrast with the hustle and straining after effect which is characteristic of most of the modern Birmingham buildings. It should be noted that this, to begin with, is not the work of a Birmingham architect. There was an opportunity once for making it part of a grand architectural combination. This was at the time of the competition for the Municipal Buildings, when Mr. Lynn of Belfast sent in his splendid scheme for placing the new building on a line normal to the Town Hall, and connecting the latter with it by a bridge, so as to put the Town Hall *en suite* with the stair-rooms of the proposed new building. The competition committee felt themselves debarred from giving the premium to a plan which contravened their instructions as to the lines of the site, but they showed their appreciation of it by purchasing from the author the right to use it, and—neglected any use of it. They thus lost for ever the opportunity of doing a great thing in Birmingham in the way of internal and external combination and climax; an arrangement which would have also given twice the architectural value and dignity and meaning to the old Town Hall. Now we have it flanked by, but entirely unconnected with, the huge mass of the Council House buildings, about as poor and commonplace a piece of Renaissance architecture (of a sort) as ever gave employment to a competition draughtsman. The general effect is flat and tame, there is not a detail in it worth looking at, and the campanile is perhaps one of the ugliest ever designed. But then it has the merit of being the work of a townsman. The façade of the older portion of the Midland Institute opposite forms an instructive contrast. This was the work of the late Mr. E. M. Barry, who did not, it must be admitted, inherit the genius of his father, but who had acquired a refinement in adopting Classic forms of architecture which at all events does not appear in the native architecture of modern Birmingham. Barry was much too fond of vases along the top of his buildings, a very commonplace detail; but the treatment of the order on the building and of the basement upon which it rests is carefully worked out; the proportions of the

whole elevation are good and harmonious; and though this kind of thing has had its day and is (like the Town Hall) unsuited to a manufacturing town in this climate, it is at any rate gratifying to see it well done in its way, and on the whole this facade may be said to be one of the best bits of architectural work in Birmingham. Its merit will be the more apparent if it be compared not only with the flabby Classic architecture of the Council House, but with the new Post-office buildings now approaching completion just below. This we presume is a piece of official architecture, and for once we may congratulate Birmingham on having set down in her streets, from a foreign source, something as coarse and commonplace in architectural design as any of her native developments. The display of vases on the balustrade of the Midland Institute buildings is a piece of elegant detail in comparison with the growths on the new Post-office buildings. Pots and tea-urns of abnormal dimensions are perched about on ledges and on cornices; the whole of it is fussy, pretentious, and totally wanting in dignity or breadth of effect. Things by no means so bad as this have been turned out from the Office of Works' mill; it is difficult to understand the production of anything so ostentatiously bad as this. Has it been the result of a kind of *spirituel* attempt to "harmonise with the environment"?

Some of the developments of Birmingham Gothic occupy the same neighbourhood of which the Town Hall forms, as we observed, the central feature. It is painful to feel that one cannot speak with much sympathy of the work of such a man as the late Mr. Chamberlain, who at heart was an artist in his wishes and intentions, an enthusiast in his work, and who certainly had a strong intention of doing something good for its own sake, and was in every way a man much and, we believe, most deservedly respected in his native town. But the Gothic addition which he made to the Midland Institute buildings is imbued with the same spirit of fustiness and coarseness of detail which seems to pervade everything produced in the town. The Lecture Hall within is even worse in this respect. It has indeed the great merit of being admirably adapted to its purpose in a practical sense, and is one of the few rooms in the country in which over a thousand people, seated on one floor, can be addressed and can hear without the least effort to the speaker. But the treatment of the room architecturally, with its brick fire-works on the wall, is almost irritating, and enough to put out of tune any one who goes there to lecture on anything connected with art. The School of Art is better, and the effort to give relief and brightness to the walls by the insertion of coloured tiles, and other devices, was thoroughly well meant, but the result is unfortunately patchy and inharmonious, though there is something of picturesque treatment in the general design.

The Mason College and the High School for Girls form two large blocks of Gothic building in such close contiguity as almost to make one group. The High School, originally built for the Birmingham Liberal Club but found too large for its purpose (rather a surprising result in a town supposed to be so radical in its politics as Birmingham), is much the best of the two externally, though both are by the same architect, and is perhaps the most favourable specimen of the class of Gothic work which obtains in Birmingham. The pretentious and what may be called jerky style of the architecture of this building, not without a certain degree of vigour, is of a type not of course confined to Birmingham; we find it in large Gothic buildings of the past twenty years in other large towns; but it has that same "note" of want of repose and refinement which is the general characteristic of the modern architecture of the town. Sir Charles Barry's "King Edward's Grammar School" in New-street is no doubt, from the point of view of the present day, very tame Gothic, and Gothic in fact was never Sir Charles Barry's strong point. But it is a useful and instructive contrast to

even the best of the modern Gothic buildings in the town, in its character of refinement and good taste; it has not that air of striving after showy effect which the visitor to Birmingham meets with on every hand among the recent buildings. Taking the average street architecture of the town as exhibited in Corporation-street, which is the costliest street in Birmingham in this respect, the impression left on the mind is quite painful, the more so from the amount of display and the show of lavish expenditure in making buildings "ornamental," which is to be seen everywhere. While there are few business streets in any provincial town more "handsome," as the common expression is, than Corporation-street, there are few, perhaps none, in our recollection, that are so destitute of real architectural beauty and interest. If we begin to consider where the fault lies, we shall probably come to the conclusion that it is in want of refinement of detail, coupled with an exuberance of ornamentation which only serves to emphasise this defect the more. We see large coarse mouldings, heavy bands stuck on everywhere round shafts and columns, florid but coarsely-designed carving got in wherever it can be got in, as if architectural beauty was to be acquired by dint of loading a building with ornamental detail without consideration of the quality of the detail itself.

Is there any reason why this kind of thing should be so peculiarly prevalent in Birmingham? The causes which influence the special character of the architecture of a modern town are always difficult to trace, but we think that the taste of Birmingham has been influenced by the fact of its being a town largely occupied in industries of a practical kind, which require a great deal of energy and ability to carry them on successfully, which bring in a great deal of wealth, but which do not in any way tend to turn the attention towards the consideration of beauty in the objects produced. The wealth is there, and the desire to make an architectural show with it, which in one sense or another always follows the accumulation of wealth; but the feeling and taste which should preside over such architectural display have been less cultivated even than usual in modern cities, because the occupations from which much of the wealth has arisen are such as tend to deaden rather than to foster the artistic sense. A strong light is thrown upon this view of the subject by the style of ornamental *bijouterie* which is characteristic of Birmingham. A few years ago there were placed in the Art Museum Galleries (we know not if they are still there) cases of specimens of recent gold work by eminent Birmingham firms, to show, amid the ancient examples, what the modern jeweller could do. The whole style of these was that of work in which the chief desire was to show the costliness of the object, the thickness and weight of the gold and value of the stones set in it, without any attempt at beauty of design beyond the most commonplace devices of star-patterns, &c.; designs with no thought and no beauty in them. The mere sight of such work, as the best produce of the town in that way, would in itself lead one to expect that architectural refinement would find no home in such a region. The spirit which puts refined and thoughtful work into jewellery is the same spirit which puts refined and thoughtful work into architectural mouldings and architectural ornament; which leads to the perception that it is not the money value of the material and labour which makes a valuable work of art, but the thought of the designer, the patient striving after the best by the worker; and that a little ornament well placed and carefully designed is of infinitely more value than a great show of coarse and carelessly-designed work, whatever cost it may represent. This is the lesson which Birmingham, with all her energy and commercial success, needs to learn, and in this respect there may we hope be some teachings during the Congress of next week which may not be without value in the end, though they may not be popular at the moment.

Among the new buildings now getting up in Birmingham is a large corner block in Corporation-street, which we fear has all the characteristics we have already alluded to in modern Birmingham architecture, and the new buildings for the Prudential Assurance Company by Mr. Waterhouse higher up in the same street. We doubt whether this will prove, when it can be seen completely, one of the most successful of its distinguished architect's numerous works, but it is at all events free from that florid character of ornamentation of which so much is to be seen around. Opposite the new Law Courts some building is going on which we understand is a waterworks establishment, of which there is now evident a small building with some half timber work in front, and the commencement of a couple of towers; what is to come of this architecturally has yet to be learned.

The new Law Courts is of course by far the most important new building in Birmingham, and is an altogether new departure in Birmingham architecture. This also, as our readers are aware, is not by a Birmingham architect, but the joint design of two London architects, Mr. Aston Webb and Mr. Ingress Bell. The building is now complete architecturally, only the interior fitting remaining to be done; but the lofty boarding in front prevents the total effect from the street being judged of as yet. As far as one can judge from inspection of a building before the actual traffic and business in its courts and corridors has commenced, the plan seems entirely admirable for its purpose. This is not one of your "rabbit-warren" plans, but one in which the whole scheme is simple and symmetrical, and every department and corridor seems just in its right place for the purposes of the building. By placing the great hall or *salle des pas perdus* parallel with the front, the architects have been enabled to connect it in a most convenient manner with the three main corridors which run up the building, from the centre and from the two ends of the large hall. Opposite the main entrance runs the centre corridor which leads between the civil and criminal courts and up to the semi-private corridor for the bench and the bar, which runs across the upper end of the building, and beyond which is the barristers' library. The side corridors give access to the minor courts, and rooms for various purposes in connexion with the courts. The public entrance to the galleries of the courts is entirely separate from the street, and keeps those who go merely as spectators entirely out of the way of those having business at the courts, as in the London Law Courts; but the access is more commodious and better arranged than in Street's building with its corkscrew staircase.

Detailed description of the building as completed we reserve for another occasion, our concern just now being rather with its architectural character. In this respect it is far in advance of any other recent building in Birmingham, and, as observed, constitutes almost a new departure, and gives a new architectural interest to the town. Whether the effect of the red terra-cotta is calculated entirely to convert one to the love of terra-cotta in place of stone may be a question. It is no doubt a much better material than stone for durability and retaining its appearance and effect in a smoky town, where the best stone buildings soon come to have a more or less grim aspect; but there is a smooth and almost waxy-looking texture about it which is not so effective as the texture of stone; and the material here used, though excellent of its kind and admirably worked, is to our thinking a little too deep a red for the best effect. Terra-cotta has of course the advantage over stone, besides durability in regard to atmospheric influence, that a great deal of decorative detail can be produced in it at less cost than by stone-carving; but this advantage is not unaccompanied by drawbacks. The question of texture comes in again, and the ornament which would be carved if in stone, has a somewhat hard and cast-iron look in terra-

otta. May we add also that we cannot but think the plastic character of the material has betrayed the architects into a somewhat too exuberant form of ornamentation in some places. The rounded mouldings and detached shafts of the external entrance, with the scrolls curling off the mouldings rather like wrought-iron ornament, have rather a want of repose and solidity of effect; and we regret to meet here and there with slight symptoms of what Fergusson called "the horrors of German interpenetration" of mouldings; in the heads of a good many of the corridor doors, for instance. The effect of the hall, with its heavy pitch-pine open timber roof and stained-glass windows, is indeed very rich and effective, and derives the more effect perhaps from the plain treatment of the floor (of Yorkshire stone slabs) and the simple but suitable treatment of the ground-floor doors. We could have wished that the arcades across the ends of the hall had not been of stilted arches; the evident object is to make the line of the impost coincide with the main surface line of the hall, and thus bind the whole together; but a stilted arch is not a very satisfactory architectural form. The courts are very well treated both architecturally and practically, with some good wood and plaster work, not too ornate for the occasion; and the ceiling of the Grand Jury room is a very rich and effective piece of plaster decoration in low relief. The treatment of some of the leaded glass windows, as in the barristers' library, is exceedingly effective and well designed in a simple manner. Some of the overmantels in the principal rooms (e.g., that in the barristers' library) again suggest a note of intergradation as to terra-cotta; the ornament and small figures in some of them give a general rich effect, but totally without the sharpness of carving. For the general lining of the walls of the interior, on the other hand, nothing could be more suitable than the light-coloured terra-cotta here employed, which combines a look of warmth and comfort with monumental effect. In the interior as well as in the front we find the ornament rather too exuberant in places, and would have liked the example to be set, in Birmingham especially, of reticence in this respect. But as a whole the façade presents a piece of rich architectural picturesqueness and originality of which there is certainly no other example at present in Birmingham.

NOTES.

**A** REMARKABLE episode in the capital and labour war occurred last week in reference to the Australian strike. A telegram from the strikers in the Antipodes, which ran thus: "Require 20,000. United Australian Unions guarantee repayment. Success assured," was read at a special meeting of the London Trades Council. It was decided that this sum should be raised. This incident is very important. It emphasises in the most vivid manner the international character which these disputes have now reached. It will also bring home very keenly to the English working man the costliness and the waste of strikes. We hope it will make him pause and consider whether the use of strikes may not be carried too far. The money must come out of the pockets of the working men, and if higher wages are to be spent in taxes of this sort, is the working man much better off for the increase in his remuneration? But if it comes to a fight between money-bags, which is most likely to succeed, the capitalist or the labouring man? It is true that Mr. Tom Mann observed that "many of the unions were very rich," which is, perhaps, the cause of their aggressiveness, but rich unions merely mean that money has been collected from the working classes for the propagation of strikes. Thus it is again shown that what the working man receives with one hand in the way of increased pay from his employer he hands with the other to his union. That strikes are sometimes necessary is undeniable, but it is obvious that

when thousands of pounds are asked for, and it is hoisted that the unions are "very rich," we have quite got beyond the period of legitimate strikes for reasonable wages.

**T**HE resolution of the Court of Common Council to promote a Bill next session to establish a Commission to manage the water-supply of the Metropolis, either by taking over the present water companies' undertakings or by establishing an alternative supply, is likely to have important consequences. The Corporation of London is not a Radical body, and the fact that it has, after due consideration and investigation, taken this step shows that popular opinion is ripe for an end being put to the supply of water to London by private enterprise. It is also a welcome sign of public spirit. Should the scheme be carried out, it will have an extraordinarily vivifying effect on the Corporation. It will be useless to speak of it as an effete body, it will have accomplished a great and valuable public work, which will prevent any one from saying that it is an effete and worn-out body. It remains, of course, to be seen how events turn out, but, taken up by practical men, acting on behalf of the people of London, the matter is likely to have a more successful issue than if it were taken in hand by a Government, which can take no step of the sort without laying itself open to political attacks from some quarter, and which has to be constantly on the alert not to hurt the feelings of its supporters. The sooner the Water Companies are bought out on reasonable terms, the better it will be for the people of London.

**A**N important conference was held at the Board of Trade on Tuesday between the officials of the Department and a deputation of railway managers, upon the question of rates and charges for merchandise. The object of the deputation was to convince the Department that the adoption of the schedules of maximum rates which they have recommended would involve losses of revenue as compared with the present actual charges. Summaries were handed in showing the amount of loss which would thus be sustained.—The London and North-Western being calculated at 113,600*l.*, the Midland at 117,700*l.*, Great Northern 34,489*l.* (1) and so on, the Brighton Company—who do not depend upon goods traffic for revenue,—closing the list with 4,000*l.* The companies have arrived at the conclusion that, although there is nothing to complain of in the principles which guided the Board of Trade in compiling their schedules, the schedules themselves fail to give due and fair effect to those principles. Sir Michael Hicks-Beach, in his reply, took occasion to refer to the directions to the Board of Trade which the Bill contained as originally drafted, as to the principle upon which maximum rates should be fixed, which were struck out, leaving simply the words "just and reasonable." He declined to enter into any argument, preferring to wait for the traders' answer to the statements now made. It is understood that these, together with the statistics to which we have alluded, will be made public, and they will doubtless be challenged. Of course, any inquiry into these figures would be of a purely character.

**I**N regard to the question so much debated at present as to the ventilation of sewers whether by street-grids or by high ventilating shafts, the following extract from an article in the *Lancet* may be of interest to some of our readers as representing a medical opinion on the subject:—

"That the gases bred of putrefactive processes in sewers must be allowed some means of escape other than into our houses no one doubts; but while some advocate putting the vent-holes at the street level, others advise the use of ventilating chimneys which shall conduct the effluvia above the roofs of the houses. The sewer grating, be it remembered,

"Like the toad, ugly and venomous,  
Wears yet a precious jewel in his head,"

by which we mean that the stench arising from a sewer when rightly considered has its uses, for it

ought to make us instantly take measures to remove the cause of offence by flushing, disinfection, or other means. Sewage is so offensive to the eye that we have put it out of sight, and by so doing we deprive ourselves of the protection of one of our senses. If we take measures which will prevent our smelling it, we deprive ourselves of the protection of another of our senses. It must not be forgotten that by the use of high ventilating shafts we do nothing to stop the putrefactive process which is the cause of the mischief. The gases which result from putrefactive processes are not probably very dangerous to health, and those delivered at the roof level would be diluted beyond recognition before they struck the nose of a passenger in the street, although it might be otherwise with the denizens of the attics. There can be no question that offensive gas gives less annoyance to the nose when given off by a high chimney than when discharged in a confined space flanked by houses. As regards the infective microbes which, infinitesimally small though they be, are distinctly ponderable, it is at least conceivable that those having to fall to earth through 60 or 80 ft. would stand a better chance of being inhaled or swallowed than when delivered at the street level. On a sultry July day there comes a heavy downpour, and the torrent flowing to the sewer causes a copious escape of gas from the high ventilators. Infective microbes accompanying the gases are washed down by the rain, and in falling past the windows of five or six stories, and so to the ground, have a better chance of being inhaled than when they are hattered to earth again as soon as they emerge from the street grating. We have learnt by experience how infective particles escaping from the small-pox hospitals drift about to the neighbouring houses, and we must admit that the same kind of thing might happen in the case of infective particles given off from the high ventilating shafts."

**I**T is the fashion of politicians to regard a session as fruitful or barren according as it is prolific or barren in regard to sensational political measures. Many people regard such legislation as of less importance than mere homely Acts of Parliament. One of these passed last session is the Housing of the Working Classes Act, 1890, a measure of 103 sections, without taking into account the several schedules. It is very largely a Consolidating Act, for it repeals all the previous Artisans and Labourers' Dwellings Acts, and also the Housing of the Working Classes Act, 1885, except sections three and seven to nine. The full advantage of such a consolidation as this will be better appreciated when we point out that between 1851 and 1885 inclusive, no less than fourteen Acts of Parliament were passed dealing with working men's dwellings, most of these containing amendments of preceding statutes. In such a Consolidation Act various amendments of the existing law are necessarily to be found, but they can hardly be profitably noted in any other way than by a verbatim comparison of the last Act with those which have gone before. In regard to the part entitled "Powers of County Councils," we have already referred to the circular of the President of the Local Government Board on the subject of appeals to those bodies against the inaction of sanitary authorities. The practical value of the procedure yet remains to be seen.

**S**INCE the passing of the Railway and Canal Traffic Act the railway companies generally have been looking rather sharply after "extras"—such as warehousing and wharfage, and the charges for use of sidings. We notice that the Midland Railway Company took a case of this description into the County-court at Bedford last week, a coal dealer in a small way of business being sued for 15*l.* 11*s.*, "for rent of siding accommodation since March, 1889." The company issued a notice in February last year stating that on and from March 1 they would charge a shilling per wagon per day for siding rent upon all wagons not unloaded within four days after arrival. It was added that this step was rendered absolutely necessary by the increasing detention of wagons, which greatly impeded the working of the railway. There is no doubt that some merchants take a most unreasonable advantage in this way, and it is to be hoped that the County-court Judge upheld the right of the company to make these charges, giving judgment in the case referred to for the

full amount, with costs. At most stations stacking-ground is provided, for which a rent is charged; and it is not likely that the company care to have their sidings blocked by traffic belonging to persons who do not take sufficient stacking-ground to accommodate it. In this matter, however, as in others, the weakest are the most likely to suffer. A clause in the notice provides that the company may enter into an agreement whereby a trader may be allowed to take an *average* of four days upon each wagon consigned to him during each month, the average being ascertained at the end of each month. Thus, a large merchant would be able to leave some of his trucks under load for the greater part of the month, claiming as a set-off those which are liberated on the day of arrival. The smaller merchant cannot manage these things so conveniently, and, it seems, has to pay the penalty.

SOME anxiety has been expressed as to a threatened restoration of the interesting timber church at Greensted in Essex, of which a sketch is subjoined; and a few words as to what is really the state of the church, from a special visit of inspection, may be of interest. Greensted is close to Chipping Ongar, and a path of about three quarters of a mile through the "Avenue" of Greensted Hall leads to the church. Formerly a simple wooden hulling, built it is supposed as a resting-place for the body of St. Edmund on its way to Bury, it is now a small church, consisting of nave, chancel, and western tower, with a projecting porch on the south side. The walls of the nave appear

of interest. We give the south-east view of the church, and the panel in the corner is a part of the monument just mentioned, the upper portion, with the shield of arms in a circular panel, having been omitted.

ONE of the most interesting features in connexion with the Art Congress at Birmingham next week will be the collection of more than 450 of David Cox's works, brought together by Mr. Whitworth Wallis, Director of the Museum and Art Gallery there. Among these, we are told, will be the signboard which Cox painted for the Royal Oak inn, Bettws-y-Coed. This painting, as some of our readers may remember, was exhibited in the then Court of Appeal, Lincoln's Inn, during the hearing, in March, 1881, of Lady Willoughby de Eresby's appeal in the matter of a liquidation petition by a Miss Thomas in the Bangor County Court. It appears that in 1847, David Cox, a frequent visitor to the inn, was asked to repaint its sign, fixed with boldfasts, outside, over the door. In 1851 he retouched his work. In 1866 the signboard was removed and hung up indoors. By an assignment of the lease and business (1876) to Miss Thomas, the picture was expressly excepted; Lady Willoughby de Eresby, who died November 13, 1888, being owner of the freehold. Lords Justices James, Cotton, and Lush, were unanimously of opinion that the signboard belonged to the freeholder as part and parcel of the house, having ceased to be—if, indeed, it had ever been—a tenant's fixture on the granting of the second lease, in 1871, to David Richards, whose widow sold her term

hence. The ground lies next to the Église de Notre Dame de France, where the Barkers' and the Burford's Panoramas were formerly exhibited, and where the late G. C. Selous was employed as a scenic painter for more than thirty years.\* The opening of a thoroughfare into the square from Coventry-street, with the making of Lisle-street and of Cranbourne-street as a widening of Cranbourne-alley, were included amongst Metropolitan improvements proposed in 1760. Fifty years ago, Cranbourne-street was widened along its southern side and extended into St. Martin's-lane and Long-acre. But the alley had existed as a foot thoroughfare from 1679. It seems to have formed a favourite quarter for silversmiths—amongst them being Hamlet, and, at the sign of the Golden Angel, Ellis Gamble, to whom Hogarth served his apprenticeship. Gamble's shop-bill, engraved by Hogarth, bears the address, "Cranbourne-street." Having fulfilled his time there, Hogarth, *teste* Walpole, entered into the academy (Sir James Thornhill's) in St. Martin's-lane, to study drawing from the life. In 1720, he had set up as an engraver on his own account. "Engraving on copper," he afterwards said, "was, at twenty years of age, my utmost ambition."

IN the St. Anne, Soho, rate-books for the year 1740 we have found the entry of a rate of 4s. made upon "Mrs. Hogarth." Hogarth's sister Anne was then alive; his mother died in 1735. She died on June 11, through fright at a fire, which broke out two days before in Cecil-court, St. Martin's-lane, and burnt thirteen houses, amongst them that of John Huggins, late warden of the Fleet. Huggins bought that office of Lord Clarendon for 5,000*l.*, for himself and his son, the translator of Dante and Ariosto's "Orlando Furioso," and sold it to the infamous Thomas Bambridge and Dougal Cuthbert. Cecil-court and Cranbourne-street were so named as being built over the property of the Cecils, Earls of Salisbury, and Viscount Cranbourne. The court lying next, south of St. Martin's-court, has been gradually pulled down within the last two or three years. Its site will be occupied by some new premises for the Camera Club facing Charing-cross-road (*olim* Castle-street in this part), and blocks of shops, residential chambers, &c., to face St. Martin's-lane, and forming the southern side of St. Martin's-court. When Leopold Mozart brought the little Wolfgang and his sister "Nannerl" to London they first lodged, April 10, 1764, in Cecil-court, removing thence to Williamsons, in Thritnow Frith-street, Soho. Abraham Raimbach, the engraver, was born, 1776, in Cecil-court.

Greensted Church, Essex.

to be the original fabric, and are of wood logs about 4 ft. 4 in. in length, and varying between 2 ft. and 3 ft. in width. They rest on a plinth of brick, and above them is the plate which carries the roof. There being no windows in the walls, this part of the church is lighted by six dormers, three on either side. The tower is of wood, with a shingle broach spire. The chancel is of brick, including the jambs of the windows and priest's door. The east window is of stone, and likewise the inner order of a modern window on the south side eastwards of the priest's door. During 1848-9 the church was extensively restored, and the roof of the nave with its dormers, and the south porch, are practically new. Unfortunately proper care was not taken to ventilate this roof under the boarding, and dry-rot has attacked it, rendering the renewal of the roof again necessary. There is one fragment of old glass—a bead, appearing to be that of Henry VII., and probably coeval with the building of the chancel. On the north wall, inside the chancel, is a good mural monument to "Irene, sister of Sir Thos. Smith, of Mont, and second wife of Alane Wood, of Snodland, Kent," 1585; but this is the only object

to Miss Thomas. David Cox, who was the son of a whitesmith, was born at Birmingham in 1783. Originally destined to follow his father's trade; but temporarily disabled by an accident, he was ultimately sent to Joseph Barber's night school there. For a while he found employment as assistant to De Maria, the scene painter to the theatre, under the elder Macready's management. On first coming to London (1804) he sold for two guineas a dozen sepia and Indian ink drawings "which were disposed of by the dealers to country drawing masters chiefly, who visited London twice a year to purchase 'copies' for the use of their pupils." The "Lancaster Castle" which Cox sold for 20*l.*, was purchased at the Gillott sale for more than 150 times that sum.

THE site that has been cleared on the northern side of Cranbourne-street, Leicester-square, will be occupied by the theatre which Mr. George Edwards is about to build, after the designs of Messrs. Phipps and Spencer Chadwick, architects, and which will, probably, be ready in twelve months

\* William Hall's "Biography of David Cox;" edited, with additions, by J. T. Bunce, 1881.

THE Grosvenor Gallery is dead, and the New Gallery reigns in its stead. Such we take it, is the practical result of Sir Coutts Lindsay's recent letter to the press which forms the funeral éloge of the deceased gallery. It is a comic triumph for Philistinism, for in place of the late art gallery we now have a social club. If there is one thing in the world more full of commonplace and more antagonistic to art it is the modern social or political club of the Metropolis. Sir Coutts Lindsay tells us that art is still to be cultivated, for a certain number of pictures are to be hung on the walls which will be for sale. But we can scarcely imagine a more hopeless mart than such a place, where neither rich amateurs nor active dealers are likely to congregate. We can, indeed, only regard this portion of Sir Coutts Lindsay's letter as part of a decent ceremonial over the interment of the deceased gallery. Indeed, we can scarcely bring our imagination to contemplate the spectacle of a true Grosvenor Gallery picture criticised by a party of City gentlemen on their way to the smoking-room, after an ample banquet in the dining-room. But the Grosvenor Gallery, in spite of

\* Robert Barker removed thither in 1794 from Castle-street, Leicester-square. To him succeeded his son, Henry Aston Barker, whose pupil, John Burford, was in turn succeeded by his son Robert Burford in 1825.

inglorious end, has done some service to it. It has inaugurated small and comfortable galleries; it has protested, not unsuccessfully, against crush and commonplace at the exhibitions. There is a career open to its legitimate successor—the New Gallery, if the latter will avoid cliques and favoritism, and endeavour to collect annually a choice and representative exhibition, in a small space, of the able works by contemporary artists, without regard to name or popular fame.

LETTER FROM PARIS.

THE promised road from the Avenue Suffren to the Avenue Bourdonnais, across the Champs Elysées, has now been made, and there is talk of another carriage road to be commenced from the Pont d'Iéna, round the Eiffel Tower to the central dome, winding round by the Palais des Arts Lihfrax on the right. There is an idea of making this a kind of artery to the Champs Elysées and the Bois de Boulogne as a promenade, though it may be doubted whether this will be accomplished, and it is evident also that, now that the conservation of the principal Exhibition buildings has been terminated upon, there is some difficulty as to what to do with them. M. Alphand has a number of projects which are to turn them to account. The Galerie des Machines is talked of as a winter place for grand displays of aviation, a kind of hippodrome; but it is doubtful whether this would be a success, at all events it is not likely to draw the fashionable world of Paris.

The Metropolitan Railway scheme is more looked than ever, but without apparently getting any nearer to realisation. It is the subject of numberless public meetings and of a great deal of press warfare. The supporters of the Haag's viaduct scheme criticise warmly the subterranean scheme of M. Eiffel. This latter scheme was not really anything more than a cable railway for the centre of Paris; a circle starting from the Madeleine, underground, passing by Rue Taitbout, the Faubourgs Montmartre and Poissonnière, the Boulevard des Capucines, the Place de la République, the Rue Oberkampf and Rue du Chemin Vert, the railway stations of Vincennes, St. Denis, and Orléans, the Pont Sully, the Pont Louis Philippe, the Boulevard Sébastopol, the Pont Neuf, the Rue du Louvre, the Palais Royal, the Rue des Pyramides, the Rue Castiglione, and the Place de la Concorde. The plan is a very defective one, and it is objected with reason that it would not be worth while to dig a row and tunnel for years in the middle of Paris to get a subterranean line which would be out of connexion the Gare St. Lazare and the Gare du Nord. Now, the number of passengers passing through Gare St. Lazare alone during the past year has been 30,280,000, a total not to be despised. It is objected also that M. Eiffel has not taken into consideration the difficulty of the subsoil lake which caused Garnier such trouble in forming the foundations of the Opera House. It will need gigantic engineering operations to render this portion of ground fit for a railway. The great system of sewers laid out under Belgrand will also be interfered with, at more than one point, by the new line. To get over this obstacle would demand another complete pulling up of streets which have already for the last six months been devastated by the operations of the electric car companies.

Nevertheless the idea of a Metropolitan Railway has taken such hold on the public mind of Paris that many people are disposed to accept the scheme, the best they can obtain if not the best in itself, which would contribute something to the facility of locomotion in Paris. The Committee dealing with the subject has also required certain modifications in the scheme, among them that of a branch line from the Gare St. Lazare to the Madeleine, another from the Gare Cluny to the Gare d'Orléans by the elevated St. Germain, and a connexion with the line which the Compagnie du Nord intend to push forward to the Halles Centrales. These important modifications or rather additions have been accepted by the Eiffel Company, and a few days the Municipal Council will discuss the whole project in this form.

The art exhibitions recommence with the usual. That of the "Blanc et Noir" has succeeded the series in the Pavillon de la Concorde de Paris, on the Champs Elysées. This exhibition, the fourth of its class, includes no

less than 1,500 drawings, pastels, engravings, etchings, &c. There are some very remarkable works there, among the foremost of which must be mentioned the remarkable cartoons, "Ludus pro patria" and "Légende de St. Geneviève," exhibited by M. Pavis de Chavannes; the drawings of M. Charles Jacques; the sketches of MM. Forain, Pille, Renouard, and Régamy, and the last drawings made by M. John Lewis Brown, whom a lingering but hopeless illness has unhappily debarred from any more exercise of his art.

The Service des Beaux-Arts has opened at the Hôtel de Ville an interesting exhibition of the works which were sent in competition for the decoration of the Galerie Lobau in the Hôtel de Ville. This gallery, which runs parallel with the Salle des Fêtes for its whole length, includes nineteen cupolas and two half cupolas. It has been already the object of one competition which came to nothing. We now find forty-six competitors, among whom are many names well known to the public. M. Charles Toché, the author of the decorations of Chenonceaux, has sent a series of watercolours, very spirited works, symbolising the leading corporations of Paris. M. Chabas, who has already obtained in competition the decoration of the Mairie of the fourteenth arrondissement, has associated himself with a talented young architect, M. Maubert, in a series of designs personifying the ancient and modern fêtes of Paris. M. Guillaume Dubufe has designed a green and gold scheme of decoration, with allegorical figures. M. Lucas sends a well-composed and interesting design. Many architects have entered into the competition independent of any aid from painters. Among these are M. Houllier, whose design for "Les Mois" are very pleasing, and M. Despony (Prix de Rome, 1884), whose ingenious designs are shown in black on a sky-blue ground, with very unfortunate effect. Of the political allegories (always too numerous on these occasions), the historical Republican scenes, and the apotheoses of revolutionary heroes, it is hardly necessary to speak, except to observe that they are entirely out of place in a decorative scheme of this nature. There are no doubt some very good designs, but no one of them seems to us to have realised what is required for a gallery in such a position, partially connected with a grand hall, and of which the decoration ought to form a portion of the scheme for the hall itself. Is it to be recognised that, at the close of the nineteenth century, the decorative art of France is in its decadence?

The centenary of the foundation of the Louvre Museum falls next year on the 26th of May. Many Parisian journals are proposing that this should be made the occasion of a public fête. Without going so far as that, we quite agree that the occasion may well be commemorated in some manner, either by the erection of a monumental group in marble or bronze, or by the issue of a medal; but which proposals have been made. In the meantime it is much to be regretted that the Louvre has not space at present for all the treasures which it possesses, and much to be wished that the Pavillon de Flore, no longer occupied by the Préfecture of the Seine, should be made use of to exhibit works which are now hidden away in attics. Regnault's celebrated picture of "Marchal Prim" was thus hidden away, when the public demanded its production, it was necessary to remove Gericaule's "Cuirassier"; and the same thing has happened in other cases, and the utilisation of the Pavillon de Flore for the purposes of the Museum entirely is the only way out of the difficulty.

In the matter of new buildings Paris has now possessed, for some days, the "Casino de Paris." This large block, between Rue Blanche and Rue de Clichy (on which latter is the principal façade), includes a hall of 2,000 square metres of area, and 18 metres high, the roof carried by a double row of light columns with caryatids at the top. This concert-room or ball-room, whichever it is to be, surrounded by a loggia, forms the vestibule to a "salle de spectacle" which will seat 1,600 persons. The whole is blazing with gilding, and is lighted by 2,000 electric lights; it is effective enough, but in a heavy and tasteless manner. The façade is hardly worth mention, except that the centre portion is occupied by an immense window which is filled with stained glass by Champigneulle, with a design signifying music, dancing, &c., according to the usual tendency of the decorations in places of public amusement of this kind.

The works at the Galliera Museum are advancing by slow degrees. The architect (M. Ginain) intends to construct in front of the principal façade a staircase which will be reached across a floor or court paved with mosaics. On the other side, the sculpture of the gable surrounding the pavilion which faces the Rue Pierre Charron has just been completed. The gable itself is decorated with the letters G. B. interlaced (Galliera-Brignolles).

The Minister of Public Works has given the order to proceed with the reinstating of the cornices, balconies, and colonnettes decorating the interior façades of the Palais Royal.

A few days since the École des Beaux-Arts opened the exhibition of the works executed at Rome, in 1889, at the Villa Medici. Among the architectural works M. Tournaire, a first year's pupil, exhibits four sheets of details of the Forum of Trajan and a drawing of a votive altar from the Vatican Museum. M. Chédanne, a second year's pupil, has sent in ten sheets of drawings, including a remarkably fine one of the Theatre of Marcellus. M. Defrasse (third year) sends plans, sections and details of the theatre at Epidaurus, and a drawing of the Ca d'Oro at Venice; and M. André (fourth year) has sent a restoration of the Forum and theatre at Ostia. The jury has given judgment on the architectural drawings of the first class of architectural students. Among fifty-eight designs sent in for the subject of "A Pantheon," second medals have been awarded to M. Banhain, pupil of MM. André and Laloux; to M. Vallat, pupil of MM. Douillard and Thierry; and to M. Desperthes, pupil of his father and of M. Ginain. In the sketch competition second medals have been awarded to M. Schule and M. Clousson, pupils of M. Ginain.

A few days previously, the competition for the Sévres prize took place, the subject of which, as before mentioned, was a table service and dessert service. Out of eleven designs submitted, the prize was awarded to M. Fournier, and three equal prizes to MM. Bonafoux, Maldémé, and Sandoy; all four being pupils in the National manufactory at Sévres.

We regret to record the death on October 16, of the painter Auguste Toulmouche, author of many charming genre pictures which have been popularised by engravings and photographs. He was born at Nantes in 1829, and came at an early age to Paris to study in the atelier of Gleyre, and exhibited his first work, a portrait, at the Salon at the age of nineteen. His early works after this were historical subjects, one of which gained him a third medal in the Salon of 1852. But he soon abandoned classic painting for genre and scenes of modern life, for which he obtained a great reputation. Among the best known are "Le Terrasse," "Après le Dîner," "Le Premier Chagrin," "Le Lendemain du Bal," "Un Mariage de Raison," "Le Lilas Blanc," &c. He received medals also in the Salons of 1861 and 1878, and in the great Exhibition of last year. He was a man much liked among those who knew him, and not spoiled by success.

We have to mention also the death of M. Gaston Melingue, former pupil of Léon Cogniet, who exhibited many times at the Salon; his last year's picture being "La Cigale et la Fourmi." He was a son of the eminent actor Melingue who created the part of Benvenuto Cellini at the Porte St. Martin Theatre, and who was also a sculptor of great ability.

THE ENGLISH IRON TRADE.—There is scarcely any change in the English iron market. Business is quiet, but a steady tone continues to prevail. In pig-iron trade is still restricted, and the greater part of such iron as is required for immediate wants is either supplied by second-hand holders or drawn from stocks, makers declining to sell except at their own prices. There has not been much fluctuation in Scotch warrants, but the tendency has been upwards. Middlesbrough pig is practically unchanged. Bessemer iron in the North-west is quiet, but steady, and the consumption is larger than the output. A moderate business is doing in finished iron, rates being tolerably steady. In steel a fairly active demand prevails, with prices firm. Shipbuilders and engineers continue busy.—Iron.

FRENCH GALLERY, PALM-MALL.—The private view at the French Gallery, 120, Palm-Mall, has been postponed from October 25 to November 15, in consequence of the death of Mr. Henry Wallis, the well-known owner of the Gallery, under whose management so many interesting exhibitions have been held there. The exhibition to be opened on the 15th will consist of a collection of the works of Mr. B. W. Leader, A.R.A.

A NEW BOILER-TUBE.

DURING last week some boiler trials were made at the works of the great Sheffield steel-makers, Messrs. John Brown & Co., Limited. As these trials are likely, so far as can be judged, to have a considerable influence on the engineering practice of the future we will give a few details of them, and also of the invention which they were intended to test.

This invention is of French origin and is of the simplest description. In place of the ordinary plain cylindrical boiler-tube, M. Serve, the inventor of this new tube, places on the inside eight continuous longitudinal ribs which project radially into the interior of the tube. These ribs are in depth (or height) about one quarter of the inside diameter of the tube. The object, of course, is to give additional surface for the absorption of heat from the gases and products of combustion passing through the tubes from the furnace, or combustion-chamber, to the smoke-box. It is a well-known fact that the stream of gases passing through a tube is generally hotter in the centre, or core; and the parts which have been cooled by contact with the metal of the tube remaining on the outside of the column as it passes; or, in other words, the gases travel in straight lines parallel to the axis of the tube. This being the case, it will be at once seen how effective in tapping the flow of heat these projecting ribs are likely to be. It may be objected that although there is more surface for the collection of heat from the gases, there is not any additional surface for the transmission of heat to the water of the boiler, as the outside of the Serve tube is the same as that of an ordinary tube; in fact, that there would be a choking of the flow of heat at the base of the ribs. The answer to this objection is that the chief resistance to the flow of heat through metal is experienced at the surfaces, and that once the heat is absorbed by the metal it can travel through the interior with great facility. This fact, the knowledge of which was first deduced from theoretical reasoning, has been amply proved by practical experiment; and it is well known to engineers that two boiler-plates of, say,  $\frac{1}{2}$  in. placed together, will not transmit heat so readily as one of 1 in., because of the increased surface resistance. Having said so much of the theory of the Serve tube, we will give a few practical details.

Some time ago the French Admiralty made a very exhaustive trial of the Serve system at the Dockyard at Brest. A boiler of ordinary construction was set apart for the purpose. It was first fitted with ordinary brass tubes, and tested under certain conditions. These tubes were then taken out, and Serve tubes of brass were fitted. We have before us a copy of the official report, but, without wearying our readers with the elaborate and complete details which are characteristic of French reports, we may give the chief results obtained in brief.

The heating-surface of the boiler was 375 square feet, and the grate surface  $14\frac{1}{2}$  square feet. There were sixty-four tubes, 6 ft.  $7\frac{1}{2}$  in. in length, and 3 in. outside diameter. The height of chimney was 40 ft. 8 in., the diameter being 18 in. The trials lasted over several days, and resulted in the following percentages of gain due to the Serve tubes:—

First day with natural draught	13.9 per cent.
Second ditto	15.6 "
First day with forced draught	
at $1\frac{1}{2}$ inches	17.2 "
Second day, ditto, at $1\frac{1}{2}$ inches	20.4 "
Third day, ditto, at 1 inch	22.2 "
Fourth day, ditto, at $\frac{3}{4}$ inch	19.8 "

We will not pause to comment on these remarkable figures, the importance of which is apparent on their face. The only thing against them, at the time they were made known in England, was that they were considered too good to be true.

Last week we had, however, the trials at Sheffield, to which allusion has already been made. The high standing of the firm making the experiments, and the fact that they were carried out under the inspection of several well-known engineers, including Mr. Ellis, of the Admiralty, and Mr. Milton, the Chief Engineer of Lloyds, was guarantee that everything would be done to ensure a fair trial. We may also be permitted to add our testimony to the willingness shown to allow the results to be verified in every way possible.

For the purposes of trial two ordinary return tube boilers had been constructed, each 10 ft. 6 in. long, and 10 ft. 6 in. in diameter, and exactly alike in all respects excepting that one had plain ordinary tubes, and the other Serve tubes. In each there were 126 tubes of  $3\frac{1}{2}$  in. outside diameter. In each boiler the area of grate surface was 31 square feet. The total area of heating surface in the Serve tubed (No. 1) boiler was 1,536 square feet, and of the boiler with ordinary tubes (No. 2) 956 square feet; the difference being entirely due to the ribs on the tubes being calculated as effective heating-surface. The total area for passage of gases through tubes was 802.36 square inches in No. 1 boiler, and 852.18 square inches in No. 2 boiler. This difference again was due to the ribs in the tubes only. The boilers were fitted with fans in the chimneys, so as to give an accelerated draught on the Martin principle. The coal used was of the very best quality, being Nixon's Navigation.

The trials commenced on Tuesday of last week, the 21st inst., there being a three hours' run with each boiler in the morning with  $\frac{1}{2}$  in. induced draught, as shown by the water-gauge. The result was briefly as follows:—

No. 1 Boiler (Serve Tubes).

Evaporation of water ...	32,500 lbs.
Coal burnt ...	34 cwt.

No. 2 Boiler (Plain Tubes).

Evaporation of water ...	31,000 lb.
Coal burnt ...	37 cwt.

This would be equal to 4.8 per cent. greater evaporation, and 1.1 per cent. more economy in fuel for No. 1 boiler.

In the afternoon a three hours' run was made with natural draught, the results being as follows:—

No. 1 Boiler.

Evaporation of water ...	18,200 lbs.
Coal burnt ...	16 cwt., 0 qr., 18 "

No. 2 Boiler.

Evaporation of water ...	20,100 "
Coal burnt ...	20 cwt.

This would equal 9.4 per cent. less water evaporated and 12 $\frac{1}{2}$  per cent. economy of fuel for boiler No. 1.

These trials may be taken as simply preliminary. In fact, they were of too short duration to afford any very conclusive test.

On the following day a twelve hours' trial was made, the coal consumption in both boilers being equal, this result being obtained by regulating the draught. The following results were obtained:—

No. 1 Boiler.

Water evaporated in 12 hrs.	114,600 lbs.
Coal burnt	11,872 "

No. 2 Boiler.

Water evaporated in 12 hrs.	103,000 lbs.
Coal burnt	11,872 "

These results show a superiority for the Serve tube of 11.26 per cent. in evaporation on the given quantity of coal.

On October 23 a seven hours' trial was made, the draught being  $\frac{3}{4}$  in. in both cases. The results were as follows:—

No. 1 Boiler.

Water evaporated	61,500 lbs.
Coal burnt	6,496 "

No. 2 Boiler.

Water evaporated	53,200 lbs.
Coal burnt	6,496 "

In this case, the Serve tube boiler showed an additional efficiency of 15.6 per cent.

On the last day of the trials, a 7 $\frac{1}{2}$  hours' run was made, under somewhat similar conditions to the last, when a superior efficiency of 15.86 per cent. was shown for the boiler with Serve tubes.

It will be seen by the above that a very remarkable advance has been made in the generation of steam,—the more remarkable, because so small a price has to be paid for the advantages derived. No doubt, the Serve tubes will be somewhat dearer than those of the ordinary kind, but we should imagine the extra cost would be but trifling compared to the advantages gained.

It should be stated that the French experiments were with brass tubes, whilst the tubes in the Sheffield boilers were of steel.

THE ARCHITECTURAL ASSOCIATION.\*

In May, 1887, a general conference of architects was held, and a day devoted to the question of architectural education. It is interesting to note the views of the various speakers, and I think that I cannot do better than give you a few extracts from the papers that were read on the subject on that occasion. These papers, as you are aware, were published by Mr. Cates in the form of a small hook, and a very useful and interesting book it is, too, as recording the views of those best able to speak on the subject. The hook also contains an introductory note by Mr. Cates, in which he says, speaking of the course of instruction adopted in three institutions in America: "These systematic courses, which have counterparts in Germany and Austria, contrast forcibly with the custom of pupillage adopted in England, which ensures only some three years of office training, such as it is, and leaves the student to acquire in a haphazard manner without due guidance or encouragement, or neglect altogether, knowledge which is indispensable; he thus too often becomes only a sketcher or draughtsman, or a mere practical man without sound scientific knowledge;" and further on: "A thorough and systematic scientific, practical, and artistic training, based on a sound general education, will ensure that the title of architect shall imply that its possessor may reasonably be expected to be a reliable and trustworthy adviser on all artistic and practical details..."; and again he says: "The burning questions of Federation and Registration which were to be considered at succeeding meetings, were less important to the well-being and prosperity of the profession than this vital one of education, which must largely influence any decision upon either of the others." We thus see that in 1887 Mr. Cates thought that the systematic course adopted in America contrasted forcibly with our English custom of pupillage, that a thorough and systematic scientific, practical, and artistic training was advisable, and that the burning questions of Federation and Registration were less important than the vital one of Education. Note that the words training and education are used, and not cramming and examination. I think we may therefore, look to Mr. Cates to help us either to persuade the Institute to start a course of instruction of its own or to help us with ours.

Professor Babcock in his paper insists upon the advantage of a thorough technical education for architects. His opening words are: "May I not assume, in the presence of educated gentlemen whom I have the honor to address, that the question of the desirability of educating young men specially for the profession of architecture is one that needs no discussion? May I not take it for granted that technical education is necessary in order that architects may keep up with the times? They must have a knowledge of art, of science, and of certain mechanical trade work. How can that knowledge best be acquired? Will the young men get it most readily and thoroughly in an office, through the casual and hurried hints of his employer, and the directions given by the chief draughtsman, supplemented by such reading as he can find time for? Or in a proper school, under skilled teachers, whose sole business is to instruct?" Professor Babcock says much more to the same effect, clearly advocating systematic training and I think we can judge for ourselves, by the work we see in the illustrated American papers, that the American architects are doing most excellent work, in spite of the disadvantages of living in a new country with no old work to study from. Although Professor Babcock advocates a complete course of school training before a young man enters an office, which is not quite what we are agitating for at present, yet his concluding words are of much interest and I give them here. "A few words in regard to the practical results of the effort which our schools are making to teach architecture. Students who graduate from the four years' course are enabled at once to get employment. Their acquirements in drawing, designing, and mathematics make them particularly useful to their employers, and they commonly get rapid promotion. Whatever can be learned in an office they are particularly well qualified to profit by. Their habits of study lead them to investigate anything that on first presentation may not be

\* President's address, continued from p. 327, ante.

ite clear. Their education has given them a wer of absorption and assimilation by which ey take in and digest knowledge from every available source. They soon learn the business ethods of an office, and after two or three ars of service may safely venture upon the actice of the profession." What a glorious uture for a young Englishman to contemplate, id for the English architect to sigh for! Com- ent assistants after four years' training, and mpetent architects after seven. On our side am afraid it is more like moderately com- ent assistants after seven years' training, and y more moderately competent architects after ten twelve.

The next paper that was read was by Mr. obins. It is full of interest from beginning to d, and you cannot do better than read the iginal for yourselves, as I can only give you re a few of the more pithy remarks made by r. Robins. He begins: "The examination of ichitects has long been an established fact. s first start was in the form of voluntary xaminations. The present examination is mpulsory for all who aspire to be associated ith the Royal Institute of British Architects. he education of architects is by no means an established fact; it is but an inference. It is ken for granted that architects are educated en, and that the examination was all that was eeded to show their title to the diploma, hich it was contended was necessary to give to he public the confidence they required, and to e architect the distinction he deserved."

"But if the examination has served any good urpose, it has certainly been the means of ening our eyes to the necessity for more eaduation, both general and technical."

And again, "the chance knowledge picked up by a pupil in an architect's office, brought ere straight from an ordinary middle-class hool innocent of either art or science, with uthing to learn, and nobody to teach him, not the sort of person calculated to dishonour he Institute, though he may have just eezed through and obtained a pass entitling e to become an Associate of the Institute."

"The standard of the Institute examination ill certainly have to be raised in the near uture, but it must be gradually done, and that onnexion with some well-organised scheme r imparting to architects the special know- edge they are admitted to require as professional en and practising architects seeking the Insti- tute diploma."

Further on he says: "While we are not satis- ed with the old system of apprenticeship, and ink it is not now sufficient for the needs of he profession, we are not now proposing to do way with apprenticeship, but, on the contrary, o render it more effective."

The last extract I will give you from Mr. obins' paper is as follows, and shows pretty early what his views as to the Institute "not eing a teaching body" are,—or, at any rate, ere:—"As to the day courses for pupils in offices, here again the want will create its means of satisfaction. And it is not altogether isionary to suppose that the Institute itself ight organise a system of teachers and lec- urers for architects' pupils."

I feel sure that the above extracts show that r. Robins is in favour of more systematic raining for architects, and that he will help us ither to persuade the Institute to supply the want, or help us to do so ourselves.

Sir Philip Magnus sent a communication to be the chairman of the meeting, in which he ys:—"It seems to me that there are distinct advantages in our own system (over the erman); but having regard to the scientific know- ledge which architects now require in the onstruction of all buildings, our present system, I venture to think, needs to be supple- mented by special instruction in a technical hool."

Mr. Arthur Hill, of Cork, next read a paper of considerable interest, beginning in the fol- lowing terms:—"In all professions, special training of some kind is an acknowledged necessity. The old-fashioned system of apprenticeship, whatever advantages it possessed, is now as much out of date for professions as it is for trades."

"If any one desired to make his son a doctor, would he bind him apprentice to the old family physician; to copy prescriptions; to read such medical books as might come in his way indiscriminately; and occasionally, perhaps, to have the benefit of a little carriage-exercise in his master's brougham? Would the process be likely to produce the highly-trained body of

scientific men who, as physicians and surgeons, are now to be found in every corner of the kingdom?"

Further on Mr. Hill says: "People fancy that the routine of an office and the payment of a fee will supply all the education that is needed from the time a boy leaves school until he is expected to be able to swim for himself. And even if any one thinks otherwise, where will he find the professional training he requires?" Mr. Hill later on adds: ". . . I believe the necessity of some system of education for architects is no longer in question; that nothing remains but to devise the way and the means. Since then (referring to a suggestion he made thirteen years before) the Royal Institute of British Architects' Examination has come into existence, and any system of education that may now be devised should be so built up that this examination may become the keystone of the whole." Mr. Hill, you observe, speaks of the Institute Examination as the keystone of a course of education, but what is a keystone without an arch? Something rather worse than a ship without a rudder. Having got our keystone first, how- ever, let us now go to work with our arch before it is altogether too late; but let us see what more Mr. Hill has to say on the subject. Continuing from my last extract, he says: "Now, examinations conducted without a properly-connected underlying system of tuition cannot be productive of any uniformity of result; a defect fatal to any broad influence of general benefit to the profession. But with a system of collegiate training not confined to the metrop- olis, but scattered in many parts of the king- dom, all working in harmony, preparing candidates for this examination, a very different result would be attained; for there can be no doubt young men who had spent two or three years in some college where their time was wholly devoted to study, and not frittered away in the common-place duties of a drawing-clerk, would ineffably surpass those whose reading was of the present promiscuous type, thereby tend- ing (1) to raise the standard of the examina- tions and consequently of the profession at large; (2) to impress the public with the advantage of proper preliminary training. . . . Of course, any scheme of education would be doomed to failure unless it were taken up by the profession at large with the intention of making it an ultimate success; and it is upon this particular aspect of the education question that the conference may be so influential." Mr. Hill is therefore clearly in favour of a system- atic training for young architects, and he further sees the advisability of any scheme of educa- tion being backed by the whole profession. (On this point I quite agree with him, and it is for this reason that I think our proper course is now to memorialise the Institute, either to start an educational course of its own, or to back and help us with ours. Mr. Hill's opinions being what they are, I think there can be little doubt but that he would help in whichever of the above courses was adopted.

Professor Aitchison followed with a paper which, though somewhat lugubrious in tone, yet advocated training of a systematic nature. He says: "It seems to me that as we cannot produce men with great intellects, and with a taste for architecture, our only plan is to look at what is wanted, and to render the acquisition of the necessary knowledge as easy as possible, and, above all things, to bear in mind that, though we cannot produce a genius, we may spoil one by smothering his talent under a mass of know- ledge (1) . . . We have, therefore, not only to provide the proper instruction for the one born architect, but we have to furnish the others with something that will more or less take the place of natural powers and invention." . . . "Though 'self-taught is well taught,' real systematic instruction is, in my opinion, invaluable; it not only saves time, but it is more thorough and complete; only the teaching must not be by pedants, however learned or able, but by men who know that their teaching is towards another end, and who will render it as useful as possible to that end. . . . From a look of preliminary knowledge pupils seem to me to leave an office at the very time the know- ledge they can only get there is beginning to be of use to them." Professor Aitchison would therefore help us, I have no doubt.

Professor Roger Smith in his paper advocated the formation of a studio, "where regular systematic instruction day by day, at the drawing-board chiefly, could be given, and, therefore, different from and in addition to the classes at

King's College or University College or the Architectural Association." The Professor's idea has been carried out by Messrs. Baggallay and Millard with considerable advantage to those attending; and in our proposed curriculum the "studio" plays a very important part. Therefore, as far as that goes, we may count on Professor Smith's support. As his paper was almost entirely confined to the suggested studio, I will only quote one more passage from the Professor's paper. He says: "No proposal for architectural education is, in the judgment of most of us,—certainly in mine,—likely to supersede pupillage as the most valuable way of fitting a youth for the practice of architecture. But something is needed that shall supplement pupillage."

Mr. Spiers followed with a paper describing the work done in the architectural school at the Royal Academy, of which, as you know, he is master. Mr. Spiers approved of the methods there adopted, and, in the course of his remarks, said: "I feel strongly, in these days of progress in education, that it is impossible to stand still, and, although the advance in architectural design, which has taken place in England during the last fifteen years, is greater than the most sanguine of us could have hoped, that very progress should give us hope, and incite us to further endeavours in the promotion of greater development." As we propose to introduce something after the manner of the Academy architectural school into our curriculum, and as Mr. Spiers says that in these days of progress we cannot stand still, he presumably would help us to move the Institute either to help us or start a system of training of its own.

Mr. Lawrence Booth, President of the Man- chester Architectural Association, said: "The Institute having obtained, under Royal sanction, enlarged powers, intended to increase its usefulness, there appears to be an implied obligation that no time should be lost in applying them to some practical purpose. . . . But if the Institute would only assume its proper position as the Alma Mater of the whole pro- fession, receiving and distributing valuable assistance without distinction or favour, it would at once become apparent that the pro- vince are capable of giving as well as re- ceiving something substantial for the general good." Again: "But, above all, there would be opened out for the Institute itself such a sphere of beneficent educational administra- tion as would enable it to justify even its regal title; and, by exhibiting to the world a body of high-minded men unselfishly seeking to qualify those of their own 'calling' as efficient and useful members of the community, it would assuage the doubts of those who, with an instinct pronouncedly national, might otherwise suspect in an application for the power of also- lute control over the entry into the practice of our profession only an attempt at a selfish monopoly, or, in other words, a mere develop- ment of trade unionism. . . . Once placed the education and training of students in the fore- front, as one at least of the Institute's most im- portant aims, recognised by it both as a privi- lege and as a responsibility, with equal earnest- ness, and there would be such an accession of numbers and strength as has not been either developed or even suspected to have an exist- ence." Mr. Booth is clearly with us in our endeavours to get established a more systematic course of training for our students, and he evidently thinks the Institute is the body to do it.

The last paper read at the meeting was one by Mr. Gotch, whose opinions on the subject are, I think, well known in this Association. However, I will complete the series by giving you two extracts from Mr. Gotch's paper. Speaking of the system of pupillage, he says: "And when he" (the young man) "is article- d, what does his apprenticeship do for him? In nine cases out of ten it makes him at the best an architectural practitioner; but as for being an architect, with a desire to tread the higher and nobler paths of the profession, very few offices make him that,—at least, pro- vidential offices. . . . Our supplemental charter will give us greater scope, and it will be one great step towards improving our system of education as if we establish such a series of examinations as has been sketched. It will bring the question into focus. There will yet remain the more difficult task of providing the agency by which the instruction necessary to meet these examinations is to be obtained. As a stop-gap, the course of study to be followed at existing institutions will be of great use; but I

for one shall hardly be content till the function now fulfilled on a voluntary system by the Architectural Association has devolved upon an authority recognised by the profession, and in a manner to reach not only students living in London, but those whose lot is cast in the obscurity of the provinces." We can count upon Mr. Gotoh, therefore, to assist the Institute on either to recognise and assist us or to do the work of education itself.

After all these papers,—ten in number including the chairman's opening remarks,—each one advocating education, the meeting promptly (probably with the assistance of a little wire-pulling) passed four resolutions in favour of examination! It is hard to understand, but so it was. However, I think the time has come when we all agree that something more than examination is necessary to ensure the production of a creditable generation of architects. I hope I have not tired you with the numerous extracts from the papers read at the conference of 1887. I have embodied them in this address to show that neither I nor our Committee are by any means alone in advocating a proper course of training for architects; neither am I alone in thinking that the Institute should bestir itself to provide, in some shape or another, such a course of training. I also referred to them to show that, if we approach the Institute on the subject, we have very good authority on our side for so doing; and, therefore, I once more press my suggestion that we should go boldly to the Institute, as it is the representative body of the profession, and ask the Council to either establish some course of architectural training itself, or help us to amend and strengthen our methods so as to meet the urgent requirements of the case.

Mr. J. D. Sedding proposed a vote of thanks to the President for his address. That meeting was no ordinary meeting, but was epoch-making; nor was the address which they had listened to an ordinary address,—for it was nothing less than a rallying-cry which asked for the co-operation of all the friends of the Architectural Association to come forward and help in what the President had called the crisis of its affairs. He did not think that was the right time or place for him to make any declaration upon the leading points of the President's address, but he could promise that when the proper occasion arose he would not be backward in furthering the interests of the Association as well as he could. He was heartily in accord with the proposals which had been made by their President and the Special Committee for improving the work of the Association and for giving ampler scope and permanence to its educational agencies. He fully trusted their judgment as to the best way for increasing the efficacy of the Association as an educational body. The present position of the Architectural Association afforded a vindication of the aims of its founders. To his mind, the nineteenth century, rich as it was in architectural trophies, had no more wonderful piece of building to show than that of the Architectural Association, and let them not blink the fact that that chief and only institution for the regular training of young architects represented the voluntary work of young men; and to him that was one of the noblest and saddest facts connected with its history. It was born of the thought, and sustained by the aspirations of the younger members of the profession. While the older men of the profession were busy looking after the main body of architects throughout the country it was left to the young men to provide the means of proper systematic teaching for the rising generation of architects, and right well had they carried out their task so far. But times changed, and movements grew, and development was a law of life. They could not stand still. For his part he liked a fine ideal, but he thought they were not ambitious enough in their proposed curriculum. They were seeking to systematise the knowledge of architecture as an art and as a science, and they desired to give a thorough, and systematic, practical, scientific training to the young architect. He was heartily with them in that, but he went even farther than they did. By all means let them have all they asked for,—book learning, class knowledge, examinations, &c.,—but let him of the ancient "picking-up system" plead for something to be added to their proposed curriculum, in the way of actual craft knowledge. What he wanted to insist upon was, that in any ideal scheme for an architect's academy, a youth that

was instructed there should have ample means of educating himself in practical art. In these days something besides class-knowledge and book knowledge was required. If they were artists, the labour of learning would be a joy in itself, and attainment their highest reward. To him an architect was an artist first, and as could make him; but he was an artist first, and should know his craft before he practised it. A young man learnt *technique* enough to imitate well before he grasped the meaning of expression, and he could not help thinking that they began as a rule to design too early. If they could only wait, and work, and study, and store their souls and imagination, and train their hands, it would be a great boon to architecture. It was because he believed that as in Medieval times, so now, the excellence of English architecture would be found to lie along the lines of interesting handicrafts, he hoped to see them find room for those classes of craft-instruction even in the proposed high curriculum of their ideal Architectural Association of the future.

Professor Roger Smith seconded the vote of thanks to the President for his address. With regard to his (the speaker's) recent remarks on the scheme of the Architectural Association in his opening lecture at the University of London, it had been said that he seemed to be too critical. He had no wish at all to suggest that, for the scheme was not only exceedingly satisfactory, but exceedingly creditable and encouraging. But every new scheme that was designed had some provisions which did not commend themselves to people outside with the same degree of force that others did; and with regard to the general proposals, it seemed to him that they were very extensive. In the Chairman's address, an idea was expressed that it would be desirable to get some help in the matter. If there was a general feeling that any help was needed beyond the support and good-will of every member of the architectural profession, he thought it might be due to the fact that the proposal as it stood was so very large and complete, and would re-cast the whole system of the Architectural Association. He wished to make the suggestion whether it might not be practical, useful, and safe to begin with part of their proposals by thoroughly establishing some of their classes for the first year; more in the second year; and more in the third; but always keeping the whole scheme in view. By all means, if it would call forth support, let them memorialise the Institute, but do not let them wait until the Institute was able to take up the matter of architectural education. He would strongly urge them to take the matter in hand and to carry it into execution themselves. Let them get as many friends as they could to help them; but he must say that if the active power in architectural instruction existed anywhere in England, it existed in that room. He cordially wished that they might obtain assistance from the Institute, or from a conference of architects or any other body that could help, but Heaven help those who help themselves, and the certainty of success which belonged to self-help was never more necessary than in the present case.

Mr. J. M. Brydon said that it seemed to him that they had the nucleus of a great deal in the curriculum which had been foreshadowed. There was no doubt that they had within them an amount of effort and strength which was bound in the end to succeed in which they desired. It had been said that good architecture or had architecture was a matter of opinion. It was nothing of the kind: it was a matter of knowledge, and the more strongly it was insisted on that what was good or what was bad in architecture was a matter of knowledge, the stronger would be their position in the future as architects. The idea of the proposed curriculum seemed to be an excellent one. They must not be afraid of losing their individuality, for that would come out strong enough. We dwell too much on individuality,—at all events in England,—and lost sight of the great movements which carry on the architecture of our country. Speaking as one without responsibility, he thought the Institute ought to help them. It was all very well to say, "God helps those who help themselves," but men were born to help each other; and if a reasonable, sensible scheme was brought before the Institute, he thought it would receive the greatest consideration.

Mr. Reginald T. Blomfield said that the question of education, under certain aspects, had been

thoroughly thrashed out; but one particular corner remained untouched, and that was the education of architects as artists. A certain amount of technical knowledge,—knowledge of construction, sanitation, and practice,—was indispensable to every architect; but given that there must be added the finer feeling, the strong imagination, the executive skill of the artist pure and simple, before a man could call himself an architect. The point he would like to raise was how far, in view of the existing state of architectural education and architectural attainment, are we justified in considering ourselves artists at all? They knew Lord Grimthorpe's position, and, unfortunately, that was the position of the great majority of the British public in regard to architecture. In the case of the sculptor, in the art nearest allied to architecture, years of patient study were spent on one specific subject, the figure. The sculptor did not rest till he had mastered each subtle change of line and plane, nor merely the anatomy of the muscles, but the whole relation and rhythm of the figure. He laboured with a singleness of eye and tenacity of purpose which, to an architect immersed in all sorts of studies, was amazing. Could we point to any single study which we followed out with a deliberate and sustained purpose all on a level with that of the sculptor or the painter? He was talking of the art of architecture, and did not know of any such himself. The architectural student read standard books and measured buildings, or parts of them, and made innumerable sketches; but he seldom considered draughtsmanship as much more than the acquisition of certain tricks of drawing, instead of what it is,—the basis of all art, the power of drawing rightly what the eye sees. And architecture was studied as a style, not as an organic and very flexible language. If the fault of the last generation was deadly dullness, the danger to the present generation was amateurishness. An architect no less than a sculptor or a painter dealt with form and colour; and in his sculpture and colour decorations the architect was in the same field as the sculptor and the painter; and to place himself in proper touch with those men an architect ought to go through some of their training. He would suggest as a means of advancing in that direction that architects ought to pay much more attention to figure-drawing. The figure was the standard of proportion for all architecture, and we had no other rule of infallible and unalterable certainty which we could apply to the architecture of all ages and all countries. It might surely then be expected of an architect that he should have something more than an amateur's knowledge of the proportion of the figure; and the readiest means of obtaining that was by incessant study, first from the antique and then from the model. Power of drawing the figure was the final test of all draughtsmanship. No less important for an architect who reckoned himself an artist was the power of modelling. Modelling the figure was out of the question for any but the most gifted, but there were many kinds of architectural sculpture; which, in themselves, did not require any great technical skill in modelling, provided there be behind it power of design and knowledge of the effect desired, such as foliage and those subtle gradations of abstract form in which the refined designer delighted. It was most important for the architect to control the general scale and arrangement of his sculpture, for he alone knew its relation to his building as a whole, and the readiest means of doing that was to sketch out himself in the clay the main lines and balance of the piece. He hoped we had left behind us for ever the time when architecture was one art and sculpture another. Between all the arts there must be complete interdependence if ever a great national art was to arise again among us. The first step in this direction was for the architect to place himself in touch with other artists, and in sympathy with any good workman in his craft, whatever it might be. The arts wanted shaking up together; the architect should go and work under the sculptor, and perhaps the sculptor and the painter might learn something from the architect, if they would deign to consider that poor practitioner an artist at all. They had excellent opportunities for cultivating that fellow-feeling in the Academy schools. To say nothing of their own technical improvement, it was a great thing to see how their own art was regarded by others; and if they could further that fellow-

THE KONIGSTRASSE, NÜRNBERG.—FROM A DRAWING BY MR. A. BERESFORD PITE, A.R.I.B.A.

THE PHOTO-LITHOGRAPHIC ARTS, WESTMINSTER AND ST. ANDREW'S, LONDON, E.

between the sister arts, it would be one forward towards the reinstatement of literature in her true position as the oldest of them all.

Mr. Thomas Blashill referred to the increased practical advantages which existed at the present time as compared with his year of office President of the Association, twenty-eight years ago. He thought the education of the artist was much too slow. Let them compare themselves with other professions. In the legal profession, for instance, a young man would spend five or six years in it, and at the end of that time he would be turned out, perhaps far from being a first-rate physician, but qualified to be entrusted with responsible work as no architect would be called upon to undertake in the whole course of his life. He would venture to suggest to those gentlemen present the matter in hand to get up some system which should turn out competent men in a few years.

Mr. A. W. Earle believed that the claims of the Association to the position of Alma Mater in educational matters was recognised by the profession generally.

The vote of thanks having been put and read unanimously, the Chairman briefly lied, and the meeting terminated.

LECTURES ON HOMERIC GREECE.

The subject of Mr. Leaf's second lecture on Wednesday last week was "The Comparative Remains of the Prehistoric Remains and the Homeric Ages," a question, he said, of great complexity, difficult to treat within the space of an hour. The lecture began with a brief review of the prehistoric remains in Greece. *Properly* speaking, it will be remembered, had been discussed in the first lecture. As regards Tiryns, town seems to have completely sunk in importance before the "Homeric" age, at that time obviously Argos is supreme. Mr. Leaf drew special attention to the chambers in the walls at Tiryns. Similar structures have been discovered at Carthage, and this has led Dr. Dörpfeld to a hypothesis that the Tiryns fortification is of Phoenician origin. Mr. Leaf admitted the possibility, but laid great stress on the fact that local tradition had always assigned Mycenaean origin to the Tiryns structures.

Passing to Mycenae, the lecturer noted that two epochs must be carefully distinguished—(1) that of the shaft-tombs; (2) that of the above chambers. The citadel walls, following the contour of the circle which contains the shaft-tombs, must be later than those, and from their excellent masonry it appears that they are roughly contemporaneous with the beehive tombs. The pottery, known as Mycenaean, has been found also in Egypt, and it can be accurately dated as of the fifteenth century, B.C. It is a marked advance on that found at Hissarlik. Beehive tombs have, it is well known, been found in many other parts of Greece,—notably Menidi, Spata, and Vaphio. The art of Vaphio, as seen in the famous gold cups, is by far the most developed of this particular civilisation. Nor is this surprising, as the Achaean civilisation held its own against the incoming Dorian longer at Mycenae than at any other stronghold. It is in the older of the beehive tombs that we must look, according to Mr. Leaf, for the Achaeans of Homer, if anywhere. The objections urged by some in this view were discussed and refuted. Passing to literary matters, which we note only so far as they are related to archaeology, Mr. Leaf stated that in the "Iliad," three stages of development could be clearly made out: (1) the original poem of the "Wrath of Achilles," mainly books 1, 11, 16, 22, and next the later additions, *i.e.* (2) songs in "praise" of the deeds of particular heroes; (3) portions composed for the sake of the poetry only. Dating these three strata with respect to the Dorian invasion,—the only possible means of dating them,—it is probable, according to the lecturer, that the first and second strata were composed before the Dorian invasion, the third after. On this point Mr. Leaf differs from Professor John. The main result is that the "Iliad" is the work of many minds, whereas the "Odyssey" has a unity that shows its final form, at least, is the work of one mind; hence its greater readability.

As to the relation between the remains and the poems, a general correspondence certainly exists. In matters of detailed topography this correspondence is precise in all the portions be-

longing to the third stage of development,—*i.e.*, the part written in Ionia,—very rough in the first and second strata, where the poet was only acquainted by hearsay.

Dr. Leaf's third lecture at the Chelsea Town Hall on Wednesday last dealt with the Homeric House. The chief literary sources of our knowledge are the descriptions of the palaces of Priam and Paris in the sixth Iliad and the complete account of the Palace of Odysseus in Odyssey 17-23. In accordance with his usual method, the lecturer took these as read, and proceeded to show the plan of the Homeric House as restored by Professor Jehb and Professor Gardner. All are agreed that the three main divisions were the Anle or courtyard, the Megaron of the hall, and the Thalamos, which Dr. Leaf prefers to translate as dwelling-house rather than, as it is often taken, as Gynaikonitis, or women's apartment. In certain matters of detail, however, the lecturer showed that the plan must be corrected from the remains excavated. Thus the hearth must be placed in the middle of the megaron, not at the further end. Four columns instead of eight (as on the plan) supported the roof, and colonnades in all probability surrounded at least a portion of the anle or courtyard. The idea that the thalamos was a women's apartment from which men, save the husband and son, were strictly excluded, is wholly un-Homeric, and savours of Orientalism. In the "Odyssey," Penelope, it is true, dwelt apart in the thalamos, but there is no hint of entire seclusion,—it was simply natural that she should not go down needlessly into the megaron when it was beset by the unwelcome suitors. One of the main points for which Dr. Leaf contended was that whereas in pre-Homeric palaces, like that, *e.g.*, of Tiryns, the women's apartment was remote, in the genuine Homeric house there was easy intercommunication.

Noting briefly the main points of the much-disputed topography of the "house of Odysseus," the lecturer said that he differed from Messrs. Butcher and Lang in respect to the question of the stone and wooden thresholds. In the plan as at present accepted the two are regarded as distinct, the wooden threshold is placed at the end, near the courtyard, the stone one near the thalamos. Dr. Leaf believes there were no two thresholds, the wood and the stone ones are all the same. Homer's epithets, he pointed out, are always decorative rather than descriptive. Further, if there were two thresholds, it would manifestly be improbable that the wooden one would be towards the outside, the stone one towards the thalamos.

A point of great interest is the significance of the tholos in the Homeric house. The single mention of it is in the Odyssey,—the wicked serving-maids are caught and killed between the tholos and the wall. In the prose translation of the Odyssey by Messrs. Butcher and Lang, the word is rendered "kitchen-dome." The idea of a dome is essential to the tholos; kitchen is a mere conjecture. In place of this conjecture Dr. Leaf hazarded a new and very interesting theory. Mr. Frazer, in his recent treatise on Vesta, has shown clearly that the primitive form of the house was among many people the tholos. It has already been seen that the tholos was the primitive form of a tomb, and the tomb,—the house of the dead man,—is instinctively modelled by all primitive races on the home of the living. The tholos contained the sacred fire—sacred at a time when fire was difficult to procure, and must be carefully guarded. It is remarkable that the worship of Vesta or Hestia, the primitive hearth-fire goddess, nowhere appears in Homer, and it seems possible that this cult was absorbed by the great Olympian—absorber of many a local cult, Zeus. It is noticeable that an altar of Zeus Heiois—Zeus of the homestead—appears in Homer, and it is an ingenious conjecture of Dr. Leaf's that this altar may have had a circular tholos covering of some perishable material. The next lecture (Wednesday, 5th, at 5 p.m., Chelsea Town Hall) will deal with Homeric dress and armour. We propose to note, as before, such points as are novel in the treatment.

ROYAL VICTORIA HALL, WATERLOO BRIDGE-ROAD, S.E.—The following are some of the arrangements for Tuesday evening lectures at the above hall during November.—November 4, Mr. Arnold Mitchell on "Old Buildings and the Story They Tell." November 18, Mr. A. P. Laurie, "Air and Water," with experiments. The oxyhydrogen lantern will be used with these lectures.

ELECTRIC TRAMWAYS IN AMERICA.

ONE of the features most interesting to an Englishman now revisiting the United States, after an absence of a few years, is the great advance that has been made in the system of street railways, or tramways, as they are more popularly called in England. We use the word "advance" in this connexion advisedly, for there can be no two opinions as to the great superiority to the passenger of the methods of mechanical haulage, by means of electricity or cable line, now so universal, over the old system of horse traction. A paper read by Mr. F. J. Sprague supplies us with some rather striking facts in connexion with electric traction. Six years ago, he says, there were scarcely a hundred electric motors in operation in the United States for any purpose. At the time he read his paper there were fifteen thousand in use, applied to two hundred different industries. With regard to street railways, Mr. Sprague says that the storage battery system has been quite outpaced, it being necessary to have a weight of 3,500 lbs. to propel an ordinary street car. This limits the speed and the grade of line upon which the cars can be worked. The expense, too, is about double that of the overhead conductor system, although less than that of horse traction. The conduit system, in which the electrical conductor is placed in a trough beneath the roadway, has also been tried, and found to be inferior to the overhead wire, only a very short section in Allegheny city remaining in use out of the many miles laid down in various towns of the States. It is, as has been intimated, the overhead conductor system that has made the greatest progress. There are, or rather, were when Mr. Sprague read his paper, 130 towns or cities in the United States with one or more electric railways in operation or under contract, comprising about 1,500 miles of track. They were equipped with 1,700 motor cars, and 3,000 motors. The roads then in operation were making 100,000 miles per day, a mileage which, if arrangements then made have been duly carried out, has since been doubled. Grades of 12½ to 14 per cent. have been ascended by a motor car pulling a second car. In crowded cities the speed has increased 50 per cent., and in the suburbs twenty miles an hour are made.

Electric traction is, however, moving with such rapid strides in the United States, and, as Mr. Sprague's paper has been read some time, no doubt the figures would prove much more startling were statistics available to bring them up to date; for instance, we learn by a recent American contemporary that the Westinghouse-Pullman Company has just been formed, and will start by erecting works to the value of 500,000 dollars, for the manufacture of electric street cars.

The chief objection to the overhead system is the inconvenience of having standards erected at intervals along the street to carry the wire. In a country that tolerates the elevated railroad this is but a trifle. Whether English local authorities can be educated to allow such an obstruction remains to be proved. An electro-motive force of 500 volts is used, and this, although unpleasant to the human frame, is not in itself dangerous to life; besides which the wire is placed far out of reach. Another objection is the disturbance caused to telephones through induction, but this will not apply for long if we may credit what Mr. Prece has recently said, that all telephones will soon have metallic returns; a step which we may remark in passing will render the telephone a real convenience, and not, as it was recently described, "an invention of the Evil-one, devised to propagate the use of profane language."

OVERFLOW OF WATER-TANK AT THE FOREIGN OFFICE.—On Sunday morning the overflowing of the water-tank which surmounts the tower of the building, facing St. James's Park, caused considerable commotion. Some weeks ago plumbers were engaged to repair the tank, and fixed in it some new ball floats, which, it appears, were placed so that they could not rise and fall freely. This, it seems, caused the overflow, and the water entered almost every room in the building. A messenger was despatched to the Office of Works, where a plumber is always on duty. The latter succeeded in turning off the water, when the flow soon ceased, but not until great damage had been caused to papers and furniture. The Tower Room was flooded, as was also another apartment between it and Lord Salisbury's room.

## Illustrations.

## KÖNIGSTRASSE, NÜRNBERG.

**T**HOUGH Nürnberg has earned the title of the "Birmingham of Germany," its ancient walls still enclose a city almost without a rival for Mediaeval character and picturesqueness.

The electric light and steam tramways that it now enjoys, as well as the enormous railway-carriage manufacturing industry, have refrained themselves, as becomes such creatures of the nineteenth century, from altering to any serious extent the streets and buildings in which Albert Dürer and his friends lived and moved. The principal street of the St. Lawrence side of the town is represented in the sketch, and is called the Königstrasse. The proud free city of the Middle Ages must have had some other name for its high street than this in its golden days, before it was handed over to the Bavarians by Napoleon in 1806.

The Church of St. Lawrence stands at a bend of the street, with its twin "gridiron" helly stages. Opposite its western end is the Nassauer House, on the left of the picture the fine Halle Gebäude, and on the right, in suggestive contrast, a large modern drapery establishment. The general character of the streets of Nürnberg, its wonderful dormers and quaint oriels, is well illustrated by the Königstrasse. A. BERESFORD PITE.

## SCULPTURE, SOLDIERS' AND SAILORS' MONUMENT, CLEVELAND, OHIO.

This is a monument to soldiers and sailors of Cleveland who fell in the great American war between the North and South, now ancient history in a sense, but the memory of which still has the greatest interest for all who can appreciate the great issue of the struggle, and the amount of military genius and heroism which it called forth.

The monument was designed, and the sculpture modelled, by Mr. Levi T. Scofield, who also took an active part in the war, first as soldier and then as officer, and, in modelling the four sculpture subjects which stand on pedestals opposite the four faces of the monument, was to a great extent illustrating scenes in which he had himself taken part.

For the architectural design of the monument, of which we give a small sketch (mainly to indicate how the sculpture groups illustrated are connected with it), we fear we cannot express much admiration, and perhaps of criticism will hardly pass the ordeal of criticism from the London or Paris studio point of view; but we think our readers will agree that there is a considerable interest in this attempt to make sculpture subservient to the representation of actual and realistic fact from the battle-field, and by an eye-witness of the scenes represented.

The groups are in bronze, but the illustrations were photographed from the plaster models in the artist's studio, under the disadvantage of restricted space which did not allow of an advantageous position for the camera, and hence a certain degree of unavoidable distortion in some of the figures.

The Artillery group "At Short Range" represents an actual incident in the battle field, when the man who had just withdrawn the rammer from the gun was shot in the heart and staggered back with his left arm over the gun for support and his right still grasping the rammer. The Infantry service is represented by "Colour Guard," and also records an actual incident in the war, which we give in the sculptor's own words:—

"At the battle of Resaca, the 103rd Ohio Infantry, charging in line, had carried the two outer lines of the enemy, and had been ordered to lie down in the abattis for a short rest, preparatory to the final charge over the main line. The brave colour-sergeant and the eight corporals forming the guard would not lie down, and were all killed or wounded. The sergeant, Martin Striebler, was of gigantic stature, and while waving the flag over the line, was shot with a bullet through the centre of his forehead, and had from twenty to thirty other wounds on his body. The tattered colours are now in the flag-room at the Columbus capital, and after twenty-seven years still retain the blood stains of the dead hero."

The Cavalry group, "The Advance Guard," represents a detachment that has struck the line of the enemy; we give the author's description again:—

"A trooper is still astride his horse

Soldiers' and Sailors' Monument, Cleveland, Ohio.

that has fallen with a bad wound. A venturesome Confederate soldier has noticed his predicament, and has made a rush for the guidon, but the cavalryman has whipped out his revolver, has given "Johnny Reb" one in the face, and is prepared for another shot. A Confederate officer has seized the rebel flag from the fallen bearer, and is cheering his men to the assault. A dismounted trooper in front, on one knee, is covering his man with his carbine. The bugler has been sent forward from the reserve by his officer to see how matters were progressing at the front. Finding them hard pressed and stubbornly trying to hold their ground, he has dismounted, and is sending back a bugle-call for assistance. The Confederate soldiers were introduced in this historical group to show to posterity what they and their flag were like."

The Navy group, "Mortar Practice," represents a scene near Island No. 10 on the Mississippi river, where an officer and five men are landing a mortar preparatory to shelling the intrenchments.

The statuary, as already observed, will be of cast bronze, the building and shaft of dark granite. The total height, to the top of the crowning figure of "Liberty," is 125 ft.; the base of the whole monument is 100 ft. square, and the building 40 ft. square; the pedestals on which the groups rest are 19 by 7 ft. The figures are about 8 ft. in height. The interior of the building will be marble, and will have coloured marble tablets on which will be engraved the names of the soldiers that were sent to the war of the rebellion from Cleveland, 10,000 in number. The total cost of the monument will be 100,000 dollars.

## DESIGN FOR A PUBLIC LIBRARY.

This design for a public library for a small country town, by Mr. W. Pywell, gained its author the Architectural Association medal for this year. We give the perspective view and the ground and first floor plans.

The following was the definition of the subject which was given to competitors:—"A

Public Library for a County Town.—On a corner site, the principal frontage measuring 100 ft., with a depth of 50 ft. down side street. Accommodation required:—Storage for books, porter's residence, and heating-chamber, &c., in basement; lending library, with space for 30,000 volumes, and a news-room, with small room off same for magazines, lavatories, &c., on ground-floor; reading-room, with accommodation for 20,000 volumes; small room off reading-room for librarian, and a committee-room on the first-floor. On the second floor should be placed residential chambers for the librarian and storage for books."

## HOUSE AT WIMBLEDON.

This house, designed by Mr. J. Ransome, stands on a corner site, facing the Malcolm and Worple-roads, at Wimbledon. The roof and walls (to the level of the first floor) of this house are hung with tiles taken off an old barn, which has been lately pulled down.

Owing to the age of these tiles the building has escaped the glaring red colour which is the chief defect in all new tile-hung structures. Below the level of the first floor the walls are of red brickwork, the mullions and transoms of the windows being in wood painted white. The dining-room and drawing-room open on to a verandah with a southern aspect. The surgery and dispensary are approached only from the lobby and have no communication with the rest of the house.

The large angle window, on the first floor, lights the morning-room, which is off the landing half-way up the staircase. Mr. Ernest Knight, of Morden, was the contractor.

## HOUSE AT SUTTON.

This house has been erected at Sutton, Surrey. The walls up to the first floor are hollow, and are faced with red bricks; the walls above and the roofs throughout are hung with Broseley tiles. The external woodwork has been stained dark brown, oiled and rubbed down; the hall being treated in the same manner. The casements throughout are of

THE ART CONGRESS AT BIRMINGHAM.

THE prospectus of the proceedings at the Art Congress at Birmingham next week has only just been finally arranged in all its details. The following is the list as it now stands; the sections referred to by letters of the alphabet are as follows:—

- A=Painting.
- B=Sculpture.
- C=Architecture.
- D=Applied Arts.
- E=Museums and National and Municipal Encouragement of Art.

Order of Proceedings.

Tuesday, November 4. — 10 a.m., Meeting of Council, No. 1 Committee Room, Council House. 11 a.m., Mr. P. H. Rathbone, Presidential Address in Section E; Mr. J. Thackray Bunco on "Encouragement of Art by Municipalities;" Mr. T. Stirling Lee on "Municipalities in their relation to Art Schools;" 2 p.m., Combined Meeting of Sections B and C; Mr. Roscoe Mullins on "Sculpture as an Internal Decoration;" Mr. Ralph Nevill on "The Study of Local Architecture, especially for Schools of Art;" Combined Meeting of Sections A and D; Mr. Selwyn Image on "Colour in relation to Internal Decoration;" 8 p.m., Inaugural Address by the President, Mr. J. E. Hodgson, R.A., at the Midland Institute.

Wednesday, November 5.—11 a.m., Mr. T. G. Jackson, F.S.A., Presidential Address in Section C; Mr. E. T. Blomfield, on "Architect and Artist;" Mr. H. H. Statham, on "Ancient Buildings and Modern Architectures;" 2 p.m., Section A; Papers by Mr. John Brett, A.A., on "Education in Art;" Mr. Stanhope Forbes (not fixed); and Mr. W. J. Wainwright, A.R.W.S., on "Some remarks on the English School of Water Colour Painting;" 2 p.m., Combined Meeting of Sections B, C, D, E; Mr. Heywood Sumner on "Advertisements;" Mr. C. Bidlake on "Architectural Drawing;" Mr. T. R. Abbott on "The Drawing Society;" 8 p.m., Reception by the Mayor (Alderman Clayton) at the Council House.

Thursday, November 6.—11 a.m., Mr. A. H. Mackmurdo, Presidential Address in Section D; and Mr. Alfred Gilbert, A.R.A., on "Metalwork;" 2 p.m., Mr. Henry Holiday, on "The Figure in Design;" Mr. J. W. Teas, on "Art as applied to Jewellery and Personal Ornament;" 2 p.m., Combined Meeting of Sections A, B, C, E; Mr. James Crook, R.I., on "A Gallery of British Art;" 4 p.m., Reception by Royal Birmingham Society of Artists, New Street.

Friday, November 7.—11 a.m., Mr. G. Simonds, Presidential Address in Section B; Mr. E. Onslow Ford, A.R.A., on "The Modern Education of Sculptors;" Mr. B. Creswick (Modelling Master Birmingham Municipal School of Art), on "The Relation of Sculpture to Architecture;" 2 p.m., Section E; Mr. William Kenrick, M.P., on "Technical Education as applied to Art Industry;" Mr. C. B. Ashbee, on "How can we foster Art at our Polytechnics?" 2 p.m., Combined Meeting of Sections A, B, C, D; Mr. Aston Webb, on "Architecture and Education in the Future;" Mr. F. G. Jackson (Master of Design Birmingham Municipal School of Art), on "Art Education in relation to Industry;" 8 p.m., Reception by Local Committee at Edgchaston Assembly Rooms.

Saturday, November 8.—11 a.m., Mr. W. B. Richmond, A.R.A., President of Section A, followed by the General Meeting.

There will be three Evening Lectures for Working Men, at 8 p.m., on Wednesday, Thursday, and Friday evenings, in the Large Lecture Theatre of the Midland Institute. They will be by:—Mr. Starke Gardner, on "Metalwork;" Mr. J. E. Hodgson, R.A., on "Art Books;" and Mr. Henry Holiday on "Glass."

The reception room will be in the Town-hall. The sections will meet in the large lecture theatre at the Midland Institute, and in the Council-chamber at the Council House; but we observe that the card of meetings sent out does not state in which of these two rooms each set of papers will be read; this is not very business-like, and the omission is likely to cause inconvenience to visitors.

Various local manufacturers will be open during the week to members of the Congress, including those of the Birmingham Small Arms and Metal Co.; Messrs. Elkington's Electroplate Manufactory; Messrs. Hardman's Stained Glass Works; Messrs. Hart Son & Peard's "Art Metal Works;" Mr. T. Moore's Die Sinking Medal and Seal Engraving Works;

Messrs. Osler's Glass-cutting rooms; Messrs. Wexley & Sons' gun and rifle manufacturing; Messrs. Winfields, where tube drawing and metal rolling is combined with stained-glass work. But the great show of the year, among the accompaniments to the Congress, is the collection of the works of David Cox, got together with great pains by Mr. Whitworth Wallis, the energetic curator of the Art Museum, and which is such a representative collection of the great water-colour artist's work as probably will not be seen in one room again.

THE LONDON COUNTY COUNCIL.

THE usual weekly meeting of the London County Council took place on Tuesday, at Spring-gardens, Sir John Lubbock, M.P., in the chair.

Improvements at Bethnal-green.—Nearly the whole time of the Council was devoted to the consideration of a report of the Housing of the Working Classes Committee or a scheme for the improvement of a certain part of Bethnal-green. The following is the greater part of the report:—

"On July 19 last the Medical Officer of Health for Bethnal-green made an official representation to the Council under the Artisans and Labourers' Dwellings Improvement Act, 1875 (better known as Cross's Act), relating to an unhealthy area in that district, and on September 19 the Medical Officer for Shore-ditch represented a small area in that parish immediately adjoining the Bethnal-green area. Since the representation relative to Bethnal-green was made, Cross's Act has been repealed, and your Committee have obtained a fresh representation under part I of the Housing of the Working Classes Act, 1890, which is practically identical with Cross's Act, except that some of the compensation clauses are a little improved. The representations were referred to the Medical Officer of the Council for report, and his report substantiates the statements as to the condition of the area contained in them. The representations from Bethnal-green and Shore-ditch are dealt with as one in the report, as the officers of the Council advise that the receiptment and opening-up of the area in Bethnal-green are materially assisted by including the small neighbouring area in Shore-ditch. Your Committee have at various times personally inspected the area, and were especially struck by the narrowness of the streets, the widest measuring only 28 ft. There is also a great difference of level between the streets and the floors of the houses, in some cases as much as 18 in., and the appearance of the inhabitants indicates to your Committee a low standard of vitality. In many cases there are no back-yards. The total area is about fifteen acres in extent, and is bounded on the north by Virginia-road, and St. Leonard's churchyard, on the west by Boundary-street and High-street, on the south by Church-street, and on the east by Mount-street. The streets are twenty in number. The average population per room is about 2½, and 107 rooms have five or more inhabitants each. There are many small courts, a very few lanes. The area comprises 730 houses, of which 652 are occupied, wholly or partly, by persons of the labouring classes; the remaining 78 houses consist of 12 public-houses and beer-shops, 21 shops and factories, 2 registered lodging-houses (153 beds); and 43 empty houses. The population, exclusive of those in lodging-houses, is 5,596—viz., 3,370 adults and 2,196 children, who occupy 2,445 rooms subdivided as follows:—2,118 persons occupying 752 single-room tenements; 2,265 persons occupying 608 two-room tenements; 1,183 persons occupying 211 tenements of 3 or more rooms (781 rooms). Including those in the lodging-houses, the total number of persons of the labouring classes displaced will be 5,719. The above facts effectually remove any doubts as to the metropolitan importance of the scheme. The houses (mostly two-story dwellings) are generally small, old, and dilapidated. In many of them the ground floor is situated below the level of the street pavement, which renders the lower rooms very damp. The floors themselves lie on the earth, and there are no damp courses. On the eastern side of the area are many ill-ventilated courts and narrow streets. The Medical Officer for Bethnal-green reports that 'a low condition of health prevails in the area, and that this is due to the bad condition of the houses, and to the bad arrangement of the streets and courts.' He further says that 'the lighting and ventilation of many of the houses are defective, and that a number of them are insufficiently provided with proper sanitary conveniences, inasmuch as the only access to the closet in the yard is through a dark, badly-ventilated cellar.' The opinion which has been formed by your Committee as to the condition of this area is fully borne out by the statistical evidence which has been adduced concerning it. The following striking figures are extracted from a report furnished by the medical officer of Bethnal-green. The deaths registered and relating to that part of the area situated in

Bethnal-green, being nineteen-twentieths of the total area, give the following rates of mortality. Those in Bethnal-green as a whole are also stated for the purposes of comparison—

	Bethnal-green	Represented green area	Represented area
	(1886-88)	(1889-88)	(1889 only)
	Per 1,000.	Per 1,000.	Per 1,000.
General mortality	23.3	49.0	40.13
Deaths from zymotic diseases	2.7	7.9	10.71
Deaths from tubercular, &c. diseases	3.9	8.5	7.26

It is therefore evident that about twice as many persons die in this area each year as would die if the mortality were the same as in Bethnal-green as a whole. Your committee have made further inquiry as to the rate of infant mortality in the area as affording yet more precise evidence, and find that while in the four years 1886-89 in Bethnal-green as a whole an average of 159 deaths occurred annually among children under one year of age to every 1,000 births, in this particular part of Bethnal-green the average annual number of deaths of such children was during that period 252 to every 1,000 births. It will be seen that, whether judged by the general death rate or by death-rates from those classes of diseases which are especially associated with unwholesome conditions, this area is pre-eminently one that demands a comprehensive scheme. The density of the population alone shows that some radical re-arrangement is necessary, and in this area, consisting almost entirely of one-story houses, there are living 373 persons per acre, whereas over Bethnal-green generally, by the last census, the population is 163 per acre. The Valuer's estimate of the gross cost of the scheme is 371,000l., from which must be deducted the estimated recoupment of 106,000l. There must be added the Engineer's estimate of the cost of the new and widened streets, a sum of 35,000l., bringing the total estimated net cost of the scheme to 300,000l., which, reckoning on a loan for 60 years, becomes a burden to the ratepayers (including interest) of 14,000l. for the first year, a charge which will diminish each subsequent year. The gross cost of the scheme has been carefully considered by your Committee, but they are of opinion that the large saving of life which may be expected as the result of the scheme more than compensates for the cost. Your Committee, in their report presented on April 22 last, dealt with the re-housing of people displaced under such a scheme as this, and expressed the opinion that they should, if possible, have some means of re-housing, however temporarily, some of those displaced. Your Committee have taken steps to ascertain what vacant land, if any, exists in the vicinity, and hope to embody the information obtained in a later report. It is not, however, the intention of the Committee, if the scheme is approved by the Council, to clear the whole area at once, but rather to deal with it in sections, and thus avoid the necessity of disturbing more than a limited number at a time. Your Committee draw the attention of the Council to the fact that October 28 is the latest day upon which the area can be dealt with under a scheme without a year's delay, as Part I. of the Act of 1890 prescribes that advertisements must be published in three consecutive weeks in the month of November. Your Committee submit the following formal recommendations:—

(a) That, subject to the necessary estimate being submitted to the Council by the Finance Committee, as required by the statute, the necessary resolution under section 4 of the Housing of the Working Classes Act, 1890, be passed by the Council, and that the seal of the Council be affixed thereto.

(b) That the draft scheme submitted by the Committee for the improvement of the area referred to in the foregoing resolution, be approved, and that it be referred to the Committee to complete the scheme, and to take all the necessary steps for depositing and obtaining confirmation thereof."

Lord Compton, M.P. (Chairman of the Committee), in introducing the report, said that the scheme was the first big scheme brought before the Council by the Housing of the Working Classes Committee. The local authority had stated their distinct opinion that the whole area was unfit for habitation; and they had also informed the Council that in their opinion the area should not be dealt with except as a whole, and that it should be considered a metropolitan and not a local improvement. The death-rate was very high, and in consequence of the insanitary condition of the whole area, two people had died, as compared with one who died in other parts of Bethnal-green. The Committee had very carefully inquired into the matter, and had come to a unanimous conclusion that the whole area was in a very insanitary condition; but as to the manner in which the area should be dealt with, there was a difference of opinion even on the Committee. The eastern part of the area was rather more insanitary than the western part; but the death-rate in the two parts was about the same. The matter could be dealt with under Cross's Act or Torrens's Act, or under both partly. A strong

opinion prevailed that the area should be dealt with as a whole under Part 1 of the Act, and as a Metropolitan improvement. They did not propose that the improvement should be carried out immediately by pulling down all the houses, for that would cause a great deal of misery; but that they should gradually put the whole area into a better state. With regard to the cost, he frankly admitted that 300,000*l.* was a large sum to ask for; but the matter was one of human life. He hoped the Council would act in no niggardly spirit. If they dealt with the area in small sections, they would be merely tinkering with the matter, and the scheme would have to be gone into at a subsequent date. An extraordinary amount of immorality also existed in this area, which was the inevitable result of its insanitary character. He concluded by asking that they might deal with the matter as a whole and shed a little more purity into that part of London.

Mr. Watney moved as an amendment:—"That it be referred back to the Committee to report to the Council whether, under the Act of last session, the Council is not able to make the owners put their houses in a satisfactory condition without charge to the ratepayers." If the report was adopted, he said, the Council would be adopting a precedent which would involve them in great expenditure.

Mr. Manle seconded the amendment. If they agreed to the proposed expenditure, they could not complete the work throughout London under a cost of three hundred millions sterling.

Mr. Austin supported the recommendation of the Committee. The death-rate in the area referred to was 40 in the 1,000, or more than double the ordinary rate.

Mr. Beauchamp said he believed it was admitted on all hands that this was an unhealthy area. He thought that part of the area, the western, could be dealt with under Part 2, but not the whole.

Mr. Hutton, who opposed the scheme, said he thought the Council should set the local authorities in motion, and see that the buildings were put in a proper condition.

Dr. Longstaffe gave a number of statistics to show the terribly insanitary condition of the area.

Colonel Edis thought they should make the local authorities do their duty. The scheme offered a premium to those who kept unhealthy dwellings.

Lord Lingen said there were many points requiring consideration. He was entirely in favour of doing everything that was reasonable, prudent, and practicable in carrying forward the movement for the better housing of the working-classes. The amendment, however, for which he intended to vote, would give time to consider the proposals made by the Committee.

Mr. Boulnois, M.P., moved the adjournment of the debate.

Lord Compton opposed this. On a division the adjournment was carried, and later on the Chairman said he had received a requisition to call a special meeting on Monday to consider the scheme.

*New Fire Brigade Station for Wandsworth.*—The Fire Brigade Committee recommended, and the Council agreed to accept, a tender of Messrs. Stimpson & Co. to erect, at a cost of 7,980*l.*, a new station at Wandsworth; and also that power be taken for the erection of a station on ground adjacent to Clapham Common.

The Council soon after adjourned.

**ARCHITECTURAL ASSOCIATION LYRIC CLUB.**—The opening concert of this club was held at the headquarters, Mona Hotel, Covent-garden, on Tuesday, October 23. A good programme was arranged by Mr. J. Douglas Scott, and conducted under the President, Mr. W. Burrell. The following members and friends contributed towards the entertainment:—Messrs. J. D. Scott, Pywell, Lidstone (violin), W. E. Johnson, S. B. Garcia, F. H. Collins, and C. D. Imhof (who again appears as accompanist). Any member of the Architectural Association wishing to join the club should write to the hon. sec., Messrs. W. Henry White and Theo. Moore.

**REMOVALS.**—We are asked to state that Messrs. C. S. Worssam & Co., wood-working machinery manufacturers, have decided to remove from Queen Victoria-street to the vicinity of their works, at 172, Burrage-road, Plumstead, S.E.—We are also asked to notify the removal of the City offices of Messrs. Coles & Sons, builders, from Moorgate-street to No. 5, Coleman-street.

### ARCHITECTURAL SOCIETIES.

**GLASGOW ARCHITECTURAL ASSOCIATION.**—The second lecture of the present session was given on the 21st ult. by Mr. Wm. Paton Buchan, on "The Ventilation of Buildings," in the Philosophical Society's Rooms, Bath-street, Glasgow, the President (Mr. Wm. J. Anderson) in the chair. Beginning with the chemical composition of air, and the quantity absolutely necessary for life and desirable for health, the lecturer compared these with tables of analyses made of the atmosphere found in theatres, churches, schools, and dwellings. Some experiments were made with a lighted candle to show the vitiation of air caused by our necessary illuminants. The lecturer then passed to a criticism of the practical methods that have been, and are, adopted to secure at once the admission of fresh and the extraction of foul air,—a problem that, simple as it may appear, was beset with difficulty if draught and the loss of all heat was to be avoided. Mechanical power was now more commonly employed than hitherto. For churches, however, automatic ventilation was, of course, much cheaper, and might be quite effectual. By diagrams the principal patent systems were illustrated, and their merits discussed. At the conclusion of the lecture a hearty vote of thanks was passed to Mr. Buchan.

### Correspondence.

To the Editor of THE BUILDER.

#### CEMENT TESTS.

SIR,—I have frequently noticed in your valuable paper references to the Prussian standard rules on Portland cement (see p. 323, October 25, 1890), and as I have myself encountered great difficulty in finding out what these rules are, I have thought it might be of some interest to your readers to have a translation of them. The translation is made from an official copy supplied to me from Berlin. This copy gives at the same time instructions and explanations under each head, which I have not translated, so as to give the rules in a short and handy form, but if any of your readers should care to have them, I shall be glad to supply this information.

H. ALFRED ROEHLING.  
23, Highfield-street, Leicester.  
October 24, 1890.

*Prussian Standard Rules for the Uniform Delivery and Testing of Portland Cement. Circular of the 28th day of July, 1887.*

*Definition of Portland Cement.*—Portland cement is a product obtained by burning an intimate admixture of substances containing, as chief ingredients, lime and clay, to clinkers, and afterwards grinding and pulverising the same.

1. *Packing and Weight.*—As a rule, Portland cement is to be packed in standard casks of 180 kilogrammes (= 3.54 cwt.) gross weight, and about 170 kilogrammes (= 3.34 cwt.) net weight, and also in half standard casks of 90 kilogrammes (= 1.77 cwt.) gross weight, and about 83 kilogrammes (= 1.63 cwt.) net weight. The gross weight is to be clearly marked on the outside of the casks.

If cement is packed in casks of different weight, or in bags, it is also necessary to show the gross weight in plain figures on the outside of the cask or bag.

Loss through leakage or differences in weight up to 2 per cent. cannot be claimed for. The barrels or bags must besides the weight bear on their outside, in plain letters, the name of the firm or the trade-mark.

2. *Time of Setting.*—Portland cement may be ordered either as slow or quick-setting, according to requirements. Cement that only sets in two hours or longer is to be called slow-setting cement.

3. *"Blowing" of Cement.*—Portland cement must not alter its volume, i.e., "blow." The following may be considered a decisive test. A cake of cement may be mixed on a plate of glass, and is to be protected from drying up whilst setting. It is then, after setting, to be submerged in water, and if, after twenty-four hours, it shows small bends on the edges, or cracks, it is to be considered a "blowing" cement.

4. *Fineness of Cement.*—Portland cement must be ground so finely that it leaves, when placed upon a sieve of 800 meshes per square centimetre (= 5,806 meshes per square inch, or 76 meshes per linear inch), at the outside a residue of only 10 per cent. The thickness of the wire is to be equal to half the width of the meshes.

5. *Tests of Strength.*—The cohesive strength of Portland cement is to be tested in a mixture of cement and sand. The test, which must include both the tensile as well as the compressive strength,

is to be made in a uniform manner on specimens of equal shape and cross-section, and with machines of the same type.

It is advisable also to test the strength of neat cement.

The test for tensile strength is to be made on bricks of a breaking area of 5 square centimetres (= 0.775 square inches), and those for compressive strength on cubes with sides of 50 square centimetres (= 7.75 square inches).

6. *Tensile for Compressive Strength.*—Slow-setting cement shall possess, when mixed in the proportion of three parts, by weight, of standard sand to one part, by weight, of cement, and after having been exposed to the air for one day, and placed under water for twenty-seven days, a tensile strength of at least 16 kilogrammes per square centimetre (= 227 lb. per square inch).

The compressive strength must at least be 160 kilogrammes per square centimetre (= 2,270 lb. per square inch).

In the case of quick-setting cement, the strength after twenty-eight days is, generally speaking, lower than that given above, and it is, therefore, necessary to state the time of setting as well as the strength.

### WHITEFIELD'S CHAPEL COMPETITION.

SIR,—Without wishing to enter into any discussion on the above, I shall be glad if you will kindly permit me to controvert Professor Smith's dictum, in his letter last week, that a domed ceiling is neither suitable nor safe where clear hearing and speaking are of the first importance. Really it is much to be regretted the Professor should give the weight of his name to a general statement of that kind. It depends entirely on the skill with which the dome is carried out, and no more beautiful or suitable covering for a large central area has ever been devised. Acoustically it has been successful over and over again. Let me instance two other examples in support of this,—the well-known St. Stephen's, Wallbrook, and Union Chapel, Islington, the latter being practically a domed church. Both are about the size of that proposed in "Lux Mundi," and both are admirable for hearing and seeing. The question of cost has already been more than answered in Professor Smith's report, but I have always understood that,—within reasonable limits,—the great object is to produce good architecture, not cheap. The whole question is begged in this case by the limit of cost being unreasonable.

J. M. BRYDON.  
5, Cambridge-place, Regent's Park, N.W.,  
October 28, 1890.

SIR,—Professor Roger Smith's letter makes the result of the above more puzzling than ever. I therefore inquire—If Mr. Brydon's design was so successful, and so expensive that it could not be carried out within, or even very near, the limit of cost fixed, why was it awarded a premium?

JOHN JOHNSON.

### OBITUARY.

MR. J. MACLAREN.—The architectural profession has sustained a great loss by the death of Mr. James MacLaren, of 21, King William-street, which occurred on October 20. He will probably be chiefly remembered by his new work at the High School at Stirling. Among his recent works are a large hotel at Las Palmas, Santa Catalina, and a large number of works for Sir Donald Currie, for whom two houses are now being built from his designs at Palace-court, Kensington. Some "Additions to the Park, Ledbury," will be found illustrated in our issue of June 12, 1886; and a house and studio at Avonmore-road, October 13, 1889.

MR. R. A. LEDWARD.—The death is announced, at the age of thirty-three, of the promising young sculptor, Mr. R. A. Ledward. During his three years' studentship at South Kensington he gained, amongst many awards, a gold medal for modelling, and was afterwards appointed a master of modelling in these schools. He had been an exhibitor at the Royal Academy for the last eight years.

A TALL TOWER FOR THE ISLE OF MAN.—The foundation-stone of the great tower to be erected at Douglas, Isle of Man, was laid on the 21st ult., by the Earl of Lathom. The tower is to comprise six floors, to be used severally as a theatre, dancing-saloon, concert-hall, bazaar, shops, and the top-most has an observatory. The tower will be as high as St. Paul's Cathedral, the estimated cost is about 80,000*l.*, and it is expected that it will be completed by the midsummer of 1892. Mr. Floyd, of Westminster, is the engineer.

DEPARTMENT OF SCIENCE AND ART.—We are informed that the Government institution, now known as the Normal School of Science and Royal School of Mines, will in future be called the Royal College of Science, London.

The Student's Column.

HOT-WATER SUPPLY.—XVIII.

IMPROVED AND OTHER SYSTEMS (continued).

**O**CCASIONALLY advocates for carrying the primary flow-pipe direct from the boiler to the highest point in the house (constituting it both primary and secondary flow), and having the return pipes connected into the cylinder only, as fig. 43.

FIG. 43.

are to be met with. This is a practice that should only be resorted to on special occasions, as we have to bear in mind that the store of hot water in the cylinder is not added to, except by the pipe which has been all round the house, and probably lost the major portion of its heat.

By this means, however, hot water is obtained at the taps very quickly, though it is a late hour before there is any in storage of a high temperature; but, as an instance of its successful application, might be mentioned the case of a large residence where trouble had always been experienced in obtaining hot water at the bath in the early morning, as the bath-room was situated a great distance from the kitchen (100 ft. run of pipe), and a considerable time was needed with an ordinary kitchen range boiler to get really hot water at this point, it having first to pass through the cylinder; a change was, therefore, effected, as fig. 43, and the trouble was at an end, as the hot water reached the bath-room in much less time, and, as the pipe was of great length, it held enough in itself for one bath without depending upon the reservoir; but this successful instance must not be construed into a recommendation of the method described.

Another arrangement of connecting-up the pipes to the cylinder and the boiler is as fig. 41, known as "Dyer's system." With this apparatus we must content ourselves with a description

with the secondary flow, as already explained. The cold supply is carried down and connected into the cylinder at the bottom, and is continued and connected into the boiler at the bottom also, and the secondary return is connected into the cold supply at a low point as shown.

A prevailing notion amongst the majority of hot-water fitters, particularly with some of the stubborn ones, who have been faithfully practising for years what they were taught in their boyhood, is that on no account must the flow-pipe descend anywhere in its course, nor must any circulating-pipe descend below the boiler; nor must, in fact, any pipe take a course that is irregular with the ascent of the flow-pipe and descent of the return which has become traditional, and from which a departure would be looked upon as an offence against all accepted principles.

In theory, several of the best authorities agree that under what we may term common circumstances a circulation can be effected about three-fourths the distance below the boiler that the circulation extends above it, as fig. 45, and the result is arrived at as follows:—

First, it is necessary to impress upon the mind that the circulation of water is brought about by the fact that cold water is heavier than hot, *not* that hot water is lighter than cold. This is a distinction with a considerable difference, so far as it affects this argument, for it can be seen plainly that heated water has no inclination to rise unless it is lifted or pushed, so to speak, by a superior force. If we take a vessel of warm water the contents will not rise out of it, but if we take an exactly equal quantity, by measure, of hot water and cold water, and place one in each pan of a pair of scales, we should then find that the pan of hot water would rise, for the simple reason that the superior gravity of the cold water caused it to do so. Now, in an apparatus as at fig. 45, when heat is applied to the boiler its contents become rarified, or lightened, and a circulation will set in as indicated by the arrows; if, in a short time, we apply the hand to the pipe, we shall find that, starting from the top of the boiler, the pipe is of a less and less temperature as we pass round it towards the bottom of the boiler (in the direction indicated by the arrows). The difference in temperature may be due to two causes, firstly, loss of heat by radiation from the pipes, which, of course, is greater the further we get from the starting-point, and, secondly, the boiler may not have had time to heat up the whole of the contents of the apparatus to boiling-point (for we cannot have a uniform heat everywhere in a circulating apparatus until this temperature is reached, which seldom happens), consequently this makes plain to us that the pipe which ascends from the bottom of the apparatus up into the boiler has the coldest and heaviest water in it, and this is the obstacle that more or less interferes with a good circulation being effected below a boiler. If the lower part of the apparatus extends a greater distance below the boiler than the upper part extends above it, we are given to understand that no circulation will take place, and although this is not strictly correct, it cannot be practically applied in hot water supply work, and, what is more, it is but very rarely required.

It very frequently happens that a fitter would find it very convenient if he could make a dip in his flow- (and return-) pipe, as fig. 46,

FIG. 46.

for instance; but, according to all accepted ideas, it would possibly ruin the apparatus, but this is not the case, although it might give a good deal of trouble. The trouble experienced in this instance is the difficulty in dislodging the air from the upper part of the service, *a a a*, for it will be found that in such a place the air will remain with the greatest persistency, and to remove it effectually an air-cock would have to be provided for periodical use, as, although we may allow the air to escape when first charg-

ing the apparatus, it does not wholly overcome the difficulty, as there is always a certain amount of air carried into the pipes with the water, and this will collect at any such point and require removing regularly, which we cannot expect servants to do. If it was not for the collection of air at this point, there would be no objection whatever to dipping the flow-pipe in the manner indicated, as it would be found that a dip of a few inches only would make no appreciable difference in the circulation.

GENERAL BUILDING NEWS.

**ST. MARY'S CHURCH, SOMERS TOWN.**—This church was re-opened on Saturday, October 25, after being closed three months for repairs and improvements. The building was originally erected in 1826 by the brothers Inwood, the architects of the neighbouring church of St. Pancras, at a cost of 13,000*l.*, and, with the aid of immense galleries, was estimated to hold nearly 2,000 persons. That its extreme badness was recognised even by contemporaries is proved by a long notice in the *Gentleman's Magazine* for 1827, in which it is described as "the worst specimen of carpenter's Gothic yet erected in this country." The first attempt to bring about some improvement was made two years ago, when a ritual chancel was constructed by raising the floor, and a small apse thrown out, under the superintendence of Mr. Ewan Christian, F.S.A. In the present alterations the galleries have been entirely removed, the walls and roof painted, and to some extent decorated, and new systems of lighting and heating introduced. The *loms*, two-light windows have been broken by the introduction of a hand of stone tracery at the level of the old galleries, thus enabling the memorial windows to be worked into their old positions. A set-off under the galleries has been made to carry the line of this tracery hand round three sides of the church by means of a moulding and cresting. The piers consisted of thin iron cores surrounded by four three-quarter shafts of wood, and crowned with hideous spreading capitals. An attempt has been made to improve their character by inserting a nail-head moulding between the shafts, and to substitute good Early English types for the "fungoid" caps of the original work. The limited funds at the disposal of the committee were seriously encroached upon by the necessity of removing and making good to the large quantity of bond timber built into the walls, and the whole work would have been greatly hampered had it not been for the generosity of an anonymous benefactor who made up the deficit. The architect is Mr. Reginald Colebrooke Reade, M.A., of Torquay.

**NEW CHURCH, CHAPPELKNOWE, GHESNA GREEN.**—A new United Presbyterian church has just been opened by Principal Cairns at Chapelknowe. The new building is built of stone, accommodates over 200 persons, and has a lofty, open roof. The acoustic and ventilating properties are said to be excellent. Mr. Geo. Dale Oliver, of Carlisle, was the architect.

**A NEW BANK FOR LEEDS.**—A new branch bank about to be erected for the Birmingham and Midland Bank at Leeds will be situate in Kirkgate, on the south side, and immediately opposite to the Market. The facade will have a frontage of 41 ft. and an elevation 55 ft. in height, which will be executed in stone. The walls of the interior are to be lined with Italian marble; the floor will be paved with mosaic work; the ceiling of the bank richly panelled; and the whole of the counters, desks, and fittings will be of solid walnut. The safes and the voucher-rooms are to be placed in the basement and made fireproof with brick vaulting. The private office, lavatories, and the caretaker's-rooms are to be placed on the first floor. The design has been prepared by Mr. William Bakewell, architect, of Leeds, and will be carried out under his superintendence. The work has been let to Messrs. Nicholson & Son, Heavyside, Barrand, Moore, and Bateman.

**ST. JOHN'S CHAPEL, CROOKES MOOR, SHEFFIELD.**—A new Wesleyan chapel in Crookes Moor-road, Sheffield, was opened on the 22nd ult. The chapel is in the Gothic style of architecture. The principal entrances are from the Crookes Moor-road, with a side entrance from Dam-road. In addition to the chapel, which has sittings for 800 persons, there are two large school-rooms, one over the other, and connected by a staircase, around which are clustered on the different levels vestries, classrooms, and committee-rooms, a large band-room, an infants'-school, and a ladies'-room. The work has been done by the following tradesmen:—Masonry, Mr. J. Fidler, Eckington; joinery, Messrs. W. Crookes & Son, Sheffield; slating, Mr. W. J. Tune; plastering, Messrs. Carter, Unwin, & Son; plumbing and gasfitting, Mr. J. B. Corrie; glazing, Mr. H. Sutton, Birmingham; painting, Mr. C. Chadwick; carving, Mr. F. Tovey; warming apparatus, Messrs. J. C. & J. S. Ellis. The pulpit has been erected by Messrs. Johnson & Appleyards, from the architect's designs. Mr. C. J. Innocent, of Sheffield, is the architect, and the clerk of works is Mr. George Malpas.

FIG. 44.

FIG. 45.

only, as it does not come within the province of these papers to discuss the merits or demerits of individual systems. It will be noticed that in this the primary flow has communication

**HOLBORN TOWN HALL.**—The London County Council having required additional exits to be provided at the Holborn Town Hall, a new staircase has been constructed at the eastern end, leading into a corridor on the ground-floor, opening into the Clerkenwell-road. New retiring-rooms for gentlemen have also been built on the ground floor, and for ladies on the first floor, in connexion with the great hall. The principal staircase has been reconstructed in grey and white marble, by Messrs. Farmer & Brindley, of Westminster Bridge-road. An improved system of ventilation has been carried out by Mr. Papier, of Islington, in the great hall, the committee-room, and the residential portion of the building. The whole of the interior of the building has been redecorated by Mr. John Crossley, of Newark. It is proposed to establish an installation of electric lighting in the building. The structural works have been executed by Messrs. Kilby & Gayford, of Worship-street, Finsbury. The work has been carried out under the superintendence of the architects, Messrs. L. H. Isaacs & H. L. Florence.

**THE NEW FARRINGTON FRUIT MARKET.**—The first stone of the new fruit and vegetable market, in Farrington-road, was laid by the Lord Mayor on the 22nd ult. The building, which will be erected at the corner of Charterhouse-street and Farrington-road, is destined to be a permanent structure embracing an area of about 54,000 ft. with a frontage of 166 ft. to Charterhouse-street, and 184 ft. to Farrington-road. The main vehicular and footway entrance to the new building will be in the middle of the Charterhouse-street front, and will be 35 ft. wide. A further entrance, 14 ft. wide, for carriages and pedestrians will be placed at the north end of the Farrington-road front. Two footway entrances are provided on the Charterhouse-street front, and one on the Farrington-road front, all three affording access to gangways of similar width, traversing the market from south to north and west to east. The height of the building to the plate level will be 28 ft., and to the ridge 45 ft. The basements and the adjoining markets will be occupied by the Great Northern Railway Company. The area of these basements is about 100,000 ft. Large hydraulic lifts are designed to raise the produce to the market, and inclined railways for horse traffic are to be provided as means of access from the basement to the street level. The design is by Mr. Alexander Peebles, the City Architect. The contract for the substructure and basement works has been taken by Messrs. Budd & Son, of Grantham, at 41, 97/3d. The estimated cost of the superstructure is 15,500l.

**NEW CHURCH, NORTHINGTON.**—The new church of St. John the Evangelist, situated on the slope of Northington Down, was consecrated by the Bishop of Guildford recently. The church, which is Late Gothic freely treated in detail, was designed by Mr. T. G. Jackson, M.A., and consists of nave, chancel, tower, and north aisle. It has been erected principally by the estate workmen, and under the superintendence of Mr. Thomas Potter. The walls are of Portland cement concrete, those of the tower being 4 ft. in thickness, faced externally with flint-work and Chilmark stone dressings, and Caen stone internally. The flintwork is inlaid in panels of various designs. The rapid fall of the ground allows of a vestry below the chancel, which takes the form of an octagonal chamber vaulted with a central pillar, from which radiating stone ribs with panels of red-ribbed bricks and stone in bands, spring to the side walls. The chancel terminates in an apse, and contains six two-light windows which are filled with stained glass executed by Messrs. Powell, of Whitefriars. The windows are pointed, with stone mullions. Each of the twelve lights contains the figure of an Apostle. The seating throughout the church is of black American walnut; the nave seats have traceried ends, and carved panels containing heraldic and other devices. The chancel stalls have high backs and canopies and carved standard ends, in which are introduced figures of the four Evangelists and their emblems. The organ case is of the same material, rich in tracery and carving, and overhangs the stalls on the north side. The pulpit is of Caen stone. The reredos is alabaster, with a panel representing the Last Supper, under a canopy with carved and pierced cresting. The woodwork is Chilmark stone with flat panel inlays. It consists of two stages, the upper of which is lighted on each face with two tracery-headed louvre windows, 24 ft. in height, a parapet of tracery work surmounting the whole. From each angle springs a pinnacle with crocketed spirelets. The wood work generally, including the nave seats, chancel stalls, and organ case, was made in the estate workshops by the estate workmen. Messrs. Farmer & Brindley executed the carving and pavement of the chancel, the reredos, and font. Messrs. Hart, Son, Peard & Co. made the lectern and altar rails. The church is heated by Messrs. Haden & Son's hot air arrangements. The total cost has amounted to nearly 15,000l.; the seating accommodation, including choir, is for 290 persons. We gave a view of the church in the *Builder* for June 21, 1890.

**NEW MISSION CHURCH, ROMFORD.**—On the 23rd ult., the new Mission Church of St. Alban's, Romford, was dedicated by the Bishop of St. Alban's. The church occupies a site at the upper part of Victoria-road. The designs have not yet been entirely carried out, but when completed the church will consist of a nave, 43 ft. 6 in. by 27 ft., a chancel and sacristy, 25 ft. by 17 ft., a south porch, a vestry, and a north vestry on the north side, with a *tabernacle* at the east end of the nave. The vestry, porch, and spire are the portions which remain to be added. The cost of the whole design is estimated at about 1,200l. The architect is Mr. James Kennedy, of London, and the builders are Messrs. Dowling & Davis, of Romford.

**NEW HOSPITAL FOR BROMSGROVE, NEAR BIRMINGHAM.** The foundation-stone of the Cottage Hospital, which is to be erected on the New Road, Bromsgrove, was laid on the 22nd ult. by Mr. John Corbett, M.P. The buildings will consist of a central block and two side wings connected by corridors. The wings will form the male and female wards respectively; they will be 35 ft. by 18 ft. 6 in. by 12 ft. in height, and they will each have six beds. The material used will be red brick, with pressed bricks for certain portions, and stone will be used for the main entrance and certain of the windows. The gables will be finished in the half-timbered style, and the whole of the roofs will be covered with purple Staffordshire tiles. The floors are to be of stone, and the walls are to be of brick with wood, those of the wards being laid double. The central hall will be warmed with hot-water pipes, and special arrangements are to be made for ventilation and lighting. The builders are Messrs. J. Brazier & Son, of Bromsgrove. The architect is Mr. John Cotton, of Birmingham and Bromsgrove.

**NEW CHURCH, CANTERBURY, S.E.**—The Bishop of Rochester, on the 22nd ult., consecrated a new church and hall at Canterbury-road, S.E., which has been erected by Corpus Christi College (Cambridge) in connexion with their Mission at Camberwell. The building consists of two floors, having a large hall, &c., on the ground-floor and a church on the first-floor. The church is distinct from the tower part, and is approached by two wide stone staircases with direct access to the street. The building has ironproof floors, and has cost nearly 5,000l. The architect is Mr. Richard J. Lovell, A.R.I.B.A.

**THE ENLARGEMENT OF STAMFORD-HILL SCHOOLS.**—We understand that the Tottenham School Board has instructed Mr. Charles Bell, architect, to prepare designs for the enlargement of the Stamford-hill Schools for 500 children. A new school which has been erected by the Sheffield School Board, at Abeydale, was opened on Monday last. The building is two stories high. Coursed wallstone is used on all sides of the school, with cast-iron dressings, and a central chimney. Pine is applied for all interior woodwork. Accommodation is provided on the ground floor for 420 boys, and on the upper floor for 420 girls, one class-room being fitted up for cookery instruction. Wood block flooring is laid, and the interior is well lighted, warmed, and ventilated. The contractor for the building is Mr. Phipps, and the boundary walling is 57/70d. The contractors for the work are Messrs. Thomas Lowe & Sons, of Burton. The architect is Mr. C. J. Innocent, F.R.I.B.A., of Sheffield, and Mr. J. Laidler has acted as Clerk of the Works.

**CHURCH RESTORATION NEAR CARDIFF.**—We are informed that the restoration of Peterston-up-Ely Church, for which a faculty has been granted, has been entrusted to Messrs. Kempson & Fowler, architects, of Llandaff. The work includes a new solid oak chancel, arch screen, and pulpit, new oak chancel seats, new two-light chancel window, the raising of the east window and filling both with painted glass, new mosaic floor in chancel, and the wall decoration of same, a new heating apparatus, and the restoration of the tower, &c. The painted glass is being executed by Messrs. A. Savell & Co., London, and the screen and pulpit by Mr. Wm. Clarke, of Llandaff.—The old tower of Llanmsh Church, near Cardiff, has also been restored under the superintendence of Messrs. Kempson & Fowler. The work has been carried out by Mr. G. Hartnell, builder, of Crwys-road, Cardiff.

**SANITARY AND ENGINEERING NEWS.**  
**THE NEW ROYAL INFIRMARY, LIVERPOOL.**—The heating and ventilation, as well as the steam and hot-water service supplied for this building have been carried out by Mr. Wilson W. Phipson, Men. Inst. C.E., who was selected, in a limited competition, prior to the contract for the building being given out. By this means the architect, Mr. Alfred Waterhouse, R.A., was able to devote much time and attention to the subject, and to embody all details of the scheme in his plans. The heating is by low-pressure steam, the water of condensation being returned to the boiler-room after having passed through the several systems of heating mains

and radiators, being finally put into the boilers by means of a Worthington steam pump. Two 50-h.p. Galloway steam-boilers are provided for this and the other services. They are set on the Livet principle, and are fitted with all the latest improvements, in order to ensure an economical cost of the main supply of steam. The service-pipes are taken from the main connecting the two boilers, No. 1 being for heating, No. 2 for the kitchen and ventilating coils, Nos. 3 and 4 for the laundry, No. 5 for the pumping service, and No. 6 for the disinfecting apparatus. On each of them stop-valves are fixed, by which means all these services are under the control of the engineer in the boiler-room. The supply-main for heating, which is 4 in. in diameter, is carried in the pipe-tunnel constructed below the corridor of communication running east and west. At the intersection of this corridor by the several blocks, an outlet is left in the main, fitted with a stop-valve, and reducing pressure valve for the supply of steam to each block. By this means, while still retaining the boiler pressure in the main pipe, in order to overcome the loss of pressure caused by the great distance the steam has to travel, the supply for heating and in circulation over each ward is delivered through the reducing valve at any pressure required to meet the variation of the external temperature. From the boiler room, the main supply of steam is arranged, it is found that the steam in the main is distributed through the radiators at a pressure of from 3 lb. to 5 lb. on the square inch. It will thus be understood that though all the blocks are connected to the one steam supply from the boilers, they are independent in their action, and the operation of any one block does not return mains leave and re-enter the main tunnel above referred to. The mains are of the best quality of steam-pipe, faced flange-joints being used for all pipes over 2 in. in diameter, while right and left screw joints are used for pipes of 2 in. and under. In all cases due allowance is made for the expansion and contraction of the pipes, and the use of long and easy bends, and swinging the mains where necessary. By this practice the disadvantage of telescope or other forms of expansion joints is avoided. In order to estimate the extent of this apparatus, it may be mentioned that over 13,000 superficial feet of steam and hot-water mains have been coated with Messrs. Henry & Co.'s non-conducting composition, and in addition to this there are 6,000 superficial feet of branches that are not coated, while the direct heating surfaces fixed throughout the building are estimated at 8,000 square feet. The heating of the building throughout is by means of steam radiators, now known as the "name of 'Sunbeam,'" and constructed by Messrs. W. G. & Co., of Sheffield. The advantage of these radiators is that the loops are connected to the base by a Whitworth screw joint, and all parts of them are interchangeable; therefore, should a loop be accidentally broken, no trouble is experienced in renewing the same while the radiator is in position. In the wards the radiators are circular, and are placed in a central position, the heating in all cases is from the centre, because it is found in practice that it causes less disturbance of the atmosphere in the wards than when the radiators are placed against the external walls. The heating from the central position causes a current of warm air down the side walls. To all the circular radiators is supplied a central supply of steam, and the heating surface fixed upon has been calculated to ensure, in conjunction with the open fire-places, during the winter months a mean temperature of 61 deg. Fahr., with an amount of air admitted through the radiators and from other sources equal to the entire renewal of the atmosphere in the wards four times in the hour. The fireplaces in the wards are also central, and constructed to form the main upcast shaft for the extraction of the vitiated air. The flues from the fireplaces are carried up in iron pipes, quadruple on plan, each stack serving for four fireplaces and the extracting shaft. By this means a simple system of extraction is obtained by utilizing the waste heat from the fire, the area of the area of outlet for smaller wards being 6 square feet, and for the large wards, through two central fireplaces, 12 square feet. In each outlet the gratings fixed are provided with valves. In the other departments of the building inlets and outlets are constructed, but in these rooms the up-cast air is drawn into a block of duct where they are collected and conveyed by means of a main trunk into the general extract shaft situated over the central block. In this shaft steam coils are fixed so as to ensure in all seasons a powerful up-cast. The hot-water supply to baths, sinks, and lavatories is obtained by means of four steam beaters with cylinders attached, the horizontal circulation being of 3 in. cast-iron galvanized pipe with all rising mains and branches of steam galvanized pipe. Valves are fixed on all branches so that, in case of repair to pipes, no interruption will take place in the general supply. In order to economise fuel, the condensed-water mains are passed through the heaters before being returned to the boiler-house. For the admission of fresh air, a direct trunk with valve and reducing-pressure valve, is taken from the main steam supply, for heating, ventilation, and hot-water service supplies.

**THE SKIPTON WATER SUPPLY.**—A statutory meeting of the members of the Skipton Local Board was held on the 22nd ult. for the purpose of considering and deciding upon the expediency of promoting a bill in the next session of Parliament for an extended water supply. The Chairman read and explained the scheme as proposed by Mr. Hill, the Engineer, which provided for the construction of a reservoir at Skitbedu capable of holding 40,000,000 gallons of water, which, together with the purchase of land, &c., would cost not more than 40,000*l.* Resolutions were passed in favour of the scheme.

**WYEMOUTH HARBOUR.**—We briefly mentioned in our issue for the 18th ult. the ceremony of laying the final stone in connexion with the new quay. We omitted to state then in connexion with the improvements to this harbour that an amount of about 40,000*l.* had been expended under the directions of Mr. Barlow-Morgan, Civil Engineer.

#### STAINED GLASS AND DECORATION.

**NEW WINDOW, PRIORY CHURCH, CHRISTCHURCH, HANTS.**—The old Priory Church of Christchurch, Hants, which dates back to early Saxon times, has received another stained glass window, the gift of Mrs. Buss, the wife of the present vicar. The window consists of three lights with tracery above, and represents "St. John taking the Blessed Virgin home," "Mary at the feet of Jesus," and the calling of St. James and St. John. The work has been designed and executed by Messrs. Mayer & Co., of Munich and New Bond-street, London.

**STAINED GLASS WINDOWS FOR MANCHESTER CATHEDRAL.**—On the 22nd ult. in the north aisle of the Manchester Cathedral, two stained glass windows were presented to the authorities of the Cathedral by Miss Pickup. They are the two last in the north aisle which remained plain. The easternmost is dedicated to the memory of George and Elizabeth Pickups, the mother of the donor, and that next to the porch is in memory of Mr. James Pickup. The work has been carried out by Clayton & Bell, of London. There are small figures in the principal lights formed by the upper tracery, and the main portion of each window is divided by the millions and transom into eight lights, in each of which is a figure illustrating some Biblical or sacred subject.

#### FOREIGN AND COLONIAL.

**FRANCE.**—An international fine art exhibition is to be opened, on February 18, 1891, at the Place Bellecour at Lyons.—The committee for the industrial exhibition at Lyons in 1892 have awarded MM. Borleau, Migman, & Maistrasse, architects, of Paris, the first premium in the competition for the extension building.—Baron Alphonse de Rothschild has presented to the museum at Bordeaux an important series of medals executed by M. Ringel d'Ilzsch.—M. Guillaume, the architect of the Louvre, has discovered in the Pavillon de Flore, in the rooms formerly occupied by the Prefecture of the Seine, a number of mosaics, probably from some town in the South of France, but of which nothing certain is known. They had been sent before the war to the architect Leteblé.—A group of French capitalists have formed a scheme for opening next summer, at Buda Pesth, an industrial exhibition organised on the model of the French exhibition of 1889.—M. Louis Schneider, witness of Louis Schneider, the engineer, has left a sum of more than 100,000 francs to the Association of Painters, Sculptors, Architects, and Engravers.—The Société des Artistes Français has been authorised to accept the legacy left to it by Heilbuth, consisting of a house, 47, Rue Ampère, Paris, valued at about 250,000 francs.—The Municipality of Rouen proposes to celebrate next year the centenary of the birth of Géricault, the painter, who was born there on September 26, 1791.—The Municipal Council of Chambéry have opened a subscription for the erection in that town of a monument commemorating the annexation of Savoy to France in 1792.

At the little town of Auffay a monument is to be erected to the memory of a brave woman, Marie Biard, who during the Franco-German war many times traversed the Prussian lines at the imminent risk of her life, in order to carry despatches to the French army. In the town of Clichy, in the Department of the Seine, are to be commenced shortly the works necessary for conducting the Paris sewage, by lifts established at Clichy, into the forest of St. Germain and the plain of Achères, where they are to be utilised for agricultural purposes. This operation, often spoken of, has now received the sanction of the Government, and public subscription has been opened for the erection at Carpentras of a statue to the celebrated chemist François Raspail, who was born in that town in 1794. The sculptor is not yet selected.—A new line of railway has been opened from Montanoux to Grasse (Alpes Maritimes) with a view to facilitate Nice, for strategic purposes, with Grasse, Toulon, and Marseilles.—The French Government intends to erect at Navarino a monument in commemoration of the celebrated Naval victory gained there over the Turks, in 1827, by the combined fleets of England, France and Russia. The monument will stand by

the seashore, and will be nearly 40 metres in height.

**NORWAY.**—Seventeen designs have been received for the new Historical Museum to be built in Christiania.—The new theatre building in the capital is now approaching completion. It will seat about 1,000 persons.—A few years ago a Norwegian architect, who takes great interest in Norse architecture, purchased the Hauges church, ju Sogn, on the west coast of Norway, and one of the oldest in the country, for the sum of 23*l.* He has since expended some 50*l.* and a great deal of labour in restoring the church, and furnishing it in accordance with its date.—The first venture in cement manufacture in Norway, to which we recently referred, seems likely to be a success. At some trials the other day in Christiania by a body of experts, the Norwegian material is said to have proved quite equal to English briquettes in quality.

**SWEDEN.**—It is proposed to obtain a State grant of 8,500*l.* towards sending Swedish architects and engineers to the forthcoming Chicago International Exhibition.—New barracks for the cadet corps in the town of the Swedish Life Guards are to be erected in Stockholm.—The designs have now been completed for the Museum of Northern Antiquities to be erected in Stockholm, and the work will be commenced next spring.—In the town of Helsingborg there has just been completed a Masonic hall at a cost of 13,000*l.*

**DENMARK.**—Work is now in full progress with the erection of the new great central electrical station in Copenhagen. It is estimated to cost about 75,000*l.*

**THE WATER SUPPLY IN EGYPT.**—It is stated that Mr. Cope Whitehouse has renewed his application for leave to carry out the Baijan project. He offers to deliver water in sufficient quantity to double the available volume during low Nile for 70*l.* per million cubic metres of water delivered at Cairo, with a right of purchase of the canal and reservoir by the Egyptian Government at one million pounds. He insists that the Egyptian Government has no legal right to prevent the execution of the proposed works as a private enterprise.

#### MISCELLANEOUS.

**DOVERIDGE HALL.**—On October 23 last, at the Mart, the Doveridge Hall estate was bought in at a bid of 170,000*l.* Owned by Lord Waterpark, this property extends over 2,000 acres, and includes East Lodge (a hunting-box occupied by Lord Waterpark), Cavendish Lodge, fourteen farms (chiefly dairy land), several cottages in the village, a water corn-mill, with several small holdings. The annual rental amounts to 5,750*l.* The mansion, now tenanted by Lord Hindlip, was built in 1763, in the Classical style, of red brick with stone dressings. The main front, between two low wings, has a rustic ground-floor, supporting a two-storied pediment with four pilasters, and two (central) columns partly engaged, in the Ionic order. The Hall is distant one mile and a half eastwards from Uttoxeter, whence the main road to Derby traverses the estate, which is bounded along its western side by the Dove. Nine miles northwards lies Ashborne, famed for its neighbouring beauties of Beresford Dale and Doveisle, and for its own parish church of St. Oswald. Samuel Johnson often visited Dr. Taylor when rector here; whilst the memories of Lord Watson, his friend Cotton, Rousseau, Congreve, and Tom Moore are associated with this locality. The church was dedicated in 1241 by Hugh de Pateshull, Bishop of Coventry. It contains several monuments and tombs of the Cockayne, Bradburne, and Boothby families and a Banks statue of Penelope, only child of Sir Brooke Boothby, Bart., who died aged five years, in 1791. The tower, with its lofty spire, was restored in 1873; the chancel, by the late Sir G. Gilbert Scott, four years later. The Cockaynes were settled at Ashborne Hall from the twelfth to the seventeenth century, when Sir Aston Cockayne sold it to the Boothbys, who, in two days, were dispossessed by Prince Charles Edward, with the Marquess of Pultenardine and James Drummond, Duke of Perth, on his advance and retreat through Derbyshire. This part of the county will be rendered more accessible by a proposed line of the London and North-Western Railway to pass from Ashborne and Hartington to Cromford, near to Matlock, and so on to Buxton.

**OPENING OF A NEW LONDON PARK.**—Maryon Park, Charlton, was formally handed over to the London County Council on the 25th ult. by the donor, Sir M. Maryon Wilson, Bart., Lord of the Manor of Charlton. The ground covers an area of about thirteen acres, and is of an undulating character, its special features being a high, abrupt, and rugged hill, called Cox's Mount, a precipitous cliff on the opposite side revealing 60 ft. of geological strata, and a small plain between suitable for cricket and other games.

**ASSOCIATION OF MUNICIPAL AND SANITARY ENGINEERS AND SURVEYORS.**—The following gentlemen having submitted to the examiners at the examination held in London on the 3rd and 4th ult., they have been granted certificates of competency by the Council of the Association:—Messrs. C. F. Ball (Croydon), W. Dyach (Aberdeen), F. J. Edge (Neath), W. Hall (Ealing), J. Manley (Chacewater), and F. Sumner (Kilburn).

The next examination will be held in London in April, 1891.

**HEATING FEED-WATER.**—There is something very remarkable in the alowness with which steam users recognise the great saving they may make in their weekly coal bill by the use of feed-water heaters. In many places the gain, which might be secured at no very great outlay, would make all the difference between a dividend and no dividend. At a meeting of a paper manufacturing company a short time since, it was mentioned that this one firm used 250 tons of coal per week, and that the recent increase in the price of coal made an increase of 2,600*l.* per year in the fuel bill, which made a reduction of 4 per cent. in the dividend, or from 12 to 8 per cent. This is only one of many works whereat such large quantities of fuel are consumed, and it is well known to engineers that it is the exception rather than the rule to heat the feed-water on its way to the boilers. Yet by this means some firms are now making a saving which represents a large income. A very moderate estimate of the value of a heater which raises the feed-water from a normal temperature to about 200 degrees is the saving of 10 per cent. of the fuel used. This, where coal costs 1*l.* per ton, and where, as in the above case, 250 tons per week are used, represents a saving of 1,250*l.* per year; or probably a dividend of 50 per cent. to 60 per cent. per year on the capital expended on the feed-water heaters.—*Engineer.*

**IS THERE COAL BENEATH LONDON?**—Professor T. G. Bonney gave a lecture on the 25th ult., at the Working Men's College, Great Ormond-street, on the above subject. Professor Bonney said borings had been made at Dover, and at a depth of 1,220 ft. (190 ft. below where coal had been struck in Calais) a seam of good burning coal had been struck 3 ft. in thickness, which showed that the coal measures must pass under the Channel, and if the beds were trending in the same way as in approaching Calais, it was obvious that they should pass very nearly through London itself. The difficulty, however, was to trace them. In his opinion there was no chance of striking coal measures north of Croydon, though they might underlie the ground at no great distance from south of Croydon. But he was of opinion that coal was not to be obtained underneath London. Even if, in the future, collieries did spoil the scenery of Kent and Sussex, they were not likely to much increase by their smoke the thickness of our London fogs.

**IMPROVEMENTS IN NAPLES.**—According to a recent report of the Acting British Consul at Naples, the sanitary reorganisation of the old parts of the city was commenced in May last year, and the works have been carried on with great activity ever since. The "Società di Risarcimento" have contracted to complete the whole work of demolition and reconstruction in ten years. In the new buildings, 35,881 square yards are to be devoted to habitations for the poorer classes, and 95,683 square yards are to be built over with habitations of an economical type, consisting of dwellings having one, two, and three rooms, with the necessary offices. All the works are to be carried on under the inspection of a Special Municipal Commission appointed by the Communal Council. The new embankment at Santa Lucia proceeds rapidly. The new part near the "Castello dell'Ovo" and the new dwelling-houses for fishermen and stores for boat gear and fishing apparatus have been completed.

#### LEGAL.

##### BUILDING BEYOND THE LINE OF FRONTAGE.

At the Lambeth Police-court on Monday, two summonses were heard against the City and South London Railway Company for building stations at the corner of New-street, Kennington-park road, and Harleyford-road, beyond the line of frontage, and without consent in writing of the London County Council, contrary to the Statute 25 & 26 Vict., cap. 102, and 45 Vict., cap. 14.—Mr. William Graham appeared in support of the complainants, the London County Council, and Mr. R. C. Glen for the Company.—From the opening statement of Mr. Graham and the evidence of several witnesses, it appeared that the company's stations, one at the corner of New-street, Kennington-park-road, and the second at the corner of Harleyford-road, had been built upon the old forecourts of houses, and brought out right to the garden rail, and beyond the original and proper line of frontage. A good deal of evidence was gone into as to the size and style of the stations, and the necessity of having them built in the way complained of. The County Council considered the Company had built such stations without sanction, and contrary to the Building Act. The defence was that the Company had powers under their own Act of Parliament to do as they had.—Mr. Mellis, clerk to Mr. Barrister Fletcher, District Surveyor, was called, and he stated that in May, when the station at New-cross was in course of erection, communications had been sent to the Company, and a caution was given them that such building was beyond the proper line of frontage, and that they might be proceeded against. The further hearing of the case was adjourned.

COMPETITION, CONTRACTS, AND PUBLIC APPOINTMENTS.

COMPETITION.

Table with columns: Nature of Work, By whom Advertised, Premium, Designs to be delivered. Includes 'Designs and Estimates for Church, Exmouth'.

CONTRACTS.

Table with columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, Tenders to be delivered. Lists various construction projects like 'Public Road Improvements', 'Supply of Timber', etc.

CONTRACTS.—Continued.

Table with columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, Tenders to be delivered. Continues list of construction contracts.

PUBLIC APPOINTMENTS.

Table with columns: Nature of Appointment, By whom Advertised, Salary, Applications to be in. Lists various public roles like 'Clerk of Works', 'Rate Collector', etc.

Those marked with an Asterisk (\*) are advertised in this Number. Competition, p. iv. Contracts, pp. iv., vi., and viii. Public Appointments, p. xvi.

A SPECIAL RECEIPT FORM CASE.

At the Walsall County Court recently, before Judge Griffith, the case of Broadbent v. Lewis came on for the fourth time. Mr. Toller was for the plaintiff, and Mr. A. Young for the defendant. The plaintiff, a builder's merchant in Leicester, claimed 39l. 2s. 3d. (less 5 per cent.) for goods sold and delivered, and the defendant, a builder in Walsall, pleaded that the money had already been paid to a man named Lane, formerly the plaintiff's traveller, but since dead. The payment to Lane was not denied, but it was contended that it was an invalid payment, the defendant having disregarded a notice printed on all bills and invoices, that no receipt would be valid unless given upon a special printed form, and having accepted a written receipt upon the account. When the case was first heard a verdict was given for the defendant. Then on an application to the High Court to set aside that verdict, a new trial was ordered, and the case was subsequently before the Walsall County Court on two occasions, on each of which the jury disagreed. Mr. Toller, in opening the case on this occasion, said the real point at issue was whether the defendant had exercised such reasonable care as ought to be exercised by an ordinary business man. Mr. Young, for the defence, contended that express notice ought to have been given to the defendant that Lane was not authorized to receive money. The jury was unable to agree. Mr. Toller asked that the case might be sent for trial in another Court. Mr. Young objected, but suggested a reference to arbitration, but Mr. Toller declined to consent.

PROFESSIONAL FEES.

DURMAR and GIBBS V. DUNN and SONS.

In the Westminster County Court, on Monday, this case came before Judge Bayley. The plaintiffs, a firm of architects and surveyors, sought to recover 35l. for professional services rendered to the defendants, builders, of 31, Brewer-street, W. Mr. Elliott appeared for the plaintiffs, and Mr. Beaumont Maurice for the defendants. The plaintiffs' case was that the defendants had a lease of the above-named premises, which would shortly fall in, and, being desirous of renewing it, they applied to the Commissioners of Woods and Forests for a new lease, and then the plaintiffs were introduced to the defendants, and were instructed to draw plans and submit them to the Crown Surveyor, for which they said it was necessary to make an extensive survey, and for that they were to be paid 10l. and 5 per cent. on the estimated cost of the work for drawing the plans. If the work was not done the commission should be 2 1/2 per cent. The work was never carried out, and the defendants had paid nothing for it, hence the present action. The defence was that the 10l. paid into Court was more than sufficient to pay for the work done. The plaintiffs represented that they had interest with the Crown Surveyors, and that the plans they drew were absolutely necessary, when they were not. The plaintiffs had agreed to do what was done for seven guineas. His Honour held that the plaintiffs led the defendants to believe that extensive plans were necessary and that they had influence with the Crown Surveyor. He thought the amount paid into Court was sufficient, and gave judgment for the defendants, with costs.

MEETINGS.

SATURDAY, NOVEMBER 1.

Association of Public Sanitary Inspectors.—Inaugural Address by the President, Dr. J. W. Richardson, F.R.S., entitled, "A Pioneer of Sanitary Science." 8 p.m.

MONDAY, NOVEMBER 3.

Royal Institute of British Architects.—Opening address of the Session by the President, Mr. Alfred Waterhouse, R.A. 8 p.m.

Society of Engineers.—Mr. Percy Griffith on "The Treatment and Utilisation of Exhaust Steam." 7.30 p.m.

Clerks of Works' Association (Carpenters' Hall).—Paper by Mr. T. Edmond. 8 p.m.

Royal Institution.—General monthly meeting, 5 p.m.

Liverpool Architectural Society.—Paper by Mr. J. H. Woodhouse entitled "A Few Recent Notes in Holland and Belgium." 7 p.m.

TUESDAY, NOVEMBER 4.

National Association for the Advancement of Art and its Application to Industry.—Annual Congress, Birmingham.

Sanitary Institute (Lectures for Sanitary Officers).—Mr. J. E. Sykes on "General Powers and Duties of Inspectors of Nuisances." 8 p.m.

Society of Biblical Archaeology.—Mr. R. J. Gildard on "Greek Architecture—Late Period." 8 p.m.

WEDNESDAY, NOVEMBER 5.

National Association for the Advancement of Art and its Application to Industry.—Annual Congress, Birmingham (continued).

London Society for the Extension of University Teaching (Chelsea Centre).—Mr. Walter Leaf on "Heroic Fortresses and Architecture." 6.15 p.m.

THURSDAY, NOVEMBER 6.

National Association for the Advancement of Art and its Application to Industry.—Annual Congress, Birmingham (continued).

Royal Academy of Arts.—Professor A. H. Church, M.A., F.R.S., on "The Chemistry of Painting." 4 p.m.

FRIDAY, NOVEMBER 7.

National Association for the Advancement of Art and its Application to Industry.—Annual Congress, Birmingham (continued).

Sanitary Institute (Lectures for Sanitary Officers).—Mr. J. E. Sykes on "Objects and Methods of Inspection." 8 p.m.

SATURDAY, NOVEMBER 8.

National Association for the Advancement of Art and its Application to Industry.—Annual Congress, Birmingham (concluded).

RECENT PATENTS:

ABSTRACTS OF SPECIFICATIONS.

16,890.—DOOR CLOSER: E. C. Urry and another.—This invention consists of a door acting with a shoe, like many other patterns, but with a special arrangement of arms and levers acted upon by springs and guided by friction-rollers, which, while lessening the friction, give ease and efficiency to work.

plaster and borax, to be used as wished, for ceilings, walls, or enrichments, or for artificial stoue. 17,895.—VENTILATING DRAINS: A. Young.—According to this invention, the bell-shaped receivers or chambers are used, and these chambers are heated by gas and by coils and with asbestos packing. The sewer gas passing up is drawn through these chambers and burnt, the small volume of any escaping by the outlet provided—say, the ordinary street-lamp. 8,402.—WATER-CLOSET FITTINGS: R. Frame and A. C. Crane.—This invention relates to the construction of water-closets, &c., holding water at a fixed level, the permanent overflow point to be discharged on additional water entering the bowl by siphonic action, and consists of a new and improved device for this and also a device for reducing the noise made in such closets by the breaking of the siphon when the closet is discharged of its contents. 11,444.—SPIRAL STAIRS: W. Thompson.—Metallic sections according to this patent, are adapted to be combined to build up a complete spiral stairway and to form, if desired, a double spiral stairway from a common centre. The risers and treads have an eye or socket and groove which fits them together round a common centre. 12,095.—DETECTING LEAKAGES IN SOIL-PIPES: R. T. Crane.—This invention has for its object a method for detecting leaks in soil-pipes. A detectable fluid with pungent scent is introduced in a phial through a perfectly sealed receptacle and then broken in the pipe so that wherever the colour is detected a leak is certain, and there is no uncertainty from the colour hanging about without coming through the pipe.

NEW APPLICATIONS FOR LETTERS PATENT.

October 13.—16,924, P. Crean, Kilm for Burning Bricks, &c.—16,835, J. Gradwell, Ryegate for Gutters, &c. for Ridge and Furrer Roofs.—16,834, T. Edwards, Use of Concrete, Cement, Artificial Stone, &c., for Building Timber. October 14.—16,930, T. Pollard, Chimney Pots or Flues.—16,905, A. Ross, Water Cisterns.—16,328, H. Green, Spirit Levels. October 15.—16,872, S. Meggitt, Automatic Window Fastener.—16,873, J. Littler, Prevention of Steam or Moisture on Windows, Walls, &c.—16,304, F. Ham and H. Preston, Siphon Cisterns. October 16.—16,473, E. Blount, Door Checks.—16,470, J. Jones, Cowls or Ventilators.—16,835, S. Bouchier, Window Sash-fasteners. October 17.—16,510, J. Wood, Preventing the Escape of Smoke from Chimneys. October 18.—16,554, S. Bouchier, Window Sash-fastener.—16,601, A. Middle, Sash-fasteners.—16,609, W. Horn, Mitre Cutting Machine.—16,622, W. Drayson and T. Bright, Basins for Lavatories, Urinals, &c.

PROVISIONAL SPECIFICATIONS ACCEPTED.

9,321, Don Pastor de la Sala, Jolery.—14,162, J. Bott, Circular Saws.—14,184, J. Sears, Ventilators.—14,328, R. B. Bonney, Gears, &c.—14,329, E. Rymer, Factory and Non-Conducting Bricks, &c.—14,760, R. Haddon, Windows and Window Fasteners.—14,823, J. Sears, Ventilators.—15,393, W. Wall, Combined Door Bolt and Indicator.—15,523, E. Thomas, Ascending and Descending Ladders.—15,524, R. C. Cox and E. Kimberley, Combined Plane and Old Stone.—15,622, R. Barker and J. C. E. Thomas, Lamps for Smoky Chimneys and Robins, Switches for Walls or Ceilings for Electric Light.—15,782, J. and A. Chiverrall, Polishing and Enamelling Imitation Stone, &c.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to Opposition for Two Months. 16,301, S. Hill, Door-closing Springs and Checks.—20,237, R. Painter, Raising and Lowering Windows.—20,406, H. Lake, Apparatus for Cutting Veneer.—1,905, T. Willford, Screw Fastener for Windows.—3,355, W. Barker and J. C. E. Thomas, Lamps for Smoky Chimneys.—12,837, J. Costello, Sewing Traps.—14,427, K. McKenzie and G. Anderson, Chimney Tops.

TIMBER (continued).

Table with columns: Deal, Canada, Spruce, 1st, 2nd, 3rd, 4th, 5th, 6th, 7th, 8th, 9th, 10th, 11th, 12th, 13th, 14th, 15th, 16th, 17th, 18th, 19th, 20th, 21st, 22nd, 23rd, 24th, 25th, 26th, 27th, 28th, 29th, 30th, 31st, 32nd, 33rd, 34th, 35th, 36th, 37th, 38th, 39th, 40th, 41st, 42nd, 43rd, 44th, 45th, 46th, 47th, 48th, 49th, 50th, 51st, 52nd, 53rd, 54th, 55th, 56th, 57th, 58th, 59th, 60th, 61st, 62nd, 63rd, 64th, 65th, 66th, 67th, 68th, 69th, 70th, 71st, 72nd, 73rd, 74th, 75th, 76th, 77th, 78th, 79th, 80th, 81st, 82nd, 83rd, 84th, 85th, 86th, 87th, 88th, 89th, 90th, 91st, 92nd, 93rd, 94th, 95th, 96th, 97th, 98th, 99th, 100th.

METALS.

Table with columns: Iron, Bar, Welsh, in London, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

OILS.

Table with columns: Linned, Coconut, Copra, Palm, Rapeseed, Tallow, Lubricating, Tar, Archaengal.

TENDERS.

[Communications for insertion under this heading must reach us not later than 12 noon on Thursdays.]

BALBERTON (near Newark).—For erecting almshouses (six dwellings), Messrs. J. W. Bonwell & W. Taylor, architects, 25, Park-square, Leeds.—

BARTON-UNDER-NEEDEWOOD.—For sewerage works at Barton, under Newstead and Newhall, near Barton-on-Trent, for the Burton Sanitary Authority. Mr. Geo. Watton, surveyor, 39, Derby-road, Barton-on-Trent.

BRAITHWAITE.—For the construction of water-supply works at Braithwaite, Cuckfield, Mr. Theo. Weatherston, Surveyor, Cuckfield.

CARDIFF.—For alterations and additions to Police-station at Cardiff, Cardiff Corporation. Mr. W. Harpur, C.E., Borough Engineer, Town-hall, Cardiff.

CATFORD.—For building one pair of villas residence at Catford, for Mr. Ch. Adams.—

CHESTERLE-STREET.—For further additions to jam factory, Chester-le-Street, county of Durham, for Mr. John W. Lacey, Messrs. Frymoyer & Birchall, architects, 40, Cloth Market, Newcastle-on-Tyne.—

COWBRIDGE.—For the erection of a house and three cottages at Cowbridge, Glamorganshire, for Mr. W. Nevill, Mr. Fred J. Veal, architect, 6, Arrol-buildings, Cardiff. Quantities by the architect.—

DONCASTER.—For draining, levelling, paving, and channelling roads on the Highfield Estate, Doncaster, for the Doncaster Urban Sanitary Authority. Messrs. Brunell, Simons & Brunell, Engineers, 1, Prince-street, Doncaster.—

POWEY.—For additions to the "Powey Mill," Powey, Cornwall. Mr. Henry J. Small, architect, Plymouth. Quantities by the architect.—

RELY.—For additions to bakery and new stables, at Kelly, N. B., for the Kelly Co-operative Stores. Mr. John Houston, architect, Dunfermline, N.B.—

KINGSBURY.—For the erection of stabling and coachman's rooms at "Oakfield," Kingsbury, for Mr. A. O. Crook, the Hyde, Hendon. Mr. Henry Hill, architect, 19, Doughty-street.—

LEWISHAM.—For kerbing and paving the footpaths and channelling and metalling the roadway of Alerswood-road, Lewisham, for the Lewisham Board of Works. Mr. John Carlin, Surveyor, Board of Works Office, Catford, S.E.—

LIANELLY.—For the erection of the "Halfway Mill," near Lianelly, Messrs. J. Buckle, Wilson and Glemingham, Bushan, Lianelly.—

LONDON.—For the erection of Camberwell Public Baths, East Dulwich-road. Messrs. Spalding & Cross, architects, 15, Queen-street, E.C.—

LONDON.—For making up seven new roads or portions of roads, viz. Milton-road (second section), Addington-road, Quernmore-road, Oakfield-road (second section), Fairfield-road, Millers-road (first section), and Whitcomb-road (fourth section), for the Hornsey Local Board. Mr. T. de Courcy Meade, Engineer and Surveyor, 15, St. James-street, E.—

LONDON.—For alterations and additions to the "Penton Arms," Pentonville-road, N. for Mr. W. Martin. Mr. John Cox, Esq., architect, 117, Great Russell-street, Bloomsbury, W.C.—

LONDON.—For new storm-water sewer, Ferme Park Estate, for the Hornsey Local Board. Mr. T. de Courcy Meade, Engineer and Surveyor, 15, St. James-street, E.—

LONDON.—For new sewers from Hackney to Highgate, for the Hornsey Local Board. Mr. T. de Courcy Meade, Engineer and Surveyor, 15, St. James-street, E.—

LONDON.—For work at Harlesden College, for Mr. R. McKee. Mr. F. S. Shaw, architect, Harlesden, N.W.—

LONDON.—For alterations to the Temperance Hall, Swanemore-street, Canning Town. Mr. A. Crow, architect, 33, Queen Victoria-street, E.—

LONDON.—For repairs at Hampton, Camberwell, for Mr. Augustus Jones. Mr. Thos. P. Shaw, architect, Harlesden, N.W.—

PRICES CURRENT OF MATERIALS.

\* Accepted. † Informal.

At Portland (Mrs. High-street, St. John's Road).—In our last issue (page 356) we gave the name of S. E. Todd as accepted for the above; it should have been G. E. Todd.

Alterations to the "Ruin Punchon" Public-houses.—We are asked to state that the amount of the tender for the above work, which appeared in our issue of the 11th ult., should have been £262, not 400. The mistake was not ours.

SUBSCRIBERS IN LONDON AND THE SUBURBS, by prepaying at the Publishing Office, 15s. per annum (or 4s. 6d. per quarter), can ensure receiving "The Builder" by Friday Morning's post.

TERMS OF SUBSCRIPTION. "THE BUILDER" is supplied twice from the Office to residents in any part of the United Kingdom at the rate of 15s. per annum. Foreign, to all parts of Europe, America, Australia, and New Zealand, 25s. per annum. To India, China, Ceylon, &c. 30s. per annum. Remittances payable to DOUGLAS FOURDRINIER, Publisher, No. 46, Catherine-street, W.C.

TO CORRESPONDENTS.

A. W. & Co.—W. G. F.—S. C. (thanks, but hardly suitable. Please send address.)—J. L. (shall have it done)—P. E. P. All statements of facts, lists of tenders, &c. must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline printing out books and giving addresses. Next.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors. We cannot undertake to return rejected communications. Letters or communications (beyond news items) which have been duplicated for other purposes, are NOT DESIRED. All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

PUBLISHER'S NOTICES.

Registered Telegraphic Address, "THE BUILDER, LONDON."

CHARGES FOR ADVERTISEMENTS.

SITUATIONS VACANT, PART-TIME, APPRENTICESHIPS, TRADE, AND GENERAL ADVERTISEMENTS. Six lines (about fifty words) or under..... 4s. 6d. Each additional line (about ten words)..... 5s. 6d. Terms for series of Trade Advertisements, also Special Advertisements on front page, Competitions, Contracts, Sales by Auction, &c. may be obtained on application to the Publisher.

PREPARATION IS ABSOLUTELY NECESSARY. FOUR Lines (about thirty words) or under..... 3s. 6d. Each additional line (about ten words)..... 5s. 6d. \* Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, Cornhill, London, W.C. PREPARED BY DOUGLAS FOURDRINIER, Publisher, Addressed to No. 46, Catherine-street, W.C.

Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on TUESDAY, but those intended for the front Page should be in by TWELVE noon on WEDNESDAY.

SPECIAL ALTERATIONS IN STANDING ADVERTISEMENTS OR ORDERS TO DISCONTINUE same must reach the Office before TEN o'clock on WEDNESDAY morning. The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

Persons Advertising in "The Builder" may have Replies addressed to the Office, 46, Catherine-street, Covent Garden, W.C. Letters will be forwarded if addressed in envelopes are sent, together with sufficient stamps to cover the postage.

AN EDITION Printed on THIN PAPER, for FOREIGN AND COLONIAL CIRCULATION, is issued every week.

New ready. READING CASES, 9 NINEPENCE EACH. (By post carefully packed, 1s.)

### A Few Norman Stones.

WELVE years ago, *i.e.*, on Feb. 15, 1878, a circular was issued from Versailles by the Minister of Public Works to the members of a Committee (which was then appointed) to

examine and report on the various kinds of stone in use or capable of being used on the roads in France. This Committee, composed of eight officers of superior rank in the department of the "Ponts et Chaussées," under the presidency of M. Graeff, an Inspector-General in that department, presented their report in 1880; and, as no great change in the relative value or condition of the varieties of stone then reported on can have occurred in the comparatively short period of ten years, we believe that a brief glance at that exhaustive compilation will be an appropriate preface to the further consideration of such varieties as might possibly be utilised with advantage in this country. The engineers employed on the roads of the different departments and arrondissements were directed to send samples to the Committee, with reports of their relative value, prepared on such a basis that uniformity was ensured in the computation of those values. The total number of samples so received amounted to no less than 2,414, but as this number appeared to be in excess of that which was really necessary, the Committee decided to select seven or eight varieties from each department, and they actually tested 637 samples, representing seventy varieties of stone.

We have prepared from the elaborate tables appended to that report, a list of the most important varieties, arranged according to their ascertained value for work, irrespective of price, into which we need not at present enter. Besides those now tabulated, there were a great many rounded gravels and pebbles brought under test, but the results recorded by the Deval machine ought not in fairness to have been brought into computation, as the loss by weight was, in consequence of the previous removal of all angles, naturally very slight in such stones.

The experiments carried out by this Committee were conducted with such scrupulous care that it forms the most valuable record possible to obtain of the actual value of such

stones. The table below gives the averages and the aggregate of those averages for many samples; but, of course, in most classes a very great variation occurred between those which gave the best results and those which gave the worst. It will, however, be noticed that though flints and millstones head the list in column 5 (resistance to crushing), they only occupy the seventh and eighth places in order of merit, and that those stones which are reported as the best by the engineers who have used them, are also first in the order of merit in the combined laboratory tests. Quartz, porphyry, eruite, and the basalts, have all practically the same value, and are well behind quartzite. Grès, which is a variety of quartzite, closely follows basalt, and the grautes are only better than the limestones. It may be mentioned also that the ninety-one different samples of pebbles and gravels which were tested only averaged 96 in column 6 (reports of the road engineers).

TABLE A.

1	2	3	4	5	6	7
Order of Merit.	Class of Stone.	Average number of samples tested.	Coefficient of wear by means of the Deval machine, for registering revolutions of spherulite.	Coefficient of resistance to crushing by gradual pressure.	Coefficient of wear based on consumption of material per cubic centimetre per kilometre.	Aggregate Value.
1	Quartzites.	25	16.6	14.2	14.0	44.8
2	Quartz.	53	14.3	14.3	14.2	42.8
3	Porphyries.	29	16.0	12.8	13.9	42.7
4	Eruite.	9	16.0	13.4	13.0	42.4
5	Basalts, Traps, and Diorites.	41	15.0	12.8	14.3	42.1
6	Grès (metamorphic sand-stone).	43	15.4	13.2	12.5	41.2
7	Flints.	77	11.1	16.6	11.3	39.4
8	Millstones.	19	11.1	15.2	11.1	37.4
9	Schists.	13	13.4	12.2	11.6	37.2
10	Grautes.	14	14.3	12.0	10.2	35.5
11	Granite and Syenites.	55	13.6	10.2	10.5	34.3
12	Limestones.	137	10.2	9.9	8.0	25.1

When the Report which we have had under our consideration was prepared, an additional method for testing relative value had not then been brought into use. This method is by means of a machine invented by a M. Dorry, and has already been briefly alluded to in our columns in connexion with the Paris Exhibition last year.\* It is a frictional

machine, and has further demonstrated (as indicated in the table below) the superiority of resistance to constant wear of quartzites over any other kind of stone on which experiments have recently been conducted.

TABLE B.

Results of Tests of different Road Materials made at the Laboratory of the Ponts et Chaussées, in Paris, in 1880, with the "Dorry" Machine.

N.B.—The annexed numbers give in decimals of an inch the thickness of stone removed by friction from the lower side of a prism loaded with a constant pressure of 511 lbs. on the square foot, the grinder (64.5 in. circumference) revolving 4,000 turns at a speed of 2½ miles per hour:—

1. Quartzite of Cherbourg (Manche) ..... 11
2. Quartzite of Domfront (Orne) ..... 15
3. Quartzite of Votré (Mayenne) ..... 16
4. Quartzite of Croixille, near Harcourt (Calvados) ..... 18
5. Grès de St. Sauveur le Vicomte (Manche) ..... 21
6. Grès d'Erquy (Cotes du Nord) ..... 22
7. Grès d'Eperton (Eure et Loire) ..... 24
8. Porphyry of Lessines (Belgium) ..... 24
9. Granite from Norway ..... 24
10. Grès de St. Cheron (Seine et Oise) ..... 24
11. Porphyritic granite of Clefay (Vosges) ..... 25
12. Granite of Sauc (Mayenne) ..... 26
13. Porphyry of Quenast (Belgium) ..... 27
14. Granite of Flamanville (Manche) ..... 27
15. Granite of les Chausey ..... 29
16. Granite of Arkoze ..... 29
17. Granite of St. Brieuc (Cotes du Nord) ..... 29
18. Granite of Rostelle (Finisterre) ..... 33
19. Granite of Brest (Finisterre) ..... 39

And many others with greater loss by friction. It will be noticed that the relative aggregate wear of the different varieties of stone here given is approximately as follows:—

Quartzite ... 1  
 Grès ... 1½  
 Porphyry ... 1¾  
 Granite ... 2

That is to say, granite would wear out twice as fast as quartzite, an approximation to the results arrived at by the preceding tests.

If we examine the geological maps of the north-west of France, it will at once be seen that the volcanic and metamorphic rocks are almost entirely absent from Picardy and the eastern portion of Normandy, and it is consequently the case that, though in the interior of those provinces local stone has to "be made the best of," large quantities are imported from many parts; for instance, the porphyry of Lessines and Quenast finds its way to Arras from Belgium, and the quartzite of Cherbourg is used to a great extent in the towns along the coast, such as Havre, Dieppe, Boulogne, and Calais. Starting from the north-west corner of the horn of the Depart-

\* The Builder, June 15, 1889, p. 440.

ment of Manche, viz., Cape de la Hague, great beds of metamorphic rocks stretch down in a south-easterly direction through Manche, Calvados, and Orne, having their northern limit a little to the south of Caen, and their southern down in Brittany and the northern portion of Touraine. Through this vast mass of excellent road material, granite and other volcanic rocks of many kinds protrude here and there as usual, and Normandy is rich indeed in the stones it possesses.

In the hilly district inland from Avranches, a capital white quartzite is found in the hill-side above the very picturesque town of Mortain; it is used generally throughout that district, but the price at Granville (the nearest port),—viz., 8s. 8d. per ton for 2½ in. stone,—is too high to enable it to be available for export in competition with other places, as, however good a stone may be, it is generally useless for export unless it lies near a good port. Proceeding round to Cherbourg, we find the two requisites,—the port and the stone,—close together; for, immediately at the back of the town lies the so-called mountain of Roule, the top of which is about 400 ft. above sea-level. The northern portion of this hill, which faces the harbour, is a solid mass of quartzite, in beds of from 2 ft. to 7 ft. in thickness, which, as a rule, no intervening strata of rubbish or inferior rock. The dip to the north and north-east varies from about 50° at the west end of the hill (which is precipitous and cut off by the little stream of the Divette), to vertical in the centre, with a reverse slope to the south towards its east end. Starting from the west end, which is nearest to the docks, the first quarries are those which belong to the Department of Marine, from which, together with others, the great Digue, or breakwater, has been constructed. No machines are employed in either of these quarries, and but few men; but the quality of the stone is very good. Next to these is the quarry of the *Société Anonyme Française*, which is one of greater importance. M. Menut, who is the manager of this Company, employs a considerable number of workmen, and has recently erected a crushing mill of some size, supplied by a French firm of engineers. There is no apparent difference in the quality of the material here from that in the above-mentioned quarries.

Proceeding eastward we arrive at the extensive quarries of MM. Fonty et Cie, who employ about 300 workmen, 150 of whom break stone by hand, the remainder being employed in quarrying and dressing sets, and at the crushing-mills, of which they possess two. The first, which was provided about a year and a-half ago by Mason, of Leicester, is of the usual type, having a riddle 12 ft. long and 3 ft. 6 in. in diameter, divided into three sections, pierced with 1, 2, and 2½ in. holes respectively. It is set at an angle of about 20 deg. to the horizontal. The 4½-horse power engine which works it also works a grinding-mill and a small, very fine riddle, set up expressly for producing the sand of crushed quartzite, which is used almost, if not quite, exclusively now at the Government and other laboratories in Paris and in the cement factories in France for testing the quality of cement. The variety of processes through which the stone passes before it is converted into sand, passing the requisite tests of the Government, runs up its cost to a somewhat high figure, viz., 8s. per ton. But this is not a matter of any great significance, for the quantity required is never very great; it, however, furnishes us with an admirable example of the extreme care taken by the French Government to obtain the most reliable data from the tests to which they subject materials. They recognise that the results obtained by an admixture of cement with sands of various textures, and whose grains are of various forms, are unreliable. For instance, sand with, in the one case, sharp-angled grains, and, in the other case, round grains (such as sea-sand), would produce the same difference in tests for strength as those in concrete in which broken stone and round pebbles had been severally used.

The other crushing mill, which has been in use for about four months, has been supplied by Marsden, of Leeds, and is in many respects so different to those in general use that it will be instructive to give a more detailed account of it. The rough blocks of stone (from the size of a man's foot to that of his head, or a little larger) are shovelled or thrown at required intervals from the railway trolleys (mètre gauge), each of which holds about five cubic yards, into the hopper connected with the crushing jaws, from which the broken stone is carried by a shoot into buckets attached to an endless chain; this is set at an angle of about 60 deg., and empties the contents of the buckets into a hopper, which feeds the lowest of two riddles. This riddle is set horizontally, and with a diameter of 3 ft. 6 in. at the end next the hopper, increasing to 6 ft. at the outlet, is consequently in the form of a truncated cone. Its length is 12 ft., which is divided into four sections, pierced with circular bores 1, 1½, 2, and 2½ in. respectively, the smallest bores being next the feeding hopper. This riddle revolves, and the larger stones gradually work towards the other end, parting in their progress onwards with the smaller particles. That which remains falls into a shoot, which feeds another series of buckets on an endless chain, set at an angle of 50 deg. by means of which the bulk of the stone, now partly screened, is raised to an upper level and discharged into a hopper which feeds a second riddle. The spindle of this upper riddle lies about 6 ft. above, and the same lateral distance from the spindle of the lower riddle. This is also set horizontally, and is also in the shape of a truncated cone, being 3 ft. 6 in. in diameter at the inlet, and 5 ft. diameter at the outlet. It is 10 ft. 6 in. in length, divided into three sections pierced with holes of 1½, 1¾, and 2 in. respectively. All stone which fails to pass through the holes in the last section passes out at the end to a shoot, which sends it back automatically to the crushing jaws. Beneath each section of each riddle is a container, from which the trucks below can be filled by means of sliding trap-doors, capable of being opened and closed by cranked arms. Consequently, two lines of narrow gauge (half mètre) rail can be placed under the mill, carrying trucks, each of which contain half a cube metre of broken stone, and the various sizes of metal and material for concrete are readily sorted and run to heap. The arrangements of this very compact mill, which is worked by a 35 h.p. engine, are stated to have been designed by M. Fonty (one of the members and Managing Director of the Société) and are undoubtedly most complete and creditable.

With these first-class machines, a very small proportion of flaky stone and a very large proportion of well-cubed stone is produced; so much so, that the difference between this and hand-broken metal is, even to a well-practised eye, scarcely apparent, and, practically, the value of each for road work is the same.

Taking one week with another, the 150 hand-breakers, from one cause or another, do not turn out more than about 700 tons of metal, whilst the two mills will produce more than double that quantity per week.

The quarries are, as usual, sub-let to gangs of from six to twenty men each, who find their own tools, or they can be supplied and kept in order for them by the Société at fair prices. They also find their own blasting-powder, which (as is usual in similar quarries elsewhere) is preferred to any other nitrogenous compound, and the quarrymen and stone-dressers are paid solely for the sets they produce, the whole of the remainder of the quarried stone, which is afterwards broken up generally into road metal, being the property of the lessees of the quarry, and supplied free of cost to the hand-breakers and to the mills. The cliffs or exposed faces of these quarries are in some cases of considerable height, even up to about 200 ft., and, as is frequently the case elsewhere, the best stone is distinctly better than that near the surface. A small proportion of the stone is

of a very light grey colour—almost white. This is comparatively easy to work, both for sets and for metal, and can be supplied at slightly lower price than the pale blue-grey which is the most durable, and the characteristic stone of Cherbourg. There is also a little slightly tinged with iron, which is probably as durable, but not, of course, as desirable where colour is deemed important. The durability of this stone is well exemplified by the fact that at the approaches to the dock bridge at Cherbourg, where the traffic is very considerable, the wear on the quartzite sets is much less than that on some granite rarer blocks which have been once renewed, the two being laid side by side with each other.

It is usual in France to pave with sets of a much greater width than those which are commonly used for English streets, and it is believed by the Cherbourg stone-cutters that narrow sets could not be made from their stone without an enormous waste of material. That might be so, but it could be tried. They, however, maintain that there is no real advantage to be gained by the narrow sets which only make more joints, and add so much to the cost of the paving, considering that the security of foothold does not, or should not, depend particularly on the joints in the pavement, but in the irregularities on the surface of the stone, a view supported (so far as that point is in question) by Mr. Dunscombe, the late eminent engineer to the Corporation of Liverpool and the County Council of London. But the heaving of the sides of these large sets seems unnecessary and erroneous in every way. The size of metalting most frequently demanded is about 2 in., and a large trade is being done with the constant ports of France, and (more recently) with some few places in England, viz., Southampton, Sheerness, Erith, &c. It appears to be an excellent material and deserving of confidence, more especially as it can be supplied to any places where good durable stone is scarce at very moderate prices, i.e., from 10s. to 11s. a ton for 2 in. metal. It would probably pay the proprietors well to make a railway to the dock in place of transporting it in the unwieldy carts which are invariably used in that part of France, and are sometimes loaded up with as much as six tons of stone, the usual allowance of horses being one per ton of stone. This gives a gross weight of nearly three-quarters of a ton per inch of tire, which necessitates stout roads.

The laboratory reports on this quartzite of Cherbourg are very satisfactory, and are as follows, computed on the same principles as in Table A:—

Co-efficient for resistance to crushing	20.4
Do. do. to shock	21.5
Do. for actual wear on roads	18.5
Total	59.4

which is far beyond the average of 44.8, the highest on the list in Table A.

The chemical analysis of the sand is also very remarkable, giving 99.45 of silica, which does not leave much room for anything else.

The next, and last, place which we need consider in connexion with this branch of the subject is Caen. About eight miles south of that town lie the celebrated quarries of grès stone near the village of May. Those close to the village and running from it down a huge artificially-cloven gully to the bank of the river Orne are M. Caval's, and those lying to the north of M. Caval's and running in two lines parallel to the above-mentioned gully are M. Barrier's, a gentleman who also owns the quarries of white grès at Perrieres (between Mezidon and Falaise), a stone which is used for similar purposes to those at May, and is, in the opinion of some of the engineers, even its superior in quality. This grès is a very compact metamorphic rock of moderately fine grains of sand solidified by a cement of extraordinary tenacity. As has been frequently remarked, it is very difficult to determine the distinction between grès and quartzite; nevertheless, the stone of May and the stone of Cherbourg are in appearance very dissimilar, the latter being a

pale bluish-grey, and the former varying from a deep copper colour to a buff-grey, and is not infrequently grey, mottled with copper. The power of this stone to resist abrasion has already been noted in our columns in connexion with an article on "The Paving-stones in the Paris Exhibition," and it is very extensively used throughout all that part of Normandy. The strike is W.N.W. and E.S.E., and the dip about 45 deg. to the north. In these quarries a good deal of poor rock (especially in the quarries of M. Barrier) intervenes between the main strata, which vary very much in thickness, some being very thin and in much demand for flagging and foot-path work generally.

There are also quarries of grès on the west side of the river Orne, opposite to those at May, and nearer to the station of Fouguerolles. These are little more than superficial scratchings, but many thousand tons of broken metal are piled in little heaps all over a large area, which belongs to a M. Thomasse, who, for some reason or other, has allowed most of it to remain there for a considerable period. It does not appear to be quite the equal in quality to that on the opposite side of the river. The setts and squares from May find their way to Paris and many other towns. There does not appear to be any difference in quality between the copper-coloured grès and that of other colours: and, though some may fancy that the red is the best, no difference is apparent in the wear of the little squares which pave most of the footpaths in that part of France, whatever their colour may be; but the more crystallised outwears the duller portion of the rock.

The prices of this stone, free on board at Caen, are as follows:—

Setts, from 11s. 6d. to 13s. 6d. per ton, covering from 2½ to 2¾ yards super. They are from 6 to 7 in. in depth, and are 5 to 6½ in. by 7 in. in area.

Squares, from 22s. to 36s. per ton, covering from 7½ to 10½ yards super. They are from 1½ to 3 in. in depth, and from 5 in. by 5 in. to 6½ in. by 6½ in. in area.

2 to 2½ in. stone broken, 5s. 6d. per ton. Unbroken stone in blocks, 4s. per ton.

The stone from May is transported chiefly by cart, if intended for export, and put straight on board at Caen, which saves the double shift into the railway-trucks at Fouguerolles, and out again at Caen Station, notwithstanding the proximity of the former station to the quarries. The canalisation of this part of the Orne would not be an expensive or a difficult matter, and would considerably reduce the cost of transport of this stone. Below Caen the river is tidal.

Through many miles of this red grès the line of railway passes on its way from Caen to Fiers, and as the river Orne winds through it, leaving steep wood-clad bluffs of some 200 ft. in height, first on one bank and then on the other, we become aware that beautiful scenery is obtainable in Normandy, of a character not dissimilar to that of the finest parts of Derbyshire, and therein lie the homes of the road stones.

NOTES.

**T**HE Art Congress at Birmingham has been in one sense more successful than either of the previous ones, owing to the alteration in the grouping of the meetings, by which in the mornings there has been a collection of all the members at one meeting only, and in the afternoons there have only been two meetings in progress simultaneously, the subjects connected with various sections being more or less grouped together. This is a much better arrangement for promoting the interest and spirit of the meetings than dividing the proceedings up into five sections meeting simultaneously in five different rooms, which leads to the splitting up of the audiences into a number of small groups, or the entire desertion of one or two sections in favour of one particular one which happens to be popular. This led to some of the best and most

useful papers at both the two previous Congresses being read to audiences of half-a-dozen people. The new arrangement is certainly advantageous to the cause of Architecture, which is always the unpopular section with the majority of the subscribers, as the subject they know least about. Under the new arrangement they can be got together into one room by something they care about, and can then be caught and taught about architecture. There was a fair attendance at the Wednesday morning meeting, which was a specially architectural one, when Mr. T. G. Jackson read his address as President of the Architectural Section, which was an admirable and very moderately-worded protest in favour of the purely artistic view of the architect's function, as that of an artist, and not a surveyor. A short and very spirited paper by Mr. R. T. Blomfield, which was evidently much enjoyed by the audience, followed very aptly as a protest in the same direction, but in a lighter and less serious vein. In next week's issue, when the whole of the papers will have been read and can be considered and compared, we may be able to give something like a summary and critical estimate of the general results of the teachings of the third Art Congress.

**A**S will be seen by our report of the meeting of the London County Council, that body, after about four hours' further discussion, on Tuesday last adopted by a large majority the extensive scheme, propounded and recommended by the Housing of the Working Classes Committee, for the clearing away of a large slum in Bethnal Green. The proposals of the Committee were fully detailed in their report, presented to the Council last week, and printed by us nearly *in extenso* at the time. The opponents of the scheme did not deny the wretched and insanitary condition of the hovels which cover the fifteen acres of area in question; they merely differed from the majority as to the best means of procedure, and they very rightly urged that it would be desirable to proceed with great caution in the promotion of such schemes if they did not wish to put a premium on "the cultivation of slums for the improvement market." They also urged, and with much justice, that the local authorities should be far more sharply kept to their obligations, in such matters as paving and scavenging, than they have been hitherto. From a personal inspection of the area in question made on Wednesday last, we must testify to the apparently utter absence of scavenging, the streets being strewn with garbage of all kinds. The paving, in places, notably in front of the house No. 1 Sherwood-place, at the corner of Christopher-street, is in a disgracefully broken and dangerous condition, full of holes admitting of the passage of surface water, more or less foul, to the sub-soil of the houses. Some of the houses on the area scheduled are very dilapidated and old. In the side of the house at the corner of Mount-street and Church-street is an ornamental tablet with a rose in the centre, and inscribed "Rose-street, 1725." We trust that in carrying out the scheme care will be taken to avoid wholesale evictions, which can only lead to overcrowding in other parts of the neighbourhood. There are on the area scheduled several vacant sites, or sites only cumbered by condemned houses, which might be made available for the commencement of the work of erecting new and sanitary dwellings to receive the inmates of the adjoining hovels.

**T**HE country fire season has now commenced. A serious fire, for example, occurred not long ago at Sir George D'Assent's house at Ascot. Of course, the first thing is for occupiers to do their utmost to prevent fires by seeing that the structure of the building is in proper condition, and that due care is taken with lamps and candles. But it is a matter of doubt whether, generally speaking, England is not behindhand in regard to appliances for extinguishing fires. It has

been stated more than once, on good authority, that the London Fire Brigade is underrmanned, but in many provincial districts there can scarcely be said to be proper appliances for putting out fires at all. In some instances there is a Volunteer Fire Brigade, with an engine which is often very weak, or not in good order. The Towns Police Clauses Act, 1847, is incorporated with the Public Health Act, and contains a clause giving power to Commissioners to obtain proper appliances. But what seems to be required is some general system. There should be fire brigades in every town of a strength in proportion to the size and population of the town, and in the country there should be engines and escapes at certain defined centres, and the cost should be defrayed from the rates. Until this is done properly can never be as safe from injury by fire as it might be, and the rates of insurance for buildings cannot be safely lowered.

**W**E have received from Messrs. Flockton & Gibbs, of Sheffield, the specification of the patent which they have taken out for their improved plan for the arrangement of public buildings, as illustrated in their plans sent in competition for the Sheffield Municipal Buildings. The complete specification lays down the main point thus—

"The plan for which we claim novelty is the placing of the rooms of each department in a separate wing or compartment of the building, arranging the rooms within it as if each wing or compartment were a separate building with entrance for the public to each department through or by an inquiry or general office, and with no other entrance for the public to the private offices; and combining the several departments into one building by grouping the wings or compartments around a central public hall or passage, through which alone the public can gain admittance to the inquiry or general offices of the several departments."

This is a clear and definite statement of what is claimed by the patentees as an invention for protection, and it will no doubt be a matter of considerable interest for the architectural profession to have the question, whether there can be a patent-right in a special plan of building, discussed and definitely settled. Messrs. Flockton & Gibbs ask us to draw attention to the fact that notice of opposition to the patent can be given within two months after the date of advertisement (October 29), "on the grounds stated in section 11 of the Patents Act of 1883. The subsequent procedure is set forth in sections 12 and 13 of the same Act, and in Nos. 34 to 44 of the Rules under the Act."

**I**T is satisfactory to learn that the principle of arbitration has been upheld by the decision of the Board of Conciliation which took the Tyneside shipbuilders' dispute in hand. It will be recollected that this Board was formed on the recommendation of the Mayor of Newcastle, and was composed of representatives of the various crafts connected with shipbuilding, with full power to settle the dispute. They considered,—as, indeed, did all parties except the disaffected joiners,—that all those concerned were bound to comply with their written agreement to adhere to Mr. Burt's award; and the strikers were accordingly ordered to resume work this week. Certain minor points connected with the apportionment of work between the carpenters and joiners have yet to be decided upon. Disputes arising from "division of labour" have been rather numerous of late, especially in the shipbuilding trades, though few, fortunately, have resulted, as this affair has done, in a strike extending over a period of three months. For instance, there exists at the present time a considerable amount of dissatisfaction amongst the ships' plumbers, &c., arising from similar causes, which also threatens a cessation of work. These are matters which the men take very largely into their own hands, and whatever the merits of the case may be, and whichever section of the men is really aggrieved, the employer is bound to suffer in the event of a strike,—although he may be on the best of terms with

\* Builder, October 19, 1889, page 271.

each department concerned. Nor is it to be charged against him that it was in his province to have apportioned the work satisfactorily at the outset, and thus have left no room for complaint. For gradual but revolutionary changes in the style and build of vessels, and in the methods of constructing them, has by degrees effected a disarrangement of the original apportionment of the labour. This, at least, appears to be one of the principal features of this very irritating, among the many causes of strikes,—and one with which Conciliation Boards would seem to be best able to deal.

AN apparently inspired article in a recent issue of the *Times* again refers, and at some length, to the so-called Grand Junction Railway—that is, to the amalgamation of the Manchester, Sheffield, and Lincolnshire Railway Company with the Metropolitan Railway. Some kind of scheme for joining these two lines appears to be in the air, but as two hicks do not make a white, so two poor companies joined together do not make one rich and flourishing company. It was stated in the article to which we allude that a terminal station will be constructed near Lord's Cricket Ground for the purposes of the distant traffic, and that Baker-street will continue to be the terminus for local traffic. A terminus in such a northerly part of the metropolis as St. John's Wood is not one which is likely to increase main line traffic to the North, and for purposes of public convenience, and for the future prosperity of the new system, we have little doubt that Baker-street is the proper place for a terminus. But, as we have more than once pointed out, it would be necessary to double the existing St. John's Wood line and spend an enormous sum of money in the purchase of land at Baker-street. The fact is that the main line of the Metropolitan is being constructed before a terminus has been found, and if one is built at St. John's Wood it will be rather that of the Sheffield Company than of the Metropolitan.

THE Exhibition of the Institute of Painters in Oil Colours, which opened this week, is strongest in landscape, and contains some fine works of this class. Among these are Mr. Hughes-Stanton's "A Peep of the Arian" (43), Mr. David Murray's "Hallowed Ground" (87), a scene in the churchyard of a village, very fine both in sentiment and colour; Mr. Wimper's "A Fresh Day" (92), a health scene with great piles of clouds travelling on the wind—a fine example of the old school of water-colour painting; Mr. Parton's "Summer days at Wargrave" (162), and Mr. Johnson's "Richmond Bridge" (630), Mr. Hope McLachlan's two landscapes, "A Pastoral" and "On Ashkam Common" (234, 244), are remarkable little works of their kind, but rather landscape *fantasies* than transcripts from nature. Among figure pictures Mr. J. H. Bacon's "A Song of Long Ago" (111) has real feeling and artistic power. Mr. Joseph Clark sends a picture entitled "Familiarity Breeds Contempt" (384) in which the figure of the boy seated on the left should be noticed as one of the best things in the Gallery; as a whole the picture is not as interesting as many of his. Mr. John Burr's "Better is a Dry Morsel and Quietness Therewith" (377) is a very interesting little work, and Mr. Hugh Carter, in "A Dutch Coghler" (586) has achieved a remarkably good imitation of Israel. Mr. T. B. Kennington, who is never commonplace or uninteresting, sends two or three works, among a rather large one, "His Daughter's Balm" (237), representing an old man and his grandchild seated together, which is quite above the average level of the work at this exhibition, not only in execution but in the refinement and character shown in the two thin and sad faces. Mr. John R. Reid's various works give one in another sense rather a melancholy feeling—the work of a gifted artist who is going astray in search of an original style; he may be said to have found it, but it is a style

essentially false and sensational, in spite of a certain power of colour. Mr. Pullylove has a couple of little views of Ely Cathedral; Miss Maud Gruttwell's cleverly-painted little works, "Students" (345) and "Egyptian Still Life" (376) show remarkable talent in their way; Mr. T. Farquharson has made a realistic study of "The Banks of the Nile" (561); and Mr. F. D. Millet has one of his interiors with a figure under the title "Michaelmas Daisies" (319) which, besides the general merit belonging to his careful and refined but rather inexpressive work, is remarkable for the brilliant colour effect produced from the jar of bright flowers which forms the central "accessory" of the scene. The Exhibition suffers, like most of its predecessors, from being too large and including too much work which can be of no value or interest except to cover the walls; it would be far better to hang fewer works and keep the standard higher. There are some (figure pictures especially), which we do not care to particularise, the admission of which into anything pretending to be a high class exhibition is absurd, and most detrimental to the reputation of the Institute.

TWO collections of works have been exhibited simultaneously this week at Messrs. Dowdeswell's Galleries in New Bond-street: a collection of pastels of Hampstead Heath views, by Mr. H. Muhrman, and a set of paintings of Highland cattle by Mr. T. Denovan Adam, an Associate of the Scottish Academy. Mr. Muhrman's pastels are marked by what we should deem an affectation of roughness of execution, and are certainly not suggestive of open air and daylight; and in some cases the worship of smudginess is carried to such an extent that it is difficult to tell what is intended at all. Mr. Adam's cattle-paintings, which are the result, we are told, of many years' study of the Highland cattle in their native scenes, are also somewhat rough in execution, painted with a certain defiant vigour which seems indifferent to superficial finish, but they are many of them very powerful works, and show the rough, shaggy, and almost truculent physiognomy of the animals with every appearance of truth. Some of the scenes are very fine in colour also, and there are some among the smaller paintings that remind one of Troyon.

THE Pastel studies of wild animals by Mr. Nettleship, now on view at Mr. Dunthorne's pretty little gallery in Vigo-street, are of unusual interest. In the note prefixed to the catalogue we are told that each of these studies is a direct record from Nature, the attitude and action being in every case drawn from the animal itself as actually seen at a given moment of action or repose. They produce the impression of truthfulness which this system would seem to promise, and many of them are remarkable examples of drawing. Among the best are the "Tiger stretching" and the "Tiger walking" (20 and 21), "The Bison" (22), the "Head of a Lion" (25), the "Polar Bear" (53) emerging from the water, and the "Young Lion" (62). Most of them, we believe, are studied from the animals at Regent's Park. The drawing of the "Wapiti Stag" (56) seems to fail in giving the true character of the head, which appears too heavy and blunt in shape. But in general these are very fine studies, and the author is not one of those who regards Pastel as a medium that affords an excuse for roughness of execution: the sketches are nearly as fine and delicate in finish as sketches can or should be.

FROM a statement prepared by the Burgh Assessor of Edinburgh, it appears that the rental of the City for the year 1890-91, exceeds that of the previous year by the sum of 41,270*l.* The first valuation after the passing of the Act, for the year 1855-56, was 761,963*l.* 9*s.* 1*d.* That for the current year is 2,106,395*l.* 1*s.* 4*d.*, showing a total increase for the last thirty-five years of 1,344,531*l.* 12*s.* 3*d.* As Edinburgh is not a

manufacturing town, this increase is owing to its attractions as a place of residence. It is, therefore, incumbent upon the citizens to keep a sharp outlook upon any attempt to decrease the amenity of the city.

TIME final closing, as a Chapel Royal, of the Banqueting House, Whitehall, puts the period to the last stage in the history of the building. What the next will be remains to be seen. Inigo Jones's original plans are still preserved, we understand, at Worcester College, Oxford, to which foundation they were bequeathed by J. Oliver, City Surveyor, who died, 1736. They would have covered an area of about twenty-four acres, consisting of seven courts, with frontages of 874 ft. to the river and St. James's-park, and return frontages of 1,200 ft. towards Charing Cross and Westminster. Three sets of them, differing in certain particulars, have been published, one in Campbell's "Vitruvius Britannicus," 1717, of which set the authenticity has been questioned; another, being four large prints, by Lord Burlington, 1748-9; and another, several plates, by Kent, 1727. A series may also be seen in the Crowle Pennant, at the British Museum; and there is a large collection of views and drawings in the Guildhall Library. Wren made three designs for additions to the Banqueting House for King Charles II., and after the fire of 1697, for King William III. Portland stone is said to have been used for the first time in its construction.\* Inigo Jones was paid 8*s.* 4*d.* a day, as surveyor, with 46*l.* a year for house-rent, clerk, and expenses. Nicholas Stone, his master-mason, received 4*s.* 10*d.* *per diem*. For the painted ceiling Rubens was paid 3,000*l.* The modern annexe, a sad disfigurement, by J. Wyatt, on the northern side, replaces a building which is shown in one of Hollar's set of views, that of the western front and Holben's gate, which was deposited in the Popsyan Library, at Magdalene College, Cambridge. In a privately-printed chirochre of the Palace for the period 1514-1876, drawn up by Mr. Richard Massey who was organist to the chapel during the interval 1837-77, we read that the organ was the first built (1662) by Father Schmidt in this country. The carved oak case, and some of the original pipes, are preserved in the present instrument, which was altered in 1814 by Elliott & Hill; and again in 1844, under Massey's directions, by Messrs. Hill, when a swell organ and a solo organ on a fourth row of keys, with additional stops, were added. Purcell was a choir-boy here, and afterwards organist. In the Loan Collection at the Church Congress, Derby, 1882, was exhibited by the late Mr. A. J. B. Beresford-Hope, a picture of the interior of West Minster, showing the marble altar-piece, erected in 1705, by Wren's advice, which had been made "for a chapel [the old chapel marked in Vertue's plan] at Whitehall." This was replaced, *circa* 1820, with a compo. restoration of the old reredos, and that again by Sir G. Gilbert Scott's alabaster restoration of the same. The Banqueting House was converted into a Chapel Royal in 1715; and there, over the altar, were placed from 1811-29, some eagles and standards captured from the French armies. Sir Robert Smirke restored and refitted the interior, 1837.

THE public recreation-ground, Maryon Paris, to which we adverted last week, forms part of the original manor which King James I. gave to Sir Adam Newton, his son Henry's tutor. Newton employed Inigo Jones, a resident of Cherry Orchard, in Charlton parish, to build the existing house (1607-12), for which were planned a saloon and gallery, a chapel, state dining-room, and

\* The exterior was largely repaired, 1839-50, by Sir John Soane. See s. n. Soane, in "The Dictionary of Architecture."  
† Inigo Jones was also the architect of Norton Court, near to Faversham; the Queen's House, Greenwich; and the front (centre) of Cobham Hall. Also, in this same county, are attributed to him Gilling Castle (portions), Juddie House, Deptford; Broom Hall; Chevening House; and Lees Court (front).

great hall. The west front was added by Sir Henry Kneivitt. The parish church of St. Luke, rebuilt 1630, is said to have been the second erected in England for Protestant worship. About twenty-five years ago the Dutch almshouses in Moorfields, under care of the Consistory of the Dutch Church, Austinfriars, were acquired by the London and North-Western Railway, and the charity was transferred to Old Charlton. The new Alms-houses and Convalescent Home—see the *Builder* of May 14, 1887—designed by Messrs. E. Panson & Son, were opened by the Countess Charles van Iylandt, wife to the Netherlands Minister. The cost of the extension works, about 7,000*l.*, was defrayed by the Consistory trustees. In the immediate neighbourhood Sir John Morden, Bart., founded, towards the close of the seventeenth century, the Morden College, which he endowed after his wife's decease with his whole estate and Old Court, of about 1,300*l.* a year, for decayed merchants.

THE School Board for London have just drawn up their annual schedule of sites and premises which they propose to acquire for purposes of school supply in the course of next year. These consist, in many cases, of additions to their existing schools. Allowing for two alternative sites in the Hackney Division, and for two others in the East Lambeth Division, the total number of new or enlarged schools is twenty-three (37)\* distributed in the Divisions as follows:—City: Swan-street, Minorities, one. Chelsea: Marlborough-road and Droop-street Schools, two. Finchbury: Wellington-road and Blackstock-road Schools and Hildrop-crescent, all in St. Mary's, Islington, three. Hackney: Cufford-road or Enfield-road, St. John's, one. Marylebone: Lydford-road, Paddington; Fleet-road School, St. John's, Hampstead; Stanhope-street School, St. Pancras; and Nightingale-street School, St. Marylebone, four. Tower Hamlets: "Ben Jonson" School, Mile End, one. Greenwich: Whitbread-road, Lewisham; Elizabeth-street, Woolwich; and Purrett-road School, Plumstead, three. East Lambeth: Grove-vale or Lyccott-grove, Southampton-street and Bird-in-Bush-road Schools, all in St. Giles' Camberwell, three. West Lambeth: Tooting Craveney (Broadway) School, one. Southwark: Albion-street and Midway-place Schools, Rotherhithe; West-gate School, St. George-the-Martyr; and Alma School, Bermondsey, four. These represent an aggregate of 39,724 (78,622) square yards, or nearly 8½ (16½) acres.

WE have received a copy of Dr. R. Bruce Low's Report to the Local Government Board, on an outbreak of diphtheria in the parish of Brinkworth, in the Rural Sanitary District of Malmesbury, Wilts. The following are some of the facts given under the heading "Sanitary Circumstances," but which one would think ought rather to have read "Insanitary Circumstances":—

"There is no proper sewerage in the parish. Sometimes slop-water is conveyed into the highway drains. The excrement disposal is by means of privy pits, which are emptied at irregular and often long intervals. The ashpits are not covered; their contents are from time to time removed by the scavengers, and are utilised on land. The water supply is from open ponds, locally called 'pits,' dug in the clay near to dwellings, the same pit sometimes serving several houses. In one instance six houses, containing nineteen persons, get their supply from a single pit. Occasionally the pit abuts on pasture land, and in that case cattle and horses drink direct from it. These pits vary in size from about 4 ft. to 16 ft. square, according to the number of houses using them. The depth varies from 2 ft. to 5 ft. The water in most of these 'mud holes' (as some local medical men term them) is generally turbid, and the surface at the time of my visit was covered with a thick green scum. It was stated that in summer the water sinks, and even in spring time it smells unpleasantly. Most people have to boil it, as it is unfit for use when drawn from the pit. This green, stagnant, stinking water is merely collected rain-fall on the clay soil, and contains mud and bacilli. The pits mostly swarm with newts and other forms of animal life."

\* The figures in brackets are the corresponding figures for last year.

At the conclusion of the report Dr. Bruce Low recommends that the Rural Sanitary Authority should at once seek skilled advice and assistance with a view to obtain a better supply of drinking-water for the inhabitants of Brinkworth village, and that the present system of privy-pits should be abolished, and tub or pail closets substituted, arrangements being made for their frequent and systematic emptying. It is to be hoped these recommendations will be acted upon without delay; a moral duty, if it cannot be made a legal one.

THE opening of the Staffordshire Technical Art and Industrial Museum at Hanley, (Messrs. W. Sugden & Son, architects) was announced to take place on Thursday this week, Lord Dartmouth and Sir Henry Roscoe taking the honours of the occasion. In commemoration of the opening, Mr. W. L. Sugden one of the architects, has collected in a square pamphlet\* with a tastefully-designed cover a number of mottoes from eminent writers bearing upon art and industry. The cue for this seems to have been given by the painting of a certain number of mottoes on the frieze of the building by order of the Committee, and these are distinguished by being printed in capitals, the rest are Mr. Sugden's selection. The selection does honour to the good taste and judgment both of the Committee and the compiler, and forms a very interesting collection of noble and suggestive thoughts, in some cases from writers not much read or known at present. Mr. Sugden takes for his general motto, as a heading to the whole collection, the following sentence from Sir Joshua Reynolds:

"An Institution like this has often been recommended upon considerations merely mercantile; but an Academy, founded on such principles, can never effect even its own narrow purposes. If it has an origin no higher, no taste can ever be formed in manufactures; but if the higher arts of Design flourish, these inferior ends will be answered of course."

The first of the Committee's chosen mottoes for decorative purposes is the sentence from Isaiah—"To give unto them beauty for ashes, the oil of joy for mourning." Nothing could be more expressive and suitable. Among those selected by Mr. Sugden we may mention two, one a serious one, from Sir Matthew Hale—"Idleness is the nursery of vain and sinful thoughts"; the other a happy satirical adoption of the Archbishop's adieu to Gil Blas: "I wish you all manner of prosperity with a little more taste"; a wish that might be appropriately addressed to many a manufacturing town in England.

THE ROYAL INSTITUTE OF BRITISH ARCHITECTS:

THE PRESIDENT'S ADDRESS.

THE opening meeting of this Institute was held on Monday evening last at 3, Conduit-street, when the President, Mr. Alfred Waterhouse, R.A., delivered the following address:—

Gentlemen and Colleagues,—Since I last had the pleasure of addressing you at the opening of a new session you have conferred on me a great honour in electing me your President for a third year. I can assure you that I am deeply sensible of this proof of your confidence and esteem, and I take this opportunity of expressing my heartfelt acknowledgments, not only for the honour itself, but also for the kindness and forbearance you are ever so ready to extend to me.

I have to congratulate you on possessing premises much the better for the additions made to them by our Honorary Secretary during the recess. The room in which we are now assembled is certainly better lighted than it ever was before, and I hope we shall find from experience that it is better ventilated. It is now a convenient room in which to study and consult books. The original and restricted library and the old council-room, to be henceforth chiefly used for the storage of the most valuable collection, will make excellent committee-rooms; while the arrangements for the permanent staff and Council downstairs could

\* London: W. Reeves; Leek: T. Mark.

hardly be much improved so long as the Institute occupies hired premises.

It is gratifying to record that the direct representation of architecture upon the General Council of the Imperial Institute—a matter to which, in common with my lamented predecessor in this chair, I referred in a previous address, has been cordially conceded; the Councils of the Royal Academy of Arts and of the Royal Institute of British Architects will in due course send one representative apiece to the governing body of the Imperial Institute.

A communication made to the Council to-day will also be received by you with interest and satisfaction. You are aware that a sister of the late Owen Jones presented a sum of money to the Institute for the purpose of endowing a travelling studentship, worth annually 50*l.*, in memory of her distinguished brother. Miss Jones died in September last, and by her will the residue of her estate, amounting to about 2,000*l.*, is bequeathed to the Institute as an addition to the original endowment (applause).

The Examinations.

Since the commencement of last session the new system of progressive examination has come into operation. Two preliminary examinations for candidates qualifying as "Probationers" have been held in various centres, 169 students presenting themselves; of these, 62 have been declared exempt, and 77 have passed the examination, making a total of 139 who are qualified in due time to come up for the intermediate examination, which, as sufficient candidates have presented themselves, will be held for the first time this month. In addition, 51 gentlemen have passed the qualifying examination in architecture, entitling them to become candidates for associateship.

Every student intending to prepare himself for these progressive examinations should read the clear and complete account of them given by Mr. Cates in the *R.T.I.A. Journal* of January 23, 1890; and if a man is to take a creditable position as an architect in the future, he must begin by passing these examinations. It seems to me as essential at the present day to have passed them as it was in former years to have spent a certain period in an architect's office as a pupil. I do not say that both courses are not still desirable, even necessary; but I think it will soon be found that the passing of these examinations is a *sine qua non*.

In this connection I would draw attention to a memorial from our colleagues in Edinburgh, supported by many distinguished names, to H.M. Commissioners for the Scottish Universities, recommending the establishment of a curriculum in architecture at the University of Edinburgh, and the institution of a degree or other University distinction for those who have successfully pursued it. The memorialists suggest what would be a proper course of study to lead to such a degree, and point out the advantages likely to accrue if effect be given to their proposals. They make appreciative mention of the Institute examinations, and it must be a cause of gratification to those who have architectural education at heart to find our Edinburgh brethren so anxious to continue what the Institute has begun, and even to go beyond it.

Bills of Quantities.

In my last address I animadverted on the impropriety of expecting builders, competing for the execution of contracts, to verify the correctness of the quantities on which they tender,—a practice, I believe, adhered to by H.M. Office of Works after it had been discontinued by London architects generally. This led to your Council addressing the Commissioners of Works on the subject, and brought, I am happy to say, a speedy reply to the effect that the practice would be discontinued. It is to be hoped that the high example thus set will be followed by those bodies in the provinces who may still adhere to what we cannot but consider an objectionable practice, not justified by equity, and calculated to bring the functions of the quantity surveyor into disrepute.

Deputations from the Building Trades.

We have received two deputations from several of the building trades, inviting us to use our influence for the insertion of certain clauses into our heads of builder's contract:—1st, to prevent the subletting of any portion of the work; 2ndly, that all labour employed by the contractor should be of the best quality; and 3rdly, that the contractor should not pay

less than the recognised or trades-union rate of wages, and should observe all recognised rules or customs as to working hours. The proposals of the deputation met with the consideration which they merited, without the Council seeing its way to take any collective action in the matter. Mr. E. T. Hall has communicated his views in an article contributed to the July number of the *R.I.B.A. Journal*, going fully into the subject, and showing in what trades snibbling is practised in London and to what extent. He takes the view that, when snibbling is allowed in the interests of one's clients, as, for instance, when stone is wrought in or near the quarries, instead of in London, and the general contractor, knowing that such a permission will be granted, reduces his tender accordingly, it may be our duty to allow it, especially when, though it may deprive the London masons of some work, it will give it to others probably equally deserving in the country. Few will, I think, disagree with him there.

#### Building Legislation.

Among the subjects which have engaged our earnest attention during the past session, none is of more importance, in my opinion, than the revision of the Acts which affect building operations in the metropolis. The general public may view the subject with apathy, as not understanding how vitally it affects its comfort, health, and well-being; in fact, the very magistrate on whom devolves the administration of the said Acts in cases of dispute is said to hate the sight of the District Surveyor when he brings his unfathomable technicalities into court. When, therefore, apathy, or disinclination to unravel the threads of a complicated and perplexing subject, is so general,—though the subject itself is so essential to the well-being of the community,—it is the duty of men, whose education and experience fit them above all others for the task, to help those engaged in the framing of such Acts with their advice and assistance. Now, this is precisely what the Institute has been doing.

A paper on "Building Legislation," read in this room by Mr. John Slater, in February last, was the theme of, and prelude to, two very interesting and important discussions, and to correspondence conducted by those who may be called specialists in this matter. Those who took part in them seem to be agreed almost unanimously that the time has at length arrived for the codification and thorough amendment and simplification of the some fifteen or twenty Acts and amendments of the same which now regulate building operations in the metropolis. A warning voice, however, that of Professor Aitchison, was raised against our striving after perfection,—by making the cost of houses too great for those who are to live in them. Others objected to building regulations being too definite, so as in some cases to become tyrannical and absurd, but it seems to me that because an existing definition may be found to work in this way in practice,—as, for instance, the clause in the Act which limits the sum of the openings in a wall to half its total area,—it is a reason for the amendment of the clause rather than for its exclusion. The fault, in my opinion, lies not with being too definite, but with the definition not being broad enough to meet with varying contingencies. The Act of 1855 having been framed chiefly for preventing the spread of fire from one combustible wooden-floored building to another is out of touch with improved fireproof construction, which ought, when properly applied, to allow of an increase in the cubic contents of buildings beyond the area now prescribed, at least, where the building does not contain goods of an inflammable description. The Act does not allow for the increased amount of glass called for by the ever-increasing pollution of our atmosphere; and, on the other hand, does not make due provision against the danger from fire incident to the use of lifts. It does not realise our greatly extended requirements in the present day; nor our extended building knowledge—our knowledge, for instance, of the treacherous nature of stone and iron in case of fire. The Act does not deal with important questions affecting the rights and obligations of adjoining owners; it does not concern itself, except by implication, with the underpinning of party-walls and of adjoining structures in cases where the new structure, going below the old one, affects the safety of the latter, and involves such a procedure. It ignores sanitation; and does not trouble itself

about the formation of new building estates, where, of course, the evils we have most to deplore in our streets and thoroughfares can be most readily prevented. Mr. Slater urges, with reason, the necessity either of making our Building Acts of the future sufficiently expansive to meet such cases, or of giving our district surveyors a discretionary power to enable them to deal with special cases in a practical way, and probably his first alternative would present, in practice, the fewest difficulties.

The meeting in this room, when this subject was so fully debated, did not feel itself justified in sending Mr. Slater's valuable paper and the report of the discussion to the London County Council, but it is to be hoped that your Council will see its way very shortly to take decided further action in the matter; the urgency of this subject has been pressed upon us lately by the London Council (General Powers) Bill, which appears at first as if it chiefly related to a bridge at Barking Creek and the acquisition of a new park for South London, was in reality of much more widespread interest. It proposed, in fact, important amendments in the metropolitan building regulations, some of which could not be looked upon with favour. Action was thereupon speedily taken by your Council, and a memorial addressed to the London County Council on the subject. We pointed out that many of the changes proposed were of temporary expediency, and many wanted further consideration, as, for instance, those clauses affecting sites at the corner of two streets, in one of which the line of frontage had to be set back, where the owner of the corner site would have had to set back also without compensation; and those affecting the heights of new buildings. We further pointed out the desirability when an application was refused, of the grounds of the objection being stated, so as to enable the applicant to amend his designs to meet such objection. We also respectfully remonstrated against this indirect mode of introducing legislation affecting seriously private rights and questions of principle; and urged the advantage of promoting a thorough amendment and consolidation of the metropolitan building regulations. Some of these recommendations were accepted by the London County Council and their Bill was amended accordingly.

One of the most important provisions of this new Act is the establishment of a Court of Appeal in questions of lines of frontage, &c. The Court is to consist of three members: one appointed by the London County Council, one by your Council, and another by that of the Surveyors' Institution. The County Council deserves praise for its initiation of this reform—a rather timely revival, under fresh conditions, of a tribunal established by the Act of 1844, but which from its peculiar constitution became a dead letter; and I sincerely hope it will work so well in practice as to show the propriety of giving to such Courts greatly extended powers in the future. The Act also fixes for the first time in London a limit to the height of new buildings not being the rebuilding of existing structures of a greater height. Ninety feet is the limit, exclusive of two storeys in the roof, and of exceptional features, such as ornamental towers or turrets and dormers. This should satisfy even the most aspiring among us; if it does not, there is still the right of appeal to the tribunal before referred to. It is with pleasure that I allude to the part taken by this Institute in criticising, amending, and, I may add, ultimately aiding the passing of this Bill. As an entirely disinterested body, and yet one most fully able to appreciate the tendency for good or evil likely to result from any change in building regulations, it is only proper that its voice should be heard and well considered at such a juncture; and it is gratifying to reflect that in this case the Institute was represented by Mr. Cates, who—the *locus standi* of the Institute having been admitted—claimed and successfully sustained the right to be heard personally on behalf of your Council, and to adduce evidence in support of our petition, without the costly intervention of counsel. His observations and the evidence given by Mr. E. T. Hall, on behalf of the Institute, were received with marked consideration by the Lords' Committee to whom the Bill was referred; and I am glad to state that both these gentlemen have received the special thanks of the Council for their very efficient services in connexion with its passing.

I cannot but feel, however, that even were we to get the most perfect Building Act for the

regulation of our practice, it should be the function of some one,—or rather of some collective body,—to take a broad artistic view of that immense chaos called London, and, as opportunities arise, to point out in what way it can be improved as a work of art. The members composing such a body must be, I admit, men of business as well as artists; or their recommendations would soon cease to have any practical value. In laying down the line of a new street, it would be their duty to see that its extremities either ended in some existing building worthy of closing the vista,—as, for instance, the Strand, in the Church of St. Mary; or that a site was reserved for some future erection with that object in view. It would be their duty to see that the best sites along its course were reserved for buildings of a character becoming their position, and that a flagrant want of harmony was not suffered in contiguous elevations; and, while always dealing indulgently with such as were modest and refined, the tribunal would be resolute in refusing the acceptance of designs of vulgar ostentation,—creations of the nightmare school, of which, unhappily, we have examples already thrust upon us. Indeed, we may have more than there be no authority to check this worst form of inflated advertisement, the worst because it involves the prostitution of a noble art, and when once created, is not easily got rid of. I am not forgetful of Professor Kerr's pathetic inquiry, "If Heaven has made us Philistines, how can we help it?" But this, as it seems to me is hardly a question of a man's right to do what he will with his own, provided he does not injure his neighbour. A street is public property, made not only for the use, but for the enjoyment, of the public, and it cannot be an enjoyment so long as it is vulgar or monotonous and ugly. I plead for the creation of some responsible body of men, by position, education and cultivated taste, specially fitted for the task whose main duty should consist in advising upon and controlling, from an artistic point of view, those works on which the future of London so much depends. I repeat the words I used in my address of last year, that a member of the Architectural Council, to be appointed by Government, and to be partly composed of professional men, is wanted in London. It is most difficult for those who have had no technical training to judge correctly of the probable effect of a contemplated building from an inspection of the drawings prepared for its erection. I plead, moreover, for the public exhibition of the plans of all metropolitan improvements prior to any final decision being taken upon them. Such a course would tend to create an intelligent interest in improvements which at present does not exist in London, and it would enable those who have to pay for them to consider in time if the proposals be good, practically and aesthetically, or otherwise.

We have obtained a tribunal before which certain building cases defined in the "London Council (General Powers) Act" will be tried, and if success attend the labours of this tribunal, other and perhaps more important matters relating to building may be referred to its judgment. So far so good. But more wanted—namely, an Architectural Council of National Works, which should also be entrusted with the consideration of proposed improvements, and of all those questions, I repeat, on which the future of London so much depends.

#### Students' Work.

The system recently inaugurated of publishing criticisms on the work of students competing for the various scholarships and prizes offered by the Institute itself, or by others under its administration and direction, is to be regarded as one of great value. It shows an unsuccessful student wherein he has failed, and so guides him to a better chance of success in the future, pointing out even to the winner how to attain greater excellence, if willing to listen to the friendly advice of experience. I would again venture to remark, with reference to the work of those to whom Travelling Studentships are awarded, that what we should like to see is not mere evidence of their industry,—that is seldom or never wanting,—a greater desire to make quality, apart from draughtsmanship, and not mere quantity, their aim. The student, nowadays, is sometimes possessed of the restless, hegetotten of the locomotive engine:—stays, it may be, but a day in a place; that day, to be sure, he does a marvel

amount of sketching, and he contrives to visit in the time which he has to devote to his studentship an astonishing number of interesting buildings, the most salient features of which he transfers to paper. I do not see, however, as often as I should like, that the student has sat down before a building to lay siege to it with the determination before he has done with it to make it his own,—to enter into the spirit of its builders, and to seek to discover their way of arriving at the ends they had in view. There should, in my opinion, be among our students a little more of the thoroughness which characterises the work of the French students, whose magnificent studies displayed in the Galerie Rapp, in last year's Exposition, so much impressed those of us who had the opportunity of examining them. I say "a little more," because in France, perhaps, this work is carried out with too great elaboration. Still, I would have our students make themselves so conversant with any work they analyse as to be able to pass an examination on its construction and features; and I think it would be well if the knowledge thus previously acquired by the candidate in the study and delineation of some ancient example were put to the test in our examinations more strictly than appears to be the case. Those who read for their amusement, or for their fancied instruction, do not generally read half so carefully as those who know they are going to be examined on what they read. And so I believe it is in objective drawing. If the painter-student knew he were going to be judged, not by his actual study from the life, but by what he could put of it on paper from memory afterwards, would not his attention be quickened to every subtlety of curve and proportion? Would he not become by such practice the readier artist? If the architect-student knew that it was not by the mere number and beauty of his sketches, and by the accuracy of the measured drawings of old edifices, that he would satisfy those who had sent him forth on his travels, but by the proofs he was able to afford that he had absorbed and digested what he had seen, I believe our student-work would sometimes be more thorough, and the men themselves in some cases would be the more ready designers after having had such preparation. Having got the ancient examples into their heads, instead of merely into their sketch-books, they would learn to lean not on illustrations and other extraneous help, but on what had become a part of themselves, and so prove not mere copyists, but self-reliant and original designers. Of course, if such careful analysis of a single example of architecture is recommended to the student, it is highly important that he should know beforehand what buildings will best repay the time thus devoted to them; and it would be a work of very great interest and utility if those best qualified for the task were to catalogue such buildings, giving at the same time their date and most noteworthy features and characteristics, not disdaining to mention also their distance from the nearest railway station, and the existence and name of the neighbouring inn, if any. There is abundance of such information in a scattered form in our professional journals, and in the fascinating papers read by the rambling architect; and I do not forget the more substantial work which the Architectural Association some time ago undertook and carried out for certain localities. Still, a complete and concise list would be of inestimable service to every one of us, and if divided into counties, each with a short introduction as to the county's leading architectural characteristics, and with a good index to the whole, would be of easy reference. It would be of special value to the student, who should, of course, be encouraged to go where he could study good architecture rather than redundant and often misapplied elaboration.

The President of the Royal Academy, in his recent discourse on Spanish art, devoted much of his attention to Spanish architecture, a difficult subject, but treated by him with perspicuity and breadth of view. The interest which his address awoke in me led me to visit Spain a month or two later, and to notice the justness of the conclusions arrived at by our distinguished honorary member, who has shown therein his grasp of the intricacies of our art. Spain is a country which all architects ought to see, though the difficulties of locomotion and hostility are still such that few can hope for more than a partial acquaintance with its architectural wonders. For the reasons pointed out by Sir Frederic Leighton, the visit ought to be postponed until the student's views are

formed, or he may be led away by much that is as pernicious as it is alluring.

#### Architectural Training.

A question is often asked as to the best mode of training a youth intended for the profession of architecture. How should the early days of one who intends to study architecture as a calling be spent to the best advantage? To such I reply: He should have received in his schooldays some preliminary training of a scientific as well as of an artistic character. He should learn early to understand and appreciate the beauties of a fine building,—of the civic and domestic edifices, the grand cathedrals and churches, the noble streets and open spaces, with which many a city in this country is endowed. He should be taken to museums of "comparative sculpture," such as the initiative of Viollet-le-Duc created in the Trocadero; and, in default of similarly arranged educational institutions at home, to the sculpture galleries of the British and the South Kensington Museums. In fine, he should, in his early pliable days, be shown the works,—or casts or drawings of the works,—of the great architects of various countries, and thereby acquire an insight into the magnitude, the nobility of the career upon which he is about to enter. At the same time his ordinary education,—the ordinary education of an English gentleman,—should not be neglected. He must pass the matriculation examination of a university, or the local examination conducted under the authority of a university; or he must obtain some testimonials of proficiency granted by well-known educational bodies. Then, armed with such letters of introduction, he should come to the Royal Institute of British Architects, where I know that he will be cordially received; and thereupon, after the necessary inquiries as to his certificates and after examination of his powers of draughtsmanship, he will be admitted a Probationer. His name will be entered on the Register of the Institute as one intending to qualify for admission to the Class of Students, and afterwards to the Class of Associates, of the Institute.

His next proceeding is to be articulated, say, for three years, to some practising architect on the conditions suggested in the form of articles which has recently been published,—a most important item of which states:—

"That, with the object of enabling the pupil to qualify himself for passing the examinations for studentship and associateship of the Royal Institute of British Architects, he, the Principal, shall and will allow the pupil such absence as he, the Principal, shall deem reasonable for the purpose of attending lectures, classes of instruction, and the said examinations."

During the term of his articles the pupil, or rather the probationer to whom I am alluding, will have to prepare the "testimonies of study" (described in the *R.I.B.A. Calendar*), which he has to submit to the Board of Examiners before he can be admitted to the intermediate examination; and to assist him in the preparation of these "testimonies" in London he will, if properly advised, become a member of the Architectural Association, attend its classes, periodical visits to buildings, &c., and thus mix with others engaged in a similar course of study. During all this period, the reference library of the Institute is open to him, and he can borrow books not only from the lending library of the Association, but also from that of the Institute. At the end of his articles he passes the intermediate examination, is qualified as a student of the Royal Institute of British Architects, and his name and address are inserted in the Register of Members of the Institute, and published in our *Calendar*. He afterwards competes for the prizes offered by the Association, and then for those offered by the Institute. He gains a prize, perhaps a studentship, which enables him to travel in France or Italy, or even as far as Greece. He returns to England, enters an office as assistant, prepares his probationary work for the final examination to qualify for candidature as Associate; he is admitted, he passes the examination, is registered Associate, and instead of being a mere stranger to those whom he will hereafter call his professional brethren, he is known to many of his elders, and counts among his contemporaries numerous friends. I confess, gentlemen, that this record of the younger days of an architectural student seems to me a fairly complete one. No President of this Institute, forty or even twenty years ago, could have told a similar tale. I remember nothing in my early

days as a pupil which approached the facile and systematic training of the course now laid down by us for admission to our ranks—ranks which I think must ultimately include the entire profession of architecture in the United Kingdom.

I have endeavoured to describe what the education of the young architect should be upon existing lines. Possibly, in a not distant future, we may find it better to use a course of instruction somewhat analogous, let us say, to that pursued by Professor Ware\* in New York, as a preparation for entering an architect's office, than that theoretical instruction of the sort just indicated should go on *pari passu* with pupillage. For a pupil to reap the full benefit of his time in an office, he should as soon as possible find himself set to practical work, and work of this sort in a busy age can hardly wait for one who spends a considerable portion of his time in abstract study. After his class work is once completed his powers will be so strengthened thereby as to allow of his entering upon office work with an intelligence unknown to the ordinary pupil of the present day, and his term of pupillage might be greatly shortened were it to follow rather than be contemporaneous with theoretic training.

#### The Architectural Association (London).

For many years the professional education of our pupils has been assisted by the well-directed efforts of the Architectural Association from Viollet-le-Duc in 1872, at a time when, numerically, it was not much more than half as strong a body as it is to-day. Its method consists in the members helping themselves and each other; and no better can be devised. The particulars of its *modus operandi* are all well known to you; but I must not omit to mention that the General Committee of the Association recently formulated a systematic course of instruction to meet the requirements of the Institute examinations, the programme of which course was to include the study of the principles of design and construction on the drawing-board in class,—a practice pursued in the Royal Academy schools with success. I hear, however, that this more complete system of instruction was not adopted by the general body of members of the Association, and that the inauguration of the scheme has been postponed.

I reiterate what I said last year from this chair, that the Institute should, if the way be made clear, give substantial aid to those who, during a long and prosperous period, have shown an earnest determination to help themselves. But how or in what manner this helping hand should be offered to the junior body—how it would be received, or whether it would be taken at all—are points which do not appear to have received due consideration from those most concerned. Are we to indirectly support the Architectural Association, when it has made up its mind as to what it would like to accomplish in the way of teaching, and when it asks the Institute for aid? Or are we to set on foot some corporate machinery of our own for the systematic instruction of those members of the Association and others who are studying to pass the progressive examinations of the Institute? These are vital questions, gentlemen, which demand our most serious attention; and I will attempt, with your permission, to lay before you a short statement of facts relating to them.

At the present moment the educational work done by the Association does not appear, from the statistics with which I am furnished, to afford any great material assistance to the Institute. The Association numbers 1,120 members, of whom 276 are also members of the Institute, and 40 more are probationers of the Institute. The total number of our probationers is already 164, and, as I have just said, of these only 40 are members of the Architectural Association. Again, the number of applicants admitted to the preliminary examinations to be held this month in Bristol, Glasgow, London, and Manchester, is 73, of whom only 10 are members of the Association; while not one of the 8 probationers admitted to the first intermediate examination in London is a member of the Association. One thing therefore is certain: the relative positions of the junior and senior bodies of our profession in the matter of recruits has undergone,

\* I commend Professor Ware's Paper on "Instruction in Architecture," read before the Alumni Association of Columbia College, June, 1888, to those interested in the subject.

or at least is undergoing a great and sensible change. The Institute has emerged from the state of a dilettante society into one of an eminently business-like kind, with recognised functions of a public as well as professional character. The Architectural Association, on its own showing, does not appear to possess at present the means to adequately fulfil the functions of a teaching body. In former days the architectural student first joined the Association, and then, in the course of years, the Institute. The position of affairs may now be said to be reversed. The aspirant's first thought is to qualify for registration as a probationer of the Institute; his next, perhaps, if he live in London, is to join the Association for the purpose of qualifying for the studentship, and afterwards for the studentship of the Institute. Such being the case, it behoves us to look the new aspect of our relative positions in the face in a business-like way.

The General Committee and the subordinate Committees of the Architectural Association are largely, if not mainly, composed of members of the Institute; and the instructors in most of the classes are members of the Institute. The Association holds its general meetings in the Institute rooms; when its honorary secretaries apply for the use of a room in which to hold a class, the Institute lends one. Every member of the Association under twenty-three years of age has the use of both the reference and the lending libraries of the Institute; and any member over that age, if he ask permission, is allowed the use of the Institute library, which, as a matter of fact, is open all the year round to every architectural student properly recommended. The presidential addresses, and many of the papers delivered to the Association, are published in the *Institute Journal*, and the pages of our *Journal* are open to members of the Association on almost the same conditions as to members of the Institute. The President or a representative of the Association has a seat at the Council table of the Institute; in fact, it has the right, under our by-laws, to be there represented. The actual connexion between the junior and senior bodies is much closer, much more intimate, than the majority of those who talk about the subject are aware; and the Institute has never seen cause to regret the closeness of that connexion.

It sees with interest and approval that the Association is asking itself the pertinent question whether the facilities it affords are sufficient for the requirements of the time, and whether several things which involve considerable outlay of Association funds might not with advantage be abandoned with a view to augmenting the sum available for teaching purposes. At the present moment, in spite of the close connexion which exists between the Institute and the Association, in spite of the fact that we both inhabit the same building, the two bodies maintain two distinct libraries and two distinct registers of architects' assistants; the two bodies publish two distinct Kalendars and two distinct journals. Now, though fully alive to the advantages of healthy competition, especially to the young and aspiring, I question the utility of thus doubling our labours if not our expenses; and from a business point of view alone, I venture to urge upon the members of the Association the desirability of considering, in conjunction with the Institute, the present duplication of our expenditure and consequent division or diminution of our forces.

If I may be allowed to make a personal suggestion, and one in which I have had as yet no opportunity of consulting the Council of the Institute,—I should say, let us join, not divide, our forces, and in such a manner that, while maintaining the autonomy of each body, the Association might devote its funds more exclusively to teaching purposes. We already house the Association for its general meetings; why should we not house its library, leaving the administration of the same to its honorary officers? Why should we not combine the two registers of assistants in one, to be kept in the office of the Institute by a clerk, who should also answer the many and often unheeded applications that I understand are made on the subject of the Association, its membership, its classes, &c.? Why should we not include the *A.A. Brown Book* in our Annual Kalendar? Why should we not devote a definite portion of our journal to the able pens of the Association? Here, at least, are points which a joint Committee of the two bodies might well consider, and in suggesting them I have only to

repeat that I do so on my own personal responsibility; and, further, that I have no thought or wish to see the two bodies, senior and junior, welded into one. On the contrary, any such amalgamation is impossible under the present constitution of the Institute; and, even were it possible, it is not, in my opinion, desirable in the interests of either the Institute or the Association.

I have been much struck by the excellence of the lectures which the Association obtains from its members and others. There was a paper read last session by Mr. Frank T. Bagge on "Angles and Terminal Features," which was a well-considered essay on an important element of design. There was also one by Mr. Reginald T. Blomfield on "Drawing," which took a broad and masterly view of the art. The power of draughtsmanship exhibited of late by many a young architect is of such excellence that it ill becomes an old fogey to criticise it, and yet I would venture to emphasise what Mr. Blomfield advocated: that it would be well to consider before beginning a drawing what the qualities and impressions are we wish to perpetuate and convey to paper, never to draw a stroke which has not a definite purpose in view, and to avoid all conscious tricks and mannerisms. I would not discourage the delineation of cast shadows and reflected lights, for in them much of what is most delightful in the aspect of an architectural work depends; but the shadows should be as flat as possible, and the reflected lights as tender. The scratchy, unrestful style adopted by some who are otherwise masters of pen and pencil delineation, is in my opinion much to be deprecated, and a return to the brush would be desirable if such blemishes cannot otherwise be avoided. It would be well, also, if our students spent some of their energies in studying cloud forms and vegetable growth, as many an excellent architectural drawing is ruined by the introduction of clouds and trees which often mar otherwise attractive work.

#### Arts and Crafts.

The "Arts and Crafts" are still holding their annual exhibitions in the New Gallery, and doing the work which I cannot but think ought to have been done, and still would be done, by the Royal Academy of Arts, if it took a wider view of its mission, and gave itself to the hearty encouragement of all branches of art, instead of mainly to painting in oils, with scanty patronage of water-colour art, sculpture, and architecture, so far as the last can be illustrated by the pencil and brush. Its winter exhibitions of old masters have been hitherto of great value, but the supply of masterpieces belonging to those generous enough to lend them must in time become exhausted. I am, therefore, personally not without some hope that the future may find the Royal Academy inclined to look with favour on a winter exhibition which will embrace Art in all its forms, and which will do more for national art progress generally than a mere exhibition of pictures is likely to do. Meanwhile, let the younger members of our profession whose time and talents may not be fully occupied in the pursuit of architecture proper, devote themselves to the design of such things as are to be found in the Arts and Crafts Exhibitions, which, to be successful, must be designed on sound principles, for the observance of which the architect's training renders him peculiarly apt. The exhibitions in question are undoubtedly of great interest, but not as yet of such surpassing excellence in all their departments as to discourage earnest attempts to make them better. I feel persuaded that no body of men can apply themselves to such a task with better chance of success than architects, no work could be more useful in raising the art tone of the community, and in this way elevating the public appreciation of architecture itself.

The President and Council of the Arts and Crafts Society have been good enough to invite the Institute to visit their exhibition at the New Gallery, on the evening of Tuesday, the 11th inst., and the invitation has been cordially accepted. I hope to meet a large gathering of our members there, that we may discuss with the craftsmen whose works are there exhibited points of mutual interest and importance.

#### The Library.

It should be borne in mind that the prosperity of the Institute as a corporate body is not exclusively dependent upon the exertions of its

members alone; it cannot afford to dispense with the goodwill of outsiders indirectly connected with the objects for which the Institute was founded. The list of donations made to our library in the course of the past session suffices to show that we possess many friends and supporters whose names are not included in our register of subscribing members, but who are, nevertheless, helpers in the good cause, and in the good work we have at heart. Monsieur Edmond Bonaffé, of Paris, has presented his admirable work on the "French Furniture of the Sixteenth Century"; Monsieur Lucien Magne, the son of an architect distinguished for the works executed in Paris from his designs during the rebuilding of that capital under the Second Empire, has presented two folio works of his own on French architectural works, recently published; Monsieur Planat, regularly sends his "Encyclopædia of Architecture and Construction"; Herr Stier, of Stuttgart, has given us a magnificent folio of illustrations of buildings recently erected in Germany; Mr. William Scott, who duly passed the Voluntary Examination, but who now works in Venice, has given us some excellent views of that city, etched by himself; and Mr. J. Drayton Wyatt, who is well-known to most of us, is a determined contributor of rare and useful works and of valuable pamphlets. The late John Turner, a member of the Architectural Society, which in 1834 was absorbed in the Institute, but who never joined us, bequeathed some beautiful drawings and a most interesting MS. work of John Goldcutt, the first Hon. Secretary, with Professor Donaldson, of our body. Some conspicuous presents have also been received from members, notably, a large collection of Daniell's original drawings of Hindoostan, the gift of Mr. John D. Grace, which formed the subject of an interesting notice by Mr. William Simpson in our *Journal*; and a large illustrated folio work by Mr. Frederic Chancellor, of Chelmsford and London, on the "Sepulchral Monuments of Essex."

#### A French Architect on English Work.

One of the donors I have mentioned, Monsieur Lucien Magne, has recently written a criticism of the British architectural drawings exhibited last year in Paris. He thinks that our works are distinguished by their quality of picturesque composition, but they lack, he says, that original note which is the result of the proper appropriation of details and profiles to the desired effects of light and shade. Modern English architecture is of particular interest to our French confrère, in that it does not appear to be the expression of conventional teaching; but, on the contrary, a manifestation of particular wants. In the irregularity of plan, the determination to give to each part of the façade a form resulting from the destination of each room within, Monsieur Magne sees a reminiscence of the traditions of our art in the Middle Ages and the early Renaissance. He then goes on to compare the design for the Imperial Institute with the majority of the compositions of the Pensionnaires-de-Rome, and says that in it Mr. Colcott displays a liberty and boldness in his disposition of masses, an elegance in treating the silhouette of his building, which are not often to be found in the contemporary work of French architects. Such praise, coming from such a pen, is, of course, very gratifying to us; but it contains also a note of warning against the dangers attendant on the established teaching of architecture, not as a science, but as an art. I hope we may carefully lay to heart the true lesson which our French confrère in so many generous words would instil, not to lose our freedom and liberty in design, by reviving the formulae of an architectural education conducted everywhere on the same lines. I do not think there is at present any danger of this. The exercise of our liberty grows with what it feeds on; indeed, it seems to tend in many cases to licence, and there are modern buildings in this country which display in their details a recklessness of what thoughtful men, with ordinary reasoning powers, consider appropriate.

#### Contemporary Works.

One of the dangers to be dreaded in alluding to contemporary work is that it may not have been my good fortune to have seen some of the best and most characteristic specimens of it, and that, therefore, mention of them may be unintentionally omitted. Speaking generally, I cannot help noticing a curious tendency in the work of some of the most esteemed of my con-

must remain,—a constant source of trouble to himself, of derision to his friends and the public. We have, therefore, to show ourselves worthy in every way to be trusted. We have to be sympathetic, putting ourselves, so far as we can, into the circumstances of our clients,—not leading them into unexpected expenditure, not, on the other hand, following their whims if our greater knowledge and experience tell us plainly that such a course will lead to disappointment: for what would he thought of the doctor who suffered his patient to dictate the nature and strength of the remedies to be prescribed? The architect, therefore, has to be not only an artist and a skilled constructor, but he must learn to appreciate the value of other people's money; he must be considerate, honest, patient, firm; and, above all, he must learn to imagine to put himself in the place of his clients, so as to understand their desires. If he were all this, I believe we should hear little of complaint against the profession. I believe we should be respected as we respect ourselves, each other, and our art, which ought to be to us the first consideration, entirely irrespective of material reward.

It is because this Institute is doing all that such a corporate body can do to elevate our profession and to give a higher tone to its practice, that I believe in its continued success. Its advance of late years has been very marked. It has not only grown in numbers, but it has fostered a higher standard of professional probity; and that alone is well worth all the trouble which many have taken in its affairs. Its efforts in the cause of architectural education have been already crowned with success, and we are only now on the threshold of that success; its continued prosperity will depend upon the exertions and the conduct of each of its members. May we all remember this, and do all that in us lies to further the increasing usefulness as well as the corporate interests of the Royal Institute of British Architects.

Professor Kerr rose at the conclusion of the address to propose a vote of thanks to the President. They would all agree, he said, that the address was one which deserved their special thanks for its peculiarly practical tone, going as it did to their hearts as men of business, and as artists and scientific men, in a way which, without any undue comparison, they had seldom experienced. The President occupied so exceedingly dignified a position in the profession, before the eyes of Europe, that every word he had addressed to them would be perused with interest all over the Continent, as well as in this country. At the same time, his discourse had been so peculiarly discursive, that it was quite impossible to make remarks upon it, even with a desire of assisting the good work which the address itself was calculated to effect. It was not the custom in that Institute to criticise the speech of the President, and he hoped it never would be the custom. But even were it customary to criticise the address, he did not know what one could find in it for criticism. He was not one of the school of critics with whom fault-finding was the essence of criticism. And if, on the other hand, he endeavoured to take the opposite course of supporting what had been so well said, it was difficult to see where one could find a subject to which the President had alluded which required support. With regard to the public action of the Institute, he was sure every member would agree that the Institute did not do enough before the public. The President had quoted a haphazard expression of his (the speaker's), which he was quite ready to defend, to the effect that "if Heaven made us Philistines, how can we help it?" He did not mean to say that Heaven had made the Royal Institute of British Architects Philistines. If Philistinism, as they all knew it, was not merely a bad habit, but really an inherent and constitutional taint in the character of the English people, all the greater was the need for those who were selected, who selected themselves, or who selected each other, for the purpose of dealing with this great industrial art, of historical eminence and importance, to do their duty towards the public whom they represented, and to endeavour to improve and ameliorate the Philistinism which was inborn in the land. The Government, unfortunately, was always a particularly Philistine institution. The reason for that it was not the time and place to enter upon, but many of them knew what the reason was, and it was not likely within any reasonable period of time that

the habit of looking at everything as a matter of pounds, shillings, and pence, and nothing else, would be dropped at Whitehall. At the same time, the tendency of the public mind, at the present moment, was unquestionably in the direction of improving the artistic feeling of the country. The old-fashioned systems of thought were gradually disappearing. Some of them were old enough to distinctly recollect how very differently every artistic matter was treated a good many years ago. Many of those present, however, were at that happy age that they did not remember those things, and they would scarcely believe him if he were to relate what happened fifty years ago. But those who were young and had to look forward to what he hoped would be a prosperous and happy life would be astonished, perhaps, when they reached old age to find what a difference would have been accomplished between the thoughts of men at the present moment and the thoughts of men then. This country was destined to be a distinctly artistic country. There were evidences of that abroad in all directions. These evidences were distinctly to be seen in other lines than in their own and by themselves, and he believed there were those present who were destined to hold prominent places in the advancement of the new school of art and artistic criticism, which would be a credit to the land in which they lived. He had, therefore, much pleasure in proposing a most cordial vote of thanks to their distinguished President for the discourse to which they had listened with so much pleasure that evening. Mr. W. White, F.S.A., seconded the vote of thanks, which, on being put to the meeting, was carried by acclamation.

The President, in replying, said he hoped from his heart that Professor Kerr's prophecy would be fulfilled.

The proceedings then terminated.

#### THE ART CONGRESS AT BIRMINGHAM.

PRESIDENTIAL ADDRESS IN THE SECTION OF ARCHITECTURE.

THE Birmingham Congress of the National Association for the Advancement of Art, and its Application to Industry, commenced on Tuesday, under the Presidency of Mr. J. E. Hodgson, R.A.

On Wednesday, in the Section of Architecture, Mr. T. G. Jackson, M.A., F.S.A., the President of the Section, delivered the following address:

In these days, when more is said and written about art than at any other time in the world's history; when art has become fashionable, which, be it remembered, is a very different thing from becoming popular; when, instead of sitting like Cinderella in the ashes, she walks, as John Bunyan says of fashionable religion, "in her silver slippers"; and when, amid all the loose talk and easy cant which flows so abundantly from the lips of every disciple of culture, artists begin to wonder when society will let them and their craft alone, and instead of talking and theorising about the art of the day, sit down and simply try to enjoy it; it was a happy thought of the Council of this National Art Congress to bind us down to one particular branch of the subject instead of leaving us to range at will over the whole of it.

Our attention this year is directed to education,—artistic education,—and that, it may be assumed, not only of the artists themselves, but of the public at large. In that particular branch of art about which I am asked to address you, we are invited to inquire whether we are going the right way to form good architects; whether anything can be done to teach people generally how to appreciate good architecture and to know it from bad; and, further, how we are to arouse their interest in the subject, so as to make them discontented unless they can surround themselves with architecture really worthy of the name.

That things are not as they should be in either respect may be taken as granted on all sides, for otherwise there would be no sense in our being here to-day to discuss the matter. It is, unhappily, beyond dispute that most people are ignorant of the true canons of architectural taste, and perfectly content with the most deplorable architecture, provided the building be showy and comfortable. A walk through the streets of London or any of our great cities, or even along our country lanes and meadows, is enough to convince us that to

the average Englishman or Englishwoman good architecture and had are as one. Unless the public taste were satisfied, such architectural horrors as abound on all sides would not be endured. And, again, on the other hand, they would not have been there to offend us unless the majority of architects, so-called, were ignorant of their craft, or, in other words, unless their education were defective and misdirected.

Let us, then, first take the case of the artists, and trace the career of a young man who wishes to become an architect, in order to find out what is wanting in it, and how the present way of training him may be bettered. This education is a matter about which there is no lack of literature, for it has, of late, formed the principal topic of the architectural societies and the theme of leading articles in the architectural papers. One lecturer is at the pains to trace the studies of the young aspirant almost from the cradle, and sees him at his spelling-book and dictation,—we need not go back so far. A theological professor once began a course of lectures with the words, "We will assume the doctrine of the fall of man;" we will take a similar liberty, and assume the student to have had the ordinary education of his class. He now wants the technical teaching necessary to our craft, and to that end, in accordance with the usual practice, he enters an architect's office as an articulated pupil or apprentice. There he stays for three years or more, and at the end of his time he is supposed to be able and qualified, and in favourable cases really is so, to undertake such simple work as his friends may have the courage to entrust to him.

Now the good he will have got as a pupil obviously depends on two things—his own industry and the choice he has made of a master. Pupils sometimes go through their time without learning anything. I remember one case where the pupil of a well-known architect began by tracing drawings, and, being an easy-going youth, devoid of ambition, went on tracing drawings all his time, and left off as ignorant as he began. I remember another case where a young man went into an office where there was little or no work going on, so that, though he had no lack of industry and was anxious to learn, he came away knowing no more than when he went. Such cases of what one can only call gross dishonesty are, I fear, by no means uncommon, and it is unnecessary for me to characterise them further. But in cases where the pupil is eager to learn, and enters an office where there is plenty of work going on of a high character, I can imagine no better way of teaching him how the designing and construction of a building is carried through, and of qualifying him to do it when his own turn comes. He gets there what he could get nowhere else. Draughtsmanship and the principles of building construction may be learned in a science and art school, but there is all the difference in the world between drawing out plans of buildings that will exist only on paper, in which blunders will do no harm, and making drawings which are to be put into the hands of workmen to be really carried out, and which must be right, or else disaster will follow. There is no comparison between the educational value of the two; the difference is as great as that between a review and a battle. It is only in an architect's office that the student can learn how a building is carried out from beginning to end, what drawings and specifications are required to explain the design to workmen, how to meet and overcome unexpected difficulties of arrangement and construction, how to economise materials and labour, and, lastly, what is of no little importance, be there seen something of the professional side of an architect's work, and learn how a business is managed, and work superintended from a distance. Still more important is the opportunity he enjoys of cultivating his taste by seeing good work done, and taking part in the doing of it, if he has chosen wisely and put himself under one who is a master of his craft. Above all, perhaps, when I look back to my own time of pupilage, I should be disposed to rank the benefit of associating with the fellow-students and draughtsmen whom he finds there, among whom debate and criticism run furiously high; opinions are freely expressed, none the less confidently for being immature, artistic reputations are madly exalted to heroic heights or ruthlessly pulled down to unmerited degradation, and designs of all but the idol of the hour are mercilessly

picked to pieces, those of the master himself by no means escaping unscathed. In the keen fire of these ardent little societies the pupil finds the same opportunity of shaping, tempering, and sharpening his views of art which exists in the larger societies of a foreign atelier; but he has the inestimable advantage, on which I have already touched, that he is engaged on real work and not on paper exercises.

But highly as I am disposed to rate this system of apprenticeship, which is, in fact, the way in which all the sculptors, architects, and painters of the past learned their crafts in the palmy days of art, it is clear that the pupil will not find in it all that he wants. He will see in his master's office only the kind of work that happens to be going on, and will have to supplement it by private study. He must read books on construction, drainage, and what, for want of a sensible name, is called sanitation, ventilation, heating, and other practical building works, which are not architecture, but nevertheless underlie all architecture, and for which, if they are neglected, no architectural excellence will compensate. That an architect must be master of these practical matters goes without saying. They are elements of good building, and good building must precede good architecture, and form the foundation of it; for history teaches us that it was by honestly meeting the necessities and suggestions of building construction that the different styles of architecture in the past were shaped into what we see them, and there is no doubt that if any new style should arise in the future it will owe its existence, and its peculiar character, to a similar reason.

But to these practical studies the architect must add that which is to make him an artist, and to that end he has to take into consideration not only the current art of the day, but that of the past. Art under its present conditions has its literary and historical side, and he will have to study this independently of the work of the office, by reading and by visiting ancient buildings. Sketching must always form a principal part of an architect's education; and living, as we do, in an age with no vernacular style of its own, we naturally look to the work of former ages, which were happier in this respect. It is generally, and rightly, thought essential that the student should travel widely and sketch largely from old buildings, measuring and studying them in detail, and so forming his taste and adding to his resources. The great builders of bygone times are still our masters; we are bound to acquaint ourselves to a greater or less extent with all the styles of the past, and, as I think, for purposes of practical utility, to study in particular those of mediæval and modern Europe which are nearest to us historically, ethnically, and socially, and which, therefore, most concern us. Above all, as Englishmen, it must be ours to know best the native styles of our own country, styles that will safely bear comparison with those of any other land, and in which, if anywhere, lies dormant the germ of that future living national architecture which is so long in coming to the birth.

But sketching has its snares and pit-falls. In his anxiety to acquire a happy touch with the pencil or brush, and to fill as many sketch-books as his companions, the student will often forget the reason why he should sketch at all, and will make the production of drawings his object instead of the knowledge of his craft to which they should be instrumental. His business should be to study a beautiful building when he finds it, by analysing it carefully, dissecting it, and finding out why it pleases him. This means a good deal more than simply sitting down and sketching it. I do not say he should not sketch pictorially as well; on the contrary, I would have every architect able to produce sketches that would not only be useful as records of facts, but also beautiful as drawings. But remember this, that making pretty drawings will never teach you to be an architect; so far as that is concerned you may as well burn them as fast as you do them. In after days when, in want of an idea, one turns over a sketch-book or portfolio of finished drawings, how rarely does one get a suggestion to help one out of one's difficulty! It is from the brief analytical notes made never to meet the eye of another, rough dimensions of proportions, of mass, of the scale of details, and memoranda of modes of construction that one gets the hint one wants. Only let whatever you draw, however slight, be drawn well and truly; let it be right as far as it goes, and

artistically expressed within its own limits. And yet after all the great value of sketching is not the sketch but the doing it. Its main use is educational. It is by drawing beautiful things, or parts of them, that one learns to understand them. So studied, they are never forgotten, and though the sketches may be thrown aside and never looked at again, which will in most cases be their fate, their good remains behind stored in the treasure-house of the memory.

And now to turn from artistic or fresh drawing to mechanical drawing, which forms so large a part of an architect's work that many seem to think it begins and ends there. Neat geometrical draughtsmanship up to a certain point has its use, but very often a great deal too much stress is laid upon it. It is easily acquired, being purely a mechanical art; and as it makes no demand on the artistic sense, any dillard can excel in it. The highly-finished look of elaborate geometrical drawings takes in the vulgar, with whom they pass muster as beautiful works of art. But what is the real use of geometrical drawing? Clearly not to be beautiful,—that is nothing to the point; they are merely diagrams made for use, in order to explain to workmen and others how things are to be made. They have no other use or object than that. It is clear they can have no artistic value, because they are absolutely unnatural. Regarded as true pictures of what they stand for they are barbarous and absurd; whatever else the future building will look like, we know that it will not look like that. As drawings they have no value, and cannot fairly be criticised at all from that point of view. They have but one standard of merit—that of accuracy. They need not, and should not, be slovenly; but, so long as they are accurate and clear, and, above all, intelligible, so that the workman may be able to follow them without blundering, that is all that should be expected of them, and any further elaboration is perfectly idle and absurd. It is appalling to think of the labour thrown away in our offices in smartening up plans and elevations. An immense amount of mischief is done in art schools throughout the country, by encouraging students to think that highly-finished and shaded geometrical drawing is an accomplishment worth years of study, and by making proficiency in the manufacture of such drawings the ground on which the national prizes in the Department of Science and Art are awarded. The architectural drawings sent up to South Kensington from the various art schools throughout the land, and still more those produced by architectural students in France and Austria and other Continental countries, where this sort of finish is valued even more highly than with us, are often miracles of misdirected dexterity; the elevations are elaborately shaded, the columns carefully rounded, cast shadows are logically projected at an angle of 45 degrees, breaking correctly round every projection, reflected lights are carefully observed, and all the tricks of mechanical draughtsmanship exhausted, while the only thing forgotten is the architecture itself, all this labour being frequently bestowed on a design which is beneath contempt. The worst of it is that the student learns to think these geometrical exercises, which, as I have said, must from their very nature be mere mechanical performances, are really works of art, and that by learning to produce them he is really learning architecture. If the schools of art think that by training lads in this way they are qualifying them to be useful assistants in an architect's office, it is high time they were undeceived. A lad would be of far more use to us who had spent his time in learning building construction, and had been taught that the only use of geometrical drawing is to explain the construction of a building to the workmen, so that they may measure it with rule and compass, and cut their stone and wood and lay their bricks accordingly. Let the pupils be reminded that, as no one will build the shadows they so ingeniously project, there is no use in projecting them. Let them be told "the mason will not make his columns any the rounder because you stipple them up with light side, dark side, and reflected light; and one sectional line drawn across your elevation will be of more service to the workman than all the shading in the world, and for that reason will be more proper, however much in vulgar estimation it might be thought to disfigure your drawing." After all, it is the public who are to blame for the false value attached to this kind

of drawing; architects would not get up their drawings with this expensive and unnecessary elaboration unless they found that, with most unprofessional critics, the execution of the drawings carried more weight than the merit of the design; and it is quite certain that in a competition, no design, however good, would have a chance of success unless the drawings were finished with all the tricks of the mechanical draughtsman, far beyond what was necessary to make the design intelligible.

Let us, then, suppose the would-be architect to have acquired a fair knowledge of practical construction, and of the mode of making drawings for workmen to work from, and also some skill in freehand drawing, so as to be able to sketch with facility, and express his ideas readily on paper, both for his own use, and to convey his meaning to others. He has, we will suppose, done a great many sketches of old buildings, and acquainted himself tolerably well with the history of architecture, and the succession of styles. Is he now furnished for his flight, and ready to take wing as a full-fledged architect? So, no doubt, many people would think, and unhappily this is, often enough, all the education he gets. But to those who understand what architecture has been, and may be again if proper measures are taken, this will seem but the beginning of a real art education,—the more familiarising oneself with the tools with which the real work is to be done. Of all arts, architecture is the most practical; it can never be mastered from books and drawings. The lore thus stored up must be digested and assimilated, or it will never nourish our artistic nature. Our knowledge of ancient styles will result in mere antiquarianism, unless we apply it to the conditions of modern life. As artists, our business is not to study, but to create; not to admire and reproduce the work of other days, but to produce work of our own for others to admire and profit by in their turn. We shall never do this by sitting at our drawing tables and scattering our designs thence among the workmen through the penny post. An architect's work is the direction of a variety of handicrafts, to none of which he has himself been trained. All the more necessary, therefore, is it for him to know enough about them to be able, in the first place, to design his work so that it can be made at all; and next, so that it can be made without needless trouble and expense. This knowledge he can only acquire in the workshop, and on the building; books will never teach it; and the student cannot begin too soon to frequent the masons' sheds and the carpenters' shops. I would have every young man during his pupilage, or at the end of it, pass a few months under a clerk of works at some building, best of all on one for which he has been making drawings in the office, so that he may see how his work on paper looks when realised in stone or wood. This is an education that never ends; as necessary for the architect as for the pupil; for it is by watching our own work, and that of our brother artists, that we learn how to improve our style; and so, if we are good for anything at all, we go on learning something fresh, and gaining fresh power of design to our dying day.

It is in this *rapprochement* of architecture to the handicrafts,—of the architect to the craftsman,—that I see the only opening by which we are likely to make any sensible progress. The need of it is the more obvious when we consider the extent of what an architect is now required to do. Happily, the day has gone by when his work was supposed to begin and end with the bricklaying, the carpentry, and the drains. No architect who respects himself and pretends to the character of an artist, will now resign the decoration of his building to other hands. Architecture pure and simple, robbed of her attributes, is not enough to satisfy him; he will never be content to let others finish what he has roughed out; he will conceive his building as a whole, harmonious and consistent in all its parts, in the smallest details as well as in the general mass; and we have only to turn to experience to see that this is the right view for him to take. The only modern buildings which command the respect of competent judges are those that have been carried out on this principle. Whatever may have been the case in former days, there is now, under the present condition of art, no other road to excellence. When every man works in a way of his own, and there is no such thing as a vernacular style in which every artist naturally expresses himself, the architect is the only element of unity in the building; and

unless his handiwork can be traced throughout it will be no better than a museum of odds and ends, and a collection of jarring discords. The architect of to-day, therefore, is expected to be able to design everything, from the building itself down to its furniture, and to work in all kinds of materials, from marble to stone, from stone to wood, and from wood to iron. He must understand colour as well as form, and be able to design not only the carving on his walls, but the needlework of the hangings, the wrought-ironwork of the gates and screens and railings, and all the metalwork down to the hinges, locks, handles, and finger-plates of his doors. But in order to design successfully in so many handicrafts, it is necessary that he should understand the technical difficulties and the possibilities of everyone of them. If he fails to do this, his design will either result in complete failure, or in unnecessary and extravagant expense; he will either set the workmen to do impossibilities, or, at the best, waste their labour by giving them difficulties to get over which anyone who understood the technique of the craft in question would never have put in their way. Let me, by way of illustration, give you a blunder of my own. I had designed a rather delicate ironwork grille, with interlacing rods threaded through one another in a way well-known in old German and Italian examples. To make this, the smith has to weld some of the rods at short distances between the eyes through which they are threaded, also to open some of the eyes and weld, or "shut," them down again. This grille was made successfully. Some time after, when designing another piece of ironwork in which the same feature of interlacing rods occurred, I thought the effect would be better if the mesh of the interlaced parts were smaller, and therefore reduced each square opening about  $\frac{1}{2}$  in. After the smith had had the work in his hands a little time, it occurred to me to go and watch him at work in order to see exactly how he did it, and then I found that this  $\frac{1}{2}$  in. reduction had simply made a possible task impossible, by leaving him no room to make his weld, so that only about half the eyes could be welded, and the rest had to be merely closed down. Now, the British workman never likes to be beaten, and if you give him an impossibility he will manage to get over it somehow or other, and very likely you will never hear anything about it. But this makes it no better.—It should be the architect's business to design in such a way that no unnecessary difficulties occur, and that everything may be done by the natural and usual processes of the craft in question; and this he can only do by mastering the technical methods of work in each instance, by seeing the thing made, and consulting the workpeople who have to make it.

There is another way in which close contact with the handicrafts and handicraftsmen will be of use to the architect; nothing perhaps will do more to cure him of that tendency to antiquarianism, which is one of our besetting sins. The care and repair of ancient buildings, the study of the vast literature of which they form the subject, the habit of looking to them for examples of style, and taking them for our models, and the amount of antiquarian knowledge which is indispensable to us in the exercise of our calling, all tend to blind us to the real use of ancient example, and to make us think that our goal is the revival of ancient architecture, and not that of architecture itself. No mistake can be more fatal to the progress of art than this. Without denying the beauty of some of the best modern work which professedly imitates, and indeed imitates only too well, the work of the Middle Ages, it is, I think, evident that it is unfruitful and can lead to nothing further. Old work should be studied, not because it is old, but because it is good. The glamour of historical association must be ignored, and ancient architecture should be analysed and criticised as freely as if it were modern,—and nothing will do more to encourage this modern way of looking at art than familiarity with actual handicraft. It is in seeing a thing done, or, better still, doing it oneself, that new ways of doing it suggest themselves, and so a step onward is gained. It is in the workshop that the art-student, be he architect or what else, will find the readiest stimulus to his fancy and the best antidote for a slavish adherence to precedent. It is essential that he should be able to handle the modelling clay, if he wishes to get his carving done to his mind; and if he could wield the hammer and forge an iron scroll, so

much the better. I can testify from personal experience that something may be learned even by so humble an exercise as building a brick wall. The day has gone by when architecture was believed to be produced with compasses and T-square. The cry of the day among artists, and the theme of most of the speakers at the two preceding National Art Congresses, is the solidarity of art, the kinship of architecture, painting, and sculpture, as three modes of saying the same thing, three vehicles of artistic expression that ought never to have been forced asunder, and cannot thrive apart. It is the healthiest sign of the day that this intercommunion of the arts and artists is gaining ground, and that the number of men is increasing who can design not only the building but also its decoration, and not only the decoration, but also the building itself. Let the architectural student lose no chance of associating himself with art students of all kinds, not only his fellow-architects, for discussion and interchange of ideas. Why should not a large town like Birmingham have something like the Art Workers' Guild in London, a club of artists of every kind, painters, sculptors, architects, painters on glass, furniture-makers, bookbinders, engravers, and half-a-dozen other varieties, who meet together once a fortnight to hear papers on each craft in turn from its own craftsmen, accompanied, when possible, by practical demonstrations, and followed by a general discussion in which men of all branches of art freely engage? And why should not the industries of Birmingham result in a local exhibition like that of the Arts and Crafts now open in London, when artists of all kinds meet on the common ground of design, and when the individuality of the craftsman is not hidden behind the name of the firm that employs him?

This, then, is the education by which I would have our young architects trained for their work; not one that begins and ends on the office stool on which he perches as a pupil, and with mastering the principles of construction as explained in books and drawings, but one supplemented by reading, by sketching, by thinking, by following his work into the workshop or to the building, by constant communion with other artists, and last, though not least, by learning to model, and above all to draw the figure from casts and from life, as the root and key of all decorative design and the centre of all art education.\*

#### COMPETITIONS.

**THE PROPOSED BATTERSEA POLYTECHNIC.**—The Committee of the South London Polytechnic Institutes have, with the advice and assistance of their Consulting Architect, Mr. Rowland Plunbe, F.R.I.B.A., just selected six sets of drawings from the fifteen sent them in the preliminary competition for a design for the proposed Battersea Polytechnic. The authors of the six selected designs have been invited to take part in a final competition in which the drawings will be made to an enlarged scale, viz.,  $\frac{1}{4}$  in. scale to a foot in lieu of  $\frac{1}{8}$  in. to a foot scale in the preliminary competition. The six successful competitors are Mr. John Belcher, F.R.I.B.A., Messrs. Henman & Harrison, Mr. E. W. Mountford, Messrs. Roger Smith, Son, & Gale, Mr. J. Osborne Smith, and Mr. Sidney R. Smith. The proposed Polytechnic is to cost a sum of 40,000*l.*, and will be erected on a site of about two acres facing the Battersea Park-road. In order to complete the committee's scheme, and fit up the Institute when built, a sum of nearly 10,000*l.* is still required. The date for sending in drawings in the final competition is (as at present fixed) January 21 next.

**PUBLIC BATHS AT CAMBERWELL.**—We hear that the professional referee in this competition, Mr. Charles Barry, F.S.A., has recommended the design of Messrs. Spalding & Cross for the public baths on the Camberwell green site, and that it has been adopted by the Camberwell Baths Commissioners. The estimated cost of the building is about 24,000*l.*

**WESLEYAN CHAPEL AND SUNDAY SCHOOL MELLOE, NEAR BLACKBURN.**—We are informed that in a limited competition for the above chapel and school, the design of Mr. Walter Barrow, of Preston, has been accepted.

\* We will print the remainder of Mr. Jackson's address, and other proceedings of the Congress, in our next. Another paper read before the Architectural Section of the Congress, by Mr. H. H. Statham, appears on pp. 367-69.

#### Illustrations.

##### THE NEW "DRESDENER BANK" BUILDING, BERLIN.

THE new building of the "Dresdener Bank," situated most advantageously on a corner site, with main front looking on to the Opera Place, has been erected for the purpose of furnishing ample and dignified office room for carrying on the lately much enlarged business, in which a staff of upwards of 300 persons is employed.

The new building as it now stands has a ground floor and a first floor devoted entirely to public despatch business, offices, and board; a basement, in which the strong rooms and the vaults of the "safe deposit" are situated; and a second floor, containing some of the head officials' residences, each part independent in itself. The main feature of the interior is a central hall, on three sides of which the counters of the general cashier, the security and coupon departments, have been placed, these being backed by their respective offices, and at the same time being in close connexion with the Stock Exchange department on the one side and with the otherwise quite independent exchange-office and deposit department on the other. On the first floor, looking towards the front, easily attainable by main and side staircases, have been placed the board-room, together with the reception-rooms, and private offices of the managers; and in close connexion with this administrative department, situated on the same floor, extensive accommodation for the secretaries, corresponding clerks, and book-keepers has been planned. The strong room of the bank proper, having its position in the basement below the central hall, is constructed entirely of steel plates, and resembles an enormous double box, the room between the sides of which is used as a patrol way for the night watchmen; it is so placed that it can only be entered after passing through the security vaults, situated on the same level, and these again only by means of a special staircase from the security department.

The façades are of a Saxon freestone with a Bavarian granite base, and the style of design is a very typical example of the modern Berlin architecture; monumental but somewhat cold and formal. The frieze, showing the motif "work" from the ideal as well as practical point of view, and the central sculpture illustrating "The Justice of Fortune," was executed by Herr Geiger. The architect is Herr L. Heim.

##### DESIGN FOR COMPLETION OF HOLY TRINITY CHURCH, CORK.

This design for a tower to Holy Trinity Church, Cork, was submitted in competition by Mr. Thos. Drew, of the Royal Hibernian Academy, the object of the competition being a memorial to Father Mathew.

The design was unsuccessful in the competition, but we are glad to publish it as the work of a well-known and talented architect of the sister island (if one is still to be allowed to call Ireland so).

##### DECORATION FOR A RECEPTION-ROOM.

This design was made along with others for the decoration of a house in Buenos Ayres, and has been carried out in rosewood inlaid with box, with silk panels above and a painted frieze. The artist is Mr. Roland Hill, of London.

##### NORWICH CATHEDRAL: INTERIOR VIEW FROM THE NORTH TRANSEPT.

This is a view taken nearly under the north arch of the crossing at Norwich, showing one of the transitional piers and the triforium arcade beyond, with the late clearestory and vaulting above.

The original drawing, by Mr. A. D. Smith, was exhibited in the Royal Academy this year.

##### TUPWOOD LODGE, CATERHAM, SURREY.

A SMALL residence formerly occupied the site, and this has been incorporated in the new building, but the old structure is not left visible externally. The walls are of red brick, with half-timbered work for the upper stories, and the roof is covered with Broseley tiles.
