What I have hitherto wished to impress is the necessity of observing the various traits of character of the many varieties of our several fruits, that disappointments and losses might be less frequent and success more certain. Often I have grieved over the many evidences to be met with of gardeners neglecting to think sufficiently. I know of no calling where exists such scope for thought as in connection with the everyday experience of gardeners. Every plant has its own peculiar characteristics, and it is the work of gardeners to grapple with these characteristics and to understand them. Pray allow me to be plain; and if recently I have been more a reader than a contributor to your columns my silence has not been through a lack of contributions that tempted criticism. One gardener partly fails in growing Vines satisfactorily; a neighbour publishes that the water applied ought to have been increased by "fifty times." This is what I term having "water on the brain," when thought would have convinced that enough was sufficient, and all beside waste. But it was about hardy fruits I meant to write, though of Vines I will here take the opportunity of saying that to feed them sufficiently is wisdom, whilst to gorge them to an extent that necessitates their borders being washed is folly.

APPLES.—Had we had sufficient sun heat last year to perfect the wood and fruit buds of our outdoor trees, I believe that this year there has been nothing to contend with that would have resulted in the general barrenness experienced. We had no spring frosts of importance, neither the gales nor hailstorms that was experienced in the south of England. Standing side by side we had trees equally laden with blossom, whilst the one variety has carried crops that bent the branches to the ground, and others have not had a solitary fruit; and the reason I say has not been that one variety resisted frost better than the other, but simply that the one variety required less heat last year to perfect its fruit buds than did the other. How else are we to account for the barrenness of *Court Pendû Plat*, which bloomed in June under the most favourable circumstances? And how otherwise are we to account for the very great crop that has been perfected of our old favourites, *Cellini* and *Lord Suffield*, and of the two varieties that are not so generally well known, the *Ringer* and *Golden Spire*? To growers in the north of England and Scotland I say, plant largely of these four, and the result will be with such seasons as has been those of recent years an abundant crop of first-class kitchen Apples.

PEARS.—Regarding Pears, of blossom here I had also an abundance, but on only two varieties have I had any Pears. I have before written of *Marie Louise d'Uccle*, and now, as a hardy companion, I have the pleasure of adding *Mr. Rivers' Fertility*. But they, too, have singularly demonstrated not only their natural hardiness, but the frost that last year materially affected them in this. I have had a crop of Pears without a pip in the whole lot; and this deformity I maintain has in no way been contributed to by the present season, but is the result alone of last year's sunless season. The freak I take as simply evidence of the extreme hardiness of these two varieties; we have them with fruit buds only half matured setting a crop.

STRAWBERRIES.—Of Strawberries I wish to speak of *Roden's Duke of Edinburgh*. Some time ago I alluded to a variety that was uninjured by wet—this is the variety. Here it is light in

colour but of delicious flavour, and is always asked for by those who have previously had it. It ought to be grown by every gardener, and then, no matter how wet the period during the Strawberry season, a dish of delicious Strawberries could be had. Next year I intend it to form my main crop; also of advantage, it has a long season, and every blossom appears to produce a perfect fruit. I have also the other Duke of Edinburgh, but it does not appear to thrive on my rich loamy land.—JOSEPH WITHERSPOON, *Red Rose Vineries, Chester-le-Street.*

HYACINTHS AND TULIPS.

AMONGST all the beautiful plants in our gardens which flower in early spring few surpass Hyacinths and Tulips for great and pleasing effect. These flower in April and May—a season when flower gardens generally are comparatively dull. Flowers out of doors in spring are always welcomed. For many years I planted annually about £80 worth of Hyacinths and Tulips (reckoned at wholesale prices) in flower gardens, and it was my happiness to know that in spring they gave great pleasure and satisfaction to my employers. Families that go to London or leave their country seats during the spring months will not care for a display of flowers then in their gardens, but to those who remain at home I strongly recommend planting bulbs now for a spring display. October or early in November is the best time for planting Hyacinths, Tulips, and Crocuses—as soon as the bedding plants are removed. Early planting is doubtless advantageous, as the bulbs obtain a better hold of the ground, and thus gain strength to produce stronger flower stems. If planted late in November they do not root so well. The soil is too cold, and the time for rooting too short before the winter frosts arrive. Late planting is altogether disadvantageous, for the bulbs so planted flower at the same time as those planted earlier.

In buying Hyacinths for outdoors, only those with single flowers should be selected. Indeed, I prefer the single varieties for culture in pots also, as they produce far better bells and more massive and effective spikes. In arranging the colours of Hyacinths in planting I employed the three colours red, blue, and white in equal proportions—that is to say, thirty-three of each colour in a bed of one hundred bulbs, mixing them in planting, and not keeping the colours in separate rows. Massing the three colours separately is not so pleasing. In planting Hyacinths in shrubbery borders it is better to plant three in a group than singly. As the heads of single flowers are heavy they should be secured to neat stakes before the flowers expand. Even in a conservatory I prefer three bulbs in a pot. For outdoor display the mixed reds, mixed blues, and mixed whites are used, being much cheaper than named varieties. After they have done good service in the flower garden the bulbs should be carefully taken up and preserved for forcing for cut flowers in their second year. The second year's flowers from good Dutch Hyacinths are quite large enough for cutting, and at market prices are worth nearly their original cost.

Tulips are planted about 8 inches asunder in beds, and about 3 inches below the surface. If the most effective sorts are used, and the colours are well balanced in planting, no other known flowers can produce a more striking effect in a flower garden than a bed of single Tulips during the month of May. I have found that the most brilliant effect was produced by three colours only—scarlet, yellow, and white, mixed in the proportion of three scarlet, two yellow, and one white. The best scarlets for effect are Vermillion Brilliant and Samson; for yellows I like Canary Bird and Yellow Prince—both are excellent and cheap. For white there is none better than White Pottebakker—a rather high-priced Tulip, but pure white. Double varieties are objectionable for outdoor work, owing to the weight of the flowers and length of flower stems. In mixed borders Tulips should be planted in patches of a dozen bulbs rather than singly. To all who want to have charming beds in spring I commend a trial of such Tulips as those named above, and planted as I have indicated. Bulbs may be forced a second year for cut flowers at Christmas.

Crocuses are so cheap, early, and pleasing that they should be largely used in gardens. In small gardens they should be planted in large patches, and in gardens with large shrubberies sheets of Crocuses about the grounds are very pretty. Crocuses once planted will last for many years.—A. PETTIGREW.

POTTS' SEEDLING APPLE.

ACCORDING to Mr. Petch, the experienced representative of Messrs. Richard Smith & Co. of Worcester, this Lancashire Apple possesses a property that entitles it to the consideration of those who have gardens in smoky districts. "There is no Apple in existence," Mr. Petch says, "that will grow so well in and

near large towns as Potts' Seedling, and it should be recommended particularly for that purpose." As confirmatory of the accuracy of this estimate we recently saw fine crops of splendid fruit in Mr. Firth's garden at Riverdale, Sheffield. Mr. Abbott, the gardener there, regards it as the most useful Apple in the collection, and wishes that half of the entire number of trees were of this variety. Many of the Sheffield-grown fruits were much larger than that represented, which is submitted as a fair average specimen.

The fruit of this Apple emits a powerful scent of ether or chloroform. It is very irregular in outline, roundish and flattened, very angular on the sides and at the base, also puckered and ribbed round the eye. Skin smooth, shining, and unctuous when ripe, of a uniform greenish straw colour, and sprinkled with russet dots. Eye large and closed, set in an angular and ribbed basin; tube wide, conical; stamens marginal. Stalk half an inch long, stout, inserted the whole of its length in a deep cavity. Flesh very tender and pleasantly subacid, with all the character of the flesh of Codlins. Cells of the core open; cell-walls elliptic, obovate, with toothed fungoid veins. An early Apple, ripe during September, of the Lord Suffield and Domino class, but heavier and keeps longer, often remaining firm until November. The tree is a good grower, with large roundish leaves like the Hawthornden, and bears freely.

Mr. Nelson of Catcliffe, near Rotherham, found this Apple

Fig. 71.—Potts' Seedling.

about thirty years ago in the garden of a Gooseberry grower at Oldham, who, he stated, had procured his trees from a Mr. Potts, who had raised it. Mr. Nelson's letter appears on page 322 of our issue of the 5th ult., and he speaks in high terms of the Apple in question.

USEFUL HINTS.

PELARGONIUMS.

To have short and sturdy Pelargoniums of the show and decorative types next season they should now be placed on a shelf close to the glass in a cool and well-ventilated house, and have moderate supplies of water. If the Pelargoniums have been well ripened under this treatment the growths they make will be very healthy and sturdy. If they are growing through the winter the shoots will be weak and watery. Subsequently the plants will be very drawn by the time their flowering period arrives, and the blooms will be poor.

TUBEROUS BEGONIAS FOR BEDDING.

The past season has again shown how well adapted the Tuberous Begonia is for bedding. I think a few beds should be in every garden, if only for a late display, when Pelargoniums are past their best. The plants should now be lifted and placed in a dry shed until the tops decay, after which they should be packed closely together in boxes and placed in a cool and dry place safe from frost. I find the best tubers to plant are those that are not distinct enough to name and too good to discard, of which some

nurserymen have some thousands every year from seed. I should like to know the best edging plant for a Begonia bed. I find none so well suited for that purpose as *Polemonium eceruleum variegatum*.

CULTURE OF FICUS ELASTICA.

Of all plants that are useful for growing in rooms *Ficus elastica* is doubtlessly the best. The finest specimen I have seen had been grown in a house for several years. It was 8 feet high, with broad healthy foliage down to the rim of the pot. It had a good position in a bay window, and in such a position this *Ficus* looks very well. It is also well adapted for subtropical bedding. The best time to propagate it is the beginning of the year. If old plants have to be propagated from, cut off the leading growths about 6 inches long and insert them singly in small 60-pots, plunging them in a propagating frame in a bottom heat of 90°, where they will soon strike. If many are required take all the eyes with a leaf attached, and if each is secured to a small stick they may be readily placed firmly in their pots. After they have rooted they must still be kept in the same bottom heat to start them. After they have started well pot them firmly in 48's, in a compost of two parts loam and one of peat. Give them stove treatment the following summer and winter, when they may be hardened off, and kept in a greenhouse for use as required.—A. YOUNG.

AUTUMN-PLANTED CABBAGES.

YOUNG plants which were inserted in their permanent quarters early in September now have a firm hold of the soil and will be growing freely. It will be a great gain in spring if they can be carried through without receiving any check. Severe weather may come and stop their growth, but this will not injure them so much as being disturbed at the roots, which often happens if care is not taken to earth up the young plants in good time. It is an excellent plan to have plants in drills 3 inches deep, as the soil can be levelled in from each side to the stems of the plants. This prevents the wind twisting them, breaking the roots, and thus retarding the growth considerably. In cold weather the earthing-up acts as a great protection to the young plants. In fact, we have noticed plants which have had no such aid completely swept away during a strong gale, or seriously crippled in severe weather, while those protected appeared little the worse.—J. M.

PLANTING ROSES—SPRING v. AUTUMN.

I SEE that our friend "D., Deal," has raised a point in Rose culture of some interest—viz., as to whether it is better to plant Roses in the autumn or to defer doing so until February, and appeals to me to supply a few particulars as to the temperature of the soil at moderate depths during the late autumn, winter, and early spring months. This I have much pleasure in doing; but since my own observations extend only over a few years it will be perhaps better to quote instead some of the mean values for six years given by Mr. G. J. Symons, F.R.S., in a paper read before the Royal Botanic Society in 1877:—

MEAN TEMPERATURE OF THE SOIL AT 9 A.M.

	At 1 foot.	At 2 feet.	At 4 feet.
	deg.	deg.	deg.
October.....	50.1	51.6	54.0
November.....	42.6	44.9	48.3
December.....	38.9	40.7	44.0
January.....	38.2	39.8	42.3
February.....	38.1	39.5	41.6
March.....	40.8	41.5	42.6

Comparing the temperatures at 1 foot in the above table with the mean for the whole year (49.2°) I find the soil in October to be 0.9° warmer, and in the remaining five months respectively 6.6°, 10.3°, 11.0°, 11.1°, and 8.4° colder than this annual average. It will thus be seen that the ground is, as a rule, not only very much warmer in November than in February, but also a good deal warmer than even in March, while at the greater depths of 2 and 4 feet these differences are of course still more marked. It will also be noticed that the most sudden fall in temperature is that which usually occurs between October and November. So that, given seasonable weather and taking the temperature of the soil alone as our guide, November would appear to be the most generally favourable month both for the removal and planting of Roses.

In practice, however, I believe it will be found that the condition of the soil is a matter of far greater importance than its temperature. It is, therefore, my decided opinion that in a season like the present it would be advisable to defer the planting of any Roses received from the nurseries until the ground is in some-

thing like really good working order. The careless and ill-timed planting of Roses is, I believe, the cause of more failures than any other that could be named.—E. M., *Croydon*.

"How would it answer to get Roses from the nurserymen as usual in the autumn and lay them in until February?" To this question, asked by "D., Deal," on page 402, I for one can say the plan will answer well. It is certainly the safest method to adopt in districts where the winters are usually severe, because, as your correspondent observes, it is "far easier to cover the Roses and protect them from frost" than if they were planted in the beds.

I found the advantages of the plan indicated by accident, and subsequently adopted it as a system. Some fifteen or sixteen years ago a number of purchased Roses arrived late in November, and their planting was commenced forthwith; but, fortunately as it proved, frost and snow came suddenly before half of them had been inserted, and the remainder—the bulk—were laid in by the heels near the ridges of late Celery, a row of Roses being placed along each ridge, not bundled together anyhow, and there they remained till the end of February. They were examined occasionally, and just when the roots were covered as with white specks, the first evidence of the production of new fibres, the plants were taken up carefully during a dull moist day and planted quickly in the beds, the roots not being permitted to become, even to the slightest extent, dry during the process of removal. The result was this: Every Rose so treated grew as well as it was possible for Roses to do, while every one planted in autumn was killed by the frost. Those near the Celery ridges were protected with the same litter that preserved the Celery, and thus no additional labour was involved in this respect.

This method of protecting Roses in winter and planting in spring has ever since been followed with the same good results; and I can only conceive it possible for failure to occur by permitting young roots to form and become dry when taken from their winter quarters and placed in the beds, and then the system would not be at fault, but the operator.

I have not read what others have written on this subject, but simply record my own experience. So convinced am I of the safety of the practice, that if I had a thousand Roses to plant for next season I should order them at once, this being important, and treat every one of them as above described.

The plants thus laid-in in November have never commenced rooting until spring. I have examined others at different times for determining this point, nor would they have rooted sooner if planted in the beds in autumn.

I am convinced than the method described, carefully carried out, is the safest and best for northern districts, and "D., Deal," might test the system in the south this season and let us know the results next year.—A NORTH COUNTRYMAN.

[We have received other letters on this subject, which will be published next week.]

NOTES ON PLUMS.

THE Plum is a very useful, and, where grown for profit, a remunerative fruit. It may be cultivated in several ways—either against walls, or in the form of bushes and pyramids, or as standards for orchards. The Plum season may be prolonged considerably by planting suitable varieties. From Early Prolific, Plums may be had after the middle of July; and with Coe's Golden Drop and Ickworth Impératrice, if the fruit are allowed to stay on the tree until they shrivel, then wrapped in soft tissue paper and placed in a drawer in a dry room, they may be kept until November. Some people think that about two varieties of Plums are sufficient; but I find that most of the varieties do not bear well every year; sometimes one kind bears extra well, sometimes another. So I find it is best to be prepared with six varieties or more. Standard Plums should be planted in orchards about 16 feet apart. If the trees are to be planted for profit, an orchard that is cultivated is the best, and then the trees may be planted bush shape 6 feet apart, to be thinned out to 12 feet. If the orchard is in grass and on gravel standard trees must be planted.

As to pruning, standard Plums, like Apples, require the branches to be thinned out to prevent them crowding and for keeping the centre open. Pyramids and bushes require to be summer and winter-pruned, shortening the growths in summer and attending to them in winter as you would an Apple tree. Pyramid and bush trees, where planted in kitchen gardens, should be root-pruned or lifted every two years; then the trees do not make so much growth and are more fruitful. Plums may be grown on all aspects or walls, but the south, east, and west are best. If a west or south wall can be provided for them the fruit is more luscious

than any other; but trees against an east wall produce good Plums.

Fan-shape training is the best for walls. Keep the lower branches well down and the centre open until the tree is furnished. Young trees do not require the leading growths pruned back very much; only shorten the strongest growths to balance the tree, and lay in as many laterals as there is room for, pruning the others to form fruit spurs. The following will be found a good selection either for culinary or dessert in succession:—Early Prolific, Oullins Golden Gage, McLaughlin's Gage, Green Gage, Transparent Gage, Jefferson, Victoria, Kirke's, Belle de Septembre, Prince Englebert, Reine Claude de Bavay, Ickworth Impératrice, and Coc's Golden Drop.—A. Y.

THE MANURIAL VALUE OF PHOSPHATE OF MAGNESIA.

ROUGHLY analysing the field trials referred to in my two last letters (pp. 383 and 406), we find that from November, 1881, to October, 1882, the results recorded in the Journal of the Chemical Society stand thus:—

No. of trial.	Superphosphate or soluble acid phosphate.	Precipitated or retrograde phosphate.	Bone dust or coprolites.
1.	best	—	—
2.	—	best	—
3.	equal	equal	—
4.	doubtful	doubtful	—
5.	—	slightly best	—
6.	best	—	—
7.	best	—	—
8.	best	—	—
9.	slightly best	—	—
10.	slightly best	—	—
11.	slightly best	—	—
12.	equal	equal	—
13.	—	—	best
14.	best	—	—
15.	—	—	best
16.	equal	equal	—

Thus—

Dissolved, or perfectly soluble phosphate, gave the best results	5 times out of 16.
" " " " " slightly best	3 " "
" " " " " equal to precipitated or reduced	3 " "
" " " " " doubtful	1 " "
Precipitated or reduced (soluble to the extent, say, of 5.56 grs. per gal. of water)	best results 1 " "
" " " " " slightly best	1 " "
" " " " " equal with soluble phosphate	3 " "
" " " " " doubtful	1 " "
Bone dust, or powdered coprolite.....	best results 2 " "

So far, then, as the weight of the crops is concerned, we can hardly hesitate to place the—

Perfectly soluble phosphate... in the front rank of activity and efficiency.
The precipitated or retrograde... " second " " "
Bone dust or coprolite " third " " "

And these results are in as much accordance as could be expected from comparisons made under differing conditions of soil, crop, and weather, with the conclusions drawn from laboratory experiments and theoretical reasonings; but my chief object is to show the superiority of phosphate of magnesia and ammoniacal phosphate of magnesia to any of these forms of phosphate of lime.

To this point I now turn from the views of Liebig given at page 342 concerning these two magnesian compounds, and from the facts stated in my letter concerning the money value of magnesia as a manure (page 225), it will be seen that theoretical conclusions are absolutely in favour of the fertilising effects of phosphate of magnesia and its combination with ammonia, and the proofs derived from their solubility are most convincing. It is, however, a strange fact, that though Liebig's attention was directed to magnesian phosphates he deals only with the tribasic form, and does not refer to the bibasic salt, though the solubility of the latter is very much greater. Voelcker, again, when testing the solubilities of phosphatic materials, experimented with tribasic phosphate of magnesia (his attention being called to it, as was Liebig's, because it is found in the ashes of plants), but he leaves the far greater solubility of the bibasic salt unconsidered. This could only have arisen, as it appears to me, from the supposed impracticability of procuring the latter substance for commercial application. Voelcker, in common with Liebig, manifestly believes that ammoniacal phosphate of magnesia is practically sufficiently soluble to meet the wants of all cultivated plants. Bousingault, moreover, was much impressed with its manurial qualities, and urged its use. Liebig found that its solubility in weak solutions of ammoniacal salts was between 8 and 10 grains

per gallon (page 342). That of bibasic phosphate of magnesia far exceeds this. It is, in fact, soluble to the extent of 217 grains per gallon at a temperature of 45° Fahr. Now this is a degree of solubility which must practically be equal, so far as respects a manure, to the solubility of soluble acid phosphate; and the absence of acidity in phosphates is a great desideratum in Voelcker's opinion, as well as in that, I believe, of all agricultural chemists, when the manure is applied to land deficient in lime. Neither can there be, I think, any difficulty in selling phosphate of magnesia, as soluble as the bibasic, with a guaranteed percentage, the impracticability of doing which is often advanced as an objection to the more general use by farmers of precipitated phosphates of lime.

Of field trials with the phosphate of magnesia I shall refer to two cases only—first, to the results obtained with this salt at Easter Ardross, the report on which was ably reviewed in the *Journal of Horticulture* (page 110, No. 1766), and secondly to a trial which was made by Dr. Hogg at Stillyans in Sussex, on Potatoes in the year 1877. This has been already referred to by me at page 381 (No. 98). Briefly, Dr. Hogg found that "fimus" manure, which contains phosphoric acid in the form of phosphate of magnesia, produced double the effect he obtained with a heavy dressing of farmyard manure; and Mr. Cameron obtained results which showed that 1 lb. of phosphoric acid, in the combination to which I have here called attention, produced the same effect as 2 lbs. of that substance in soluble acid phosphate of lime. Need I add more to encourage horticulturists to prove or disprove whether similar effects would result from its use in the special soils they may have to deal with? A saving of half the sum now expended on superphosphates would be no trifling consideration.—INQUIRER.

SINGLE DAHLIAS.

HAVING read with pleasure paragraphs in your valuable Journal referring to single Dahlias, I venture to offer as a correspondent another contribution from my experiences in the growth of these beautiful and popular plants.

The reputation of Paragon, coccinea, lutea, Vivid, alba, &c., is already established, and I have grown them to perfection, but the varieties will soon become inexhaustible, as you may imagine from my experience.

A packet of mixed seed was sown in a pan last February. The young plants so obtained grew stronger than cuttings. I planted them in round clumps, and the effect has been very striking and brilliant from the variety of colours, the most beautiful I have named being a pure crimson Regina; yellow veiled with red, Destiny; yellow centre, shaded into scarlet and deep crimson, Gloriana; white, shaded into pink, Cecilia; pure yellow, curious shape, Cross Roads.

The varieties, however, will become endless, and as to the nomenclature of single Dahlias it will be impossible to name them all. One thing is established—the single Dahlia can be grown from seed as an annual. It will commence to bloom in July, and as an autumnal-flowering plant there is no better. There is a profusion of bloom still, and I expect when the seed is harvested to have a still greater variety next year, and hope for a successful result in having already associated alba and Paragon, as suggested by a correspondent.—P. L.

SCRAPS ABOUT FRUIT.

A DOUBLE CROP OF PLUMS.—My attention has been drawn to a remarkable instance of fruitfulness in Plum trees. We have here two trees which have this unfavourable season ripened two crops of fruit. The first crop ripened early in September; the second is now ripe. The trees are apparently about twenty years old, and I am told in all favourable seasons they bear a second crop. The first crop was very like the Victoria; those ripe now are of the same colour and flavour, but differ in shape from that variety. Not having seen or heard of such a thing before I would like to know if it is usual for Plum trees to bear two crops in one season, especially an unfavourable season like the present.—JOHN LINDSAY, *Exton Park, Oakham.*

[Two fruits sent with this communication were crushed into a flattened mass of pulp in transit through the post.]

LARGE PEARS.—I desire to thank your Maidstone correspondent, "F. O. M.," for the weight of Pitmaston Duchess Pear recorded on page 385. I have grown one of the heaviest, if not the heaviest, fruit of that Pear in England; it weighed 1 lb. 14½ ozs. I have one fruit of Beurré Diel weighing 1 lb. 4½ ozs. I have not grown Easter Beurré before this year; a small tree from the

nursery in 11-inch pot produced six Pears weighing 2 lbs. 11 ozs., one of them turning the scale at three-quarters of a pound. These are grown in pots in a cold house—our only way to get good fruit in this locality.—G. HAWKINS, *Evenny Priory, Bridgend.*

THE PARSLEY-LEAVED BRAMBLE.—Your correspondent, "W. K. W.," gives great praise to the Parsley-leaved Bramble on page 391. The roots of ordinary Brambles are very troublesome in gardens, because like the upper canes they run a great way and shoot up here and there. Could your correspondent say if the roots of the "Parsley-leaved" would render it unsuitable for growing in a garden close to other small fruit trees? I should be glad to know also where plants of it can be had.—P. B. J.

[American Raspberries were recently advertised in our columns by Mr. Vans Randell, Preston Brook, Chester.]

SCARCE VARIETIES OF PEARS.—In reply to a communication in the Journal last week from "J. E.," I may state that, so far as I know, there are not many of the Pears mentioned by him that have been tried in this country. I have myself grown a few of them, and the following is my experience. Frederic de Wurtemberg I had from the continent some years ago, and I found it very uncertain in its quality. In some seasons it was as good as an autumn Pear could be, but in others it was very deficient of flavour. As it ripened at a time when we have so many better and more certain kinds I discarded it. Soldat Laboureur I have always found to be the same as Beurré d'Aremberg; but I know that Soldat Esperen is sometimes called by that name. Beurré Dubrusson is probably intended for Beurré Dubuisson, a Belgian variety of which I have not yet seen the fruit. Bezi de St. Waast, I see by the "Fruit Manual," is a synonym of Bezi Vaet, an old and excellent late Pear. Perhaps some of your correspondents will be able to give us information about the other sorts mentioned in "J. E.'s" list.—A PEAR FANCIER.

THE DOMINO APPLE.—Having heard this Apple highly spoken of as one of the best and most productive of culinary Apples, I should be glad if you or any of your readers can give me any information about it. Is it as early as Lord Suffield, as productive and as hardy? The Apple just named is our first, but I can hardly add best, as it "falls to nothing," our cook says. That, however, is an exaggeration; but it certainly does seem to melt away to a great extent in cooking. It also "falls" in another respect—namely, its liability to be blown off the trees by a storm in August. Can anyone who has grown the Domino say if it is an improvement in these respects—i.e., is the fruit firmer, and does it adhere to the trees better? I should like to know the origin of this variety.—J. L., *Derby.*

[We shall be glad if any of our readers can state either the raiser of this Apple or by whom it was named.]

THE DYMOND PEACH.—A correspondent, "IRISH RECTOR," has sought information on this Peach. It is one of the most hardy and certain bearers, and the fruit is large and excellent. It has produced an excellent crop this year, and I think I could better spare any other tree than this. Reinctte Franche Apple must either be grown under glass or on a south wall in this country to have the fruit in high condition.—J. E. P., *Notts.*

COMING CHRYSANTHEMUM SHOWS.

THE following list of approaching Chrysanthemum and autumn fruit shows will be useful to our readers.

November	9th (Thursday).	—Brixton.
"	13th (Monday).	—Stoke Newington (two days); Lambeth (three days).
"	14th (Tuesday).	—Royal Horticultural Society (Fruit and Floral Committees); Putney, Twickenham, Walton-on-Thames, Tooting (two days); Southampton (two days); Plymouth (two days).
"	15th (Wednesday).	—Bristol (two days); Westminster Aquarium (two days).
"	16th (Thursday).	—Kingston (two days); Tunbridge Wells (two days); Croydon.
"	18th (Saturday).	—Leicester.
"	21st (Tuesday).	—Liverpool (two days); Manchester (two days); Brighton (three days); Oxford.
"	22nd (Wednesday).	—Northampton (two days); Birmingham (two days); Wimbledon.
"	23rd (Thursday).	—Staines.
"	29th (Wednesday).	—South Shields (two days).

WINTERING STRAWBERRIES IN POTS.

THE time was when Strawberries for forcing were wintered in houses or heated pits, or placed on their sides in ridges, in which position the plants were nearly dried off with a view to resting

them, under the impression that plants thus treated would more readily respond to the combined influence of heat and moisture when removed to the forcing house later on. But now, happily, this somewhat barbarous and incongruous method of procedure has become a thing of the past, and in its stead a more natural, simple, and productive one has come into practice—namely, plunging the pots to the rims in beds of sifted coal ashes out of doors, leaving space enough between the beds, which should be about 6 feet wide, for getting to the plants as they are required for the forcing house, and also for the purpose of putting a slight covering of bracken over them in the event of severe frost. This, however, should be removed on every favourable opportunity. Thus wintered, and notwithstanding the fact that the whole—ashes, pots, and soil—have been one frozen mass for weeks at a time, we have had very few pots broken—not more than a couple of dozen out of nearly three thousand plants—by the action of frost. The fact is that hardy plants, whether they are grown for their fruit or flowers, once placed in a flower pot, have heretofore been coddled too much.—H. W. WARD, *Longford Castle.*

IN the biographical notes which accompany the excellent PORTRAIT OF DR. HOGG in the last issue of the *Gardeners' Magazine* reference is made to the "late" Mr. G. W. Johnson, the founder of the *Cottage Gardener*, and for many years co-editor with Dr. Hogg of the *Journal of Horticulture*. As the allusion in question has prompted inquiries from friends of the gentlemen to whom it refers, I have the pleasure to state that Mr. Johnson is quite well, and trust he will long enjoy the repose which he has so well earned after a long, active, and successful literary career.—J. WRIGHT.

— ON the occasion of the recent visit of the Duke and Duchess of Albany to Blythswood, Renfrew, the seat of Sir A. Campbell, a pretty idea was successfully carried out in the presentation of a bouquet to the Duchess, which was largely composed of the fragrant BOG MYRTLE (*MYRICA GALE*), which is THE BADGE OF THE CAMPBELLS. This little shrub is a native of Britain and very abundant in some parts of Scotland, where its leaves have been used as a substitute for hops. It is related to a well-known North American plant, *Comptonia aspleniifolia*.

— A GARDENER recommends *CHRYSANTHEMUM MADAME DESGRANGES* as an excellent early-flowering white variety of the small Japanese type, which blooms very freely, and is thus especially useful where a large supply of blooms is required.

— MR. GEORGE DICKSON, late of Sutton Place, Surrey, has been engaged as head gardener to Capt. G. H. Elliott, Farnborough Park, Farnborough, Hants.

— MR. J. F. SHARPIN sends us particulars of what he describes as one of the most prolific Potatoes known, and adduces as evidence of this that one large tuber planted in the spring yielded produce weighing 20 lbs. This is not equal to the record of Col. Humberstone on page 409—namely, one tuber of *Magnum Bonum* yielding 25 lbs. 5 ozs. Mr. Sharpin's seedling has the high-sounding name of the Archangel.

— AT the annual meeting of the NEWCASTLE-UPON-TYNE BOTANICAL AND HORTICULTURAL SOCIETY the Secretary, Mr. James J. Gillespie, read the annual report, which gives a most favourable account of the past year's shows in a financial point of view, "the Society's indebtedness having been reduced by £321 6s. 8d., or from £401 11s. 5d. to £80 4s. 9d., notwithstanding the extremely adverse character of the weather during the spring show and on the second day of the summer show." The schedule

for next year has been issued; the shows being fixed for May 2nd and 3rd, and July 25th, 26th, and 27th, the usual liberal prizes being offered.

— MR. HUDSON, gardener to H. J. Atkinson, Esq., Gunnersbury House, Acton, grows that old but useful plant *SPARMANNIA AFRICANA* exceedingly well, and a method he has now adopted deserves notice. He is training some young plants as standards with clear stems about 5 or 6 feet high, at which height they are stopped and allowed to branch freely, so as to form a compact head. For conservatory decoration such plants will be extremely useful, as the flowers will be seen to much better advantage than on taller specimens. As an example of the rapid growth made by this plant, it may be remarked that cuttings struck last March are now vigorous specimens 5 to 7 feet high; and an older plant that was cut down has made even stronger growth in the same period.

— A CORRESPONDENT writes:—"I find SUTTONS' GIANT SHALLOT the largest, best, and most prolific I have ever grown. It cannot fail to prove a boon to our large market growers generally, as in it we have what is needed—quality and quantity combined. It is also admirably adapted for exhibition, the bulbs being large and handsome. In the spring I purchased 2 lbs. of seed direct from Messrs. Sutton & Sons, and no especial care was taken in the preparation of the ground, it being simply manured and dug in the ordinary way, and the produce has far exceeded my expectations."

— IN reference to Messrs. Carters' CROWN JEWEL BEGONIAS noticed last week, we omitted to state that the flowers had been cut from plants in the open ground on October 25th. This fact affords evidence of the great value of Tuberous Begonias for affording a late and bright display in beds, as suggested by Mr. Young in another column.

— MR. C. WARING, Prince's Park, writes:—"I do not think it is generally known what a useful plant *CHRYSANTHEMUM LA NYMPHE* makes. I find it far more useful than many of the Pompons for house or conservatory decoration. Cuttings taken about the end of February or early in March and pinched once or twice will make dwarf compact plants requiring no stakes. The flowers, when the plants are allowed to grow naturally, reflex, but when pinched they grow erect."

— AMONGST the novelties announced for the ensuing year by a Marseilles nurseryman the two following are especially noteworthy—viz., *PELLIONIA RODOCANACHIANA* and *BEGONIA SEMPERFLORENS MASSILIENSIS*. The former is said to be superior to *P. DAVEAUANA*, having larger leaves, covered with a fine brownish down, striped and spotted with white. The Begonia is a hybrid between *B. semperflorens* and *B. Schmidtii*, and appears to be very similar to the hybrid of the same parentage shown by Mr. Smith, gardener to Mrs. Joad, Oakfield, Wimbledon, at the last meeting of the Royal Horticultural Society, under the name of *B. Smithii*. It is of stronger habit than *B. Schmidtii*, but dwarfer than *B. semperflorens*, the stems being of a reddish tinge, and the flowers pure white, of medium size, but very freely produced.

— AMONGST the *CYPRIPEDIUMS* now flowering in Messrs. Veitch's great collection of these plants at Chelsea, *C. selligerum majus* commands attention by the great size of the flower and the extreme vigour of the plant. The dorsal sepal alone is 3 inches in diameter, and its longitudinal markings of ivory white and bronzy brown render it a conspicuous object. The leaves are 2 inches broad and 18 long, dark glossy green, and arching gracefully. This imposing variety is the result of a cross between *C. barbatum* and *C. lævigatum*, and must be increased largely, as assuredly it will be in great demand when its merits become fully

known. The chaste *C. cardinale* is also flowering; the flowers combine the chief characteristics of *C. Sedeni* and *C. Schlimi* in a remarkable manner. It is very chaste. A free and very fine variety now in beauty is *C. calurum*, raised from *C. Sedeni* and *C. longifolium*. It bears a somewhat close resemblance to the former useful variety, but is larger and deeper in colour. The distinct and attractive *C. Fairrieianum* that was recently certificated at South Kensington is still flowering, and there are several blooms of the species, which all who see long to possess—namely, *C. Spicerianum*, with its pure white corona-like upper sepal. In striking contrast is the dark *C. purpureum*, a very dwarf free-flowering species from Hong Kong; while *C. insigne* and its much-improved variety *Maulci* are numerous and effective. With so many valuable additions to this fine genus of plants it is not difficult to have beautiful flowers during every week in the year.

— REFERENCE has been occasionally made during past seasons to the value for decorative purposes of *CHRYSANTHEMUM SÆUR MELANIE*. The merits of this variety for conservatory adornment, and for yielding flowers abundantly for bouquets and vases, is well exemplified by a number of plants now arranged in the great vinery at Chiswick. The collection there is large, but the most useful of all the varieties, for the last-named purpose especially, is the one above named. The flowers are white, small to medium-sized, the petals reflexed, and the blooms and buds borne in the greatest profusion. It may be remarked that the plants at Chiswick were planted out during the summer, and have recently been taken up and placed in round baskets about a foot deep and wide, such as are obtained at a cheap rate from Covent Garden. A few leaves were placed round the sides before filling-in the soil, and the plants appear to be thriving quite as well as if established in pots.

— THE *CHRYSANTHEMUMS* IN THE VICTORIA PARK are now fast approaching their best condition, and intending visitors should take the first opportunity of inspecting them. Mr. McIntyre has an erection about 250 feet long and 9 feet wide devoted to the plants, which are healthy vigorous specimens and flowering profusely. A large number of varieties are represented—Japanese, incurved, reflexed, and Pompons, the last-named forming a margin to the taller varieties; such old favourites as Mrs. G. Rundell, Mrs. Dixon, George Glenny, Dr. Sharpe, and James Salter being very numerous. The tent, or whatever it might be termed, which is reserved for the plants, is evidently unsuited for the purpose, and it is regrettable that a more convenient structure cannot be provided for them, especially as in other public parks and gardens such well-directed liberality has been displayed in this respect. It may be added, for the convenience of visitors, that the exhibition is near the main entrance at the south-west side of the park.

— THE *FINSBURY PARK CHRYSANTHEMUMS* are now extremely fine, the blooms being large, richly coloured, and many up to the exhibition standard in quality. As might be expected they have attracted large numbers of visitors, and will continue to do for several weeks yet. In addition to a good collection of the older varieties several of the most promising novelties are included, especially amongst the Japanese, which are generally of excellent quality. Both Mr. Cochran and his foreman Mr. Marsden have gained a most satisfactory success in their efforts to render this exhibition one of the best of its kind around London.

— THE show of *CHRYSANTHEMUMS* IN THE MIDDLE TEMPLE GARDENS was opened to the public last week and is now in very good condition, the flowers being very abundant. The plants are rather later than those in the Inner Temple, but Mr. Snelling has grown them very well, and his exhibition is improving every year. They are arranged to form a sloping

bank, and the colours being bright they produce a very pleasing effect. It is quite unnecessary to enumerate the varieties, as a large proportion of the best in cultivation are grown, all sections being well represented. Particularly noticeable, however, were some fine examples of White Globe, with James Salter, Mons. Delaux, Striatum, and many others.

— IN addition to the above public displays there are now also very handsome SHOWS OF CHRYSANTHEMUMS AT SLOUGH AND SWANLEY in the nurseries of Mr. C. Turner and Messrs. Cannell & Sons respectively, both firms having a great number of plants in most satisfactory condition. The varieties represented include all the best of the old and new forms, and excellent opportunities are thus afforded for making selections.

— ACCORDING to the *American Cultivator* about \$30,000 worth of COCOA NUTS are annually shipped from Jamaica to the United States. Limes, Pine Apples, and Mangoes are shipped in small quantities. The MANGO is the most common fruit in Jamaica. It was brought there from the East Indies in 1772 by Capt. Marshall of Lord Rodney's squadron, and was first planted in a private garden in Kingston; thence it spread all over the island. It is the popular fruit of the natives, and is for them the mainstay of subsistence during June, July, and August.

— THE *London Gazette* recently published a copy of a decree of the Belgian Government, received by the Board of Trade from the Secretary of State for Foreign Affairs, by which the provisions adopted by the International Convention at Berne with a view of checking the ravages of the PHYLLOXERA are enforced. The importation into and transit through Belgium of Vines and dried cuttings, and also of slips and suckers of Vines from phylloxerated districts, is prohibited, but the latter articles may be imported from non-infected districts, subject to special authorisation from the Minister of the Interior. Market-garden produce, cereals, fruit, and cut flowers may be imported without special formalities; but all other plants, shrubs, and vegetables (not being Vines or parts thereof) can only be admitted by the Custom Houses of Antwerp, Brussels, Ghent, Liège, and Ostend, or, if coming by the land frontier, by any Custom House situated on a railway. The import of such plants is also subject to certain conditions set out in the decree.

— IN reference to BEES ATTACKING GRAPES a correspondent sends the following:—

"It has been thought, not only in this country but in America and on the Continent, that the bee is the enemy of Grapes, and that it destroys not only luscious fruit, but also other sweet pulpy fruits. A very observant correspondent of the 'Scientific American' defends the popular honey-gatherer from the charge. He has watched the little workers for years, and has been loth to believe it. He observed long ago that they never attacked sound Grapes, but when defective or split as the result of a rainy spell they would then suck out the juice. Being unable to convince others of the harmlessness of the insect in any other way, he devised for that purpose the following experiment, which anyone may try for himself. At the mouth of the hives he places several bunches of various varieties of thin-skinned Grapes, and for days, although the bees were constantly crawling over them, not a berry was injured. He then punctured half of the berries on each bunch, and instantly the bees went to work on all so punctured, in a short time sucking them dry. The remainder of the berries were untouched, and remained so until punctured by him, when they in turn were attacked as promptly as the former. This experiment demonstrates that it is necessary for the Grape to have been previously injured, so as to allow exudation of juice, otherwise the bee will not molest it. And when we reflect that the berries thus injured would decay, it will be seen that the bee actually saves to us what would otherwise be lost, by storing it up as honey."

BUCKLAND SWEETWATER GRAPE.

ON page 391 "W. L. H." describes this as a comparatively worthless Grape. My experience leads me to differ from him, although I do not wish to criticise his choice of white Grapes in search of a companion to the Black Hamburgh for an early vinery. It is only reasonable to expect that each would speak well of the

bridge that carries him safely over. As regards colour and size of berry, I fail to see how either the Dutch Sweetwater or Ascot Citronelle can be preferred to Buckland Sweetwater. "W. L. H." also states that when Buckland Sweetwater is most perfect in flavour the fruit is only just beginning to colour, the quality even then being no better than Sweetwater, and at any exhibition on the ground of colour alone it would be discarded by all good judges, it partaking of an objectionable brown tint. In reply to this I have only to refer to the fact that amongst white Grapes, so extensively shown at York, Leeds, and other early spring shows, Buckland Sweetwater is invariably amongst the leading prize-takers, and I have never heard a judge condemn this Grape in point of flavour, size of berry, or "objectionable brown colour." As regards the Vine's fruiting character, I have generally one-half the bunches to cut off to obtain an even crop. As regards Foster's Seedling there remains no doubt of its good qualities. It is a Grape found almost in every establishment, and some gardeners prefer it to Buckland Sweetwater, but as an early Grape I do not. —H. A. M., *St. Vincent's*.

"G. R. A." (page 412), anent my note on Buckland Sweetwater Grape, says that this Grape "realises a higher price in the market than Foster's Seedling." Permit me to say that I did not make any allusion to its value as a market Grape, but regarded it solely from a private gardener's point of view. I have no doubt but that it sells better than Foster's Seedling, but it must be remembered that those who have to grow Grapes for a gentleman's table and growers for market have a very different object in view. The one studies quality, or should do, whilst the other, generally speaking, gives the preference to appearance and size of fruit in particular.

With regard to Golden Queen, I may state that this is not an early Grape, as some might infer from "G. R. A.'s" note, it being at least six weeks longer in ripening than the Black Hamburgh; and my note was penned with a view of eliciting opinions as to the best white companion to the Black Hamburgh other than, from my point of view, the unsatisfactory Buckland Sweetwater. —W. L. H.

HECKFIELD PLACE.

AT Heckfield there reside two celebrities—one a giant in the parliamentary world, a veteran in the service of his country, which he has served well through successive generations. This is the noble owner—Viscount Eversley, once known as Charles Shaw Lefevre, Esq., who occupied the responsible position of Speaker of the House of Commons sufficiently long to entitle him to the possession of three Speaker's chairs, which now comprise part of the furniture of the mansion, and destined without doubt to become historical, for the value of such trophies cannot but increase with age, and be prized by future generations of the family in possession of them. The other celebrity is his lordship's gardener, Mr. Wildsmith, one of the most able, active, persevering, and successful workers of the day in the ancient industry of horticulture. But Lord Eversley is a gardener too, his technical knowledge being great, his taste admittedly good, and the interest which he takes in his garden and grounds, their improvement and adornment, active and real. When we thus find master and man alike capable and earnest, both devoted to the same object, and working together in unity, the former honoured and the latter trusted, we expect also to find something worth seeing, and hence recording; and much that is noteworthy was certainly seen at Heckfield in September.

My acquaintance with the products of Heckfield was, until six weeks ago, limited to the examples at public exhibitions. Both in London and the provinces an exclamation that is familiar to many has often greeted my ears—"What! Wildsmith first again! he is determined to be in." Yes, but skill must be added to energy to enable a competitor in the fruit classes at a Royal Botanic show to secure the splendid prize offered by the Fruiterers' Company to the premier exhibitor when a Coleman is in the field. This is one of Mr. Wildsmith's many honours, and perhaps the most prized, that he has succeeded in winning in some of the leading contests. Let us now look at his work at home; but first at the scene of his labours.

Heckfield is situated in one of the most picturesque and salubrious districts of Hampshire, and is about five miles from Winchester station on the South-Western Railway. The mansion stands on a knoll or spur in a well-wooded and beautifully undulated park. The pleasure grounds are agreeably diversified with grand deciduous trees, handsome Conifers, luxuriant evergreens, excellent walks, charming lakes, and splendid lawns. The terrace flower garden, while not being one of the largest, is without question one of the most beautiful and best kept of its kind in the kingdom; the kitchen garden one of the most productive; and the glass department not

only famed for superior fruit, but for the unusual, if not unique, feature of "Vines growing on their heads." The site is somewhat elevated, the soil light yet fertile, and the rainfall low, conditions which will probably account in a great measure for the wonderful crops of Pears with which nearly every tree in the garden was loaded. Such is Heckfield in outline. Let us now try to fill in the picture, commencing with the

FLOWER GARDEN AND PLEASURE GROUNDS.

Fortunately we have the aid, in such a case indispensable, of the artist's skill to show what no pen could adequately portray—the characteristic beauty of the flower beds at our feet, and the splendid near and distant view before us. We will first ascend the terrace, and then take our standpoint where the artist took his, and see how the garden verges into the park, and the park is lost in the far-off range of hills which bound the horizon. The terrace is formed along the east and north sides of the mansion, and is probably about 100 yards long by 20 wide, supported by an ornamentally built wall, the side facing the grounds being partially masked with evergreens. The approach is by a short flight of steps at the south-east corner, and near the foot of the steps on the lawn stand two grand sentinels, natives of another clime than ours, yet evidently acclimatised, healthy, and happy—namely, a remarkable pair of *Chamaerops Fortunei*, planted in 1869, and now grand specimens, with massive trunks and noble heads, which would afford shelter to a good many Wildsmiths if they could but stand still. The plants, or trees, have had no protection afforded them since the first winter after they were planted, but they are supported with fresh soil annually, the turf being removed for that purpose and laid down again. It is to this care that must be attributed the large, handsome, glossy leaves. They are well matched in every respect, as they are not only of the same size but of different genders, and are the parents of many plants that have been raised from them since they were established in their positions. It is doubtful if the same can be said of any others in the same latitude in this country, and thus these Chinese visitors may fairly be said to have taken up their nationality at Heckfield. To the left of them is a sort of shrub-clad rockery, on which the beautiful Conifers *Cupressus Lawsoniana argentea* and *C. L. erecta viridis* show to great advantage, the Rose of Sharon, or St. John's Wort (*Hypericum calycinum*), forming a pleasing groundwork, and contrasting effectively with the darker evergreens. Elevations such as this are precisely adapted for small choice Conifers, including the elegant *Retinosporas*, of which there are so many distinct forms, and the suggestions afforded by such examples as this should not be lost. But we pass onwards and reach the terrace.

The broad walk is close to the mansion, with the lawn and flower beds slightly below us on the right. The walk terminates in an alcove or fernery, that is often used as a breakfast room in summer, and delightful it must be when the slanting rays of the morning's sun flit and dance among the Palm leaves and Fern fronds. At this end the terrace is bounded by a hedge of the Nootka Sound Cypress (*Thujaopsis nutkaensis*, syn. *T. borealis*), which extends westwards for a considerable distance, and forms a fine screen separating the kitchen garden from the pleasure grounds.

We will now stand where the artist stood, near the centre of the north terrace, and look around. On the left is the terminal Cypress screen just referred to, and its background of Limes. As will be seen in the engraving (p. 433) the centre of the lawn is occupied with large baskets of flowers. These are made of terra cotta, are oval in form, and of chaste design. The two larger are about 14 feet long, the four smaller 8 feet, and all of them about 2 feet high. They were filled chiefly with the intensely bright double Cactus Dahlia *Juaresii*, and the rich single variety Paragon, not formally staked, but each plant affording support to the other, the whole forming a great tangled mass of flowers. These were relieved by groups of white and golden *Marguerites*, *Heliotropes*, &c., with *Tropæolums* scrambling among them and falling over the sides here and there, as if escaping from an overlaid receptacle. The plants appear to have been inserted, and then as regards their outline left to take their chance. Their growth has been a floral struggle as if to represent the survival of the fittest; and the freedom, almost wildness, of the arrangement was not only pleasing in itself, but by force of contrast the trim and highly finished compact beds were shown to great advantage. It is not easy to imagine how a terrace of this kind could be rendered more effective. If the whole of the beds were carpeted the effect would be heavy and too severely formal; while if they were all planted like the baskets, and especially if they were filled with hardy border plants, they would be quite out of harmony with the site and surroundings.

The round beds in the design are carpet beds pure and simple—that is to say, contain no flowers. A *Cordylone*, variegated *Yucca*, or *Phormium* occupies the centre, which is cushioned with *Sedum*

glaucum and belted with *Echeverias*, then a raised star of *Sedum*, similarly banded with rays of *Alternantheras*, resting on a groundwork of *Herniaria glabra*, the centre of the crescent-shaped segments containing a plant of the silvery *Chamaepeuce diacantha*. This is only a typical method of planting, as any attempt at accuracy is not called for where the designs vary from year to year. The oblong beds have flowers in the centre, with a carpeted margin 30 inches wide, the groundwork being *Herniaria*, the bands *Veronica incana*, and the designs in character with the round beds. Thus the central flowers balance with the baskets, while the margins are in keeping with the carpet beds. The general effect of the terrace is bright yet chaste, and altogether excellent.

The east terrace is somewhat different, some of the beds surrounding the central groups being barred with such plants as *Ageratum Cupid*, *Pelargonium Manglesii*, *Gazania*, &c., with smaller beds near the walk carpeted, some of the panels in the *Herniaria* being outlined with Golden Feather, very small, mere streaks of yellow, while the back beds next the terrace wall were mostly occupied with single Dahlias. It should be stated that all the beds are raised above the surface 3 or 4 inches, and covered with *Herniaria*; the margins, however, not sloped in the usual manner, but perpendicular, like squarely-cut Box edging, and so smooth and accurate is the work done that the beds appear as if placed on the grass. Between them on this terrace are small specimen Conifers on the lawn, such as *Retinosporas*, and the beds in winter are filled with these, Golden Yews, and variegated evergreens in place of the tender plants removed, the groundwork and belting, consisting mostly of hardy plants, remaining untouched. Thus this terrace, while strikingly beautiful in summer, is agreeably furnished in the winter with comparatively little expenditure in material or labour.

Of its kind this is a model garden both in design and execution. Surpassed by none and equalled by few, both the noble owner and his gardener have great reason to be proud of it, while the public during one week in the year have a great treat generously provided; and although distant from any large town, two thousand persons availed themselves of the privilege of inspecting it during the open week of the present season. This plan of giving a whole week to the public is found more convenient to all than having visitors during one or two days of each week over a period of two or three months.

The view from the windows of the mansion across the terrace to the pleasure grounds and scenery beyond is extremely beautiful. From the flat roof of the house, where a tent is erected and tea had almost daily in the summer, it is grandly picturesque, the whole district far as the eye can reach resembling a magnificent park. In the foreground are boldly swelling hills smooth as velvet, some 20 or 30 acres being regularly machined, and not a "bent" to be seen to mar the effect of these splendid lawns. The valley conducts the eye to the distant lakes, with the island of *Rhododendrons* in one, and a handsome bright green cone-like specimen of the Deciduous Cypress (*Taxodium distichum*) at the head of the other, and all around grand specimens of Oak and Beech, which cast their shadows, clear and strongly defined, on the closely shaven grass.

On our way to the lake we traverse the pleasure grounds to the right of the engraving, and here we find many handsome Conifers—*Abies Douglasii* 100 feet high, a magnificent specimen of perfect shape, and of that rich dark green colour which is characteristic of this fine Fir when in its best condition, with dozens of younger specimens 20 to 30 feet high planted by Mr. Wildsmith not more than a dozen years ago. Also *A. cephalonica*, *A. nobilis*, *A. Nordmanniana*, *A. magnifica*, and *A. grandis* from 30 to 80 feet high; the graceful *A. Albertiana* and *A. canadensis*, many Cedars of Lebanon, Deodars, fine *Araucarias* and *Cryptomerias* in excellent health and colour, and a splendid bush of *Pinus insignis* distinct by its own peculiar soft yet verdant green. Captivated by the handsome appearance of this Pine an experienced gardener practising in the south of England recently strongly urged that it should be more generally planted. Unfortunately it is too tender for our climate "generally," and the greater part of the country has been practically denuded of specimens by the severity of the frost, and the fact should not pass unrecorded. Passing the imposing specimens mentioned, the walk conducts into a wood remarkable for splendid Larches, Fern dells, and pheasants. Turning to the left the junction of the two lakes is reached—a charming spot. A winding walk has been cut through masses of *Rhododendrons*, and we find an alcove here, a seat there, a secluded nook on one hand, a rockery on the other, all attractively furnished, and in a sheltered depression a subtropical garden filled with elegant plants growing luxuriantly, and relieved with handsome specimen *Cupressuses* and *Retinosporas* on the lawn. *R. plumosa aurea*, *R. obtusa aurea*, and *R. alba nana*, with *Thujaopsis dolabrata variegata*, range from 7 to 9 feet high, and must be included amongst the choicest, hardiest,

and most elegant Conifers in cultivation. From here the walk curves and passes an old vinery—the Vines sixty years old and bearing good Grapes, a rosery in front, splendid Conifers and handsome standard Portugal Laurels with heads 20 to 30 feet in circumference—and enters the kitchen garden on the left of the engraving through the Cypress screen previously mentioned, and the end of which is seen near the flower garden.

THE KITCHEN GARDEN.

This is ornamental as well as useful. The central walk is bounded by hedges of Cupressus Lawsoniana, with borders about 5 feet wide in front of them attractively planted. At the back next the hedge the Cactus and Paragon Dahlias were planted alternately a few yards apart, with Golden Marguerites between them. A splendid row in front of Sedum spectabile very rich in colour, the front of them being carpeted with Herniaria, in which were small round and oblong panels a yard apart, containing alternately neat examples of Cupressus Lawsoniana erecta viridis and Retinospora plumosa aurea in the oblongs, and Chamæpuce diacantha in the round beds, the latter having a groundwork of Alternantheras, and the former of Silver Thyme and Sedum glaucum. The cross walk is arched over with Pears at intervals of 4 or 5 feet, and every arch was wreathed with fine fruit, the whole viewed from the end resembling a tunnel of Pears. The pyramids and bushes in the borders were equally laden, as also were the cordon, fan, and horizontally trained trees on the walls. My gardening tours have extended over some two thousand miles this year, but I saw more Pears at Heckfield than in all other gardens put together that I had the pleasure of visiting. One large tree of Pitmaston Duchess on a wall was the pride of the garden, the huge clear fruits hanging in the greatest regularity about a foot apart, indicating first that the fruit had been carefully thinned and then well supported. The crops of Peaches and Apricots on walls were similarly good, and the trees in the most healthy condition. Great attention is evidently paid to hardy fruits, and to this in conjunction with climatic advantages must be attributed the remarkable crops referred to.

The soil, as before mentioned, being light, and district dry, deep trenching after every crop is resorted to in the vegetable department. A fine breadth of the Reading Exhibition Brussels Sprouts, unquestionably one of the best strains of modern selection, showed the efficacy of the practice, as equally did the large handsome Onions, a selection from the Improved Reading; Mr. Wildsmith having thus undertaken the high task of improving the "improved." In fact he seems to be animated with the desire to improve everything, and has had quite a fair share of success.

GLASS DEPARTMENT.

Apart from a range of vineries and Peach houses of considerable dimensions the glass structures are not large, but they are numerous. Small span-roof houses, half-spans, and lean-to pits have been packed together wherever there was a little space to be covered in the enclosure—useful structures turned to excellent account. There are pineries filled with sturdy, healthy, vigorous plants, Melon and Cucumber houses, a Fig house, Strawberry house, forcing and plant pits, one containing Gardenias in pots plunged over their rims in leaves and growing like Laurels. The Strawberries in pots were excellent, Vicomtesse Hericart de Thury and President chiefly—the former for ripening in February, the latter for succession. But space diminishes, and we must pass much that is worthy of note; but cannot pass the Vines in silence.

There are eight vineries. Mr. Wildsmith has a fancy for having the roots of Vines either wholly in inside or entirely in outside borders. That the plan answers well the results testify; but it is not improbable that equally good crops of Grapes would be had under what may be termed the mixed border system. No one will be surprised to hear that Muscat Vines in an inside border were in every way superior—full heavy well-shaped bunches, and large and highly finished berries. But it is not everywhere that first-class Black Hamburgs can be ripened in April with the roots of the Vines entirely outside and no fermenting materials placed on the border. But such Grapes are produced under these conditions here. In a mixed house Mrs. Pearson and Golden Queen were admirably represented by large bunches and fine clear berries, while Gros Colman and Alicante were of exhibition quality. In a house of young Vines, inside border, Alnwick Seedling is succeeding so well that the Vine is being managed on the extension system. The crop is extremely heavy, the large fully set bunches being numerous, and berries fine in size and finish.

The Vines in two other houses demand special notice—in one case because they have been raised in a manner that is not usual, and in the other because they are, mountebank fashion, "standing

on their heads." First as to the young Vines. The eyes were inserted in curves in the spring of the present year, started, placed in the borders (inside) at once, and covered with bellglasses. The canes are now in the most satisfactory condition, stout, strong, well-matured, and ready for bearing an excellent crop next season. In fact, some of them have produced bunches already, one or two of which were allowed to remain. This is certainly not a common occurrence, and must be taken as a satisfactory index of the state of Vines only about nine months after the eyes were inserted, and good augury of future work.

And now we come to the topsy-turvy, or mountebank Vines. A lean-to house facing south was planted in 1869 with Lady Downe's and Mrs. Pinck alternately. The latter, as being least satisfactory, were eventually removed, and an additional rod taken from the former. The crops were excellent, and the lean-to was converted into a span-roof, the rods being trained down the new roof facing north. When they reached the base of the rafters it occurred to the cultivator to take them a little lower, even to the earth. There they rooted freely, so that each Vine had three sets of roots, and in that state the Vines produced splendid crops for some years. "But in that form they cannot be said to be wrong end upwards," some may observe. True, but the case is proveable. During the past winter it was determined to clear half of the roof of one side of the house, make a new border, and plant young Vines. The south side was naturally preferred, but it was on this side that the original Vines were planted; yet notwithstanding, the rods were sawn asunder under the apex of the roof, and the old Vines cleared out, leaving the rods on the other side that had rooted at their extremities to take their chance. This proved a very good one, for the crop of Grapes on them, curious as they look with their thick ends at the top of the house, is excellent, quite as good as those at the other end that have yet each three sets of roots. It is a regular, useful, and good crop, such as hundreds of persons would be glad to possess. On the side cleared eyes were inserted in the border as above described, and now the roof is covered with fine young canes. There is no doubt whatever that the topsy-turvy Vines are precisely as stated, and they have not declined in vigour in the slightest degree by the ruthless treatment to which they have been subjected.

And now we leave Heckfield. I have seen many beautiful scenes on the fair face of Nature, but this is certainly one of the fairest and the brightest. It is cherished, too, by its noble owner, who has spent nearly ninety summers in its shady woods and verdant slopes. His eye still bright, taste keen, and mind as clear as ever, he is the trusted adviser of the great, while he lives in the hearts of those by whom he is surrounded. His kindness to his gardener during the long illness following his sad accident of a year ago, and from which he has not yet recovered, it is pleasant to record, and pleasant also to note the devoted attachment of the gardener towards his excellent master. Here is the secret of the high condition of the place—mutual trust. Good taste in arrangement, economy in management, excellence of culture, and extreme neatness are here found. Long may they remain, and may he who has worked to such good purpose have as a reward the great blessing of restored health.—J. WRIGHT.

THE DURDHAM DOWNS NURSERY, BRISTOL.

FOR many years Messrs. J. Garraway & Co.'s establishment at Bristol has held a deservedly high position amongst the nurseries of the west of England, and under judicious management its prestige is not only being satisfactorily maintained but also considerably increased. The Durdham Downs Nursery may claim a position amongst the historic trade establishments of this country, for during the greater portion of the present century it has been devoted to the cultivation of plants, and in its earlier days to the extensive growth of indoor fruits. Like many others in the suburbs of populous towns, it is now, however, being fast surrounded by houses, and in the course of a few years little except the ground occupied by the glass erections will remain of the original nursery, which is even now much less in dimensions than it was in its youth. This is chiefly due to the site being one of the finest in the immediate neighbourhood of Bristol, greatly elevated above the busy, smoky, and uninviting town; moreover, in proximity to a fine expanse of common-like land, and the picturesque Clifton district, the salubrity of which has attracted all the wealthy Bristolians. In consequence, Messrs. Garraway & Co. have found it necessary to take another nursery at a greater distance from the town, and the traveller cannot now fail to notice near the railway, about half way between Bristol and beautiful Bath, a considerable extent of land occupied with fruit trees, Roses, with abundance of hardy evergreen and deciduous shrubs and trees, all appearing exceedingly healthy and vigorous, as they should be in so fine a climate. Thence are drawn the supplies for executing the firm's numerous large orders for hardy plants and trees, and more satisfactory samples could scarcely be desired, particularly the fruit trees

and Roses, which form special features, as the old nursery has secured a well-deserved renown in these departments.

Returning to what is still the headquarters, the principal characteristics of the indoor stock may be briefly referred to. It should be observed that in this branch of the business all the best stove and greenhouse plants receive a large share of attention, the collection being select in the strictest sense of the word, as the space at command is necessarily limited; and although the houses are numerous, and several of good dimensions, with frames and other conveniences, all are well filled, and it is not easy to find accommodation for the large stock which has to be annually provided. One of the chief features at the time of my visit, early in September, were the Tuberous Begonias, which, to meet the rapidly increasing demand, are grown in very large numbers. Most of the best-named forms are included, but by careful crossing and selection a meritorious strain has been obtained, which is of such general excellence that it is not considered necessary to name individual variations, but to supply either seed or tubers as purchasers may require. The plants were of good compact habit, and distinguished by remarkable floriferousness; and though the blooms were slightly smaller than some of the recently raised varieties, the colour (various shades of scarlet), was remarkable for its brilliancy, the sturdy habit and abundant flowers far more than

compensating for the slight deficiency in size. It is a regrettable fact, indeed, that too many of the large-flowered varieties are shy bloomers, and for decorative purposes they cannot be compared with the smaller but freer sorts. Besides the scarlets, there is a race of the yellow-flowered Pearcei type. A dwarf race of the Davisi and Veitchii types, with representatives of several other species, are also grown in large quantities, and were extremely beautiful. *B. Frœbeli*, so very distinct from the others, is a rather attractive plant with its large rough woolly leaves and round scarlet flowers, and it is rarely seen in such good condition as it is at the Durham Down Nursery. The useful *B. semperflorens*, with its rosy-tinted variety, is grown by the thousand, and certainly the two plants are almost invaluable for winter decoration, not only on account of their freely-produced white and rosy flowers, but because the foliage is of such a fresh, shining, bright green colour—in itself a great recommendation.

Florists' flowers constitute an important feature at this nursery, all the popular kinds being largely and well grown. The firm is much noted for their Balsams, and, judging by the plants in some of the houses, their fame is well merited. Three self colours are particularly good—viz., purple, scarlet, and white, all pure; the purple rich, the scarlet brilliant, and the white clear. The flowers, too, are very large, full, of good form, and abundant. Striped, mottled, and other parti-

Fig. 72.—HECKFIELD PLACE—THE FLOWER GARDEN AND PLEASURE GROUNDS. (See page 431.)

coloured forms are similarly fine; but the greatest praise must be accorded to the three first, which scarcely admit of improvement. Well-grown Balsams are always admired, and they prove most welcome additions to any conservatory in the summer months. A very large per-centage of the seed yields plants with double flowers, and this is attributed in part to keeping the seed a year or slightly longer before sowing it, a practice which is adopted by many others with the same view; but whether it has a substantial foundation is not quite certain, though results I have myself obtained seem to point to that conclusion.

Pelargoniums of the Zonal and Noscgay types were in grand condition, the collection including the finest old and new varieties, a houseful in full bloom rivalling the Begonias in effectiveness. Viewed in contrast like this, the difference between the scarlet shades of the Pelargoniums and those of the Begonias was very surprising—a difference that can be scarcely expressed by words, though as regards brilliancy a verdict would have been given unanimously in favour of the first-named. It is unnecessary to give a list of the varieties, as they were so numerous, and each possessed some special merit to commend it. Of other softwooded flowering plants Primulas were advancing fast and giving promise of a fine display later in the

season, while due provision had been made for Cinerarias, Calceolarias, and Cyclamens.

In the warmer houses Palms, Ferns, and miscellaneous fine-foliage plants occupy much space, healthy specimens of various sizes. Gardenias, those indispensable plants wherever fragrant white flowers are valued, are evidently very carefully treated, for it is seldom that such healthy specimens are seen. With Gardenias as with other plants it is highly important to make a good start; and unless vigorous plants are obtained that have been grown robustly without a check it is extremely difficult to ensure successful results, and nurserymen who give particular attention to the culture of such plants in their early stages render the gardener's task much more easy. Bouvardias, Stephanotis, and in cooler houses Lapagerias red and white, are similarly largely and well grown; while amongst the novelties the graceful *Gymnogramma scbizophylla*, the double Bouvardia, and *Gynura aurantiaca* with its peculiar purplish velvety leaves, were being fast increased to meet the demands for them.

The borders outside were occupied with choice collections of hardy plants, amongst which Delphiniums, Phloxes, and Sweet Williams were prominently noteworthy, the varieties and strains of these plants being remarkably good. Annuals, too, are extensively grown,

some very handsome Mimulus attracting much attention ; while that widely famed Mignonette, Garraway's White, which holds so high a position in popular favour, was represented by an admirable sample. It should be added that every department, though only briefly noted here, indicates most careful superintendence, while the preparations being made at the time of my visit for the autumn seed and bulb trade prove them to be important branches in the business of the firm.—SAXON.

KITCHEN GARDEN.

WHEN the haulm of Asparagus is decayed cut and remove it, giving a good dressing of well-decomposed manure, and point it in, avoiding covering the crowns too deeply with fresh soil, for when that is done they are seriously injured, the roots not unfrequently perishing. The decayed leaves of Seakale may also be removed, and the crowns covered with spent tan, cocoa-nut fibre refuse, or ashes ; but when this is grown for forcing under cover it is better to take up the roots at once and lay them in a sheltered place, covering only the crowns of that to be forced or blanched outdoors. Globe Artichokes having been cleared of decayed leaves have the growth hardened, and should be protected before severe weather, ashes being very suitable, the soil being removed from the stools, and the space filled with ashes brought well up about the crowns. The ashes are not only a good protection against frost, but help to check the slugs. Fill any vacancies in plantations of Cabbages and Lettuces, keeping them free from weeds, and the soil stirred in favourable weather around the plants. Similar remarks apply to Winter Spinach and Onions. All decayed leaves should be removed from Brussels Sprouts, Winter Greens, and Broccoli, so as to admit light and air, and thereby harden them against frost. Where Broccoli are very vigorous and long in the stem the plants should be laid down with the heads inclined to the north, and the stems up to the leaves covered with soil. This, from checking the growth, will enable them to withstand severe weather.

Forcing Department.—Where Potatoes are required early a first planting may now be made, the sets being placed to sprout in boxes of leaf soil in a house with a temperature of 55° to 65°. For their reception a hotbed should be formed in a pit to which artificial heat can be applied in severe weather to maintain a temperature of 60°, and permit ventilation when external conditions are favourable without depressing the temperature, but allowing an advance with free ventilation to 70° or 75°. Two or three parts leaves to one of stable litter are suitable materials for forming the bed, if well incorporated and turned over occasionally, and damped if necessary. This should be put in firmly, so that when settled down it will be about 18 inches from the glass. Six inches depth of light rich soil being placed in, the sets should be introduced when the soil is warmed through and they have grown a couple of inches, being careful to preserve their roots and the sprouts, planting about 4 inches deep. Early Bird and Veitch's Ashleaf are fine kidney varieties, and Coldstream or Smith's Early Selected a good round sort. Plant in rows 15 inches apart and 1 foot asunder. Failing an artificially heated pit a hotbed may be made of the materials above indicated to a height of about 3 feet, well beaten together, covered with a frame, 6 inches of soil being placed in, and when warmed through sets inserted at the depth and distance above stated, taking care that the heat does not exceed 70° to 75°. If desired Early Forcing White and Scarlet Turnip Radishes may be sown in the same bed, in which case the lights should be withdrawn except when frost prevails until the Radishes have formed their second leaves, when their growth may be accelerated, but ventilating freely on all favourable occasions, protecting with mats over the lights in severe weather, and applying linings to the sides of the bed to maintain the heat.

Beds about 2 feet in height well beaten down will be suitable for Radishes ; tree leaves, with a portion of stable litter to bind the

material together, afford a suitable heat. Four inches of light rich soil is ample, and, the seed being sown and covered, the lights may be put on until the seed leaves are appearing through the soil, when the lights must be withdrawn whenever the weather is mild, continuing this until the rough leaves appear, when their growth may be forwarded more rapidly with due attention to free ventilation. Early Forcing White and Scarlet Turnip are admirable varieties, and so are French Breakfast and Wood's Frame. In the same frame with the Radishes Carrot seed may be sown in alternate rows about 4 inches apart, and these will succeed the Radishes. French Forcing is the best very early variety. French Beans must be sown in pots at intervals of a fortnight or three weeks according to the demand, earthing up those advanced, and keeping them as near the glass as practicable. Supply those advanced for flowering and podding with weak tepid liquid manure, giving them a temperature of 60° to 65°, advancing to 70° or 75° with sun heat.

A few roots of Rhubarb may be placed in the Mushroom house or other suitable house, a temperature of from 55° to 65° being necessary. Seakale with well-developed early-ripened crowns should likewise be placed in the Mushroom house, but light must be excluded so as to insure blanching ; light moist soil is necessary, just covering the crowns. Water should not be given until growth commences. For the successful forcing of Asparagus a bed of leaves and dung is necessary, mixed and turned occasionally so as to secure a mild heat. If required early a bed may now be made, and when the heat does not exceed 75° a couple of inches depth of soil being placed on the bed, the roots introduced, and soil worked in amongst them level with the crowns, the crowns—*i.e.*, the whole surface of the bed, covered with about 3 inches thickness of light sifted soil or spent tan. Unless the demand be absolute there is nothing gained by the very early forcing of this vegetable, which to be full-flavoured requires free ventilation after the heads appear.

FRUIT HOUSES.

Peaches and Nectarines.—Where ripe fruit is required early in May, and of the very early kinds in April, and the trees in the earliest house having been dressed with an insecticide, the branches secured to the trellis, the borders surface-dressed, and the house thoroughly cleansed and repaired as advised in former calendars, the house may now be closed ; but air must be given freely when the temperature in the house exceeds 50°, and artificial heat must only be resorted to when needed to exclude frost, for the slower the trees are started the stronger will be the blossom and the greater the probability of a good set. The inside border should be given a good watering at 70° to 75°, repeating if necessary to bring the soil into a thoroughly moist state. In the case of weakly trees tepid liquid manure will assist them considerably in swelling the buds and blossoms. Damp the trees and available surfaces in the house twice daily in bright weather, but it is necessary to syringe early in the afternoon so as to have the trees dry before night. If fermenting materials are at hand a sufficient quantity of three parts Oak or Beech leaves and one part stable litter should be thrown into a heap and incorporated, damped if necessary, and after being turned twice these may be employed for making up a bed inside the house a couple of feet in height, and being turned over occasionally and fresh material added, a genial condition of the atmosphere will be secured, highly favourable to the swelling of the buds and expanding blossoms, also lessening the need of fire heat. The outside border must be well protected with litter or dry fern ; and if shutters or tarpaulin be put on the top it will not only throw off heavy rains and snow, but prevent the materials being blown about.

As the trees in succession houses cast their leaves they should be pruned and dressed, the house thoroughly cleansed, and the borders surface-dressed. If summer-pruning has been properly attended to there will be little need for the knife—indeed, we have not used the knife for some years when the trees are leafless to trees under glass, as they ripen and are furnished with fruit buds on shoots of several feet in length to their points. Beyond thinning the growths where too crowded, and any weakly old wood, for the encouragement of stouter growth, pruning Peaches and Nectarines when leafless is fast becoming obsolete. The exposure of the trees is highly bene-

ficial, and should be practised annually when the roof lights are moveable to secure the thorough moistening of the borders by the autumn rains, perfect rest for the trees, and the cleansing of them from insect pests. Where the lights are not moveable admit air both top and bottom to the fullest extent, and be careful not to allow the soil of inside borders to become dry.

THE BEE-KEEPER.

THE ART OF BEE-KEEPING.

INTRODUCTION.

WE may safely assume that no apology is required for the issue of a new series of papers on the art of bee-keeping, seeing that in principles and practice it has of late made such astonishing progress that works on the subject are considered behind the times, though only a few years old. The advances in the art since the introduction of the moveable-comb hive by the late Mr. Woodbury in England and the Rev. L. L. Langstroth in America, with the succeeding inventions of the honey-extractor, comb foundations, and sectional supers, mark the last quarter of a century as an era of revolution in bee-keeping; and signs are not wanting to indicate that we have now at length reached a stage of practical unanimity and fixity of opinion as to the main principles of the art. To embody these principles in a succinct form, and to indicate the methods employed by the most successful of modern bee-keepers, will be the aim of these papers.

Bee-keeping has for thousands of years been one of the most attractive of rural arts. Poets have sung its praises and philosophers have studied its mysteries for many ages. To this day many are attracted to it more for the pleasure it affords, and the marvellous exhibitions of animal instinct it yields, than for the profit it undoubtedly gives to those who know how to turn these instincts to account. It is an art that lies within the reach of all who delight in rural employments and recreations, from the student of physiology to the plodding country cottager. It has been successfully practised by delicate women as well as by robust men. It has absorbed the attentions of many whom it has attracted from listless apathy or misspent time and talents, and it has been a source of increased comfort in the circumstances of many whose great concern is how to get "ends to meet."

We do not, however, urge the universal adoption of bee-keeping as a sure and easy road to wealth; for, being an art that requires perhaps more than the usual application of intelligence and industry, it will be readily understood that it numbers among its practisers the successful and the unsuccessful, the latter of whom are perhaps oftenest heard of. What we do urge is that all who have a suitable situation for a few hives, with the necessary habits of industry and attention and a little time to spare, should make a fair trial of the pursuit; and what we do promise to all who enter the pursuit with spirit is that they will find attractions to fascinate, make discoveries that will cause wonder, have their habits of observation cultivated and quickened, find scope for invention, ingenuity, and fertility of resource; and all these combined with the material gain that adds to the attractions of the table and the weight of the pocket.

HISTORY OF THE ART.

Our limits forbid us to do more than state the fact that the ancients are known to have kept bees in a domesticated state more than two thousand years ago, and that probably much in the same fashion as is common in eastern countries to this day. Hives were made out of hollowed logs, or, where timber was scarce, of cylinders of clay or of wickerwork plastered with clay. Such hives are still used in the East, where it never has been the practice to kill the bees in order to get their honey. These logs or cylinders are placed in a horizontal position, and the honey taken at certain seasons from the end most distant from the entrance. The natural tendency of bees to store their surplus at a distance from the entrance is thus taken advantage of. In the Russian log hives another advance is made, based on the tendency of the bees to store above as well as beyond the brood nest. The hives are raised a little at the back, and thus the certainty of finding virgin comb at the further end is increased. There is evidence in ancient chronicles and among the laws of our Anglo-Saxon forefathers that bees were at one time altogether wild in this country. Previous to the eighth century they were classed with foxes and others as incapable of private ownership. Whoever found them in the woods was entitled to their honey and wax. The honey was highly esteemed as an article of food, and was largely

used in brewing mead and in medicine. The wax was in great demand by the clergy, who taught that bees had been sent from heaven because the mass could not be celebrated without wax, and under their influence they were gradually domesticated, being kept in hollow logs or hives of bark (Lat., *Rusca*). Hence a hive of bees was called a "rusca" of bees, a word surviving to this day as a name for a straw skep. As bees now came to be looked on as property, the law recognised the right to a wild swarm as belonging to the person on whose land it had settled for three consecutive nights. If he failed to discover it within that time the finder had a right to 4*d.*, and if that sum were not paid he might claim the swarm. At that time a rusca of domesticated bees was valued at 24*d.*

Under the stimulus of a demand for honey and wax we find great lords, about the middle of the tenth century, having *beo ceorls* specially detached to attend on the bees, and the slaves gradually becoming serfs who paid their feudal lord a fixed amount of the produce of their hives. About this time also the name "rusca" often gives place to the Anglo-Saxon word *beo cist* (bee chest), or the Latin word *alvearia*, which marks an advance from mere shells of bark to more regular hives. Domesday Book mentions them repeatedly, and they were even tithed as valuable property.

Comparatively little progress was made in bee-keeping until the close of the last century, when the discoveries of Francis Huber afforded the ground for a great advance. Previous to this, the natural history of the bees, and especially of the queen, was very imperfectly understood. Huber was the first to announce the true nature of the three classes of bees found in a hive—the queen, workers, and drones. The German Shiraeh and the Scottish Bonner discovered the method of causing bees to rear queens at pleasure. At a later date Dr. Dzierzon and Baron Berlepsch established the fact of the parthenogenesis of queens—that is, of the power they have of producing male progeny while still in a virgin state. They also proved that queens mate in the open air, and that within from two to twenty or thirty days of their birth. The impetus thus given to bee-keeping was followed, as has already been mentioned, by those welcome mechanical aids, the bar-frame hive, comb foundation, &c., which have brought bee-keeping to the position of a science. This sketch would be imperfect without at least a mention of those agencies of the present time for the diffusion of knowledge in bee matters—viz., bee journals and associations. These are now established in Germany, Italy, France, Switzerland, America, and England. In England nearly every county has its association, and Scotland and Ireland have several, most of these being affiliated with the great central association of British bee-keepers, whose head-quarters are in London. Simultaneously with the establishment of associations have come those interesting and instructive exhibitions of honey and appliances, now the order of the day, by a visit to which a beginner will learn more in an hour than he could formerly have done by reading and practice for a season. As a result of this revival of neglected industry, honey and honeycomb are fast becoming articles of regular commerce, and no difficulty is found of disposing of them at remunerative prices. It is still to be desired that the remnants of the ancient and cruel system of destroying the bees to get their honey should be rooted out of many places where they still prevail. The better way, however, makes such rapid progress, that within a few years the brimstone pit may reasonably be expected to become a thing of the past, and the more cleanly and convenient products of the modern system take the place of the doubtful mixtures of honey, brood, and pollen, so often inseparable under old methods of routine.—WILLIAM RAITT, *Blairgowrie*.

(To be continued.)

BEEES, BEE APPLIANCES, AND HONEY AT THE DAIRY SHOW.

JUDGES' REPORT.

THE unfavourable weather that prevailed in June and July, the two months during which the bee-keeper usually gathers the great bulk of his harvest, has this year told sadly against the supply of honey, so that the classes for sections and honey in jars was not so well filled as on former occasions. The quality, however, was good, and the interest of the public in the bee department generally was remarkable, large numbers visiting this part of the Show every day, and making careful inquiries of the Assistant Secretary, who was daily in attendance.

There was a good competition for the best bar-frame hives not exceeding 15*s.* and 10*s.* 6*d.* in price. The first prize in the former class was awarded to the Standard Reversible Hive, exhibited by Mr. Blake of Dallinghoe, Suffolk, and is certainly cheap at the price. This hive is divided into two compartments. The front compartment contains ten frames of the standard size, which are reversible. There are two moveable sides or dummies. The partition is a fixed frame, 1½ inch thick in the centre, on which is suspended a bar-frame, started with

comb foundation, with a quarter of an inch clear space all round, the queen and drones being excluded by perforated zinc on the inner side. The back compartment contains two suspended crates of sections $4\frac{1}{2}$ by $4\frac{1}{2}$ inches, which are interchangeable, with the standard frames in the front, and also one dummy board. The outer walls of the hive are double, with 1 inch dead air space between. The hive stands on stout legs, is filled with entrance shades and carpet, and there is a spacious roof for supering.

Dr. Benthall's second-prize hive in this class is also worthy of notice. It is intended particularly for obtaining section honey at the sides of, and in the same direction, as the brood combs. The sections are placed in summer in the air space at the sides of the hive, and are enclosed, in accordance with a plan well known in America, by sides moving on hinges. The inner wall of the hive is perforated, the perforations being fitted with zinc, which admits the worker bees only. A shutter is placed against this in winter, and the space filled with chaff. The floorboard and ends of the hive are lined with half-inch linoleum, made specially for the purpose.

In the class for the best hive not exceeding 10s. 6d. in price the silver medal was awarded to Mr. Blake for his British Standard Cottagers' Hive. This hive has a single wall, made of 1-inch deal, and contains ten frames of the British standard size, a roof with ample room for supering, a crate of fourteen 1-lb. sections fitted with entrance slides, two division boards and carpet, together with a floorboard.

The first-prize observatory hive, exhibited by Mr. Gibbons of Hungerford, was an ordinary Standard bar-frame, with a moveable top provided with slits, in which any frame can be lifted up for observation. The moveable top is arranged so that it can be brought just over any frame.

Mr. Neighbour exhibited an extensive and excellent assortment of bee appliances.

All the sections and honey offered for sale were purchased at good prices, and it is evident that there is an opening for a largely increased supply of honey in an attractive and marketable form.

EDWARD BARTRUM,
GEORGE RAYNOR,
JOHN N. HOOKER,
HENRY BLIGH.

ANTS AND BEES.—Sir John Lubbock read an interesting paper on his favourite study, the Habits of Insects, at a recent meeting of the Linnæan Society. He mentioned that he had queen ants which had lived with him since 1874. They are now, therefore, no less than eight years old, and they had eggs last summer as usual. His oldest workers are seven years old. Alluding to the industry of bees, he gave particulars of an experiment by which he ascertained that the wasp for which he had provided honey began work at four o'clock in the morning, and went on without any rest or intermission till a quarter to eight in the evening, during which time she paid Sir John 116 visits.

TRADE CATALOGUES RECEIVED.

Kelway & Son, Langport, Somerset.—*Catalogue of Gladioli.*
George Cooling & Son, Broad Street, Bath.—*Catalogue of Roses, Fruit Trees, and Shrubs.*
William Etherington, Manor House, Swanscombe, Kent.—*List of Chrysanthemums.*

* * All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

The Fruit Manual (*Clivius*).—The new edition of the "Fruit Manual" is now in progress, and is expected to be published next spring. It will be very much enlarged, and consequently the preparation of it involves a great amount of labour.

Heating Greenhouse (*J. C. C.*).—If the house is a lean-to two rows of 4-inch pipes—a flow and return—along the front and across one end will be sufficient. If it is a span-roof the pipes should be taken all round the house. Three-inch pipes would exclude frost, but the larger size would enable a genial temperature to be maintained without hard firing.

Cucumbers (*Vectis*).—We do not think it would be of any use your applying to the grower you name, as he does not sell seed nor is he likely to aid in the distribution of the variety he has selected. Nor is that variety exclusively adapted to the system of culture alluded to. Any prolific variety is suitable—the Cardiff Castle, for instance, raised by Mr. Pettigrew in the gardens of the Marquis of Bute. The raiser would, no doubt, inform you to whom he has supplied seed for distribution.

Epiphyllums (*A. M.*).—The plants may be kept moderately dry at the roots, but not to cause the fleshy stems to shrivel. They may be placed in heat at any time now, and kept moist according to the period when they are required to flower. They are very beautiful when well grown, and may be had in beauty from the present time to Easter if a cool stove is provided for advancing their growth during the winter. A temperature ranging from 45° to 60° is suitable for them throughout the winter.

Gros Colman and White Lady Downe's Grapes (*J. H. W.*).—The former is a strong-growing and productive Grape, with good-sized bunches and very large berries of good quality if grown in a warm house. If you can afford lateral space of 5 feet for the Vine you may include it in your collection. The white Lady Downe's is too uncertain for being included in a small collection. Try a Vine of Alnwick Seedling, and if you can set the fruit (which you will probably succeed in doing) it will give you satisfaction. We will publish your note relative to the destruction of ants, in case any of our readers who may have been successful in extirpating them will state their methods for the benefit of you and others who are annoyed by these troublesome insects.

Nitrate of Soda (*S. Henry*).—As you ask how much nitrate of soda you should use per acre we presume you require it for farm crops. Farmers find about 3 cwt. per acre a sufficient application to Wheat and cereal crops. The best time for applying it is in the spring. If used too liberally, and to crops already full and in good soil, it is apt to induce a too luxuriant growth of straw. If applied to vegetable crops in gardens about 3 ozs. per square yard is sufficient, and may be applied about once or twice during the early season of growth. For using as liquid manure from a quarter to half an ounce to a gallon of water is ample, but should not be used until the pots are filled with roots and the plants require more support than the soil affords them, nor should it be applied to garden or farm crops of any kind at this season of the year.

Carbolic Acid v. Weeds (*Idem*).—Mr. Luckhurst, who has had much experience in destroying weeds in the manner suggested, has stated in our columns that half a pint of the acid diluted with a gallon of water destroys strong weeds of two or three years' growth, and a third less acid to the same quantity of water is sufficiently powerful for small weeds. The water is first placed in a garden can with a fine rose, the acid measured and poured into it. No stirring or further mixing is requisite, but it is immediately poured over the weeds through the rose, care being taken to make the entire surface of the path wet in order to destroy the weeds. A gallon of water with the acid will do 9 square yards of path. This will enable anyone to make a clear computation of the quantity of acid required to do a given area. Care must be taken not to let the acid touch the hands, clothes, or boots. You had better not use the acid for destroying weeds on land that has to be afterwards cropped, as sufficient to kill the weeds would also prevent the growth of the crops you might desire to cultivate.

Grevillea robusta (*Idem*).—You have done right in cutting the plants down in preference to simply removing the leaves; but we have a doubt if either process was necessary. It is not at all unusual for the tops of the plants to appear as if "almost frosted," and we do not think there has been frost in your district severe enough to injure these plants under glass this autumn. They are quite safe where the temperature is not below 40°, but 45° is preferable for keeping the plants healthy.

Cellini Apple (*Disappointed*).—Although you have been as you say "deceived" with this Apple, it is nevertheless a very useful variety. There are very few Apples that succeed alike well in all soils and localities. In one garden we have failed entirely in attempts to grow the Hawthornden, in another it was in every way satisfactory. We know a very large garden where Cellini refuses to grow; but on that account we should not be justified in condemning it, seeing that we are acquainted with a hundred other gardens where it flourishes admirably and bears heavy crops of handsome fruit.

Veronica salicifolia alba (*D. E., Bradford*).—Although this plant has occasionally survived the winter in favourable positions, it cannot be regarded as hardy, and you had better take up such of your plants as you wish to preserve, pot them, and winter in a frost-proof pit or greenhouse. Small bushy plants established in pots are valuable for decorative purpose in the autumn and early winter months, their slender sprays being very elegant both on the plants and cut and arranged in vases.

Climbers for a Conservatory (*Rugby*).—You do not state how many kinds or how many plants are required, nor whether you have a large or a small house, the space at command being of much importance in making a selection, as some very strong-growing kinds, though useful in a large house, would be quite unsuitable for a small one. We can, therefore, only give you an approximate reply, and your choice must be regulated by the dimensions of the house and the number of plants required. The following are six strong-growing sorts:—*Tacsonia Van-Volxemi*, *Bougainvillea glabra*, *Passiflora recemosa carulea*, *Lonicera sempervirens*, *Cobæa scandens*, and *Bignonia speciosa*. The following are good climbers of moderate growth, the six first being the dwarfest or slowest growing:—*Lapageria rosea* and *alba*, *Hardenbergia monophylla*, *Swainsonia Osborni*, *Rhodochiton volubile*, *Solanum jasminoides*, *Mandevilla suavcolens*, *Plumbago capensis*, *Rhynchospermum jasminoides*, *Jasminum grandiflorum*, *Kennedyia Marryatta*, *Habrothammus elegans*, *Cestrum aurantiacum*, *Tecoma capensis*, with the following added if the above are not sufficient:—*Bomarea Carderi*, *Sollya heterophylla*, *Hibbertia dentata*, *Clematis indivisa lobata*, *Berberidopsis corallina*, and *Akebia quiuata*. For growing in pots *Convolvulus mauritanicus*, *Tropæolum azureum* and *Jarrattii*, *Othonna crassifolia*, *Fragaria indica*, *Pratia littoralis*, *Saxifraga sarmentosa*, with the *Clematis* and *Hibbertia* named above, would be suitable.

Cinerarias (*G. W. L.*).—It is not necessary to stop the central growths of Cinerarias, provided the plants are grown in a cool temperature, the root-action active and the growth of the plants free, as under these conditions the plants branch naturally and form fine heads. The many thousands that are grown so well for Covent Garden Market are never stopped; but occasionally when the plants are drawn unduly in a young state, or where dwarf flat specimens are needed for any particular purpose, the central growth is pinched out. This, however, is exceptional, the rule being as we have stated. The non-flowering of your plants was due to defective root-action, but whether caused by excessive wet, drought, or poverty of soil we have no data for determining. Fowl dung makes very stimulating liquid manure. Mix a peck with 40 gallons

of water, and when clear use it in a diluted state, adding more or less water according to the plants and their condition to which it is applied. It is stronger than soot water.

The Purple-leaved Birch (*A Nurseryman*).—You are right. It was raised in America, and its discovery was described by M. Ed. André in *L'illustration Horticole*. "On the 5th of June, 1872," writes M. André, "whilst going through the horticultural exhibition at Orleans as one of the party of judges, the attention of myself and of my companions was drawn to a number of shrubs consisting of forty plants all of one species, which were almost hidden in the recess of a somewhat darksome corner. It required but a moment's contemplation to enable us to grasp the full importance of the remarkable plant, which was, without doubt, the chief object of interest in the exhibition. It was a very beautiful variety of the common white Birch (*Betula alba*), but the leaves were completely purple or purple-black, like those specimens of the Beech so often seen in our parks. Here was indeed a real discovery, and a golden medal was with one accord awarded to it. It was obtained by chance by an old hand of the firm of Transon Brothers, named Duhois, from a sowing of the ordinary Birch. He very soon observed the unaccustomed appearance of the plant, and after having raised it he took grafts therefrom, and placed them on young stocks of the common variety, and afterwards established them in pots. It will be a great acquisition for our parks, and may be most advantageously associated with the Purple Beeches, the habit of which is quite different. It succeeds in the poorest soils, at the same time preserving all the strength and rural beauty of the original type."

Hanging Rats (*G. Burton*).—After some trouble we think we have found what you require. This method of catching rats was described by Mr. Graves as follows:—The trap consists of a hooked stick (fig. 1), a piece of straight stick about 4 inches long, with one end chisel-pointed and a slit in the other end, and a hender, or rod, about 4 feet long, not too stiff. A piece of string is tied to one end of the bender, and a piece of fine wire with a noose is attached to the string and made fast to the chisel-pointed stick about an inch from the slit end. To set the trap the hooked stick is driven firmly into the ground about 9 inches from the rats' run or hole, and the bender is driven into the ground about 3 feet from it on the same side of the run or hole. The hender is then drawn down to the hooked stick, and the chisel-pointed stick is put under the hook and fixed in the notch, as shown in fig. 2. The wire snare is put in the

Fig. 73.

slit and adjusted in the run about 1 inch from the ground. There may be several traps set on the same run. Fig. 2 shows the trap when set. When the rat is caught he pulls the stick out of the hook and is immediately suspended in the air, and is soon dead and out of the way of the next comer, which passes on to the next trap, and is very soon suspended likewise. There is no fear of catching game, poultry, or cats in such traps, as is the case with iron ones.

Names of Fruit (*J. M., Barton-on-Humber*).—We are unable to identify the Apple you have sent, which is evidently a good culinary variety. It is probably one of the many local varieties which have been raised from seed so freely in North Lincolnshire and South Yorkshire.

Names of Plants (*D. T.*).—1, *Cestrum aurantiacum*; 2, *Clematis viticella*; 3, *Physalis Alkekengi*. (*O. W. D.*).—The white flower is *Chrysanthemum maximum*; the leaf we do not recognise, and cannot determine its name without flowers as well. (*W. J.*).—1, *Æschynanthus longiflorus*; 2, *Selaginella Wildenovii*; 3, *Doryopteris palmata*; 4, *Platyloma cordata*. The Ferns have been extremely well grown, the fronds being firm and healthy. The price of the work on *British Ferns* is 3s. 6d., post free 3s. 9d. The "Vegetable Kingdom" is out of print, and cannot be supplied; you might perhaps obtain a copy second-hand. Stamps or post-office orders should be sent to the publisher. (*W. E. B.*).—Your plant is a *Gesneria*, and it closely resembles that described on page 337 of this Journal as *Jeannot*.

Bee-keeping (*Odyssus*).—1, A bee-house is by no means indispensable; most advanced bee-keepers prefer hives on separate stands, as being more easy of manipulation and affording other advantages over houses. 2, We consider the autumn the best time to purchase, as the cottagers will then sell their hives at about their honey value, in preference to burning the bees. At spring they object to part with them, having generally reserved two or three colonies only to keep up their stock. A strong colony in March is worth at least 20s. in a straw skep. 3, Moveable-comb hives are now supplied by the chief hive-makers at prices so low that we advise you to purchase at least one as a pattern, in preference to constructing one yourself. The prize hives at South Kensington and the Dairy Shows, manufactured by Messrs. Dines of Maldon, Essex, and Mr. Blake of Dallinghoe, Suffolk, with roof, stand, and crate of sections for surplus honey-comb, well made from sound material, are being supplied in large numbers at

10s. 6d. each. A good frame hive without stand can be obtained for 7s. 6d. You would do well to purchase a colony in a straw skep, and allow it to swarm, when you can place the swarm in a bar-frame hive previously procured. If failing to purchase a stock swarms may always be obtained of cottagers on the day of swarming at 10s. each in May and June, and these may be placed in any hive you please.

COVENT GARDEN MARKET.—NOVEMBER 8TH.

OUR Apple market is now considerably depressed owing to American importations reaching us, superior sorts alone maintaining quotations. English Pines are in demand, and Kent Cohs selling freely at previous rates. Grapes in excess of demand.

POULTRY AND PIGEON CHRONICLE.

NEGLECTED PASTURES AND WASTE LANDS.

(Continued from page 417.)

NEGLECTED grass land may also be improved and renovated under one operation—that of paring and burning the old turf, which will clear away many weeds and objectionable grasses, rushes, and hassoc tufts. After this is completed the land will be free to receive new seeds without any cultivation or labour at all except that of sowing the seeds. As fast as the seeds are sown the ashes should be carted from the heaps and spread from the carts, so that the seeds may be covered about 2 inches deep, which will insure germination directly if sufficient moisture is contained in the soil, for it should be understood that the work of paring, turning, seeding, and spreading the ashes should be done during the three months of March, April, and May. It is considered that the paring and turning, utilising the ashes, &c., cost some £3 or £4 per acre, according to the soil and the weather during the work required. Yet our experience in this matter enables us to estimate the ashes to be of far more value as manure than the cost of paring and burning, irrespective of the advantages to be derived from the method pursued of seeding and the certainty of its growth. Besides, we have known various instances in which the roots of some of the most permanent grasses from the old turf will shoot up again, and greatly assist in the formation of the new turf in conjunction with the newly sown seeds, more particularly as the heavy dressing of ashes is one of the most valuable dressings, as proved by the chemical contents that can be used for raising a new turf.

The seeds which we advise being sown are exclusively of per-

manent grasses, and such as may be sown with the full promise of success in the formation of a first-class permanent pasture upon any soil suitable in other respects for the production of a turf, and are as follows:—Cocksfoot (*Dactylis glomerata*), Meadow Fescue (*Festuca pratensis*) and its ally Tall Fescue (*Festuca elatior*), Catstail or Timothy (*Phleum pratense*), and Meadow Foxtail (*Alopecurus pratensis*). These five grasses should form the bulk of all pastures on nearly every soil as furnishing food for sheep or cattle. The Clovers to be used in smaller quantities or proportions than the grasses are permanent Red Clover, Alsike or Yellow Suckling, and permanent White or Dutch Clover. We must not, however, forget that upon all dry soils intended for sheep walk or park lands seeds of Milfoil or Yarrow (*Achillea millefolium*) ought never to be omitted. The above-named are really all the plants required for a permanent pasture of the highest feeding value and quality on first-rate or medium soils in nearly all parts of the kingdom. On inferior soils, however, these grasses may not all of them be suitable, and a selection must be made. Thus on most strong cold soils Foxtail rough meadow grass may be used, and some of the finer grasses should be omitted and a smaller quantity of Meadow Fescue and Tall Fescue used, while a greater proportion of Cocksfoot should be substituted. Before saying more we must state that it is a common thing, as recommended by the seedsmen, to use a certain portion of the seeds of perennial, biennial, and annual grasses. The two latter, however, if not all three of them, ought in our opinion under ordinary circumstances to be carefully excluded when a permanent pasture is desired, for reasons which we have previously stated.

With reference to quantities of seed, we recommend per acre is as follows:—Cocksfoot, 8 lbs.; Meadow Fescue, Tall Fescue, Timothy, and Meadow Foxtail, of each 5 lbs.; Red Clover, 3 lbs.; Yellow Suckling, 3 lbs.; White Dutch, 6 lbs. Upon dry land for park purposes and sheep walk we would leave out the Red Clover and substitute 3 lbs. of Yarrow. The total will be 40 lbs. per acre, and by no means an excessive or expensive seeding in any season, because none of the sorts recommended will die away if properly cared for and manured every year. There is, however, one point to be considered—that in the absence of chalk on good loams, marl on light and gravel soils, lime on very strong soils, and sand or gravel on peaty soils, none of our best grasses however manured can be made permanent and really productive, for when these items are absent the real and true bases of valuable pasture are wanting.

We must now make some reference to the various modes of manuring, as well as the substances at our command and their mode of application—whether by the means of direct manuring or by the consumption of cake, &c., by sheep and cattle. It is well known that in the majority of grazing farms in Cheshire the direct application of bones and bone ashes have been most successful; but upon inquiry as to the nature of the soils, it is ascertained that these clay soil pastures contain upon analysis a large amount of potash—one of the chief ingredients required in the successful formation of permanent pasture, but a more or less absence of lime. At the same time there appears to have been in other districts a constant inquiry why bones should not have the same effect on pasture land of a similar nature, as well as in Cheshire. The correct answer to this is, that wherever there is present in the soil a large or sufficient amount of carbonate of lime, in whatever form or mixture with soils it may be found, bone earth is of but little use, that also on clay soils potash may be wanting. Upon ascertaining this by analysis, farmyard manure, as well as the German kainit containing potash, should be applied in connection with bone manures where grazing of cattle and sheep has been constantly carried out; for this removes, but especially by dairy cows, a large amount annually of carbonate of lime and bone earth. It is from this circumstance that the fattening of cattle or grazing by dairy stock eating cotton or linseed cake is advised, not only for the sake of fattening the animals, but that the pastures should benefit by the manurial residue of the fattening substances, all of which being stated in the tables presented as estimated by Sir J. B. Lawes and printed in the Journal of the Royal Agricultural Society of England.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—Much of the horse labour on the home farm has been seriously delayed or stopped entirely upon the land intended for Wheat. Fallow-ploughing for the land to lie the winter, however, has been possible on the driest and chalk-hill soils, as well as the gravel and sandy lands, but upon strong soils and flat-lying tenacious clays no advantage has been obtained by ploughing them, although they may be required to remain untouched during the winter months. The home farmer should remember that there is much to be done rather than allow the horses to remain idle when work cannot be

done upon the land. It is important that all parts of the farm premises, including the rickyards and various corners of the premises, will be sure to bear grass and weeds of various kinds; and in order to keep up a cleanly and neat appearance, so much valued by many gentlemen who have farms in their occupation, the horses and carts should be employed in carting away all these refuse matters, which may have been shovelled together by labourers employed for the purpose. The benefit to be derived from this work at odd times not only consists of keeping the premises in decent appearance, but that the materials of various kinds in earthy and vegetable substances which may be heaped will be decaying and forming a useful basis for many purposes, but especially for the use in connection with dung and chalk for making composts suitable for improving pastures. It is to be noted that any roadside earth, or that which can be obtained from banks and borders in the fields, should be carted together at odd times and formed into a conical heap, so that it may be covered or rough-thatched with hedge-trimming, sedge, and similar materials, in order that it may be kept dry for the purpose of making bottoms or floors for removal in all the pig pens, cattle pens, and boxes, including the stalls for dairy cows as well as for the cart-horse stables. This earth after being in heap for nine or ten months will prove mellow and may be picked down, taking a portion of the heap as may be required. We make these heaps about 12 feet wide at the bottom and draw upon them to tip the materials, except the portion at the top, which will be cast into form for the purpose of keeping the main portion of the earth heap dry and fit for use when required, thus giving it an absolute power suitable for the above-named purposes. Large quantities of earth may thus be obtained, and the heap when extended lengthways may be reduced as required without at all disturbing any portion of the heap which may have been recently put together. We have for many years used earthy compounds for the purposes named, as much as from 150 to 200 cartloads in a year, according to the extent of the farm. This practice not only serves to fill up the odd time for horses which would be otherwise idle, but it also furnishes an enormous amount of manure, much of which would often be lost altogether; at the same time it tends greatly to the health and cleanly appearance of all the cattle when properly carried out, and which has been described by us at different times during the past five years in this Journal under separate headings, where the management of cattle in all its detail has been minutely described as carried out in our own practice.

Hand Labour.—The late flooding rains will have made it quite necessary for the water meadows to have been carefully attended to by the drovers and labourers employed. The cutting of underwood in the coppices and in the hedgerows, as well as the cutting of Ash and Elm timber, will have been going on. Planting young trees also should now be done, for the purpose of growth of Larch and Chestnut trees for hop-poles in the future.

Live Stock.—The shepherd will have now the double care of attending the sheep, whether of ewes, hoggets, or wethers, and endeavour to keep them healthy by feeding on the driest land, also to avoid the dirt on some soils. All the food, whether of roots, cake, or hay, should be given in troughs, to avoid waste, and by carefully feeding and filling the troughs with as much, and no more, food than the animals will eat before leaving the troughs great economy and avoidance of waste will be the beneficial result. In letters published lately in the *Times* newspaper, the question of "ensilage" has been brought to the farmers' notice. This is neither more or less than a plan for preserving green fodder, such as Vetches, Trifolium, grass, and Clovers in "silo," which is a pit or tank formed for the purpose of receiving these green substances to be preserved for the feeding of cattle in the winter and spring months. This is not altogether a new practice, but it is fast coming to the front, and the home farmers may live and learn, for many have yet to be taught the best way of saving grass and other green crops. We have not tried it, but there is much to be said, and has lately been said, of the plan, and that is worth a trial at any rate at the time of year, say the month of May and other summer months. It is recommended to cut your green fodder and bring it home immediately, cut it at once into the smallest pieces you can, and cast it into a pit, or silo as it is called; press it down closely so as to keep out the air, and cover it quite securely with earth or other heavy substances, and in a few months we are told that you will be able to cut it like cheese, and that your cattle will like it and thrive upon it. We are informed that this has been a practice on a farm in France a short distance from Paris by Vicomte Arthur de Chezcles, who puts into one pit the produce of 170 acres, and cuts it out for his cattle when wanted. They are said to enjoy it, and, according to their respective destinations, fatten or give milk upon it admirably. We hope to refer to the subject again more fully and in detail.

SPOILING THE DORKING.—No. 2.

I WAS certainly taken by surprise on finding that the Poultry Club are about to publish the points of excellence in poultry; still

for all that I do not see any reason why I should not finish my Dorking notes, as I am totally ignorant of any decision they may have arrived at with regard to this ancient breed, and therefore what I say cannot in any way be considered as written with any antagonistic feeling as regards the Poultry Club. Nor do I mean to be personal to anyone, and therefore I refrain from mentioning any names. I wish it clearly to be understood that I write only in the interest of the Dorking fowl.

In my last I confined my remarks to the Dark Dorking; but now I wish to point out that the White Dorking has been tampered with almost, if not quite, to the same extent as the old coloured variety. It is quite apparent, and has been for some time, that the White Cochin has been used to get size, as may be observed to the most uninitiated eye; the looseness of feathering, the cushion on the back and general carriage, also the red earlobe, has appeared, whereas there never was such a thing in true White Dorkings; also I have seen slightly tinted legs, and at the last Tonbridge Wells Show one hen was shown with a decidedly blue tendency on the shank bones. As an excellent Dorking fancier remarked to me, looking at the bird, "Where will it all end? Is the prize for a Dorking or a crossbred?" I could but refer him to the schedule. The prize was for a "White Dorking." Was the bird before us one? Certainly it was not like the White Dorking I and many others kept years ago, neither in compactness, smallness of bone, colour of earlobe, colour of legs, nor carriage.

To me it seems a little odd that the Dorking should be so entirely altered, and to my mind for the worse; and yet those who have helped to spoil it have maintained all through the fifth toe, which so many writers have stated was so difficult to keep true, though I never had any difficulty, the true breed never throwing four-toed birds. I say it does seem a little odd that the fifth toe has been kept, as it has been so much abused also, even to the nonsensical statement that it was the cause of the bumble foot. For my part I have always found the fifth toe one of the least difficult points to maintain, and it is entirely owing to the aptitude to breed a fifth toe that the various crosses have been made, and a mongrel fostered on the fancier of to-day, many of whom cannot remember the fair-fleshed small-boned fowl of forty years ago, but take for granted the coarse flesh and large bones of the now show Dorking as being the genuine.

Broadly it may be stated that all the European varieties of fowl have *white earlobes*, and all the Asiatic *red earlobes*, and if the former have red earlobes it is conclusive to my mind that there is a cross.

Now take the Black Hamburgh with its white earlobes, cross it with an Asiatic, and so breed back to get size. I wonder whether the judges would alter the standard to suit the cross, and say henceforth the Black Hamburgh shall have a red earlobe. I feel sure they would not, and yet that is what they want to do with the truly unfortunate Dorking. Poultry shows must be very useful institutions, and the judges wise when they unite for the purpose of laying down a fresh standard of excellence, because the original breed has become so muddled by crossing and crossing that many if not nearly all the original is lost, and this by their either want of capacity to distinguish the true, or an utter indifference to the real merits of the breed. The classes at the shows were formerly for Coloured Dorkings; then any colour could compete, and the fowls were judged by their table qualities, smallness of bone, white and fine texture of flesh, and general plumpness of form, and the old breed being tight and close in feather, and having such well-rounded breasts, never looked the birds they were. Their excellence was to be felt as much as, or even more than, seen.

In the schedule of a poultry show issued more than forty years ago occurs the following:—"The fowls should be plump, deep, long, and capacious in body, with short white legs, of small-sized bones, of very white, juicy, fine-grained flesh, the fat and skin equally white, and of delicate flavour."

Now, I put it to any Dorking fancier of the present day, Is the foregoing a description of the now so-called Dorking? I say most emphatically, It is not; but it is that of the true old English Dorking of the past, and everyone who knew and kept the true old sort will say it is right word for word. Truly our poultry judges and poultry shows have done us good service in this case.—HARRISON WEIR.

THE NEW STANDARD OF EXCELLENCE.

IN accordance with my promise I enclose herewith draft Standards of Dorkings, Game, and the French breeds.

I shall have much pleasure in submitting any comments which reach me on or before Monday next to the meeting of fanciers to be held on Tuesday at the Crystal Palace.

The particular places of meeting I shall endeavour to have clearly indicated by a notice on the first pen of each breed. The hours will be as follows:—Brahmas, 12 noon; Game, 12.30 P.M.; Dorkings, 1 P.M.; Cochins, 1.30 P.M.; French, 2 P.M.

The General Annual Meeting of the Club will as usual be held at 3.30 P.M. on the same day (Tuesday).

All interested are invited to attend the meetings.—ALEXANDER COMYNS, *Hon. Sec.*, 47, Chancery Lane, London, W.C.

DORKINGS.

GENERAL CHARACTERISTICS.—COCK.

Beak.—Stout.

Comb.—Either single or rose in Coloured, single in Silver-Greys, rose in White or Cuckoo Dorkings. (If single) Upright, thick, well and firmly set on the head, evenly serrated and free from sprigs at the side; outline semicircular from beak to back of the head; texture fine. (If rose) Moderate in size, firmly set on head, evenly spiked, square in front with no hollow in centre, and a good spike at back.

Head.—Large.

Eye.—Full and bright.

Wattles.—Long and pendulous.

Neck.—Thick, rather short, with full hackle.

Breast.—Full and prominent, with long breast bone.

Body.—Large, deep, and square.

Back.—Broad, rather long, flat at shoulders, rounding slightly towards the tail.

Wings.—Large and carried well up.

Tail.—Large and flowing, carried moderately high, but not in squirrel fashion.

Sickle Feathers.—Long, broad, and well arched.

Tail Coverts.—Large and full.

Thighs.—Thick and stout, well hidden by feathers.

Legs.—Short and strong with the spurs set inside.

Feet.—Large and broad with five toes, the fifth turning upwards, the rest straight.

General Shape and Carriage.—Massive and square shape, with proud and bold carriage.

GENERAL CHARACTERISTICS.—HEN.

Beak.—Stout.

Comb.—Either single or rose in Coloured, single in Silver-Grey, rose in White or Cuckoo Dorkings. (If single) Large, falling on one side of head. (If rose) Neat, firmly set on the head, evenly spiked, with no hollow in centre, and a straight spike at the back.

Wattles.—Moderate in size and neatly rounded.

Head.—Large, but not coarse.

Eye.—Full and of soft expression.

Neck.—Thick and of moderate length.

Breast.—Full and round with long breast bone.

Body.—Large, deep, and square.

Back.—Broad and flat.

Wings.—Large and carried well up.

Tail.—Broad and full, carried neither too upright nor straight.

Thighs.—Thick and stout, well hidden by feathers.

Legs.—Short and stout; [spurs, if any, inside].

Feet.—Large and broad with five toes, the fifth turning upwards, the rest straight.

General Shape and Carriage.—Massive and square.

POINTS OF COLOUR IN COLOURED DORKINGS.—COCK.

Head.—White or white striped with black.

Neck Hackle.—White striped with black or steel grey to match saddle (?).

Comb and Face.—Red.

Earlobes.—Red preferred, white admissible.

Beak.—Horn colour.

Eye.—Orange.

Wattles.—Red.

Breast.—Black, or black slightly ticked with white.

Underpart of Body and Thighs.—Black.

Back and Shoulder Coverts and Saddle.—White, with black markings or steel grey.

Wing Bow.—Black and white mixed. *Coverts.*—Metallic black.

Primaries.—Black. *Secondaries.*—White, or nearly so.

Tail and Sickle Feathers.—Black, or black with a little white, the former preferred.

Tail Coverts.—Black or grey.

Legs.—White.

POINTS OF COLOUR IN COLOURED DORKINGS.—HEN.

Head.—Dark on top, lighter round base of bill.

Comb.—Bright red.

Face.—Red.

Earlobe.—Red preferred, white admissible.

Wattles.—Red.

Beak.—Horn colour.

Eye.—Orange.

Neck.—Black, dark, or with dark stripes on lighter ground.

Breast.—Moderately light to dark brown, in some cases salmon colour, deeper under throat; in others, neatly spangled with black.

Back and Shoulder Coverts.—Dark, with white line down shaft of each feather.

Wing Bow.—Ditto, and free from red.

Coverts and Flights.—Ditto, or black.

Tail.—Black or dark brown.

Thighs.—Dark.

Legs and Feet.—White.

POINTS OF COLOUR IN SILVER-GREY DORKINGS.—COCK.

Head.—Silvery white.

Hackle.—Pure silvery white, as free from stripes as possible.

Comb, Face, Earlobes, and Wattles.—Bright coral red.

Beak.—Horn or white.

Eye.—Orange.

Breast.—Glossy black.

Thighs and Underparts.—Black.

Back.—Pure silvery white.

Shoulder Coverts.—Ditto, free from patches of colour.

Saddle.—Pure silvery white.

Wing Bow.—Silvery white. *Coverts.*—Greenish black. *Primaries.*—Black, edged with white. *Secondaries.*—White outer web, black inner web, and black end to each feather.

Tail.—Glossy black.

Sickle.—Feathers greenish, glossy black.

Legs and Feet.—White or pinky white.

POINTS OF COLOUR IN SILVER-GREY DORKINGS.—HEN.

Head.—Silvery white, with slight grey marking.

Hackle.—Silvery white, clearly striped with black.

Comb, Face, and Wattles.—Bright coral red.

Eye.—Orange.

Beak.—Horn or white.

Breast.—Rich robin red or salmon red, shading off to grey on lower parts.

Thighs and Underparts.—Grey.

Back, Shoulder Coverts, Saddle, Wing Bow, and Wing Coverts.—Bright silvery grey, with minute pencilling of darker grey on each feather; the shafts of the feathers white. *Primaries.*—Grey or black. *Secondaries.*—Grey.

Tail.—Grey, of a darker shade than body; quill feathers black.

Legs and Feet.—White or pinky white.

POINTS OF COLOUR IN WHITE DORKINGS.—COCK OR HEN.

Comb, Face, and Wattles.—Bright coral red.

Beak.—White.

Eye.—Orange.

Plumage.—Pure white, free from any shade of any other colour.

Legs and Feet.—White.

POINTS OF COLOUR IN CUCKOO DORKINGS.

Comb.—Bright red.

Face, Lobes, and Wattles.—Bright red.

Beak.—White or horn.

Eye.—Bright orange.

Body.—Light bluish-grey ground, each feather barred with bands of a darker grey or blue.

Legs and Feet.—White, red veins showing between the scales; nails white.

GAME.

GENERAL CHARACTERISTICS.—COCK.

Beak.—Long, strong, and slightly curved.
Comb.—(If undubbed) small, thin, straight, erect, well serrated.
Head.—Long, lean, bony, cleanly set on neck.
Eye.—Large, full, round, bright and quick.
Face.—Lean, thin, with fine skin.
Throat.—Long, lean, fine skin, cleanly cut (?)
Wattles.—(If undubbed) very thin, round, small, and smooth.

Neck.—Long, thin, slightly arched, and tapering finely at the base of the head.

Hackle.—Short and close.

Back.—Flat, short, broad at shoulders and tapering to tail.

Breast.—Broad and full.

Stern.—Very fine and carried well up; must not be full.

Wings.—Short, powerful, standing well from body at the shoulders.

Tail.—Small, carried low and very close.

Sickle Feathers.—Narrow, hard, and tapering to a fine point.

Tail Coverts.—Narrow, fine, and short.

Thighs.—Long, very strong and muscular, standing well out from the body, and straight.

Legs.—Long, bony, with fine scales, round.

Feet.—Large, with well-spread flat toes, hind claw well set back.

Plumage.—Short, hard, and bright.

Body in Hand.—Firm, compact, muscular.

General Shape and Carriage.—Erect, fearless, alert.

GENERAL CHARACTERISTICS.—HEN.

Beak.—Long, strong, and slightly curved.

Comb.—Small as possible, thin, straight, erect, low at front and evenly serrated.

Head.—Long, lean, bony, tapering, neat.

Eyes.—Prominent and brilliant.

Face.—Smooth, bony, lean, with a fine skin.

Deaf Ear.—Small, and hanging close to the neck.

Wattles.—Small, thin, fine, and round.

Throat.—Clean and well cut (?)

Neck.—Fine, long, and slightly arched.

Hackle.—Short and close.

Back.—Short, flat, broad at shoulders, and tapering to tail.

Wings.—Short, firm, standing out from the body at the shoulders, but carried close in and well up at the flights.

Tail.—Formed of narrow feathers of moderate length, well whipped, and carried low.

Breast.—Full and broad.

Thighs.—Long, firm, muscular, standing clear from the body.

Legs.—Long, bony, with fine scales, round.

Feet.—Large, with well-spread, long, thin toes, the hinder one well set back, and the foot flat on the ground.

Plumage.—Short and hard, and bright.

General Shape and Carriage.—Smart, upright, fearless, and showing high breeding.

POINTS OF COLOUR IN BLACK-BREASTED RED GAME.—COCK.

Head.—Bright orange.

Comb.—Bright red.

Face and Jaws.—Red.

Eyes.—Bright red.

Beak.—Horn colour or yellow.

Neck Hackle.—Bright orange, free from stripes.

Back.—Dark rich red.

Shoulders and Shoulder Coverts.—Red.

Wing Butts.—Black. *Bow.*—Rich red. *Greater and Lesser Coverts.*—Glossy black with metallic reflections, forming a distinct bar. *Primaries.*—Black except two lower feathers, the outer web of which should be edged with bay. *Secondaries.*—Clear bay outer web and black inner web.

Saddle.—Rather darker red than hackle.

Tail.—Black.

Sickle Feathers.—Green black.

Tail Coverts.—Glossy green black, but grey at roots.

Breast.—Black up to the throat.

Underpart of Body and Thighs.—Black.

Legs.—Willow or olive.

HEN.

Head.—Golden.

Face, Comb, Deaf Ear, and Wattles.—Red.

Eyes.—Bright red.

Beak.—Horn colour or yellow.

Neck Hackle.—Golden with narrow black stripes.

Back and Shoulder Coverts, Wing Bow, Shoulder, and Coverts.—Partridge.

Wing Primaries.—Black or dark brown. *Secondaries.*—Outer edge partridge, remainder black (?).

Tail.—Black except the two top feathers, which should be powdered with partridge.

Breast.—Salmon, shading off to ashy brown towards the thighs.

Thighs.—Pale salmon.

Legs.—Willow or olive.

POINTS OF COLOUR IN BROWN RED GAME.—COCK.

Head.—Dark red.

Comb.—Gipsy-coloured—i.e., dark purple.

Face and Jaws.—Very dark ditto.

Eyes.—Black.

Beak.—Black or nearly so.

Neck Hackle.—Lemon-coloured, with a very narrow dark streak in the middle.

Back and Shoulder Coverts and Saddle.—Lemon.

Wings Butts.—Black. *Shoulder.*—Black. *Bow.*—Lemon. *Coverts.*—Green black. *Primaries.*—Black. *Secondaries.*—Black free from grey.

Tail.—Black.

Sickle Feathers and Tail Coverts.—Green black.

Breast.—Black ground colour, feathers with brown shafts and laced with light brown.

Thighs.—Black.

Legs.—Black, or dark willow in aged birds.

HEN.

Head.—Black or dark brown.

Comb, Face, Deaf Ear, and Wattles.—Black or dark purple.

Eyes.—Black.

Beak.—Black or nearly so.

Neck.—Black, with very narrow black stripes.

Remainder of Plumage.—A black or marbled breast indifferently; the rest of the plumage black.

Legs.—Black; very dark willow admissible in adults.

POINTS OF COLOUR IN YELLOW DUCKWING GAME.—COCK.

Head.—Very pale straw.

Comb, Face, and Jaws.—Red.

Eye.—Bright red.

Beak.—Horn colour.

Neck Hackle.—Clear cream colour, absolutely free from black stripes.

Back.—Brassy.

Shoulder Coverts.—Black.

Bow of the Wings.—Brassy, of an even shade.

Wing Butts.—Black. *Greater and Lesser Coverts.*—Black, forming a distinct bar. *Primaries.*—Black, excepting the lower edge of the two last feathers, which should be very pale brown. *Secondaries.*—Black inner web; clear white outer web.

Saddle.—Straw.

Breast.—Black.

Underpart of Body, Thighs, and Tail.—Black.

Sickle Feathers.—Glossy black.

Tail Coverts.—Black, with grey at the roots; lower coverts straw.

Legs.—Willow.

HEN.

Head.—Silvery grey.

Comb, Face, Deaf Ear, and Wattles.—Red.

Eye.—Bright red.

Beak.—Horn colour.

Neck.—Silvery grey or pale straw, with narrow dark stripes.

Breast.—Salmon.

Back and Shoulder Coverts.—Slaty grey.

Wing.—Ashy grey free from pencilling.

Shoulder, Bow, Wing Coverts, and Secondaries.—Ashy grey. *Primaries.*—Black.

Tail.—Black, excepting two top feathers, which should be grey.

Thighs.—Very pale salmon.

Legs.—Willow.

POINTS OF COLOUR IN SILVER DUCKWING GAME.—COCK.

Head.—Clear silver.

Face and Jaws.—Bright red.

Comb.—Red.

Eye.—Bright red.

Beak.—Horn colour.

Neck Hackle.—Clear silver.

Breast and Underpart of Body and Thighs.—Black.

Back.—Clear silver.

Shoulder Coverts.—Black.

Saddle.—Clear silver.

Wing Butts.—Black. *Bow.*—Clear silver. *Coverts.*—Black. *Primaries.*—Black, excepting the lower edge of the two last feathers, which should be very pale brown (?). *Secondaries.*—Black inner web, clear white outer web.

Tail.—Black.

Sickle Feathers.—Glossy black.

Tail Coverts.—Black with grey at the roots; lower coverts straw.

Legs.—Willow.

HEN.

Head.—Silvery grey.

Comb, Face, Deaf Ear, and Wattles.—Red.

Eye.—Bright red.

Beak.—Horn colour.

Neck.—Silvery grey or pale straw with narrow dark stripes.

Breast.—Salmon of a paler shade than in Yellow Duckwings.

Back and Shoulder Coverts.—Slaty grey.

Wing Bow, Coverts, and Secondaries.—Ashy grey. *Primaries.*—Black.

Tail.—Black, excepting two top feathers, which should be grey.

Thighs.—Salmon of a paler shade than in Duckwings.

Legs.—Willow.

POINTS OF COLOUR IN PILE GAME.—COCK.

Head.—Bright orange.

Comb, Face, and Jaws.—Bright red.
Eyes.—Bright red.
Beak.—Horn colour or yellow.
Neck Hackle.—Orange or chestnut.
Saddle.—Rich red.
Breast.—White or slightly marbled.
Back.—Dark rich red.
Shoulder Coverts.—White.
Bow of the Wings.—Rich red.
Greater and Lesser Coverts.—White.
Wing Secondaries.—Red on the outer edge and white on the inner.
Primaries.—White.
Thighs.—White.
Tail.—White ticked with black (?) or white.
Legs.—Yellow or willow, yellow preferred.

HEN.

Comb, Face, Deaf Ear, and Wattles.—Bright red.
Eyes.—Fiery red.
Beak.—Horn colour or yellow.
Neck.—Light gold.
Breast.—Salmon.
Thighs and Tail.—White.
Remainder of Plumage.—White with some red, which is known as "a Rose" on the wing.
Legs.—Yellow or willow, yellow preferred.

POINTS OF COLOUR IN BLACK GAME.

Comb, Face, Deaf Ear, and Wattles.—Deep red.
Eyes.—Black, dark brown, or red.
Beak.—Black.
Legs.—Dark willow or black.
Remainder of Plumage.—Black with metallic lustre.

POINTS OF COLOUR IN WHITE GAME.

Comb, Face, Deaf Ear, and Wattles.—Red.
Eyes.—Bright red.
Beak.—Horn colour or yellow.
Legs.—Yellow.
Remainder of Plumage.—Pure white.

POINTS OF COLOUR IN BIRCHEN YELLOW GAME.—COCK.

Head.—Cream-coloured.
Face and Jaws.—Dull red.
Eyes.—Red.
Beak.—Horn colour.
Neck.—Cream-coloured.
Breast.—Clay, with mixture of brown.
Back and Shoulder Coverts.—Cream and rusty brown.
Saddle.—Cream.
Wing Butts.—Dark brown and rusty black. *Bows.*—Cream. *Coverts and Secondaries.*—Rusty brown. *Primaries.*—Black.
Tail.—Black.
Sickles.—Black.
Tail Coverts.—Black, with mixture of bronze.
Legs.—Willow.

HEN.

Head.—Dark grey.
Comb and Face.—Dull red.
Deaf Ear.—Blue red.
Wattles.—Dull red.
Eyes.—Bright red.
Beak.—Horn colour.
Neck.—Dark grey.
Breast.—Dark bronzy grey.
Back and Shoulder Coverts.—Very dark grey.
Wing Bow.—Dark grey or sometimes black. *Coverts and Secondaries.*—Dark grey. *Primaries.*—Black.
Tail.—Black.
Thighs.—Black or dark grey.
Legs.—Dark willow.

POINTS OF COLOUR IN GINGER RED GAME.—COCK.

Head.—Red.
Face and Jaws.—Reddish purple.
Eyes.—Brown.
Neck Hackle.—Clear rich red colour.
Back and Shoulder Coverts.—Rich red.
Wing Bow.—Rich red.
Wing Coverts and Secondaries.—Brownish red. *Primaries.*—Black.
Saddle.—Rich clear red.
Tail.—Black.
Sickle Feathers and Tail Coverts.—Rich black.
Breast.—Ginger red.
Thighs.—Dusky red.
Legs.—Olive or dark willow.

HEN.

Head.—Yellowish brown.
Comb, Face, Deaf Ear, and Wattles.—Purple.
Eyes.—Brown.

Neck.—Yellow, striped with black.
Breast.—Yellowish brown, shading to dark dusky brown at the lower parts.
Remainder of Plumage.—Yellowish brown.
Legs.—Olive or dark willow.

POINTS OF COLOUR IN WHEATEN GAME.—HEN.

Head.—Light brown.
Comb, Face, Earlobes, and Wattles.—Bright red.
Beak.—Horn.
Eye.—Vermilion.
Neck.—Golden buff striped with black.
Back and Shoulder Coverts.—Light partridge intermixed with buff.
Wing Bow.—Buff or fawn colour.
Primaries, Secondaries, and Breast.—Buff or fawn colour.
Thighs.—Lightish grey.
Legs.—Willow or olive.
Tail.—Black with a shading of brown.

HENNY GAME.

NOTE.—It has not been considered desirable to frame a standard of Henny Game. These may be of almost any of the colours described; the cock is hen-feathered and hen-coloured, and the legs are in all cases white (?)

GAME.

NUMERICAL VALUE OF POINTS.—COCK.

Points to be deducted for defects.

Bad colour	15
Bad head	10
Bad tail	10
Bad eyes	5
Bad feet	10
Too much feather	10
Want of symmetry	20
Want of condition	10
Bad legs	10
100	

A perfect bird to count 100 points.

DISQUALIFICATIONS.

Duck feet and bent breasts if bad, wry tail, crooked back. If shown together, birds not matching fairly well.

NUMERICAL VALUE OF POINTS.—HEN.

Points to be deducted for defects.

Bad head	10
Bad tail	10
Bad legs	10
Bad feet	10
Eyes bad in colour	5
Too much feather	10
Bad colour feathers	15
Want of condition	10
Want of symmetry	15
Large or twisted comb	5
100	

A perfect bird to count 100 points.

DISQUALIFICATIONS.

Same as for cock. If shown together, birds not matching fairly well.

HOUDANS.

GENERAL CHARACTERISTICS.—COCK.

Crest.—Large, full, and compact, with a sufficient inclination backwards to fully expose the comb.
Comb.—Well-defined even leaf comb, neat, medium size, placed in the centre of the head.
Beak.—Short and stout.
Eye.—Bold.
Wattles.—Rather short and well rounded.
Muffling or Beard.—Large, full, compact, and even.
Face.—Should be much hid by muffling.
Breast.—Broad, deep, and full.
Back.—Broad, moderately long, and straight.
Wings.—Carried well up.
Tail.—Full and well arched, with prominent sickles.
Thighs.—Short, stout, and rather wide apart.
Legs.—Rather short and stout, and perfectly straight.
Toes.—Five in number, straight, and well spread apart. The fifth toe, starting from root of fourth toe, should curve gently upwards.
Carriage.—Bold and lively.

GENERAL CHARACTERISTICS.—HEN.

Crest.—Large, compact, and, above all, globular in shape.
Comb.—Leaf-shaped, and very small.
Eye.—Full and bright.
Wattles.—Small and rather round.
Muffling.—Large and full, and beard pendulous.
Neck.—Full, and not too long.
Breast.—Broad, deep, and full.

Back.—Broad and straight, moderate length.
Wings.—Full and well tucked up.
Tail.—Medium size, carried well away from the body.
Thighs.—Short.
Legs.—Rather short and stout, and perfectly straight.
Toes.—Five in number, straight, and well spread apart. The fifth toe, starting from root of fourth toe, should curve gently upwards.
Carriage.—Sturdy and active.

POINTS OF COLOUR IN HOUDANS.—COCK OR HEN.

Comb.—Bright red.
Face.—Bright red.
Wattles.—Bright red.
Earlobe.—White.
Eye.—Red.
Crest.—Black and white, but may be rather lighter than the rest of the plumage.
Muffling.—Same as above.
Remainder of Plumage.—Glossy black and pure white, mottled. The former may preponderate somewhat in chickens, which have a tendency to get lighter after their first moult.
Legs.—Pinky white, mottled with blue or black.

NUMERICAL VALUE OF POINTS.—COCK.

Points to be deducted for defects.

Deficiency of crest	12
Deficiency of beard and muffling	10
Deficiency of size	18
Deficiency of symmetry	12
Faulty comb	18
Faulty colour	12
Faulty feet	10
Faulty condition.....	8
	100

A perfect bird to count 100 points.

DISQUALIFICATIONS.

Many red or straw-coloured feathers; crooked legs, backs, or any other deformity; outside spurs; squirrel tail; absence of fifth toe; any comb other than leaf.

NUMERICAL VALUE OF POINTS.—HEN.

Points to be deducted for defects.

Deficiency of crest	15
Deficiency of beard and muffling	12
Deficiency of size	20
Faulty colour	15
Bad feet.....	10
Faulty comb	8
Faulty condition.....	10
Lack of symmetry	10
	100

A perfect bird to count 100 points.

DISQUALIFICATIONS.

Red or straw-coloured feathers; absence of fifth toe; deformity of any kind; total absence of either black or white feathers; spurs on the outside of legs.

CREVE CŒUR.

GENERAL CHARACTERISTICS.—COCK.

Crest.—Large, inclining backwards, so as to show comb.
Head.—Erect and stately.
Comb.—Even, two-horned, V-shaped, not curved, and free from branches or tynes; moderate size; standing well up against the crest.
Eye.—Full and bright.
Deaf Ear.—Small, well covered with muffling.
Face.—Well muffled.
Wattles.—Moderate length.
Mufflings.—Very full and deep.
Beak.—Strong and well curved.
Neck.—Rather long and graceful; hackle full.
Breast.—Broad and full.
Back.—Broad, long, flat.
Body.—Square and large.
Wings.—Fairly large, well tucked up.
Tail.—Full, and carried moderately high; large sickles.
Thighs.—Short and well covered with feathers.
Legs.—Shanks short; toes straight and long.
Carriage.—Bold and elegant.

GENERAL CHARACTERISTICS.—HEN.

Crest.—Large, compact, and globular.
Head.—Well set on, rather large.
Comb.—Two-horned, as in cock, but small and neat.
Eye.—Full and bright.
Deaf Ears.—Small, well covered with muffling.
Muffling.—Very full and deep.
Wattles.—Moderate length and rounded.
Neck.—Medium length; hackle full.

Breast.—Deep, prominent, and full.
Body.—Square and well developed.
Back.—Flat and broad.
Wings.—Rather large, and well tucked up.
Tail.—Broad and full.
Thighs.—Stout.
Legs.—Short; toes straight.
Carriage.—Lively and bold.

POINTS OF COLOUR IN CREVE CŒURS.—COCK OR HEN.

Comb.—Bright coral red.
Face, Wattles, and Earlobe.—Red.
Eye.—Bright red.
Legs.—Black or slaty blue.
Plumage.—Very lustrous greenish-black. No other colour admissible except perhaps a few white feathers in crest (?).

NUMERICAL VALUE OF POINTS.—COCK.

Points to be deducted for defects.

Bad comb	20
Deficiency of size	20
Deficiency of condition.....	15
Deficiency of symmetry.....	15
Deficiency of crest and muffling.....	20
White in crest	10
	100

A perfect bird to count 100 points.

DISQUALIFICATIONS.

Any deformity; coloured feathers, except white in crest, which, however, is a fault.

NUMERICAL VALUE OF POINTS.—HEN.

Points to be deducted for defects.

Deficiency of crest and muff	25
Deficiency of condition and plumage	12
Deficiency of symmetry	12
Deficiency of size	20
Bad comb	15
White feathers in crest	16
	100

A perfect bird to count 100 points.

DISQUALIFICATIONS.

Deformity of any kind; any coloured feathers (except white in the crest, which, however, is a defect).

LA FLECHE.

GENERAL CHARACTERISTICS.—COCK.

Beak.—Rather long; nostrils elevated.
Comb.—Consists of two very even, round, V-shaped horns, without any branches; medium size and neat.
Earlobes.—Neat, free from folds; medium size.
Head.—Rather long, thin, and flat at the side.
Eye.—Full and bold.
Face.—Free from feathers.
Wattles.—Long and pendulous.
Neck.—Long and stylish; hackle not too much developed.
Back.—Long, not too wide, and sloping towards tail.
Wings.—Large and well tucked up.
Breast.—Full.
Tail.—Long, not too full, slanting backwards.
Thighs.—Long.
Legs.—Long; dark slate colour.
Toes.—Even and straight.
Carriage.—Sprightly, graceful, and upstanding.

GENERAL CHARACTERISTICS.—HEN.

Beak.—Rather long; nostrils elevated.
Comb.—Consisting of two very even, round, V-shaped horns, without any branches; small and neat.
Head.—Rather small.
Eye.—Full and bold.
Face.—Free from feathers.
Deaf Ear.—Small.
Wattles.—Small and round.
Neck.—Rather long and graceful.
Back.—Broad, tapering and slanting slightly towards the tail.
Body.—Rather plump.
Breast.—Broad.
Wings.—Large and well tucked up.
Tail.—Small, rather erect.
Thighs and Legs.—Rather long.
Carriage.—Upright and sprightly.

POINTS OF COLOUR IN LA FLECHE.—COCK AND HEN.

Face.—Bright red.
Earlobes.—Pure white.
Wattles and Comb.—Red.
Eyes.—Bright red.

General Plumage.—Black, with brilliant green gloss.
Legs.—Dark slate colour.

NUMERICAL VALUE OF POINTS.—COCK.
Points to be deducted for defects.

Bad comb	20
Stained earlobe	10
White face	10
Deficiency of size	20
Deficiency of symmetry and condition.....	15
Showing any crest	15
Squirrel tail	10
100	

A perfect bird to count 100 points.

DISQUALIFICATIONS.

Deformity; coloured or white feathers; red earlobes.

NUMERICAL VALUE OF POINTS.—HEN.
Points to be deducted for defects.

Bad comb	18
Stained ear	15
White face	15
Want of size and condition	15
Want of symmetry.....	12
Showing crest	25
100	

A perfect bird to count 100 points.

DISQUALIFICATIONS.

Deformity; red earlobes; white feathers.

COURTES PATTES.

GENERAL CHARACTERISTICS.—COCK.

- Beak.—Short and stout.
- Comb.—Single, upright, and large.
- Head.—Small.
- Eye.—Bright and vivacious.
- Wattles.—Very long and pendulous.
- Neck.—Thick and well feathered.
- Breast.—Full and carried forward, and very close to the ground.
- Body.—Thick, square, and very low.
- Back.—Medium length.
- Wings.—Large and not tucked up.
- Tail.—Very full and large.
- Sickle Feathers.—Long and very ample.
- Tail Coverts.—Long.
- Thighs.—Very short.
- Legs.—So short that the fluff almost touches the ground.
- Feet.—Medium size.
- Carriage.—In consequence of the shortness of leg much resembles that of a Duck.

GENERAL CHARACTERISTICS.—HEN.

- Beak.—Short.
- Comb.—Of medium size and falling over.
- Wattles.—Well developed.
- Head.—Small.
- Eye.—Bright and soft.
- Neck.—Short.
- Breast.—Very full, carried close to the ground.
- Body.—Square and low, long in proportion to its depth.
- Back.—Long.
- Wings.—Low and rather long.
- Tail.—Large.
- Thighs.—Very short.
- Legs.—Very short, so that the keel of breast is but little removed from the ground.
- Feet.—Medium size.
- Carriage.—Very low and waddling.

POINTS OF COLOUR IN COURTES PATTES.—COCK OR HEN.

- Head.—Black.
- Face.—Red.
- Eye.—Bright red.
- Wattles.—Red.
- Earlobe.—White.
- Legs.—Black.
- Remainder of Plumage.—Very black and glossy.

NUMERICAL VALUE OF POINTS.—COCK AND HEN.
Points to be deducted for defects.

Length of leg	25
Want of size.....	15
Defective carriage	10
Red on lobe	10
Defective comb	10

DISQUALIFICATIONS.

Feathers on legs; many white or any coloured feathers in plnmage; lobe red.

OUR LETTER BOX.

Cow-keeping (A. L. L. W.).—There being 20 acres of land, 15 acres being pasture, and 5 acres including large gardens and shrubberies, the first question that arises is whether any portion of the garden land can be yearly cropped with Mangolds, Carrots, Cabbage, or large cattle Potatoes, and if so how much? Can any portion of the pasture land be converted into tillage, say about two acres, for the growth of vegetables for the cattle in the winter months? If the gardens cannot be made to produce roots for the cows, or if none of the pasture can be turned into tillage, roots will have to be purchased for feeding the cows in winter. We think that five cows may be kept, and recommend three Guernsey cows, two to calve in the spring and one in the autumn, in addition to the two Kerry cows. The pasture to be made available should be divided in the centre with a strong, fixed, flat-barred iron fence, and a moveable fence to be used across strong flat-barred iron hurdles, so that one-half of the pasture should be cut for hay each year alternately, the other being fed off by cows, and the moveable fence could be used across as to give the animals a change occasionally. If the pasture is broken up in part, Rye and Trifolium may now be sown for green fodder in the spring, to be followed by Mangolds, Cabbage, and cattle Potatoes.

Farm Horse Stables (J. O.).—If the horses are stalled and tethered they should stand in pairs as they work together. The double stall is best, and should not be more than 10 feet in width, each animal being tethered at the extreme corner of the manger; they cannot then cross each other, nor can they eat except separately. The rack or manger should be 36 inches above the floor of the stall; the top edge of the manger should be 2 feet wide; at each corner the manger used for corn food, &c., should be 2 feet square at the top and 15 inches deep; the intervening space between these should be for hay or chaff, of the same width and depth, so that each animal may feed in common without disadvantage in any respect. Earth floors should be 2 feet deep, filled with strong loamy earth, perfectly dry and screened to remove stones. When the excavated stalls are filled with dry earth it should be rammed down whilst being filled with a heavy iron-headed rammer—it will then absorb the liquid manure immediately. The earth in places where it is saturated will have to be removed and replaced with dry fine earth as at first, but the removal and renewal need not extend beyond the portion stained. The guide as to the time and necessity for removal must be noted by the tainted atmosphere of the stall, for until they begin to give off the fumes of ammonia sufficient to injure the health of the horses the floor need not be disturbed beyond the actual removal of dung and stained straw. How often the removal of the earth will be required will depend upon the manner and correctness of working out the details we have given; but it will require constant attention on the part of the proprietor, for it must be remembered that the teamsmen or carters are often men of strong prejudices, and will render any plan abortive which they do not happen to approve of. We must, however, observe that the best plan is for each horse to have a box to itself of not less than 10 feet by 12 feet, and then with the earth floor it would not require removal or renewal of earth for several years, because the urine would fall in different parts of the box, the whole surface of the floor would be used for absorption. Still in either case, whether of stalls or boxes, especially for nag horses, if the earth is properly rammed down it will during use remain hard and smooth. Such a floor can be swept clean, and used as well as a concrete or any other floor, without straw or litter of any kind when the animals are absent. We have carried out this system for many years with great success.

REMARKS.

- 29th.—Fine, with bright sunshine; fine prismatic solar halo 3.30 P.M.
 - 30th.—Fine early; damp hazy day, with rain.
 - 31st.—Fine generally.
 - Nov. 1st.—Fine at first and warmer, afterwards high gusty wind and showers; gale at night.
 - 2nd.—Generally dull, but some bright sunshine at intervals; gusty wind; very heavy rain at 7.10 P.M.
 - 3rd.—Fine bright morning; overcast in afternoon, with sprinkle of rain; high wind in evening.
 - 4th.—Very heavy gale in early morning; bright breezy day.
- Temperature higher than in the previous week, and slightly above the average. Much wind.—G. J. SYMONS.

HYBRID PERPETUAL ROSES IN POTS.

THE cultivation of Roses in pots is becoming more general, judging by the numerous questions asked and answered in these pages. All are anxious to grow a few plants in pots to yield a supply of flowers before they can be gathered outside. In gardens where there is only a glass frame some good Hybrid Perpetual Roses may be grown, and blooms will be produced long before any can be gathered outside.

The cultivation of Roses in pots is easy in comparison to that of many plants, and none need fail to produce blooms of first-rate quality from plants in pots if care and attention is devoted to them. No time is more seasonable than the present to commence their cultivation. When blooms are wanted without losing time in preparing the plants it is decidedly the best way to purchase a number, as plants can be had at moderate prices quite suitable for potting. Young plants can afterwards be raised to increase the stock.

It is difficult to obtain good Roses on their own roots suitable for this purpose, as the majority prepared for sale are worked upon various stocks. The question arises, Upon what stock are Roses likely to succeed the best when grown in pots? Upon this, as upon many other subjects, there is a variety of opinions. Some prefer the seedling and cultivated Briar, others the Manetti, and others plants upon their own roots. For pot culture I have found the last-named preferable to worked plants. Roses do well on the Briar, and where standards, half-standards, and others on short stems are required no stock can excel it. Roses also succeed on the Manetti for a few seasons, but will not last long if the union of the stock and the Rose is above the soil. Where there is no choice, and circumstances compel cultivators to pot Roses upon the Manetti, those worked close to the root should be selected. Some work them very low, while others work them so high that it is impossible to bury the union when first placing them in 7-inch pots. In ordering the plants for potting it is well to state what the plants are required for, and request that they be worked close to the root. When the union is buried the plants quickly emit roots from it, and in two or three seasons are independent of the stock. When worked upon the Briar it is immaterial whether the union is buried or not.

Where Roses have been annually raised from cuttings and the cultivator is in possession of plants from fifteen to eighteen months old that were grown for a time in pots and then planted out for a clear season's growth, he will have a good start.

These plants, if they have had liberal treatment, will be equal to any worked plants that have taken three years to produce. When practicable I prefer lifting the plants before the foliage falls, and then roots are formed after they are potted before winter. Roots are seldom formed in autumn when the plants have to be purchased late and perhaps travel a long distance. After potting the plants should not be pruned further than merely removing the long straggling ends of the shoots.

The autumn treatment is simple after potting. They should be plunged outside, covering the pots with ashes or other material. They will need no water if the soil used was sufficiently moist, as the material in which they are plunged will prevent them drying. High winds quickly dry the soil in the pots checking root-action if the plants are stood outside, and on these grounds alone I recommend plunging. It will be found upon examination in a very short time after potting that many roots have reached the sides of the pots, and in consequence vigorous growths will be produced in spring.

The winter treatment entails but little labour. They should have the protection of a cold frame on the approach of severe frosts. Abundance of air on all favourable occasions, and water at the roots when they require it, is then all the attention needed.

The first pruning should be done during the month of February, but before that the frame in which they have been during the winter should be kept rather close, so that growth will commence from the top of the shoots. By this means root growth is encouraged, and after the final pruning the plants start vigorously. In pruning the wood should be well cut back, leaving only about two eyes on each shoot, as no advantage is gained by leaving them longer. The pruning after the first season's growth will much depend upon the cultivator, whether he is an advocate for hard or moderate pruning. The shoots can be left 8 or 9 inches in length, and tied out, bringing the ends of the shoots well down, otherwise they are liable to break only from the one or two buds nearest the end, thus leaving the lower buds dormant. Although this system can be practised with marked success, I prefer subjecting the plants to a more severe system of pruning, and trust more to growths thrown up from the base to form a good plant than by tying out the shoots. The plants cut back closely will produce better wood and finer blooms than by a more moderate system of pruning.

After pruning, and when growth has fairly commenced, air must be carefully admitted to the plants. If this is injudiciously carried out much injury may be done during March, when the foliage is tender and the air at times piercingly cold. It is a frequent practice in spring to start these young plants in heat for the sake of the few blooms they will produce. This is a great mistake, as it proves detrimental to their future development. They should remain under cool treatment, and be allowed to grow and bloom—that is, if the blooms really are required—with the protection only of the frame. If the blooms are not wanted they should be removed as soon as they appear, which will prove beneficial to the plants, and the growth in consequence will be stronger.

Very little syringing is needed early in the season, as the leaves will be covered with dew every morning while the frame is entirely closed during the night, which should be the case

until the season is well advanced and it is safe to ventilate the frame all night. When daily or frequent syringings become necessary about 2 lbs. of soft soap should be boiled for about half an hour, then mixed with four gallons of water. Half a pint of this should be placed in each large canful of water every time syringing is done. The soft soap will leave no stain upon the foliage, but impart to it a fine dark green colour, and the plants will be free from mildew, red spider, and green fly.

Roses while growing require liberal supplies of water, as, if the soil is allowed to become dust dry, the roots soon suffer. When the pots are full of roots liberal treatment should be resorted to; we generally commence giving weak stimulants as soon as the flower buds can be seen.

When the plants are grown in cool frames freely ventilated on all favourable occasions but little staking is needed the first year. Staking, however, is necessary after the first season in order to regulate the head of bloom, as some shoots will grow much longer than others before they show bloom, and if they are not neatly staked they present an irregular appearance when in flower. When all fear of frosts are past the plants should be thoroughly hardened and placed outside. The summer treatment consists of syringing and watering.

When potting is done care must be taken that the drainage is good, and the soil should be pressed firmly into the pots. Roses in pots can be repotted at almost any time during the summer, and sooner than allow the plants to become root-bound in their first pots we prefer transferring them into others 2 inches larger. This can be done after flowering, or as soon as their pots are well filled with roots. We have found the plants do better under this system the following year than if allowed to grow in their first pots until autumn, as their roots would then require to be disentangled, which must be done very carefully, or the plants may be seriously checked. Plants of good size can be grown in 10 inch pots, but plenty of root room should be given them in their early stages, as they make greater progress than if confined in very small pots. After the plants have attained to a fair size and are growing in 10-inch pots, which are large enough for all ordinary decorative purposes, they should be repotted annually. The old ball may be partially reduced and the plants placed again in the same size pots. When the plants are once established the time repotting should be done entirely depends upon when the plants are wanted to bloom. For instance, those required to produce flowers towards the end of February should be attended to towards the end of July, others in August, and none later than the month of September, which gives the plants ample time to become thoroughly established in their pots before they are required for forcing.

The soil most suitable is a strong fibry loam, to which should be added an 8-inch potful of bonedust, and the same or nearly as much soot to each barrowful of soil, with sufficient coarse sand to render the whole porous. If sandy loam only can be procured clay should be spread out to dry during the summer and crushed into dust, by which means it can best be incorporated with the loam. If plants are divided into two batches, and one lot potted in light sandy loam, and the other with a fair quantity of clay mixed with the same kind of material, the wood, quality, and colour of the flowers from the plants growing in the latter will show a marked superiority over those produced by plants grown in the former.

The following are twenty-four useful varieties that thrive well in pots:—La France, Abel Grand, Anna Alexieff, Comtesse d'Oxford, Marie Baumann, Victor Verdier, Charles Verdier, Annie Laxton, Charles Margottin, Jules Margottin, Duke of Edinburgh, Alfred Colomb, Glory of Waltham, Baronne de Rothschild, Senateur Vaisse, Duke of Wellington, John Hopper, Madame Lacharme, Général Jacqueminot, Coquette des Blanches, Mdle. Eugénie Verdier, Hippolyte Jamain, Capitaine Christy, and Magna Charta.—W. BARDNEY.

ALNWICK SEEDLING GRAPE.

I HAD a Vine of this variety direct from Mr. Bell, and my experience of it last year, when it was allowed to carry a few bunches, was exactly that of Mr. S. Castle—a very few large berries and a host of small ones. This year it is everything that can be desired—

fine in berry, bunch, and colour. The colour is as deep as Black Alicante (which I find one of the best Grapes for colouring), and the flavour is far superior to that well-known variety. The way I attained the desired end was by dusting the Alnwick Seedling with the pollen from Trebbiano, care having been taken to perform the operation in the middle of the day when the pollen was dry, ventilation being afforded by the back and front lights to facilitate this. I may mention that I left one bunch unfertilised for trial, and this one was exactly the same as the whole of the bunches in the previous year—viz., a number of small berries and a few large ones. I have no doubt the Alicante would be a good variety to fertilise the Alnwick Seedling with. We have it planted in a late house with only a flow and return pipe.—GEORGE COOKE, *Nannan Park Gardens*.

So much has been written about Alnwick Seedling Grape in respect of its setting qualities that I have sent you a bunch of it to show its character here. I bought the Vine in January, 1879, and planted it in a late vinery well heated, and where there are Vines ten years old of Black Alicante, Lady Downe's, Black Hamburgh, White Frontignan, and Buckland Sweetwater all fruiting well. My employer is so disgusted with the Black Currant type of Alnwick Seedling Grape that he has condemned it; therefore I inarched Black Alicante on the rod last March, and it is doing well.—F. BEZANT, *St. Peter's Hill, Caversham*.

[There were seven full-sized berries on the bunch sent, and upwards of a hundred like Black Currants.]

CULTURE OF GARDENIAS.

IT is surprising that in many good gardens these beautiful flowering plants are so much neglected, as their culture is simple, and the fragrant pure white flowers under proper treatment are produced in abundance nearly the whole year round. The proper flowering season is during the months of April and May, and almost equally profusely in September and October, yet there need scarcely be a week during the whole year when a few blooms cannot be had. Cuttings of the half-ripened wood can be taken in January or February; three being inserted in a 60-sized pot and placed in a close moist heat will strike root readily. They should be potted before the roots become matted, and be again placed in strong heat till they are established in the new soil. It is best to strike a few in this way every year to maintain a stock of young plants. The most suitable soil is a mixture of about one-sixth well-decayed cow manure, the same quantity of broken bones, charcoal, and coarse sand, the remainder to be good fibrous loam.

A well-heated pit having a south aspect is the best structure for Gardenias either in pots or planted out at discretion, but for convenience I advise that they be grown in pots, as the plants may then be taken out to be cleaned, and the pit may also be cleansed with greater facility than when planted out. This is a very important point in their culture, as they are very subject to attacks of green fly, scale, and mealy bug. The latter when once established is very troublesome, and the only effectual way of dealing with it is to grow-on a batch of clean young plants in another house or pit, and as soon as possible to destroy the old stock; then thoroughly cleanse the pit, and introduce the young plants. For scale and fly syringe the plants during the summer months about once a week with a solution of fir-tree oil insecticide in the proportion of about a wineglassful to four gallons of tepid water. The plants should be plunged in leaves, as this will lessen the labour of watering, and during the growing period they must be liberally supplied with water, giving weak liquid manure on alternate days.

A light shading is necessary during the spring and summer months on bright days, with sufficient ventilation to maintain a circulation and no more, as these plants delight in a strong moist heat whilst making their growth. When the shading is removed and the pit closed for the day they should be syringed heavily with tepid water. The best season for repotting is immediately after they have flowered in spring, which will be about the first week in June.

Provided the plants have done well the shift needed will be into pots a couple of sizes larger than those they have occupied, as they are very quick-growing plants. The drainage should be carefully formed of broken pots, pieces of charcoal, and bones, perfect drainage being of the utmost importance, as the quantity of water they require is so large. The larger roots round the outside of the ball should be loosened with a pointed stick to enable them the more readily to take to the new soil, the compost to be the same as that previously advised, and be pressed firmly in the pots, for if this be not done the water will pass away through the new soil, having very little effect on the old ball. The leaves in which they

are plunged should be renewed every autumn, but care should be exercised that the bottom heat does not exceed 70°; therefore leaves only should be used, and these not in any great bulk. A minimum winter temperature of 60° is necessary to keep the plants in robust health.—W. L. H.

THE FORMATION OF DEW.

IN his laudable endeavour to set me right in the matter of dew-formation "W. Y." has confused two distinct phases of the subject. He rightly says that "the cause of the deposit is an interesting one," and when I tell him that my whole theory and practice of giving air, which is a somewhat elaborate one, is entirely based on what I have stated about dew-formation he will readily acknowledge that I am quite alive to its importance. If he succeeds in proving me wrong in this part of the subject my whole treatise stands condemned, but I hope I shall be able to show that what I have stated is tolerably correct.

"W. Y." says, correctly enough, "that hot air can hold more moisture invisible than cold air, and that as the cooling process goes on the air becomes saturated—*i.e.*, can hold no more invisible moisture, but must deposit it or make it apparent in the form of fog, &c." This agrees with a text-book I have by Professor Ansted, where minute particulars and calculations are given thus: "It is found that when the temperature is 50° each cubic yard of dry air (about 168 gallons) can hold nearly 150 grains (one-third part of a fluid ounce) of water. At 32°, or the freezing point of water, only one-half this quantity is contained, and at 70° nearly double can be absorbed and retained in an invisible form. . . . When a change of temperature occurs, and the alteration is in the direction of increased heat, the air continues to absorb; but the moment that a diminution of heat takes place, owing to any cause, not only does the power to absorb cease, but the power to retain is lost, and visible vapour represents the difference."

So far, then, Professor Ansted, "W. Y.," and my humble self are in perfect accord; but when "W. Y." comes to apply the theory to the dew-formation in my fruit houses he is not on such safe ground. He says "It is not the rise of temperature caused by the sun coming out which causes the dew to deposit on the Vines, slates, &c., because any rise of temperature must infallibly cause an increase in the moisture-carrying capacity of the air before it can cause much moisture to be evaporated from the ground in the house or anything in the house; but it is the radiating power of the plants and other substances which have, so to speak, chilled themselves, and thus previously caused the air to deposit dew on them."

Now a dew-deposit in any way is one of the things we have to guard against, and we do not generally allow our fruit houses to fall rapidly to a sufficiently low temperature to cause dew-formation in this way; and practically in well-managed forcing houses, unless in the earlier stages of growth, before the fruit is far advanced, no dew-deposit takes place from a decreasing temperature. Like the outside temperature, that of our houses keeps declining generally till sunrise, when it reaches the lowest point; but it does not decrease so rapidly as that outside, owing to the presence of a warming apparatus and the screen of woodwork, glass, and foliage, which checks radiation, so that what is generally called the dew point is not actually reached. In the earlier stages of the growth of some fruits we are not careful to prevent dew, and with such decorative plants as have not very soft foliage we often find it to our advantage when no flowers are present to allow the dew to form on them. But all this is entirely at our command, and it is not a matter of haphazard work, as "W. Y." seems to imagine. A very little precaution will prevent its formation altogether, and on the other hand, the atmospheric conditions being favourable, dew can be created at will.

For the purpose of my argument dew may be called distilled vapour. We have seen that when the temperature of what is called dry air is 50° there can be present in it as much as a third of a fluid ounce of water to the square yard, and that the temperature has only to rise 20° higher for the water-carrying capacity to be doubled. Now I have repeatedly said that a moist atmosphere is not of itself inimical to the keeping of fruit, but that a dry air is so; and in practice there is certainly no lack of moisture at any time in the houses under my charge, so that dew or no dew is merely a question of warming and ventilating. In distillation the vapour is condensed when it comes in contact with the cold surface of the refrigerator; in our fruit houses, when badly managed as regards ventilation and warming, the fruit may too often be a refrigerator, and condensation take place on its surface.

It matters not how warm the air may become, and its water-carrying capacity consequently increased, if a cold surface is

presented to it there will certainly be condensation, just as there would be on a piece of cold metal held in the steam from the spout of a tea-kettle.

There are, then, two distinct and separate conditions of the atmosphere during which dew is deposited. Firstly, when the air becomes suddenly cooled it can no longer hold all the moisture it contained in invisible suspension, and must deposit it in the form of dew, or it changes to fog, &c. Secondly, when the temperature rises rapidly it takes up of necessity a greater quantity of moisture, and any surface with which it comes in contact that is sufficiently cold acts as a refrigerator, and vapour is condensed on it so long as the said surface remains cold as compared with the air surrounding it. Under the second conditions it will be found that the order of things is somewhat reversed; for whereas under the first-mentioned conditions it is, as said in the book just referred to, the case that "plates of metal (good conductors of heat) remain quite dry, while wood (a very bad conductor) becomes quite wet," under the second conditions, or when the deposit takes place from a certain rise of temperature, the metal (the good conductor) is the first to become wet, and the wood, if not painted, is one of the last.

Everybody must have noticed that when the weather suddenly changes from cold to warm that slates, stones, metal, and many other things become damp in proportion to the suddenness and extent of the change. These substances cannot be warmed so quickly as the surrounding air; the moisture consequently is condensed on them, and there it will remain till sufficient time has elapsed for the warm air to penetrate them. This is just what happens in our houses, if we allow it to happen, almost every day during summer and autumn, and is the cause of a great deal of decay in fruits of different kinds, the disfigurement known as rust on Grapes, the damping-off of flowers and plants, and many other evils. In the dwelling house it is the source of rusty fire-irons, damp clothing, spoiled pianos, and endless colds.

The remedy for all is the same—to guard against sudden fluctuations of temperature. A little fuel to keep up the temperature of a dwelling house during cold weather saves many an aching heart and a heavy bill. I often hear people complain, "Oh! my house is so damp, it gives me the rheumatism; yet I always keep a good fire during damp weather." The mistake is a very general one, and as damp weather frequently comes after frost the saddle is put on the wrong horse. When a sudden change of weather comes after frost I take care not to remain long in any building, public or private, which I know has not been kept well warmed, and the younger members of my family have the benefit of an absence from school till the dew at least has taken its departure from the inside walls of that building.—WM. TAYLOR.

ASPARAGUS IN AUTUMN AND WINTER.

As a vegetable of the highest class there is nothing in our gardens more generally esteemed than Asparagus. It is easily cultivated, and may be grown to give a supply over a period of almost eight months—namely, from early in November till June.

This autumn being so exceptionally wet and sunless, we were rather doubtful whether our Asparagus crowns would be matured and submit to early forcing, but they have stood the test well and promise to be very satisfactory. On October 21st we cut the withered stems from three or four dozen plants. They were then lifted and at once transferred to the bed of a Cucumber pit. Here the bottom heat averages 65° and the surface temperature 10° less. Over the slates in the bed a thin layer of soil was spread, and on this the roots were placed together closely, lightly covered with soil. In a few days many young crowns could be seen pushing through the soil, and on the 4th of November the first dish was cut. The heads were good, and looked both tender and sweet. This is one of the best ways of forcing Asparagus we have ever practised, and if we continue to put two or three dozen roots in fortnightly we shall be able to cut two or three dishes weekly so long as needed.

Respecting the roots it may be well to say a few words. Had the plants been grown on the old-fashioned system, and so close together that the ground could not be seen between them in summer, we should not have expected them to produce useable heads at this season; but our Asparagus is growing now on what is known as the trench system. When one year old they were planted 3 feet apart each way, and now when they are three and four years old we are lifting every alternate one for forcing. At this rate the permanent rows stand 6 feet apart. It is in this way that large crowns are developed and become thoroughly ripened in autumn. One large crown every 6 feet will give more produce, and that of a very superior character, to roots 1 or 2 feet apart. Crowding vegetables is a mistake in every case. I have mentioned the permanent plants as standing 6 feet apart,

but in reality we have no "permanent" Asparagus, as a number of young plants are raised from seed annually, and all follow in rotation for forcing. When the roots have been thinned out to 6 feet apart they are left there for a year or two, and then they are used for forcing too, as in my opinion the only way to keep up a supply of good Asparagus for all purposes is to have abundance of robust young roots coming forward in a rich and suitable soil.—J. MUIR, *Margam*.

BUCKLAND SWEETWATER AND GOLDEN QUEEN GRAPES.

IN reply to "W. L. H.'s" remarks on page 430, my object in saying that Buckland Sweetwater realises a higher price in the market than Foster's Seedling was to show that it is in greater demand, and on that ground, looking at it in a commercial point of view, it must be considered a better Grape than Foster's Seedling; but tastes differ, for what suits one palate does not suit another. I may add that I have to grow Grapes for a gentleman's table, and Foster's Seedling and Buckland Sweetwater are grown side by side under exactly the same conditions, but the latter is in greater demand than the former. I have not a word to say against Foster's Seedling; on the contrary I am of opinion that no collection should be without it. I can bear out all your correspondent "H. M." says respecting Buckland Sweetwater as an exhibition Grape. I have known this variety take first honours at horticultural exhibitions, where competent judges have been employed. The Vine with me grows freely, is very prolific, and the berries set as freely as those of the Black Hamburgh, the berries being large, even, and of a beautiful amber colour. I consider it indispensable in the early vinery.

In reference to Golden Queen, I did not intend to infer that it was an early Grape. It has not been very favourably spoken of. I have heard it does not succeed in all situations, but I find it a free grower and bearer and good setter; bunches not extra large, but symmetrically shaped; berries oval, medium-sized, and of a beautiful amber colour; quality fairly good. It ripens well in a late house with Lady Downe's and Alicante.—G. R. A.

HEATING GREENHOUSES—RIPPINGILLE'S STOVES.

THE present dull, wet, and foggy weather reminds me that the heating arrangements of all glass structures should be at once put in proper working order, as too often frost takes us by surprise. These remarks are not intended for practical gardeners, but all who have a greenhouse filled with plants I would advise to employ a little fire heat to dry such houses once or twice a week, even if it is not frosty weather. It should be borne in mind that more damage is done to plants by ill-ventilated houses than by frost. Ventilate in the daytime on all favourable occasions, and avoid as much as possible fire heat at night. Amateurs and others who have a greenhouse and no heating apparatus are often at a loss to know how to utilise the house through the winter months, but for such there is a remedy by using one or two of Rippingille's stoves, which burn petroleum. They can be placed on the paths as near the front of the house as possible. As this is the coldest part, they will not injure the most delicate Fern if properly managed and if plants are not in direct contact with them. These stoves are managed in the same way as ordinary lamps. Properly trimmed and filled they will burn from eight to twelve hours according to size. During the late severe winters I used them where we had any doubts of the ordinary means of heating being insufficient. They were managed in this way: At 10 P.M., if it appeared likely there would be frost after midnight, the stoves were lighted as a precaution. It often happens that when the most heat is required there is not sufficient—that is, say, five and six o'clock in the morning; at that time the heat generally is on the decline. In such cases the stoves in question will be found invaluable for temporary heating.

The price of petroleum, as a rule, is about 1s. per gallon. Two or three years ago I made some trials with these stoves so as to learn the cost per night for oil, and if my memory serves me the cost was about 3d. per night of, say, eight or nine hours. The simplicity of these stoves will, I think, recommend them; indeed, I know some ladies who manage these little matters themselves, and find pleasure in the occupation.—A. O. W.

AMERICAN APPLES.—It is noticeable that the export shipments of Apples from New York have been larger of late than from Boston, which is the reverse of what they have been in former seasons. The total export shipments for the week ending October 21st were from New York 15,633 barrels against 10,949 from Boston. There had been previously shipped from New York 35,616 barrels, so that

the total export for the season would be 51,248 barrels; from Boston there had been exported this season before last week 24,613 barrels, so that the total exports thus far this season have been 35,562 barrels. The total exports of Apples from Boston and New York this season have been 86,811 barrels. A cable dispatch from Liverpool recently announces the sale of 4000 barrels of American Apples at prices as follows:—Kings, 22s. to 25s. per barrel; Baldwins, 17s. to 20s.; Northern Spy, 15s. to 20s.; Roxbury Russets, 16s. to 18s.; Greenings, 14s. to 16s. Up to the present time the European market for American Apples has been mainly confined to Great Britain, but if the opinion of our Minister to Sweden, Mr. J. L. Stevens, is correct, there seems to be an opening for them in northern Europe, where no good Apples can be grown, as is the case in Denmark, Sweden, and Norway. The few that find their way to these countries are mostly from France, and are to be found only in the larger cities, where they are sold for an average of 6 cents each. Mr. Stevens thinks that the keeping qualities of some American Apples, and their adaptation for transportation, as well as the fact that they are of better flavour than any now found there, make them admirably adapted for the markets of northern Europe. The journey is longer than to England, but the prospective price is greater.—(*American Cultivator*.)

PLANTING ROSES—SPRING v. AUTUMN.

IN reference to this question, raised by "D., Deal," I much prefer the autumn for planting Roses and most trees and shrubs. Roses may be taken up and planted any time from the middle of October until the end of November (weather permitting), and these will give much better flowers the following season than those planted in March: at least that has been the case here in dry soil. In reference to root-action, I may say in the autumn of 1879 snow and frost came on before I had finished planting Roses, therefore the remaining plants had to be laid in until early in February; but although the plants were laid in during a snowstorm, which tended to make the ground very cold, and were frozen in all the winter, when taken up at the above date they had made roots from 1 to 2 inches in length. The Roses in question were dwarfs on seedling Briars. I do not know if Manettis would have made roots similarly when the soil was frozen at the surface, but this instance quite clears up the point about Roses making roots in cold soil. If those Roses had been in their proper place the risk of breaking off many of the very tender rootlets would have been avoided. The plants planted in autumn were much stronger than those planted in spring, all being on the same piece of ground.

Another advantage in autumn planting is that the supply of sap is checked, and they are, therefore, much harder to withstand the frost than free-growing robust plants that have received no check. I have noted this for many years, more particularly in 1866. Early in the autumn of that year I planted a considerable number of standard Roses amongst others in free growth—*i.e.*, having taken out all the weak plants from the beds and filled in with the new. A severe winter followed, and the result was that three-fourths of the plants not moved were killed outright or died during the following summer, whereas the fresh-planted Roses were in most cases quite safe. But it must be remembered there are exceptions to all rules, and it would be better to plant in spring than to plant into very heavy wet soil in the autumn, planting them as early as possible in the spring as soon as the ground is in good condition; thus, as in all cases, practice must vary according to circumstances.

In reference to Teas, I would prefer to plant them in autumn if on the seedling Briar; if on their own roots out of pots in May. Plants in general suffer much from March winds when they are planted in spring, and if very dry even require water. Mr. Prince's Teas were very fine, but if Mr. Prince was asked the question I have no doubt but he would prefer planting in the autumn and giving slight protection; but, as I said before, practice must vary according to circumstances. I should much like to hear what other rosarians have to say on the matter.—J. BROWN, *Great Doods, Reigate*.

I AM surprised to learn from your correspondent, "D., Deal," on page 402 of the Journal, that the "weight of evidence" tends towards spring planting as against autumn planting of Rose trees. I prefer the autumn for planting. But there is autumn and autumn. September, October, and November represent autumn, therefore when we talk about autumn-planting we take the mean, which means October. Surely the earth is warm then. It is not fair, I think, to condemn autumn planting because this year it seems to be an impossibility. Surely in ordinary seasons the last week in October and the first in November are the best weeks for planting. Moreover, if the weather is wet and cold and the winter severe the soil will be colder in February than it is today (4th November); moreover, I distinctly assert from actual

experience that root-action in autumn is a most positive fact. The winter of 1879 and 1880 was a very severe one. The previous autumn I bought in a goodly number of Roses, and had them all planted early in November. They were well mulched with light dry material. In February I had occasion to transplant many of these newly planted trees, and I was astonished to find how their roots had started; in every plant one could see innumerable little white rootlets. So much for root-action in winter in "cold" soil.

And now to argue from the other side of the question. If you always plant in February you must prune before trees are established. If you delay pruning for six weeks after planting your blooming season is too late for the first shows. I am writing only of Hybrid Perpetuals, with Teas the case is quite different. These precious darlings require much looking after; they are the first out and the last in. Whenever I buy in any Teas I invariably heel them in and plant out as early as possible in March—that is to say, as soon as the ground is in working order. In six weeks they are growing fast, and the middle of April sees them beginning to develop flower buds on the top shoots; but it does not matter, for Teas are much better if pruned when the sap is very active, whereas with Hybrid Perpetuals the opposite is the case. At least this is my impression. "D., Deal," says that Mr. Prince's experience is worth a bushel basket of theory. So it is; but Mr. Prince and "D., Deal," in the matter under consideration, had their eyes on Tea Roses only.

And now let me strongly advise all young rosarians to plant Hybrid Perpetuals very early, and not use rich farmyard manure as a mulch. Whatever is put on the ground both as a stimulant and a protection should be of a dry nature. I feel assured that many thousands of Rose trees have been killed the past four years by heavy dressings of very wet "muck," so heavy that the moisture has been retained for weeks, to be thawed every day that the sun shines and frozen again every evening Jack Frost chooses to come. Put it on dry and light, not heavy and wet. At least this is my experience.—J. A. W., *Alderminster*.

YOUR correspondent "D., Deal," in his letter on "Planting Roses in Autumn" asks your readers for their experience in this matter. As my limited amount of Rose-growing is conducted on a soil which I should imagine to be most highly suited for autumn planting—viz., a deep and dry loam on limestone subsoil, I offer my experience such as it is.

For the last ten years I have planted Roses both in November and February, and never thought there was much to choose between the two seasons until two years ago, when I bought 150 dwarf Roses, twelve Teas, and the rest Hybrid Perpetuals. These I laid in the ground, covered a foot above the roots until February. The winter was very severe, a thermometer registering 40° of frost, but I only lost two or three, one of which was a Tea; the others, though a few were killed down to the earth line, were fairly fresh and uninjured, and when planted grew and flowered well. At the same time well-established trees of two and three years' growth in the open beds were either quite killed or much injured, but not quite so universally so as in the preceding year, 1879. But why should a frost of 29° in 1879 do more harm than one of 40° in 1880? I think for two reasons: firstly, because in 1879 we had a late damp summer and autumn without early frost, keeping the wood in a growing and unripe state until December: early in which month my second reason, an exceptionally severe frost for the time of year, came, the effect on the sap vessels, still full, being to burst them and kill the trees; indeed, it treated the unripe Rose shoots as it often does full water pipes and bottles.

I think the best way to protect Roses from frost is to take them up about November 1st, and lay them in until February; but I hear some people say, "Oh! my Roses are still growing." Then there is all the more reason for taking them up to stop their growth. This season Roses are growing very late, and now is the time to put this theory into practice. To summarise: my experience says, "Plant in February and prune close."—I. F., *Lincoln*.

I THINK this question is a matter of season, soil, and climate. As to season, for instance, last November I transplanted several hundred Rose trees, many of them old plants. Not more than three or four of the most sappy ever flagged; the majority went on growing, and many actually opened during the next month (December) buds which had been previously formed. On the other hand, on *May 10th*, 1879, I moved about two dozen Rose trees from another county five or six hours' journey by rail. They all lived and grew well. I cut a bloom from one for a show, but cannot remember whether I actually placed it in my stand or not.

As to soil and climate, I have found that in a light soil and east-midland climate (which are the only conditions of which I have any experience) Roses do begin making fresh roots very soon after planting in an average November. I would therefore, under my conditions of soil and climate, always plant in November, and avoid "laying-in," for fear of breaking the new roots, as much as possible. In my light soil I can plant when others cannot because of the wet. I have been planting to-day (11th), and found the soil after the late heavy rains as friable as I could wish. I also expect that, as a rule, the ground is not only colder but also wetter in February than in November; but in a heavy soil, or the climate of "A NORTH COUNTRYMAN," there is, doubtless, much to be said for spring planting. If one could make sure of getting them, would it not in such a case be better to buy in the spring, and let the nurseryman run the risk of frost?—A. F. M.

[It is unsafe to defer purchasing Roses until the spring, as the best plants of many varieties are always sold in the autumn. We have more letters awaiting publication on the subject under discussion.]

THE DOMINO APPLE.

MANY inquiries have been made from time to time relative to this Apple, and we have endeavoured, but hitherto without success, to ascertain the origin of the Domino. We have received several letters on the subject, and also samples of fruit. We publish a section of one of the finest. It was grown in the garden of A. S. L. Melville, Esq., Longhills, Lincoln, and the following

Fig. 74.—The Domino Apple.

note from the gardener, Mr. G. Picker, accompanied the parcel:—"I have made many inquiries respecting the origin of the Domino Apple, but no one to whom I have applied appears to know anything about it. It is our best early culinary Apple, and reached here by mistake—a mistake of the right sort. Mr. Melville some years ago ordered some fruit trees from Mr. Henry Merryweather of the Southwell Nurseries, and although this variety was not ordered it was sent, and on the error being pointed out to Mr. Merryweather he wrote and said Mr. Melville would not regret planting the Domino, and he was right. The cook does not care to use any other cooking Apple for the dining-room whilst the Domino can be had. Her reason for this is because it is the best and whitest-fleshed Apple that she ever cooked—time for cooking from fifteen to twenty minutes—and it breaks down in the dish well, but not too well; also it takes less sugar than Lord Suffield. As an early kitchen Apple I repeat it is the best of all here. The tree is a healthy and free grower, forming a good pyramid, and is a great bearer. It comes into use here the last week of August, and Lord Suffield the first week of September. I have seen Domino described as an October Apple, but with us it will

not keep sound until then. On the 4th of October I examined fruits that I had left for the purpose of knowing how long it would keep, and each fruit was dotted with dark patches that showed plainly through the skin, and the flesh had turned very soft. I may mention that we lifted the tree two years ago, and placed the roots nearer the surface. That may have caused the fruit to be a little earlier; but other trees in this neighbourhood prove that this is a very early Apple."

Our description of Domino is as follows:—A Codlin. Fruit large, somewhat cylindrical or blunt-conical in shape, with a prominent rib on one side, which makes it larger on that side of the axis, and consequently if measured through that diameter it is as wide as it is high. It has five more or less prominent ribs, which terminate in corresponding ridges round the eye. Skin of a uniform greenish yellow when ripe, and pale grass-green before it ripens, and covered with distinct russet dots, but no colour. Eye closed, set in a deep, angular, and irregular basin; tube long conical, inclining to funnel-shaped; stamens median. Stalk half an inch long, inserted by the side of a fleshy protuberance, which is generally well developed. Flesh yellowish white, soft, and juicy, with a mild acidity. Cells open, Codlin-like; cell-walls elliptical.

This is a very useful Apple, and is, we think, in the Chiswick collection. It belongs to the class of Lord Suffield, Golden Spire, and such early-bearing and prolific culinary varieties.

DESTROYING ANTS.

IN reply to "J. H. W." I may state that we have had plenty of ants in the vineries here. The method adopted to eradicate them is to find out their hiding place or home, and if it be among soil. When practicable remove the whole body containing ants and eggs to some distant exposed part of the garden where they will probably be picked up by birds. I need not say there will be numbers left behind, as I have seen them busy night and day. To capture those remaining procure a dead bird, or several to make short work of it, cut them open at the breast, and lay them where the ants frequent. Go round as often as it may be necessary. The birds will be often found covered with ants, when they should be immersed in a can of boiling water, and laid again in their runs.—C. WARDEN, *Clarendon*.

AT one time I was much troubled with ants in my Peach house, which were very destructive when the fruit was ripe. I tried treacle, which was of little or no use; I also used hot water, which killed what it touched, but I do not think that safe where the roots are inside and near the surface. I also tried a strong dose of hellebore, both liquid and the powder, but I found they only went to fresh quarters of the house. At last I tried some freshly slaked lime. I had some standing in a pot ready, and whenever I saw any ants about I gave them a good sprinkling; also where I found they made their nests I placed a quantity, and washed it in as well as I could. By a little perseverance I have entirely cleared the house of the insects, and I think if "J. H. W." will give the lime a good trial he will not be disappointed with the results. It is not so disagreeable to use as paraffin, nor so dangerous.—J. GILBERT.

A CORRESPONDENT of the Journal asks how to deal with the small ants which sometimes appear by thousands in gardens and houses. Mr. Newman strongly advised the following plan:—Dip lengths of stout twine or rope into a syrup made of coarse sugar, and lay these near the holes whence the ants issue, or in their favourite haunts. Upon these the ants will cluster thickly, and the strips taken up can then be plunged into boiling water.—J. R. S. C.

THE GREENHOUSE AND ITS INMATES. POPULAR FLOWERING PLANTS.

BIGNONIAS.

THESE are useful plants for training up rafters and pillars, and for covering walls inside greenhouses or conservatories. For small houses they are not quite suitable, but when room can be spared for their due development they are most acceptable. They should be planted out in good fibry loam and peat in equal proportions, with a little sand and broken bones and charcoal to keep the compost porous and open. The kinds ordinarily grown are *B. Chamberlaynii*, *B. grandiflora*, *B. speciosa*, and *B. venusta*.

BOUVARDIAS.

These may be had in bloom at any time. Most people like to

have them in flower during winter, for they will bloom as freely and as satisfactorily at midwinter if a temperature of from 50° to 60° is maintained as at any other time. Where this cannot be afforded they may be prepared to flower late in summer or in autumn. Plants which were bought in autumn may be treated like a *Fuchsia* during winter and cut down in spring; afterwards they should be started and grown in a temperature of 60° until June, when they may be placed in cold frames. In spring, after the young shoots are a couple of inches long, they may be taken off with a heel and struck in bottom heat along with other cuttings, say on a hotbed. After the cuttings are rooted they will require potting off, and for this purpose fibry loam and leaf soil with a little sharp sand should be employed. After potting they should again be returned to the frame and plunged, keeping a genial top and bottom heat.

Potting and pinching must be attended to as may be necessary. Young plants may be placed in 5 or 6-inch pots the first year. After the pots are well filled with roots a little liquid manure should be given occasionally. To keep the plants dwarf and bushy they must be kept near the glass and repeatedly pinched. By June they may be placed into ordinary frames without bottom heat, and liberally ventilated during fine weather. Pinching must be discontinued early when early flowering is wanted, but in no case should the plants be pinched later than July. They must be transferred to their blooming quarters by the middle of September at the latest. They are subject to the attacks of different insects. Syringing or dipping in tobacco liquid may be occasionally resorted to as a preventive or check. These remarks apply equally to young and old plants; only old plants require more root room. The following kinds are all good:—*elegans*, *Hogarthii*, *Bridal Wreath*, *Queen of Roses*, *jasminoides*, *Vreelandii*, and, although not free-flowering, *B. Humboldtii corymbiflora*.

CALCEOLARIAS.

If seed was sown during July or later, and the young plants obtained pricked out, they should when large enough be potted and grown on in the cold frame. As long as the weather is so mild that frost can be kept out of the frames with the aid of mats, the plants should remain there, the frames being ventilated on all favourable occasions. They must be shifted before they are root-bound, this being important, until they are established in the pots in which they are required to flower. When they are removed to the greenhouse they should be placed in a light and cool position. Heat is their worst enemy, and after that aphides. Should the latter appear fumigation must be resorted to, or the plants will not thrive. Syringings of soapy water will prevent its appearance.

CINERARIAS.

These need similar treatment to the *Calceolarias*, only tobacco smoke injures and very little frost destroys them. Sponging may be necessary in order to keep down aphides.

TREE CARNATIONS.

Tree Carnations are beautiful plants for winter blooming. They are easily propagated by layering, or even by cuttings in spring, if these last are placed on a slight bottom heat. During summer they do better planted out than when kept on in pots. A compost of loam, cowdung, and sand suits them. They should be carefully lifted and potted in October, and placed for a few days in a shady position until new roots are produced.—J. H.

LIFTING PEACH TREES—SHALLOW v. DEEP BORDERS.

PROBABLY many of your readers will arrive at the conclusion that I have "caught a Tartar" in "A. B. C." (page 405), and perhaps I ought to be thankful for being "let down" in such a kindly manner. However, I venture to return to the subject, not because I am desirous of having the last word, but with the motive of righting myself in the estimation of my critic.

Relative to the disposition of the fertile surface soil, it does not follow that the whole of this was placed at the bottom of the border and out of the reach of the majority of the roots. On the contrary, at one end of the house the border, independent of the drainage, was found to be upwards of 3 feet in depth and the roots were very low. Now, we were not in a position to entirely lift the whole of the trees and materially change the depth of the border, neither would it have been wise to have done so owing to the age and size of the trees. Under the circumstances we did not attempt to bring all the roots preserved to the surface, the only plan being to bring them up so as to distribute them throughout the new soil to a depth of about 18 inches. In this manner the fertile surface soil was not entirely thrown away, neither did

it much encourage a downward tendency in the roots. It was not a question of making a new border; what we had to do was to make the most of or renovate the old one.

It appears "A. B. C." would have added to the drainage, so as to make the border more shallow, and in my opinion would thereby have greatly injured the border by over-draining. I preferred an extra foot of soil to one of drainage, but it does not necessarily follow that I advocate the formation of deep new borders for fruit trees. On the contrary, for some months past I had set myself to write upon the subject of forming both shallower and narrower borders, but "A. B. C." anticipated me; yet I may still publish my ideas on the subject.

Perhaps I was wrong in asserting there is a danger generally in lifting the trees annually. At the time I was thinking of our Peach houses, where I am confident under the circumstances it is both impracticable and unnecessary to lift annually. "A. B. C." must surely err in stating (page 405), "Lifting three trees in a house, say, 60 feet in length occupies no more time than top-dressing the border." His must be a case of partial lifting. If he does the same as Mr. Bardney—viz., digs up his trees and transplants, he is favoured with most excellent labourers. That Mr. Bardney is most successful in his practice I can and have borne testimony, but I also happen to know he is fortunate in having an unlimited supply of water, and which can be applied at a minimum cost in the shape of labour. What if others imitated his practice of digging up without being either in a position to be able at all times to give abundance of moisture to the roots? In this case it would be to a certain extent risky, as if the necessarily much-reduced balls became dry, the same as frequently happens with newly potted plants under the same conditions, a partial failure must inevitably result.

I repeat, annual lifting is quite unnecessary and may be risky. I hold it is a better plan to lift a few trees every season rather than lift all every third year, and to trust to the annual top-dressings and abundance of moisture at all times to keep the roots near the surface. The whole of our borders will shortly have the surface soil cleared off so as to bare the roots, and on these will be disposed a top-dressing of loam, short manure, and wood ashes. This during next season will be thoroughly taken possession of by the roots, and I have every confidence in securing valuable crops of fruits from all the trees.

The Vine border, which it will be remembered I stated is composed exclusively of brick ends, mortar rubbish, bones, and charcoal, was formed by Mr. Challis, the very able gardener at Wilton House near Salisbury. It is one out of several formed in low forcing houses, which are planted permanently in preference to fruiting Vines in pots, this preventing hard forcing in the larger vineries. The Vines in this border have necessarily to be more frequently watered, and, as before stated, look even more vigorous than, and are said to be quite as profitable as, those planted in the usual compost. Beyond this at present I can say but little, as my visit was unfortunately of much too short duration. I alluded to the curiously constructed Vine border in order to strengthen my argument with regard to the employment of what "A. B. C." terms rubbish in the composition of Peach borders, as there does not appear to be a marked difference in the respective requirements of Vines and Peach trees. Shallow well-drained borders such as "A. B. C." prefers, coupled with annual lifting, neither require root-formers nor acrating, but as our case is totally different we prefer not to separate the brick ends from the mortar rubbish.—W. IGGULDEN.

[The difference between our correspondents arises entirely from the differing conditions of the trees and soil. While those in charge of "A. B. C." and Mr. Bardney may be lifted without any risk whatever, Mr. Iggulden would have acted unwisely to have wholly uprooted the old neglected specimens which he is endeavouring to renovate. Having seen all the trees referred to we have an advantage over our contributors, both of whom are excellent cultivators, and are thus able to settle the point at issue.]

CULTURE OF THE TUBEROSE.

THERE are several varieties of Tuberose, such as the pale yellow, white, and double white African and American; it is, however, unnecessary to enter into details as to these, for we have grown all and found the same treatment suitable for each variety. To maintain a long succession of bloom it is best to procure bulbs at different seasons, say early in autumn and again in spring. There is no difficulty in getting these to flower; in fact, their treatment is very simple indeed. Pot them as soon as received in a 32-size pot, placing three or four bulbs in each pot, according to the size of the bulbs, or two or three in a 48-pot. The soil should consist of good turfy loam, leaf soil, and sand, pressing it down firmly

round the bulbs. After the pots are full of roots watering with liquid manure is an advantage; a small quantity of guano placed in the water we find very beneficial. Pot the bulbs in the above soil, and plunge in ashes in a cold frame. After being in this position for a few weeks they may be placed in bottom heat if desired to flower at once, or they may be introduced in batches so as to prolong the flowering season. The principal point to observe is not to give the tops too much heat, or they will be sure to draw up weakly and prove almost worthless. A brisk bottom heat of 65° or 70°, with plenty of ventilation night and day, will soon start all the bulbs into flower.

By keeping them in different temperatures the early autumn batch may be made to last till the early spring ones succeed them, the treatment being the same. Keep them in frames till growth commences, then plunge them in bottom heat, having the roots warm and the tops cool. They may be placed out of doors when all danger of frost is past, and by so doing a long succession of bloom may be obtained. They will grow and flower freely in an ordinary greenhouse after the flower-stems appear.—J. SMITH, *Mentmore.*

AT a general meeting of the ROYAL HORTICULTURAL SOCIETY, held on Tuesday at South Kensington, Colonel R. Trevor Clarke in the chair, the following candidates were duly elected Fellows—viz., J. E. Lewis Boulton; Adhae Singh Gom, Assist.-Commissioner, Central Provinces, India; James Loomes, and William Warren.

— THE PROPOSED PINK SHOW is postponed for the present on account of the exceeding paucity of cultivators who might be counted on to exhibit Pinks in London in June, 1883. The promoters of the Exhibition held a brief conference at South Kensington on Tuesday last, and agreed that while there would be no difficulty in obtaining the needful funds, there might be great difficulty in obtaining the needful flowers. It is satisfactory to hear that considerable interest in the Pink has been aroused, and it may be found an agreeable task to organise a show for 1884.

— WE are informed that there is a very fine display of CHRYSANTHEMUMS IN THE PINE APPLE NURSERY, including many varieties that have not hitherto been seen in bloom in this country.

— THE handsome specimen of MASDEVALLIA TOVARENSIS shown last week at the Brixton Chrysanthemum Show by Mr. Salter, gardener to J. Southgate, Esq., Selborne, Streatham, proved the great value of this species admirably, as it had about five dozen of its pure white flowers, though growing in a pot of moderate size—about 6 inches in diameter. It is unquestionably the freest of all the Masdevallias, and it is surprising what small pieces will produce flowers. When associated with some of the richer-coloured species, such as M. Lindeni or M. Harryana, it has an excellent effect. The flowers are also useful for bouquets and buttonholes.

— MR. J. CLARKE sends us the following note on the NEW PEA GENERAL GARFIELD:—"A valuable addition to our list of new Peas will be found in Suttons' General Garfield, the haulm being laden with handsome pods containing eight or ten large peas in each pod of excellent quality. It will prove a fine Pea for the exhibition table, while its hardy constitution enables it to a certain degree to resist the mildew."

— A CORRESPONDENT writes as follows relative to MIXING FLOWERS:—"We have a house filled with white and yellow Chrysanthemums—Mrs. G. Rundle and Mr. G. Glenny—and the effect far surpasses any mixture of colours I have seen. A house

alongside is filled with Zonal Pelargoniums in various shades from white and pink to deep crimson, and the effect at this season is rich and glowing; but for chaste effectiveness I greatly prefer the mass of pure white and soft yellow. We all admire the meadows in early summer besprinkled with Buttercups and Daisies, but do not always follow Nature in these matters. The truth is, we like to get together so many kinds of particular flowers that we often secure mere prettiness in effect when we might either have something strong in simple colouring, as in the case of our Chrysanthemums, striking in simplicity. It really cannot be too often insisted on that rigorous selection not only gives the gardener the best returns for his labour, but lightens his work to a very considerable extent. Amateurs especially have a strong desire to get everything into their gardens they can lay hands on, nor can it be denied that many gardeners have the same desire to multiply their floral dependants. It may be safely set down as a truism that he who grows the fewest kinds of flowers, and these few again well selected as to variety, will be always better prepared to meet sudden or continued demands than he who in trying to grow everything, has only a little of anything, and that little is quickly used."

— AMONGST NOVELTIES IN VEGETABLES now being distributed by Mr. Laxton we find, amongst others in the list, two new Peas—*Evolution*, described as "the largest and finest-podded Pea yet issued," and *William Hurst*, a prolific blue wrinkled variety ripening with *Sangster's No. 1*; also a new Runner Bean—*The Czar*, which is stated as producing pods 14 inches long by $1\frac{1}{2}$ inch wide; a new Longpod Bean, *John Harrison*, the result of a cross between the *Mazagan* and *Aquadulce*, the finest type of the *Seville Bean*; the *Early Purple Argenteuil Asparagus*, and *The Schoolmaster Apple*, a variety of great promise that has been certificated by the Royal Horticultural Society.

— GARDENING APPOINTMENT.—Mr. John Miller, recently of Clumber, has been appointed head gardener to R. G. Hargreaves, Esq., Cuffnells, Lyndhurst, Hants.

— A GRANTHAM correspondent sends us flowers of *CHRYSANTHEMUM SEGETUM*, and observes:—"This beautiful little yellow flower grows in a field about three miles from Grantham. I consider it very pretty. I have had some in water for three weeks, and they now look as fresh as when I first gathered them." The *Corn Marigold*, as this species of *Chrysanthemum* is popularly named, is one of the most attractive of our native plants, and in some gardens it is cultivated for the sake of its rich golden flowers. A double form is also included in some gardens.

— M. LINDEN, the Director of the *COMPAGNIE CONTINENTALE D'HORTICULTURE*, informs us that they intend opening in their grounds, on the occasion of the great Horticultural Exhibition to be held in Ghent next April, a special exhibition of their products. When the new conservatory and greenhouses, which are in course of construction, are finished, the nursery will contain upwards of 100,000 square feet of glass, not counting the frame surface, heated by over 8 kilometres (five miles) of piping. A new and principal entrance by the *Boulevard de la Coupure* will put the establishment in almost immediate communication with the casino, where the International Show will be held.

— THE melancholy tidings of the sudden death of Mr. F. FAULKNER, gardener to F. R. Leyland, Esq., Woolton Hall, Liverpool, which occurred on the evening of the 7th instant, caused quite a sensation amongst *Chrysanthemum* growers in the metropolitan district. Mr. Faulkner was one of the three winners of the twenty-five-guinea challenge cup, offered by the Vice-Presidents of the Kingston *Chrysanthemum Society*, the contest for the final possession of which has been fixed for this day (Thursday), the other competitors being Mr. Tunnington of Liverpool and Mr.

Harding of Putney. Mr. Faulkner was a good gardener and successful exhibitor of plants, flowers, and fruit at some of the leading shows in the kingdom, and a career of great promise has thus terminated in a painfully unexpected manner. He was, we believe, a native of Tooting or the neighbourhood, where he was well known and highly respected. He had every appearance of being a very strong and healthy man about forty years of age, and on that account his death has caused the greater surprise amongst his numerous friends. We regret exceedingly to learn that he has left a family of seven children, all under fourteen years of age. Great sympathy is expressed with the widow in her bereavement, and we doubt not this will be shown in a substantial manner by the friends and acquaintances of the deceased, for there must be many who would be glad to aid, if aid is needed, in such a melancholy case as this. We believe Mr. Leyland will place his blooms, grown by Mr. Faulkner, in competition at Kingston.

— THE following paragraph on RAILWAY GARDENING, which we have seen before, has been sent to us for our opinion thereon:—"If our railway companies would employ a forester and a gardener or two, they might utilise their thousands of acres of waste land for crops, grass, fruit trees, and so on, with profit. In many parts of Belgium the land has been planted with fruit trees and other things several years, and in Wurtemberg, for about twelve years past, a forester has had charge of the lands. He pays particular attention to planting the slopes of excavations and embankments to prevent washing and slipping, grows quick fences, and, where practicable, fruit and timber trees. The gardens at the stations are largely devoted to fruit, and so made useful and ornamental at once. A profit of about 14s. an acre has, it is said, been made for the past five years on the ground so utilised. Why should it not be done in England?" We add: because more than half the land on the embankments is worthless—barren rocks or inert subsoil—all the best material having been removed in excavation; besides, a much greater inducement than "14s. an acre" must be offered before such work will be attempted on any large scale in this country. There is plenty to do in reclaiming waste land and increasing the productiveness of thousands of acres already reclaimed without at present engaging in enterprises of the nature suggested.

— THE *American Cultivator* states that Erastus Corning of New York owns a \$130,000 collection of ORCHIDS, and Jay Gould has a collection worth \$60,000, in English money about £26,000 and £12,000 respectively.

— "VICK'S ILLUSTRATED MAGAZINE" recently described a NEW AMERICAN STRAWBERRY named JAMES VICK in the following terms:—"The points of merit claimed for the James Vick are briefly these: 1, Fine quality, unusual vigour, and hermaphrodite or perfect blossoms. 2, Colour, form, and firmness of berry, which approach the ideal. No white tips, no coxcombs. 3, Ability to stand on the vines a week after ripening without becoming soft or rotting, or losing quality or much lustre. Instead of softening it shrinks a trifle, and becomes firmer than when first ripe. 4, Uniformly large size, and productiveness unequalled by any other variety. One hundred and eighty berries were counted on one average plant, and from one row about 100 feet long nearly two bushels of berries were gathered. How well this variety will sustain the claims made for it is yet to be proved, and possibly it might have been better to have given it another season's trial before making it known, but we respect the judgment of those having it in charge, and trust it may prove to be the acquisition that it now promises." Unfortunately American Strawberries have not been found to succeed in England.

— AS affording a striking contrast between the insect pests

of this and warmer climates, the following in reference to LOCUSTS IN CYPRUS, from the *Colonies and India*, is worthy of note:—

"A regular campaign has been carried on against the locusts in Cyprus, the reward offered by the Government of Cyprus of one piastre per oke, or about a halfpenny for every pound of eggs—subsequently raised, however, to three times that sum as the eggs became scarcer—having so stimulated the natural desire of the people to rid themselves of this pest, that the enormous amount of 1320½ tons of eggs were collected in seven months. Besides the eggs vast quantities of locusts were caught by means of screens and traps placed all over the island. Many of these insects were got rid of by burning them in great heaps, and the eggs were probably destroyed in the same way; but it would surely be worth while for the Government, which pays a sum of £30,000 or £40,000 in the shape of 'head money,' to get some direct return for this expenditure, or enable the people to derive a further advantage from the destruction of the insects by devising some means of utilising the dead insects. At the other end of the Mediterranean and in the Bay of Biscay a paste made from the bodies of Algerian locusts is used with great success in the sardine fishery, and it is probable that the same bait might be used in other fisheries as well. The locust eggs could, perhaps, be still more easily utilised in the same way. All that would be necessary would be to kill the eggs by placing them in boiling water, and if then placed in bags, bottles, or casks they would make an excellent bait for shore fishing. By carrying boatloads of their spoil out to sea the locust-hunters might develop an important fishing industry round the coasts of Cyprus."

CULTURE OF HARDY PLANTS.

It is pleasing to find, that although the Rev. Wolley Dod is an ardent lover of hardy plants, he does not recommend their use without at the same time assuring his readers that, in order to have them do well, constant attention is required. My experience has been that there is more work in connection with these in keeping them in good order, especially from July to November, than with ordinary bedding plants. This year I saw a large flower garden of ordinary bedding plants, and some large borders of hardy plants managed with a minimum of labour, and the bedding plants had much the best of it in effect. There had been no time to stake and tie plants as they required it, nor to remove decayed flower stems; consequently in September, when the tender plants were glowing, the hardy flowers were comparatively wild.

As I find it a good system periodically to lift hardy plants and retrench the borders and replant young plants instead of the older plants, and have recommended this system, I will give a short reply to your correspondent's statement that "this is a bad plan." Our plan is to have strong rooted plants ready of those which are to be thrown away, and before commencing to trench the borders condemned plants are first cleared off; then the borders are manured; then as the ground is turned all bulbous plants are lifted carefully and set back into their old positions, or if too large divided and replanted as smaller clumps. Your readers may be assured that if properly performed the borders will be much better the first year than they will be the third, as it always happens, at least with us, that notwithstanding surface dressings the borders are never so fine after the second year.

With regard to Phloxes, the simplest way to increase these is to divide the plants now and replant at once. Our Phlox beds always receive a dressing from 6 to 9 inches thick of manure, and with three to six shoots left to each plant we have few flowers to rival a bed of these. Mr. Wolley Dod's plea for "real cultivation," as he calls it, is worth the consideration of all. Starved flowers afford no pleasure.—B.

SCRAPS ABOUT FRUIT.

PEASGOOD'S NONSUCH APPLE.—Your correspondent, "J. W." (page 364), has made a slight mistake in reference to Lady Henniker Apple. The variety to which he refers is Peasgood's Nonsuch. I have not yet fruited Lady Henniker Apple, but from specimens which I have seen I should say it partakes more of the Codlin type, while Peasgood's Nonsuch is evidently nearly related to Blenheim Orange. Peasgood's Nonsuch is certainly very handsome, and when it succeeds it is a most desirable variety to grow. My own experience of it is very limited, and I should be glad if some of your readers who grow this Apple would state their experience of it as a free-fruited variety. It is now some years since Messrs. Brown of Stamford distributed this variety, so that there should be plenty of bearing trees in the country.—J. SMITH, *Mentmore*.

SOLDAT LABOUREUR PEAR.—In reply to the inquiry of your

correspondent, "J. E." in the last number of your Journal (page 404) I beg to state that I have two trees of Soldat Laboureur, one of the Pears about which he asks for information, which I had many years ago from Mr. T. Rivers' nursery under the double name of Soldat Laboureur or Orpheline d'Engheim. It was there described in his list as "very productive and of the highest excellence," and so it has fully proved with me until the last two or three years, when it ceased to bear well. This year it has resumed its character and borne a good crop. It is of medium size, coming in about Christmas, and in quality most excellent.—C. P., *Herts*.

MARIE GUISSÉ PEAR.—A correspondent recently desired information about this, amongst other Pears, that are not commonly grown in gardens. Marie Guisse I had from Belgium a dozen years ago, but it has not given satisfaction, the fruits often failing to ripen, or at least to develop the good qualities that this variety is reputed to possess. The fruit is large, uneven, and of a brownish tint, and when in good condition is juicy and pleasantly flavoured. But in the north, at least in Yorkshire, it is not by any means a Pear to be depended on, although it may succeed better in more favoured localities.—M. D.

DOUBLE CROP OF PLUMS.—In answer to your correspondent on page 427, we have here some young pyramids of Victoria that bore two crops this year. In the second crop the fruit was not so large as the first, but they were well coloured, and proved useful for kitchen purposes. This is the first time that I have known Plums bear the second time and bring them to perfection.—G. T.

APPLES FOR THE NORTH.—I observe (page 424) Mr. Wither- spoon strongly recommends as a suitable Apple to plant in the north of England and Scotland a sort called "Ringer." Can he or any of your correspondents tell the difference, if any, between Ringer and variety largely grown in the west of Scotland called Tom Montgomery? It will also be interesting to know something about the origin of Ringer. Tom Montgomery is an old sort. However, there were large trees of it in my father's garden more than thirty years ago. I have not had an opportunity of comparing Ringer with Tom Montgomery, but, judging from memory both of the tree and fruit, I am strongly of opinion that they are the same.—J. MACINDOE.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 14TH.

A LARGE and interesting meeting was held on Tuesday last, Pelargoniums, Chrysanthemums, and the vegetables in competition for special prize forming the chief features.

FRUIT COMMITTEE.—Harry J. Veitch, Esq., in the chair. A bronze medal was awarded for four extremely handsome Smooth Cayenne Pine Apples from Mr. C. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury, which weighed 29 lbs. 4 ozs., the pips large and eight or nine deep. Mr. Horley, Toddington, Dunstable, sent some fine Naseby Mammoth Onions and several seedling Apples. Mr. T. Laxton, Bedford, sent a seedling Pear something like Beurré Diel. Mr. Nelson, Dunmore House, Stanwell, near Staines, sent six fruits of a seedling Apple named Nugget. Mr. C. Ross exhibited tubers of his new Potato termed Rival, even and clean, which was referred to Chiswick for trial. Messrs. Downie & Laird, Edinburgh, sent a seedling black Grape with large berries, juicy, and of good flavour. The Committee considered it a promising Grape, and desired to see it in January. Messrs. Carter & Co., High Holborn, exhibited their new Golden Queen Onion. A letter of thanks was awarded to Mr. E. Pond, The Vineries, Jersey, for some fine samples of his Giant Red Shallots. Mr. J. Tilley, Lincoln Road East, Peterborough, had a dish of Peter Pippin Apples. Mr. J. T. Miles, The Gardens, Wycombe Abbey, sent some fine samples of The Lyon Leek, for which a letter of thanks was awarded. Three bunches of Alwick Seedling were sent from Chiswick, the berries of good size and beautifully coloured, for which a cultural commendation was awarded, Gros Colman also being well shown. Messrs. Saltmarsh & Son, Chelmsford, exhibited a dish of their new Apple The Queen, large, and of fine colour. Mr. Gandy, Maidstone, sent a dish of Loddington Apples. Mr. C. Roberts, The Gardens, Highfield Hall, sent a fine cone of *Encephalartos horridus*. Mr. C. Tyler, The Gardens, Shelton Abbey, had a scarlet-fleshed Melon named Shelton Abbey, of moderate size and well netted, but of poor flavour.

Messrs. Sutton & Sons, Reading, exhibited a very large collection of Potatoes, Kales, Cabbages, and other vegetables in very fine condition, and occupying one side of the vestibule. Messrs. James Veitch & Sons, Chelsea, contributed a number of Curled Kales and Endives, the latter including the White Curled, Green Curled, Picpus, Moss Curled, Hardy Winter, and Fraser's Broad-leaved. A collection of Shallots was sent from the Society's gardens, comprising the Russian, Exhibition, New Russian, Large Russian, Small Red, Large Brown, and Large Red.

FLORAL COMMITTEE.—George F. Wilson, Esq., in the chair. Messrs. H. Cannell & Sons, Swanley, Kent, staged a fine group of Zonal Pelargoniums, consisting chiefly of the rich scarlet Henry Jacoby and the Salmon Vesuvius Surprise, the group being margined with small plants of the variegated Silver Gem Pelargonium, a neat dwarf variety, and Adiantums. In addition to the plants a large number of single and double Zonal Pelargoniums and Salvias were shown from Swanley, and greatly admired. One stand of the deep blue Salvia Pitcheri and the slightly lighter *S. angustifolia*, arranged with flowers of Heliotrope White Lady, was charming, the contrast being most striking. The single Pelargoniums were represented by trusses of extraordinary size, some having over thirty blooms. The best varieties were Eureka, white; Edith George, pink with a white eye; Attala, large bright scarlet; Paul Bauer, deep rose; Mrs. Strutt, pale pink, large; Dr. Orton, dark scarlet; and Jean Ill, rich rose. Double varieties were also admirably represented. Besides the Salvias already mentioned the scarlet *S. rutilans* and Bruanti splendens, the scarlet and white Mons. Isanchon, and the rich purple Hoveyi were shown. Several new Chrysanthemums, such as La Vierge, Perle des Blanchés, and Dupont de l'Enre, also the older and rich King of Crimsons, were notable. A medal was recommended for this handsome collection.

Mr. R. Clark, Twickenham, sent a collection of extremely well-grown Cyclamens, white, purple, and crimson, the flowers being distinguished by their size and breadth of petals. A medal was awarded for this group. Mr. B. S. Williams, Upper Holloway, had a small group of choice Orchids, including a plant of the soft purplish *Pleione præcox*; a plant of *Odontoglossum Alexandræ virginalis* with large pure white flowers, the lip dashed with yellow; specimens of the small yellow-flowered *Odontoglossum pardinum*, the new *Cypripedium Spicerianum*, a pretty little example of the dwarf *Nepenthes ampullacea vittata*, and a large panful of *Dendrobium superbiens* bearing six large racemes of rosy-purple blooms. Messrs. Jackson & Son, Kingston, sent a stand of eight seedling Japanese Chrysanthemums, three blooms of each, comprising the following:—Madame Brun, compact blooms, pale lilac; Perle des Blanchés, white, loose, of the Fair Maid of Guernsey type; M. Desbrenx, narrow, bronzy-brown twisted florets, the margins revolute, a compact striking flower; Japonaise, quilled lilac florets; F. A. Davis, deep maroon narrow florets; Safrano, yellowish; and Nuit d'Automne, rosy-crimson, under side of narrow twisted florets whitish. A new Pompon named La Purité, with neatly formed pure white flowers, was also shown.

Messrs. J. Veitch & Sons, Chelsea, had a group of new Chrysanthemums, raised by Alfred Salter, Esq., amongst which were the following:—Rex Rubrorum, Japanese, deep maroon, neat flower, free; La Candeur, apparently intermediate between the Japanese and the incurved types, pure white, broad florets; Lord Beaconsfield, Japanese, florets with margin revolute, full, large, compact, upper surface claret-purple, lower surface yellowish; Ringleader, quilled, lilac-purple, neat; Comet, Japanese, flat florets, deep orange, with bronze tinge, very free; and Duchess of Albany, large Japanese, flat florets, loose, creamy white. Messrs. Veitch also exhibited a group of new plants, the greenhouse hybrid *Rhododendrons* largely predominating, and including representatives of their recent handsome varieties. Other noted plants were *Bouvardia Priory Beauty*, which has good trusses of pale pink flowers; *Begonia socotrana*, and a hybrid between that and *B. insignis*, termed Autumn Rose, which resembled the former chiefly in the foliage and the latter parent in the flowers and stronger habit; *Impatiens Sultani*, the neat Campanula-like *Tachadenus carinatus*, and a rich scarlet Carnation named Lucifer. Mr. Higgins, gardener to H. Little, Esq., Hillingdon Place, Uxbridge, contributed a group of remarkably fine single and double Zonal Pelargoniums, well-grown specimens, flowering most profusely. This fine group well showed the value of these plants for winter flowering, and well merited the medal awarded for it. Mr. George, Putney Heath, exhibited a seedling Carnation named Sir Garnet Wolseley, the blooms being of a dark scarlet colour, full, and of good form.

Mr. C. Green, gardener to Sir G. Macleay, Pendell Court, Bletchingley, was awarded a vote of thanks for flowering sprays of *Cestrum aurantiacum*, the orange-coloured *Habrothamnus*-like plant; *Amicia zygomeris*, a Leguminous plant, with short axillary racemes of large bright yellow flowers; and *Fuchsia arborescens*, with small purplish-crimson flowers, produced in large loose corymbs, a very striking and pretty species. Mr. Z. Stevens, The Gardens, Trentham Court, sent about twenty plants of *Odontoglossum Alexandræ*, representing extremely fine varieties, and flowering most freely, some heavy spikes of twelve to fourteen blooms, pure white, spotted, or flushed with purple. A vote of thanks was awarded to Mr. A. Waterer, Knap Hill, Woking, for a group of seedling Golden Yews, chiefly of fastigiata type. Some very handsome Golden Cypresses were also shown. A group of *Bouvardias* and *Salvias* were sent from Chiswick, and included good examples of the white double *Bouvardia* Alfred Nenner, *B. elegans*, *Salvia Pitcheri*, and *S. Bethelli*.

First-class certificates were awarded for the following plants:—

Odontoglossum crispum, var. *Dormannianum*.—This was shown by Mr. Coningsby, gardener to C. Dorman, Esq., The Firs, Laurie Park, Sydenham. It is a very handsome variety, with neatly formed blooms heavily barred and blotched with chocolate, the lip being also stained with yellow.

Salvia Hoveyi (Cannell).—Very distinct, the corolla 2 inches long,

deep rich purple, the calyx almost black. They are produced in dense terminal spikes, the flowers being slightly pendulous.

Chrysanthemum Lord Wolseley.—This is a sport from Prince Alfred, shown by Mr. Orchard, gardener to J. Galsworthy, Esq., Coombe Leigh, Kingston. It resembles the parent in general form, but is larger, of more substance, and of a bronzy hue.

Chrysanthemum Crimson King (Dixon & Co.).—A pretty reflexed variety with compact blooms, the florets comparatively short, flat, deep red, almost maroon. Very distinct.

Odontoglossum crispum Wilsonii (Stevens).—Flowers very large; petals broad, fringed, with a few chocolate spots in sepals and lip.

Pleione præcox (Williams).—A charming species, with lilac-purple sepals and petals, a white-fringed lip dashed with yellow in the centre. Very free.

Odontoglossum Alexandræ virginalis (Williams).—Flowers large, beautifully formed; broad petals, pure white, lip blotched with yellow. A very handsome variety.

Chrysanthemum M. Desbrenx (Jackson).—A large full bloom of the Japanese type; the florets narrow, margins revolute, of a rich bronzy brown hue. Very distinct and handsome.

Chrysanthemum F. A. Davis (Jackson).—A Japanese variety with narrow florets, the margins revolute, and deep rich maroon in colour.

Pelargonium Albert Crousse (Little).—One of the Ivy-leaved varieties of strong compact habit; flowers large, double, of a rose-scarlet colour.

Pelargonium Aglaia (Little).—A double Zonal with close trusses of purplish crimson-coloured flowers, very distinct in shade.

SPECIAL PRIZES.

Messrs. Sutton & Sons, Reading, offered a number of prizes for vegetables, and the competition was extremely keen, the exhibits being of excellent quality. For a collection of vegetables, twelve kinds, Mr. J. Austen, gardener to Sir G. Smythe, Bart., Ashton Court, Bristol, secured the chief prize with an even collection of clean handsome samples of Hatbaway's Excelsior Tomatoes, Canadian Wonder Beans, Improved Reading Onions, Leicester Red Celery, White Stone Turnips, Telegraph Cucumbers, Veitch's Autumn Giant Cauliflowers, Dell's Crimson Beet, Imported Brussels Sprouts, Hollow-crowned Parsnips, and Lapstone Kidney Potatoes. Mr. A. Miller, gardener to W. H. Long, Esq., M.P., Rood Ashton Park, Trowbridge, Wilts, was second; Mr. J. Haines, gardener to the Earl of Radnor, Coleshill, House, Highworth, a very close third; Mr. R. Phillips, The Deodars, Meopham, Kent, was a good fourth; and Mr. G. Summers, gardener to the Earl of Scarborough, Sandbeck Park, Rotherham, was fifth. There were nine entries.

For twelve Improved Reading Onions Mr. Haines, Mr. Spottiswood, The Gardens, Queen's Park, Brighton; Mr. Austen and Mr. C. Osman, gardener, the South Metropolitan Schools, Sutton, were the prizetakers, showing very fine examples in a class of fourteen competitors. For nine tubers each of Woodstock Kidney and Reading Hero Messrs. Miller, Ross, F. Millen, The Gardens, Hamstead Park, Newbury, and J. Haines won the prizes, fine collections being staged.

For nine tubers each of Suttons' Early Border and Prizetaker Potatoes Mr. C. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury, was first; Mr. Austin second; Mr. Emson, Dorchester, third; and Mr. Ward, gardener to the Earl of Radnor, Longford Castle, Salisbury, was fourth in a class of six competitors. For the same number of tubers of Suttons' Reading Russet and Fiftyfold Potatoes Mr. Finlay, gardener to Colonel North, Wroxton Abbey, Banbury, took the lead; followed by Mr. Donaldson, The Gardens, Keith Hall, Inverurie, N.B.; Mr. Haines, and Mr. F. Millen, gardener to J. T. Friend, Esq., Northdown, Kent, in a class of ten exhibitors. For the same number of Magnum Bonum and First and Best Potatoes Messrs. Donaldson, W. Finlay, F. Millen, and C. Ross won the honours in a class of seven competitors.

Messrs. Webb & Sons of Stourbridge also offered prizes for twelve Improved Schoolmaster Potatoes, seven dishes being staged. Mr. C. W. Howard, Bridge, Canterbury; C. Osman, and R. Dean, Ranelagh Road, Ealing, were the prizetakers, all showing neat samples.

SCIENTIFIC COMMITTEE.—Dr. M. T. Masters in the chair. *Magnolia Campbellii*.—Mr. Mangles described the very fine specimen of this tree at Lakelands, near Cork, on the grounds of Mr. W. H. Crawford. The height was 33 feet, and circumference of the stem 33 inches. This species has never flowered in Europe. It grew against a wall with the late Mr. Gorey at Edinburgh. It was supposed that the warmth of the climate is insufficient to enable it to flower. It was suggested that attempts should be made by grafting to induce it to blossom. Remarkably fine *Magnoliæ* were described by Dr. Low at Milan. Others at Nantes were destroyed in the late severe winter.

Carlina acanthifolia.—Dr. Low exhibited dried specimens of this large dwarf Thistle of the continent. He also showed apparently a wild form of the garden Artichoke, the bracts being particularly small.

Vitis gongyloides.—Mr. Lynch brought fine specimens of this curious Vine from the Botanic Garden at Cambridge. The "tubers" on the stems are terminal, disarticulate with the axillary bud, and may be kept a twelvemonth and will then germinate. In one case in consequence of the end of the bough having been removed the swelling took place at the base of the internode.

Agave Victoria Regina.—Dr. Masters exhibited photographs of the

plant in blossom in the Botanic Garden of Cambridge, U.S.A., where it threw up a gigantic spike of blossoms; also a drawing of *A. bracteata* from the same locality.

Chrysanthemum Sport.—Dr. Masters also showed a blossom half white and half yellow, the two kinds of florets equally dividing the head. Remarks were made upon the way to obtain large flowers, there being not only the terminal one in point of position, but lateral ones of a certain period of development.

Friesia odorata and *Babiana rubrocyanea* (?) were sent by the Hon. and Rev. J. T. Boscawen from Cornwall. The latter comes from South Africa.

Glass with Pattern.—Mr. J. Clarke of Snakeleys, Uxbridge, sent a pane of glass from a lean-to house which had been whitewashed. The whitewash had partly disappeared, leaving a peculiar pattern on the glass. No explanation could be suggested as to the cause.

Proliferous and Monstrous Flowers.—The Rev. G. Henslow exhibited the following specimens:—Proliferous states (*Rhododendron balsamiflorum aureum*, from Mr. Veitch), with flowers proceeding from the centre of the pistil. The latter organ had dehisced longitudinally, and a cluster of malformed orange-coloured petals protruded from the orifice. Mr. Henslow observed that every flower on one bush in his garden of a common pink kind had during the last season formed a blossom within the pistil, though in this instance the flowers so formed had perfect as well as petaloid stamens. In every case the flowers sprang from the base of the ovary. Carnation with a secondary flower proceeding from within the calyx tube (received from Miss Owen, Gorey). Blue Bell, each flower being elevated on a long pedicel (2 inches), and bearing secondary flowers from the axils of the perianth leaves. In one case a normal flower was replaced by a raceme. Solomon's Seal with leafy racemes occupying the position of each flower.

Monstrous Flowers—Pistillody of Calyx.—Violets, virescent in part or entirely, with sepals abortively ovuliferous, and the petals lacinated; in some instances purple, in others green. The sepals bore papilliform structures on margins and midribs resembling rudimentary ovules, the only recorded instance of ovuliferous sepals being one of the common garden Pea, figured and described in *Gard. Chron.*, 1866, p. 897. *Pistillody of Stamens*.—He exhibited drawings illustrating various stages of ovuliferous stamens in the Alpine Poppy, (received from Miss Owen). Syngenesism in *Diploxys tenuifolia*.—In this case the anthers of every flower cohered laterally, so that the pollen could not escape. The consequence was that in no case did a flower set seed, the siliques remaining small and abortive. Received from Mr. Marshall of Ely.

Placental Protrusion in Begonias.—In these flowers the placentas bearing many ovules had protruded at the summit of the ovary, apparently from an hypertrophied condition of the former (from Miss Owen). Movement of pedicels in *Meconopsis nepalensis* (received from Miss Owen) illustrating observations recorded in the *Gard. Chron.*, July 10th, 1882, p. 767. Mr. Henslow suggested that this prevented the seeds from being dropped close to the parent plant, as the fruit dehisces at the base of the style, as in *Papaver*, below the stigmas. In both cases the pod is held erect, but when a capsule is pendulous, as in *Campanula*, the pores are at the base, so that in every case the plant is enabled to scatter its seed as it is swayed by the wind.

Fasciated Stems.—A remarkable example of *Carduus lanceolatus* some 3 feet in length and 6 inches broad (received from Mr. Marshall of Ely), a peculiarity of which was that it had appeared for four years successively in this condition; and another of *Lilium auratum*.

Enations on Yucca.—Leaves of *Yucca filamentosa* (?) with peculiar horn-like protuberances of about half an inch long, probably caused by some insect (from Miss Owen).

LECTURE.—The Rev. G. Henslow took the *Chrysanthemum* as the subject of his lecture. This plant is referable to two distinct species—*C. indicum*, *L.*, and *C. sinense*, *Sab.*—though until Mr. Sabine so determined them in 1823 they had been confounded. The former appears to have been in the Chelsea Gardens in 1764, but was lost. The latter was first introduced in England in 1790, though called and figured as *C. indicum* in the "Botanical Magazine," No. 327, being supposed to be only an enlarged cultivated variety. The first-named species is with very little doubt the origin of all the "Pompons." It was reintroduced by Mr. Fortune in 1846 as the "Chusan Daisy" or "Minimum," and now numbers probably more than one hundred varieties. With regard to the large kind, or *C. sinense*, the first notice of its cultivation in Europe was by Breynius, who describes six kinds in Holland in 1688; but it is strange that they all disappeared, and were only reintroduced one hundred years afterwards into Europe by M. Blanchard in 1789. Many varieties had been long cultivated in China and Japan, as Kœmpfer in 1712 observes; while Rumphius in his "Hort. Amer." notices that they were grown in 1745 in India, having been brought from China.

The reintroduction of this kind into Europe was by M. Blanchard into Marseilles, thence it passed to Paris and England. From this (a purple kind) the sport called the Changeable White was soon obtained. Sir A. Hume introduced several new colours between 1798 and 1808. Many others soon followed, so that in 1827 forty varieties were in cultivation. In 1865, Mr. Salter tells us, they had risen to seven hundred. In 1830 seed was obtained for the first time in France. Previously, besides forms introduced, the *Chrysanthemum* being particularly liable to sport, cuttings only had been propagated; but seedlings caused a vast influx of new forms of both species.

In 1862 Mr. Fortune introduced the new Japanese races, some with long petals and curious mouths to the corollas, suggesting the title of "dragons." It appears, however, on the authority of Mr. Crawford, Consul of Oporto, that the Japanese forms had been long cultivated there before their introduction into England.

The origin of the different forms of these flowers lies mainly in the changes undergone by the corollas of the disc or eye florets. In the wild form the ray florets have strap-shaped, the disc florets regularly five-toothed, tubes to their corollas. The principal changes may be thus enumerated:—I. To strap-shaped, becoming flattened from base to apex: (1) rolled inwards; (2), rolled outwards; (3) loose and spreading; (4), ditto, but much attenuated, pointed or bifurcating. II. The tube retained: (1), short, with five slightly enlarged teeth (*Anemone*); (2), teeth much enlarged and multiplied (*Dragon*); (3), tube elongated, with no teeth (*quilled*); (4), quilled, but open at the end and spoon-shaped, as in the Emperor of China.

STRAWBERRIES.

IN a recent number of the Journal a correspondent, writing about fruits, asks which is the best Strawberry. That is a difficult question to answer, and one about which there is sure to be a great diversity of opinion, and as difficult to decide as to say which is the best Rose or the best of any other flower. Before you answer the question you want to ask another—For what purpose? One variety is suitable for one thing, and another for something else, and the soil and situation make a considerable difference. Sometimes a Strawberry which thrives well in a certain garden and gives every satisfaction will not succeed at all in another only a stone's throw away. But the soil must not be blamed too much, for very often it is the cultivator who is in fault. He lets the weeds smother the poor Strawberries, and is not sufficiently particular in keeping the plants entirely distinct, so that in a wet season like the past there is such a development of foliage that the fruit cannot mature. Although it is difficult to say which is the best, I have no objection saying that if I only grew one it would be Keens' Seedling. Now I can quite understand some people would not concur in this, and say as a reason it is not large enough. Nothing delights some people more than to grow Strawberries so large that you must make two bites of them; but I do not see any advantage in having Strawberries so very large, and Keens' Seedling may be obtained of a respectable size by making a selection of plants. Some of them produce fruit larger than others, and if size is the object save runners from them. At the same time it must be admitted that the fruit cannot be grown to the size of Sir J. Paxton and others. And then the question is, Why not prefer a larger variety? The reply I should give is that Sir J. Paxton is a midseason variety, and if I only had one it would be rather tantalising to see plenty of Strawberries in the market for weeks before I had any. Then, again, Sir J. Paxton, although a good cropper in a general way, is liable to have the produce diminished in a cold wet season like the last, and also in a very hot and dry one, and the same remark applies to others.

Strawberries, like French Prime Ministers, have their day. They come out, they obtain popularity, they rise to the highest pinnacle, and remain there for some years, then their fortune is on the wane, another comes to the front, and they are finally supplanted and never again resume the position they held before. At one time it was British Queen, at another Sir Harry, at another Victoria, and now it may be said to be Sir J. Paxton. How long it will continue in its present position it is difficult to say. There are other candidates in the field, but I must wait until next year before I can give an opinion as to their merits.—AMATEUR, Cirencester.

RENEWING BORDERS OF HERBACEOUS PLANTS.

A GOOD border of hardy herbaceous plants, intermixed with some of the best half-hardy and tender annuals, is greatly appreciated in gardens now; and although in many gardens such borders receive a due share of attention, there are still numbers of places where they are much neglected. The strong-growing plants are allowed to take possession of the border, and any plants of weaker habit are ousted from their position for the want of a little attention. To have a satisfactory border it is necessary to trench the border and give it a dressing of manure or decayed leaves about once every two years; and as the season has arrived when the annuals are past and most of the perennials out of flower, the present is a favourable time for carrying out the work. Before commencing operations the material for dressing the border with should be placed near at hand; then lift all the plants for about 3 or 4 yards at one end of the border, and lay them in near to where it is intended to finish off the work. This will give ample room to start the trenching. As the work proceeds lift the plants

and transfer them to the newly prepared ground, taking care to plant them firmly in their new positions. The coarse-growing species may be reduced, and the weak growers will be benefited by having a handful of fresh loam placed about their roots. Be careful not to destroy clumps of bulbs, and when replanted their position should be indicated by a strong stick.

Some judgment will be required in disposing of the plants. Amongst those suitable for the back of the border will be *Pyrethrum uliginosum*, *Chrysanthemum maximum* (both fine for autumn), *Helenium autumnale*, some of the perennial Asters, *Campanula lactiflora*, *C. macrantha*, *Rudbeckia californica*, *Saponaria officinalis*, and *Lythrum salicaria*. Any spare spaces can be filled with Dahlias, Sweet Peas, Sunflowers, or tall-growing annuals. In front of the above may be planted *Achillea Ptarmica plena*, *Delphinium formosum*, *Fuchsia gracilis*, *F. Riccartoni*, *Lychnis chalcedonica*, *L. coronaria*, Pentstemons, *Antirrhinum*, *Harpalum rigidum*, *Eriogonum fruticosum*, *Aster Amellus*, *Rudbeckia speciosa*, *R. purpurea*, Pæonies, and summer-flowering *Chrysanthemums*. Next come *Aquilegias*, *Anemone japonica*, *Potentillas*, *Orobis vernus*, *Spiræa palmata*, *S. filipendula*, *S. japonica*, *Bahia lanata*, *Campanula glomerata*, *C. persicifolia*, &c., *Geranium pratense*, *G. sanguineum*, *Hieracium aurantiacum*, *Polemonium cœruleum*, *Mimulus luteus*, *Scabiosa caucasica*, *Statice Limonium*, *Saxifraga cordifolia*, *Catananche cœrulea*, *Veronica incana*, and *Geum coccineum*. For the front plant *Polyanthus*, Primroses, *Aubrietias*, common white Pinks, *Alyssum saxatile*, *Silene alpestris*, border *Auriculas*, *Phlox setacea*, *Prunella grandiflora*, *Campanula pulla*, *C. carpatia*, *C. carpatia alba*, *C. rotundifolia*, *Ajuga reptans*, white *Arabis*, red and white Daisies, *Gentiana acaulis*, and the following will be found useful annuals for filling up vacant spaces:—Sweet Scabious, Cornflower, *Salpiglossis*, *Bartonia aurea*, *Linaria bipartita splendens*, *Coreopsis tinctoria*, *Nemophila insignis*, *Limnanthes Douglassi*, *Hymenoxys californica*, *Schizanthus pinnatus*, *S. retusus*, *Calandrinia discolor*, *Godetia Lady Albemarle*, *Lupinus subcarnosus*, and *L. nanus*.—E. B.

ARAUCARIAS.

AS one of the few existing genera of plants linking the vegetation of the present time with that of the distant geologic ages, the Araucarias are invested with much interest alike to the scientist and the horticulturist, an interest which is shared in varying degree by the whole beautiful family of cone-bearing plants, as well as by their curious relatives the Cycads. Geologists have by their patient investigations revealed that at one period of the earth's existence, termed the reign of the Gymnosperms, these types constituted a large portion of the luxuriant vegetation, which resulted in the formation of those enormous coal fields that have proved so valuable to the English nation. Amongst the *Lepidodendrons*, the *Calamites*, the *Lycopodites*, and the *Pinites* of those days were others which are termed *Araucarites*, from their resemblance to the Araucarias now known, especially to *A. excelsa*, and some well-preserved specimens have been obtained in various parts of the kingdom, particularly in the neighbourhood of Edinburgh. From observations made on these it appears that not only did these plants grow and thrive here then, but they attained to heights rivalling, or perhaps exceeding, the species now found in other and warmer climates than our own. Though we could scarcely desire a return to the climatic conditions then prevailing on the globe, it is regrettable that only one of the Araucarias now in cultivation is sufficiently hardy to endure the low temperatures we occasionally experience in Britain. Fortunately there is another use to which they can be applied with satisfactory results, and that is for conservatories, greenhouses, or winter gardens, in fact any position where they can be protected from frost. In a small state for decorative purposes they are valuable, but when grown in a structure sufficiently large to permit their free development they cannot be excelled in majestic beauty.

With the *Dammaras*, the Araucarias may be considered as the representatives in the southern hemisphere of the northern Conifers; for while we there lose the Pines, Firs, Cypresses, and Junipers which are so familiar in Europe, Asia, and North America, we have instead the two genera first named, with *Arthrotaxis*, *Fitzroya*, some *Libocedrus*, *Podocarpus*, and other distinct forms, some of which are partially hardy in England. The Araucarias are not numerous, about eight species being known exclusive of varieties, and these are natives of Australia, New Caledonia, or South America, forming large forests often at a considerable elevation. As timber-yielding trees some of them are highly valuable, while the seeds in several cases form important articles of food to the natives. These matters can, however, be more fully referred to when describing the species, and a few notes may be first given upon the

CULTURE.—All the species of *Araucaria* agree in requiring a soil of substantial loam, but not too retentive, thorough drainage to prevent stagnation of water around the roots; and without these be provided suckers cannot be expected, whether the plants be in pots, in conservatory beds, or out of doors. The hardy *A. imbricata*, the Monkey Puzzle, now so common in British gardens, exemplifies this, for on shallow or light sandy soils it makes but poor progress, losing its lower branches, and is in fact far inferior to specimens grown under more favourable circumstances. This distinct Conifer also appears to thrive far more vigorously in those districts of England where the rainfall is above the average, and we find in the west of England some of the most symmetrical and handsome specimens in cultivation. I recently noticed this very markedly in the neighbourhood of Bristol, where this *Araucaria* is represented by many handsome examples; and still farther west, in Devon especially, it grows almost as vigorously as it does on its native mountains in South America. All the other species are too tender to be planted out of doors in this country, though specimens of moderate size in pots may be placed out in the summer months, and for subtropical gardens they are very suitable in this way. In the south of Ireland *A. excelsa* has been tried out of doors, but even there the results have been most unsatisfactory; a few degrees of frost injure the points of the branches, and quite disfiguring the trees, while frost of greater intensity kills them completely. Some years ago it was recorded in these pages that "*Araucaria Cunninghamii sinensis*" had withstood five winters in the gardens of Elmham Hall, Thetford, Norfolk, quite unprotected; but I should think *Cunninghamia sinensis* must have been intended by the writer, as I have not heard of this species being planted out, and the variety is unknown to me. The *Cunninghamia* resembles some of the large-leaved *Araucarias*, and is, moreover, rather tender. They nearly all succeed very well in a greenhouse, or indeed any structure where the temperature is not permitted to fall below 40°; but *A. Rulei* thrives better in a warmer house, the cool end of a stove suiting it admirably.

PROPAGATION.—It is seldom, perhaps, that gardeners are required to increase their stock of these plants by propagation, especially as plants can be so readily obtained from nurserymen, who grow them in large quantities, but a few notes may be given as to the methods adopted. Imported seeds have been the chief source from which the numberless specimens of *A. imbricata* have been obtained, a few having been obtained from home-grown seeds, but these are comparatively few, and the others are far preferable. It has been observed in the case of several of the choicer Conifers that plants raised from seed produced in England have been greatly inferior to the type, being more weakly in constitution, and seldom forming handsome specimens. This point should be kept in mind, not only in the case of *Araucarias*, but with other Conifers also, as the seeds, either from imperfect fertilisation or immaturity, do not seem to be fitted to perpetuate their race. It has, indeed, been suggested that in collecting cones regard should be carefully paid to the locality where the trees are growing, those in the coolest districts or highest elevations being preferably selected, as the plants raised from such seeds are more likely to be vigorous and successful in our climate. It is usually recommended to sow *A. imbricata* seeds in cold frames or houses, but I have found them succeed better in a temperature of about 50° or 55°, as they germinate more freely and quickly, and can afterwards be removed to the cool frame until ready for planting out. Well-drained pots or pans of loam should be employed, the seeds being pressed in narrow end downwards, in the case of *A. imbricata* and the species of that section, to about half their length; the others can be inserted with their upper ends level with the soil or partly covered. *Araucaria excelsa* can be increased by cuttings, and doubtless some of the others could be propagated in the same way, but they are usually grafted on seedling stocks of the stronger or common species. Cuttings and scions are obtained in this way: The tops of the plants are cut off close to a whorl of branches, and the young shoots springing from these are removed when a few inches long, and either inserted in sandy loam and placed in moderate heat, or they are employed as scions for grafting on stocks. Occasionally, too, shoots are produced on the upper surface of the branches, and these may be taken off and treated similarly, but not the points of the main horizontal branches.

The botanical structure of the Araucarias need not be discussed here, but a peculiarity of the germinating seed may be noticed, as with other characters it has been adopted to divide the species into two groups. This is the fact, that in some species the cotyledons remain underground, being never released from the seed, which sends a young root downwards and then a small shoot upwards, while in others the cotyledons are developed. These

two sections have been termed *Colymbea* and *Eutacta*, the first including, according to Parlatore in Decandolle's "Prodromus," *A. imbricata*, *A. brasiliensis*, *A. Rulei*, and *A. Bidwilli*; the second containing *A. Cunninghamii*, *A. excelsa*, and *A. Cookii*, but for convenience they are taken in alphabetical order, describing the characters and uses of the species in the following notes:—

ARAUCARIA BIDWILLI.—This is a very distinct and handsome species, which is found in a comparatively small district in

Queensland, about thirty miles long by twelve broad, but it is very abundant in that space. It there attains a great height, and is valued both for its wood and seeds, the latter forming such an important article of food to the natives that the Colonial Government have issued orders forbidding the destruction of the trees by those who have a licence to fell timber. The tree is known as the Bunya Bunya, and are said to be the only property possessed by the natives, certain trees being claimed by tribes

fig. 75.—CONE OF *ARAUCARIA COOKII*, WITH SPRAYS OF *SAXEGOTHEA CONSPICUA* AND *FITZROYA PATAGONICA*.

or families, and their rights are recognised. The seeds when uncooked have been considered to be intermediate in flavour between a raw Potato and a Chestnut, but when roasted, the usual method of treating them, they more nearly resemble the latter: Though the seeds are produced every year the principal crop occurs every third year, when the natives assemble for a great feast; and Mr. Walter Hill states that, contrary to their usual custom, "they sometimes store up the Bunya nuts, hiding

them in water holes for a month or two. Here they germinate and become offensive to a white man's taste, but are considered by the blacks to have acquired an improved flavour."

In 1842 Mr. Bidwill, after whom the species is named, introduced some plants, one being purchased by the Duke of Northumberland for a hundred guineas, and the others were transferred to Kew, and in the temperate house there are now two grand specimens about 25 or 30 feet high, and in admirable con-

dition, well displaying the character of the species. The branches are strong, of considerable length, slightly bending towards the ground, the branchlets being closely set, drooping, and 2 to 3 feet long. The leaves are lance-shaped, flat, about half an inch broad at widest part, and of a rich shining green colour, somewhat suggestive of *A. imbricata*. One of these trees produced cones, the first borne in this country, in 1873. For such winter gardens this *Araucaria* is very useful, as it has a noble and striking habit.

A. BRASILIENSIS.—In the same house as the above at Kew are also fine examples of several other species, amongst them being one of *A. brasiliensis* 25 feet high. It has long slender drooping branches, four or five in a whorl, the branchlets being from 1 to 3 feet long and pendulous. The leaves are tapering, closely set, 2 to 2½ inches long, and bright green, or with a slight glaucous hue. A variety included in the same collection named *Saviana* is distinct, the leaves being larger and more closely set; another variety being also known of more slender habit and named *gracilis*. This species is found on the Brazilian mountains in dense woods at elevations of 1200 to 3000 feet. Small plants of this species are not very plentiful, but I should think it would be useful in pots for the stages or shelves of a greenhouse.

A. COOKII.—It is recorded in Captain Cook's account of his second voyage, that an island observed near New Caledonia was so thickly covered with enormously tall trees of this *Araucaria*, the width of which is small in proportion to its height, said to be sometimes 150 feet, that they were mistaken by some for basaltic columns, and this peculiarity has doubtlessly given rise to the synonym by which the plant is known—viz., *A. columnaris*. When it was ascertained by the above-named navigator that the supposed columns of basalt were really living trees their situation was termed the Isle of Pines, and some elaborate considerations are indulged in by the recorder as to the fitness of the stems for masts. The species is also found in New Caledonia, and plants were introduced to this country by Mr. Charles Moore of the Sydney Botanic Garden in 1851, being consigned to the London Horticultural Society, and a plant was first exhibited in the following year. I am not aware that there are any large specimens of this in cultivation. The finest I have seen is at Kew, about 12 feet high, which has slightly drooping branches clothed with short branchlets bearing closely set needle-like leaves about half an inch long. A very well-grown specimen has lately been sent to Kew from Floors Castle, and this well shows the characters and beauty of the species.

In the woodcut (fig. 75) a handsome cone of the above-mentioned *Araucaria* is shown, and may be taken as an example of the larger cone-bearing *Araucarias*. The two sprays accompanying it are *Saxegothaea conspicua* on the left, and *Fitzroya patagonica* on the right, both pretty little Conifers from the southern hemisphere, which succeed in the warmer sheltered parts of England.

Notes on the other species of *Araucaria* must be reserved.—
L. CASTLE.

JUDGING AT THE EDINBURGH SHOW.

I HAVE watched with much interest the correspondence that has been going on in your columns regarding the fruit-judging at the International Show held in Edinburgh in September. Complaints, I am sorry to say, have not been confined to the judging of fruit alone; but it is always thus at important exhibitions. Grumbling and fault-finding will continue to exist as long as human nature itself does. According to a west of Scotland newspaper the vegetables likewise came in for a good share of attention, and it was asserted that the first-prize Leeks were "soft and flabby, while the second lot were firm and equally well blanched." The writer of that signs himself "A GARDENER." I would ask in all fairness if any unprejudiced person thinks that the Judges, be they who they may, would have awarded a first prize to Leeks that were "soft and flabby," and more especially when there was such a close second. No, I am afraid the matter has a different interpretation. I know, and it was observed by many as well as by myself, that the Leeks in question bore evident traces of having been roughly handled after being judged, thus spoiling their appearance.

My object in writing to you is to impress upon your wide circle of readers the non-desirability of paying much attention to complaints about judges, because nine-tenths of them will be found to be without foundation. The task of judges is often very difficult and too often thankless. In my experience I have always found them actuated by a desire to deal out even-handed justice to the very best of their ability.—A STIRLINGSHIRE OBSERVER.

[No doubt this is so, and the Judges at the Show in question were all men of ability. In reference to the awards that have been

questioned in the fruit classes the Judges had a more than usually difficult task to perform. It is for the committee of a show to clearly express what is required of exhibitors, and the duty of judges to act in accordance with the published conditions. In a fruit show where the question of whether fruit should be "ripe and fit for table" is left open, dissatisfaction with the awards is sure to follow; and whether complaints are merited or not, the judges are not responsible, but the committee. The question of judging fruit at Edinburgh is not a personal one at all.]

CHRYSANTHEMUM SHOWS.

THE season appears to be favourable to the Chrysanthemums, and the shows held to the present time have been extremely good, cut blooms being particularly well shown and the plants generally in satisfactory condition, though many would have been better a little later. As usual, the majority of the exhibitions are crowded into about a fortnight, no less than ten having been held in the first three days of the present week. In consequence we are unable to give anything more than condensed reports, indicating the chief features of the displays and the leading exhibitors in the principal classes.

BRIXTON.—NOVEMBER 9TH AND 10TH.

The exhibiting season was this year commenced by this energetic Society, and their twenty-third Show was alike creditable to the gardeners of the district and to the Secretary, Mr. Hall, who so admirably superintends the arrangement of the exhibits. The Show was held in the lecture hall adjoining the Congregational Church, Streatham Hill, which was well filled, indeed it proved scarcely large enough, but by a judicious disposition of the plants and stands space was economised as much as possible, and yet a pleasing effect was produced. Chrysanthemums formed the principal feature of the Show, and must be therefore first briefly noted, commencing with the

Cut Blooms.—These were remarkably good in several classes, incurved Japanese and Anemones being well represented. For twenty-four incurved Mr. J. Holmes, gardener to G. M. Storey, Esq., Nightingale Lane, secured chief honours with a stand of even, fresh, substantial, and beautiful blooms of the following varieties:—Conqueror of India, Baron Beust, Princess Teck, John Salter, Jardin des Plantes, Princess Beatrice, White Globe, Nil Desperandum, Beverley, Prince Alfred, Mr. Bunn, Lady Hardinge, Mr. Brunlees, Alfred Salter, Mrs. Haliburton, Princess of Wales, Mrs. Heale, White Venus, Queen of England, Cherub, and Lady Slade. Of the five other competitors Mr. A. Holmes, gardener to A. B. Hill, Esq., Clapham Park, and Mr. Salter, gardener to J. Southgate, Esq., Leigham Court Road, were second and third respectively, both showing good blooms. Seven collections of twelve incurved were staged, Messrs. A. Holmes, J. Holmes, and T. Sadler, gardener to Ch. Lambert, Esq., Leigham Court Road, were the prizetakers in that order. Mr. J. Holmes was again the most successful exhibitor of twenty-four Japanese blooms, securing the leading prize with large richly coloured examples of *Cry Kang*, *Soleil de Levant*, *Gloire de Toulouse*, *Red Gauntlet*, *Hiver Fleur*, *Red Dragon*, *Dr. Macary* (fine), *Bronze Dragon*, *Abdel Kadir*, *Curiosity*, *Jane Salter*, *Elaine*, *Plantagenet*, *L'Incomparable*, *Baronne de Prailly*, *Peter the Great*, *Magnum Bonum*, *Fair Maid of Guernsey*, *Fulgore*, *G. Delaux*, *Sarnia*, *Criterion*, *Rosa Bonheur*, and *Nuit d'Hiver*. Mr. J. Young, gardener to T. Hicks, Esq., Streatham Hill, and Mr. W. Clark, gardener to J. Rains, Esq., Nightingale Lane, were second and third with praiseworthy blooms. The best twelve Japanese were from Mr. A. Holmes, who took first honours, followed by Messrs. W. Green, gardener to H. Russell, Esq., Clapham Common; and E. Cherry, gardener to Mrs. Gabriel, Streatham. Two very pretty collections of Anemone-flowered varieties were staged by Mr. J. Howes, gardener to Mrs. F. Besant, Tulse Hill, and Mr. J. Swain, gardener to Mrs. Wilson, Lower Tulse Hill. The first named had the following Pompon varieties: *Toinette*, *Sidonia*, *Marguerite de Willemar*, *Aglaia*, *Firefly*, *Madame Chalarge*, *Perle*, *Miss Nightingale*, *Antonius*, *Calliope*, *Mr. Astie*, and *Marguerite de Coix*; while the large-flowered varieties shown by Mr. Swain were *Acquisition*, *Lady Marguerite*, *Gluck*, *George Sands*, *Louis Bonamy*, *Prince of Anemones*, *Fleur de Marie*, and *Princess Louise*. Other exhibitors in these classes were Messrs. Young and Livermore. In the class for twelve incurved blooms, confined to those who have not previously taken a prize, Mr. J. T. Salter, gardener to Mark Sheppard, Esq., Roupell Park, and Mr. C. Prestoe, gardener to B. F. Smith, Esq., Tulse Hill, were accorded the first and second prizes for blooms of fair quality.

Specimen Plants.—Some neat examples of these were shown, indicating a steady improvement. The best class was that for six plants, large-flowered varieties, in which Mr. Cherry was adjudged chief honours for well-grown specimens, not too rigidly tied, and bearing fine blooms. The varieties were *Prince of Wales*, *Barbara*, *Mrs. Haliburton*, *Venus*, *Mrs. Dixon*, and *Elaine*. Mr. J. Howes followed with good plants, but rather stiff, and the blooms not fully developed. Mr. Cherry also had the best six dwarf Pompons, being well-flowered plants of *La Vogue*, *Cedo Nulli*, *Sunset*, *Mr. Astie*, *Fanny*, and *Jean Hatchett*; Mr. J. Howes following in that class also. Trios were shown by Messrs. Cherry and Salter, who were placed in that order,

Messrs. Livermore and Cherry contributing pyramid Pompons, and Messrs. Livermore and W. Clark standards, none being superior.

Miscellaneous Plants.—Very conspicuous amongst these were the Orchids in competition, as well as the fine group contributed by Mr. Salter, which the Judges highly commended. For six specimens Mr. Salter won chief honours with good examples of *Cypripedium Harrisianum*, *Odontoglossum grande* with three spikes, *Cœlogyne ocellata*, *Dendrobium heterocarpum*, *Vanda cœrulea*, and *Oncidium crispum*. Mr. Young followed, having a fine *Dendrobium nobile*, *Calanthes*, and *Zygopetalum Mackayi*. Trios were shown by Messrs. Salter, A. Holmes, and Poole, while in the single specimen class Mr. Salter took the lead with an exceedingly fine plant of *Masdevallia tovarensis* bearing about five dozen flowers. Mr. Clark had the best four fine-foilage plants—viz., *Dracæna Youngi*, *Croton Weismanni*, *Corypha australis*, and *Croton majesticus*—all healthy specimens of moderate size; Mr. H. Wright, gardener to Mrs. Hyatt, Palace Road, and Mr. Cherry taking the other prizes in that order. Several good collections of Ferns were also contributed, Mr. Young having four handsome plants, and winning the principal prize. His *Adiantum gracillimum*, *A. Farleyense*, *Gymnogramma peruviana argyrophylla*, and a golden-coloured seedling of the same genus were in first-rate condition. Messrs. Poole and H. Wright competed in the same class with creditable examples.

Fruit was not largely shown, but three dishes of dessert Pears from Mr. W. Hall, gardener to W. Stevens, Esq., Tulse Hill, which were placed first in the class, were even, of fair size, and well ripened. Dessert Apples were also well shown by Mr. W. Collins, gardener to T. Schizman, Esq., Clapham Park, and kitchen Apples by Mr. F. Yates, gardener to S. Lutwyche, Esq. Mr. Holmes, gardener to T. Wallace, Esq., Clapham Common, had the best black Grapes—two well-coloured bunches of Alicante, Mr. W. Howe securing the same position in the white Grape class with Muscat of Alexandria small but ripe. Vegetables were satisfactorily represented, the prizewinners being Messrs. Young, Swain, Cherry, Sandy, Yates, and Collins.

Amongst the contributions not in competition were two bunches of Gros Guillaume weighing 9 lbs. from Messrs. Lane Brothers, Brixton Road, and fairly coloured. Messrs. J. Peed & Son, Norwood Road, also had two bunches of Grapes—Alicante weighing 3½ lbs., and Trebbiano weighing 2½ lbs. Mr. Salter sent fruits of his Cucumber Selborne Rival, which were highly commended, as were also two dozen handsome blooms of the white sport from James Salter—Lady Selborne. Mr. Todman exhibited a plant of a new Azalea named Master John Connell, a hybrid between *A. obtusa* and *A. Todmani*, with small deep red flowers, the petals rounded, and the general appearance very neat. A certificate was awarded for it.

STOKE NEWINGTON.—NOVEMBER 13TH AND 14TH.

As one of the oldest and at the same time one of the most important shows in the neighbourhood of London, the Stoke Newington Cbrysanthemum Exhibition possesses more than ordinary interest, and it has gained a well-deserved fame for the high quality both of blooms and plants there shown. The present season's display was no exception to the rule, well maintaining the credit of the Society in all respects, entries being quite as numerous as usual, the competition keen, and the general freshness of the exhibits most satisfactory. The Lecture Hall in Defoe Road, Church Street, was chosen for the occasion, as it has served the same purpose several years previously, and the arrangements were well conducted under the superintendence of the Secretary, Mr. W. Goldsmith, to whose efforts the steady progress of the Society is largely due.

Plants.—The various classes for these were well filled, several very handsome collections being shown, though there was a deficiency in others that has not been so noticeable in some previous years' shows. The finest specimens were those in the class for ten plants in pots not exceeding 12 inches in diameter and arranged for effect, the veteran exhibitor Mr. W. Monk, gardener to W. Fowler, Esq., Leytonstone, securing the chief prize (a £7 silver cup) with a collection of great merit, the plants healthy, the blooms abundant, large, and well formed. They comprised good standard specimens of Fanny and George Glenny, pyramidal examples of Mrs. G. Rundle, Golden George Glenny, and Venus, with Antonelli, Julia Lagravère, Sœur Melanie, and Lord Stanley as dwarfs. Mr. Payne, gardener to C. C. Payne, Esq., Cedars House, Stamford Hill, followed closely, his best examples being beautiful standards of Marie Stuart and Bob, with the dwarfs Sœur Melanie and Lilac Cedo Nulli; these were exceedingly well flowered; Mr. Langford, gardener to J. Barnet, Esq., Coleraine House, Stamford Hill, taking the third place with but slightly weaker specimens. Three good lots of four standards were staged, Mr. Monk securing the chief award with neatly trained specimens of The Cossack, very well flowered; Venus, Golden George Glenny, and Mrs. G. Rundle. Mr. Wells, gardener to W. A. Smee, Esq., The Limes, Woodbury Down, Finsbury Park, and Mr. Payne took the second and third positions, the last-named having two pretty examples of Prince Victor and Antonius. Mr. Wells contributed the best six Pompons—freely trained and abundantly flowered plants of Prince Victor, Golden, Lilac, and White Cedo Nulli, Sœur Melanie, and Fanny; Mr. Payne being second with smaller plants. The above-named exhibitors, with the addition of Mr. Gilbey, gardener to B. Booth, Esq., The Cazenoves, Upper Clapton, were also prizetakers in other classes.

Blooms.—There was a grand display of blooms; a long table in the

centre of the Hall was occupied with two lines of boxes, the space between these in the centre of the table being filled with Palms, Ferns, and similar plants, which greatly relieved the formality of the boxes. The leading class for competitors from the boroughs of Hackney and Finsbury was for twenty-four incurved blooms, in which Mr. Gilbey not only won chief honours but was also awarded a silver cup for his stand as the best twenty-four in the Show, though the Judges spent considerable time in determining its position, as Mr. Mark's collection in the open class was extremely close in merit. Mr. Gilbey exhibited fine specimens of Queen of England, Mrs. Heale, Jardin des Plantes, Emily Dale, Princess Beatrice, Golden Eagle, Hero of Stoke Newington, Mrs. Haliburton, Guernsey Nugget, Lady Hardinge, Antonelli, Princess Teck, Rev. J. Dix, Isabella Bott, John Salter, White Globe, Enamel, Barbara, Prince Alfred, Golden Empress of India, Mr. Bunn, and Refulgence. Mr. Martin, gardener to H. Matthews, Esq., The Cedars, Finsbury Park, and Mr. Payne followed in that order. In the borough classes for twelve and six incurved, the above, with Mr. Hawke, gardener to Miss Allan, 1, Bethune Road, Stoke Newington, Mr. Chalkley, and Mr. Hammond were the prizetakers.

The prizes in the open class for twenty-four incurved were well contested, the first and second collections containing extremely fine blooms, and were nearly equal in merit. Mr. W. Monk gained chief honours with a grand lot, having superb examples of all the best varieties. Mr. J. Udale, The Gardens, Sbierecliffe Hall, Sheffield, was a very close second, but the first had a little more weight in his favour, though considering the distance the blooms had been brought they were very fresh, bright, and creditable. Unusually good specimens of Golden Queen of England, Golden Empress of India, Beverley, Mr. Bunn, Mrs. Heale, Lady Talfourd, Princess of Wales, and Venus were included. Mr. Young, gardener to G. Thompson, Esq., Stamford Hill, was second. Messrs. Monk, Wells, Langford, and Young were also the principal competitors in other classes for incurved blooms. The remarkably successful exhibitor, Mr. Monk, again led with twelve Japanese blooms, richly coloured substantial specimens of Peter the Great, Cry Kang, Fair Maid of Guernsey, Gloire de Toulouse, James Salter, Rosa Bonheur, and others. Messrs. Langford and Gilbey secured second and third places. The best six Japanese were similarly from Mr. Monk; Mr. W. Goldsmith, Grove Road, Stamford Hill, and Mr. Langford following. Mr. Goldsmith won first prize for twelve incurved blooms in the amateurs' class, and Mr. R. W. Wright, 42, Darley Road, Hackney, had a similar prize for twelve fine Anemone Pompons.

Miscellaneous plants were well shown by Messrs. Archer, gardener to J. Griffiths, Esq., Highbury; Payne, Jones, Gilbey, and Hawke; while the contributions not in competition were also numerous, prominent amongst them being a handsome collection of fruits, bouquets, and salads from Mr. J. Smith, 128, High Street, Stoke Newington; twenty-four fine incurved blooms from Mr. Cockrane; and some particularly good Mushrooms from Mr. Hawke.

LAMBETH.—NOVEMBER 13TH, 14TH, AND 15TH.

The eighth annual Exhibition of this local amateurs' Society was opened on Monday last in the Lecture Hall, Borough Road, and unquestionably indicated considerable advance upon previous shows, good as some of those have been. The entries also appeared to be more numerous, and considering the district in which the growers reside—within a radius of a mile and a quarter of the "Elephant and Castle"—the general quality both of blooms and plants was most praiseworthy. Some honorary members who reside outside this radius are, however, admitted, but special classes are provided for them.

In the specimen plant classes the two most noticeable were for a group of twelve and six standards. In the first Mr. Ball took the lead with well-grown Prince of Wales, Guernsey Nugget, and Fair Maid of Guernsey amongst others; Messrs. Clarke and Tozer following. Mr. Tracy had the best standards, neat examples of Mrs. G. Rundle; Mr. Williams securing the second place. In other classes for plants Messrs. Howett, Williams, and Tracy were the prizetakers.

Blooms were numerous and excellent. For twelve incurved Mr. Ball won chief honours with even symmetrical blooms, Beverley, Prince of Wales, and White Globe being especially good. Messrs. Tozer and Childs secured the remaining prizes; and with Messrs. Crisp, Williams, and Howett took the chief positions for the other classes. Mr. Crisp, the Honorary Secretary, was the only exhibitor in several of the honorary members' classes, and staged some very satisfactory blooms, but his twelve Japanese, which were deservedly awarded the first prize, were surprisingly rich in colour, comprising really handsome blooms of The Cossack, Le Negre, Gloire de Toulouse, Fulgore, and Cœur Fidèle. Japanese were also beautifully represented in the collection from Messrs. Child, Tracy, Williams, Addison, and Davison, a bloom of Père Delaux in Mr. Child's stand being remarkably fine. Anemone, reflexed, and other varieties were provided for and well shown.

Messrs. J. Laing & Co., Forst Hill, contributed a handsome group of Palms and other fine-foilage plants, which were arranged at the end of the room, forming an attractive group. In addition to the ordinary money prizes it should be remarked that several special prizes were given by members, and comprised a silver teapot, a handsome album, and a writing case, which are greatly valued by the recipients.

PUTNEY.—NOVEMBER 14TH.

The Assembly Rooms, Putney, were well filled with exhibits of Chrysanthemums, both plants and blooms, miscellaneous plants, fruit and vegetables, on Tuesday last, on the occasion of the fifth annual Exhibition of the above Society. Though the room devoted to the Show is of considerable size it was by no means sufficiently spacious for the numerous exhibits, and in consequence there was a too noticeable crowding in several cases. Near the walls the plants and groups were arranged, a central table bearing the blooms, fruit, small plants, bouquets, &c., all the space at disposal being utilised in the best possible manner, producing as a result as pretty a show as could be desired.

Plants.—In the classes devoted to these by far the most important was that for a group arranged with a view to effect, and the contributions in this formed a grand feature in the Exhibition. Messrs. Mahood & Son, Putney, were deservedly adjudged chief honours for a bank of admirable plants in most vigorous health, and bearing blooms of surprising size and substance, the Japanese and incurved being superb. Excellent taste had also been displayed in the arrangement of the colours, a pleasing harmony distinguishing the whole group. Mr. Stevens, St. John's Nursery, Putney, was a close second, many of his blooms being equally as fine as those in the first; but plants in the front row were too high, and this gave a somewhat unfinished appearance to what would have been otherwise as meritorious as the other. More incurved varieties were employed than in the leading group, but a number of Yellow Dragon contributed greatly to the brightness of Mr. Stevens' collection. Mr. Tyte, gardener to Mrs. Reed, Heath Croft, Putney Heath, followed with smaller but healthy plants well arranged; Mr. Hopkins, gardener to A. Burr, Esq., Riverdale, Putney, being fourth. In other classes for specimen Chrysanthemums the Pompons were particularly well represented, a fine collection of six dwarf-trained gaining Mr. Tyte the leading prize in that class. The best of his plants were *Mlle. Marthe* and its golden form, *Liliputian*, *Fanny*, and *Eleonore*, all compact, evenly trained, freely flowered specimens. Mr. Hoskins, gardener to S. Williams, Esq., The Laurels, Putney, was a good second; and Mr. Stevens secured the third place. Mr. Stacey, gardener to E. Nixey, Esq., Meaburn House, Upper Richmond Road, won chief honours for a single specimen Pompon with a dwarf-trained President 4 feet in diameter and profusely flowered. The same exhibitor also took the lead with two large-flowered varieties, trained plants, *Mrs. Sharp* and *Elaine* in good condition.

Blooms—There was an excellent show of blooms, the incurved and Japanese being grandly represented in the principal collections. The class for twenty-four incurved was particularly fine, Mr. Harding, gardener to J. D. Galpin, Esq., Bristol House, Putney Heath, securing first honours with magnificent blooms, every one of great merit, large, of symmetrical form, clean, and fresh. Very notable were his examples of *Queen of England* (the premier incurved bloom in the Show), *Empress of India*, Mr. Gladstone, John Salter, Baron Beust, *Golden Empress of India*, *Empress Eugénie*, Mr. Bunn, *Refulgence*, and *Prince Teck*. Mr. E. Berry, gardener to the Countess of Leven and Melville, Roehampton House, was a close second with meritorious but slightly smaller blooms; Mr. W. Green, gardener to H. Russell, Esq., Clapham Common, following with an even collection. Mr. Berry took the lead with twelve incurved, staging fine examples of *Golden Empress of India*, John Salter, *Refulgence*, *Prince Alfred*, and *Prince of Wales* amongst others. Messrs. A. Coombs, gardener to F. A. Browne, Esq., Lawn Bank, Teddington, and J. Bentley, gardener to T. E. Baring, Esq., M.P., The Cedars, Roehampton, secured the second and third positions, both showing creditable specimens. The Japanese were similarly fine, Mr. Berry's premier stand of twelve including grand blooms of *Madame Moulise*, *Peter the Great*, *Red Gauntlet*, *Cry Kang*, M. C. Hubert, *Fair Maid of Guernsey*, *Criterion*, *Triomphe de Nord*, *Baronne de Rilly*, and *Fulgore*. Mr. E. Coombs' second-prize stand contained several handsome, large, and richly coloured blooms, a superb example of *Comtesse de Beauregarde* being selected as the premier Japanese bloom in the Show. Other smaller classes were well filled.

Several small groups of miscellaneous plants were contributed, Messrs. Hoskins and Bentley winning the chief prizes with healthy specimens of Palms, Ferns, Begonias, and Crotons. Ferns, too, were shown in good form, especially by Mr. Stevens and Mr. Woodhams, gardener to R. Davis, Esq., Earlsfield, Wandsworth Common. Primulas, plants of table decoration, Pelargoniums, and bouquets all contributed to the display; while in the classes for fruit the Black Alicante Grapes from Mr. R. Holmes, gardener to J. Wallis, Esq., Clapham Common, the dessert Apples from Mr. Coombs, and culinary Apples from Mr. Haines, were very satisfactory. Messrs. Mahood & Son exhibited a seedling Japanese Chrysanthemum named *Mrs. J. Mahood*, for which a certificate was awarded; it has narrow twisted drooping florets, which are creamy in colour, the bloom being full and distinct.

SOUTHAMPTON.—NOVEMBER 14TH.

Established twenty years, the Southampton Horticultural Society has had many successful shows, but never one in the autumn so good as the one we can only refer to too briefly. Chrysanthemums, both as regards plants and cut blooms, showed a great improvement on past efforts; indeed, contrasted with the results of half a dozen years ago the advance is little short of marvellous. Of fruit the display

was not so large as last year but better, Grapes, Pears, and Apples being excellent, not a few dishes splendid; while the exhibition of vegetables, both for extent and high average quality, was such as is seldom seen at an autumn show.

Mr. Molyneux, gardener to W. H. Myers, Esq., Swanmore Park, Bishops Waltham, was the premier exhibitor of cut blooms, winning the chief prizes in every class in which he competed—namely, in the open and gardeners' classes for twenty-four blooms, in the class for twelve incurved or reflexed, and in those for a similar number of Japanese and large Anemone-flowered varieties. Nor was this achievement the result of poor competition—on the contrary, the other successful exhibitors staged meritorious stands. The truth is Mr. Molyneux must rank amongst the foremost growers of the day. His blooms are remarkable for their high finish, symmetry, solidity, and, many of them, large size. The Japanese variety, *Madame C. Audiguier*, has never before been represented so splendidly—nearly 7 inches in diameter, 6 high, with flat petals interlaced like loose basketwork, colour satiny-rose. Growers, make a note of this, obtain the variety, grow it similarly, and be thankful. Several other Japanese blooms merit notice, but they must reluctantly be passed. Amongst his incurved flowers *Princess of Wales* has rarely, if ever, been excelled, and *Mrs. Heale*, Mr. Howe, *Jardin des Plantes*, *Golden Empress*, and *King of Crimsons* were about equally fine; the stand included a bright and good bloom of Mr. Bunn, and the new sulphur yellow, *Miss Mary Morgan*, was well represented. Mr. Allen, gardener to J. Bailey, Esq., Elmfield Hall, was an excellent second in the open class; Mr. Pope, gardener to G. Hatherley, Esq., Northbrook House, was third; and Mr. Wills, gardener to Mrs. Pearce, The Firs, Basnett, an exceedingly close fourth. Messrs. Allen and Wills followed Mr. Molyneux in the gardeners' twenty-four and in the open class for twelve Japanese blooms, Mr. Pope being an equal third, all staging most meritoriously. Mr. Osborne, gardener to H. J. Buchan, Esq., was second, with highly creditable examples in the incurved (open) class for twelve blooms, and Mr. Allen third. In the gardeners' class the prizes went to Messrs. Pope and Osborne, with good stands of nearly equal merit. Amateurs exhibited neat blooms, many being good, in the classes provided for them, but these it is impossible to particularise.

Although the plants were effective and some decidedly good in their way, yet several were inferior, and in one or two instances the Judges were liberal in granting prizes. Mr. Allen was clearly the premier exhibitor in these classes, his specimens being about 3½ feet high and the same across the tops, in form somewhat resembling blunt pyramids standing on their apex—not quite the best style to adopt, yet the Japanese examples were undeniably imposing, and his single specimen reflexed, *Mrs. Forsyth*, 5 feet in diameter, was the best in the Show; while the Japanese *Triomphe du Nord* was almost equally good. The second in this, a large and striking plant of *Sultani*, just lost the chief position by rather defective foliage. Mr. Allen was first in every class in which he competed, including the groups, which were good. Mr. Osborne was first for six plants, the remaining prizetakers in these classes being Messrs. King, Ams, and Wills. Several of the plants were tied much too late, and the stems bent too near the top. Where twisting must be done it should be done earlier and lower, and the result would be far more satisfactory. We should like to notice the amateurs' plants and to dwell on Dr. Buchan's charming group of Orchids, but neither time nor space permits this being done. Mr. Wills' group of miscellaneous plants was far the best in the building; the plants in the second-prize group of Mr. Ams being very good but too closely packed. In the nurserymen's classes Messrs. Ransom and Kingsbury were the prizetakers.

Grapes from Messrs. Hall, Sanders, Cox, and Matthews; Pears from Messrs. Mair and Gates; Apples from Messrs. Turton, Fowle, and Hall; and vegetables from Messrs. Pope, Sanders, Allen, Molyneux, and Tyler, were all superior and in the highest degree creditable to the respective cultivators; while other exhibitors, whose names we failed to obtain owing to the dense crowd, also staged excellent produce.

Captain Gibbs, Mr. Fudge, and the Managers of the Show generally merited the thanks of the Society and the public for the excellence of the arrangements, while the schedule was clear and the conditions admirably defined, thus greatly assisting instead of, as faulty schedules always do, perplexing the Judges.

SILKWORMS AND SILKWORM REARING.—19.

(Continued from page 412.)

EUROPEAN missionaries in these modern days have, like some of the monks of the olden time, rendered good service to art, literature, and science while pursuing their more sacred duties. Many a valuable product of distant climes has been discovered and thereafter sent over to the fatherland by a missionary who has not lost his home instincts whilst living or wandering amongst less civilised races. North China, and more especially the province called Manchouria, is the head quarters or natural locality of another feeder upon the Oak, *Bombyx* or *Attacus Pernyi*. The specific name was given in remembrance of the fact that by Archbishop Perny, a French cleric, the first examples were sent to Europe. Possibly this plan of designating animals and plants

out of honour or compliment has done some harm to science, at least "the line must be drawn somewhere," as several entomologists thought when it was proposed to call a new moth "Blanchella," after a young lady. For who could say that we might not have inflicted upon us next a *Johannesii* or a *Billella*? In the Universal Exhibition of 1855 the cocoons and silk were shown to the public, specimens of this species having been reared by M. Jordan at Lyons.

Figuiet highly commends the silk yielded by *Attacus Pernyi*, in which he thinks are united most of the excellent qualities of linen and cotton, as well as of silk. The colour is somewhat against it, since this is greyish-yellow or light brown, nor does it take a dye very readily, in this particular being inferior to the silk of *A. Yama Mai*. Another disadvantage we have had to contend with: As yet any attempts at reeling the cocoons have

Fig. 76.—*Attacus Pernyi* Moth.

proved a failure in Europe, owing to the weakness of the thread at the apex. Corded, however, a strong and soft thread is obtained readily. The Chinese, it is said, do reel their cocoons; perhaps in its own region the insect forms a cocoon rather different from those spun with us. Indeed, the silk of *A. Pernyi* is an established article of commerce in China, recognised at once from its colour as the product of the silkworms, wild or tame, that have been reared in the mountainous districts. Goods that are manufactured from it are called "pingees," and probably about ten thousand bales or more come into the market each year.

The moth (fig. 76) is a trifle less in size in the average than that of *A. Yama Mai*, of a greyish-brown colour, tinged here and there with red, having the four spots or eyes that are usual in the group, and antennæ very conspicuous in the males. They are more active than their partners, the females being disinclined to fly, although their wings are the broader of the two, but they move from twig to twig when depositing their three hundred or four hundred eggs. As the insect passes the winter in the chrysalis state, the moths that appear during the warm weather of spring lay eggs which hatch in a fortnight or three weeks. The little worms begin by being restless, yet they show a partiality for each other's society, liking to sip the morning dew, but not such thirsty creatures as are the juvenile *Yama Mai*. After the first cast of skin they cease to be gregarious, and their black jackets are changed to greenish.

Each of the four moults alters their appearance; the last exhibits them of a yellowish-green, the surface of the body dotted over with long spines, which are curiously clubbed at their tips. The head is of a conspicuous brown hue, nearly black in some individuals. When they are roaming at liberty, just as they are getting large, these silkworms are fond of working their way to the tops of Oak twigs from which they have stripped the leaves, and resting there to sun themselves they hold out an attractive bait to caterpillar-hunting birds. Our observations upon them in confinement, made up to the present date, indicate that they suffer less from diseases than the *Yama Mai* silkworms. By means of a pedicel or footstalk of silken cord the cocoon (fig. 77) is attached to a twig, and swings there securely through the winter season. Hence there is not much difficulty in detecting these cocoons when the leaves are fallen or diminished in number, and the Chinese go out to hunt for them amongst the woods and mountains where the species occurs wild, obtaining a good many if the season has been favourable and the birds not too destructive. As the cocoon is large and spun rather loosely, the chrysalis within is apt to shake about and receive injury if it is exposed to the chances of a journey, so that purchasers of unopened cocoons may have their hopes frustrated should they wish to obtain moths for

breeding. Eggs, however, may be had from various dealers in May or June at about the same price as is charged for those of *B. cynthia*. Moths also sometimes appear during August, the species being naturally double-brooded; but there is difficulty in rearing an autumn brood of the worms in this country from the eggs deposited then, and it is generally considered advisable to check the progress of the summer chrysalids by keeping the cocoons cool, so that the moths may come out in the spring of the next year.

Mr. T. T. Meadows, from personal inquiry in North China, was able to ascertain that the rearers of *A. Pernyi* there usually obtained two crops of the mountain silk each year. The second gathering of cocoons is in September or October, and those to be preserved for continuing the brood are kept at a temperature rather above that they would be subjected to in the open air, as the frosts of their winter are occasionally severe enough to kill the chrysalis in exposed places. When the females are ready to deposit eggs they are placed upon sheets of the native paper spread over tables. It is often necessary to force the Oak for the food of the young worms, twigs being cut and placed in tubs within doors. The newly hatched worms are carefully fed with tender leaves until they are about an inch long, then they are transferred to suitable bushes in the hill slopes, where they seem to thrive better than in spots more sheltered. The summer of the region is seldom hot, and the few warm days are separated by cool intervals. No particular attention is bestowed upon the silkworms, only they are moved from bush to bush as they strip the leaves. The food is several species of Oak, examples of which have been named at Kew. What is called by the Chinese *tsing-kang-lev* is considered to be *Quercus Mongolica*. Their *hoo-po-lo* is *Q. obovata*, and a third

kind named *tseen-tse-tszeo* is *Q. serrata*, and this is supposed to produce the finest worms. With us the worms give a preference to the leaves of the Evergreen Oak, but they feed freely upon our common British species of *Quercus*. Not only are the caterpillars easy to rear, the moths are found to pair very readily, another circumstance in favour of *A. Pernyi* compared with its relatives *Polyphemus* and *Yama Mai*. The species is hardy enough to live out of doors in England if birds and predatory insects would keep away from the worms.

The Chinese informed Mr. Meadows that the spring worms were of more rapid growth than the autumn brood, coming to their full size in about sixty days, while the latter required ninety, or even a hundred. He observed that if all the available spaces on the sides of the slopes were planted with Oak, the yield of silk might be ten times as much as at present. With their wonted omnivorous tendencies, the Chinese are said to cook the chrysalis, regarding it as a delicacy.—J. R. S. C.

GAS-TAR WALKS.—Dry mild weather at this time of year affords the season for making or repairing the surfaces of gas-tar walks. The

Fig. 77.—Cocoon of *Attacus Pernyi*.

two requisites are—first, good drainage, which is secured by about 8 inches of broken stone pounded compactly down, with free outlet for water at the lower end; and second, a waterproof layer over the top. The whole being thus kept dry is as little harmed or disintegrated by frost as the stone walls of a building while covered by a roof. A very cheap waterproof surfacing is afforded by mixing sand or sifted ashes or cinders with gas-tar until the whole is saturated, yet not fluid, but about the consistence of damp snow or sugar, and capable of being packed down solid. The mixing is easily done when all the material is warm and the sand or ashes dry. There appears to be no advantage other than that in heating the tar. The stone foundation being covered with cinders and rolled or beaten solid, the mixed preparation is spread on about 2 inches thick and well packed down. The packing is often done with a roller, but a beating with a spade-back is best if the mixture sticks on the roller, as it is apt to do if damp sand is used. Sometimes a roller is used to finish smoothly, or a flat-bladed shovel weighted with hot bricks is drawn over. This leaves a very smooth, compact, even surface. A covering of sand and a board laid over for the first weeks of use will prevent heel marks, &c.

being impressed into the freshly laid pathway. A curb of brick or plank soaked in petroleum serves to keep the edges even. Sometimes the walk is made slightly lowest in the middle in order to keep the edges as dry and free from danger of crumbling as possible. If the surface should crack during the summer following it should be well brushed over with tar on a warm dry day to fill all fissures, and if sand is sprinkled over it can be immediately used. An old broom serves to do this well and quickly. It is said, we know not how true, that a little sulphuric acid put into the tar serves as a thickener and drier. A heating of the tar before using answer the purpose probably as well. This sort of path is easily kept clean, and all rain runs off. A gallon of tar will suffice for about 8 square feet of coating 2 inches thick.—(*New York Tribune.*)

HARDY FRUIT GARDEN.

WHERE trees against walls have lost their leaves commence pruning and nailing at once. Apricots are usually the first to lose their leaves, closely followed by Cherries, Plums, and Pears. Where time can be spared it is desirable to loosen the trees from the wall. When time cannot be spared for the entire disengagement of the trees they should be carefully examined to see that none of the ties or shreds are too tight. Any old bare wood should be cut out and young trained in its place, also thinning the spurs where too crowded, and shortening any spurs that have grown to a considerable distance from the walls. This in most instances is all that is required for Apricots where summer-pruning has been duly attended to. Plums will only need any attenuated spurs shortened, and where too crowded judiciously thinned, whilst shoots more than 3 inches long should be cut back to a couple of joints from their base, but any short stubby shoots should not be shortened. Cherries and Pears should be treated similarly. Trees in course of formation must have the main shoots disposed 9 to 12 inches apart, and be trained in their full length unless their extremities be unripe, when they should be shortened to firm ripe wood. The central shoots will likewise need to be cut back to originate shoots at suitable distances for furnishing the trees. If the trees have been infested with aphides or other insect pests it will be advisable to dress the wall as well as the trees with an insecticide. Half a gill of petroleum mixed with four gallons of water will prove fatal to most insect larvæ. For scale on Pear trees whale oil is efficacious, and it is equally so against American blight or woolly aphides. After the trees have been pruned, nailed or tied, the loose surface soil should be removed down to the roots, and a good dressing given of good rich compost; turfy loam, with an equal proportion of well-decayed manure, and about a twentieth part of charred vegetable refuse intermixed will be beneficial. Borders that have received heavy dressings of manure for vegetable crops will be benefited by a dressing of unslaked lime. Half a bushel per rod will be a suitable quantity, pointing it in.

The season so far has been very unfavourable for planting fruit trees on heavy soils. With a change for the better no time should be lost in planting the trees contemplated; but with the soil in a wet state it will be preferable to defer planting until spring, this especially applying to cold heavy soils.

STRAWBERRIES IN POTS.

The earliest batch of these will now have well-developed crowns, and be at rest so far as top growth is concerned; but the roots are still in a more or less active state, and under no circumstances must they be allowed to suffer by want of water, it being necessary that they be kept in a thoroughly moist condition. The plants intended for early forcing should be moved to a cold frame, the pots being plunged in ashes, the lights only being employed in case of heavy rains and when frost prevails. Plants for successional forcing will succeed very well plunged to the rim of the pots in ashes in a sheltered situation open to the sun, where protection can be given them in severe weather, a little dry litter being all the protection that is needed. See that none of the plants lack moisture, as a dry condition of the soil is very injurious.

FRUIT HOUSES.

Pines.—The most useful structures for the general requirements of Pine plants are properly heated and ventilated pits or small houses, as with little labour they afford the most suitable atmospheric conditions; but the closeness of these structures will at this season necessitate strict attention to the ventilation, or the plants soon become drawn and weakly—a condition that is irremediable, and should be strictly guarded against by commencing to ventilate a little at the top of the house at 65°, and unless the temperature in the house falls below that degree the ventilation should be continued throughout the day. When external influence raises the temperature in the house to 75° a free circulation of air should be allowed through the house or pit. Keep the plants near to the glass, and do not crowd them: 60° at night is a suitable temperature for all young stock to be kept gently moving through the winter, falling a few degrees when the weather is severe, and 65° in the daytime by artificial means. The heat should be kept steady at the roots at 80°. Avoid too much moisture in the house. If the plants are in fermenting beds sprinklings will not be necessary, but water—weak liquid manure—must be given whenever the plants become dry. If there be likely to be a scarcity of suckers for starting next March it will be advisable to keep for this purpose those which are ready now, as well as recently potted ones, which thrive best wintered in 5-inch pots. Instead of potting the suckers now ready it will be best to keep them on the stools after the fruit is cut, cutting off the leaves and placing the suckers in a moist pit with a bed having a slight bottom heat and a temperature of 55° at night and 60° to 65° by day, keeping near the glass and moderately dry at the roots. Continue former instructions in other departments.

Vines.—The excessive rainfall and consequent saturation of soil and atmosphere have caused an unusual amount of damping, particularly in Hamburgs and other thin-skinned varieties. Slight fires will be necessary in the daytime to allow of ventilation, but an equable temperature should be maintained as far as practicable, 45° at night being suitable for Hamburgs and 5° more for Muscats. Although a dry atmosphere is advisable it must not be produced by too much fire heat, or the Grapes will shrivel, a similar result accruing from too dry a condition of the internal borders. These should be neatly covered with straw or mats, which will keep the soil in a good condition as to moisture. Outside borders, it is presumed, have been covered with shutters, lights, or other protective material against rains some time ago, if not it must not longer be delayed. Vines from which the fruit has been cut should be pruned, and not being required for plants should be kept cool by free ventilation, merely excluding frost, as a few degrees of frost will not do them any harm. Remove the inert surface soil down to the roots, and add good loam and a few half-inch or crushed bones. The house must be thoroughly cleansed and the Vines dressed, especially if they have been infested with red spider or other insect pests.

Frequently turn over the litter in very early houses, and replenish as the heat declines by working in fresh material direct from the stables. Similar remarks apply to outside borders, which if not covered with fermenting materials should at least have shutters or a good covering of straw or dry fern, with a slope so as to throw off heavy rains, and prevent the roots of the Vines being chilled and a predisposition given to shanking and other ills. The earliest-started Vines in pots and houses will be showing signs of breaking, and should have the temperature increased to 60° at night and 65° in the daytime artificially, advancing to 75° from sun heat. Very little ventilation will be needed for some time to come, giving it when necessary at the top of the house.

Cucumbers.—Careful attention in the admission of air will be needed for some months to come; and as no opportunity should be lost of affording a little, it should not be admitted so as to lower the temperature, and certainly ought to be excluded when the air is cold, a few degrees extra warmth from sun heat being better than a cold current of air. A night temperature of 65° or 60° on cold nights will be sufficient, with 70° to 75° in the daytime. In dull foggy weather be very sparing of moisture, and cease to charge the evaporation troughs, but in bright weather a good amount of moisture will be necessary. Cut over the foliage regularly every week,

encouraging as much fresh growth as can have exposure to light, but avoid overcrowding and overcropping as the greatest of evils.

PLANT HOUSES.

Epacris.—These are coming into flower, and if encouraged with a slight heat will soon be in full beauty. They are fine for conservatory decoration, their long shoots being excellent for cutting, and especially useful in large vases. In flower now are *Ardentissima*, *Salmonea*, *Lady Panmure*, *The Bride*, *Devoniana*, *Eclipse*, *hyacinthiflora*, and its vars. *carminata* and *candidissima*; *miniata splendens*, *Vesuvius*, and *Viscountess Hill*.

Heaths.—These, though not so accommodating as *Epacris*, are not, however, injured by employment for a few weeks when in flower in the conservatory, provided they are kept in a light, airy, cool part of the house, and not too crowded, the last spoiling more plants than anything else. Some of the best for winter are *Erica hyemalis*, *E. gracilis autumnalis*, *melanthera*, *persoluta alba*, *ventricosa* vars., *caffra*, *colorans*, *grandinosa*, *scabriuscula*, *regerminans*, *candidissima*, *mammosa pallida*, *cerinthoides coronata*, and *Lambertiana rosea*.

Lachenalias.—These are useful plants, pretty alike in foliage and flowers, they being easily grown. A position on a shelf near the glass should be given them, and, growing as they now are freely, a little weak liquid manure should be given occasionally. They do well in sandy loam, and do not require a great deal of pot room. A dozen bulbs can be grown well in a 6-inch pot; six or eight in a 5-inch.

Tropæolums of the tuberous section, as *tricolorum*, *Jarratti*, and *pentaphyllum*, are not so common as they deserve to be, few plants being more effective when well managed. Early training is necessary, so as to cover the bottom part of the trellis with young growth before the shoots get to the top, or there will afterwards be a difficulty in furnishing them well at the base. They do not require a great amount of pot room, ought never to be overpotted, and should not be overwatered, just keeping the soil moderately moist, or allow to become fairly dry, and then afford a supply of water.

THE ART OF BEE-KEEPING.—No. 2. NATURAL HISTORY.

THE basis of successful bee-keeping is an accurate knowledge of the instincts and habits of bees. Matters of detail, such as their anatomical structure, the mathematics of comb-building, and the peculiar harmony between the structure of flowers and the bees that fertilise them, can scarcely be expected to occupy space in a series of papers purposely limited to what is of most practical importance to bee-keepers. Students of natural history desirous of entering into these most interesting details are recommended to such works as those of Huber, Bevan, Darwin, and Lubbock. We meantime confine ourselves to outlines of practical importance.

First of all we invite attention to that feature in the honey bee which makes its domestication possible—viz., its perfect *sociality*. While other bees and wasps are only semi-social—that is, exist as colonies during only a part of the year, the hive bee maintains its social habits from one season to another. While the queens of wild or bumble bees and wasps exist by themselves during the winter, and develop all the instincts and powers necessary to originate colonies during the following spring, the queens of the hive bees cannot exist apart from the workers, and possess no power of building, foraging, or even of nursing their own progeny. In harmony with this special character the hive bee finds a high temperature necessary for all active operations inside the hive, in this respect resembling warm-blooded animals. Ordinary temperatures soon chill both bees and queens, and cause the death of their young; while under these same conditions the wild bees and wasps exist even in a solitary state, their young hatching without any brooding heat. These facts have an important bearing on the question of hives, their material, capacity, and management.

Notwithstanding the immense importance of the *queen* in a colony as the mother bee and centre of attraction, the *workers* are the agents on whose labours and instincts the colony is maintained, and to which the bee-keeper mainly looks for the results of his attention. Let us therefore shortly consider the ways of the workers, leaving the queen to be dealt with in a special chapter.

The worker is the typical bee, the bee of our childhood, the “busy busy bee” of the poet, the bee for whom both queen and drones exist, and without whom they would cease to be. They are the active agents in all the offices which bees seem destined to fill in the economy of Nature, the unwearied producers of the honey and wax we so much prize, and seem specially destined for the important work of fertilising blossoms. Numerically and potentially they are far the most important inmates of the hives, and the bee-keeper’s aim should be to discover in what ways he can best assist them in their willing work. Nature must be studied with a view to giving her assistance—all attempts at thwarting her must prove ruinous. Such sentiments do not, however, give any encouragement to the let-alone system of bee-keeping, which is so often boasted of as the more natural one. In it little or no assistance is afforded to the bees—calamities are allowed to come as they may, stocks perish of queenlessness or disease, a greater or less percentage are allowed to die of starvation every year, and the survivors are cramped for room to store their supplies, till they are forced to swarm and swarm again as they never do in a state of nature. Let us remember that reason is superior to instinct, and that the latter often finds itself in straits and ready to accept help from the former.

Worker bees are hatched in about twenty-one days from the egg—viz., three days in the egg, four days as a larva, and fourteen days in the scaled state. They do not generally leave the hive till about a week old. As in the grub state they do not seem to void any excrement, their bowels are generally pretty much distended with the excreta of their food, and their first flight seems mainly with a view to clear themselves. Bees bred in winter, as from untimely feeding, are thus in danger of perishing either through distension of the bowels or while endeavouring to take the needful flight. The early stages of the bee’s life are occupied with the labours inside the hive: preparing and supplying the pap for the numerous larvæ, sealing them up when about to change into chrysalides, cleaning out the cells just vacated by hatching bees, feeding the queen, secreting wax, and building combs. As they grow older they partially lose the instinct for such employments, and probably also the power, and betake themselves to the fields as foragers for the community, or take their turn as sentries and defenders. Thus old bees that happen to become queenless often seem either indifferent to their loss or unable to avail themselves of the chance of raising a new queen, and in this queenless state will often keep together, and carry on their foraging for months, or until they dwindle away altogether.

Each of the operations above referred to seems to be the result of a special and highly endowed instinct. We have already noticed how their *social* instincts keep bees together as a colony, preserve the due relations between the queen and the workers, and award to each individual a share in working for the common good. The same instincts work in apparent discord when the time comes for casting swarms, when the colony is split and split again as swarm after swarm departs. But there is no contrariety: all is done without discord or strife, all is done for the common weal. The bees, whether they realise it or not, are, in the act of swarming, making the very best provision for the continuance of their species. Were there no swarms there would soon be no bees, for it is only a question of time when every colony would perish from one or other of the evils of queenlessness, disease, or robbery.

In considering the attitude of the bee-keeper towards these social instincts we must remember that bees are kept by us in circumstances not altogether natural. Our hives are necessarily very different from the abodes naturally selected by the bees themselves. In regard to these, it should be our aim to furnish a habitation so arranged as to encourage every object for which bees cluster together, due provision being made for warmth, ventilation, and storage. We must remember also that circumstances may arise where instinct will be powerless, such as queenlessness or disease; or that circumstances alter matters, as when a large number of colonies are kept close to each other, in which case the production of drones sufficient to fertilise all the queens of a neighbourhood may be restricted to a single stock or to a few from each. In regard to swarming, too, it should be remembered that bees learn nothing from previous experience, those of a former year having long since perished. They have no idea how long or how short the honey season in any locality may last, consequently they may and do often indulge the swarming instinct to an excessive extent, and that, too, at a season when, in their own interest as well as ours, it should either be strictly controlled or altogether prevented.

In like manner the bee-keeper should take into account the other instincts of his bees. The *provident* instinct should be encouraged to the utmost, room for storage being provided at all times slightly in excess of immediate requirements, so that no idle clustering bees may be found hanging about the hive entrances, and the bee-keeper should know how to aid his bees by timely

feeding, whether of syrup or pollen, when from ungenial weather their instincts are baffled by the poverty of natural supplies. The possibilities with strong stocks properly aided in this way are immense, for the bees are not content with gathering enough to supply their immediate wants, but make provision for themselves and their successors for many months to come. Lazy bees mean a lazy and ignorant bee-keeper, who leaves his hives unsupered and un-eked, till from sheer want of storage room his bees, gorged with honey, hang idly all around.—WILLIAM RAITT, *Blairgowrie*.

(To be continued.)

COSTLY HIVES AND RESULTS.

THE question of profit and loss in bee-keeping is important to a great number of apiarians, and ought to be the essential consideration in practical apiculture; but for some reason or other it has not of late been much discussed. The sooner this question comes to the front and receives due and general attention the better it will be for apiculture and beginners. During the last ten years money has been wastefully spent on new hives, and during that time there have been great losses and failures in bee-keeping. Some working men and others higher in station write and tell me of their losses and disappointments, and it is lamentable to know they are samples of others throughout the land who have bought costly hives and bee furniture which as yet have yielded no return for the outlay. How long will such unwise expenditure continue? Stories are told even in Lancashire and Cheshire of gentlemen and working men spending money lavishly on new bees and costly hives, almost all ending in disappointment. What did the late Mr. Quinby, who was one of the most extensive and enlightened bee-keepers of America, say touching this question? He said 1s. 6d. is enough to give for a hive, and every cent or halfpenny beyond 1s. 6d. per hive would yield no return for the extra outlay. Mr. Quinby wrote for the advantage of American bee-keepers, and though he used wooden hives he predicted that some day straw would be preferred to wood; but here we should bear in mind that wood is cheap in America, and that hives of sufficient size, either in wood or straw, cannot be had in England at that price. However, beautiful, excellent, and capacious hives can be had in this country at a price cheap enough even for working men. Only twice have I paid more than 5s. for hives, and these were in wood, and when English apiarians hold broader views of bees and bee-keeping than most have at present, expensive hives will speedily go out of fashion.

Hive-dealers are having the best of it just now, but no one can blame dealers for making the best of their goods. Ten years ago I was somewhat anxious to see the prize hive of the Bee-keepers' Association. In one of the midland counties I saw it in the apiary of an advanced bee-keeper. It cost, I think, 35s. I examined it, and came to the conclusion that I would not accept the gift of a dozen of such hives for my own use if they were offered. Some time afterwards the gentleman wrote to me that the others in his garden, which cost only about one-eighth of the price of the prize hive, were far superior to it for work and profit. I trust no one will be offended at my suggestion that it is desirable the British Bee-keepers' Association should not offer prizes at their shows for costly hives. By withholding prizes from hives beyond a certain price the gentlemen of the Committee will express their disapproval of a practice not advantageous to bee-keeping.

In order to succeed and make money of bees the utmost economy is necessary. Expenses must be kept low. For years I published annually the balance sheet of my apiary, and in doing this I saw the importance of rigid economy. Another point became more and more evident—viz., that if bees have room enough and are let alone they will seldom disappoint their masters. Meddling with bees is not good for them. Since I began to write these letters on the Stewarton hive an Ayrshire correspondent has informed us through the Journal that some bee-keepers there have used the straw Stewarton for years. I am greatly pleased to know this, for it shows the thought we have been dwelling upon has long since passed into established practice. Both Mauchline and Stewarton are Ayrshire villages situate a few miles from Kilmarnock. I shall now arrange to have twenty or thirty straw Stewartons made for my swarms next season, about 15 inches wide by 14 deep, neatly sewed. I expect they will be pretty hives, as useful as hives can be, and cost about 5s. each. If the reader has seen a bushel measure—which is 16 inches deep and 14 wide—he will be able to form an accurate idea of the shape and size of my Stewartons. I am obliged to a gentleman in Aberdeenshire, who has written privately to say that supering bar-frame hives there is not done through a hole in their crowns, but through a modification, as it appears to me, of the Stewarton principle. Mr. Raitt

is probably the inventor of this way of supering bar-frame hives, for he practises it and instructs others to do so. We may therefore expect to get some time a full description of this mode of supering. If the Stewarton hive appear in straw and become a general favourite, I would not advise working men to abandon their present hives and get Stewartons. By removing the crown boards of bar-frame hives, and adopting the Stewarton principle of supering, much may be done at little expense. Commending the consideration of this subject to bee-keepers generally I leave it for the present.—A. PETTIGREW.

TRADE CATALOGUES RECEIVED.

James Cocker & Sons, Aberdeen.—*Catalogue of Roses, Trees, and Shrubs.*

T. Laxton, Bedford.—*List of New Fruits and Vegetables.*

James Dickson & Sons, Newton Nurseries, Chester.—*Catalogues of Forest, Fruit, and Evergreen Trees, Roses, Hardy Flowers, &c.*

Francis and Arthur Dickson & Sons, Upton Nurseries, Chester.—*Catalogue of Forest and Ornamental Trees and Shrubs, Fruit Trees, Roses, &c.*

L. Spath, Berlin.—*Catalogue of Plants.*

H. Cannell & Sons, Swanley, Kent.—*Catalogue of Roses Chrysanthemums.*

* * * All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (J. M. B.).—Mr. Cuthbert Johnson's work on fertilisers is published by Messrs. Ridgway, Piccadilly, London. (*A. Booth*).—"Hops from the Set to the Skylight," by Charles Whitcadd, F.L.S., published by Effingham Wilson and Co., Royal Exchange, will answer your purpose. (*D. Watson*).—There is no work so "cheap, concise, and comprehensive" on the culture of plants, fruit, and vegetables as our "Garden Manual," price 1s. 6d., post free from this office 1s. 9d. (*J. D.*).—Simmond's "Tropical Agriculture," Spon, Charing Cross, will probably suit you. It can be had through a bookseller. Shaw's work on "Market Gardening" (37, Southampton Street), and Earley's "Profitable Market Gardening" (170, Strand), might give you some of the information you are seeking.

Unlevel Houses (J. E.).—So far as the heating of the houses and the circulation of the water is concerned you may have the structures as much out of level as you like. When not level and square they cost more to build and do not look well when completed. Some of the finest crops of Grapes we have seen are grown in houses "out of level."

Apples for Market (J. E., Ireland).—The letter to which you refer certainly never reached our hands. If you will state the number of trees you require, whether standards for orchard or otherwise, or name the extent of ground you desire to occupy with trees, we will readily name varieties that are likely to be useful.

Pears for Wall (G. P., Hants).—Your reference to a "former letter" is insufficient. In our great mass of correspondence it is impossible for us to remember the purport of former letters. If you want simply twenty-four varieties of Pears for succession we will publish their names next week; but any information that you may need different to or beyond this can only be given on your repeating your requirements.

Auriculas in Frames (A Beginner).—The plants will be far better in the frame than crowded amongst others in a greenhouse. Provided they are moderately dry at the roots, and the frame is in a sheltered position, they are not likely to sustain any injury by frost. Still, if the weather is severe you will not err by packing straw round the sides of the frame and covering the glass with mats or other protective material. We have had the soil in the pots frozen quite hard and the plants sustained no injury, but they are injured if frosted in the spring after growth commences. It is then that protection is needed more than at any other time.

Dahlias in Winter (J. Allen).—It is quite true that Dahlias will pass the winter safely in the open ground provided the soil is light and well drained, and ashes or cocoa-nut fibre refuse are placed over the roots and for a good distance beyond their extremities; but not only will the blooms which the plants produce next year be late, but they will be small, and in all respects inferior to those afforded by plants that are raised from cuttings established early, well prepared, sturdy and strong, for planting towards the end of May or early in June in deeply trenched and rich soil. Dahlias should be taken up at once, carefully dried, and be wintered where they will be perfectly safe from frost.

Jersey Gratioli Pear (J. E. B., Surrey).—This is an excellent Pear, and you may safely plant it in your garden where you say Pears usually do so well. The tree grows well and bears freely, the fruits being juicy, vinous, and enjoyable.

This variety is known in Jersey by the name of Gratioli, and under this name it had for some years been grown by Mr. Norris of Sion Hill, Isleworth; but as Gratioli is the Italian name of Bon Chrétien d'Été, to prevent confusion Mr. Robert Thompson named the present variety Jersey Gratioli. It must have been a considerable time in this country, as there is a tree growing in the garden of H. M. Bucknall, Esq., of Bedminster Lodge, near Bristol, which he considers (1856) to be fifty years old. Specimens from Mr. Bucknall and from Mr. Norris were both one variety.

Stove and Greenhouse Plants (M. T.).—There is no small manual of such a comprehensive nature as you appear to require. The "Cottage Gardener's Dictionary," which can be had from this office post free for 8s. 3d., gives information on the culture of all kinds of plants, fruits, and vegetables, also on the different methods of heating glass structures; but no work contains plans of heating precisely adapted to your small house. There are ironmougers in nearly all towns quite able to do what you require satisfactorily.

Rochea falcata (A. Boyle)—An ordinary greenhouse is suitable for wintering this plant, which is quite safe in a temperature of 40° as a minimum. The plants should be kept rather dry at the roots in the winter, and the atmosphere of the house dry also. Water applied once a week or fortnight, or even less seldom according to the weather, is usually sufficient until February, when more moisture must be gradually afforded, and a very light position be assigned to the plants. During their season of growth they cannot be too much exposed to the sun. They are planted out in the flower beds of some of the London parks in the summer, and strong plants produce larger heads of scarlet flowers.

Standen's Manure (Worcester Subscriber).—In reply to your question as to where Standen's manure can be bought, as you "never saw it advertised," we believe it is sold by most nurserymen and seedsmen. Messrs. Corry, Soper, Fowler & Co., 18, Finsbury Street, London, E.C., are the proprietors, but we are not able to say whether they sell it retail or not. This excellent manure is perhaps not sufficiently advertised.

Carnation A. Alegatiere (M. T., Halifax).—If you mean by a "tree" Carnation a variety that flowers freely and continuously you may include this in your collection, but it is so dwarf in habit that the term "tree" is a misnomer. It is one of the dwarfest, brightest, and floriferous varieties we know, and flowers with great freedom in winter when the plants are young and vigorous. A light house, with a temperature of 45° to 50°, is essential for insuring a supply of Carnations through the winter.

Planting Potatoes in the Autumn (B. L. E., Surrey).—In some soils, seasons, and districts autumn planting has been successful, but we believe it is neither adopted as a system by those who grow tubers for exhibition nor for providing them in quantity for the market. It is not a new system by any means, but has been practised more or less for at the least half a century. If you choose to try the plan the present is the time for inserting the tubers, covering them quite 6 inches deep; but we decline the responsibility of advising you to plant your entire stock, or even half of it, now. You had better try the method on a small scale as an experiment, and judge for yourself.

Pruning Clematises (G. Godson).—They do not require pruning so severely as you have been informed. If you examine the stems you will find some round buds as large as peas, and to these buds the growths may be shortened. We should not prune the plants at present, as if the weather should prove mild fresh growth might be produced almost at once, and receive injury by subsequent severe weather. The longer the buds indicated remain dormant the more likely are the young growths to escape destruction by frost. February is a good time for pruning Clematises, and we should not prune them before then, unless the appearance of the plants was objectionable.

Pruning Fig Tree (Svanley).—The reason your Fig tree did not bear when it was pruned severely was because the subsequent growths were too strong and luxuriant. Such growths always follow after close pruning unless the roots are pruned also. As the tree is now objectionable in appearance you may remove those growths or branches that are strong, securing those of a more stubby and short-jointed character to the wall, not shortening them. This should be done now; but if you remove any considerable portion of the tree, you had better also dig a trench round it and cut off all the roots beyond a certain radius, to be determined by the size and vigour of the tree, and fill the trench with old lime rubbish and similar material, pressing it down as firmly as possible with a rammer.

Cleansing a Vinery (Regent).—No measures that you can adopt now will prevent the red spider attacking your Vines next year if preventive measures are neglected in summer, as appears to have unavoidably been the case this year. After pruning the Vines we should wash the rods with a solution of nicotine soap or Gishurst compound; or, failing these, softsoap, using 4 ozs. of either to a gallon of water, applying with a brush, scrubbing the Vines well with the solution hotter than the hand can be borne on it, or say at a temperature of 150°. If you have not time to crush the sashbars, similarly syringe the roof freely with boiling water; limewash any exposed wall surface, mixing sulphur in the wash, and remove the surface soil if the border is inside, and add fresh. A portion of the roof can be done at once, removing the plants for that purpose, and those on the back wall can be covered with mats to prevent them being injured by the hot water. We shall be obliged if you will inform us with what plants your "unbeaten vinery" is filled during the winter, and the names of the climbers on the wall.

Planting Anemones (D., Hampstead).—It is not too late to plant the tubers, but the sooner they are placed in the beds the better. You will find in our "Florist Flowers" (price 4½d.), that the Anemone requires a pure loamy soil well mixed with sand, such as sometimes is found on the sides of rivers naturally mixed with the sand. Choose a situation that is open, but sheltered from violent winds or strong twisting currents of air; then dig out the soil a foot or more according as the situation is high or low. If high it may be dug out 3 or 4 inches deeper, but if low and wet a foot will be sufficient. Mix the soil with sand if it requires it, and fill in the bed again to within 6 inches of the level of the surface; then level it, and lay on it a thin covering of thoroughly decomposed hotbed manure or cow dung, the latter is to be preferred. Mix this well with the soil below. Upon this mixed enriched soil place as much of the pure sandy loam as will raise the bed an inch or two above the walk. No dung must be among this top stratum of soil, because dung causes the peculiar disease called mould to attack the bulbs that come in contact with it. The best season for planting is from about the middle of October to the first week in November, the bulbs then form roots before severe frosts set in. Should the planting be unavoidably delayed, the bed must then be covered with fern or straw. Choose a time when the soil is moderately dry and the day fine. Draw drills across the bed 2 inches deep and 5 or 6 inches apart, and plant the tubers 5 inches apart in the rows. For choice varieties a thin layer of sand scattered under and around each tuber will be useful. As soon as the bed is planted cover the tubers with

sandy loam from a basket or wheelbarrow. Take care that the tubers are placed the right side up, by observing the side that has the old small fibres on it. That side place next to the bottom of the drill. When all are planted and covered up to the right depth—2 inches, then level the surface with a garden rake. If the plants have any kind of covering and the weather prove mild, the covering should be removed and replaced on the likelihood of a return of frost, and when the spring sets in remove the shelter entirely. Should the weather prove dry in spring give a thorough watering now and then. The bloom will be greatly prolonged if an awning of canvas, or even garden mats, be stretched over the bed upon a frame of hoops to shelter the flowers from the sun, from high winds, and heavy splashing rains. All weeds must be plucked up as they appear, and a diligent watch kept for snails and slugs.

Imported Orchids (Birkenhead).—The Orchids appear to have been very incorrectly named. 3 is probably Galeandra Devoniana; 4 is a Catasetum; and 5 is Epidendrum bicornutum; at least these are doubtlessly the names intended, though whether you have the plants true of course we cannot decide. They will not thrive in "a cool house," if by that you mean an Odontoglossum house, and they must not have a lower minimum winter temperature than 55°, and 60° would be much safer and preferable. If they are not showing any growth place them in a stove on a shelf or bed where they can be lightly syringed, but not frequently. When there is an indication of growth commencing pot them all in a compost of fibrous peat, sphagnum, with a good proportion small pieces of charcoal, well draining the pots and elevating the crown of the plants slightly above the rims. Give water liberally as growth progresses, and diminish the supply as it becomes matured. The Epidendrum is rather difficult to cultivate, but the following notes by an experienced Orchid grower who has been very successful with it will explain the treatment required.

Culture of Epidendrum bicornutum (Idem).—"The best way to grow it is in baskets suspended from the roof, or on pieces of Tree Fern stem. I have grown and flowered it under both systems, and if grown in baskets a compost of very fibry peat, moss, and charcoal should be employed. The plant roots freely in its natural habitat, but is rather shy-rooting under cultivation. The plant is a native of the West Indian Islands, particularly Trinidad, consequently it requires the temperature of the East Indian house. Having a friend living in Trinidad, I wrote him for particulars with regard to where it was found and under what conditions, and I will give his reply as I received it. He writes, 'With regard to your questions respecting E. bicornutum, if I tell you how I collected it no doubt that will suffice. I went out one day last week, hired a boat to carry me to the Five Islands, a group of irregular size, standing at no great height out of the water, in one bend or basin of our harbour, which may be called rocks left after the severance of that part from the mainland by the encroaching influence of the sea. Round these islands one can sail and soon load his boat by pulling the tufts off the ledges of the rocks or any cavity. It is subject to drenchings of water by the action of the waves, is generally fully exposed to the sun, and as it is surrounded by water the plant must be subject to heavy dews owing to the great variation in temperature of the land at night. I soon collected a load, though I am afraid they are too much advanced in growth for travelling.' By these remarks it is easily perceived that the three most essential requirements of E. bicornutum are heat, exposure to sun, moisture, and a moderately low night temperature, and if these be carefully attended to it should make satisfactory progress. Any trouble bestowed on it will, I am convinced, well repay the cultivator."

Names of Fruits (R. J. Lynch).—1, Gloria Mundi; 2, Hawthornden; 3, Fearn's Pippin; 4, Golden Noble. The Pear was too far decayed to be recognised. (Stifford).—Urbaniste. (T. Trollope).—Golden Pippin. (J. L. B. J.).—These are probably local varieties, except 6, which is Lemon Pippin. 1 resembles Mère de Ménage, and 5 Reinette de Canada. (Cambridge).—Pears: 1, Comte de Lamy; 2, rotten. Apples: 1, Melon Apple; 2, Cox's Orange Pippin. The other we do not recognise. Were not the names sent with the trees from Sawbridgeworth? (An Old Subscriber).—Large Apples Beauty of Kent, the three small green ones Stamford Pippin.

Names of Plants (Subscriber).—1, Thuia occidentalis; 2, Cedrus atlantica; 3, Juniperus virginiana Schottii; 4, Thuia Lobbi; 5, Juniperus communis hibernica. (Grantham).—Chrysanthemum segetum. (J. Humberstone).—1, Eupatorium odoratum; 2, Epiphyllum truncatum, var. Russellianum; 3, Cestrum aurantiacum; 4, Salvia Bruanti; 5, Erica colorans; 6, Lasiandra macrantha. (W. D.).—1, Asplenium viviparum; 2, Pteris scaberula; 3, Adiantum trapeziforme. (Oatlands).—1, Odontoglossum Halli; 2, Oncidium crispum.

COVENT GARDEN MARKET.—NOVEMBER 22ND.

TRADE steady with little to note. St. Michael Pines are now to hand, considerably affecting home produce; but good well-grown fruit will still find a ready market. Kent Cobs are firm, with a slight rise.

POULTRY AND PIGEON CHRONICLE.

NEGLECTED PASTURES AND WASTE LANDS.

(Continued from page 438.)

THE best and most economical means of renovating exhausted farms which have been abandoned by their occupiers or left upon the hands of their proprietors in poor condition now deserve attention. To illustrate this matter we cannot do better than support our experience by the writings of Sir J. B. Lawes, whose opportunities for a long period in the manuring and cropping of his experimental plots at Rothamsted give him the means of supplying the information which is required by the home farmer. In describing "an abandoned farm" he says: "Not far from where I live there is an unoccupied farm. It consists of rather more than 300 acres of fairly good but rather strong land. The land is almost all arable, and the late tenant sold almost everything, his system of cultivation being to grow one corn crop after another until the couch grass put a stop to his operations. As I walked over field after field I thought, if it had been my misfortune to have to be the owner of this farm, what should I do with it now? It is quite certain that nothing short of two years of summer-fallowing would make it sufficiently clean to grow corn, and when the land was clean there would be a further large outlay required for manures, as after two years' fallowing it would be poorer in condition than at present. I came to the conclusion that the plan I should adopt would be to leave the land as it was, and without attempting to clean it: that I should put a flock of sheep upon the farm, feeding them with plenty of decorticated cotton cake and folding them at night. At Rothamsted our experiments upon pastures show that the quantity of herbage depends almost entirely on the manures which are applied, and not upon the seed which is sown. As each field was folded over I should harrow in a small quantity of white Clover seed, also Cocksfoot, Meadow Foxtail, and one or two more of the best grasses; but I should trust to the manures and time to eradicate the weeds and couch grass and produce a good pasture. The distinction between this plan and that which most people would have adopted would consist in my spending but little or nothing upon tillage and everything on manure. I should turn the enemies who had taken possession of the land to the best account I could, and should expect to improve them off the surface as soon as I had finished the more vigorous-growing grasses with the proper weapons to effect this end. Whether the land should remain eventually as pasture or as a mixed arable and pasture farm would be a question to be decided in future." This is extremely satisfactory coming from such an authority, and greatly encouraging to any agent or home farmer under the like circumstances. But we shall show next some instances where persons have actually succeeded acting upon these ideas.

We have given Sir J. B. Lawes' statement as to what he would do to renew and renovate land which had been allowed to run to waste, and as far as condition was concerned thoroughly exhausted; we will now, however, give illustrations, some of which have occurred within our experience, which will at the same time show how much in accord with Sir J. B. Lawes' ideas as to what should be done has been done with the greatest benefit. In reading Mr. James Howard's essay on "Laying Down Land to Permanent Pasture," as published in the Journal of the Royal Agricultural Society of England for 1880, we noticed that especial

mention is made of the advantage of sowing Sainfoin or Lucerne on land laid down to grass, in order that a crop of great value may be obtained before a permanent turf could be derived from sown grass seeds. Mr. Howard says that, "Although Mr. Martin Sutton does not favour such a plan of proceeding, yet, from the beautiful carpet of green my field presents this spring, I have every reason to be satisfied with the experiment."

Some years ago we were visiting a farm in a southern county for the purpose of making a valuation of the tenant's claims for seed and tillage on quitting. The farm was on the chalk formation, and the land on the surface a hazel loam, the farm altogether being in very fair condition as to culture. But what we wish to note specially is, that we found one field of twelve acres one mass of couch all over. On remonstrating with the tenant as to the foul condition of the land, he replied with rather an heroic remark that the crops yielded by this field were of more value to him than those obtained from any other field on the farm. Upon further inquiry it turned out that ten acres of this field was in Sainfoin, and two acres near the farm premises was in Lucerne. Now the subsoil being chalk the Sainfoin and Lucerne gave great crops of hay and fodder, the Lucerne in particular giving three cuttings in the year. The tenant claimed that the couch-covering was an advantage, that the Sainfoin and Lucerne derived their nourishment entirely from the chalk subsoil, and the couch during winter protected and gave an earlier growth in the spring, and also retained the moisture in summer for the deep-rooting plants which were fed (when not laid up for cutting) by cows only. The sheep kept from the land, because hungry breeding ewes, would eat out the crowns and buds of the deep-rooted plants, which would then perish, and that when fed the rug of couch gave a full bite at all times for the dairy cows. On full consideration of this statement we could not deny the tenant the advantage which he claimed from his double and valuable crops both of hay, green fodder, and pasturage. Our principal object, however, in naming this matter is to show if the value of the couch was important in connection with these deep-rooted plants, how much better it would be to have a thick mat of the most nutritious and best sorts of pasture grasses in addition to the Sainfoin or Lucerne, and instead of the couch grass. We had always been of opinion that in endeavouring to obtain a permanent turf upon chalk or limestone subsoils it would be advisable to sow Sainfoin and permanent pasture grasses combined as a proper and judicious mixture, for the Sainfoin would be sure to yield full crops before the grasses were fully established.

We have next to quote from a letter which appeared in the *Agricultural Gazette* in January last from a Mr. James Ellis, The Gynsills, near Leicester, who, after having specially referred to Sir J. B. Lawes' letter on laying down foul land to pasture, says, "I know that he is right in the advice he has given as to the cheapest method of changing land filled with couch grass and other weeds incident to arable into useful turf. My father was a successful farmer, and I heard him repeatedly say that his experience was against spending money in cleansing land intended for permanent pasture. I took a small farm in very bad condition when the Leicester and Buxton Railway was opened. About an acre of foul stubble was cut off from an arable field and had to be added to a pasture. Instead of spending money on labour and seed I dressed this acre with 4 cwt. of Peruvian guano, which at that time contained 14 per cent. of ammonia. In four or five years the couch was replaced by white Clover and finer grasses, and at this time no one can tell that this land is not an old turf field. About the year 1870 my sisters had a small field of arable land thrown on their hands; it was near the village, and could be easily let if in pasture for £3 per acre. It was full of couch, Thistles, Mare's-tail, and the lesser Convolvulus. My sisters had no ploughs or agricultural horses, and to hire for fallowing would be troublesome and expensive. I said, 'Manure the land and pull up the Thistles; leave the rest to Nature.' For three years the land was dressed with about 2 cwt. of mineral phosphate and 1½ cwt. of nitrate of soda per acre, put on in the spring and grazed by cows fed on cake. The result was marvellous. In four years the land grazed nearly a cow per acre from May to October. At the end of six years a flower show was held in the field. The Judges, one of whom was a well-known seedsman, said that there was one person who ought to have had a prize, and that was he who seeded this field. I was present, and replied that it was Nature's own seeding. The hand of man had sown nothing, and further, that if anyone would find a field in this neighbourhood I would undertake to produce a like result, however full of weeds the field might be, if I could graze and manure it as I choose for seven years. In 1876 I came into the possession of a very poor farm near a quarry which is worked for road stone. Most of the farm was completely worn-

out arable land, and as an experiment I laid down three fields adjoining on three different methods. One was cleaned and sown with a corn crop and seeded with mixed Clover and Rye Grass; one was cleaned and sown with best permanent grass seeds from Messrs. Suttons, and one was left to Nature. All have since been manured and grazed by sheep and young cattle fed with cake and corn and have greatly improved, but the best of the three is the one which was seeded by Nature alone."

We consider this is one of the most valuable contributions from a practical farmer we have ever seen upon this important subject, and corroborates most entirely the recommendations of Sir J. B. Lawes, which he had based upon his own trials upon the experimental plots at Rothamsted, and showing most forcibly and conclusively the value of scientific researches and experiments when conducted by intelligent and practical farmers. Whenever I have advocated the application of earthy compound manures it has frequently been objected that the cartage of heavy manuring materials was attended with great expenses, and the objectors have advocated the use of light hand-tillage manures, such as guano, nitrate of soda, and bone earth in various forms and conditions. But in a new pasture we have no humus to fall back upon like that of old pasture; we must, therefore, refer to the best and quickest way to obtain this.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—Horses have not been employed on the strong and flat soils in seeding for Wheat for more than a month, and very little has been done even on the driest soils. We know various farms of strong land where no Wheat has yet been sown. A great mistake has been made, and the farmers have been too trusting as far as weather is concerned, or that they have not horse or steam power enough employed on the farms to prepare the land in due season. Every farmer ought to know that the month of October usually gives the heaviest rainfall of any month in the year, and strong land, to be on the safe side, ought to be seeded with Wheat on the average of years during the last week of September or the first week in October, which can easily be done if the land has been prepared at the time, because the drilling under ordinary conditions of the weather is not a long job if the period and the work has been anticipated in a business-like manner. It is reported that on the hills in the north-east of Gloucestershire and parts of Cumberland and other northern districts that a considerable acreage of crops of Oats, Beans, and some Wheat was still in the fields at the end of October. This we cannot help thinking is a matter requiring more attention than it meets with at the hands of many farmers. Why should spring Beans be grown at all in the late climates and cold soils? Why should not early white Oats be grown and winter Beans? Why should Wheat on such soils and climate be grown at all, unless of an early sort? We think that in numerous cases the farmers are more to blame than the state of the weather, because every man should endeavour to make the best provision against adverse weather. Although we may get a favourable seed-time late, every preparation must be made for it, for we well recollect certain seasons when there was no seed-time for Wheat, &c., until December, notably in 1872 and 1841, and some others during our long experience, and the home farmer now ought to be better prepared for adverse seasons than at any former period. Improved implements and improved cultivation, at least if intelligence and caution have prevailed, have been the rule in each succeeding year. Ours is, according to our version of it, the most undefinable climate of any cultivated country in the world. There are, of course, worse climates, but they are known and may be anticipated, whereas we have often endeavoured to anticipate the weather at certain seasons and as often failed.

Hand Labour.—This has been seriously hindered in the fields, &c., during the late heavy rains, and in some of the best pastures in the different counties the floods have prevailed and prevented any customary trenching and ditching being done; in fact, in some districts the work connected with Wheat-sowing, &c., has been prevented, and large areas of land have been flooded, in addition to the pastures. Men, however, at every sea-sonable opportunity, should go, spade in hand, and let off all accumulated water in the furrows where Wheat or winter Beans, &c., have been sown. Besides, the water meadows are now in flood, and require careful and constant attention by the drowners.

Live Stock.—All the bullocks now under box-feeding, especially those intended for Christmas, should be kept at a full allowance, say 64 lbs. of Swedes, or 56 lbs. of Mangolds daily. The roots, being passed through Gardener's cutter, should have strewed over them and properly mixed with 4 lbs. of cake and 2 lbs. of Bean, Barley, or Maize, all in the meal state, in order that it may adhere to the cut roots and be eaten without waste. We never feed with hay, only give clean sweet oat straw *ad libitum*, and what they do not eat may be used for littering the boxes and stalls, but we prefer boxes. If we used stalls the cattle should stand in pairs, and be tethered at each corner, so that every animal may get its share without disturbing its neighbour.

POULTRY AND PIGEONS

WHITE DORKINGS.

SOME years since we gave in the pages of this Journal our ideas on White Dorkings. Time has flown since, and we have not abandoned our favourites nor changed our opinion as to their excellence. It is always a cause of wonderment to us that the breed has not become more popular. We seldom see it in anything like purity in the farmyard or the park, nor even amongst fanciers is it extensively patronised, as is proved by the paucity of entries in the White Dorking classes of shows as compared with many other breeds. Surely it is a breed attractive to every lover of beauty, with its pure white plumage and bright coral comb. Its lack of popularity can only be accounted for by the old and, as we believe, utterly groundless prejudice against all white poultry as being delicate. Probably it is a fact that albinos, or white specimens of a race naturally and usually dark, are generally feeble in constitution; but that white races of poultry are so all our experience leads us to deny. We are not, however, now speaking of white birds generally, but of White Dorkings in particular. We have long kept both the Dark and Silver-Grey varieties as well as the White. The young stock are reared in common; all have the same treatment, and our later experience confirms our original conclusion long ago given in these pages—that of the three varieties the White are the most vigorous. We then related that in a certain disastrous season, when our chickens of many races all died, the White Dorkings alone resisted the epidemic and thrived.

We have again had a bad year, though not so much fatal as the one then mentioned to chickens in their earliest days as to half-grown birds. Our experience is the same again. A wasting and incurable consumption has ravaged one of our flocks, but while others were pining and dying of unaccountable exhaustion some White Dorkings among them grew and flourished. Our own experience has been confirmed also by that of others, notably by that of a Scotch correspondent, who years ago wrote to us as a stranger inquiring the breed of fowls we should recommend him to keep for general use on his property in the west of Scotland. To his great surprise we advised him to try White Dorkings. He did so, and has more than once since thanked us for our recommendation, speaking in the highest terms of the hardihood and productiveness of the breed. Our present subject was suggested by the remarks of a contemporary a few weeks ago in a report of the poultry show at the Agricultural Hall, to the effect that the White Dorkings there showed traces of a Game cross. We believe the reporter to have been mistaken, and for two reasons.

1, We know something about all the strains of the winning birds at that Show to which allusion was specially made, and know them to be strains which have been kept scrupulously pure, and that their owners are far too experienced fanciers to make any such injudicious cross.

2, A Game cross would probably so spoil the plumage of a family of White Dorking as to make it unfit for the show pen for generations to come. We have never tried it, but can only conclude that this would be its effect from observing other Game crosses. We have crossed White Game with other white breeds, among them with Japanese Silkies of spotless and glistening whiteness, and the produce have invariably been Piles. It has seemed impossible to breed out the red patches, doubtless from the strength of the Red Game blood, from which the White are descended.

However, though not (as we believe) with Game fowls, White Dorkings have been crossed with White Cochins, Dark Dorkings, Cuckoo Dorkings, and probably with Hamburgs. We have known cases in which the former crosses have been tried, and with disastrous effects as to the purity of plumage. Size is certainly increased, but with it a certain coarseness appears, easily recognised by a practised eye. But the chief evil is an ugly yellowish or brownish tinge of neck and saddle hackle in the cock, and of neck in the hens, in lieu of an even whiteness. The Cuckoo cross, too, has, we know, been made, and after many generations leaves its evil effects in dark feathers, which occasionally appear in the offspring of seemingly the very best stock. That the Hamburg cross has been tried we have not positive evidence, but the small neat combs of one strain, combined with a too elegant slimness of body and frequently white carlobes (a real eyesore), are tolerably strong evidence of it.

The object of these lines is to dissuade fanciers of so useful and beautiful a breed to abstain from spoiling it by such crosses. Unfortunately its admirers are too few, and consequently the

admixture of impure blood in one strain may do much harm. It is not a degenerate or declining race which must at all risks be recruited by the introduction of foreign blood; far otherwise. There are, of course, differences in different strains and families, and even in individual birds of the same strains. Some are of a purer white, others more creamy. Some seem easily tanned by exposure to sun and wet, others are hardly affected by either. Some have a yellowish tinge during the moult, others look at all times snowy. Birds of the latter hue, provided they are vigorous and sturdy, should be selected as breeding stock, and such only. Peculiar purity of plumage is as easily perpetuated by care as any other point. On the other hand, the introduction of a single bird, however fine and correct in comb and feet, which has a taint of alien blood, may do harm to the colour of a strain which can scarcely be undone. There are quite enough separate good and pure strains of White Dorkings to enable their possessors by occasional purchases and exchanges to keep them up in strength and vigour. We do trust that they will do so, and that they will not for the sake of a few extra ounces of weight spoil a race which is probably of the highest antiquity, and certainly in an unusual degree combines usefulness with extreme beauty.—C.

POULTRY NOTES AT THE CRYSTAL PALACE SHOW.

NEVER before in the history of the poultry fancy has so large a collection of birds been assembled at this Show. Over 3000 pens of poultry and some 2400 pens of Pigeons made a collection which, even under the most favourable circumstances, would have somewhat taxed the resources of even such a huge building as the Palace. This year, unfortunately, the Electric Exhibition, announced to be held in November, although it was postponed, caused some of the poultry to be thrust into the side parts of the building. Some—the Ducks in particular—were quite in the dark, and exposed to an extreme of cold which could not but be injurious. We trust the Palace authorities will another year be more mindful of what is due to so old, and, as we believe, remunerative institution as the poultry annual Show.

Dorkings.—Taken generally we cannot say that we thought the Dorking classes as good as those we have seen at other shows, notably at some of the Birmingham meetings. The best dark bird to our idea was the first-prize cock, claimed at £20, a thorough Dorking all round. The cup cockerel is huge, but has many points rather of an Asiatic than of a Dorking. Silver-Greys improve in colour, not in form; the hens specially are now almost always free from red on the wing, and the cocks have pure silver hackles and backs. Cuckoos show a deplorable falling-off, why we do not presume to say. Whites keep up well, the first cock and first hen being as fine as any we have ever seen.

Cochins were on the whole a fine show, and had two hundred entries. The cup old Buff cock (Percival) could only have been improved by having a more self-coloured tail. The three winning Buff hens were very shapely, and good in all other points, though a trifle uneven in colour. The cup cockerel was very shapely and extremely even in colour, though rather smaller than we have sometimes seen. The winning pullet (Tomlinson) was perfect in shape and feather, but a little mossy. The gem of the Partridge classes was Mrs. Turner's cup cockerel, which was large, shapely, and rich in colour. The other winners were hardly so good as we have sometimes seen. Mr. Darby's winning White cock though good was hardly equal to the exhibitor's old form, but Mr. Percival's cup White hen could hardly have been surpassed for size and quality. We noticed that the second cockerel had a good deal of colour on his wing bar, which should have precluded him from taking such a position.

Dark Brahmans as a whole were hardly as good as we have sometimes seen them. The old cocks seemed late in getting through their moult. The cup bird was the Birmingham winning cockerel of last year grown into a larger-bodied bird than might have been expected. It is but another example of the powers of growth in their second year of pure-bred birds. In this class a somewhat glaring case was discovered; the fourth prize bird was recognised as a cockerel which had last year had badly slipped wings, and these were now somewhat suspiciously close and compact. An examination showed that they were both neatly tied up with string, the fastening round the shoulders being so tight that they must have caused the bird much pain. The Judge, acting under the instructions of the Committee, disqualified the bird, and the prizes below third were re-awarded. The hens were a wonderfully good class, and it was no slight honour to gain a prize. First (Warr), second (Holland), and third (Norris) were, taken together, undoubtedly the best, and the placing of them more a matter of individual taste than anything else. We hardly agreed with the awards in cockerels. Sir Henry Thompson's Dairy winner was again to the front; we much preferred the same exhibitor's v.h.c. bird (498). Second was as shapely as possible, but had one very loose wing. The class was not as a whole up to the standard of some former years; the pullets were sixty-seven in number, and many of them were of good quality, but we must protest against the wholesale distribution of cards. A commendation ceases to be an

honour when there are forty-three noticed birds; many of them were quite unworthy the distinction. The winner was Mr. Henshall's pullet, which we selected as best at Wolverhampton; second (Lingwood) here presses her closely, being a beautiful clear grey, well pencilled all over; third (Field) very well marked and shapely, but going brown; fourth too small to take a prize here; fifth the Dairy winner; v.h.c. (Maddison) the Dairy third, and might well have stood higher here. Light cocks were a good class and well judged, though suffering from the cold. The cup-winner (Percival) was a trifle yellow, though still the best in the class; second (Nettlefold) large and of good colour; third (Norris) very pure in colour, though his comb was not of the best. The hens were hardly as good as usual, and were more or less yellow throughout; first and second were a grand pair, but might with advantage have changed places. The cockerels were also not quite up to the average; the winner (Sir H. Thompson) had rather too much yellow on his shoulders, but was still the best; second (Wood) good in all other points but comb; fourth (Thomas) might have done better but for want of condition. Pullets were as a class better than the cockerels; cup (Nettlefold) and second (Morgan) were especially good; the other winners were well placed and worthy their positions. We hope to add a few notes on the remaining classes next week.

SPOILING THE DORKING.

I CAN fully sympathise with Mr. H. Weir in his remarks on the present type of the Dorking fowl, and he deserves the best support from fanciers in trying to return to the true old Dorking, which has not been surpassed by any other variety as a good all-round useful sort. Mr. Weir points out some very practical points concerning the white earlobe and dark birds. What say the present fanciers to this colour-reforming? Will you still adhere to "Sooty feet and yellow skins, the black toenails and Brahma wings," &c.? If so, then fanciers like a manufactured bird, as it is the case with more varieties than the Dorking. The Game cock of the present day shows the Malay flat toenail. It will take some generations to obliterate these defects.

Mr. Weir's article on the Dorking could not have appeared at a more seasonable time, when the long-looked-for "new Standard of Excellence" is about to appear. I trust that those who are selected to revise the new Standard on the Dorking will at once review Mr. Weir's notes to see if this vexed question cannot be settled. One word about the Standard. I am glad to see that the Secretary, Mr. A. Comyns, has published one or two varieties, which I presume is for public criticism; this will make the work more valuable, and I hope the fanciers will come forward before the work is published, and say or suggest what they have to make, so that the book will be a standard of excellence and a work of reference that can be relied upon.—R. HAWKINS, *Seaham*.

OUR LETTER BOX.

Renovating Pastures (Diagles).—You will probably find methods suitable for your purpose described in the series of articles that are now appearing on neglected pastures and parklands. If you require further information and will state the nature of the soil and condition of the pasture we will endeavour to aid you.

SOME NOTES ABOUT GRAPES.

IT is instructive, interesting, and sometimes amusing to read the various experiences of writers who are recording their different opinions about various Grapes. I daresay there is hardly a Grape in cultivation which has not been decried by someone; and, on the other hand, many varieties that are pretty well condemned by most writers sometimes find admirers.

My experience in the cultivation of the different varieties of the Vine has led me to be slow in condemning many of those which have been introduced during the last twenty years, as, though some of these kinds have not in all places proved what they were represented to be, they have under different circumstances become valuable acquisitions. Madresfield Court, for instance, in my experience was planted in a late house and the fruit failed to keep well, the berries all cracking; but in an inside border and used as an early Grape it proves itself a capital variety. For early work I would recommend everyone to have a house of this variety and a house of Duke of Buccleuch, both planted in inside borders, where the roots can be under perfect control as regards moisture. These two Grapes make splendid dishes for the table, the Duke being specially fitted for a nobleman's table, as its grand appearance is quite in keeping with the grandeur of the tables of our nobility. When cut and dished without being subjected to packing and railway travelling the Duke cannot be surpassed. Then, as has been remarked before, another matter, which if attended to in the cultivation of the Duke is of material importance to its fruitfulness, is the maintaining a succession of young rods, which is a simple matter.

Golden Champion, though not forcing so well as the Duke, is still a very fine Grape for summer work, and should also be treated to an inside border. I well remember the two bunches of this Grape shown at Manchester some years ago by Mr. Hunter; they were simply grand. Mrs. Pince, though troublesome to get to colour perfectly, can sometimes be seen almost black, and has so many other good qualities that it is well worth a place in a collection of Vines.

What shall I say of Mrs. Pearson, Golden Queen, and Duchess of Buccleuch? They are all successfully grown by some people, and have their admirers. My own experience of the two former is that they are fair ordinary Grapes, with nothing particular to recommend them, and no great faults to condemn them. Duchess of Buccleuch has long held the palm for flavour, and had it the appearance of the Duke would be unrivalled. As it is, along with the Frontignans, Grizzly and

White, it forms a trio of which we may say "that their qualities surpass their charms." They have to yield to the grander-looking varieties; but were I growing for my own table they would have a considerable space in my vineries. Nothing need be said about that splendid Grape the Muscat of Alexandria, except that the Bowood variety is really the finest. I would, however, put in a word for Canon Hall Muscat, so often discarded for its non-setting propensity. Grown in a house where a high temperature is maintained, and artificially impregnated, it can be made to produce splendid samples, and repays the extra trouble by its noble appearance.

Another example of a Grape doing well with one person and failing with another is the Alnwick Seedling, which Mr. Bell grows to perfection, while others have failed with it. Artificial setting is required by this Grape also; and if this is done, other conditions being favourable, it should not fail to bear well and reward its cultivator with handsome bunches which keep well. A peculiarity of that grand late Grape, the Gros Colman, is its not keeping well in bottles. I have not heard of anyone succeeding with it in bottles, and would be glad to learn through your columns if anyone has so succeeded. On the other hand, how well Lady Downe's keeps in bottles! Scalding is the weakness of this fine Grape, and this has led some people to discard it, sometimes through the want of their knowing how to remedy this defect. If kept perfectly cool from the time the first berry is seen to scald, which is at the stoning period, till the first sign of colouring is noticed, this scalding can be almost entirely prevented. About the end of March Lady Downe's is splendid for eating, being then sweet, juicy, and possessed of a certain crackling freshness that is exceedingly pleasant. Black Alicante cannot fail to always have admirers on account of its fine appearance; but I confess I do not much regard it, as in nine cases out of ten it is quite flavourless. One Grape there is of which I am unable to say anything good, Waltham Cross. It proved with me a worthless variety both in its appearance and quality, being extremely like the foreign Grapes we are supplied with in the markets, and having no good qualities to recommend it for the table.

Having been long accustomed to try the different varieties of Grapes on their merits, and always having endeavoured to be just in the matter, noting that sometimes others could succeed well with varieties that my experience did not warrant me in extolling, and at other times being successful in growing varieties that I have found others failing in, I much regret the spirit in which some writers have denounced certain varieties of Grapes which have in other hands proved remarkably fine. This style of writing is much to be deprecated, and it would be much more pleasant to see different opinions and suggestions in print without the personalities which are too often indulged in.

The cultivation of such a noble plant as the Vine would be made more pleasant to all if they were allowed to record their experiences and opinions without being pounced upon, and in some cases ridiculed, for what they state. There is so great a difference in the spirit of criticism, too; few of those who assume the office of critic being actuated by a genuine desire to discover truth and expose error, but rather to assert their own views to the exclusion of all others. For the credit of horticultural journalism it is to be hoped that such captious criticism will cease, and that all who write for the gardening

press will show by their writings that it is the general good and not petty personal motives that prompt them to lift the pen.—HONI SOIT QUI MAL Y PENSE.

ECONOMY IN CUT FLOWERS.

STERN necessity compels economy in cut flowers at this season of the year, when the open air supply has come to an end and we have to rely almost entirely upon plants under glass. The supply from this source ought, of course, to be fully in proportion to our requirements, but too often it is not so, and many a man is at his wit's end to find enough. Well is it, therefore, to acquire the habit of always using as few flowers as possible for any given purpose. Upon the face of it this would seem to be a very simple matter, so simple as to fall readily within the scope of everyone; but in reality it is not so. The most common fault in the arrangement of cut flowers is crowding, the result a confused unmeaning mass of colour. Ask anyone who is constantly guilty of such faulty practice to use fewer flowers, to strive for graceful lightness, and there will probably be a falling into the equally unsatisfactory extreme of ragged unfinished looseness.

Apart from the question of economy, good taste invariably suggests, or rather compels, moderation at all seasons of the year. By way of illustration let us suppose a rich, yet chaste, floral decoration is required for a dinner-table for twelve or fourteen persons. Six or eight bracts of Poinsettia with a few Fern fronds will furnish a rich central bowl or stand, while a dozen slender glass vases, each containing a couple of white Chrysanthemums, two shoots of Selaginella cœsia, one frond of Maidenhair Fern, and two or three pieces of dried Briza flowers, will make a chaste chain around it, and the table is complete so far as the flowers are concerned. Quite recently I had to arrange a more elaborate central stand. It was a transparent glass fish bowl of the largest size, and the materials required were nine fronds of Filix-mas Fern, seven fronds of Maidenhair, six trusses of scarlet Geranium, four clusters white Marguerites, three shoots with leaves only of Begonia metallica, three long shoots of Fuchsia, one spike of Erica hyemalis, two fronds of Adiantum macrophyllum, two shoots Tradescantia multicolor, and two shoots of Panicum variegatum. The Filix-mas fronds were bent down over the edge so as to just touch the tablecloth, then came the Marguerites alternating with the Geraniums, above them the Begonias and Fuchsias, with the Erica and Adiantum macrophyllum at top. The effect was so satisfactory, and the flowers so few and common, that a note was made of it, as I submit should always be done for one's guidance in subsequent work, especially as regards the quantity of flowers used for each kind of vase or stand.

What a boon are Chrysanthemums to the floral decorator at this season of the year! The white kinds are most in request for cutting, such as Mrs. G. Rundle, George Glenny, Elaine, and Fair Maid of Guernsey. La Nympe, of a delicate flesh colour, also proves very useful for table work, and a selection of the best kinds are useful to cut for mixed stands for all sorts of purposes. The flowers keep fresh so long after they are cut that a few plants suffice for ordinary wants. An ample supply of Paris Daisies may also be had from a very few plants. Insert a few cuttings now; turn out the plants into an open border in spring, and next autumn you will have them each as large as a Gooseberry bush, so that you will not require many plants to be taken up and potted for winter flowers.—EDWARD LUCKHURST.

SIMPLICITY in the arrangement of cut flowers is very important. Ill-managed arrangements as to colour and crowding too many together are common evils. The flowers are grown at great cost of thought and labour, and the final result is rendered sometimes unsatisfactory through want of thought at the last stage. It is quite time we were learning better.

What I am about to recommend can be fairly brought before the notice of your readers, because it saves flowers, an item of importance to many, and because in the majority of cases it will please better than when a great variety of flowers is employed. In all cases I recommend that flowers be arranged loosely, small branches of Ivy being very suitable to place in large vases at this season for keeping the flowers thinly secured. In small glasses this is not required. As a rule, I like to employ the foliage with the flower, and if it can be so managed most of the flower stands should be filled with only one kind of flower. Just now a large vase may be made with five to seven Richardias with their own foliage. Of white Chrysanthemums with the leaves, Peter the Great are the most suitable. Pink and white Primulas are always best by themselves. Cypripedium insigne is another flower which should always be alone. Maidenhair Ferns should be employed

with this flower, as also for other Orchids. Pelargoniums and Camellias we like to employ singly in small glasses with one or two of their own leaves. Schizostylis coccinea makes a glowing mass by itself. Of late years I have always employed Lily of the Valley in glasses amongst its own leaves. Deep pink and crimson Tulips are very fine without mixture of other flowers, the common Duc Van Thol being especially pretty for use about Christmas time. Orchids are generally best arranged as single spikes. Phalænopsis Schilleriana, Odontoglossum Alexandræ, O. cirrhosum, O. grande, Cymbidium eburneum, Vandas, and others are much more effective when arranged singly in spikes than when with other flowers.

Of late years the fashion of furnishing dining tables with only one kind of flower at a time has come into favour. It might be thought that this would cause sameness, but it is just the opposite, for in mixing flowers it is certain that at a time of much demand the same kind of flowers must occasionally be used repeatedly, whereas in the single-flower plan we can have Roses one night, with changes of Pelargoniums, which may again be employed as changes with white, pink, and crimson flowers, Chrysanthemums, various Orchids, Primulas, Eucharis, Carnations, Bouvardias, and other suitable flowers. There is thus continual freshness, and no other mode of dressing tables, especially in the winter season, is at once so chaste and so effective.—B.

BUCKLAND SWEETWATER GRAPE.

IF the correspondents "H. A. M." and "G. R. A." will refer to my first note on this Grape they will find that my objection to it as an exhibition Grape is founded on the ground of its inferior quality when the colour is considered most perfect, as it is one of the very few kinds of Grapes that is best in flavour before it is well coloured—whilst it is green, in fact: hence I wrote, "When it is most perfect in flavour the fruit is then only just beginning to colour, and that on this ground alone (want of colour) would at an exhibition be discarded by all good judges."

If the exception ever becomes the rule in regard to judging Grapes by flavour rather than by bloom and colour, Buckland Sweetwater will find a place very nearly, if not quite, at the bottom of the list.—W. L. H.

THE CUCUMBER DISEASE.

I HAVE read with much interest Mr. Taylor's article on the Cucumber disease, as I have had some unpleasant experience in the matter; but whether Mr. Taylor's plants were infested with the same disease as mine it is impossible to say. In the autumn of 1881 my employer expressed a desire to have Cucumbers earlier than he had been in the habit of having them, and asked when I could furnish a regular supply. I replied, "At Christmas if I then had plants to start with." He acquiesced in my plans to procure plants at once. The house, a small lean-to with benches on each side, heated with four rows of 4-inch pipes, was prepared at once. Six plants were procured from a local market grower. In their transit one of them was broken close to the soil; the remaining five were placed out. The tip of the broken one was struck, and as soon as rooted was planted in the house. We cut fruit on the 31st of December from the purchased plants, which continued to bear well till some time in March. I then observed a falling-off in health, the fruit not swelling to my satisfaction. I applied stimulants in various forms, also a top-dressing of sheep manure and half-decomposed turf; but not observing any improvement for the better, we one day scraped away the surfacing to see if new roots were forming, when to my dismay I observed some pea-like excrescence on the roots, exactly as represented in the Journal in the autumn of 1881. I showed some of the roots to my employer, and he agreed with me that it was advisable to stamp it out at once. The plant struck from the cutting showing no want of vigour, we examined its roots and saw no symptoms of the disease on that; I therefore determined to leave that and destroy the rest. I removed the five purchased plants with the soil, burnt the plant left, and had the soil cleared away as closely as possible. A temporary wall was built across the bed, on each side of it some fresh soil was applied, the plant being allowed unlimited run. Where the diseased plants were removed from the benches were syringed with a solution of carbolic acid, fresh soil applied, and as soon as young plants could be raised these were placed out. They soon commenced bearing, but the variety not proving so good as the original one they were taken out, as the back bench had been filled with plants raised from cuttings of the infected plants, and with the original plant struck from a cutting were giving an ample supply. The space occupied by them was in July planted with Melons, from which I have had

a few good fruits, and not the least sign of the disease on either Cucumber or Melon.

My opinion is that the disease was introduced with the soil of the purchased plants, as I find since that the grower in question has lost considerably by it. A friend of mine told me he had some plants which suffered in a similar manner, and these were procured from the same source. The plants struck from cuttings, including the first, are now in perfect health, and I intend keeping them through the winter.

I may say I have had an abundant supply of fruit up to the present, and expect to have a continuous one, and all my plants are from the original purchased ones, therefore it is evident the disease was introduced with the soil. Whether Mr. Taylor's experience of the disease leads to the same conclusion he will be able to judge.—JOHN GADD.

THE WASHINGTON APPLE.

THIS is not an Apple for everybody, but is submitted to the notice of connoisseurs who derive pleasure from growing fruit in orchard houses. True, it is not customary to include Apples in those structures which are usually devoted to Peaches, Nectarines, Pears, Plums, and Cherries; but is not the exclusion of Apples a mistake?

The late Mr. Abram Bass of Burton-on-Trent used to say that no one could know the true character and full excellence of the Apple from outdoor fruit in this country, and the beautiful appearance and splendid quality of Cox's Orange Pippin, Ribston Pippin, and other choice varieties as grown in his orchard house imparted much weight to his opinion. The fruit of Washington, a section of which we figure, was grown in the manner indicated, and we have no hesitation in saying no one could produce similar examples without being proud of them. The noble appearance of the fruit that was supplied by Mr. Bunyard of Maidstone—its large size, faultless shape, glossy and bright colour, and especially the melting texture of the flesh, the abundant juice and deliciously perfumed flavour—was something to be remembered. A dish of Apples of this kind would be more prized at a royal banquet than the best of Peaches or Pears, as these can be had every year from Covent Garden, but Apples cannot; yet they might be grown in private gardens, and could not be had without being prized. Two years ago we had specimens of Washington from Mr. Rivers of Sawbridge-worth, which were set in an orchard house, and ripened in a pot in the open air, the flavour of which was excellent, though the flesh was not so tender as in those ripened in an orchard house. These were more truly typical of the variety than Mr. Bunyard's specimens, and the following description is from one of Mr. Rivers' fruits:—Fruit 3 inches wide, and the same in height, conical, even, regular, and handsome. Skin rich yellow, very much covered with broken stripes and mottled with crimson. Eye small and closed, set in a plaited and rather deep basin. Tube short, funnel-shaped. Stamens basal. Stalk nearly an inch long, slender, deeply inserted in a funnel-shaped cavity, which is lined with russet. Flesh yellowish, tender, very juicy, sweet, and finely flavoured. Cells open; cell walls elliptic.

THE ROCKERY IN AUTUMN.

THE flowering season of rockery plants is from the beginning of May to the end of June, though flowers ought to be plentiful quite to the end of the flower season, and many plants are well suited for rockwork, which the autumn frosts find quite at their best. Such are several of the St. John's Worts, especially that neatest of late-flowering rock plants *Hypericum reptans*. This plant has much the appearance of our native *H. humifusum*, but has a more compact habit, and is up to the present time covered with bright yellow flowers as large as half-crowns. Another invaluable plant for autumn is *Fragaria indica*, the Indian Strawberry. I plant this by the side of rough stone steps, and it trails down them 6 feet or more, sending side shoots across the inner angles of the steps, the growth being most elegant, and the whole plant covered with bright scarlet Strawberries as large as those of the *Arbutus*, and they might dispute with that shrub the right to the name *Unedo* (*un[um] edo*, I eat one), said to have been given by the Romans to the *Arbutus* because its berries are so insipid that no one who tried one wished for another. The berries

of the Indian Strawberry are luckily equally tasteless, so that even the birds do not touch them until hard pressed for food. Whether it will stand 30° of frost I do not know, but suckers are most easily saved and grow rapidly.

Polygonum Brunonii is also very bright, and flowers most freely in rather dry spots. There is no doubt of its complete hardiness, but its relation, *P. vacciniifolium*, perhaps the prettiest of the genus, is liable to be lost in very hard winters. These are now at their best, but many other plants are this season either anticipating their spring flowering or continuing their summer flowering beyond the usual time. Amongst them are conspicuous the double white *Lychnis vespertina*, *Lithospermum prostratum*, and *Erigeron mucronatum*, all of which are covered with flowers.

But the foliage of a well-furnished rockery in autumn is even more beautiful than the flowers. I refer particularly to the bright green velvety tufts of large masses of mossy Saxifrages of different kinds, allied to, or varieties of, *S. cespitosa* and *S. hypnoides*, many of which appear more distinct in their present condition than when in flower, and now is the time to visit the nurseries where good rockeries are to be seen and make a selection from the growing plants, instead of resorting to the bewildering process

Fig. 78.—The Washington Apple.

of trying to make a selection from a hundred names of Saxifrages enumerated in the catalogues. In some catalogues the Saxifrages are wisely divided into sections according to their habit of growth. Of these the London Pride section should not be despised because that plant is so common. One of the varieties of it, which I grow as *S. Colvilli*, gets as much admiration as any plant I have, being especially attractive in winter.

The glaucous green and neat vigorous look of *Euphorbia myrsinites*, the best of the *Euphorbias*, is now very distinct, and the masses of *Sibthorpia europæa* covering the moist stones with tangled shoots resembling miniature light green Ivy are a pleasing contrast to the cushions of Saxifrage.

A few remarks must be added on the work required on the rockery in autumn. Already dwarf alpines of doubtful hardiness have been lifted and potted to pass the winter in a cold frame to guard them, not against the frost, which in many cases is their best friend, but from the alternations of warm rain and melting snow incidental to an English winter. The evergreen alpines suffer most, such as the *Androsaces*, *Lychnis Lagascæ*, and most of all *Onosma tauricum*. Some recommend fixing a piece of glass over them in winter so as to exclude the rain but not the air. This, however, is very troublesome, and I find that where it is not convenient to lift plants and put them in a frame it is best to plant them as much as possible under the shelter of overhang-

ing stones, and to pack them round with pieces of old mortar or broken stone so as to prevent the leaves touching the soil. We know that many of them ought to winter beneath a covering of snow; the best substitute for it is fine clean gravel composed of pebbles the size of wheat, or of stone broken to the same size. If the soil round the stem of a plant is covered with this it prevents the growth of lichen, keeps the ground from caking, and seems to promote the well-being of nearly any alpine.

For other plants, especially the deciduous Primroses, Anemones, Hepaticas, Phloxes, a dressing of sifted peat or fine leaf soil in autumn is a great benefit where slugs abound. A little soot and coal ashes should be placed round the crown of delicate plants before the soil is applied. It is surprising what vigour many alpine plants derive from a dressing of this kind, and even a little very well-decayed stable manure may be mixed with benefit to the plants; but the soil should not be thrown indiscriminately over the rockery, each plant being treated according to its habit. Such delicate plants as *Dianthus glacialis* or *alpinus* would suffer by being buried in soil.—C. WOLLEY DOD.

ALNWICK SEEDLING GRAPE.

THIS variety has been fruited here for two seasons. Each year we have had an abundant "set," having on the lowest computation to thin out more than two-thirds of the berries during that process. The Alnwick Seedling is planted in two vineries, one of which (with this exception) is devoted to Muscat of Alexandria, the other being for late black Grapes only. Last season I had no difficulty in getting it to set in the Muscat house without artificial fertilisation, merely examining the bunches once every day while they were in bloom and slightly agitating them. The night temperature of this house at that time was kept from 65° to 70°. In the late vinery the Alnwick was in bloom that year at the same time as the Lady Downe's Seedling. We therefore used some spare bunches of the latter kind to fertilise the former, the temperature by night not being so high—often-times below 60° in the morning and hardly ever over 65° when darkness set in. Under this treatment I likewise had a most abundant set. Two of the bunches from one Vine were exhibited at the November meeting of the Fruit Committee that autumn (*vide* report of the same in the Journal of that week). This season I used the pollen from the Muscat bunches for the Vine amongst them, again having a perfect set. In the late house the Alicante was in bloom at the same time as the Alnwick, and was therefore resorted to for the same purpose with most satisfactory results. One bunch of the Alnwick, happening to be in a backward condition, was by chance overlooked, the result being a large per-centage of small berries—so much so, in fact, that the bunch was worthless.

After two seasons' success with this Vine I have arrived at the conclusion that no danger need be apprehended if artificial fertilisation is resorted to in securing an abundant set.

Whether Alnwick Seedling will eventually supersede the Alicante still remains to be proved. It has two decided advantages, in my opinion, over that variety—viz., first, in bringing its fruit to maturity at least three weeks sooner when growing in the same house; and again in the nature of its foliage, which, being more smooth and glossy, will more readily throw off any superfluous moisture that may accumulate on the same in the early morn and often remain there longer than is desirable. With me the Alicante is troublesome in this respect, the downy foliage holding so much moisture on dull days that the leaves frequently get "damp" spots on them. This would not happen, perhaps, could we keep our late vinery as we would wish. Having to use every available space at that season, and a deficiency of heating power, often causes a moisture to condense on the foliage of the Vines that could be obviated were the means at my command. The Alicante, on the other hand, is always a sure setter without any extra attention, and with us does not shrivel after hanging when ripe on the Vine, whereas we find the Alnwick does this. If I were going to plant another vinery I should grow the Alnwick with the Black Ham-burgh, believing from observation that it would make a good succession to that old and excellent variety, requiring about the same time to bring its fruit to maturity, but hanging somewhat later.—JAMES HUDSON, *Gunnersbury House Gardens*.

I AM glad to see that the remarks of Mr. Wright relative to the merits of this Grape have brought out the experience of many who have grown it since it was first distributed. The unfavourable reports that were made against Alnwick Seedling up to this year undoubtedly either prevented its cultivation on anything approaching a large scale. I know more than one who shortened the cane they purchased the first season, and raised a number of young Vines

from the eyes and planted them, but owing to the reports in question these young Vines were removed, and those that they were intended to supplant retained. This I did amongst others, and kept only the original Vine, which is growing amongst Alicantes and Lady Downe's, and this spring showed quantities of moderate-sized bunches—in fact, I had not a Vine of any other variety that produced bunches in such profusion, each shoot showing three or four. I cut all off but four before they came into bloom, the same as I generally do with all free-setting kinds, and leave those only required for the crop. This I did for the purpose of testing its setting properties and with the intention of removing it if it set badly. It was the first Vine to come into growth and flower, and consequently no pollen could be used from any of the other Vines, and the result was the four bunches set as well as any Foster's Seedling I ever saw, or any of the Alicantes in the same house. After they were set the berries swelled slowly at first, and I had grave doubts about their going on satisfactorily. Every berry, however, ultimately swelled, and they were well coloured several weeks before the other Grapes in the house. The berries did not swell quite so large on my Vine as on the Alicantes, but they carried a better and heavier bloom, and the flavour is slightly superior. I have formed a very good opinion of this Grape this season, and quite agree with Mr. Wright's definition of it being an improved Alicante. I am sorry now that I pulled out the young canes I had planted, but intend to make another start towards extending its cultivation. The Vines to which I have alluded were started moderately early in the season and assisted with fire heat, the temperature ranging while in bloom from 60° to 70° at night, according to the weather.—WM. BARDNEY.

OF HUMUS.

SHARON TURNER tells us in his delightful "Sacred History of the World" that "the vegetable classes have been created upon a system of progressive improvability, and also of an indefinite productiveness, which can be increased to the utmost extent of any probable human demands upon it." So gratifying a truth as this must be very dear to all who are engaged in agriculture and gardening; and it is, as he observes, most consolatory to reflect that these beneficial results will always follow the application of human skill and diligence to this interesting order of beings. I make no apology, therefore, for asking you to open your pages to some discussion on the value of humus as a manurial agent. Liebig, in one of the last, if not the last, of his works, writes: "It is to the united efforts of the chemists of all countries that we may confidently look for a solution of these great questions, and by the aid of *enlightened agriculturists* we shall arrive at a *rational system of horticulture and agriculture*, applicable to every country and to all kinds of soil, and which will be based upon the immutable foundation of *observed facts* and *philosophical induction*." Now, without arrogating to ourselves to be either chemists or enlightened agriculturists, we may perhaps, without vain glory, think that we may have the common sense to judge between the opposite teachings of chemists at different times; and you certainly have, sir, amongst your contributors experienced and careful observers such as are not often met with. We have, however to be careful that we do not theorise before we know, nor allow ourselves to be the slaves of prepossessions before we have collected and compared a sufficient range of facts and just inferences from them. Closer attention multiplying our knowledge and making our reasoning correct, our later opinions will become nearer the actual truth. "Succeeding criticism always disperses chimerical fancies, and we may leave the fallacies to their natural mortality."

We all know that a few years since humus was looked upon as a substance capable of contributing directly to the nourishment of plants, and, in fact, the proportion of it existing in a soil was regarded as the truest indication of its fertility. Then, when Liebig had demonstrated the utter impossibility of humus supplying the amount of carbon assimilated over a given area, and had shown that since humus itself was the product of previous vegetable growth it could not be an original source of carbon, the pendulum of men's thoughts took another swing, and the theory was taught by Petzholt and others that the beneficial action of humus depended solely upon the salts and earths contained in it. All the other useful functions of humus were to a great extent lost sight of, and, as it is stated, even Liebig "maintained that so far as humus was beneficial to vegetation at all, it was only by its oxydation and a consequent supply of carbonic acid within the soil—a source which he considered only of importance in the early stages of the life of a plant, before it had developed and exposed a sufficient amount of green surface to the atmosphere to

render it independent of soil supplies of carbonic acid."—(*Gilbert, British Association Address.*) This sentence does not, I think, do complete justice to Liebig's views, as I shall hereafter attempt to show. Neither do I think the following passage from S. W. Johnson, the distinguished professor of agricultural chemistry of Yale College, is quite a fair criticism of his opinion. "Does humus contribute directly to the nourishment of plants? Liebig argues against the view, but his reasons for doing so are scarcely satisfactory. He opposes it on the grounds that it and its compounds are insoluble. In the same book, however, he teaches the doctrine that all the food of agricultural plants exists in the soil in an insoluble form. This old objection, still maintained, tallies poorly with his new doctrine. The old objection, furthermore, is baseless, for the humates are as soluble as phosphates, which are gathered by every plant and from all soils."

While, however, I am of opinion that Liebig did not confine the useful functions of humus to its production of carbonic acid and to the assistance which this renders in the early stages of plant life (as Gilbert says), and that his writings give no true grounds for attributing to him the contradictory teachings which Johnson charges him with, I think it must be admitted that the subject is one which still merits investigation, and that agricultural chemists are scarcely justified in refusing to allow a place to humus (unless it contains nitrogen or ready-formed ammonia) amongst those fertilising elements which command a value in a manure.—INQUIRER.

(To be continued.)

WINTERING STRAWBERRIES IN POTS.

I CAN fully endorse all that Mr. Ward says on wintering Strawberries. Four years ago I was foreman at Bloxholm Hall, Sleaford. We placed our Strawberries (not plunged) on ashes in a cold frame without any covering whatever during that severe winter except snow on the glass, which was never removed. When a thaw set in for a few days the snow water went through the sides of the frame, and the Strawberries stood in the water. This froze subsequently, and the Strawberries seemed like a solid block of ice for weeks. I have never seen a better crop of Strawberries, and of large size, than we had that spring. We gathered one morning 8 lbs. of President, each one turning the scale at 2 ozs.—A. YOUNG.

PLANTING ROSES—SPRING v. AUTUMN.

I AM much indebted to "E. M." for his full and prompt reply to my request. I perceive from his table—or rather that of Mr. Symons—that in 1877 the ground was warmer in November than in February or March; but then his record refers, perhaps, to years very different from those of the five years since. And there is this also to be said, that from November the ground gradually becomes colder, while in March it gradually becomes warmer, so that, as I suppose (although I write under correction) the sap is nearly quiescent then, while as spring advances all is in motion. After a severe winter we have to cut our Roses below where we find the pith affected by the frost, as shown by its brown appearance, but I do not think even then we can ascertain the extent of the mischief. I planted two beds in the autumn of 1879—well we know what a winter that was—I cut hard in the spring, and the Roses did fairly well. Then came the severe winter of 1880-81. Again they had to be cut down, as I thought, below any affected part, but this year the plants, although we had such a mild winter, succumbed; they did not die, but only gave short and weak shoots, and I have been obliged to root them out altogether.

Then, we must remember it is not October planting of which I wrote. "Plant early," say some; but, as a poor trombone player said to his conductor when he told him to blow harder, "It's all very well to say 'Blow harder,' but where's the wind to come from?" So I say, It is very easy to say "Plant early," but where can you get your plants withal to do it? It is well known that many of our large Rose-growers send out fifty thousand to a hundred thousand and more plants each autumn. Now it is impossible for them to exercise that personal supervision which can alone prevent mistakes to execute them in time for this. Happy are they who get their plants in November. I am now writing nearly in the middle of the month and have not had mine yet. Will anyone tell me that plants which have been taken up, perhaps laid out for some hours before being packed, been two or three days in transit, and then planted, no matter how carefully, in a cold and soddened soil, are going in a most obliging manner to arouse themselves and set to work in the midst, perhaps, of a fall of snow to establish themselves? About a fortnight ago I received a small batch of some of the very finest dwarfs I have

ever seen from Mr. Prince of Oxford, and as the wet weather effectually hindered my planting them I laid them in in a sheltered position. I have now examined them, and I do not find one single proof of any root-action. There are none of those little white rootlets that indicate that a movement is going on, and if not there, what would they have done if planted in the beds?

I perceive that in a contemporary the same idea has been started with regard to trees much more hardy than the Rose, and the assertion boldly made that much of the planting done now in autumn would be better done in the spring. This rather strengthens my position, but as you have promised to insert some more communications on the subject, doubtless we shall hear the *pros* and *cons* fully and fairly set forth.—D., Deal.

I HAVE read "D., Deal's," remarks on autumn *versus* spring planting of Roses, also the articles referred to by him, and gladly give my experience in the matter. On high dry situations like my own I have found, after repeated experiments, that autumn is preferable to spring planting, and plants got in by the end of the year do much better the following summer than when the planting is delayed until the following February. In low wet situations with a strong clayey soil the results might be different; but if I were so situated, and the plants were simply to be removed from one part of the garden to another, or obtained from some nursery close at hand, where the plants could be placed in the same day as lifted, then if the soil was in good condition I would plant as early in October as possible, and if the weather was dry at the time would sprinkle the plants overhead with water daily: this, with the night dews prevalent at this time of the year, would prevent the plants shrivelling.

That Roses planted early in the autumn do make fresh roots at the time is beyond a doubt, as I have proved this repeatedly; but possibly the small thread-like roots thrown out then perish in the winter, as I have not found the early-planted trees succeed better than those got in any time up to the end of December, and think this early planting should only be resorted to in cases where there is a risk of the ground being too wet for doing the work in November and December, which in my experience are the best months for planting. The advantages of autumn planting over that of spring is that the plants are placed in when at rest, and are fairly established in their new quarters before growth commences the following season. I have frequently found on lifting trees laid in the previous autumn that new roots begin to start by the middle of February; and, as these are very small and delicate, are easily broken off when the work of planting is delayed too long, which must have a weakening effect on the plants, the growth of which in the following summer is not equal to the earlier-planted trees.

The above remarks apply more to the Hybrid Perpetuals and strong-growing Teas. With the dwarf free-blooming section of the latter the case is different; and I have found it best with these to procure in autumn good strong ground-worked plants on seedling Briars or cuttings (these are much better than grafted plants in pots), and lay these securely in, in some cool place where they are not exposed to the sun during the winter, and where a mat can be thrown over them during very severe frost; the object in view being to keep them as dormant as possible until spring, when they should be planted out about the end of February or beginning of March, as the weather permits. Why these Teas succeed better planted in spring is probably owing to the check they receive by late planting, and the harm done in this way is less than when checked by late frosts and cold winds so prevalent in early spring, as Roses of this class are much earlier in starting into growth than the Hybrid Perpetuals. I have, like "D.," found the dwarf-growing Teas do much better with very close pruning; and on established plants, as soon as growth commences in the spring, I prune close back to an inch or two of the ground. This causes the strong eyes at the base to start, which otherwise would remain dormant if the growth was left long as advised by some; and although growing my Teas in the cold north, by adopting the above plan I get growth quite equal to what I have seen in some of the leading Rose grounds in the south. In fact this hard pruning seems to me to be essential for keeping in good health Roses of all classes of a dwarf free-blooming habit. This severe pruning, however, would not answer in the case of the strong-growing Teas and Noisettes of a climbing habit, as they require exactly opposite treatment in pruning. I think the time has arrived when our Rose nurserymen in their catalogues should make one class of the Teas and Noisettes, and separate the dwarf-growing kinds from the climbers. The latter are now numerous enough to make a class of their own. This would simplify matters to those not well acquainted with the habits of individual varieties, and be a guide in pruning and selecting for bedding pur-

poses. The Teas are not half so tender and delicate as some people imagine; and if proof of this were needed it would only be necessary to visit Messrs. Macks' nursery at Scorton, where, on some of the strongest and coldest clay land and in one of the coldest counties in England, year after year are to be found as fine quarters of the best varieties of Teas budded on Briar cuttings, which for vigour often match their more robust neighbours the Hybrid Perpetuals in the adjoining quarters. The only difference made in the culture is that the earth is lightly drawn up against the Teas before severe weather sets in, and levelled down in spring when all danger of severe frost is past. This appears to be all that is necessary to save them in the most severe winters.

These Tea Roses ought to be more extensively used for bedding purposes in ornamental grounds, and would break the monotony of the usual summer bedding plants, as they bloom the whole summer and autumn, and the young foliage in spring is quite as charming and varied as the flowers later on. To give the beds a better appearance in winter when the Roses are at rest cuttings of evergreens could be stuck in the soil, which, in addition to protecting the plants in severe weather, would have an ornamental appearance.

Before bringing my somewhat lengthy remarks to a close I should like to say a few words on own-root *versus* worked plants, as there has been a tendency on the part of some writers recently to disparage the latter in favour of own-root plants. Nine or ten years ago I planted a quarter of about five hundred plants. These consisted of plants on Manetti, seedling, and Briar cutting, and a portion on their own roots. These Roses were all planted under the same conditions and have received the same treatment ever since, and on preparing a few days ago to shorten back the long shoots I was struck with the greater vigour of the budded plants over those on their own roots. Comparing plants of the same variety together, although many of the Manetti plants are over fifteen or sixteen years old, they still remain in perfect health, and give as good exhibition blooms as maidens and one-year cutbacks. The shoots made during the present season on the stronger-growing varieties on these old plants were fully 8 feet high. To say that better results can be obtained by growing Roses on their own roots in preference to budded plants is a delusion, and I feel certain, if Mr. Hinton took a poll on the question from all the principal growers, that nine-tenths of the votes would be in favour of budded plants. The union of stock and scion, both in the case of Manetti and Briar, seems so perfect that it leaves nothing to be desired, and dwarf Roses on these stocks, properly planted and pruned, will, I feel certain, last for any number of years, and grow wherever it is possible to grow Roses at all.—J. BURRELL, *Heighington*.

[Owing to the pressure on our space this week several letters must be reserved till next issue.]

SCRAPS ABOUT FRUIT.

APPLES FOR THE NORTH.—I have had Potts' Seedling Apple for about ten years, and think highly of it; but it is not quite so certain for a full crop as those I have already named. This variety, with Ecklinville Seedling, Warner's King, and New Hawthornden, here have been much alike this season. They have carried a half crop of first-class fruit. To the shelter afforded during the blooming period there is often credited the reason of a full crop. Had my place been naturally sheltered, the same shelter that would undoubtedly have been advantageous during spring would have added to the heat of the position in summer; consequently the fruit buds would have been better matured and next season's crop more certain. Position may make a few degrees' difference in the summer heat in the same locality, and this may make all the difference between fruit buds being quite ripe and almost ripe. For instance, between Berwick and Edinburgh the harvest is at least ten days earlier than it is in the county of Durham. In planting it is for gardeners to consider this average difference in the temperature, and to plant accordingly. My contention is that with wood well ripened the disaster from spring frosts is considerably mitigated; and this being so, it is for planters to discover the varieties of fruit trees that can be ripened with the least heat, that securing a crop may be then more probable. Of course I am not discarding the truth that some people thrive where others starve. I bargain for equal attention. Unripe wood, the parent of nearly all the evils that attend fruit-growing, can be contributed to in many ways.—JOSEPH WITHERSPOON.

THE KITTATINY BLACKBERRY.—Could any of your correspondents give me any information respecting the American Blackberry Kittatiny? We have it here, but it never fruits. I

have protected it during winter with fern to try and save the canes. Last winter they came safely through, but still there has been no fruit. They are growing on strong soil, and are well exposed to the sun. Of the Parsley-leaved variety some plants bear well, others do not. I think I will have a bed of them in the garden and give them closer attention.—M. E. C. B.

LANE'S PRINCE ALBERT APPLE.—This Apple has been recommended to me as a sure bearer and one of the most useful culinary Apples; but before planting it I should be glad to hear if any of the readers of the Journal have had experience with it, and if so with what results? If it has failed it would be interesting to know under what conditions it was grown as to soil and climate, and information of the same nature would be valuable where it has succeeded. Any particulars relative to this Apple—its bearing and keeping properties, would probably be useful to others besides—A SURREY AMATEUR.

THE PRUNE AND CLUSTER DAMSONS.—Will Mr. Luckhurst, or any of your fruit-growing contributors, be good enough to say which of these Damsons they consider the most likely to give the best returns in growing the fruit for market? "The Prunes," says one of my neighbours, "being the finest are sure to make the most money;" whereas another says "the Cluster kind is not only by far the most productive, but its smaller fruits meet with favour and can be invariably sold at remunerative prices." I am thus in a dilemma, and if any of your experienced readers can extricate me I shall be thankful, as I should like to plant a hundred trees.—N. FIELDING, *Hants*.

MORELLO CHERRIES.—Will these do as standard or bush trees in the open garden, or must they have walls? I have seen them recommended as bushes, but am not certain that the advice was not founded on experience gained in a warm position in the south. The question I should be glad to have answered is this, Would they be likely to fruit well and ripen their crops in a garden, moderately sheltered, in Norfolk; soil medium loam, and situation 100 feet above the level of the sea, or thereabouts? O. E. HERBERT.

HARDY FRUITS.—In reply to Mr. MacIndoe, allow me to say that I know nothing of this Apple he mentions, and that I had the Ringer first from the late Mr. Harrison of Darlington. Many of your readers as well as myself, I feel sure, would be glad if Mr. MacIndoe would give us some of his experience of hardy fruit-growing as he finds it in the north-east of Yorkshire. The many bare trees we see year after year is sufficiently convincing that we know far from sufficient yet of the many traits of character of our hardy fruit crops. With well-selected varieties, especially with early varieties, I feel quite sure that much money could be taken before the American Apples reach us. After such selection secure shelter from the west to avoid gales, plant high and dry away from destructive spring frosts, and then await with sure confidence each season and its golden returns. Last year I advised to plant largely of Scarlet Siberian Crab for jam; perhaps I may be pardoned for considering it some evidence of such advice being followed that I have not been able since to secure a tree at wholesale prices.—JOSEPH WITHERSPOON.

BEGONIAS AT SWANLEY.

MESSRS. H. CANNELL & SONS have in recent years paid much attention to Begonias generally, and a fine stock of all the types is now grown in their nursery. In a visit some time since I noted some of the best, which may be of interest to those who admire Begonias.

Foremost amongst them were the Tuberous varieties, which had been very handsome earlier in the season, but were then getting past their best. Some, however, still remained in fine condition, and notable amongst these were "The Seven Cities," which are newly raised varieties bearing exceedingly large flowers, and named after the chief cities of the world. The blooms of some of these were 6½ inches in diameter, the petals proportionately broad, and the colours bright, chiefly shades of scarlet. City of London is crimson scarlet, City of Berlin very dark scarlet, City of Peking orange scarlet; New York, Paris, Vienna, and St. Petersburg representing other shades. These have the most massive flowers of any we have seen, and they appear, moreover, to be of sturdy habit and free bloomers.

Another group of flowering Begonias—including such forms as B. weltoniensis, B. diversifolia, B. Martiana, B. Martiana gracilis, B. Ingrami, B. Knowsleyana, B. Richardsiana, B. Sutherlandi, B. Dregei, and B. fuchsoides—is especially deserving of notice, as the plants are so useful for decorative purposes, so easily grown, so floriferous, and so generally attractive that they deserve to rank amongst the

most valuable to the gardener. Most of them are well known, the handsome rosy-flowered *B. Martiana*, the coral-scarlet *B. fuehsoides*, and the pink *B. weltoniensis* being especially popular; but one or two of the others are not so frequently seen in gardens. *B. Knowsleyana*, however, with *B. Dregei*, *B. Richardsiana*, and *B. Sutherlandi*, though having no pretence to novelty, are comparatively rare, but where well grown they are greatly appreciated. The first has been repeatedly noticed in these pages, and was figured in this *Journal* December 22nd, 1881, when some account was given of its origin and usefulness. *B. Dregei* and *B. Richardsiana* are of neat habit, with small bright green leaves and small but abundant white flowers. *B. Sutherlandi* is of similar habit, but has orange-coloured flowers, a very distinct shade. *B. semperflorens* and its variety *rosea* are indispensable, the latter being a fine companion for the former, which it precisely resembles in habit, but the blooms are deeply tinged with rose instead of being pure white. *B. Martiana gracilis*, it should be observed, is a variety of continental origin, rather more slender in habit than its parent, but otherwise similar to it. All these are useful for winter flowering, and add greatly to the beauty of a conservatory when flowering plants are not too plentiful.

There is yet another section of *Begonias* largely grown at Swanley—namely, the fine-foilage type, which are represented by dozens of handsome varieties, many being comparatively new from the continent, where more attention has been paid to these plants for some time than in England. The diversity in colouring and markings of the foliage almost defy description. Some have a metallic silvery gloss, others are of the deepest velvety green with various dots and splashes of different colours, and some are deep red with green zones. Without attempting to describe them, the following may be noted as some of the best—*Marguerite Bruant*, *G. O'Gorman*, *Jules Duplessis*, *Madame Champion*, *Madame de Biehat*, *Jules Bourchett*, *Fire King*, *Berthé Rautière*, *Madame Baumelin*, and *Adrien Robine*.—VISITOR.

IN reference to the intended Congress of Horticulturists to be held at Ghent in March and April, 1883, the Syndical Chamber of Belgian Horticulturists have passed the following resolution:—
“In order to give to the representatives of horticultural industry of all countries the occasion to extend mutually their commercial relations and discuss their common interests, an international meeting of horticulturists will take place at Ghent in April, 1883. The programme will be published in due time. As this meeting will coincide with the great quinquennial international Flower Show organised by the Royal Agricultural and Botanical Society, interesting entertainments will be offered to the Congress members, and excursions organised to the different horticultural centres of Belgium.”

— IN consequence of the Assizes not being concluded, in St. George's Hall, the LIVERPOOL HORTICULTURAL ASSOCIATION'S AUTUMN SHOW has been postponed till Friday, November 24th.

— WE are desired to state that an addition of eighteen pensioners on the funds of the GARDENERS' ROYAL BENEVOLENT INSTITUTION will take place on January 11th, making the number up to 100, the largest number at one time on the books. Mr. E. R. Cutler also informs us that “The collection in aid of the Pension Augmentation Fund for 1882 will finally close on November 30th. The amount received up to this day is £478 8s. 7d., being £83 4s. 9d. behind the amount collected last year. The Committee earnestly trust that among the many horticulturists in England that this sum will be made up before the day of closing the fund, and that in a very few years it will be their unspeakable gratification to be able to announce their ability to raise the pensions by £4 each. The voting papers for the coming election of pensioners will be in the hands of the subscribers on or about December 16th.”

— A CORRESPONDENT writes as follows:—“On the 14th inst., at his residence in College Street, Bury St. Edmunds, in the seventy-second year of his age, died Mr. JAMES CLARKE. He was

one of the oldest members of the Bury and West Suffolk Horticultural Society, and was an ardent and successful amateur horticulturist until failing health compelled him to in a great measure relinquish his favourite pursuit. He was eminently successful in the cultivation of plants, but the Pink was his favourite flower, and he succeeded in raising many valuable varieties, including Lord Lyons, Derby Day, Duchess, and others. He was a genial and kind-hearted man, beloved and respected in his native town; never so happy as when in the company of horticulturists; an appreciative reader of the *Journal of Horticulture* since its commencement, and he knew, spoke of, and regarded its various writers as friends, although it is possible that he never had an opportunity of seeing or speaking to any of them.”

— THE CONSERVATORY AT NORRIS GREEN is, writes a correspondent, now a brilliant mass of flowers. Apparently there are about a thousand Zonal Pelargoniums in full beauty; *Vesuvius* and its white variety, with a salmon sport that originated in Mrs. Heywood's gardens, and increased by Mr. Bardney, being amongst the most effective. Very fine also is *Prince of Wales*, a free grower, and fine winter bloomer; colour soft scarlet. *John Gibbons* is one of the finest of the bright scarlets, and will be more largely employed in future. *Arthur and Mary Pearson* are amongst the best pink varieties. Perhaps the finest double scarlet variety now flowering is *M. Raspail*. *Guillon Mangilli* is also flowering, but this variety evidently requires more heat for developing its full beauty in winter as seen in the stoves at Longleat and Marston. Besides Pelargoniums Mr. Bardney grows seven hundred Primulas, six thousand bulbs in pots, three hundred pots of *Lily of the Valley*, still more *Spiræas*, six hundred *Roses* in pots, five hundred hardy *Azaleas* and *Rhododendrons* for the embellishment of the structure during winter and spring. Nor is the colour produced by such a number of plants overpowering; as abundant foil is afforded by the splendid specimen *Camellias* that occupy the central beds, the flowers being chiefly arranged on a stage round the house.

— OF CHRYSANTHEMUMS FOR DECORATION grown by Mr. Bardney by far the most useful is one called *Souvenir de Malange*, a small white reflexed paper white variety, a little larger than a Pompon. It is of dwarf habit, branches freely, produces thousands of flowers, retains its dark green foliage, and is never affected with mildew. This valuable variety has quite supplanted *Cedo Nulli*, and closely resembles, if it is not identical with, *Sœur Melanie* that was recently alluded to as the most useful Chrysanthemum in the Chiswick collection. *Elaine* and *James Salter* are the most useful tall light varieties at Norris Green; and by far the most serviceable among the richer colours is *Early Red Dragon*, as the plants branch freely and produce their brilliant flowers in abundance.

— WORTHY of special note is *LUCULIA GRATISSIMA*. A plant or tree of it in the above-named conservatory is about 15 feet high, and is bearing at least a hundred trusses, some being 9 inches in diameter, and the fragrance of the delicate peach-coloured flowers pervade the entire building. This is perhaps the finest specimen of this plant in the country, and it will continue yielding trusses for several months. Unfortunately it is difficult to propagate this plant from cuttings, but the difficulty will be surmounted, as a few plants a foot high in 5-inch pots are bearing heads of flowers like *Hydrangeas*, and after a little more experience Mr. Bardney will be able to tell us how such plants can be produced. *Lueulias* will then be grown in thousands, and will find their way into most or all greenhouses and conservatories.

— PRICE'S PATENT CANDLE COMPANY, in sending us a further sample of GISHURSTINE, remind us of the importance of keeping

the feet dry during the inclement period, and at the same time provide us with the means of doing so—so far, at least, as any application to the leather can secure that desirable object. We have now used this dubbing for two winters, and the experience thus gained confirms the accuracy of our first expressions relative to its efficacy. For the convenience of gardeners arrangements have been made with several of the leading nurserymen and seed firms to include this useful article in their lists of garden requisites.

— THREE houses, each 100 feet long, in Messrs. H. Cannell's nursery are filled with healthy plants of the SWANLEY STRAINS OF PRIMULAS—red, white, and purple—each an exhibition in itself. Swanley Red is a strikingly handsome variety of dwarf, compact, sturdy habit, very floriferous, with fine trusses of richly coloured blooms which, when seen in the long lines of plants, has almost a scarlet tint, so great is its brilliancy. As a really showy variety of unusual excellence this merits every commendation, and similar praise is deserved by Swanley White, which has large flowers of admirable form, great substance, and a pure dense white that is rendered even more conspicuous by the dark leaves and petioles—the latter a rather uncommon character in white varieties of Primulas. Swanley Purple was not fully developed at the time of our visit, but what flowers were expanded prove it to be of considerable merit, the colour being so deep and rich. These, with Lilacina, form the bulk of the stock; but other varieties are grown, some very promising and novel seedlings being observable, several with dotted flowers and one with a bronze zone.

— "W. L. H." writes as follows respecting CAPSICUM WILLIAMS' "LITTLE GEM":—"This is a valuable addition to our list of berried plants, which are so useful during the winter months for decoration in the conservatory or house, at a season when there is such a scarcity of plants in flower. The berries, which are but little larger than peas, are of a bright red colour, and are produced in great profusion over the upper surface of the branches. The plant is of dwarf compact habit, and in this respect as well as in its freer fruiting properties is much in advance of *Solanum Capsicastrum*."

— A SECOND EXHIBITION OF HORTICULTURAL APPLIANCES AT THE AGRICULTURAL HALL, ISLINGTON, is announced to be held from March 15th to 24th, 1883. In addition to the exhibits not in competition, prizes will be offered in fourteen classes for flowering plants, evergreens, dinner-table decorations, &c.; a first and second prize, consisting of gold and silver medals, value respectively six and three guineas, or money prizes of equal value, being offered in each. Schedules and particulars can be obtained from the Manager, Mr. J. H. Raffety, at the Agricultural Hall.

— A CORRESPONDENT writing from Biggleswade observes that they had a sudden change in the WEATHER in the early morning of the 16th inst., with a fall of 3 inches of snow, which, however, soon melted. Slender-growing shrubs have, however, suffered to some extent from the weight of snow. The river Ivel has overflowed its banks; consequently low-lying districts are again very much flooded, which has seriously impeded farming and gardening operations.

— THE following note has been forwarded to us for publication relative to the SEARCH FOR A CHRYSANTHEMUM SHOW:—"Having observed in the list of coming events in the last issue of the Journal that the Leicester Chrysanthemum Show was to be held last Friday, I entered the town with the object of visiting the Exhibition and noting the character of the blooms in the midlands. In response to an inquiry the porter said, 'There is no show in the town to-day, sir.' The company's carman was then

appealed to as a 'man who would know if anyone did,' but his verdict was, 'No show in this town.' An application to a policeman brought the same answer. A cabman was then hailed, with a request to drive to the Chrysanthemum Show. 'Don't know about a 'zanth'um show,' quoth cabby, 'but Harrison's has a tonnup show there,' pointing with his whip, 'and there's nout to pay.' So the 'tonnup' show I entered, and in addition to a really grand exhibition of roots found a small bill announcing that a Chrysanthemum and Celery Show, open to all England, was being held that day in the Hazel Street Board School, Ayleston Road. After a journey of a mile in the tram the school was found—an imposing building, but the doors were locked and 'the man gone home,' as a cluster of children informed me. They also had seen gentlemen take some boxes in, but nobody was there now. This was undoubtedly so, and I left Leicester under the impression that the shows are conducted in a very quiet manner there, and that visitors were not particularly desired, or some slight means would have been adopted to have brought the Exhibition to the notice of, say, local policemen and cabmen, who are usually supposed to be acquainted with local events. But Harrison's Royal Midland Root Show, I repeat, was splendid, and finer, firmer, cleaner examples of Turnips, Swedes, Kohl Rabi, Leicester Red Celery, Carrots, Potatoes, Onions, &c., have seldom been seen than in the tent near the market place, which was crowded with appreciative visitors."

— CH. LORENZ of Erfurt announces that he is sending out a THREE-COLOURED CELERIAC (*APIUM GRAVEOLENS TRICOLOR*), which he describes as follows:—"In general it resembles the old soup Celery, but its vigorous leaves, of a deep glossy green, are richly and most elegantly streaked with a silver grey hue in the middle of the leaflets, with a broad creamy white margin." It is recommended for decorative purposes in gardens and for garnishing.

— A CORRESPONDENT advises that "HYDRANGEA THOMAS HOGG should be grown by every gardener having a conservatory to furnish. It is easily grown into large specimens, showing flower at every shoot, no matter how weak it is. We had a specimen last season in a 14-inch pot, and which had bloomed two successive seasons in the same pots. It was 6 feet in diameter, and carried each time ninety large heads of bloom. It was kept well supplied with liquid manure after showing bloom."

— THE opening meeting of the session of the METEOROLOGICAL SOCIETY was held on Wednesday evening, the 15th inst., at the Institution of Civil Engineers, Mr. J. K. Laughton, F.R.A.S., President, in the chair. Eleven new Fellows were elected—viz., Rev. J. Brunskill, F. B. Buckland, C. F. Casella; W. H. M. Christie, F.R.S.; A. Cresswell, R. S. Culley, C. Morris, O. L. O'Connor; H. Parker, F.Z.S.; A. Rowntree, and D. R. Sharpe. The papers read were:—1, "On Certain Types of British Weather," by the Hon. Ralph Abercromby, F.M.S. The author shows that there is a tendency of the weather all over the temperate zone to occur in spells, associated with certain types of pressure-distribution. In Great Britain there are at least four persistent types—the southerly, the westerly, the northerly, and the easterly. In spite of much fluctuation one or other of these types will often continue for weeks together, and tend to recur at the same date every year. The value of the recognition of type groups is shown in the following ways:—(1) They explain many phenomena of weather and many popular prognostics. (2) In some cases they enable forecasts to be issued with greater certainty and for a longer time ahead. (3) We can by their means correct statistical results by giving the real test of identity of recurrent weather, which no single item, such as heat, cold, rain, &c., can do. (4) They enable us to treat such geological questions as the influence of changing distribution of land and sea on climate in a more satisfactory manner than

any other method. 2, "On the Use of Kites for Meteorological Observations," by Prof. E. Douglas Archibald, M.A., F.M.S. In this paper the author advocates the use of kites for meteorological observation, and describes the mode in which they may be best flown, so as not to be mere toys, but scientific instruments capable of ascending to great heights, remaining steady in currents of varying velocity, and of being manipulated with ease and rapidity by the observer. 3, "The Meteorology of Mozufferpore, Tirhoot, 1881," by Charles M. Pearson, F.M.S.

— THE inventor of GISHURST COMPOUND desires us to publish the following letter which he has received from Australia:—

"Melbourne, 19th Sept., 1882.

"When in Sydney two weeks ago I went up to Paramatta and spent a day with an old friend, Alderman Pye. He was one of the first to plant Oranges on a large scale. When I first saw his orchard twenty years ago I found his largest trees a mass of scale and smut, so suggested to him the use of Gishurst compound. That at that time was not much known in this country, as I had to send to my London agents to procure it for me. Mr. Pye acted on my suggestion, and now these trees that he planted upwards of sixty years ago are bright and clean, covered with fine fruit. Have been lately figured in the *Town and Country* newspaper, an illustrated Sydney paper. I tried to get a copy, but failed. The trees are now said to be 35 feet high, standing erect. I could not get my hands to meet round one. Mr. Pye said he had tried everything against scale, but found Gishurst best of all."

HEATING GREENHOUSES.

YOUR correspondent "A. O. W.," page 448, calls attention to the advantages of certain oil stoves, which he says "will not injure the most delicate Fern if properly managed." It is well to put in the "if," judging from the many complaints we hear of these, as, owing to there being no chimney to the burner, a very little draught makes the flame smoke, and this does undoubtedly cause injury. The trouble of filling with oil, and the difficulty of trimming wicks to burn evenly every six or eight hours, is quite as great as that of feeding a slow-combustion boiler with coke or cinders always at hand. Hot-water pipes are the safest and best, and—considering the fact that a complete apparatus can now be obtained for less than £5 which will last for twenty years, while a couple of large stoves, to give anything like the same heat, will cost quite half as much and last two or three years—it is easy to see which is the most truly economical, especially so as the cost of oil will, as a rule, be more than the fuel for a boiler. Where gas is available and at a low price, small pipes heated by a copper boiler placed outside is as economical as oil, heat for heat, and requires no attention, as it may be kept burning for weeks together if necessary in severe weather. If oil must be used it can be more advantageously burnt under a properly constructed copper boiler, with small-sized sheet-iron water pipes, the ordinary wrought-iron pipes being too thick to let the heat escape readily, unless with the more powerful flame of a gas-burner.—B. W. WARHURST.

THE NOMENCLATURE OF GARDEN PLANTS.

MR. W. TAYLOR recently had some remarks upon the above subject which should not be allowed to pass unnoticed. That an evil exists in the numerous synonyms borne by plants is manifest, but that the method of dealing with the matter he proposes would decrease the inconvenience is extremely doubtful. In the first place, it is unfair to blame the botanists for what is often due to the neglect of the nurserymen, who too seldom take proper measures to insure that their plants are accurately named, though there are some very creditable exceptions to that rule, and such purveyors enjoy a proportionate degree of confidence on the part of purchasers. It is, however, a deplorable fact, which no one regrets more than myself, that nurserymen will not take sufficient care in naming the plants, and a slight error is soon multiplied a hundred or a thousandfold. In the case mentioned, where totally different plants are obtained under the same name at different nurseries, the vendors are alone to blame, and not the botanists; and if nurserymen will not take the trouble to consult competent authorities the matter does not admit of any improvement, and the purchaser must do what should have been done by the vendor.

Certainly some plants are unnecessarily loaded with synonyms; but that, unfortunately, is not always an indication of their merit, as Mr. W. Taylor supposes, but rather points to some peculiarity of structural character that has induced different botanists to take diverse views regarding their affinity to other plants. This cannot be prevented, as, like other human beings, botanists are not

infallible, and so some have described and named plants which had been previously described under other names, and thus synonyms have accumulated. There is a simple rule, however, which is generally followed now, and that is to accept only the name first published, with a description by a competent botanist, and where this is consistently followed little difficulty will be experienced. An instance occurred recently of hasty naming and correction, which has given rise to a synonym that fortunately, however, is not likely to come into general use. A new *Selaginella* was first exhibited by Messrs. Veitch under the name of *S. platyphylla*; it was certificated under that name, and described in the reports of the horticultural periodicals. Subsequently, on the examination of an experienced pteridologist, it was named *S. grandis*, as being a more fitting title, the first signifying broad-leaved, whereas the true leaves are not remarkable for their breadth, but, being closely placed, they give the branches the appearance of fronds, and doubtless it was to this that it owed its first name.

There is one sentence in Mr. W. Taylor's notes that specially deserves attention. He says, "We do not want the collections of weeds we see in botanic gardens." Would it surprise Mr. Taylor to learn that nearly the whole of his hardy flowers, which he prizes so highly, have been either brought into cultivation through botanic gardens, or preserved in them when they would have been otherwise lost? Even now there are plants cultivated in some of the leading botanic gardens of this country that rival the best of those in general cultivation, and yet are scarcely known except to scientists, and so they will remain until they attract the attention of an enterprising nurseryman. This has been the case with hundreds of plants, and it is both unjust and incorrect to stigmatise them as "collections of weeds" when they include not only all the best that Mr. Taylor has grown or seen, but many others equally beautiful. It is the object of forming a botanic garden to obtain as large a collection of distinct species and varieties as possible, and not to grow only those which are structurally interesting—to show, in fact, a good general view of the vegetable world, including both its beauties and its curiosities; and that the leading establishments of the kind in Great Britain satisfactorily accomplish this as far as their means will permit, any competent and impartial visitor must be ready to admit.—JUSTITIA.

PRUNING GOOSEBERRY BUSHES.

THIS operation in many gardens is often carried too far, and hard cutting-in is annually practised more as a matter of form than from any good results that may follow. Some pride themselves on this, and persist in having it carried out on the lines of some hard-and-fast rule they have laid down. I could point to instances of this kind where pruning has proved repeatedly disadvantageous. Gooseberry trees in this respect are much like Apples and Pears, and the more they are cut the more useless wood they make, until the trees are so crowded that it is almost impossible for light and air to ripen the wood. I have seen Gooseberry bushes become more crowded under a severe system of annual pruning than when left untouched. I do not say fruit cannot be produced where pruning is freely practised, and I admit the fruit may be larger than that produced from unpruned trees, but the crop will not be so heavy from the former as from the latter. The question arises whether hard pruning is needed in the cultivation of Gooseberries, and more especially in moist localities where late spring frosts are general. I know some bushes that failed in the majority of seasons from no other cause than overpruning. For about half a dozen years, while under this system of cultivation, I do not think a full crop was obtained; in fact more fruit was produced the first season under moderate pruning than during the whole time under the other plan, and they have never failed to fruit abundantly during the past six years.

The only pruning I consider necessary is to thin out the branches slightly to prevent them from becoming crowded, and to remove the lower branches from those inclined to hang upon the ground. By carrying out this method failure in the crop is reduced to a minimum. Pruned bushes have but little foliage at first to protect the young fruit from late frost, while, on the other hand, a large percentage of fruit, especially on the under side of the branches, is safe from all ordinary late frosts through the abundant foliage on the unpruned or lightly pruned bushes.—LANCASTRIAN.

NOTES ON ASPARAGUS.—Now that the tops of Asparagus have decayed, cut them off and fork the soil away from the crowns into the alleys, almost bareing them. Give a good dressing of manure and a sprinkling of salt, but do not return the soil until next March, when the beds should have another sprinkling of salt, being then

earthed and trimmed. This system is practised with much success by the market gardeners around Mortlake, where Asparagus is grown by acres.—A. Y.

MENTMORE.

TRAVELLERS alighting at the Cheddington station of the London and North-Western Railway have not to proceed far, in one direction at least, before they will perceive that they are approaching a residential estate of no small importance. They will observe, too, that this estate is not characterised by extreme old age, with trees bordering on decay and a general sense of negligence pervading the demesne; on the contrary, they will recognise a property extensive and rich, trees young and vigorous, roads smooth and clean, fences firm and neat—everything, in fact, indicating careful supervision on the part of the overlooker and the possession of wealth by the proprietor—not hoarded wealth, but means sufficiently dispensed for the maintenance of everything in good condition, yet not lavished in the indulgence of unmeaning fancies, nor devoted to mere display, as if to gain the applause of passers-by. In a word, it is apparent that wealth is here used judiciously, not wasted, and the district is at once benefited and the estate improved. These are our first impressions of Mentmore, and they deepened into conviction on closer examination of the management and surroundings of that palatial home.

That benefits and improvement go hand in hand here is exemplified by the state of the parish roads which skirt and traverse Lord Rosebery's property, these to the extent of some two or three miles being kept in the best of order at only a trifling cost to the parish, amounting to little more than is necessary for retaining their public character. Thus the rates are relieved, while the estate, indeed the entire district, is rendered to the fullest extent agreeable to all. The village, too, of Mentmore though small is a model one, every dwelling resembling a detached villa of a style of architecture peculiar to itself—pleasing without being elaborately ornate, while the structures are substantial, commodious, and evidently designed with the object of rendering them convenient and comfortable for the inmates. Even the blacksmiths' and carpenters' shops, with their frontages of grass plots, shrubs, and walls covered with climbers, resemble anything but what they are, equalling in appearance many a country parsonage; and it is only by passing to the other side, which is not seen from the road, that the trade character of the buildings is recognised. Excellent schools, too, are erected for the children of the district; and here must be noticed a practice in connection with them that is not only possibly unique in its way, but testifies to the thoughtful kindness of the distinguished lady of the manor towards the little ones and their parents on this fine estate. We hear much of compulsory education now-a-days, but better than compulsion is the Mentmore system of sending round a van every morning to the scattered and widely distant cottages, collecting the "dots" and conveying them to the school door, then at night calling for them and distributing them at their respective homes. This practice is not confined to wet days and certain seasons, but is an established custom, and in wet weather and dry, winter and summer, the loads of laughing children are taken to and fro, delighted, no doubt, with their school experience, while their parents are relieved of much anxiety, and are, it is hoped, correspondingly grateful for the privilege that is so generously accorded them. These pages are perused by many of wealth and position who are kindly disposed to all around them, but it may happen they have never thought of this particular manner of doing good in isolated districts; hence its record here. In one lonely spot an instance can be named where a thoughtful employer has provided a pony and small covered conveyance for conveying his gardener's children to and from the school, which is three or four miles distant, the eldest child being the Jehu; but this is the only case known to me, though possibly there may be others, where anything approaching Lady Rosebery's system is carried out, and, as might be expected, the gardener is as industrious and worthy, and as devoted to the interests of his employer as that employer is appreciative and kind. And what is the result of this mutual confidence between a good master and a good man? It is simply this—few gardens in this country are better and more economically managed than that of Mr. Greenham, whose gardener was the raiser of Foster's Seedling Potato, which was certificated at Chiswick two years ago. This school episode, too, is worthy of record, and the subject to which it pertains cannot be uninteresting to a great number of readers of these lines. It is presumed, therefore, that this digression will be pardoned, and now we return to Mentmore.

As before indicated, it is not easy—indeed to the stranger it is impossible—to tell where the public highway ends and the private

drives to the mansion begin. Strong and neat iron fencing to the extent of about nine miles has been firmly fixed by Mr. Smith (the competent manager of the roads, woods, and gardens) by the sides of public and private roads alike, and ornamental planting has been done on an extensive scale. The principal approach is flanked by circular groups of trees and Conifers, each apparently some 50 or 60 yards in diameter and the same distance apart, and still farther from the side of the road. Thus there is no cramping, except that the groups will soon be overcrowded unless thinning is done, a circumstance to which Mr. Smith is fully alive. In each of the spaces between these groups are three specimen Wellingtonias, arranged triangularly, and with ample room for their full development. They are already effective, and show to advantage on the grass, which is kept short, but not shaven, by being cut with a reaper, not a lawn mower, a few times during the season. The ground is nearly level, being in the vale of Aylesbury, the soil mostly clay with an admixture of chalk, and the grass and trees tell us it is fertile. In such a soil, while the trees do not usually start quickly, they make good progress after once fairly established, and continue healthy and vigorous for many years. Before reaching the mansion a road, still a public highway, but very unlike one, branches to the right, and leads to the village and gardens. This road is flanked by a double row of Horse Chestnuts planted on each side, the trees being just a chain (22 yards) apart, and as much, if not more, from the road. Thus they have space for showing their true character, and will form a grand avenue some day; already it is well marked, as the trees are making sturdy and healthy growth. That rows of well-developed Chestnuts are imposing, and especially in the flowering period, abundant evidence is afforded by the fine examples in Bushy Park; and who knows but what the Mentmore trees will not at some future period become equally famous? Nearer the village a thicket of trees skirts the road, only mentioned for recording a singular fact. Amongst the trees were some old common Willows which it was necessary to lop severely—in fact, they were beheaded. They, of course, grew again; and now comes the curious part—they are all transformed into Weeping Willows, the growths having assumed the character of the true weeping variety. The change is perhaps explainable in this way—the shoots grew rapidly and attained a great length, but being under the dense shade of other trees they were necessarily weak, and hence curved downwards. At any rate, whatever the cause may have been, the branches point to the earth, arching gracefully, and the round weeping heads are attractive by the wayside.

After traversing a distance of something under two miles we arrive at the gardens, which are close to the public road, the new kitchen gardens (of which more anon) on the right, and the enclosure of glass structures and Mr. Smith's house on the left, the pleasure grounds, park, and mansion being still further leftwards, or westwards.

Mentmore, as above indicated, is a comparatively new place, the mansion having been commenced in 1851, and completed in a few years, by the late Baron Meyer de Rothschild. It is interesting to observe that the designs for this splendid building were supplied by Sir Joseph Paxton, M.P., and his son-in-law, Mr. George Henry Stokes, architect. The style adopted by desire of the Baron for the exterior has been described by the *Builder* as that which prevailed during the early part of the reign of King James I., and of which Wollaton Hall, Notts, is perhaps the finest example. A difference in the combination and arrangement has contributed to produce grouping of a picturesque character and outline, and the details and ornamentation are understood to be the result of a careful study and examination of the works of John of Padua. The mansion is built entirely of Ancaster stone of fine quality and colour; the cornices are highly enriched, and the frieze of each order is filled in with carved panels and heads. The arrangements and decorations of the interior are on a similar scale of grandeur, and altogether this is one of the most magnificent houses of the great that adorn our land—at once an embodiment of wealth and stability, and typical of the character of the "sea-girt isle."

The gardens have been formed and the grounds planted by degrees, something being added and something done every year, until in the aggregate the work accomplished is of some magnitude. At first the Baron would have no gardens, but Covent Garden should furnish him with the requisite flowers, fruit, and vegetables. Then he would grow a little fruit, and orchards were planted which now extend over 65 acres. He did not like glass structures, but eventually one house might be built; there are now, counting divisions, some thirty houses for plants, fruit, and general forcing purposes. A strip might be had for a few vegetables, and boarded fences for training trees; now there are some 16 or 17 acres enclosed, a new wall fully a quarter of a mile long, and one of the finest collections of fruit trees in the kingdom. Thus has Mentmore grown, and the pleasure grounds have in-

creased in the same manner, Mr. Smith, with a staff of from forty to fifty men, adding and improving every year, carrying out his own designs after approval by his employers, and completing whatever work he has in hand in the best manner. He evidently works on the principle, and a most excellent one it is, that is embodied in the aphorism, "First see your way, then go ahead." A headlong rush into alterations without due consideration frequently necessitates work having to be done over again, while he who commences an undertaking without a clear perception of the result when finished practically works in the dark. Neither of those mistakes, both of which are somewhat too common, is made at Mentmore.

Having reached the gardens—that is, the glass department, the character of the houses and the work that is done in them may be briefly alluded to, instead of adopting the painfully tedious practice of giving the dimensions of each house and making a dry catalogue of its occupants. The block of glass resembles a nursery, the structures being crowded together as if to utilise every inch of space. With the exception of one very lofty and commodious span-roof, erected for the accommodation of Palms and Tree Ferns, a good greenhouse and three or four vineries, the houses are low, narrow, pit-like structures, admirably adapted for preparing plants for the mansion and for general forcing purposes.

One long range is devoted to Pines, which are admirably cultivated, all the leading varieties being represented. In addition to Queens, Cayennes, Charlotte Rothschild, and Prince Albert, the newer kind, Lady Beatrice Lambton, is fruiting. This is a noble Pine of good quality; and very superior is Lord Carrington, which produces fruit abundantly large for dessert purposes where, as is the case here, a portion of a Pine must never be placed on the table. The plants are grown in pots, and are in the best possible condition; and so far from Pine-growing being an expensive luxury, every fruit that is produced could be readily sold at a price that would render Pine culture decidedly profitable. The superiority of good English-grown Pines over the foreigners that are imported is so great that it is not unlikely that Pine-growing will increase rather than diminish in British gardens; indeed the demand for plants and suckers is much greater than was the case a few years ago. The back wall of one of the Pine stoves is being covered, or rather hidden, by a hedge of Gardenias planted out in a narrow border, and the rich dark green foliage and hundreds of fine blooms suggest that scarcely anything else could occupy the space more satisfactorily. On shelves near the glass table plants are grown at one period and Strawberries forced at another, and thus every inch of space is turned to profitable account.

With the exception of a late house containing capital Lady Downe's and Alicante, also good Muscat Grapes, the vineries were cleared of fruit; but it was plain by the wood and foliage that the Vines of the earlier sorts are in admirable condition. It was observable that they had been half pruned in September with the object of "plumping" the eyes at the base of the laterals, which must be relied on for producing the next crop of fruit. Only few gardeners adopt this practice, but it is a good one nevertheless, as those will find who try the experiment on a few laterals and note the results. Some Vines were being renovated—lifted and placed in fresh soil, and the foliage kept fresh by syringing would incite the production of fresh roots at once. Peaches are grown equally well, all the pruning being done in summer; hence the shoots, brown, hard, and thinly trained, are studded with fruit buds, and full crops are inevitable. Hale's Early is found to be an excellent variety for forcing, and is mainly relied on for the first gatherings. Nearly all the vineries and Peach houses were crowded with plants of all the popular kinds for decorative purposes, as so many are needed for the mansion here and in London—winter-flowering Begonias, Salvias, Eupatoriums, *Veronica salicifolia alba*, Perpetual Carnations, these being grown by the hundred in 4 and 5-inch pots, while all kinds of winter-flowering stove plants occupy all available space in the warmer structures.

A Rose house affords a supply of these always-acceptable flowers, while cool Orchids are grown extensively and well for affording sprays for cutting, *Odontoglossum* now producing vigorous spikes. In a quaint old ridge-and-furrow structure, with brick sides and boarded doors, with small windows between them, Orchids, Ferns, and fine-foliaged plants luxuriate, thus showing that houses with side lights are not needed by plants of this nature, the light from the roof being ample, while fuel is economised and a moist genial atmosphere maintained. Overlooking the glass is Mr. Smith's commodious residence, the walls of which are entirely covered with the thick glossy foliage of Rægner's Ivy, which is rarely seen so fine, and adjoining are the garden offices,

fruit-rooms, seed-rooms, &c., all excellently arranged, and comfortable bothies for the under gardeners contiguous.

Proceeding to the mansion we pass a hardy fernery pleasingly formed in a nook in the woods, the very place in which Ferns delight. It is surprising what can be done with a few loads of soil and stones thrown up under trees in a series of irregular mounds, with curving paths between, when taste and good judgment are exercised in the arrangement. Here the Ferns have been planted in groups of species and varieties, not the whole regularly dotted and mixed in a weak diluted manner that should never be seen in ferneries of this nature. Emerging into the open is an old-fashioned garden filled with herbaceous plants, the beds, though on grass, being also edged with Box, and here and there are fine clumps of *Arundo conspiciua* with large feathery plumes. On the right is the rosery, which was figured and the planting of the beds described in the Journal a few years ago. The walk conducs to the subtropical garden, which is reached through a bowery mass of *Bambusa Metake*. This is a charming spot with its central lawn and fine Conifers, the surrounding shrub-clad banks relieved with masses of Cannas, *Daturas*, *Pilumneas*, *Wigandias*, and plants of that nature. But the most beautiful bed of all was furnished with standard plants of *Abutilon vexillarium* in a carpet of *Sedum glaucum*. This *Abutilon* grown as indicated produces an effect totally distinct from anything else, and rich as it is elegant, by the hundreds of scarlet and yellow flowers hanging bell-like from the mottled sprays. Such plants are easily produced by grafting, and are extremely ornamental. This garden, once an old gravel pit, is now one of the most agreeable features of Mentmore, and is altogether most enjoyable.

Almost skirting it is the village entrance to the grounds—a noble drive with lawn embankments crowned with Conifers and flowering trees and shrubs. Where the drive enters the pleasure grounds the left bank terminates in a spur which is occupied by a life-size model in bronze by the eminent sculptor Boehm of a favourite horse of the late Baron, standing in a group of Pampas Grass and partially hidden by a forest of great white plumes, the effect from the mansion and distant part of the grounds being very striking. On the right of the drive and skirting it is a double row closely planted of Junipers and Cypressess, standing like sentinels, with a margin of dwarf evergreens next the road and a background of *Lahurnums*, *Lilacs*, &c., in front of a mass of Pines, the Corsican having proved the quickest grower of all. On the lawn are beds of *Rhododendrons* and *Azaleas*. The park formerly reached almost to the south terrace, but now Mr. Smith is engaged in enclosing several acres and planting them ornamentally, and of the many improvements that have been effected this will probably be the greatest. The pleasure grounds were certainly disproportionate with the splendid mansion, which needed a broader-dressed base to show it to the best advantage, and this it will now have. The Italian flower gardens are on the west side of the building, and the character of one of them at least, for there are two, may be gathered from the engraving (fig. 79, page 481). In this the marble vases and statuary are such as are seldom seen in gardens, and with the masses of flowers and boundary Yew hedges a typical example of this style of gardening is produced. The other panel contains fountains and sloping banks of evergreens—*Mahonia aquifolia* relieved with corner masses of *Aucubas*. From these terraces and the mansion grand views over an undulated park of 1400 acres are obtained. This comprises some of the richest land in the kingdom, hence the rapid growth of the distant new plantations and the fine old timber trees in the immediate foreground. The view is bounded by the Chilterns, and altogether is boldly and variedly picturesque. This mere skeleton description of this imposing residence and its surroundings must suffice, for we must dwell for a moment on the kitchen garden, to which we now return.

Quite as much care is bestowed here as on the ornamental department. There are no decaying crops, no weeds, no patchiness, but everything is orderly. A systematic arrangement of crops and ground-preparation is apparent at a glance, and closer inspection only shows the excellent culture more clearly. It was the high condition of the kitchen garden at Exton that impressed an influential horticulturist with Mr. Smith's ability, and by that he lost nothing. Immediately a crop is cleared off the strong ground is ridged, it being well known that the summer aeration of such soil is as beneficial as the frost of winter. Practically all the "winter digging" was completed in October. Amongst other crops a trial of Brussels Sprouts showed that the true old imported variety that was common a quarter of a century ago, and which was not obtained without difficulty, is the best of all; the large "improved" sorts are soft and coarse in comparison. It is a pity that a vegetable so excellent as this should almost have been improved out of existence. Of Strawberries a trial is being con-

ducted of forty varieties, most of them also prepared for forcing—splendid plants as were ever produced, and of which we shall hope to hear something in due time. In this garden is one of the finest collections of all kinds of hardy fruit in the kingdom, the best varieties having been obtained from English and continental nurseries. A hint in Gooseberry planting is worth record. The bushes, about 6 feet apart, are each planted on a mound some 2 feet above the general level of the soil, by which simple arrangement the fruit will certainly be less liable to be injured by too close contact with the soil.

Besides vegetables, Violets are grown almost by the acre, being treated like Strawberries, and must afford bushels of flowers. Rose cuttings inserted in some side borders two years ago have formed hedges, hundreds of growths being 6 feet high and some 8 feet. These will be pegged down, and next June there will be a sheet of Roses 3 feet wide on each side of the walk. No Manetti, Briar, or any other cuttings inserted at the same time, and subsequently budded or grafted, could have produced anything like the growth during the same period; but it is not to be expected that everybody will admit the accuracy of this assertion. Here, however, it stands for the contradiction of those who are of a doubting turn of mind.

A large orchard house is erected in this garden filled with fruitful trees and a grand lot of Chrysanthemums; but we will wait for more glass to accompany it before saying any more about the solitary structure.

Just a word must be said about the orchards. In one enclosure there are a few Plums—600 trees of Green Gage and 500 of Victoria, with 1000 of the Crittenden and Prune Damson. In another plantation of forty acres of Apples are 250 trees of Lord Suffield, 300 of Blenheim Pippin, 350 of Dumelow's Seedling, and so on. But the best and most profitable of Apples this year at Mentmore is Lane's Prince Albert. It is a splendid sample; but perhaps the variety might not do equally well everywhere, for another sort that is generally fruitful, failing in few places, will not grow here—Cellini. The trees referred to did not grow freely for a time, but a dressing of 600 tons of London manure appears to have been a good investment, as since that was used they have made satisfactory progress. As I must stop somewhere it may as well be here, and I conclude with a vote of thanks to Mr. and Mrs. Smith for their success in making my visit, if short, pleasant and not soon to be forgotten.—J. WRIGHT.

CHRYSANTHEMUM SHOWS.

KINGSTON.—NOVEMBER 16TH AND 17TH.

No Chrysanthemum society in the kingdom has made such rapid progress as this has. It was only started six years ago, Mr. Moorman, we believe, taking the initiative, and with a few other cultivators organised a committee, and solicited subscriptions with the object of holding a local exhibition. Not only was there a fair response, but the supporters included some spirited individuals, and a 25-guinea challenge cup was provided for open competition. From that moment the Kingston Show assumed much more than a local character, and it may be fairly regarded now as being in substance, if not in name, a national exhibition. It would appear, too, as if the directorate was determined that the position the Society has won shall be maintained, if not increased; as not only are new classes added yearly (that for six blooms of any one variety having proved a great success), but another cup has been provided in place of the one that has been finally won this year, and won by a southern grower. During the three-years contest for this trophy the renowned Liverpool growers, Mr. Tunnington and the late Mr. Faulkner, have proved alike their skill and courage, for only men of mettle would have brought their blooms two hundred miles to compete with others grown, as it were, on the spot. This great "cup class" was the centre of attraction, and such was the interest the contest evoked that cultivators from the districts of Liverpool, Oxford, Bristol, Southampton, and other distant towns were amongst those who crowded round the stands. "Won easily" was a somewhat general exclamation on the first glance being had of the collections; but a critical examination of the blooms individually impressed not a few that the contest was exceedingly close—so close that in all likelihood, had the Putney blooms been taken to Liverpool instead of the Calderstone specimens being brought to Kingston, the position of the two great competitors would have been reversed. We say the two, for on this occasion Mr. Leyland's blooms, though beautifully fresh, were a week behind. Some of the incurved blooms staged by Mr. Tunnington were superior to those arranged by Mr. Harding; but the former exhibitor was overwhelmed in Japanese by the latter, a magnificent Elaine from Liverpool, by far the finest of that variety in the Show notwithstanding.

As we have indicated, the cup was won by Mr. Harding, gardener to J. D. Galpin, Esq., Bristol House, Putney Heath, with a magnificent collection, comprising blooms of the following varieties, taking the Japanese first:—Madame C. Audiguier, Bronze Dragon, Fanny Bouchardat, Fair Maid of Guernsey, Comtesse de Beauregarde, Dr.

Masters, Baronne de Prailly, Comte de Germany, Madame Burnes, Curiosity, M. Plancenau, Garnet, M. Ardene, Criterion, Thunberg, Triomphe de Chatelet, Madame Moulise, Plantagenet, Bouquet Fait, L'Incomparable, Fulgore, Madame Monarch, Elaine, and La Nympe. The incurved varieties were as follows:—Empress of India, Empress Eugénie, White Venus, Golden Queen, Mr. Brunlees, Mr. Bunn, Alfred Salter, Mrs. Heale, Princess Beatrice, Jardin des Plantes, Prince of Wales, Venus, Nil Desperandum, Prince Alfred, Lady Hardinge, John Salter, Novelty, Pink Perfection, Golden Empress of India, Hero of Stoke Newington, Mrs. Haliburton, Queen of England, Princess Teck, and La Grande. It need scarcely be said that these blooms received the principal attention of the visitors, and the admiring comments passed upon them by the more critical sufficiently indicated their merit. Mr. Harding well deserves the honour he has striven for perseveringly and won creditably. Mr. W. Tunnington, gardener to Chas. MacIver, Esq., Calderstones, Liverpool, who followed, had fine examples in his stand of Japanese of Baronne de Prailly, Criterion, Elaine (magnificent), Peter the Great, Cry Kang, Japonius, The Cossack, La Nympe, and Gloire de Toulouse. The back row in his stand of incurved varieties comprised grand blooms of White and Golden Empress of India, John Salter, and Queen of England; other fine blooms being Beauty, Barbara, Beethoven, and Prince Alfred. F. R. Leyland, Esq., Woolton Hall, Liverpool, who was third, had collections of even, fresh, and bright blooms, but not so forward as the others.

The second challenge vase was offered under similar conditions to the other, but with the stipulation that the three winners of the first would not be allowed to compete for the second this year, though they will be free to enter the lists at the next show. Five competitors appeared, all staging collections of great merit, but the premier forty-eight blooms from Mr. E. Molyneux, gardener to W. H. Myers, Esq., Swanmore Park, Bishops Waltham, were exceedingly fine, well deserving the position accorded them, and once more the vase is secured by a southern exhibitor, who, if he continues in his present style, will prove a formidable adversary for any southern or northern growers that may enter the lists in the next two or three years. His stand of Japanese comprised blooms of the following varieties:—Madame C. Audiguier, extremely fine; Hiver Fleur, Oracle, Elaine, Madame B. Rendatler, Yellow Dragon, Thunberg, Khedive, M. Delaux, Sarnia, Criterion, Cry Kang, Meg Merrilees, Comte de Germany, Soleil de Levant, Peter the Great, M. Ardene, Aurantiacum, Mdle. Moulise, Boule d'Or, Album plenum, Baronne de Prailly, Fair Maid of Guernsey, and The Daimio. The incurved were Golden Empress of India, Princess Teck, Mabel Ward, Alfred Salter, Baron Beust, Barbara, Mr. Howe, Jardin des Plantes, Margaret, Guernsey Nugget, Beauty, Princess of Wales, Cherub, Lady Hardinge, Empress of India, Refulgence, White Venus, Prince Alfred, Mr. Bunn, Orange Perfection, Mrs. Heale, Hero of Stoke Newington, Queen of England, and Eve. Mr. C. Gibson, gardener to J. Wormald, Esq., Morden Park, Mitcham, was second with an even fresh collection, but his finest blooms were in his premier stand of forty-eight at the Westminster Aquarium, and had these been shown at Kingston the contest for the cup would have been extremely keen, and might not have resulted so favourably to Mr. Molyneux. Mr. J. Jellicoe, Camp Hill, Woolton, Liverpool, took the third place, his incurved blooms being very meritorious, but the northern growers will probably appear in stronger force and better form next season to maintain their credit.

Another of the leading classes was that for twenty-four incurved blooms, the chief prize being a timepiece value four guineas. This was awarded to Mr. F. R. Leyland, and it will be remembered that the late Mr. Faulkner also won a similar prize in this class last year in addition to the champion vase, so that the Woolton Hall blooms scored three decided triumphs at Kingston. Many of the blooms in this stand were of great merit, examples of Mr. Bunn, Mr. Howe, Blonde Beauty, and Barbara being very notable. Messrs. Harding and Tunnington were placed second and third, their positions being thus strangely reversed as compared with the old cup class, and Mr. E. Beckett was fourth. For twelve incurved, Messrs. Molyneux; G. Woodgate, gardener to Mrs. Hammersley, Warren House, Kingston Hill; J. Strong, gardener to J. Sweet, Esq., Dornay House, Weybridge; and W. Burns, gardener to H. A. Bigg, Esq., Wykham Lodge, Hershaw, were the prizetakers in that order, the leading collection being particularly fine. Mr. Molyneux also took the first prize for six incurved blooms of one variety with large, even, substantial, and smooth blooms of Princess of Wales; Mr. T. Benson, gardener to W. H. Roots, Esq., Kingston, being second with magnificent examples of Empress of India, Mr. Strong following with Golden Empress also in beautiful condition.

Japanese varieties were well represented in the classes specially devoted to them, several beautiful collections of twenty-four being contributed. In this class Mr. E. Beckett, gardener to J. P. Currie, Esq., Sandown House, Esher, won chief honours with large and richly coloured blooms of M. Delaux, Bronze Dragon, Fanny Bouchardat, Comte de Germany, Thunberg, Père Delaux, Boule d'Or, L'Incomparable, Criterion, Garnet, Comtesse de Beauregarde, Grandiflorum, and Album plenum. Messrs. King, Harding, and Woodgate followed closely in that order. Collections of twelve were staged by Messrs. Burns, Croxford, Strong, and Tunnington, who secured all the prizes. However, the class for six blooms of one variety perhaps attracted more attention than the others, for the blooms entered were uncom-

monly fine, especially Mr. Molyneux's half a dozen examples of Madame C. Audiguier, which were simply superb, and most fully merited the leading prize awarded for them. Mr. C. Herrin took the second place with Hiver Fleur, also good; and Mr. King was a good third with Baronne de Prailly.

Amongst the other classes for blooms the most noteworthy were those for reflexed, Anemones, and Pompon varieties. In the first-named for twelve blooms Mr. Molyneux again occupied the principal position with fresh neat specimens of Golden Christine, King of Crimson, Chevalier Domage, Emperor of China, Cloth of Gold, Mrs. Forsyth, Dr. Sharpe, and Pink Christine. Messrs. J. Hill (gardener to A. Savory, Esq., Chertsey), and Coombs, were second and third respectively. For twelve Anemone blooms, not less than six varieties, Mr. Gibson won with Lady Marguerite, Acquisition, St. Margaret, Gluck, Fleur de Marie, Prince of Anemones, Madame Godereau, Louis Bonamy, and Princess Charlotte; Messrs. Molyneux and Orchard following. Mr. J. Lyne, Wimbledon, staged the best twelve Anemone Pommions; Calliope, Firefly, Dick Turpin, Madame Montels, and Mr. Astie being fine; and the same exhibitor was first with twelve bunches of ordinary Pommions, showing neat examples of Bijou d'Horticulture, Model of Perfection, St. Michael, Chas. Dickens, Madame Marthe, Liliputian, and Snowball.

Plants were not so well represented as the cut blooms, if the groups and the specimens not in competition from J. H. Bryant, Esq., Glencairn, Surbiton Hill, be excepted. The latter formed one of the features of the Exhibition, the plants having been admirably grown and trained with the greatest care. A central specimen of Mr. G. Glenney over 20 feet in circumference, flat-trained, and bearing about 250 blooms, was especially handsome, others of slightly smaller size being contributed, with some standards and dwarf Pommions, and it was stated that all were under eleven months old. For a collection arranged in a space of 50 square feet Mr. C. Orchard, gardener to J. Galsworthy, Esq., Coombe Lodge, Kingston Hill, won first honours with a handsome bank, the blooms large, and the colours tastefully arranged. Mr. J. Croxford, gardener to Mrs. Dunnage, Allbury House, Surbiton; Mr. J. Buss, gardener to A. S. Price, Esq., Parkside; and Mr. D. Gibbons, gardener to Mrs. Beckford, Orford House, Ham, were the other prizetakers, all contributing showy groups. The principal successful exhibitors in other plant classes were Messrs. Hoskins, Lyne, King, and Burns. Tasteful groups of miscellaneous plants were staged by Messrs. Attrill, King, and Grant; table and berried plants being well shown by Messrs. Munro, Bates, King, Hickle, and Coombs.

Fruit was not very abundant but mostly of fair quality, especially

Fig. 79.—MENTMORE. (See page 479).

the Apples and Pears. Mr. Bates, The Gardens, Poulett Lodge, Twickenham, was placed first with a collection of six dishes, which included a neat Prince Albert Pine Apple, Gros Colman and Muscat of Alexandria Grapes, and Burre Diel Pears; Messrs. Beckett and Munroe followed. Mr. C. Attrill had the best Apples, and Mr. King the best Pears, four dishes each of fair size.

Exhibits not for competition comprised a stand of new Chrysanthemums from Messrs. Jackson & Son, Kingston, including several that were certificated at the last meeting of the Royal Horticultural Society. Messrs. Hooper & Co., Covent Garden, had a pretty group of Carnations, but the most notable of all were the specimen plants already referred to. As a whole the Exhibition was highly satisfactory in a horticultural point of view, but unfortunately the weather on the first day was seriously opposed to a financial success, especially as the expenses in connection with hiring hall are larger than in previous years. However, under the care of the Treasurer Mr. J. Drewitt, and the Honorary Secretary Mr. T. Jackson, the Society will undoubtedly overcome any difficulties of that nature, and the continued prosperity will be insured.

TUNBRIDGE WELLS.—NOVEMBER 16TH AND 17TH.

Electric lighting is now being so generally tried for large public buildings, that it is not surprising flower shows should be favoured with a share of the brilliant illumination, and the results of the

experiments in that direction at Kensington proved sufficiently satisfactory to encourage further trials. It has, however, hitherto been confined to the summer exhibitions, a period when it was less needed than at this time of year; and, as far as we know, the first attempt to light a show of Chrysanthemums in this way was at Tunbridge Wells last week. There, by the liberality of Dr. Siemens, the large skating rink, about 150 feet long by 60 broad, was flooded with a brilliant yet soft and steady light on each of the two evenings of the Show. Six lamps were provided, each said to be of four-hundred candle power, and in consequence the hall was literally as light as day, the varied colours of the Chrysanthemums, the rich Poinsettias, and other plants being seen as clearly and unaltered as under sunlight. The fact of the electric lighting being employed proved almost as attractive as the display itself; and though the weather on the first day was very unfavourable, the receipts up to 5 P.M. being considerably below those of last year, yet the attendance in the evening was so large that the deficiency was nearly supplied before closing time, the second day's receipts also proving very satisfactory. It would, however, be interesting to know whether there is any probability that the experiment might have been satisfactory financially had the Society provided the lamps as well as the motive power.

Horticulturally the Show was both extensive and successful, plants and blooms being largely shown, the former including some of the

best specimens we have seen this season. Fruit is always an interesting feature at Tunbridge Wells, and though the display was not quite so large as usual, still the quality of the exhibits amply compensated for any deficiency in that respect. Sixty-two classes were enumerated in the schedule, and in the majority of these the competition was keen considering the comparatively small value of the prizes; but as we cannot give notes of all these in detail, a brief reference to the most important must suffice. It should be observed that a large bank of plants was formed at each end of the hall and along the side facing the entrance, the blooms, fruit, and smaller plants occupying two tables extending the whole length of the hall.

Plants.—Specimen plants, except in a few instances, have not been well shown this year at any of the southern exhibitions, but taking them generally those at Tunbridge Wells must be placed amongst the best. Those staged by Mr. Beilby, gardener to W. H. Tindall, Esq., Hollyshaw, were especially noteworthy, and their excellence is well indicated by the fact that they were placed first in each of the seven classes in which Mr. Beilby was a competitor, and as these were the only ones he entered he has every reason to be satisfied with his success. The most important of these were in the class for a group of eight plants in 12-inch pots, the chief prize for which was a silver cup, value three guineas, offered by the tradesmen of the town. They comprised two fine pyramidal-trained specimens of Mrs. Dixon and Mr. G. Glenny 6 feet high, healthy, and bearing numerous flowers; a dwarf example of Peter the Great, 5 feet in diameter, with good plants of Mrs. G. Rundle, Pink Venus, Fanny, and Dr. Sharpe, the blooms of which were very large and deeply coloured. The winning collection of six dwarf-trained large-flowered varieties also comprised well-grown plants, Dr. Sharpe being again noteworthy for the size of the blooms, Jardin des Plantes, Mrs. Haliburton, Guernsey Nugget, Mrs. Dixon, and Mrs. George Rundle being similarly good. The six Pompons included Calliope, Antonius, Fanny, Cedo Nulli (white and yellow) being freely flowered, 3 or 4 feet in diameter; while the two best single specimen Pompons were a fine example of Antonius, 5 feet across and in first-rate condition, and one of Mr. Astie of similar size. Pyramidal specimens were also shown by Mr. Beilby in equally creditable condition. He was followed in the above classes by Messrs. F. Earley, gardener to G. A. Brittain, Esq., Ferndale House; E. Killiek, gardener to E. Rocke, Esq., Neville Park, Gardfield; and J. Wilkins, gardener to Mrs. B. S. Williams, Shirley Hall.

In another class for a group of eight Chrysanthemums in pots, which was confined to gentlemen's gardeners and amateurs residing within fourteen miles of Tunbridge Wells, Mr. Adams, gardener to F. Grant, Esq., 3, Hungershall Park, won the silver cup offered by the ladies of the town with healthy freely-flowered specimens of Mons. C. Hubert, Yellow Cedo Nulli, Mrs. G. Rundle, Mrs. Dixon, and Mr. G. Glenny amongst others. Messrs. W. Berwick, gardener to W. W. Doke, Esq., 2, Broadwater Down, and J. Wilkins secured the other prizes in that class. Mr. Adams was also very successful in other smaller classes for Pompons, a pair of the same type and a single specimen taking the first position in each. White Cedo Nulli, Antonius, Calliope, and Mr. Astie were the varieties represented, several 5 feet in diameter, healthy, and abundantly flowered. Mr. Wilkins had a neat collection of Pompons, securing the chief position in the district section.

Cut Blooms.—Incurved blooms were generally rather small, and it was in this portion of the Show that there was the greatest room for improvement, the blooms in the majority of the stands being rather below the average. The Anemone varieties were, however, a notable exception, being extremely well represented, and several very creditable collections of Japanese were also contributed. Mr. A. Henderson, gardener to J. Deacon, Esq., Mabledon, Tonbridge, had the best twenty-four incurved in the district classes, including a good selection of varieties. He also took the lead with twelve Japanese, comprising fine blooms of Abd el Kadir, Baronne de Prailly, Apollo, and Oracle. Messrs. W. Cheek, gardener to J. F. Gibson, Esq., 10, Broadwater Down, J. Allen, and Earley secured the majority of secondary prizes in this section. Mr. Roberts, gardener to Mrs. Hollamby, Highfield House, showed Anemone varieties exceedingly well, the blooms large but neat and fresh. Mr. Allan also had some good examples of these varieties, and obtained several leading prizes. In the classes open to exhibitors in Mid-Kent and East Sussex Messrs. G. Ware, gardener to Mrs. Morgan, 2, Hungershall Park, F. Earley, and J. Roberts were the most successful competitors.

Miscellaneous plants were not shown in very large numbers, but several exhibits were of great merit, particularly the Gesnerias from Mr. Buehanan, gardener to Dr. Siemens, Sherwood, which were deservedly placed first in the class reserved for these plants. The specimens were of the zebrina type in 8-inch pots, and each had twelve or fourteen large panicles of flowers. The decorative value of such specimens cannot be too highly estimated. Dwarf handsome Pomsettias were contributed by Messrs. Charlton, Earley, and Allan, the heads and bracts being very large and richly coloured. Table plants were also shown in strong force, Messrs. Wilkins, Goldsmith, and Farmer staging the winning collections—neat, graceful, little plants. Primulas and Epiphyllums were well shown by Messrs. Allan, Earley, Read, Farmer, and Holland.

Fruit.—This invariably forms one of the features at Tunbridge Wells; and though we have seen a larger display at previous shows, yet, considering the season, the quality was most satisfactory of the

leading exhibits. For a collection of twelve dishes of fruit Mr. Henderson secured chief honours with well-coloured fine bunches of Black Alicante Grapes, fairly coloured Golden Queen Grapes, by far the best example of this variety in the Show, several other bunches being of the peculiarly dirty colour too often distinguishing it. A handsome Queen Pine and fine fruits of Doyenné du Comice and the brightly coloured Forcille Pears were also noteworthy. Mr. J. Allan, gardener to J. Hanbury Field, Esq., Ashurst Park, was a good second, his best dishes comprising Black Alicante Grapes, Beurré Clairgeau Pears, and King Pippin Apples. Mr. G. Goldsmith, gardener to P. Hardwicke, Esq., Hollenden, Hildenborough, who was third, had large examples of Beurré Diel and Delices de Hardenpoint Pears amongst others. Mr. A. Bashford, gardener to Mrs. Stoddart Douglas, Chilston House, was first in the class for black Grapes with three handsome bunches of Black Alicante, Messrs. Henderson and Wilkins following with the same variety. In the white Grape class Mr. W. Johnston, gardener to the Marchioness of Camden, Bayham, took the lead with Muscat of Alexandria, the berries large and well coloured; Mr. L. Pope, gardener to J. J. Barrow, Esq., Holmwood, being second with large bunches of Trebbiano fairly coloured, and Mr. Wilkins third with Golden Queen.

For six dishes of dessert Pears Mr. Goldsmith won chief honours with large specimens of Beurré Hardy, Glou Morceau, Beurré Diel, Soldat Labourcur, Prince of Wales, and Doyenné du Comice. Mr. Johnston had the best three dishes, comprising Beurré Bachelier, Doyenné du Comice, and Beurré d'Anjou of good appearance. Mr. Goldsmith staged the leading collection of six dishes of culinary Pears; Catillae, Uvedale's St. Germain, and Bellissime d'Hiver being of considerable size. With six dishes of dessert Apples Mr. Goldsmith was again the most successful exhibitor with fine fruits of Golden Pippin, Court Pendu Plat, Cox's Orange Pippin, Colonel Vaughan, Ribston Pippin, and King Pippin. In the classes for three dishes and one dish of dessert Apples, and six and three dishes respectively of culinary Apples, Mr. Goldsmith also gained first honours with good specimens.

Prominent amongst the not-for-competition contributions were the following:—Large collections of fruit from Mr. Bridger, and Mr. J. Rust, Eridge Castle; vegetables from Mr. J. Nutting, gardener to Col. Ramsden, Ashurst; and remarkably well-grown plants of *Bouvardia rosea oculata*, with B. Alfred Neuner, from Mr. John Charlton, Summerwell Nursery. All the arrangements were satisfactory, and much credit is due to Mr. E. Charlton, the Hon. Sec., for his energetic management of the Society's affairs.

ROYAL AQUARIUM, WESTMINSTER.—NOVEMBER 15TH AND 16TH.

The thirty-sixth annual Exhibition of the Borough of Haekney Chrysanthemum Society, held at the above popular resort, proved one of the best in their long list of successful shows both in number of exhibits and general excellence. The cut blooms particularly were magnificent in the leading classes, and though the plants were not quite so satisfactory as might have been desirable, yet ample compensation was made for this defect in the fruit and vegetable classes, which were exceedingly well filled.

Cut Blooms.—The chief interest in regard to these centred in the class for forty-eight blooms, twenty-four incurved, not less than eighteen varieties, and the same number of Japanese, the prizes offered by the Society being first £10, second £2, third £1. Six magnificent collections were staged in this class, Mr. C. Gibson, gardener to J. Wormald, Esq., Morden Park, securing chief honours with superb blooms of great size and yet not coarse. The incurved blooms were grand in form and substance, including Empress of India, Golden Empress of India, Golden Eagle, Refulgence, John Salter, Mrs. Heale, Mrs. Dixon, Queen of England, Nil Desperandum, Lady Carey, Hero of Stoke Newington, Mrs. G. Rundle, Alfred Salter, Lady Slade, Mr. G. Glenny, and Cherub. The Japanese were of wonderful size, rich and clean, the following being well represented:—Ethel, Baronne de Prailly, Elaine, M. Ardene, Album plenum, Peter the Great, Comtesse de Beauregarde, Criterion, M. Delaux, Hiver Fleur, Nagasaki Violet, Fair Maid of Guernsey, Mad. Moulise, Arlequin, Garnet, Fanny Bouchardat, and Album striatum. A pair of Criterion were greatly admired, and finer examples have not been shown this year. The second place was accorded to C. Herrin, Esq., Calfont Park, Gerrard's Cross, Slough, whose collection was very slightly inferior to the first, the Japanese being especially handsome, comprising enormous examples of The Daimio, with fine blooms of Grandiflorum, Père Delaux, Criterion, Album plenum, and Mad. C. Audiguier. Mr. F. Mease, gardener to C. F. Newman, Esq., Wyncote, Liverpool, was third with fair blooms.

There was very good competition in the open class for twenty-four Japanese blooms, Mr. C. Herrin being adjudged the leading position amongst eight competitors, all of whom exhibited fine blooms. The first-prize stand contained beautiful specimens of The Daimio, Album plenum, Magnum Bonum, Mons. Ardene, Fair Maid of Guernsey, Père Delaux, Madame C. Audiguier, Peter the Great, Baronne de Prailly, and The Sultan. Mr. Gibson followed, but the competition between these was extremely keen, as the Morden Park blooms were uncommonly good. Messrs. J. Garaway & Co., Durdham Downs Nursery, Bristol, were third, and Mr. Monk fourth. The principal open class for incurved blooms was that for twenty-four, eight collections being staged. Mr. G. Langdon, gardener to Drs. Munroe & Adams, Brook House, Upper Clapton, taking the first place with handsome blooms;

Mr. Berry, gardener to the Countess of Leven and Melville, Roehampton, and Mr. J. R. Wildman, 46, Peckham Grove, Peckham, being second and third respectively. For eighteen blooms Messrs. Berry; F. W. Griffin, Gothic Cottage, Sydenham; W. Jupp, Eastbourne, Sussex; and J. Major, Eyn Park, Barnet, were the prizetakers in that order. There was an extraordinary competition in the class for twelve blooms, not less than seventeen stands being entered, and a large proportion of these were so nearly equal in merit that the Judges had considerable difficulty in awarding the prizes. Mr. J. Ridout, gardener to R. B. Haywood, Esq., Woodhatch Lodge, Reigate, was ultimately placed first, being followed closely by Messrs. Herrin, Berry, and Hillier. Anemone-flowered varieties were well shown by Messrs. Gibson, Berry, Butcher, and Huntley, who gained the chief prizes. The special prize of a silver-plated tea and coffee service, offered by Mr. N. Davis, 66, Warner Road, Camberwell, for eighteen varieties of Pompons, three blooms of each, brought five competitors, Mr. Butcher being the successful one with a pleasing collection, the blooms of good size, form, and colour. They comprised Madame Marthe, St. Michael, Salomon, President, Lilac and White Cedo Nulli, Andromeda, Rosetta, Prince Alfred, Sœur Melanie, Adonis, Souvenir de Jersey, Adèle Priset, Fanny, Golden Madame Marthe, Marabout, Lavary, and Model of Perfection. In the numerous other classes the exhibits were also good.

Amongst the specimen plants the two groups from Messrs. Mahood and Stevens of Putney, who occupied similar positions to those they obtained at the Putney Show on the previous day, were the chief features, the blooms on most of the plants being quite up to an exhibition standard, and would not have disgraced many of the competing collections in the bloom classes. They were also well arranged, banks of Palms at the back serving to relieve the abundant colour.

Fruit.—Grapes were well represented in several classes, the best Black Alicantes being shown by Mr. R. Holmes, gardener to T. Wallis, Esq., Sister House, Clapham Common—neat bunches well coloured. Mr. S. Lyon, The Gardens, Sundridge Park, Bromley, Kent, took the lead with Gros Colman, three fine bunches, the berries large and admirably coloured, a quality in which the other exhibitors in the same class were rather deficient. Mr. E. Smith, gardener to F. H. Sewell, Esq., Warren Hill, Loughton, secured the chief position with Muscat of Alexandria, fairly good bunches, fine berries, and well ripened; while in the any other variety class Mr. G. Summers, gardener to the Earl of Scarborough, Sandbeck Park, won the first prize with very large finely coloured bunches of Gros Guillaume. Dessert and culinary Apples were represented in large numbers; Mr. Austen, The Gardens, Ashton Court, Bristol, taking the lead in the former, and Mr. W. Fowle, gardener to Sir H. Mildmay, Bart., Dogmersfield, Herts, securing a similar position in the latter. Mr. C. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury, had the best collection of dessert Pears—viz., fine examples of Beurré Diel, Napoleon, Josephine de Malines, Doyenné du Comice, Glou Morceau, and Duchesse d'Angoulême. Mr. A. Waterman, gardener to W. A. Brassey, Esq., M.P., Preston Hall, Aylesford, was adjudged the first prize for a collection of fruit. The numerous prizes offered by Messrs. Sutton & Sons, Reading; Carter & Co., Holborn; and Webb & Sons, Stourbridge; and Hooper & Co., Covent Garden, for vegetables, were well competed for, the quality of the exhibits being generally most satisfactory.

Miscellaneous exhibits were not very numerous, but the beautiful collections of Salvias, Primulas, Pelargoniums, and other plants from Messrs. H. Cannell & Sons, Swanley, Kent, were an important feature in the Show, and attracted much admiration.

TOOTING.—NOVEMBER 14TH AND 15TH.

This newly constituted Society held their first Exhibition last week at the Vestry Hall, Tooting, and proved a great success. The schedule comprised sixty-seven classes, the majority of which were well filled, and in many instances the competition was very keen; particularly was this so in the cut bloom classes, table decorations, and Primulas. The prizes for groups were only fairly competed for, the first prize going to Mr. G. Collings, gardener to J. Anderson Rose, Esq., for good plants tastefully arranged; Mr. T. Bunley, gardener to W. P. Galton, Esq., Park House, Upper Tooting, was placed second. This collection contained really the best flowers, but not so well arranged. Mr. Luff, gardener to J. Hyatt, Esq., Streatham, was third. In the classes for trained plants the principal prizes were secured by Mr. Salter, gardener to J. Southgate, Esq., Selborne, Streatham, and Mr. Bunley. In the open class for forty-eight cut blooms, twenty-four Japanese and twenty-four incurved, there were three good collections staged, the premier award being gained by Mr. A. Holmes, gardener to A. B. Heale, Esq., Hawthorns, Clapham, for remarkably even blooms of good substance, fresh and bright. Mr. Glide, gardener to J. Wilson, Esq., The Laurels, Tooting, was a very good second, and Mr. J. Holmes, gardener to G. M. Story, Esq., Nightingale Lane, third, all showing well. Mr. A. Holmes was also first in the class for twelve incurved blooms, his Empress of India, White Globe, Mrs. Heale, and Golden Empress of India being particularly fine. Mr. C. Salter gained second honours, and Mr. J. Eade, gardener to J. G. Bonner, Esq., Bridge House, Tooting, third; there were six competitors in this class. The prizes for six cut blooms went to Mr. J. Holmes; Mr. Ball, gardener to H. Doulton, Esq., The Woodlands, Tooting; Mr. J. Cushon, gardener to A. Grote, Esq., The Elms, Upper Tooting; and Mr. E. Bingham, gardener to Miss Goldsmith, Lynewood, Tooting, in the order of their names.

For twelve blooms, Japanese, distinct, Mr. Alderman, gardener to C. Carnizow, Esq., Mitcham, was a capital first, staging good blooms of the best varieties. Mr. Clarked, gardener to J. Rams, Esq., Nightingale Lane, and Mr. J. Eade, were placed second and third respectively. For six blooms, Japanese, distinct, Messrs. Cooke, Eade, and Alderman shared the honours. Large-flowering Anemones and Anemone Pompons all added to the attractions of this really good display.

Classes were appropriated to stove and greenhouse flowering plants, also for fine-foliage. Messrs. Nunn, Bunley, Austin, and Luff were the prizetakers. The competition was very close in classes for Primulas; several excellent collections were staged. Bonvardias and Zonal Pelargoniums were also well represented.

Both fruit and vegetables were shown in good condition, especially the Grapes, the Muscat of Alexandrias from Mr. Alderman and Mr. Eade being well finished. Several classes with suitable prizes were open to ladies, and well contested for; the first prize, for a centrepiece for table decoration, was awarded to Mrs. Kesterton, Dudley House, Nightingale Lane. The whole of the arrangements were well carried out by Mr. W. Hugh Gower, the Secretary, and the executive, who are to be congratulated on the success attained by their first attempt, and we hear that a summer exhibition is contemplated, which no doubt will be equally as successful under such able management.

WALTON-ON-THAMES.—NOVEMBER 14TH AND 15TH.

An Exhibition of considerable merit though of moderate extent is invariably provided by this energetic Society, and that held last week was no exception to the rule. Indeed there was a noteworthy improvement in some classes, and the general condition of the plants and blooms was all that could be desired.

Plants.—Several very creditable collections of these were staged, particularly fine being the six specimens of large-flowering varieties, with which Mr. Burns, gardener to H. A. Rigg, Esq., Hersham, won the special prize, a four-guinea silver watch, the best being Venus, Mrs. G. Rundle, and George Glenny. Messrs. Cornhill, gardener to E. Pettit, Esq., and Millican, gardener to Mrs. Cobbett, securing the other prizes in that class. Mr. Millican took the lead in the class for six standards in 12-inch pots with healthy well-flowered specimens, Prince Alfred and Prince of Wales being especially fine. He was followed by Mr. Reynolds, gardener to Mrs. Allen; and Mr. Reid, gardener to C. A. Ledward, Esq., both the latter being from Weybridge. Messrs. Burns, Millican, Cornhill, Reynolds, and Boxall carried off the prizes in other smaller classes, Mr. Millican's single specimen of Mrs. Rundle being noteworthy. Pompons were admirably represented in the chief collections from Messrs. Cornhill, Reynolds, Millican, and Reid. The standards which gained Mr. Millican the principal award in that class were very creditable, Marie Stuart, Marguerite de Coix, Mdlle. Marthe, and President being the varieties, healthy, neatly trained, and very freely flowered.

Blooms.—Numerous handsome collections of blooms were staged, a most satisfactory freshness being observable; the majority, too were characterised by their substance and evenness, the rough blooms being the exception rather than the rule, as is often the case at local shows. The principal open class was that for twenty-four incurved blooms, Mr. Strong, gardener to H. Sweet, Esq., Weybridge, gaining chief honours with examples of the finest exhibition varieties in the usual good condition that distinguishes his exhibits. Mr. Hill, gardener to H. Savory, Esq., Chertsey, and Mr. Burns followed in that order, both showing neat blooms. In the district class for the same number of blooms Messrs. Burns, Reynolds, and Cornhill won the honours, while Mr. Strong followed up his previous success by again taking the first position with twelve incurved blooms. Next in merit were the Japanese, Mr. Burns staging a beautiful collection of twenty-four, comprising handsome blooms of all the most popular varieties. He was closely followed by Messrs. Cornhill and Reynolds. Mr. Strong scored his third success by winning chief honours for twelve Japanese, Messrs. Millican, Boxall, and Plowman securing the second and third prizes, the last two named being equal. Anemones, reflexed, and Pompons were also represented, several of the above-named exhibitors carrying off the prizes. Bouquets, stands of flowers, &c., were shown by amateurs and cottagers, some displaying much taste in the arrangement.

DARTFORD.—NOVEMBER 15TH AND 16TH.

For the twelfth season this Society held their autumn Exhibition in the Victoria Assembly Rooms, Dartford, on the above dates. A considerable falling-off in the large plant classes diverted the Exhibition of its chief attraction. The cut bloom classes, on the other hand, were better filled than in former years, several new growers having come to the front, so that in these there was a really good display. The chief interest centred in the class for twenty-four incurved blooms, distinct, for which a silver cup value six guineas was offered, with second, third, and fourth prizes of 30s., 20s., and 10s., respectively. Mr. Martin, gardener to C. N. Kidd, Esq., Dartford, easily won the premier award with remarkably even blooms, comprising the following varieties:—Prince of Wales, John Salter, White Globe, Prince Alfred, Mr. Bunn, Sir Stafford Carey, Mrs. Heale, Lady Slade, Jardin des Plantes, Princess of Wales, Empress of India, St. Patrick, Golden Empress of India, Refulgence, Princess Teck, Hero of Stoke Newington, Mrs. Dixon, Baronne Beust, White Venus, Lady Hardinge, Eve, Barbara, Mrs. Shipman, and Lady Talfourd. Mr.

Dancer was placed second in the classes for twelve and six blooms. Mr. Martin was again to the front, securing the first prizes in both cases. For twenty-four Japanese varieties Mr. Dancer was a very good first, having amongst others good blooms of Dr. Macary, Madame C. Audiguier, Cry Kang, Père Delaux, Jane Salter, and M. Delaux. Mr. Dancer was also first for twelve varieties, and Mr. Martin for twelve blooms six varieties. Several amateurs' and cottagers' productions were staged both in flowers, fruit, and vegetables, and the arrangements were admirably carried out by Mr. W. Shelton (Secretary), Mr. Evitt (Chairman), and Mr. C. White (Treasurer).

PLYMOUTH.—NOVEMBER 14TH AND 15TH.

This old-established Society appears to be regaining its old prestige, judging from the keen competition in nearly all the cut-bloom classes of the Exhibition held in the Guildhall, Plymouth, last week. Mr. Tallack, gardener to C. G. Prideaux Brune, Esq., secured the special prize offered by J. H. Pulleston, Esq., M.P., for twenty-four blooms, distinct—viz., six Japanese, six incurved, six Anemones, and six Pompons, with magnificent blooms of Empress of India, Golden Empress, Prince Alfred, Fair Maid of Guernsey, Soliel Levant, Dr. Masters, Red Gauntlet, &c. Mr. Moorman of Kingston was awarded the second prize with a good collection.

For twenty-four blooms, large-flowering, the Earl of Devon and Mr. C. Norrington were first and second respectively; and for six blooms of Mrs. G. Rundle, Mr. J. B. Williams and the Earl of Devon secured the prizes in that order. Other successful exhibitors were the Rev. J. Parly, Mr. G. H. Rundle, Mr. W. Pengelly, Mr. Short, Mr. Masters, and Mr. Mallet. Numerous classes for miscellaneous subjects were well filled. Altogether it was a magnificent Show and well patronised.

CANTERBURY.—NOVEMBER 15TH AND 16TH.

A correspondent sends a report of the fifth annual Show of the Canterbury Gardeners' Mutual Improvement Society, which was held in the Foresters' Hall last week. Owing, however, to the great demands upon our space this week we can only give the names of the chief competitors. The exhibits were numerous and generally of good quality, but the weather proved unfavourable, thus affecting the receipts considerably. The principal prizes were won by the following:—Messrs. E. Martin, Elvey, Woodcock, Fairweather, E. Dines, A. Sargeant, Noble, Kennett, Hyde, Hardimans, Ewell, Hawkins, and Brooks.

BRISTOL.—NOVEMBER 16TH AND 17TH.

There are few older kindred societies than the above, and probably none possesses more apparent vitality. Much of this is due to the efforts of the energetic and courteous Hon. Sec., Mr. G. Webley, and his working Committee, who materially contribute to the success of the many meetings, and they are to be congratulated upon the fact of the nineteenth Exhibition being superior to any that have preceded it.

Specimen Chrysanthemum plants were shown in much greater numbers than usual, and in some instances meritorious collections were unplaced. This was notably the case in the class for six large-flowered varieties, in which there were six competitors. Here Mr. Bradner, as on several previous occasions, proved invincible, his specimens of White Globe, Mrs. Dixon, Prince of Wales, Alma, Barbara, and Mr. Corbay being from 3 to 4 feet through, and remarkably well flowered throughout. Mr. E. T. Hill, gardener to T. Pease, Esq., was a good second; the third prize going to Mr. W. Lintern, gardener to W. Butler, Esq. Mr. Bradner was also successful with three specimens large-flowered, six and four Pompons; Mr. Lintern, Mr. E. S. Cole, gardener to W. Pethick, Esq., and Mr. E. T. Hill, gardener to J. Pease, Esq., securing the remaining awards with good specimens. The best pyramid large-flowered variety, a creditable example of Venus, was staged by Mr. H. Smith, gardener to A. Shipley, Esq.; Mr. Hill following with Mrs. Rundle in good condition. Flat-trained specimens were well shown by Messrs. Bradner, Hill, and Smith, the varieties in this class consisting principally of the Rundle family; and the same varieties figured largely as standards in competition for special prizes offered by W. E. George, Esq., where Mr. Bradner again took the lead, being closely followed by Mr. Rye, gardener to J. Derham, Esq.

The schedule comprehended classes for a great variety of plants in pots, all of which were well filled, but our limited space forbids as full a report as we should wish to give of them. Fine-foliage plants were remarkably healthy and good, notably the specimens of *Cycas revoluta*, *Croton Weismannii*, *Dieffenbachia Bowmannii*, and *Latania borbonica* staged by Mr. Rye, and somewhat similar varieties were shown by Mr. T. Bush. Mr. J. Stevens also staged creditably in these classes. Mr. Bannister had the finest Ferns, among which were seedling *Gymnogrammas*, *Adiantum trapeziforme*, and *A. farleyense*. Mr. Rye was a good second. Table plants were shown in good numbers, and comprised many elegant Palms, *Crotons*, *Dracenas*, and *Pandanus*. Mr. W. K. Wait, Mr. Budgett, and Mr. G. F. Prideaux secured the awards in the order named. Berried plants were also creditably shown, and included *Capsicums* Little Pet and Princess of Wales, *Solanums*, and *Aucubas*. Messrs. Prideaux, W. Lintern, and S. Budgett were the successful exhibitors. *Poinsettias* were shown extensively and well, but gave evidence of being grown in a very high temperature. Mr. W. Cooper secured the first prize, and Mr. Lintern

the second. Primulas were also particularly good, and here the prize-winners were Messrs. Lintern, Bodham Castle, and C. Taggett. *Bouvardias* were well shown by Messrs. W. Rye and S. Budgett, and Zonal Pelargoniums by Mr. C. Taggett. Two groups were staged on a space 10 feet by 4 feet, Mr. Rye securing the premier award for a bright and informal arrangement, in which well-flowered *Calanthes*, *Cypripediums*, the beautiful and highly scented *Oncidium varicosum*, *Bouvardias*, *Gesnerias*, *Begonias*, and *Epiphyllums* were freely included.

Cut blooms of *Chrysanthemums* were both extensively and well shown. The stand of twenty-four blooms of large-flowered varieties which gained Mr. T. Hobbs the premier award, and which carried with it the Banksian silver medal of the Royal Horticultural Society, was remarkably good, every bloom being in excellent condition. The varieties were Golden Empress, Prince of Wales, Empress of India, Prince Alfred, Hero of Stoke Newington, Lady St. Clair, Venus, Mrs. Cunningham, Princess of Teck, Mrs. G. Glenny, and General Bainbridge. Messrs. Garaway & Co., Durdham Downs Nursery, Clifton, took second honours with a stand weak only in one or two cases, while Mr. J. Baylis was a most creditable third. For twelve blooms Mr. E. S. Cole was placed first, his most noteworthy varieties being Empress of India and Golden Empress of India. Mr. J. Waite and Mr. W. Fox, gardener to Mrs. Hurle, were worthily awarded the remaining prizes. Mr. T. Hobbs staged the best six, these including fine blooms of Mrs. Heale and Beverley; Messrs. Baylis and E. S. Cole also staging good blooms. The best twelve Anemone-flowered were staged by the Messrs. Garaway, and comprised excellent examples of Empress, Lady Margaret, Madame Clos, George Sands, Acquisition, Prince of Anemones, and Gluck. Mr. J. Baylis and Mr. Hobbs took the remaining prizes. Messrs. Garaway also secured the premier award for twelve blooms of Japanese varieties, and probably a better stand was never seen. The sorts were Fair Maid of Guernsey, Sarnia, Madame Berthier Rendatler, Mons. Ardenne, Baronne de Prailly, Criterion, Thunberg, Apollo, Agrément de la Nature, Bouquet Fait, and Mons. Delaux. Vases of cut flowers were well shown by Messrs. E. S. Cole, T. Meakin, and J. H. Virgo. Vases of outdoor autumn foliage and berries—and very beautiful all of them, placed and unplaced, were—by Messrs. J. H. Virgo and E. S. Cole. Bouquets for the hands by Mrs. M. Cole and Mrs. F. E. Stevens, and in another class by Messrs. E. C. Cole and R. H. Symes, the prizes being awarded in the order named in each instance.

Hardy fruits were not shown in such large quantities as usual, but the Grapes were in marked advance both as regards quality and quantity. The premier prize collection of six varieties was staged by Mr. Nash, gardener to the Duke of Beaufort, and consisted of high-class examples of Black Alicante and Muscat of Alexandria Grapes, East-nor Castle Melon, very fine Pitmaston Duchess Pears, Ribston Pippin Apples, and Medlars. Mr. Bannister, gardener to H. St. Vincent Ames, Esq., was a very creditable second, the third prize being worthily awarded to Mr. W. Sweeting. Mr. G. Gibson, gardener to Mrs. G. Miller, staged the best Black Hamburgh Grapes, the second prize going to Mr. W. Cope. There were several excellent stands of Muscat of Alexandria, but Mr. Nash's very fine examples easily secured the premier award, the second prize worthily going to Mr. Gibson, and the third to Mr. E. Trotman, gardener to H. A. Mills, Esq., and an extra prize was awarded to Mr. Rye. In the class for any black variety Mr. Chaffin, Bath, a distinguished amateur, had the pleasure of defeating several well-known professional growers, his examples of Meredith's Alicante being perfect in every respect. Mr. Nash and Mr. W. K. Wait took the remaining prizes also with Black Alicante. Mr. Nash again took the lead with four bunches in not less than two varieties with somewhat faulty Muscat of Alexandria and very fine Black Alicante; Mr. Chaffin followed with highly coloured fair-sized bunches of Meredith's Alicante and Gros Colman, while Mr. Gibson took third place with Mrs. Pince's Muscat and Muscat of Alexandria; this stand, in our estimation, being the best of the three. Seven other lots were shown, many of which were of more than average merit. Mr. W. Rye took the lead with six varieties of Pears, these consisting of clear fair-sized fruits of Chautemontel, Beurré Diel, Conseiller de la Cour, Duchesse d'Angoulême, Doyenné du Comice, and Beurré d'Anjou. Mr. A. T. Hall took the second prize, and Mr. Bannister the third. Mr. Rye was also first with four varieties, being followed by Messrs. Bannister and W. Lintern. The best six varieties of dessert Apples were shown by Mr. Bannister, these consisting of Claygate Pearmain, Kentish Pippin, Scarlet Pearmain, King of Pippins, Worcester Pearmain, and Blenheim Pippin. Mr. A. T. Hall and Mr. W. Hunt took the remaining prizes. Mr. Avery secured the first prize for a single dish with Ribston Pippin, Mr. Hill following with Blenheim Orange. Culinary Apples were very fine, notably the premier prize six varieties, staged by Mr. E. T. Hill, these consisting of Maid of Wilts, Kentish Pippin, Nelson's Glory, Reinette du Canada, English Codlin, and Tankard. Mr. Goddard, gardener to R. Symes, Esq., was a close second, and Mr. J. Milliner a good third. In a good class Mr. T. Bush took the lead for any culinary variety with very fine examples of Bush Seedling, Mr. H. Hockey following with Nelson's Glory.

Special prizes were offered by the Hon. Secretary for a collection of vegetables, and to the first prize was added the Banksian bronze medal of the Royal Horticultural Society. Several creditable collections were staged, but the Judges experienced no difficulty in awarding the first prize to Mr. Bannister. His collection comprised excel-

lent examples of Imported Sprouts, Major Clarke's Celery, Veitch's Autumn Broccoli, Banbury Onions, Lapstone Kidney Potatoes, Orange-field Tomatoes, London Flag Leeks, Veitch's Red Globe Turnips, and Dell's Crimson Beet. To Mr. Budgett was awarded the second prize, and Mr. Pease the third.

Many of the foregoing prizes were specially offered by the leading inhabitants and nurserymen of the district, and it must be very encouraging to these liberal patrons to find they were so well competed for.

MANCHESTER.—NOVEMBER 21ST.

Manchester is noted for the magnitude and excellence of horticultural exhibitions. The spring shows held under the auspices of the Royal Botanical Society of the North are invariably successful, while the summer exhibitions have won world-wide fame. Less provision is made for the autumn shows; but there is no difficulty in filling the grand room of the Town Hall effectively, and packing it to repletion with visitors.

The schedule only contained eight classes for Chrysanthemums—five for plants and three for cut blooms. The naturally grown and trained specimens of the incurved varieties were the feature of the Show. Finer cultivation was perhaps seldom seen than in the class for nine plants. The stems were dwarf and strong, ranging from 2 to 3½ feet high; foliage large, leathery, of a dark bronzy hue indicative of rude health, and reaching to the soil and the blooms—five or six on each plant of exhibition quality. The first prize in this excellent class was won by Mr. Thos. Cash, gardener to C. S. Agnew, Esq., Prestwick, his plants containing better blooms than any in the stands. Mr. Fletcher, gardener to W. Scott, Esq., Higher Broughton, and Mr. Taylor, gardener to E. G. Potter, Esq., Rusholme, followed somewhat closely, and secured the remaining prizes in this excellent class. In the class for four plants of the same character J. E. Best, Esq., Withington, and O. Schneider, Esq., Fallowfield, followed Mr. Agnew's, all the plants being good. None of the stems were bent, and dwarfness of many of the plants in the above classes was remarkable—most creditable to the cultivators. Pompons were very far from being of equal merit, the plants being thin, too many sticks visible, and the tying had been done too late. George Cooper, Esq., Timperley Hall; T. Dickens, Esq., Higher Broughton; and J. Slatter, Esq., Stand, were awarded the prizes in the order named. John Allen, Esq., Altrincham, secured the chief prize for six Japanese plants, similar in character to the incurved varieties—dwarf and with large blooms. The others in the class were too tall.

For twenty-four cut blooms Messrs. Allen, Cooper, and Kenworthy were the successful exhibitors, the blooms being large enough, but too flat, yet broad in the petal and fresh. Mr. Allen was first also with twelve blooms, and Mr. Moorman of Coombe Bank, Kingston-on-Thames, second—neater, fuller, better-formed examples, but not large enough for the first position. For stands of twenty-four mixed blooms Messrs. Allen and Cooper were equal firsts, and Mr. Moorman second. A great number of blooms were exhibited in the above classes, but the majority were too flat and thin, the size of not a few being also further apparently diminished by the disproportionate paper collars; in fact several stands were spoiled by the display of paper.

Mr. Allen staged very good Primulas, 2 feet in diameter, but most of the other plants appeared to have been much shaken in transit. Roman Hyacinths from Messrs. Potter, Dickens, and Jones & Son, Shrewsbury, were excellent. Bouquets were good, Messrs. Jones and Son being in the position with which they are so familiar—first, securing also the chief prize for a vase of flowers. Table plants were very good indeed, the prizes falling to Messrs. Schneider, Potter, and R. A. Farrington, Esq., Wigan. The plants arranged down the central table contributed greatly to the effect of the Exhibition.

Messrs. Dickson, Brown, & Tait staged an effective group of plants, in which Calanthes were splendid, and were granted a first-class cultural commendation. Similar awards were made to Mr. Leech for floriferous plants of his new *Dendrobium Leechianum* of the *L. Ainsworthi* type, and very beautiful; also for *Davallia fijiensis plumosa* with fronds 18 inches across. Several other groups were arranged, including a brilliant lot of cut Zonal Pelargoniums and *Salvia* from Messrs. Cannell of Swanley; fine Chrysanthemum blooms from Messrs. Dickson & Robinson; plants and flowers from Messrs. Clibran & Son, with a good group also from Messrs. Hookey of Stockport. Mr. Pettigrew had supers of excellent honey; and Mr. B. S. Williams changed his mode of showing by staging Onions weighing 4 lbs. each. This is necessarily a mere skeleton account of a really attractive and successful show, excellently managed by Mr. Bruce Findlay.

SINGLE DAHLIAS AND THE FIRST FROST.—Within the past month the temperature has frequently been very close to the freezing point (32° Fahr.) in this locality, but until the 11th of November, with 5° of frost, my single Dahlias constantly afforded blooms for cutting purposes since last July, a month after I had obtained some of them from Messrs. Cannell, Swanley, and some other varieties from Messrs. Kelway, Langport—that is, four months. Now if I were to select the most floriferous, combined with the most beautiful, of the twenty varieties I had, I would decidedly put Paragon first, and Avalanche or White Queen next. I have seen Mr. Ware's five acres and numbers elsewhere, and have raised a few good crimsons and magenta seed-

lings myself; but what is wanted is that the numberless seedlings should undergo a careful selection so as to get the really good neat flowers.—W. J. M., *Clonmel*.

HARDY FRUIT GARDEN.

WHEREVER fruit trees make a quantity of wood and do not form fruit buds, the wood not ripening satisfactorily, an examination of the roots will be advisable, and should be attended to whilst the weather is favourable, as the soil will not yet be so cold as at a more advanced period of the season. Careful root-pruning and the raising of the roots when too deep will generally render over-luxuriant trees fruitful. Weakly trees may frequently be restored to health by having their roots brought nearer the surface, and encouraged by an application of turfy loam enriched with about a fifth of well-decayed manure, in which the recently disturbed roots should be arranged. If the soil be of a tenacious or heavy nature a portion of the road scrapings, lime rubbish, or other gritty material may be added with advantage.

Bush, pyramid, espalier, and other forms of fruit trees in a limited space should, when growing too freely, be attended to in root-pruning, which, whilst lessening the necessity for summer-pruning, conduces to the fertility of the trees. Such as do not require attention in the respect above indicated should have the loose surface soil scraped off some distance from the stem all around according to the size of the trees, supplying some fresh rich material, to which has been added about a tenth of charred refuse.

Planting young fruit trees should be proceeded with as opportunity offers, it not being advisable to plant when the soil is very wet; and although most hardy fruits can be produced with success on most soils, yet the better the soil and climate the finer will be the fruit. But however good the soil, it will generally be necessary that it should undergo some preparation before the trees are planted. Draining in most cases will be necessary, and in heavy wet soil is absolutely essential. In the latter case a portion of light soil, road scrapings, old mortar rubbish, and charred refuse may be employed with great benefit, and the trees in such soil may be advantageously planted upon small hillocks slightly raised above the level of the surrounding ground. With soil of a light porous character upon a gravelly or limestone subsoil an opposite practice will need to be pursued; well-pulverised clay or strong loam should be incorporated with the original soil.

In the selecting of fruit trees, especially of Apples and Pears, it is of the greatest importance to plant those which are known to succeed well in the locality, as many varieties are excellent in all respects in one locality, whilst in another they are found to be very unsatisfactory.

A severe winter not unfrequently proves injurious to unprotected Fig trees against walls. The trees should be either unfastened from the walls, the branches tied closely in bundles, which should be encased in clean dry straw or fern kept together by mats, or the trees may be allowed to remain on the wall, the surface of which should be lightly thatched with dry bracken, straw, mats, or similar material, and the border from the stem outwards should be well mulched with partially decayed manure. Mulch also between the rows of Strawberries, employing partially decayed manure, which will be sufficiently further decomposed to allow of being pointed-in in spring. Any tender varieties, such as British Queen, may be mulched with littery manure.

FRUIT HOUSES.

Cherry House.—Pruning full-grown Cherry trees, which have had proper attention in regard to stopping the shoots during growth, will now be confined to cutting back the shoots of the current year to about an inch from the base or starting point, and the removal of decayed spurs. Young trees in course of formation will need the

central shoot or shoots cut back as necessary to originate growths for regularly filling up the allotted space. The fan mode of training is the best where the trees have a good run of trellis or wall, as by this method means are afforded of filling up vacancies occasioned by gumming, to which Cherry trees under any conditions are peculiarly liable. Except for the purpose indicated above, or where the limits of the trellis necessitates its being done, it is not advisable to shorten the terminal shoots. This should be attended to at once, and a complete cleansing of the house effected. The trees also should be washed with soap and water (8 ozs. softsoap to a gallon of water) and afterwards with an insecticide. The light must also be replaced, but the house fully ventilated until the time arrives for starting the trees.

Figs.—Pruning Fig trees requires some experience and no little judgment, local circumstances entirely governing the mode of cultivation, and consequently that of pruning. In the case of trees grown in pots or having the roots restricted to small borders, and consequently not growing vigorously, very little pruning will be necessary, provided during the season of growth proper attention has been given to stopping and thinning out the shoots. Trees, however, that have not the roots so restricted and have a good run of trellis, the object being to secure a series of young growths over the whole surface of the trellis, from which the crop of Figs is to be chiefly obtained, the pruning requires to be severe at the top part of the trees. The shoots which have attained the limit of the trellis should be shortened back to where the succeeding shoots start, in order that the latter may occupy the place of the former in the ensuing season. Elongated spurs should be removed, reserving the short-jointed and fruitful, but be careful not to overcrowd. After pruning loosen the trees from the trellis and thoroughly cleanse the house, washing or painting the woodwork and trellis, limewashing the walls. The trees should be dressed with an insecticide after washing them with tepid soap and water. Train and tie the trees regularly, allowing plenty of space in the ties. Point over the surface of the borders without injuring the roots, remove the loose material, and apply a top-dressing of partially decayed manure 3 or 4 inches thick. The house should be fully ventilated, except during frost.

GREENHOUSE.

Liliums.—If these are not yet potted no time should be lost in completing the work before they begin rooting; *L. longiflorum* roots early, and cannot endure having the soil too dry. This is one of the most useful of Lilies for early flowering, as it bears gentle forcing, and, being grown in small pots, is fine for decoration. *Lilium auratum* is also an early flowerer and roots early. The early-flowered plants will now be pushing fresh fibres, and if this is the case they should not on any account be disturbed; indeed, unless the soil be not occupied with roots, having become a close mass, it is not necessary, or even advisable, to repot Liliums annually, but if the pots are too small the plants should be transferred to larger pots with the ball entire, or the sides merely loosened and the crocks removed; whilst those not needing larger pots should merely have the surface soil removed, adding fresh, after seeing that the drainage is efficient. Those that have the soil sodden should have every particle of soil removed and be placed in fresh compost, placing a little silver sand under and around the bulbs. Turfy loam, with a fifth of old decayed manure, a sixth of charcoal broken small, and a little sand, will grow Liliums well. Although Liliums do not like a very wet soil, it ought not to become very dry even when they are at rest, but should be kept moist. If the pots are plunged in ashes in a pit where they will be safe from frost they will need but little attention during the winter.

THE BEE-KEEPER.

BEE PLANTS.

WE were somewhat surprised on glancing over the pages of the "American Bee Journal" of the 18th ultimo at finding a paragraph under the above heading from an English correspondent, Mr.

E. H. Bellairs of Christchurch, Hants, to the following effect:—"I have read your instructive article on Sweet Clover, and as it is unknown here, and not mentioned in any of our seedsmen's catalogues, I will take it as a great favour if you will send me a small packet of seed to experiment with in our climate." If Mr. Bellairs had consulted us we should have replied that the plant he was in search of, so far from being unknown in England, was remarkably well known, we having cultivated it for a period of thirty years solely for our bees, and having repeatedly seen it growing in cottage gardens in various parts of this country.

The term "Sweet Clover," like much other American nomenclature, is simply a misnomer, since all Clovers (*Trifoliums*) are sweet-scented, and preferred by the bees to any other plant grown. The proper name of this plant is *Melilotus leucantha*, in plain English White-flowered Melilot, a biennial which grows freely in any soil to the height of 6 feet, with very branching stems and large clusters of sweet-scented white flowers.

The best time for sowing is the early autumn, and generally speaking it does not bloom until the second year, flowering profusely through July and August, when it forms seed and dies. It may, however, be sown at the spring time, and succeeds well. Its one great disadvantage is that it is useless to the farmer, even as bedding for his cattle, after seeding. We have known it harvested as hay, though doubtless if well secured before blooming it might form a rough kind of Clover hay. It is of the same class as the *Melilotus officinalis*, or yellow Melilot, so common in many parts of the country, although it has been described as a distinct species—the result of cultivation. The yellow kind is an annual, grows to the height of 2 or 3 feet only, and is cultivated as food for cattle, growing in thickets, hedges, and borders of fields. When dried it gives a strong scent of new-mown hay.

From our own observation the *Melilotus leucantha* is preferred by the bees to any known plant, and is unequalled as regards the quantity and quality of the nectar secreted, and, which is even of more importance, yields its precious nectar in all seasons. We have never found any difficulty in procuring the seed from our principal seedsmen when giving its proper name, and we strongly advise our bee-keeping readers, if not already cultivating it, to give it a trial.

HIVES.

(Continued from page 415.)

AT the bottom of page 414 of the Journal for November 2nd read "When made the frame should hang clear of the floor-board and sides of the hive by a quarter of an inch."

We will now proceed to describe the other parts of the hive not considered in our last letter. The roof is constructed as follows: For the sides of the roof two pieces of three-quarter-inch wood, each $23\frac{3}{4}$ inches long, and cut like fig. 80. For the front and back two pieces $18\frac{1}{4}$ inches long, the front board to be 9

Fig. 80.—Side of Roof.

11 inches broad (A, fig. 81), and the back one 7 or 9 inches broad (B, fig. 82), according to the width of stuff one has in use, which would be either 11 inches or 9 inches broad. The lesser height will allow ample space for two tiers of sections. In the centre of the two last-named pieces (which are to form the front and back of the roof) and near the top cut three holes (C, fig. 81) about an inch in diameter with a centrebit, or if this cannot be obtained a keyhole saw will answer the purpose. On the inside over these holes tack strips of perforated zinc. These holes are to give free ventilation to the hive. All noxious vapours and dampness will rise through the quilt to the inside of the roof, and will pass off through these openings. It must be impressed on those making bar-frame hives for the first time that it is better to err on the side of too much ventilation through the roof of the hive than in giving too little. These four pieces may now be nailed together quite square. It is as well to place them over the hive on the bearers

R, R (figs. 67 and 68, page 414), when putting them together so as to nail them true. It will be seen that a quarter of an inch play is given to the roof—that is, one-eighth on each of the four sides, so that it shall not be likely to stick tight at any time. By reference to fig. 81 it will be seen that notches *n, n*, are cut in the front and back of the roof; these should fit over strong screws screwed into the hive proper just over the roof rests (R, R, figs. 67 and 68) so as to correspond with the notches in the roof. These screws will keep the roof in proper position. It is also advisable to secure the roof to the hive proper by putting hooks and small staples to the sides (H, fig. 80). Those possessing tools, or who can obtain the use of a plough plane or even gouge chisel, should also run a groove along the bottom edges of the roof. This will in a great measure prevent rain being forced between the roof and the hive during high winds. The half-inch overlap will generally prevent this occurring, but it is as well to be doubly secure. It will be seen that the inner top edge of the front and the outer top edge of the back of the roof frame will have to be bevelled off (D, D, figs. 81 and 82), then cut out the wood for the cover. Two pieces of 11-inch hoard 30 inches long answer for the roof cover, although there is hardly sufficient overlap for the sides; but we make this do in order to avoid having two seams in the cover. If 11-inch pine is not obtainable and other wood to hand, then we would have two pieces 8 inches wide and one piece between them 9 inches in width. These should be nailed on to the roof frame so as to overlap equally front and back and both sides, taking care to use well-seasoned wood, and to keep it as close as possible together where the boards join. Strips of quarter-inch wood 2 inches wide should be well bradded to the roof over the joints, driving in the brads at various angles in order to get better hold. If carefully done when well painted there will be not a chance of a leak. The whole of the outside of the hive and roof should receive at least two coats of good oil paint. A stone colour is as nice as any. We like a rather dark stone colour which does not show dust and stains readily.

The quilt is now the only thing we have left to mention in regard to the hive itself. A piece of ticking next over the frames is one of the best materials to employ. Hair cloth is perhaps better, but dearer. We have over several hives used a coarse kind of screen canvas, and this answers the purpose very well and is cheap. We do not put a rough material such as carpet or flannel next the bees, as they seem to object to anything of a woolly nature, and bite it to pieces, trying to make it smooth. A piece should be cut partly out of the middle of the various coverings, three sides of a square being cut through with scissors, leaving it so that it can be folded back like a trap door. Over this first cover of ticking, hair cloth, or canvas should be placed two or three layers of flannel, or a couple of pieces of clean old druggot or carpet, having pieces partly cut out to correspond with the hole in the first layer. This arrangement is for feeding when it is thought best to feed from the top. Instead of this arrangement a good serviceable quilt can be made

Fig. 81.—A, Front. D, Section of front.

in various ways by stuffing a case made just the size of the space over the top bars with any suitable material, such as chaff, wool, cork chips, &c. Care should be taken in this case not to use an impervious fabric, or we shall defeat our own aim to make the bees snug and warm by keeping them damp and thus causing cold and disease. In making the quilt, whether a stuffed cushion or layers of warm stuff, it must be cut accurately to fit above the frames. It will be seen by reference to figs. 67 and 68 that we prefer to leave a quarter of an inch drop all round from the level of the hive sides to the top of the frame bars. Into this receptacle the quilt should fit closely, so as to prevent escape of air suddenly, and thus to secure an equable temperature. Some hives are made so that the quilt simply rests on the frame bars and sides of hive. It is liable to get puckered up at places, and to allow too readily the escape of heat. By being made the least bit too large it can by

our method be fitted to a nicety all round the sides of the top of the hive.

We will now say a few words concerning the management of the hive. Fig. 68 shows the hive arrangement for winter. Of course the feeder (J) is not always in its place. So much importance must be attached to the proper use of food given artificially to bees that the whole subject shall be fully entered upon on a future occasion. It is only necessary now to point out the plan of feeding portrayed in fig. 68. The dummy D has, as formerly explained, a slit cut out from the centre of its lower edge a quarter of an inch high. When the number of combs is lessened for the winter arrangement this dummy is placed in the position indicated. The bees could now run into the space *s*; their movements are, however, curtailed by the tunnel T T. This is made by tacking a piece of zinc to two strips of wood, each the same length as the width of the space between the dummy and the back of

Fig. 82.—B, Back. D, Section of back.

the hive; three or four holes are punctured in the centre of the zinc. During the winter the whole space may be filled up with clean dry chaff; we use oat chaff, as being soft and light, and not liable to mat together. This chaff is easily removed when the space is required for feeding purposes in early spring. A similar arrangement is employed in the front space between the dummy and the front of the hive. Here a tunnel is made by which the bees enter from the outside; a piece of perforated zinc is here used, which assists in ventilation. This front space is then packed with chaff. Mr. Cheshire advises the use of cork chips where they can be had; we have not yet been able to obtain them, but find good chaff answers the purpose. We have this winter used a frame 2 inches deep, made of wood, with canvas bottom, made to fit accurately over the frame-bars. This filled with dry clean chaff takes the place of the quilt, and stands over the one layer of ticking or screen canvas.

Before closing this description of our hives we would give an idea of the cost incurred in making each one. The estimation is for the very best well-seasoned yellow pine, free from knots and flaws, planed at a saw-mill both edges and one side. The bars and side pieces for the frames can be also obtained ready planed in similar manner in suitable lengths for cutting up as required without waste. For the top bars the strips should be seven-eighths of an inch broad when planed. The frames can be made for 1*d.* each. We would here state that we employ nothing but French wire nails in putting together our hives and frames. They hold well when wetted at the time of using, and should, as far as possible, be driven in at various angles. When nailing together the frames the top bar should at one end be only nailed on on one side of the saw-scarf, piercing a hole ready for the second three-quarter-inch nail when the foundation sheet is put in just before use. The material required for one hive is as follows:—

	s.	d.
22 feet best yellow pine, $\frac{3}{4}$ by 11, at 3 <i>d.</i>	5	11½
Floor-board extra.....	0	9
10 frames at 1 <i>d.</i>	0	10
Nails and quilt.....	0	6
Paint.....	0	6
	8	6½

This cost can of course be greatly reduced by the employment of more common wood, which can be purchased at one-third less cost, but more likely to split when being put together. The cost can be reduced still more by the employment of the wood from boxes purchased from grocers or other firms. When comparing the cost of such a hive as we have endeavoured to describe with that of a skep ever so well made, it must be taken into consideration that the bar-and-frame hive, with an additional outlay for a coat of paint every year, would last a lifetime, whereas the straw hive would not last more than a few seasons. It would be therefore much cheaper in the end for a cottager to invest in such a hive as we advocate than to be constantly buying skeps. To every intelligent cottage bee-keeper we would therefore say, Make such a hive and give it a fair trial side by side with the

straw skep, and we are sure that after a little experience gained in managing the bees on the bar-frame system, so much more pleasure will be given by the moveable-comb system than by the fixed unget-at-able skep, that the latter will soon disappear from the garden.—P. H. P.

TRADE CATALOGUE RECEIVED.

H. & F. Sharpe, Wisbech, Cambridgeshire.—List of Potatoes.

** All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Book (W. Cheshire).—The work you refer to is reliable and satisfactory, especially the later edition revised by Dr. Masters, which is thoroughly modernised.

Culture of Fruit Trees (E. D. Carlisle).—We doubt if you can find information on the culture and pruning of fruit trees more sound and concisely rendered than in our small manual, "Fruit Gardening for the Many," which can be had post free for 4½d. in stamps. The instructions for pruning apply almost equally to trees in the orchard house; but on this method of culture Rivers' work, "The Orchard House and Miniature Fruit Gardening," published by Longmans, is the best guide.

Lichens on Wall Trees (J. W. Hall).—The lichen which is infesting your trees is usually most prevalent in districts where the soil is not well drained and the situation sheltered by trees or hills, which prevent the free dispersion of atmospheric moisture. We have known it eradicated by removing the trees from the walls and washing the masonry, also the trees, with lime toned with soot to subdue the white colour, which is to some persons objectionable. That excessive moisture contributes to the increase of the epiphyte is apparent from the fact that it is more abundant on the west than the east aspect of the wall. The bulk of the rain coming from the west causes that side of the wall to be much the wetter.

Selection of Pears (G. P., Hants).—The following varieties may suit you, being of good quality, hardy, and fruitful. For planting against the wall with a west aspect:—Gloire Morceau, Beurré Superfin, Josephine de Malines, Bergamot d'Espereu, Beurré d'Arenberg, Durondeau, Nouvelle Fulvie, Emile d'Heyst, Olivier de Serres, Marie Benoist, Marie Guise, Marie Louise, and Winter Nelis. They must be on the Quince stock, except the last named, which succeeds best on the Pear. Ten feet apart is too short a distance for the Pear stock. It is optional whether you have the pyramids on the Pear or Quince stock. The following succeed as pyramids:—Marie Louise, Beurré d'Amanlis, Pitmaston Duchesse, Beurré Hardy, Beurré Diel, Doyenné du Comice, Baronne de Mello, Comte de Lamy, Louise Bonne of Jersey, Madame Treyve, Beurré Giffard, and Williams' Bon Chrétien.

Uses of Sunflowers (J. Clark).—If you had sent us a copy of the article to which you refer we should have been better able to determine whether the "claims have been exaggerated." Some of the uses of this now popular flower may be enumerated. In France the leaves are used as forage for cattle, who are said to eat them with great relish and avidity. The stalks make an excellent fuel, and yield a large quantity of potash after they are burned; or, if not wanted for that purpose, the ashes may be used as manure by sowing it over the land or mixing it in the manure heap. In Portugal the seeds are used to make a wholesome and nutritious bread, and, when roasted, they form an excellent substitute for coffee; in some parts of the continent a kind of bouilli is made of them, which serves as food for infants. They also yield by expression a fixed oil, little if at all inferior to olive oil, which is used in some parts of Europe both for burning in lamps and for other domestic purposes to which olive oil is applied, and for making soups. As food for poultry they have been found to be very nutritious. One acre will produce 50 bushels of seed, yielding 50 gallons of oil and about 1500 lbs. of oilcake, and the stems will yield about 10 per cent. of potash. The pith of the Sunflower has been recommended by M. Perey for the preparation of moxa, for which it is well adapted by the nitre it contains enabling it to burn without being blown upon.

Planting Vines (W. J.).—Your proposed method of preparing the Vines in turves is good. The precise time for planting will depend on the temperature that you can easily maintain in the house, as, when growth fairly commences, the young Vines must receive no check, but must have a warm genial temperature constantly and a very light position. If these conditions can be insured you may start the eyes in January. We should only have the border 3 feet wide the first year, the front consisting of a wall of turves, additions being afterwards made yearly. Relative to analysing the soil, that is a question for you to determine; but if you have it done, and afterwards grow Grapes as well as the two authorities you name who did not adopt such a scientific test, you may be satisfied, and you cannot err by following the instructions of either of them. There is no doubt a competent analyst in connection with the Durham University. Dr. Voelcker of the Royal Agricultural College, Cirencester, also analyses soils. The cost varies with the nature of the analysis, and can be obtained from chemists who undertake work of this nature. You must remember, however,

that the best mixture that can be compounded will not avail to produce good Grapes if other details of management are not correctly carried out. Some gardeners can grow far better Grapes without any prepared border than others can with the most elaborate mixtures and expensive arrangements.

Origanum Siphyleum (W. T. G. W.).—This is the name of your plant that is known in some districts by the popular name of the Hop Plant. It is of easy culture, requiring ordinary loamy soil. It is a native of the Levant, and is only hardy in sheltered places in the south of England, and is generally best wintered in a frame, greenhouse, or window of a dwelling. Being of a stubby habit it does not die down; the parts bearing the inflorescence of course die and should be cut off to where the growth is healthy. It may be planted out or plunged in the garden during the summer, and taken in on the approach of cold weather in the autumn. It is one of the Marjoram, most of which are more or less fragrant, hence some of the species are used as culinary herbs.

Forcing Asparagus (W. Brown, Herts).—When the roots are taken to a hotbed the bottom heat should never be above from 75° to 80°; if there is the least danger of the heat being more the roots should merely be left on the surface, and be slightly covered after watering, and then 2 or 3 inches more covering should be put on as the heat declines. The details of these matters are of primary importance to the inexperienced. For an early Asparagus bed we seldom use a hotbed all of fresh materials, but select an old hotbed which has been used for Cucumbers or Melons. The soil is taken off, also the most decayed part of the dung; that which is not quite rotten is stirred, mixed with hot tree leaves or other fermenting material, and 2 inches or so of the dung placed on the surface. On this are packed the numerous spreading roots, taking care not to let them get dry, putting in the first row as close as it is possible to do without the buds touching. A little leaf soil and sandy loam is scattered on the long roots, then the next row of roots is placed over them with the buds on a level with the first row. In this way a large number of roots can be packed in the space of a single light of 6 feet by 4. When all the roots are packed in, a sprinkling of light soil is thrown over them, and water is given at a temperature of about 65°, so that the fibres of the long roots may have no check. When sure that there is the proper heat (50° to 60°) add a couple inches or so of covering, for, where green shoots are preferred, covering for blanching is quite unnecessary.

Pruning Vines (W. R. S.).—You may prune your Vines at once, and as they have been so much infested with thrips wash the rods thoroughly with a strong solution of Gishurst or softsoap; a strength of 6 to 8 ozs. of soap to a gallon of water will not be too much. Then turn the Vines outside, protecting them with hay only during severe weather. A few degrees of frost will not injure them. The woodwork of the house should also be thoroughly washed with strong soapy water, and the glass with clear water previously to filling it with plants, the walls also being cleansed and limewashed if that is suitable. A few days of labour devoted to that work will be well and profitably applied; indeed if you do not cleanse the house completely now you will next year have the same trouble with thrips that you have recently experienced, and the insects if not checked will ruin your Vines.

Roses in Pots (A Lady).—On page 445 of the last issue of this Journal you will find a thoroughly practical article upon the culture of Roses in pots, which contains all the information you require. If you have not seen that number it can be had from this office post free for 3½d. The Strawberry plants have been treated judiciously, and you can have them transferred from their present position to the houses as required.

Dwarf Kidney Beans (A Subscriber).—Your letter is very indefinite. Do you require plants or Beans? Inquire of some market gardener or greengrocer in your neighbourhood.

Exhibiting Fruits (S. Clarke).—As the wording of the schedule is for "collection of fruit consisting of eighteen kinds, not necessarily their own growth," you would have been justly disqualified for showing a bunch of black and a bunch of white Grapes as two kinds of fruit. Had the schedule mentioned two varieties you would have been right. The framers of schedules ought to be careful in this matter.

Names of Plants (W. T. G. W.).—The plant of which you sent a specimen is Origanum Siphyleum. See reply above. (K. L.).—1, Pteris tremula; 2, Pteris umbrosa; 3, Pteris serrulata cristata; 4, Blechnum brasiliense; 5, Doodia aspera. (M. N.).—1, Salvia Bethelli; 2, Salvia splendens; 3, Salvia Pitehery; 4, Adiantum macrophyllum; 5, Lomaria gibba; 6, Cestrum aurantiacum; 7, Gesneria zebrina.

COVENT GARDEN MARKET.—NOVEMBER 22ND.

LARGE quantities of Grapes are reaching us, keeping prices low, and meeting with a quick sale. Heavy consignments of Nova Scotia Apples to hand, arriving in good condition.

*POULTRY AND PIGEON CHRONICLE.*

NEGLECTED PASTURES AND WASTE LANDS.

(Continued from page 467.)

IN Mr. C. Darwin's work on worms there is given an excellent account of the formation of vegetable mould through the action of worms, and with observations on their habits. He says:—"Worms prepare the ground in an excellent manner for the growth of fibrous-rooted plants and for seedlings of all kinds. They periodically expose the mould to the air and sift it, so that no stones larger than the particles which they can swallow are left in it. They mingle the whole intimately together like a gardener who prepares fine soil for his choicest plants. In this state it is well fitted to retain moisture and to absorb all soluble substances, as well as for the process of nitrification. The bones of dead animals, the harder parts of insects, the shells of land molluscs, leaves, twigs, &c., are before long buried beneath the accumulated castings of worms, and are thus brought in a more or less decayed state within reach of the roots of plants. Worms likewise drag an infinite number of dead leaves and other parts of plants into their burrows, partly for the sake of plugging them up and partly as food. The leaves which are dragged into the burrows as food, after being torn into the finest shreds, partly digested, and saturated with the intestinal and urinary secretions, are commingled with much earth. This earth forms the dark-coloured rich humus which almost everywhere covers the surface of the land with a fairly well-defined layer or mantle. Von Heusen placed two worms in a vessel 18 inches in diameter, which was filled with sand, on which fallen leaves were strewed, and these were soon dragged into their burrows to a depth of 3 inches. After about six weeks an almost uniform layer of sand 4 inches in thickness was converted into humus by having passed through the alimentary canals of these two worms. It is believed by some persons that worm burrows, which often penetrate the ground almost perpendicularly to a depth of 5 or 6 feet, materially aid in its drainage, notwithstanding that the viscid castings are piled over the mouths of the burrows, prevent or check the rain water directly entering them. They allow the air to penetrate deeply into the ground. They also greatly facilitate the downward passage of roots of moderate size, and these will be nourished by the humus with which the burrows are lined. Many seeds owe their germination to having been covered by castings; and others, buried to a considerable depth beneath accumulated castings, lie dormant, until at some future time they are accidentally uncovered and germinate."

These combined scientific and practical statements are of immense value to the farmer in considering the question of forming or renovating pasture lands, for after taking into account that the worms are a factor in the matter, we should endeavour in our management to facilitate their operations, and how to effect this we shall explain further on.

Quotations have already been given from Mr. Darwin's work on worms, and the whole subject is so truthfully displayed by him that we strongly advise the home farmer and gentlemen having landed property, and especially grazing and parklands, to obtain the work. But considering as we do the importance of the subject, we will make a quotation which fitly concludes with a paragraph summing up in a few words the result of nearly half a century's observation and research as follows:—"When we

behold a wide turf-covered expanse we should remember that its smoothness, on which so much of its beauty depends, is mainly due to all the inequalities having been slowly levelled by worms. It is a marvellous reflection that the whole of the superficial mould over any such expanse has passed, and will again pass, every few years through the bodies of worms. The plough is one of the most ancient and most valuable of man's inventions, but long before he existed the land was, in fact, regularly ploughed, and still continues to be thus ploughed, by earthworms. It may be doubted whether there are many other animals which have played so important a part in the history of the world as these lowly-organised creatures."

In our practice connected with the improvement of neglected pastures, which has extended over a period of more than fifty years, we find that during the greater part of that time we have been unconsciously acting in accordance with Mr. Darwin's views—that is to say, our chief object has been to encourage the working of the worms, and we have studiously endeavoured to follow such plans and use such manures as would most conduce to their operations. One of the first experiments we ever tried was the improvement of some strong clay land where the earth had for some years been removed from the surface for tidal embankment purposes. This land had lain for more than twenty years as waste, producing nothing better than *Carex*, commonly called Carnation Grass, black bents, and a few other worthless grasses which neither dairy cows or sheep would eat. It was upon this land that we made our first experiment in order to ascertain the value of couch and the earth adhering to it, laid out on waste land as fast as the carts were filled with it without the labour of rolling or harrowing, to make it fit to burn. The couch in this instance was laid out at the rate of about 18 or 20 tons per acre and spread immediately. This was the means used to induce the earthworms to work on the surface, as we had always noticed how much earthy composts induced them to cast up earth and draw into their burrows any fragments of vegetation with great benefit to the turf, but more especially upon the poorest pastures. This experiment was made the groundwork of our future proceedings in the manuring of grass land, which we found deficient in herbage, for the result being that the couch in the green state as it was, actually proved more beneficial than farmyard manure which we had frequently laid out on poor or neglected pasture land. We found the worms worked incessantly, and drew in every stem and blade of couch in a very short time, and after a second application at the expiration of three years the pasture was wonderfully improved, for the grasses and Clovers indigenous to the soil began to appear, and it is to this day extremely useful dairy pasture, although the late tenant never dressed it at all for a period of nine or ten years.

In another position we had a well-situated park-like pasture, a portion of which (about 4 acres) was extremely wet, being on a subsoil of strong clayey gravel, and it was rendered very inferior grass land in consequence of being greatly encumbered with Rushes of two sorts. The Bunch Rushes which had formed into hassocks were easily got rid of by cutting up with the turf-cutter and burned; but not so the small Rushes, which run under the surface and throw up their stems from every knot in the roots, somewhat like the growth of couch grass. It is impossible to eradicate these entirely without file or pipe, draining the land, breaking up the turf, and resorting to cultivation, in order that the land may be chalked or limed, this being the basis of all successful cultivation on strong soils, whether intended for arable or pasture in the future. These matters determined us upon a course of cultivation, as all other attempts at improvement had failed. We ploughed off the turf rather shallow and burnt it into ashes in very large heaps, a portion only of which we used and ploughed into the soil. These contained so much of the elements, as well as the basis of manures, especially potash, that we never used any other manure except chalk, whilst for four years the land was under a succession of corn crops, which yielded a most abundant produce both of corn and straw. The large quantity of ashes we obtained enabled us not only to apply each year a portion of them to the land where they were burned, but we had also a supply which furnished enough for use on the other farm crops applied with the drill, especially the root crops, such as Mangolds, Carrots, and Potatoes.

After four years' cultivation this land was clean and fit for laying down for permanent pasture, and as we had found the land so fertile we did not hesitate to seed it in a corn crop of April Wheat, which, although it produced as much straw as could be grown, it never injured the seeds, which took remarkably well. The seeds, however, were furnished by a local seedsman as a proper mixture for such lands. As we did not then understand the matter sufficiently to enable us to select the best sorts, we insisted

only upon sowing 6 lbs. per acre of the yellow Suckling (*Trifolium minus*), and it became a regular plant all over, but the annual Rye Grass died the second year, and very much weakened the appearance of the plant. By a mere accident in cutting the grass for feeding our horses the men had allowed a portion to get over-ripe, and the seed from the Suckling and other sorts of grass fell out and struck root so thickly that this portion of the pasture proved more productive than any other part for many years afterwards, and made good all deficiency caused by the dying-out of the annual grasses.

We wish also to mention the result of successful renovation of pasture and park lands upon an estate of 300 acres. We found on first looking over the land that it consisted of about 150 acres of arable land, and a similar extent of pasture, in the most neglected state we had ever seen a property, and our experience induced us to adopt what was generally considered at that time a most unusual proceeding—namely, to cultivate the whole of the arable land without the use of any other manures except artificial or hand manures, including, however, the consumption of cake and corn by sheep on the root lain. On the other hand we decided upon the renovation of the pastures, which were almost entirely denuded of grass by the constant feeding of horses and sheep, which bite so much closer than horned cattle, that there only remained a few herbs and Daisy roots to be seen. On these pastures the experience we have detailed relating to the effect of couch and earth upon grass land induced us to adopt the plan of using a compost of earth and chalk mixed with farmyard manure, and indeed all other manures not required in the large garden of the establishment. After lying about six or eight months, and being mixed by turning the heap, this compost laid out in the autumn of the year was the only means we used for manuring, but the land being so naked and bare we thought it right to sow and work-in with the chain harrows 10 lbs. per acre of yellow Suckling. Now, this mode of proceeding, together with the assistance which we expected and did actually obtain from the action of earthworms, proved so beneficial that after three years of this management we estimated the letting value of the land to have been doubled both as to the arable and pasture upon the estate.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—This work is greatly in arrear, and this seed time for Wheat reminds us of some past seasons such as we cannot easily forget. In 1841 we could on the strong loams and flat clay soils sow very little Wheat even during the month of September. Where, however, it was sown it did not succeed, and the deficiency of plant was fatal to the crop in most instances, for there was no seed time with regard to weather from the 1st of September to the 14th of December. The years 1852 and 1872 were bad seasons, yet the late-sown Wheat maintained the best plant. Therefore if the home farmer has sown but little or no Wheat yet, he should not be over-anxious about the matter, but wait with patience and be prepared when the weather becomes suitable to make the most of every dry day. The home farmer should specially consider one point, that when the season arrives as to the condition of the land, not to be deterred from sowing by reason of the date of either month from November until the middle of February. An idea prevails that Wheat should never under any circumstances be sown in January; but from experience we say, Sow on the first fair weather which occurs after the 1st of October, and in extremely adverse periods it may not occur until December, January, or early part of February. After the latter date on the average of seasons we should do well to wait and sow Lent corn.

Hand Labour.—Much of this will depend upon the weather, but may be taken as fairly represented in our last week's "Work on the Home Farm."

Live Stock.—We fear that many sheep and some cattle may be again lost by the coathe or fluke rot this next winter; but let it be remembered that salt is the great, and we may say the only, preventive or remedy; for if the sheep or cattle are only slightly affected, salt given, and lumps of rock salt being always within reach of the fattening animals, with nourishing food, with a larger proportion of hay and less of roots, they may if not seriously affected become fit for the butcher. They should be accommodated with dry lairs either of boxes for cattle or sheds for sheep, for it is perfectly unreasonable to expect diseased animals to recover or get partly fat if they are obliged to live in the open fields in the winter months. All cattle in the boxes should now be receiving a full allowance of cake, and as the cake or corn is increased let the roots be decreased in daily allowance down to 56 lbs. per day, and to increase the cake or corn in preference to giving them any hay at all, but to give good sweet straw *ad libitum*, with rock salt accessible to every animal at all times. The team horses—these ought always to have a lump of salt within reach, especially those which receive, as they all should, an allowance daily of roots about 12 or 15 lbs. of Mangolds, Swedes, or white Carrots, the latter being the best root they can have and may without injury after they become accustomed to it receive a double

allowance per day, with hay and straw chaff mixed, not forgetting two bushels of good oats per week per horse.

At this time many of the early Dorset and Somerset lambs will be strong and able to go upon root-feeding if the land is dry, such as sand, limestone, or gravel and dry loams. They will require the best possible system of feeding, not only for their sake, but for that of the ewes also, when it is intended as usual to fatten both together, so that they may be sold at the same time, or nearly so. To make or rear and feed first-class quality of early lambs for sale at the period from Christmas to Easter is a matter requiring not only great personal attention to details of feeding, but also a course of management to secure the health of the animals. When the ewes and lambs are kept entirely in the open fields they are subject to certain disorders, some of which may be avoided. At about three weeks or a month old the lambs will be strong enough to be put on root and trough feeding in advance of the ewes, but before this they ought to be docked of their tails to about 4 inches in length, and the ram lambs castrated. On recovery from this operation they may then be fed in fold in advance of the ewes, the use of which they will have previously shown and taught on their grass lairs. It is very important when lambs and ewes are feeding on roots that the ewes should have their roots cut with Gardener's cutter, and have the cake or corn given in the meal state mixed with the roots, instead of giving cake with hay chaff, which is best given by itself. The fold for feeding the lambs in advance should be entirely cleared of all roots and greens, the object being not to allow the lambs to run out into the Turnip or Swede greens, which is often detrimental in the event of frost or snow. As the fold will confine the lambs within reasonable bounds, it will be more likely to induce than to resort to the troughs, especially if they are covered, as they ought to be; for young lambs will go to the covered troughs for shelter oftentimes, and will be then enticed into feeding at the earliest period. This is a matter of the greatest importance, because the more choice food they can be induced to eat at the trough the less milk they will require from the ewes. To induce the lambs to eat at the earliest period it is important that the food should have an agreeable aroma like white Carrots, the next best food for them would be white hearts of Cabbages. At any rate the root food must be cut into small pieces, which is done with a hook into the cutter and then passing the root pieces twice through the cutter, which, if carefully done, the small dice-like fragments will be readily eaten by the youngest lambs, especially when mixed with the best Russian or American oilcake meal and bean meal in the proportion of two-thirds cake and one-third bean meal. This is a desirable mixture, because the lambs cannot then eat their roots without eating a quantity of the superior kind of food, which it is difficult to get them to eat at the early period, either by itself or in admixture with hay chaff. We cannot name any quantity of food for lambs, because they ought never to see an empty trough, but be fed twice a day, and what they do not eat readily should be removed and given to the ewes. As the lambs ought never to feed from the same troughs as the ewes, the lambs should be fed in advance of the ewes, and the lamb gate stopped until the ewes have eaten their bait, and which, to prevent waste, they always ought to do before leaving the trough.

BIRMINGHAM CATTLE AND POULTRY SHOW.—The entries for the show of 1881 were the largest ever received for the Exhibition, and the total this year, 3920, is slightly in excess of last year. There is little material change in the numbers in the agricultural department, those for sheep and pigs showing a slight increase, whilst the cattle are over an average. Roots, corn, and Potatoes are equal to, poultry are in advance of, and Pigeons slightly under, last year. We understand that Shorthorns and Herefords will be both well represented. Some of the Devon classes will be much stronger than usual; Scots and Crosses muster well, with good reputations from over the border, and the Sussex and Norfolk men will for the first time try their Red Polled beasts, with a view to induce the Council to give them classes in the future. Birmingham is the only place to see Shropshire wethers to advantage, and nearly a hundred of these favourite sheep will be penned. There is a full show of pigs, Tamworths being in great force. The railway companies are now fully alive to the importance of the Exhibition, and excursions are promised from all parts of the London and North-Western, Midland, and Great Western systems. The judging is on Saturday the 25th, open to life members free, the general public paying 10s. for the privilege of seeing the awards made.

POULTRY NOTES.

We understand that since judging Pigeons at the Crystal Palace, Mr. T. C. Burnell has left England for some months for the south of Europe, and has cancelled all his judging engagements. His place at Birmingham will be taken on Saturday by Mr. O. E. Cresswell.

THERE seemed little competition at the Crystal Palace auction sale

for the prize birds there put up. In the Dorking classes but two pens changed hands—viz., the first-prize Dark cock at £20 and the cup cockerel at £17. Many of the winners were priced at sums which we used to consider by no means prohibitory; whence, then, comes this apathy of the public to claim them? Probably the general financial depression has something to do with it. Another reason is that there will be better choice at Birmingham, and that of birds less shown. Fanciers are by degrees realising the fact that the greatest winners are not necessarily the best breeders. At Birmingham many birds are shown which go to no other shows, hence it is a peculiarly good place at which to obtain useful stock birds. The highest price we heard of at the Palace was £50 paid for Mr. W. F. Addie's cup Game Bantam pullet.

It seems to us a pity that at so large an exhibition as the Palace, and one which ought to be so generally representative of all poultry, White and Black Cochins should be mixed together. When they were here shown separately we remember large and good classes of both varieties; now that they are amalgamated the Whites are few, and Blacks almost entirely absent.

We wish the authorities of the Palace, or some other large show, could be induced to follow the example of the Poultry Club at Cambridge, and give more extended classification for Polish fowls. In the classes for "Black or any other colour," but four cocks and six hens were entered, and the sole representative of the "Any other colour" was one Buff cock.

The popularity of Japanese Bantams seems to increase. The class for White Rose-combs had but six entries, that for Sebrights eight, and very poor ones too; White-booted five, and Cuckoos four, while no less than twenty pairs of Japanese were entered. It seemed a pity to see Lady Dartmouth's beautiful Frizzles again unnoticed here. The Judge considered that they should have been entered in the "Any other variety" class. Were Frizzled Cochins or Brahmans shown in the classes for such breeds they would undoubtedly be passed over. Why should not the same rule obtain in Japanese Bantams? There is something in this argument; at the same time, in the case of so purely fancy a breed as Japanese Bantams, the points of which have not been very accurately tabulated, we think a little more latitude might be given. However, in future we should advise her ladyship to enter her beauties in the "Any other variety" Bantam class.

We have before us the schedule of the Oxford Ornithological Society's Exhibition, to be held in the Corn Exchange, Oxford, on December 6th and 7th. To the usual show of cage birds and cats one for Bantams has been added under the patronage of the Bantam Club. There are six classes for Game Bantams and six for other varieties, all shown singly. There are two selling classes for pairs respectively of Game and any other variety of Bantams. There are also three classes for pairs of fancy Ducks—viz., Mandarins, Carolinas, and any other ornamental variety.

We understand that at the meeting of the Bantam Club, held during the Crystal Palace Show, the rules of the Club were carefully considered, revised, and improved, with reference to the now extended operations of the Club. Mr. Cresswell inquired on behalf of several fanciers of Japanese Silkies if this breed could not be encouraged by classes at shows held under the patronage of the Club, and received an answer in the affirmative.

At the Farnham Show, held on Tuesday, November 21st, the entries were—Poultry, 239; Pigeons, 109; Cage Birds, 115; Rabbits, 63; Total, 536—not a bad entry for the Show of so young a Society.—C.

POULTRY NOTES AT THE CRYSTAL PALACE SHOW.

Spanish were more numerous and better in quality than we remember to have seen for some time past. The old cocks were hardly looking their best, and were characterised by some roughness of face. The cup went to the winning hen (Street), which had a large, good, smooth lobe and a fine face. The second hen had a beautiful rounded lobe, but was hardly ready. Cockerels were a very good class, the cup going to Mr. Le Sueur for a bird large in face and lobe. Mr. Harmer's second-prize bird and Mr. Underwood's third were but little behind the winner. Pullets though very good were hardly up to the cockerels in quality. First (Street), smooth face and nicely rounded lobe.

Houdans were wonderful classes. The cup very properly went to Mr. Marx for an old cock which we have never seen surpassed for size and quality. We rather preferred third (Lindsey) to second (Boissier), as this latter was a shade too dark. We noted h.c. (Wingfield-Stratford) and h.c. (Thomas) as being also specially good in quality. The winning hen (Mrs. Lane) won by size and colour; second (Turner) being best in head properties. Cockerels were a very good class. Here we hardly agreed with the Judge, and preferred second (Nickolls) to first, which, though good in crest, was small and rather failed in comb. The Dairy Show winner was here properly passed over.

Pullets again were an especially good class and must have been hard to judge. We considered 941 (Wingfield-Stratford), only h.c., the best. First (Jackson) undoubtedly won by colour, as she was lacking in size and head properties.

Crève-Cœurs were not numerous, but the winners were quite up to the average of those recently seen. Captain Turner was the most successful exhibitor, taking the cup and two firsts; the remaining first, that for cockerels, going to Mr. J. Ward.

La Fleche were a small but good class. Mr. Calvert took first and second, Mr. Tegetmeier third. We heard two questions raised as to these birds. The first had very large combs, second and third small neat combs. Which is correct? First and second again were without crests, third had small crests. Surely one must be wrong. We will perhaps have a word to say as to this on another occasion.

The *Hamburgh* classes were fairly filled, those for Blacks being most numerous. The winners were in nearly all cases first-rate birds, but the general quality does not seem to improve. We heard some pretty free comments in reference to trimming and comb-cutting, and it seems a pity that the Judges are not more severe in putting down such practices.

Game had 268 entries, but were not, on the whole, up to the quality of some former years. Mr. Matthews' first-prize Black Red cock, Messrs. Proctor & McKinnon's winning Black Red cockerel, and Mr. C. W. Brierly's winning Duckwing cockerel were the pick of the classes, and were model birds.

Indian Game were here classed for the first time. All the winners came from Cornwall, where this breed is popular. They much resemble Malays in type and plumage, though perhaps more brilliant.

Malays were well represented. Mr. Rallinshaw's cockerel here added another to his list of victories, and the same gentleman stood first in the hen class with a hard-feathered pullet of good colour, hardly so erect in carriage as we like.

Polish had a liberal classification, and were fairly numerous. In the Spangled classes the indecision of fanciers between lacing and spangling has, we think, had an injurious effect. The winning Golden-spangled cock (Silvester) was so heavily spangled on breast as to be almost black, but otherwise very good. The winners throughout the Golden classes showed less white in crest and tail than we have sometimes seen. The cup for Polish went to a grandly crested Silver-spangled cock (Smith), whose chief fault was a straw-coloured shade on back and shoulders.

The winning *Brown Leghorn* cockerel (Verrey) deservedly took the cup for this section, and was the finest we remember to have seen. His lobe was very slightly tinged with canary colour, and we cannot say that we regard this as a fault. Too much has, we think, been made of the pure white lobe, which can hardly be attained in conjunction with bright yellow legs. The winning White cockerel (Fraser) was another noteworthy bird, though not such a wonder as the cupwinner.

Plymouth Rocks were very numerous, having no less than sixty-five entries in two classes; but there seemed to us to be a great lack of quality. The first cockerel (Jackson) was large and shapely, but had a white patch on each shoulder. Second (Macdonald) large again, but a coarse comb and traces of feathers on legs. The winning hens were better, the cup going here to Mrs. Ainsworth for a large bird. We noted in this class a tendency to abandon the characteristic cuckoo marking, in which the two shades of grey blend into each other and form bars across the feathers, for a black spangle on a white ground. This is effective, but is a new departure which we cannot say we incline to favour.

Andalusian cocks were placed in such a position that they had all the light from the back of the pens, which were not covered; this may account for the cup being awarded to a bird with far too much white in fact, although otherwise good.

Minorcas were only moderate. The winning cock about the best; second white in face again. The winning pullet (Dominy) was, we thought, the best bird in the two classes.

Langshans seem as much in need of a standard as ever. The two classes were, however, well filled, and some of the winners showed wonderful gloss.

The variety class was a failure in numbers. First went to Scotch Greys, second to Yokohamas, and third to Silkies, practically the only competitors.

Game Bantams had an extra incitement in the twenty-five guinea challenge cup offered by the Bantam Club. They were wonderful classes, but owing to the absence of back covering to the pens and to the cold exposed situation in which they were placed, they were hardly seen to advantage. Mr. Walton's well-known Pile cock added still further to his trophies by winning the challenge cup for best Game Bantam in the Show, and the cup for best in the cock and hen classes. The President of the Bantam Club was in great force, winning first with a Black Red hen (closely pressed by Mr. Anns with a beauty of the same colour), cup in Black Red cockerels with a perfect little gem, and two cups and second in Black Red pullets with two very perfect birds, of which some good judges preferred the second, claimed for £50. Black Rosecombs were a good class. The cupwinners (Crowther) good in all points, of the miniature Black Hamburgh type. The same exhibitors easily won first and second in the White class with very perfect little birds. Japanese had twenty entries and were generally good. We cannot agree with the Judge in excluding Lady Dartmouth's beautiful frizzled birds from competition. They

are undoubtedly Japanese, and properly classed as such. Sebrights have fallen off in quality and were not numerous. White-booted only five pens; the winners well shown, but rather slim and long in limb. Third contained the best cock, but very badly shown. The winning Cuckoos (Walton) were decidedly the best, being small, neat, and trim, of the Scotch Grey type. In the variety Bantam class frizzled Japanese of good quality were first.

Turkeys, Geese, and Ducks were all good classes, though some of the latter were in such darkness that the Judge must have felt inclined to wish for a special development of the obnoxious electric light exhibition in that quarter.

Table fowl we omitted to search for.

May another year see the birds back in their old quarters, and a more thorough supervision of the penning arrangements. We fear that more than one exhibitor may find there is "death in the cup" won at the Palace this year.

THE POULTRY CLUB.

THE annual general meeting of the Poultry Club was held in the Marble Hall, Crystal Palace, on Tuesday, November 14th, at 3.30 P.M. The attendance was not large, but amongst those present we noticed the Hon. and Rev. F. G. Dutton (in the chair), the Earl of Winterton, Rev. W. Serjeantson, Rev. H. Morgan, Miss May Arnold; and Messrs. G. B. C. Breeze, O. E. Cresswell, A. Comyns, T. Christy, A. Darby, J. C. Fraser, R. E. Horsfall, T. P. Lyon, S. Lucas, M. H. Mills, C. F. Montrosor. After a few opening remarks from the Chairman the Report for the year was read by the Secretary. It was as follows:—

ANNUAL REPORT.

LADIES AND GENTLEMEN,—In accordance with the precedent established last year we have the pleasure at this, your annual meeting, to submit to you the annual report of the proceedings of the Club since the Crystal Palace Show of 1881.

Your Committee have met fifteen times since the last annual meeting of the Club, and numerous meetings of the sub-Committee appointed to undertake the work connected with the preparation of the Standard of Excellence have also been held. Some twenty-six new members and sixteen new associates have been added to the Club during the year, and it now numbers 124 members and 81 associates.

For the first time since the formation of the Club a show has been held directly under the management of the Club. Through the courtesy of the Committee of the Cambs Ornithological Society a Club Show of poultry was held at Cambridge on January 4th and 5th, in conjunction with the Show of Pigeons and Rabbits of the local Society. The hall at Cambridge is eminently suited for the purpose of a show, the space being ample, and the light all that could be desired, and the thanks of the Club are due to the Cambs Ornithological Society for the cordial way in which they co-operated with the Club to make the Show a success.

We think we may congratulate you that so far as regards the quality of the exhibits and the general management of the Show, it was marked by considerable success. Exhibitors generally expressed themselves as well pleased with the result of our first attempt; but owing partly to the date being somewhat too late in the season to secure as numerous an entry as the liberality of the prizes offered would have required, and partly to the fact that the attendance of the public was not so large as might reasonably have been expected, the receipts from all sources fell considerably short of the expenditure.

In one direction a considerable advance has been made by the Club during the year.

We regard it as of much importance that the penalty attaching to disqualification by the Club should be made a substantial one. This can only be effected by the number of shows held under Club rules being so considerable that exclusion from exhibiting at them implies exclusion from many shows of importance. Since your last meeting the influence of the Club in this direction has much extended, and no less than twenty-eight shows have been reported to your Committee as held, or about to be held, under Club rules. Amongst these we may instance Belfast, Buxton, Banbury, Dorchester, Exeter, Hertford, Kendal, Liverpool, Lincoln, Nottingham, Southport, and Wolverhampton.

Subscriptions in aid of the funds of such shows held under Club rules as were of sufficient magnitude to be of more than mere local interest have in most cases been granted; but your Committee regret that in consequence of the heavy expenditure on the Club show already referred to they have latterly not been able to make such grants as freely as might otherwise have seemed desirable.

Your Committee have had to take into consideration several cases of fraud in connection with the exhibition of poultry. We regret to have been obliged in two cases to inflict the extreme penalty of perpetual disqualification, while in two others the lesser penalty of disqualification for one year was deemed sufficient. In a fifth case of some notoriety your Committee were pleased to be enabled to remove the stigma attaching to disqualification at a show from a gentleman on whom, in our opinion, it had been unjustly inflicted.

In consequence of the circumstances connected with this last-named case, your Committee have thought it desirable to vary the rules to be used at shows held under the Club's auspices, so as to entitle exhibitors at such shows to an appeal in all cases of disqualification. This step seems to have met with the approval of the local committees, and the new rules certainly afford to exhibitors an additional security against groundless charges.

The work connected with the preparation of a new standard of excellence has made considerable progress. With some trifling exceptions the draft standards of the various breeds have been prepared. As to some varieties, the replies from fanciers have been full and numerous, and the task, though difficult, has resulted in the preparation of a draft standard which is fairly complete, and probably will not require any great amount of alteration. As to the other varieties, however, the replies received have been so meagre that your Committee have had difficulty in framing a standard which could be deemed satisfactory even as a draft; and, as to these, much in the way of revision will be necessary.

The draft standards of Brahmas, Cochins, Dorkings, Game, and the French breeds have been published, with a request for comments from those interested. Copies have been sent to the leading poultry judges, asking for their assistance, and the fanciers of those breeds have been invited to meet to settle the final

standards of these breeds. These meetings have only been held to-day, so that this report cannot include any account of their proceedings.

(Signed) F. G. DUTTON, *President*.
ALEX. COMYNS, *Hon. Sec.*

November 13th, 1882.

The Secretary then proposed an alteration in Rule 22 of the Club rules by leaving out the words which provide for the sending of copies of the list of members, annual report, &c., to exhibitors at the previous Crystal Palace and Birmingham Shows, which was carried unanimously.

It was then proposed by the Secretary and seconded by Mr. M. H. Mills that

"The resolution as to the settling of the final standard [of excellence] passed at the last annual meeting be rescinded. That the settling of the final standard of the remaining varieties be entrusted to an editing committee, who should be instructed to act upon the comments upon the draft standard received from judges and fanciers, and to further consult so far as may be deemed necessary with the leading judges and fanciers."

It appeared that as to several breeds of which the draft standard had been already published, and for the settling of the final standard of which meetings had been fixed for that day, there had been a difficulty in getting a sufficiently large attendance to render a further adoption of this method of settling the final standard desirable.

After some discussion the resolution was carried.

The following resolution was then proposed by Rev. W. Serjeantson, seconded by the Hon. Secretary, and carried:—

"That in the view of this meeting it is desirable that it be known that the standard being prepared by the Club is merely intended as a guide to and for the information of judges and fanciers, and not as binding or attempting to bind the judges."

After the usual votes of thanks to the Chairman and Hon. Secretary had been passed the meeting terminated.

OUR LETTER BOX.

Insurance of Cattle (P. D.).—The Imperial Live Stock Insurance Association, offices, 446, West Strand, London, W.C., insures horses, cattle, and other live stock against death from accident or disease.

Cabbages for Cows (Cowman).—Nearly all kinds of Cabbages are good for cows in full milk if they have white hearts without decayed leaves attached, but the best sort is the Drumhead Savoy, and they will not affect the taste of the milk but very slightly if without any decayed leaves. If, however, the milk is required for butter-making we cannot recommend Cabbages, but prefer Mangolds or Carrots, but best of all the large cattle Potatoes, which do not injure the flavour of the butter.

Carrots for Horses (Idem).—The best Carrots for feeding horses in winter are the White Belgian and the Red Intermediate, more particularly if grown on a shallow gravelly soil. We think that it is the best plan to grow Mangolds and Carrots on the stretch in alternate lines, to be sown about the last week in April or the first week in May; if sown earlier they cost more in clearing the weeds away. The stretches should be about 20 inches or 2 feet apart in order that horse-hoeing may be effected between the lines. Do not hoe out the Carrots to the distance they should stand—about 8 inches apart, but thin them by hand-pulling after the roots get the size of the finger, for the pulled roots they are valuable for cattle, and the remaining ones are safe from the grub, wireworm, which are nearly sure to destroy a large portion of them, particularly when the season is dry, if hoed out when the plants are very small.

Insects Infesting Canary (J. P.).—The insects infesting the birds are termed red mites or cage bugs, and are a species of *Acarus*. The best method of destroying them is to thoroughly clean the cage, saturating the cracks with linseed oil, and then filling them with flowers of sulphur, also dust the sulphur amongst the birds' feathers and in the nest after it has been cleaned.

REMARKS.

12th.—Dry and cold, sun shining through much haze.

13th.—Wet at first, afterwards fine and cold.

14th.—Cloudy; dry and very cold wind.

15th.—Fine, with bright sunshine; evening dull, slight rain 5.30 P.M. and 9 P.M.

16th.—Sun at first, turning to cold rain; fair in evening, high wind.

17th.—Fine, bright, and cold. Red aurora visible at 5 to 6 P.M., and very pale green with streamers about midnight.

18th.—Thick fog at first, clearer afterwards; rain in evening, heavy after 10.30 P.M.

Nearly 10° colder than the previous week, and much below the average. Fine aurora on 17th, and thick fog in morning of 18th.—G. J. SYMONS.

PRUNING AND TRAINING FRUIT TREES.

WINTER pruning should be done as soon after the leaves have fallen from the trees as possible; but newly planted trees are best pruned in February. Pruning may seem a simple matter, and it is for those who know how to do it; but to be a good pruner instructions are requisite from a practical man who thoroughly understands hardy fruit culture, with careful study of the character of the trees. As many have not that opportunity I will offer a few remarks, which may be acceptable to some readers of the Journal.

Some people think that pruning is simply cutting away long growths that have been made during the summer; but where trees are properly managed those shoots are removed during August after the trees have made their summer growth. Pruning should be directed to insure the proper balancing of the tree and to induce fertility. Severe pruning is not required for orchard standards, except during their early stages, so as to produce a foundation for the future tree, after which all that is required is thinning the branches to prevent crowding and keeping the centre of the tree open. When pruning young pyramid Apple and Pear trees lay a good foundation at the base of the tree, so as to insure it becoming of good shape. It will soon make its top growth. In some cases the shoots will require to be cut back severely, so as to balance the tree evenly. After the trees have made their summer growth cut back the leading growths which are to furnish the tree to about two-thirds of their length if they have grown strong, cutting-in the lateral growths to about four eyes.

At the winter pruning balance the leading shoots, so as to form the framework of the tree, and prune the laterals in to one or two eyes to form fruit spurs. Do not cut off any fruit buds, which are easily distinguished by their round plump appearance. Old-established trees, if they have been summer-pruned, require the laterals to be pruned back to one eye or close to the fruit buds, cutting out any branches that are crowding the others. Some Apples are not well adapted for pyramids, and should be grown bush shape. These are such as Small's Admirable, Cornish Gilliflower, Betty Geeson, and others of similar habit.

Espalier Apples.—These look very pretty grown by the side of walks. The branches should be trained about 15 inches apart. Prune the growths to four eyes in August, removing all growths as they appear afterwards. At the winter pruning cut these in close to the fruit spurs, pruning the leading growths to 18 inches, so as to cause them to break back.

Cordons.—These are grown as horizontal cordons, trained about 18 inches from the ground, but are more frequently trained obliquely to a trellis at an angle of 45°. This style of growing Apples produces very fine fruit, and a large collection may be grown in a small space for exhibition. These require the same kind of pruning as for espaliers. The horizontal cordons are very pretty by the margin of walks. Plant 12 feet apart, and train to a strained wire 18 inches from the ground. When the leader of one tree meets the bend of the next it may be grafted on to it.

Pears on Walls.—Good trained trees are not seen so much in gardens as formerly. I think if young gardeners would pay more attention to hardy fruit culture it would be much better for them. Pears may be grown in different shapes on walls, but the majority are trained horizontally and fan-shaped. If the wall will permit of the trees being trained fan shape do so, if not train them horizontally. In the first place see that the trees are young and healthy. The following method of training fan shape is good. Choose a tree with each pair of branches equal distance from the others. A tree that has been trained for a horizontal will do well. Train the branches at an angle of 45°, taking the leader straight up, to be cut back at the winter pruning so as to cause three more shoots at equal distance from the others. At the August pruning cut the breastwood in, leaving the leading shoots entire. At the winter pruning cut the laterals in closely so as to form fruit spurs, or close to the fruit buds. Prune the leading shoots back two-thirds of their length, so as to cause the back buds to break. Another mode of fan-training is to procure a young tree with about six shoots, starting from the base. Train the lowest tier of branches almost horizontally; regulate those equally that are left, keeping the centre open to throw strength into the lower branches. Cut each shoot (except the lower tier, which also should be shortened a little to make the back buds break) to about 18 inches; train as many shoots from them as you can without crowding (about 1 foot apart or 18 inches will do well), and carry them on annually until the tree is furnished. If any of the branches seem wide apart as they advance train other branches from them, so as to furnish the tree thoroughly. When any of the spurs become long cut a few back annually, so as to keep the tree uniform.

The cordon system of training is very simple. The first year plant at an angle of 60°, the next year train them at an angle of 45°, or those trees that have grown well. The first year after planting cut each cordon back two-thirds of its length, and at each succeeding season cut back the leader according to its strength, always being careful to cut back to a wood bud. As the trees advance in age, if any are seen not likely to reach the top of the wall do not let them fruit, and assist them at their roots as recommended in a former article for exhausted trees. This mode of training is not yet general in England, but it is well worth practising, as many varieties may be grown in a small space.

Plums and Cherries for Walls.—These should be grown fan shape. Keep the lower tier of branches well down and the centre open until the lower part of the tree is well furnished, then fill up the centre and lay in fruitful wood as required. Cut out all exhausted and worthless wood at the winter pruning. Young Plums and Cherries should not be pruned back severely, only balancing the trees. Plums and Cherries make very fruitful trees if grown as pyramids for a fruit garden. If

for an orchard, plant standards. All the pruning that standards require is to keep the centre open and not let the branches become crowded.—A. YOUNG.

LAPAGERIAS.

THE Lapageria is certainly king of greenhouse climbers. Everybody who admires flowers admires its large waxy bells. The red kinds are most plentiful, and indeed the most beautiful, but the white is an exquisite flower, plentiful now, but long scarce.

For dressing vases where the flowers may hang in a natural way Lapageria sprays are useful, and add at once to the grace and the richness of any arrangement. For bouquets they are by no means to be despised. The most beautiful bouquet we ever saw was made of a groundwork of scarlet Begonias more than half hidden by single blooms of *Odontoglossum Alexandræ*, and a single bloom for a centre of Lapageria alba half protruding from the mass. Through the crystalline purity of the Lapageria and the Orchids the Begonias were seen, giving all an exquisitely charming appearance. Of course the only positive colour was complemented with its only proper complement—green. The green also added grace; it was furnished by fronds of *Adiantum cuneatum* all over the bouquet, and as a fringe around it.

Lapagerias are strong-rooting plants, and like good living. Few plants make a greater number of roots for the size of the plants, and this should be borne in mind. Not unfrequently I have seen plants not doing well, and all that was wanted was more root room.

No soil suits them better than very fibry rather light loam. In large pots pieces of freestone or charcoal may be mixed in the body of the soil with advantage. Some I know use peat largely or even exclusively for soil, but that is a mistake. The plant certainly likes the soil first named best; indeed, it is not particular about soil at all, as the different composts recommended by successful growers prove. At the same time it is well worth some trouble to secure a good soil for such a plant.

They like water, and when the roots have taken possession of the soil liquid manure; but a sourness is fatal to them. To guard against this the drainage must be ample and carefully arranged, and the soil porous and open.

Its great enemy is green fly, which is sure to settle in the points of the young shoots. If green fly is allowed to have its own way the shoots will make no progress, and if crushed between the fingers and thumb the shoot is likely to be injured. The best plan to keep it free is to occasionally damp the young leaves and shoots with liquid insecticide applied by means of a sprayer. Nicotine soap we have found efficacious. Scale is apt to infest the older leaves, and is easily disposed of by means of the sponge and soapy water.

A cool moist greenhouse temperature suits it best, and it will do well in a shady place. In favoured localities it does well outside. Curiously enough the white variety is hardier than the red, although scarcely so vigorous. Possibly the greater vigour of many red-flowered plants is the cause of their being more susceptible to cold.—SINGLE-HANDED.

MUSCAT OF ALEXANDRIA GRAPES.

DURING recent years I have inspected many grand houses of Muscats in various parts of the country, but never remember having seen such superbly finished examples as at Knowsley Hall gardens a short time ago. I have seen larger bunches in many instances, but the crop was heavy and even throughout, and the bunches of most suitable size for table. That beautiful amber colour so desirable in this Grape was excellent, and not one berry could be found in the two houses (the two being 70 or 80 feet in length and proportionately wide) that were not highly finished. It is seldom, indeed, that we have the pleasure of seeing such general excellence throughout a house of Muscats. In the majority of instances there are individual Vines carrying bunches of fine quality, while other Vines or bunches do not attain the same high finish. The Vines in question are comparatively young, and were lifted two or three years ago and replanted—not because the new border was exhausted, but because it had never been fully made. When the Vines were first planted only a narrow border was made for them, with the intention of adding to it in a season or two; but the large amount of renovation required to be done in other vineries, Peach, and numerous other fruit houses, prevented Mr. Harrison doing so as early as he originally intended. When removing the remaining portion of the old border it was found that the roots of the Vines had extended through it just below the surface, and found their way beneath the flags at the back of the house which formed the walk. The flags were

resting upon sand, which was crowded with nearly all the feeding roots the Vines possessed. They bore, however, grand crops of first-rate Grapes every season whilst their roots were rambling amongst the sand, which to all appearance is only poor material for Vines. I have invariably noticed that when a quantity of sand is deposited by any means on the surface of a Vine border the roots soon find it, and rapidly form quantities of fibres in it. Vines evidently like sand. Is it because it retains moisture?

The roof was well covered with moderate-sized healthy leaves, more being allowed to develop than are generally seen in Muscat houses. The opinion prevalent is that the sun must strike direct upon the bunches, otherwise a fine amber colour cannot be obtained. In many instances we find the foliage tied on one side or entirely removed, so that the sun will act with full force upon the bunches. Grapes ripened under these conditions generally commence shrivelling earlier than those ripened under the shade of moderate foliage. The system of exposing the bunches to full sunshine in order to finish them thoroughly is unnecessary. The condition of the Muscats at Knowsley this year is alone sufficient to prove that they will colour to perfection under a good roof of foliage, and in a season that has been remarkable for the absence of sun, in this part of Lancashire at least.—W. BARDNEY.

PLANTING ROSES—SPRING v. AUTUMN.

MY view of this question is that there is room for both systems. In the case of any alterations that might be contemplated which necessitated the removal of Rose trees from one part of a garden to another, I should prefer early autumn planting, say during the last week in September or the first week in October. I do not think there is anything to fear from a few sappy points withering or a few leaves turning brown, for while this is going on the roots will be taking to the new soil, and the plants will be in a better condition to withstand frost than if they had not been disturbed, owing to the check hardening the wood. But at this season care must be taken that the plants do not remain long out of the ground, neither laying in by their roots nor covering them in any way; but as soon as they are lifted place them where they are to remain, properly secure them, and in some autumns probably a little water to settle the soil about the roots might be attended with advantage, but unhappily not such autumns as the one we are now experiencing.

The young vigorous trees from the nurseries are never at rest until they have been exposed to a sharp frost, thus it is generally late in the season before they will bear transit safely. Even at that late season, if the weather were open and the ground in fair order I should prefer planting them as soon as received, and should the winter prove mild they would have a great advantage over spring-planted Roses; of course all autumn or any newly planted trees should be mulched as soon as the operation is performed.—C. WARDEN, *Clarendon*.

MY experience in regard to this subject is in distinct opposition to that of "A NORTH COUNTRYMAN" where he says that "the plants thus laid-in in November have never commenced rooting until spring." I have had convincing proof in several instances that they soon begin to make root-action after removal in the autumn.

Some few years ago, when standard Roses were more the fashion than they are at the present time, we purchased a quantity of Briar stocks for standards. These were received before the ground was prepared for them, their roots were attended to, and they were laid-in in bundles of fifties until the ground was ready to receive them. During the operation severe frost set in, which delayed the planting for more than a month, and these hocky sticks of Briars were then found to have made young roots, some of which were an inch in length. And again this autumn I had occasion to move some Roses which were laid-in from October 25th until November 4th, and even in that short time some of them had begun root-action, although the ground is this season so extremely wet and cold.

Being convinced that roots after removal make progress during autumn—and the table of the mean temperature of the earth given recently by Mr. Mawley certainly favours that view—it is evident that plants having this partial re-establishment must under any circumstances start with greater vigour in the spring than those planted at that season of the year, provided they are protected from severe frost, which, in the case of dwarfs, can easily be done; in fact it is advisable to mulch newly-planted Roses in order to check radiation, whereby the earth loses its heat. This same mulching drawn to the base of the plants will serve also as a protection against frost, and as the practice of

pruning hard back is now recognised we need not trouble about those parts which will be eventually cut away.

"D., Deal," seems to anticipate a change in the time of planting Roses somewhat as great as what has taken place within the last few years in the manner of pruning; but we must bear in mind, although success has this past season attended Mr. Prince's spring planting of Teas, the spring and summer throughout have been most favourable for such. Had there been a dry parching March and April such as we experienced two years ago the result might have been far different.—J. R., *Woodhatch Lodge, Reigate.*

SPEAKING generally, autumn-planted Hybrid Perpetual Roses must succeed best. They will have made some roots, and will be in a better position to resist the varied and trying alternations of spring temperature. I plant always as early as the nurserymen advise the removal of Rose trees, and for the last two seasons dwarfs only, and I never lose a plant. Teas also do well planted at the same time; but earlier and finer blooms can no doubt be obtained by turning out Tea Roses from pots when all danger of spring frosts is past, and this plan I mean to adopt next season, when I shall have occasion to plant out some climbing Roses. I have seen it tried in the south very successfully.

My experience is in favour of hard pruning outstanding Teas instead of simply shortening their shoots. Thus treated their growth is more vigorous and satisfactory.—A. M. B.

WITH regard to the question raised by your worthy correspondent "D., Deal," of the advisability of planting Roses in February in preference of November, I for one fail to see the advantage of this change. I have procured Roses from the nursery in autumn, and from unavoidable circumstances have not been able to permanently plant them at the time we received them, but should have them planted the first opportunity in February. What do our nurserymen say about this change? For the past ten years I have been more or less engaged in planting, and I find we have had fewer losses in planting in autumn than we have in the spring-planted trees. Certainly this has been the most sunless wet season we had here for nine or ten years; in fact, I think "D., Deal," knows some of the disadvantages we have to contend with in growing Roses in this wet and cold locality. With the exception of last February, I fear I should have to count back a number of years before I could point a February which was available for planting Roses in this locality. Would not this spring planting retard their blossoming and make them flower later in the summer than those planted in November? For the first season after planting I have found this the case here; but wet as this autumn has been, we are now busy engaged planting, and if others will do as we are I feel sure they will not regret taking the advantage of early planting. Deeply fork or dig over the ground on dry days. This is of the utmost importance to the roots of Roses or trees of any description. One error I fear many of our Rose-growers commit is incorporating a quantity of manure with the soil they plant their Roses in. This manure has a tendency to hold the wet, and decay the roots of newly planted trees before they start into growth, and the consequence is a weakly growth in spring. My advice is to plant the Roses in the soil pure and simple, and give a good coating of littery stable manure round the collar of each plant, and I think there will be but few losses. The majority of Rose-growers in this locality plant in November, stake the plants, and draw the shoots round the stake with matting, and protect the plants with bracken.—C. ROBERTS, *Higfield Hall, near Leek.*

CULTURE OF GARDENIAS.

ON page 446 "W. L. H.," writing on this subject, recommends potting to be done after flowering in June. I readily admit these plants can be potted any time during the season while their roots are active. It is, however, a question, when established plants require larger pots, whether it is not wise to carry out the operation much earlier. While their buds are swelling rapidly small growths are generally produced and the roots are active. If transferred into larger pots when in this stage quantities of roots will have reached the sides of the pots before the time recommended for potting by "W. L. H." Under these conditions the plants will be ready for starting luxuriantly into growth after they have flowered. The advantages of much earlier potting than recommended is very marked where the pruning-back system is practised after flowering, as is the case in many gardens.

I had begun to think the pointed stick, as recommended by "W. L. H." for liberating the roots when carrying out the operation of potting, was a thing of the past. It is an unnecessary practice, and destroys, however carefully performed, numbers of

roots which must be growing rapidly if potting is left until the month of June. This system does not facilitate the plants taking to the new soil readier or earlier, but cannot fail to check the plants to a greater or less extent, and thus retard their development.—A CULTIVATOR.

THE BEST PEACH-WALL PROTECTOR.

NOT one word need be written in praise of glass wall protectors for Peach trees. Their value and importance has long been an established fact, and in all gardens where a regular supply of fruit must be had they are undoubtedly an indispensable necessity, for trees left exposed on open walls are so much the sport of weather as to render a crop of fruit always a matter of uncertainty. It goes without saying, therefore, that protectors must be had, and it also follows that the cheapest and best form should be chosen for so general a want. Perhaps I ought to say the best form as cheap as possible, because a simple lean-to of a given angle must always prove cheapest; but it is not the best when the angle is more acute than 45° , because the upper branches of the trees are then liable to be too near the

Fig. 83.

glass. It was this reason which probably led to the introduction of the lean-to which we figure; but it possesses another and more important property, to which I wish to call attention.

Figure 83 represents a transverse section of a lean-to, built five years ago for the protection of Peach trees trained to the wall, and covering every part of it before the house was built. The lower slope from A to B is at an angle of 60° , and the upper slope from B to C is at angle of 37° . In early spring the sun's altitude is insufficient for its rays to fall upon any portion of the trees through the obtuse upper slope, but they do so readily enough through the lower acute angle, with the curious result of the lower branches not only being in blossom, but also making growth freely for a considerable time before there is much sign of animation in the upper ones. All the sorts of Peaches are affected alike, so that the trees have for a time the appearance of a line having been drawn along them at about 42 inches from the top, which has checked the upward flow of sap.

The effect of this early start upon the lower branches is always visible. It renders them singularly robust, and there is an equal distribution of vigour throughout each tree and a freedom from the common fault of a vigorous growth in the upper branches at the expense of the lower.—EDWARD LUCKHURST.

PROTECTING THE BLOSSOMS OF FRUIT TREES.—A few remarks may be applicable here on covering Peach trees. Some people cover the trees whilst in bloom day and night, which is a very bad practice. On warm days there are generally plenty of bees about whilst the trees are in bloom, and if the trees are covered in the daytime very few bees (if any) will be found under the canvas. The way I used to manage if the day was bright, which is generally a forerunner of a

frosty night, was to cover the trees about 4 P.M., so as to husband a little warmth, to protect the blossom, and if the night should be frosty do not uncover them until between ten and eleven o'clock, according to the weather. If, on the other hand, the night has been warm, uncover as soon in the morning as possible.—G. G.

ALNWICK SEEDLING GRAPE.

WHEN Mr. Bell sent out this Grape I remember, in explaining its character to myself, that his words were—"Without artificial fertilisation it will not set a berry." Since then the columns of this Journal have many times explained this failing. Regarding the value of the Grape, the complaint of Mr. Cooke suggested to my mind how much I would like to have had added to my vineries for next year's prospects a house of this Vine well ripened that had failed to grow a crop this. For a gentleman's table I prefer the equally well-grown Alicante; but after this, save the extra labour during the blooming period that this Vine requires, I think all the advantages are on its side. The Alicante Grape I consider to be nearly as good as the Hamburgh at any season, and certainly it is much better at this season. The Alnwick Seedling to follow up to the period of the Gros Colman—January and February—I like next, but I prefer the flavour of the Alicante, or, rather, I prefer it to the rougher pulp of the Alnwick Seedling berry. It is free-growing, and it will do better with the Black Hamburgh than the Alicante, as it requires about the same heat to ripen its wood, and less than it takes to ripen the wood of the Alicante. It is a most prolific Vine, seldom showing less than three bunches at each eye, and, what is of as much importance, during a succession of years on a single rod of, say, 18 feet, it will finish quite 5 lbs. more fruit than will the Hamburgh or Alicante, and will colour well. Here, during the blooming season, every bunch, and no matter what the variety, is dusted with a fox's tail each day at noon, and no other trouble is ever taken to impregnate with other varieties. This year from nine Vines I have had an excellent crop well set, the berries of good size, and the bunches similar to the one exhibited on my prize stand at Edinburgh, which was from a single cane 15 feet long that carried twenty bunches. I only know of another Grape that will do this, and that is Gros Colman.—JOSEPH WITHERSPOON, *The Vineries, Chester-le-Street.*

ARAUCARIAS.

(Continued from page 458.)

IN my previous notes upon the culture of Araucarias (page 456) the word "success" in the fourth line from the top of the second column was misprinted "suckers," which gives to the sentence an entirely different meaning from what was intended.

A. CUNNINGHAMII.—As a species not only handsome in itself but useful as a stock for some of the others this well merits a note, and it might be advantageously grown more generally than it is, for it is scarcely less graceful and suitable for decorative purposes than A. excelsa, though differing greatly from that in appearance. Young plants are raised from seeds either for growing-on or to serve as stocks; but it has been stated that the species has also been propagated by cuttings of the roots, a method that deserves more attention, and which might possibly be applicable to others. As with those already mentioned, there is a good typical specimen in the Kew winter garden. It is 25 feet high, having the branches four or five in a whorl, slender, with the branchlets closely placed, imparting quite a tufted appearance to the branches, especially as the lower part near the trunk is apt to become bare. The leaves are needle-like or awl-shaped, about half an inch long, the old ones dark green and the young ones very fresh bright green. Two varieties are in cultivation named glauca and longifolia, which titles sufficiently indicate the distinguishing characters of the plants. Of the two glauca is the most attractive, the glaucous tint of the foliage being well marked. It was introduced by Messrs. Loddiges from Moreton Bay, and twenty years ago was certificated by the Royal Horticultural Society.

A. Cunninghamii is known as the Moreton Bay Pine, and in Eastern New Holland forms extensive forests, particularly in the neighbourhood of Moreton Bay, individual trees having been found nearly 200 feet high. Mr. Walter Hill of Brisbane considers it "the most ornamental and useful tree in Queensland," the timber being extensively used in the colony. The wood is said to be "strong and durable when kept dry, but soon decays if exposed to alternate wet and dry;" some of it is, however, finely grained and takes a high polish. A white resin is produced, quite transparent and crystal-like, which often exudes from the trees and hangs in icicle-like masses 3 feet long.

A. EXCELSA.—The Norfolk Island Pine, as this species is popu-

larly termed, is, next to A. imbricata, the best known in England, and is more generally grown in houses for decorative purposes than any of them. In its native country it attains a great height, frequently exceeding 100 feet; but probably the largest specimen in cultivation is that in the temperate house at Kew, which is about 30 feet high or slightly over. It is a fast grower, and the distance between the whorls of branches, which are rigidly horizontal, gives the tree a somewhat formal appearance, but in a small state this is not so noticeable. The branchlets are slightly drooping, the secondary branchlets being closely arranged, 8 or 9 inches long; the leaves half an inch long, slender, and curved towards the tip of the branches. The typical form is of a peculiar green shade, but there is a variegated variety which has whitish shoots, not very handsome but distinct. The finest variety is, however, that termed Napoleon Baumann, which is distinguished by a glaucous tinge, and the habit is also graceful. Still another variety, A. excelsa speciosissima, is in cultivation and has the reputation of being hardier than the species, having been grown out of doors in French gardens. The ordinary type has been planted out of doors in Ireland, but without success, as moderate frost has killed the specimens. Small plants are occasionally used for table decoration, but they are rather too formal in appearance for that, and are better suited for the conservatory.

A. IMBRICATA.—Any formal description of this well-known Conifer would be quite superfluous in these pages: a few words may be devoted to its history. It is a native of Chili, and according to the authority already mentioned (Parlatore) it abounds upon the western side of the Andes from latitude 36° to 48°, or from Santiago to south of the island of Chiloe. It was first discovered by a Spanish officer, and subsequently by several botanists. But what we are principally concerned with is its introduction to England, and this we owe to Mr. A. Menzies, who, having accompanied Capt. Vancouver to Chili, succeeded in obtaining cones and plants, the latter being conveyed to this country in 1876 and presented to Sir Joseph Banks. One was planted at Spring Grove, Isleworth, and the others at Kew, where the only remaining specimen of the batch is still living, but not of a very promising appearance. This historical tree is near the new range, and notwithstanding the care taken of it the branches appear to be gradually dying. It is about 20 feet high, the spread of branches covering a similar space, the lowest whorl being 7 or 8 feet from the ground; the apex has a stunted appearance very different from the numerous other healthy examples in the same gardens. Had this tree enjoyed a more suitable situation we might have expected a considerable advance towards the 100 feet which it is said to reach or even exceed in Chili. As it is, the finest specimens in England are as much as 60 feet in height, though some of these are considerably younger than the Kew tree. The wood of A. imbricata is valued in its native haunts, where also a resin it produces is employed for medicinal purposes.

Several varieties of A. imbricata are grown: one named tenue from its more slender habit, another variegata, and a third variegata aurea. The last-named is said to have been raised at Castle Kennedy about a quarter of a century ago, and a few years since the original plant was still growing there in fine health and beautifully variegated. The other variegated form, Gordon states, originated in Glendinning's nursery at Turnham Green.

A. RULEI.—This is a very distinct New Caledonian species which requires more heat to ensure its success than the others, but when well grown it is very striking. Like the others this reaches a height of 100 feet in its native home; but I have not seen any in this country a tenth of that height, in fact it is rather scarce. In some of the Australian botanic gardens, however, it is said there are several handsome specimens. The branches are in whorls of three, the branchlets being arranged in a pinnate-like manner. The latter are a foot or more long, the leaves lanceolate, curved, half or three-quarter inch long, and very closely set. The colour is a rich dark green, the habit bold, vigorous, and handsome. It is a very striking species, and small specimens in pots have a noble and distinct appearance when arranged with Ferns or Palms. An unnamed species is grown with this in the Palm House at Kew, which appears to be a more slender form of it, though equally beautiful, the branchlets having the leaves so short and closely pressed that they resemble shoots of the strange little *Crassula lycopodioides*.

Several other species are known, but some are not yet in cultivation, and others are extremely rare.—L. CASTLE.

IN an article in the *Journal of Horticulture* of November 16th on Araucarias, it is stated that "plants of Araucaria Bidwilli were brought home by Mr. Bidwill in 1842," and "that one was purchased by the Duke of Northumberland for a hundred guineas, and the other transferred to Kew, and in the temperate house

there are two specimens about 25 or 30 feet high, and in admirable condition." In 1872 a similar statement appeared in another paper, but the credit of being the purchaser was given to the Duke of Devonshire, and the price two hundred guineas. It is curious upon what ground such statements can have originated. Neither is correct. The truth is this: Mr. Bidwill, on visiting England in 1843, brought with him a small plant about a foot in height, growing in a flower pot. He put it in the hands of Mr. Stevens, the auctioneer, for sale, the upset price being £25; but no bidder was found for it, and I being present Mr. Bidwill asked me to take it to Kew and take charge of it for him. I brought it home in my hand. Such is the history of the fine *Araucaria Bidwilli* now in the conservatory at Kew. It was some time before other plants were introduced which came to Kew, and I have no recollection of hearing that either the Duke of Devonshire or the Duke of Northumberland becoming possessed of plants at that time; indeed, I am not aware of any large plants being in the country than those at Kew.—J. SMITH, *Ex-Curator of the Royal Gardens, Kew.*

EARLY POTATOES.

THE weather here during the last three weeks has been most unfavourable for any outdoor work. We have had three weeks' storm and almost constant rain followed by frost on the last three nights of 2°, 3°, and 5° Fahr. below the freezing point. I fortunately had the last of my field Potatoes secured a short time previously, but I am satisfied one-third of that crop is still undug in Ireland, and a large fraction of that is hopelessly injured. I examined some left behind on the surface in the vegetable grounds and others that were an inch beneath the surface. They were all soft, spongy, and wholly unfit for anything but manure. After saving several acres of both Champions and Magnum Bonums I have had not one stone of diseased tubers, though of less size than last year, from early blighting. It is not uncommon, especially in suburban gardens where space is limited, to grow Potatoes in the same place year after year, but it is undesirable. If the Potato must be grown and the same land must be used lime would be desirable as a corrective of the sourness frequently noticed. I attribute the above satisfactory results to the crop being grown in new land and to the seed being obtained from a different district.

This brings me to the principal point I intended to say a few words about—Autumn *versus* Spring-planted Potatoes. Two years since I planted four lines each of Veitch's Ashleaf Kidney, Snowflake, Early Rose, Beauty of Hebron, Bresee's Peerless, and Gram-pian the 20th of October 6 inches deep, using stable manure. The winter came unusually severe, and I put on a few inches more of litter later on. A large number decayed, especially of the Kidneys and Snowflake; and though I removed a quantity of the surface of the drills in April to permit the heat from the sun's rays more play, the vast majority were later than those planted early in March, and with puny growths that never became robust. I make these few remarks, as I see one of your correspondents has inquired on the subject. I shall not try the experiment again. I am now trying several varieties of Cauliflower exposed in the seed bed for the winter, and shall tell you the result later on. With frame culture the trouble, and subsequent dissatisfaction "buttoning," &c., has induced me to try a hardier system of treatment.—W. J. M., *Clonmel.*

OF HUMUS.

(Continued from page 473.)

"HUMUS," says Ville, "has its origin in the actual substances of plants, which, by a kind of spontaneous decomposition, has lost a certain quantity of hydrogen and oxygen in the form of water," and he tells us that many intelligent men place humus in the foremost rank as a fertilising agent; but, as he adds, let us "go to the root of the matter, gaining our light and information from experience. How and under what circumstances does humus act favourably?" As mentioned in the latter part of my former letter, the views of Liebig upon this important ingredient of soils appear to have been somewhat misunderstood or imperfectly stated. I think it, therefore, the more necessary in what I have to say to let him speak for himself.

"Up to a few years ago," Liebig writes in his "Letters on Modern Agriculture," "scientific agriculture taught, and all practical men firmly believed, that the productiveness of a soil was dependant on the quantity of humus, or carbonaceous remains of a preceding vegetation, contained in it. Without raising doubts on the efficacy in certain cases of the organic matter of farmyard manure, it may be asserted that nobody who possesses any knowledge of the matter now believes that the produce of a field in

carbonaceous substances bears any proportion to the amount of humus in the soil, and that its fertility can in reality be estimated, as was formerly supposed, by this humus." Inasmuch as before Liebig wrote, "Humus had the honour," as Ville says, "of serving as an explanation for everything that could not be understood," the terms of this expression of opinion cannot, I think, be cavilled at. Liebig showed incontestably that it was utterly impossible that all the carbon found in plants could be derived from the amount of humus in the soil; and therefore, whether humus is capable of supplying nourishment directly to vegetation or not, we may leave this part of the question for the present, and consider how and when humus certainly exerts a beneficial action. We shall find, I believe, that we may safely credit it with more good effects than would be supposed from the above quotation from Liebig, and certainly with effects sufficiently important to justify my inquiry.

"The first of its good effects," Ville says, "is that, like clay, it possesses the property of absorbing a great deal of water, thus contributing to the maintenance of the humidity of the soil. If, however, we remember that the soil contains only a very small per-centage of humus, it is very difficult to allow that such small quantities have the power of modifying the physical condition of the soil." The remainder of this letter will be occupied by the inquiry whether, notwithstanding the apparent difficulty in believing in the modifying powers of comparatively small quantities of humus, there may not be more difficulty in rejecting the evidence in favour of their important influence.

The fact is, as it appears to me, Ville's experiments on another prominent function of humus, to which I shall allude hereafter, led him to underrate the effects produced by the humidity which it encourages—effects which will not be despised by those who, like your readers, have continually before their eyes the beneficial influence of "mulching." Davy may perhaps be looked upon in the present day as somewhat antiquated, but his results, deduced from actual experiment, must still be regarded with the utmost respect. He made careful investigations on the absorption of different soils, and he states, "I have always found it greatest in the most fertile soils, so that it affords one method of judging of the productiveness of land." He found that a thousand parts of the soils named below, after having been dried at 212°, absorbed, during one hour of exposure to the air, the quantities of moisture given in the following table.

Sterile soil of Bagshot Heath	3
Coarse sand	3
Fine ditto	11
Soil from Mersea in Essex	13
Very fertile alluvium, Somersetshire	16
Extremely fertile soil of Ormiston, East Lothian	18

—(Davy, *Agr. Chem.*, 5 ed., p. 176.)

In the next table I give some of the results of a series of experiments, carried out by Schübler, for the purpose of determining the absorptive power for vapour of water of different kinds of earths and soils.

The column of figures gives in thousandths the quantity of hygroscopic moisture absorbed, by previously dried soil from air contained over water (and hence nearly saturated with moisture), in twenty-four hours.

Quartz sand, coarse	0
Lime sand	3
Ploughed land	23
Clay soil (60 per cent. of clay)	28
Fine carbonate of lime	35
Loam	35
Heavy clay soil (80 per cent. of clay)	41
Pure clay	49
Garden mould (7 per cent. of humus)	52
Humus	120

From the facts expressed in the above two tables it is manifest that soils (though undoubtedly much depends on the fineness of division of their particles) may have their absorbent properties very largely increased by an admixture of 20 per cent. of clay, and that humus, the absorbent property of which is nearly 2½ times as great as that of clay, must influence a soil to a still greater extent. We know, in fact, that sandy soils which have little attractive force for atmospheric vapour, and are therefore arid and dry, may be greatly ameliorated in this respect by admixture with clay, or, which is better still, by admixture with humus, as is done by dressing with vegetable composts and by green manuring.

At the same time, as many sterile soils contain humus in abundance, whilst sometimes fertile ones contain but a small proportion of it, it seems that humus is by no means indispensable to the life and full development of plants, its presence cannot be regarded as any sure test of fertility. Yet, though this is the case, may we not safely regard it as a more valuable constituent, independently of the mineral salts it may contain, than Ville and

Petzholdt admit, seeing that it so materially increases the absorptive property of soils for vapour of water, and thereby (when a sufficiency of plant food is present at least) greatly ameliorates their condition?—INQUIRER.

(To be continued.)

AZALEA NARCISSIFLORA.

THOSE who possess well-appointed plant houses have no difficulty in maintaining a supply of white flowers through the late autumn and winter months; but in the case of those who have only one or two, possibly only one, it may be of some use to say that *Azalea narcissiflora*, when well treated, will yield blooms from November till March, and thus place the amateur very nearly on a level with the possessor of many houses and a skilled garden staff. Finer and handsomer *Azaleas* there are, but not another that is so thoroughly useful; indeed I hardly know any other plant that will continue yielding supplies of blooms month after month in an ordinary greenhouse temperature in winter time.—S. H.

WHITE GRAPES.

IF I were going to grow Grapes for pleasure the first that I should plant of white Grapes would be the Duke of Buccleuch, which is undoubtedly the grandest Grape grown, and only requires simple treatment. With a border ill-drained, soured by unnatural heavy liquid manuring, or mulched to a degree that the hottest sun fails to warm it, then under these conditions this Vine will probably refuse to grow, but with reasonable treatment its growth may possibly be rather too luxuriant. Last year I had this Grape very fine, this year it has been partly a failure; but the reason was not far to seek. The Vine grew too vigorously last year, and the heat that would have been sufficient to ripen less luxuriant growth failed to mature it sufficiently, and the consequence was many stoneless berries. Both this Grape and the Golden Champion rebels against high feeding. With the wood well ripened you may prune it as you do other Vines, but failing this it is well to select the eyes that are most promising. Of the Muscat Grapes it perhaps is not necessary to speak, save that I consider the Tynninghame is distinct from the Muscat of Alexandria: it sets much better. The Bowood too, I think, is a distinct Grape.

When grown under the same conditions that suit the Duke the Buckland Sweetwater is in appearance the next Grape to the Duke—that is, as a rule. I do not mean to contend that it is superior in that respect to a few of those very fine Muscats we saw at Edinburgh. With me it keeps better than the Duke, but when fully ripe the flavour of the latter is superior. Next to the Duke I would plant it for a summer Grape.

Foster's Seedling has a much longer season than any of the above—in fact, I have for long had the opinion that its good keeping properties were not half known. Ripened in September the chances are it will keep better than Lady Downe's. For certain, unless the latter be exceedingly well ripened, it will do so. For comparison I would couple the Buckland with the Hamburgh, and Foster's Seedling with the Alicante. It has this advantage over these named in requiring less heat to ripen the wood. The flavour, too, is good, and it is a Vine that will stand rougher treatment generally and more liquid manure.

For a companion to Gros Colman Golden Queen is most suitable, as it, too, requires a long season, and the two varieties will make as fine a dessert for Christmas as any two Grapes that I know. I have seen it stated that Golden Queen does best in a dry border; here it fares equally with the others, and does equally well. The bunches average from 1 to 2 lbs., but the berries are so fine in size, golden in colour, and of such a brisk desirable flavour that it is quite a favourite. For a sick person I consider it the best of all the white Grapes. Waltham Cross if grown with Muscats is a showy Grape, but it is of poor flavour, and unless the wood be ripe it is the worst setter I know of. It keeps well and exhibits well, but it must have strong heat.

White Lady Downe's is a Grape with a somewhat sickly sweet flavour. It keeps well, but otherwise has no very great commendation, though to plant one Vine in a house of Lady Downe's might be desirable, as it is quite the natural companion of its black namesake.

Of the White Frontignans I have only had experience with Dr. Hogg, a Vine with a robust constitution and fruit of delicious flavour. I have had bunches upwards of 18 inches long, but if the wood is not quite ripe two-thirds of the stalks of the bunch will dry up, the berries refuse to finish and turn sour. It requires as much heat as a Syrian.

In regard to the class to which the Syrian belongs, if they are large call them Syrian, otherwise call them Calabrian Raisin or Trebbiano. I am stubbing them all up. This family of Grapes are best just to look at whilst hanging on the Vine. If really well grown and well ripened, as we see them finished at such places as Lambton and Hutton Hall by Mr. Hunter and Mr. MacIndoe, they look magnificent, and if I were in their place I should continue growing them; but they are not at all suitable either for market or small gardens. With myself the growth is so gross that I cannot possibly ripen the wood sufficiently to prevent shanking. In this way at least a half of the bunch goes, and then in damp weather those huge bunches are difficult to keep. I have nothing to say against the flavour, which is fairly good. It will be seen that I place great value on well-ripened wood. I repeat it, First see to the wood being well ripened, and then Grape-growing is not the difficult task many find it to be under other conditions.—JOSEPH WITHERSPOON.

ALLAMANDAS.

THERE are many who do not grow these, thinking that they require a great heat and extra attention, but these ideas are not quite correct. One plant of *A. nobilis* which is growing here in a 10-inch pot came into flower in July last. Since then we have cut many scores of blooms from it, and now there are many dozens of buds to open. In August and September it was fairly well off for heat, but during October and November the day temperature in the house where it is growing has never exceeded 70°, and the night temperature ranges from 55° to 60°, which certainly cannot be regarded as great heat, or more than could be given in many temperate houses. We would advise all who can command the heat we have named to introduce the Allamandas, as none of our choicest flowering plants can equal them in supplying a constant succession of blooms, and these are most valuable in all kinds of superior floral decorations. Every shoot terminates in a large cluster of buds, and as the rich massive flowers open it is easy to detach them without injuring the unopened ones. Probably if grown in a stronger heat the blooms would be forced out more quickly, and the period of blooming would be diminished, and in this way the cooler system of growing them has one decided advantage. A mixture of loam, peat, and sand without any manure is the best compost we have tried for them, and from the time the first bloom opens until the last one is cut guano water is given weekly with good results.—M. M.

THE NOMENCLATURE OF GARDEN PLANTS.

YOUR correspondent "JUSTITIA" takes exception to my statement that "we do not want the collections of weeds we see in botanic gardens;" but speaking from a horticultural point of view, which is the only point I pretend to know anything about, and without any disparagement of botanical collections in their proper places, I have to repeat that we want selections more than collections. There is such a host of really beautiful plants for decorative purposes amongst the hardy perennials, and there is on the other hand a much larger host of those which are of no use as decorative plants, which may, I think, be honestly referred to as weeds by the gardener, though doubtless I did make a mistake in speaking of weeds in a botanic garden; for inasmuch as dirt has been defined as "matter in the wrong place," so a weed is a plant in the wrong place—*e.g.*, a Sunflower amongst the Potato crop, or a Cabbage in a bed of Pelargoniums. A botanic garden is certainly not a likely place to make enthusiastic cultivators of hardy decorative plants, for the gems are scattered about so widely that there is every probability of their being overlooked; but it is surprising what a number of really beautiful plants may be found to come in at any desired season if one has the patience to look after them and keep a definite object in view. The plants I grow are all autumn-flowering, and there are some two hundred of them, without reckoning Phloxes, Pentstemons, and the like, which are worth including in any collection. But it takes several years as things are at present to make even such a limited collection as mine, and I have had to throw away many sorts that did not possess sufficient merit, although unusual care had been exercised in the selection.

After all the trouble taken to obtain the plants and grow them it is a great drawback to their enjoyment that I do not know their names, or that in the course of twelve months I should refer to the same plant under three different names, as has lately happened in the case of what is perhaps the most beautiful autumn flower we have. When asked the name of this plant two months ago I gave it in writing as *Rudbeckia Newmani*, but was told I had given with the same plant the year before a name

beginning with the letter C. This was *Centrocarpha grandiflora*, under which name I had received the plant from the late Mr. George Wheeler, who probably did more to preserve hardy perennials when they were not fashionable than any other man in England, and I said the former was now the recognised name. Judge of my feelings when I took up the *Journal*, and was informed by Mr. Wolley Dod that botanists would not acknowledge the name *R. Newmani*, but that the plant in question was *Rudbeckia speciosa*. Well, I hope I have the right name now, but I confess I am not over-sanguine about it.

If it is unfair to blame the botanists for this confused nomenclature, as your correspondent infers I do, it is certainly quite as unfair on his part to blame the nurseryman; for as far as I recollect, when I was living in the neighbourhood of London, the nomenclature at the two great botanical gardens there was not always identical. Where, then, are we to find the "competent authorities?" It is comforting to learn that Professor Asa Gray knows Michaelmas Daisies, and that he is preparing a monograph of them; but when the monograph is completed will British botanists accept it, or will it only result in a few additional synonyms?—WM. TAYLOR.

PLANTS IN LATE VINERIES.

How often do we, on entering a late vinery where the crop is hanging, find the borders bare beneath, and the fruit and fading leaves above to look at. This is, perhaps, accounted the right thing in places where there is ample accommodation for everything. In most gardens now gardeners are obliged to make the most of every available space at their disposal in the autumn no less than the spring. Like many more gardeners I find it rather inconvenient to have even a late vinery empty for some three months in the autumn, and really, after all, it is not necessary that it should be so. This autumn we have had Ferns thinly arranged on our late house borders set on inverted pots, and amongst them *Gloxinias*, which gives the house a furnished and pleasing appearance. The Ferns—chiefly *Adiantum cuneatum*—were grown under the Vines all the summer in various sized pots for decorative purposes and for cutting from, and for both purposes the atmosphere of a late vinery keeps them in good condition. *Gymnogrammas* also thrive remarkably well. The *Gloxinias* were flowered last May and rested for two months, but not dried off, and were started in August in a Cucumber house, from which they were transferred to the late vinery as they came into bloom. The blooms are not so liable to damp in an airy house at this season as they are when more moisture is present; they require less water at the roots, they last longer in bloom. It is surprising that *Gloxinias* are not more extensively grown, for they are most accommodating plants. There are few plants indeed that can, with so much certainty and so little trouble, be had in bloom twice a year. No one need be afraid to have plants in his late vinery if he be careful to warm and ventilate them properly, and water carefully. The plants being placed on inverted pots the water passes through the latter into the border without causing any dampness in the atmosphere.—R. INGLIS.

DEW IN HOTHOUSES.

WITHOUT interfering too much in the discussion between Mr. Taylor and "W. Y." I may perhaps be permitted to make a few remarks on this subject, being much interested in the matter from the same reasons that influence Mr. Taylor, who, I think, has acted rashly in staking the value of his treatise or the correctness of his ideas on the subject of dew. In the first place Mr. Taylor, judging from his language, has a wrong conception of what is meant by the "dew point," and this I gather from the following passage at page 447. Speaking of our hothouses he says, "The temperature does not decrease so rapidly as that outside owing to the presence of warming apparatus, &c., which checks radiation, so that what is generally called the dew point is not actually reached." From this it is plain that Mr. Taylor imagines the dew point in the glass house and outdoors must necessarily be the same; and further, "that what is generally called the dew point" is some fixed point of the thermometer. So far as I can make out his words will bear no other construction than this, and on both points he is in error. The dew point under a glass roof and outdoors need not necessarily be the same, and there is no occasion for the temperature of the former to fall as low as it does out of doors in order that the dew point may be "actually reached." For a subject of this kind it is best to start with a clear conception of the meaning of words and terms, and I would here explain what the "dew point" is. I quote from Wells, Le Roi, and Wilson, the best authorities on the subject. "For

any assigned temperature of the atmosphere there is a certain quantity of aqueous vapour which it is capable of holding in suspension at a given pressure. Conversely, for any assigned quantity of aqueous vapour held in suspension in the atmosphere there is a minimum temperature at which it can remain so suspended; this minimum is called the dew point."

Mr. Taylor will therefore see that the dew point varies, and that there is no such thing as a dew point "generally called" in the sense he puts it and as I apprehend him, hence his reasoning between indoor and outdoor temperatures in the passage quoted by me is fallacious. His hothouse may stand at 100° at some period of the day, at which figure much moisture will be held in suspension, and when the minimum point is reached at which that amount of moisture can be sustained the dew point will be reached whatever be the outdoor temperature; and hence in practice we often see dew formed in hothouses and elsewhere when there is none outdoors, as, for example, under the conditions named by "W. Y.," as quoted by Mr. Taylor in his third paragraph. The rest of Mr. Taylor's remarks are not quite clear to me, but if his object be to make out that "dew formation in his hothouses" is due to other laws than that under which it is formed elsewhere, then I am afraid he has set himself a task. The time when dew is generally seen on Vines under glass most plentifully is just about sunrise, when the pipes have cooled and the foliage is cool also and filled with cold sap. Dew is then produced by condensation on the well-known principle explained by "W. Y." Soon after, however, the foliage gets warmed to the temperature of the vinery, and the dew is again dissipated by evaporation, just in the same way as a cold dry slate taken into a warm house will first become wet and then dry again on the same principle. The dew point in a hothouse must necessarily be an artificial one, and the difference between the dew points indoors and out is shown by the cold slate itself, which in the warm house immediately creates a dew point in the air it comes in contact with, causing the latter to part with its moisture, while outdoors that would not have happened.—CASUAL.

SEVERAL favourable notices of Mr. W. Taylor's work on the VINES AT LONGLEAT have appeared in continental publications, especially in *L'Illustration Horticole*, the *Bulletin d'Arboriculture*, and *L'Opinion*. It has also been decided to publish a translation of it in French in the "Transactions of the Belgian Federation of Horticulturists." The culture of Vines is being greatly extended in Belgium, and to this circumstance the interest in a really practical and lucid treatise is largely due.

— THE CONSERVATORY AT MESSRS. E. G. HENDERSON AND SONS, PINE APPLE NURSERY, Maida Vale, is now exceedingly bright and attractive, a large number of *Chrysanthemums* being very tastefully arranged around the stages, and proving the value of such plants when judiciously employed for decorative purposes. The varieties are numerous of all sections, including a good selection of old and new forms. In contrast with the Palms, Ferns, and similar fine-foliage plants which occupy the stages, the bright flowers of the *Chrysanthemums* have a most pleasing appearance.

— REFERRING to "F. H. W.'s" question about DESTROYING ANTS, Mr. J. Smith, The Gardens, Oakham Park, Ripley, Surrey, writes as follows:—"I was at one time much troubled with ants in a Melon house, and was quite unable to find their nest, so I endeavoured to poison them. For a trial I took two teaspoonfuls of best brown sugar, about a tablespoonful of water, and a small piece of phosphor paste, mixing the whole well together and placed in a wineglass, which was inserted in the bed so that the top of the glass was level with the surface. The result was that the next morning the contents of the glass was one thick mass of dead ants. It is best to have a glass vessel larger at the bottom, as this will prevent them crawling out when once they

arc in the liquid. A glass fingerbowl will do admirably. Sprinkle a little on the surface near the top of the glass to first attract them."

— MR. J. THOMAS, gardener, Brockham Park, Betchworth, Surrey, asks if any of our readers can inform him if there is a GRAVEL PIT anywhere near the South-Eastern Railway, where he could obtain gravel the same in every respect as the Shirley gravel, Southampton. He will be thankful for any assistance in the matter.

— "B." writes that "in the stove at Calderstones, Liverpool, under the charge of Mr. Tunnington, is a very fine batch of CALANTHE VEITCHII. It is seldom that this grand autumn-flowering Orchid is seen grown to such perfection as in these gardens. The pseudo-bulbs are of an immense size, many of them nearly 18 inches in length and proportionately thick, producing their spikes of beautiful flowers, which are fully 4 feet in length, with over thirty expanded flowers on a spike. These, associated with other plants and a number of Calanthe vestita rubra, render the stove very effective.

— "IN the same garden URCEOLINA AUREA is producing freely in pots and pans its scapes of pendulous flowers, which are remarkable both for shape and colour. This plant is worthy of much more extensive cultivation, flowering as it does freely at this season of the year, and it will stand while in flower in the conservatory or any cool house without injury."

— MR. G. BUNYARD, The Old Nurseries, Maidstone, sends us the following additional particulars concerning the WASHINGTON APPLE we figured last week:—"The fruit of this variety which I gave to Dr. Hogg was grown in a small unheated orchard house in a pot. The tree bore about eighteen fruits, and many were much larger and finer than the sample. They were grown at Hawkhurst by Theodore Moilliett, Esq., and he kindly sent me fruit for the information of the Royal Horticultural Society's Committee. The fruit takes two distinct forms in the same way as the Beauty of Kent (one like the fruit figured, and the other like Cellini Pippin). It is an American variety, and has remarkably fine foliage; it is also said to be equally good in flavour out of doors. In habit it is rather diffuse, and with the restricted culture (in pots) bears freely, and from its growth appears likely to be prolific on the Paradise stock."

— MR. ERNEST WILKINS, Hon. Secretary of the Sutton Amateur Rose Society, has forwarded to us a small pamphlet entitled, "PRACTICAL HINTS ON HOW TO GROW ROSES." The work has been prepared by the Committee of the Society in question, with the object of disseminating in a concise form information that will be of service to the Rose-growers of the district. Instructions are given on soils, planting, mulching, pruning, exhibiting, disbudding, and manuring. In the remedies suggested for destroying insects we observe that the quantities of the ingredients are not given whereby the applications may be safe yet efficacious. The list of Roses for exhibition is taken from our columns—namely the poll of the late election, and duly acknowledged; and "Memoranda for the Months" from Canon Hole's "Book about Roses." Though the compilers of the pamphlet are not desirous of making any capital by its sale, the work can be had from Mr. Church, bookseller, Sutton, Surrey, its price to non-subscribers being 6d.

— FOR some time past there has been a good display of CHRYSANTHEMUMS IN THE ROYAL BOTANIC SOCIETY'S GARDENS, REGENT'S PARK, a long bank extending the whole length of the corridor. About four hundred plants representing all the best varieties are grown; and though no attempt is made at formal training an excellent effect is produced, the flowers being ex-

trremely abundant. A number of specimens of Bouquet Fait are particularly noteworthy, well showing the floriferous habit of this variety, as some of them are literally a mass of flowers. Incurved, Japanese, Reflexed, Anemones, and Pompons are all represented by numerous varieties.

— A CORRESPONDENT writes on November 24th:—"Mr. S. Whitfield, gardener to J. T. Cross, Esq., Beechwood, Aigburth, exhibited a fruit of PITMASTON DUCHESSE PEAR weighing 25½ ozs. This fruit was the more wonderful for its size, because it was grown on a small cordon only obtained last November. It would be interesting to know the weight of the heaviest fruit that has been grown of this variety."

— THE Secretary of the LEICESTER CHRYSANTHEMUM SHOW, referring to the note of a correspondent last week, states that the Show was not opened till three o'clock in the afternoon of Saturday the 18th inst., as many of the exhibitors are working men, and not at liberty to attend sooner. He further considers that as 150 window bills, 100 schedules, and 2000 small bills were circulated, and 500 people visited the Show, that it was not conducted in a "very quiet manner;" and adds if our correspondent had visited the Show he would have seen blooms exhibited in both the open and amateur classes with which he would have been gratified. In the open class for twelve blooms Mr. Landsell, gardener to T. Brooks, Esq., Barkby Hall; Rev. J. Bird, Walton Rectory; and Messrs. J. & H. Hickling, Loughborough, were the prizewinners. We have not space for the prize list of exhibitors in the local classes. Our correspondent visited the school on Saturday at 1.30; not on Friday, as was printed inadvertently.

— A CORRESPONDENT writes that "At a recent meeting of the Manchester Cryptogamic Society Mr. W. Foster exhibited a remarkable variety of POLYPODIUM PHEGopteris, which he had found at Patterdale last August. The pinnae of the fronds were cut up into long narrow lobes similar to Polypodium vulgare var. elegantissimum, and if the characters prove constant the variety will be a valuable one to cultivators of British Ferns."

— WRITING in reference to CHRYSANTHEMUM SŒUR MELANIE, Mr. C. Orchard, gardener to J. Galsworthy, Esq., Coombe Leigh, observes:—"I am glad to see the above variety is attracting notice, as I have recommended it for decorative purposes several years now. I first became acquainted with it in the spring of 1873. Through a little article of mine on the culture of the Chrysanthemum in a contemporary a lady living at Rhyl, South Wales, kindly forwarded me some rooted cuttings for trial. It appeared to be a great favourite in her neighbourhood. She had then grown it three years, but had not been able to find the name except in one trade catalogue, and was only to be procured in Gloucestershire. Mr. C. Turner of Slough was the first that I know to bring it out in London amongst a group of plants that he exhibited two or three years ago at the Royal Horticultural Society's meeting at South Kensington, when it was favourably noticed by the press. Last autumn the late Mr. Faulkner, gardener at Woolton Hall near Liverpool, sent me two or three cuttings of one he grew under the name of Souvenir de Melange, but which he said was synonymous with Sœur Melanie, and I have proved it is so this season by growing them side by side and giving them the same treatment. I have always described it as a small Elaine, and have found it best grown as bushes and partly disbudded—i.e., pinch off the small side flower buds and leave from three to five on a shoot. Perhaps Mr. Bardney will tell us how long he has been acquainted with it."

— IN reference to the YORK HORTICULTURAL FETE, to be held in June, 1883, it is stated that "the Exhibition will celebrate a quarter of a century's work in the promotion of horticulture by the Committee of this Society, it having been established in 1859,

and has always been in a prosperous condition. During that period it has paid upwards of £10,000 in prizes, and has divided upwards of £700 amongst the charities of York. A circular is now being issued by the Committee to the leading members of the nursery and seed trade of the country, inviting special aid in the way of extra prizes to supplement the most liberal schedule annually issued by the Committee. Vegetables have hitherto had but little notice here, so that an excellent opportunity is offered for extra prizes in this class. The Committee is anxious to make this twenty-fifth Exhibition the most remarkable the Society has yet held, and therefore earnestly hope this appeal will be liberally responded to."

— It is estimated that the POTATO CROP OF AMERICA this year will amount to at least 150,000,000 bushels, or an average of 92 per cent. against 72 per cent. last year, on the basis of a general average of 100.

— IN an article on parasitic plants in *Vick's American Magazine* the following particulars are given of *MONOTROPA UNIFLORA*, the Corpse Plant, a peculiar member of the Heath family:—

"This is not rare in Cincinnati, but always attracts the attention of the wanderer and frequenter of woods on account of its beauty. Though not a genuine parasite, it perhaps attaches itself to the roots of various species of trees, and, drawing its nourishment from them for a time, afterwards lives on the material furnished by decaying vegetable matter. Though very innocuous in appearance, a bad story has been told of it. It is said to be poisonous. A lady when handling the fresh plant had some of the juice driven on her lips. These being chapped at the time, produced sores like the poisoning of the *Rhus toxicodendron*. There is another side to the story, for another writer says that the expressed juice taken internally is highly recommended for nervous irritation and epilepsy, and, applied externally, is good for ophthalmia. He gives an instance in which in four weeks a very severe inflammation of the eyes was cured by applying the fresh juice of the stem of the plant to the inflamed surfaces. This plant is a remarkable instance of wide distribution, as it is found nearly throughout the United States and British America and in Mexico, and it even extends across the Pacific to Japan and India, and is another one of the resemblances between the floras of the two continents."

ADIANTUM CUNEATUM.

AS this is not only one of the most useful of Ferns but a general favourite, I have thought that perhaps a few hints as to its cultivation may prove to be useful to some of your numerous readers.

As many people seem to have an idea that to grow the Maidenhair Fern, as the above is commonly called, a very warm temperature is essential to its well-being. The idea is also very prevalent, too, that it, together with other Ferns, cannot be grown successfully without peat, and as everyone has not peat to hand, and does not feel inclined to purchase any, it is not cultivated so much as it otherwise would be. Nothing can be more erroneous than such ideas. Anyone in possession of a pit or any other glass structure, with the means of keeping out frost, may grow the Maidenhair Fern as successfully as the one who has a much higher temperature and peat soil at command.

It is not very particular as to soil. Three parts loam to one of leaf soil, with a slight sprinkling of silver or any other sand, I find suits it well. The secret, if there is one, of growing it to perfection is good drainage and a plentiful supply of water when growing. It cannot, if it is in a healthy growing state and the drainage good, be too liberally supplied with water.

During its season of growth, and until, in fact, the fronds are fully matured, it should be shaded with some light material from the direct rays of the sun. When, however, it has completed its growth and the fronds fully matured it should be gradually inured to the sun and kept as cool as possible.

With such treatment as the above it can only be grown successfully, and it is far more useful for room-decoration, bouquet-making, &c., the fronds having a better texture, consequently possessing better keeping qualities for either purpose.—
J. RICHARDSON, *Calverton Hall, Notts.*

THE WHITE DAFFODIL (*NARCISSUS ALBICANS*).

(SEE PAGE 505).

OF all the *Narcissus* in our gardens there are none of more delicate beauty, none having more exquisite grace of form, than

this species, which was called *N. albicans* by old Haworth, but which was introduced to English gardens, and had been carefully cultivated and preserved in them long, long before his time. Speaking broadly, our climate is just a little too rude to this dainty stranger "from beyond the seas," as Gerard hath it: and to my mind it represents those fair southern women who, as the old chronicles tell us, were brought to England as wives by some of the early crusaders, and who "languished and dyde notwithstanding the gret love and mucche esteame in the which they were helde by their lordes." Our stern northern winters were too bitter and scathing for them, and it is even so in some sort of this "fair floure," which lives rather than luxuriates, except especial care be given to it, in our gardens at home. It deserves, however, all the care that one may well bestow upon one of the very choicest gems of the beautiful race to which it belongs. No *Narcissus* can well be fairer than is this one on rich, warm, sandy soils near the sea—indeed, many a flower far less worthy is afforded the shelter of a glass roof and careful pot culture, and so treated this Daffodil in all its sweet pale beauty yields the palm to no other half-hardy bulbous flower.—*DUBLINENSIS.*

CHRYSANTHEMUM SHOWS.

BRIGHTON AQUARIUM.—NOVEMBER 21ST, 22ND, AND 23RD.

LAST year the Brighton Aquarium Company held their first Chrysanthemum Show, the success of which induced a repetition this year, and a very pretty show was provided. There was certainly a very decided improvement in all classes as compared with last year, the plants being better in every respect, while the cut blooms in some of the classes were indeed excellent, the large Anemone-flowered section being the finest we have seen anywhere exhibited this season. The Company also made a further venture this year in adding classes for fruit; but beyond that for black Grapes, which was well filled, nothing special can be said. This, no doubt, must be attributed to the general scarcity of hardy fruits this autumn.

The plants and cut blooms were arranged in the Music Hall. Adjoining this, and in continuity of it, is a most artistic fernery composed of massive rockwork, in the recesses of which are growing luxuriantly choice Ferns, Lycopodiums, and Mosses; while from the upper portion two or three streamlets appear winding their way from rock to rock, and these, uniting about half way down, form a waterfall of such proportions to be in keeping with the *détour* of the work.

On entering the Exhibition from the central hall the effect was very pleasing. In the front ground were bold groups of Chrysanthemums, Poinsettias, Heaths, &c., and in the distance the fernery formed a grand background. The schedule of prizes was in two divisions, the first of which was open to all exhibitors, and the second for gentlemen's gardeners and amateurs only. In the class for six standards, distinct varieties, Mr. W. Balchin, Hassock's Gate Nurseries and Western Road, Brighton, obtained first honours, followed by Mr. Jas. Turner, gardener to Major Way, Wick Hall, Hove. For six dwarf-trained, Mr. Spottiswoode, gardener to G. Duddell, Esq., Brighton, was far ahead of other exhibitors with a fine collection. Messrs. Balchin and Meachin, gardener to W. Armstrong, Esq., Withdean, Brighton, were second and third. For six pyramids the first prize was awarded to Mr. W. Balchin, amongst which Peter the Great and Fair Maid of Guernsey were very good; while the first prize for six Pompons was justly awarded to Mr. R. Miller, Southdown Nurseries, Shoreham.

In the class for twenty-four incurved blooms the first prize was easily won by Mr. J. Ridout, gardener to T. B. Haywood, Esq., Woodhatch Lodge, Reigate, with a stand of grand blooms; Mr. Meachin and Mr. Lipscombe, gardener to Mrs. Padwick, Horsham, took second and third places in the order named. With twelve incurved Mr. Ridout again obtained first honours, being followed by Mr. Wm. Jupp, gardener to J. Boulton, Esq., Eastbourne, second, and Mr. J. Wyatt, gardener to H. Padwick, Esq., Horsham, third. For twelve Japanese, distinct, Messrs. Ridout, Wyatt, and Jupp were the successful competitors. For twelve large Anemone blooms, Mr. Ridout and Mr. F. Hyde, gardener to R. Bacon, Esq., Keymer, were the winners.

In the division for gentlemen's gardeners and amateurs only, for four standard large-flowered varieties, distinct, Messrs. F. Hyde, Spottiswoode, and Turner were first, second, and third respectively; while for four dwarf-trained Mr. Spottiswoode took first; also for four standard Pompons and with one single specimen Mr. Spottiswoode was again to the fore. For four pyramid and single specimen Pompons Mr. Turner took the lead, followed by Messrs. Spottiswoode and Hyde. For twenty-four large-flowered incurved Messrs. J. Wyatt, A. Russell, Lewis, and W. Cornwell, gardener to F. Borchard, Esq., Uckfield. Twelve incurved the first was awarded to C. Goode, gardener to H. Stone, Esq., Eastcote; C. Fowler, gardener to E. R. Hall, Esq., Henfield, second; and J. Wyatt third. For twelve Japanese J. Wyatt, Jupp, and Harris, gardener to C. S. Eversfield, Esq., Denne Park, Horsham, won in the order named; and for six Japanese Wyatt, Harris, and C. Funnell, gardener to J. Thorne, Esq., Southove Grange, Lewes, were first, second, and third.

For six plants suitable for table decoration in or out of bloom the first prize was awarded to Mr. McBean, Cocksbridge, Lewes; though the second-prize collection shown by Mr. Balchin was in the opinion

of many far before the first-prize lot, and comprised a pair of beautifully coloured Crotons, two highly coloured Dracaenas, and elegant plants of Cocos Weddelliana; Mr. E. Spary, Queen's Grape Nurseries, Brighton, third. For six berried plants in pots Mr. Balchin was first and Mr. Spary second; and for six Poinsettias Messrs. Charlton, Summerwell Nurseries, Tunbridge Wells, were first with a grand six, having bracts of immense size and splendidly coloured; they were followed by Mr. Balchin with smaller plants carrying their foliage down to the pots; and Mr. Spary was placed third.

For six *Erica hyemalis* Mr. Balchin was an easy first; and in the fruit classes open to all that for three bunches of black Grapes was well contested, not an inferior exhibit in the class. The first prize was, after a very close scrutiny, awarded to Mr. J. Ridout; and the second to Mr. R. Holmes, gardener to T. Wallis, Esq., Sister House, Clapham Common. The positions of these two were thus reversed from what they were the week previously at the Westminster Aquarium. They showed in both instances bunches of superior quality and finish. Mr. Balchin secured the third prize in this class. Mr. Apted, Broadwater, took the first for three neat and well-ripened bunches of Muscat of Alexandria. Mr. F. Hyde was first with six good dishes of dessert Apples, and won the same honour for six dishes of kitchen Apples; while Mr. R. Fowler was awarded first for an extra fine dish of stewing Pears, Uvedale's St. Germain's. A very handsome group of Poinsettias was contributed by Messrs. Charlton of Tunbridge Wells, who make this one of their specialities, and miscellaneous plants by Mr. Balchin and Mr. Spary; Mr. Balchin exhibiting amongst other fine plants a grand variety and superb specimen of *Cypripedium insigne*.

BIRMINGHAM.—NOVEMBER 22ND.

We have seen both larger and better shows than this the twenty-second autumn Exhibition, held in the Metropolis of the Midlands, yet the fine Town Hall was rendered attractive with Chrysanthemums, Primulas, and other winter flowers. There was also a creditable display of fruit, while several miscellaneous collections of plants and flowers contributed materially to the success of the Exhibition.

The principal class was for nine specimen Chrysanthemums, the first prize being a silver cup. This was well won by that good cultivator Mr. Dyer, gardener to Walter Showell, Esq., Edgbaston, with symmetrical plants about 2 feet high and 3½ feet in diameter, fresh in foliage, and with blooms of good average quality, especially Mrs. Rundle, George Glenny, Lady Slade, and John Salter. Mr. Newell, gardener to L. Hayman, Esq., Edgbaston, followed with smaller plants. These exhibitors occupied the same relative positions in the class for six Pompons, the plants being 4 feet in diameter and about half that in height, not closely trained, but free, yet tolerably close bushes, no stakes being visible. For a single specimen Pompon the positions of these exhibitors were reversed, both staging well. In the class for six large-flowered specimens Mr. Crook, Calthorpe Road, Edgbaston, was the foremost exhibitor, staging the best plants in the Show, followed somewhat closely by Messrs. Dyer and Padbury, gardener to R. Yates, Esq., Gravelly Hill. Mr. Dyer was also first in the single specimen incurved class with an admirable specimen of Mrs. Dixon 4 feet in diameter, very neat, and containing good blooms. The only Japanese Chrysanthemum noticeable was the first-prize specimen of Elaine with twelve fine blooms, exhibited by Mr. Shingler. Groups of "natural grown" Chrysanthemums were disappointing. By far the finest plants of the year for conservatory decoration were those exhibited by Mr. Allen the previous day at Manchester, and referred to last week. The production of such plants should be encouraged, as they are valuable for home decoration, and have an imposing effect in an exhibition.

In the classes for cut blooms the competition was not great nor the stands good as compared with the blooms at the London, Liverpool, and Southampton Shows. Mr. Comfort won the silver cup in the class for eighteen incurved varieties, and also the first prize in the class for twelve flowers; and although this was the best stand in the Show, it would not have been placed at the leading exhibitions. The other prizewinners in these classes were Messrs. Shingler, Tonks, and Padbury. Creditable stands of Japanese varieties were exhibited by Messrs. Shingler and Comfort, who obtained the prizes, the best blooms in the stands being fairly good. The season has evidently not been propitious for Chrysanthemums in this district, as very few of the blooms staged were of high-class character.

Of Primulas there was a great display, Messrs. Stacey, Caldicott, Burdon, Price, and Doughty being the prizewinners, somewhat in the order named in the classes for single varieties. Some of the plants, of the first two cultivators especially, were extremely fine, nearly 2 feet in diameter, with massive pyramids of flowers. Two varieties raised by Mr. Tomkins—Princess Louise, white, very fine, and Marquis of Lorne, red, were prominent by their excellence; but the richest Primula in the Show was Swanley Red. Swanley White (Fern-leaved), and Lilacina, exhibited by Mr. Cannell, also attracted considerable attention as highly meritorious varieties. A variety submitted as new (but not by Mr. Cannell), and prominently named Sir Beauchamp Seymour, was apparently identical with Swanley Red. The best double Primulas were exhibited by Rev. E. H. Kittoe, Boldmere Rectory; these were Lord Beaconsfield and Marchioness of Exeter, two good varieties, which have probably never been seen in finer condition. Mr. Tomkins also staged excellent plants. Mr. Doughty, gardener to H. H. Hill, Esq., Edgbaston, was the most

successful exhibitor of Poinsettias, the plants ranging from 18 inches to 2 feet high, with half a dozen good heads. The best stove and greenhouse plants were exhibited by Mr. Stacey, gardener to S. Eaton, Esq., Harborne; and Mr. Jones, gardener to E. C. Matthews, Esq., the former having excellent foliage plants, and the latter *Erica hyemalis* 3 feet in diameter, and *Pancreatium fragrans* very good. Mr. Newell won the chief prize for table plants, and Mr. Dyer for nine ornamental-foliaged plants in 8-inch pots; they consisted chiefly of Palms, Dracaenas, and Ferns, and were in excellent condition.

The display of fruit was a prominent feature of the Exhibition, Grapes and Apples being especially good. In the class for three bunches of black Grapes Mr. Comfort, gardener to G. N. Everett, Esq., Knowle Hall, was deservedly first with full handsome bunches and good berries of Gros Guillaume; Mr. Gilman, gardener to the Earl of Shrewsbury, Ingestre Hall, being an excellent second with medium bunches and fine and well-finished berries of Alicante; Mr. Clark, gardener to Lady Edwardes, Ashbourne Hall, being a good third with the same variety. In the class for Muscats Mr. Gilman was far ahead with superb examples, large in berry and beautifully finished. He was also first in the any other white class with good bunches of Trebbiano, followed closely by Mr. Comfort with White Nice. In the single-bunch classes the same exhibitors took the chief prizes, both exhibiting well. Mr. Freeman, gardener to Z. Walker, Esq., Hall Green, staged the best Pine, a Black Jamaica, weighing 5 or 6 lbs., and a handsome fruit.

Apples were numerous and good, Mr. Gardiner, gardener to S. E. Shirley, Esq., being decidedly the premier exhibitor, securing the first prizes in the gardeners' class for six dishes, the open class for twelve dishes, and Messrs. Cranstons' prize also for twelve dishes. Mr. Bannister, Bristol, was a close second in the last-named class, and Messrs. Mitchinson and Gilman also exhibited well. In the single-dish class Mr. Newell was first with Warner's King, Mr. Gilman being second with the same variety, and Mr. Faulkner, gardener to J. H. Pearson, Esq., Handsworth, with Lord Suffield. The best kitchen Apples staged besides those named were Roundway, Magnum Bonum (highly recommended by Mr. Gardiner), Belle Dubois, Alfriston, Blenheim Pippin, and Yorkshire Greening. The best dessert—Margil, Cox's Orange Pippin, Ribston Pippin, Wyken Pippin, Adam's Pearmain, and Scarlet Pearmain. The prizes for Pears were won by Messrs. Gardiner and Clissold. Some excellent dishes of Mushrooms were staged, Mr. Mitchinson securing the chief prize with splendid produce.

Bouquets were neat and good, the first-prize example in the gardeners' class from Mr. Jones containing *Eucharis*, *Calanthe vestita*, *Bouvardias*, *Pleiones*, and *Gauze Fern*. In the open class Messrs. Pope and Jones were first with a free and good arrangement of choice flowers, Mr. Price following in both classes; but the best bouquet in the Show, though not in competition, was undoubtedly made by Mr. Spinks (Mr. Hans Niemand), and consisted of *Camellias*, *Orchids* (including white *Masdevallias*), pips of pink *Rhododendron* Princess of Wales, *Roman Hyacinths*, and three flowers of the "Blue Marguerite," *Agatheæ cœlestis*, and *Ferns*. For this a certificate of merit was awarded, a similar mark of approval being granted to the same exhibitor for a group of plants showing excellence of culture and taste in arrangement, the white *Cyclamens* being of a very superior strain. Certificates were also worthily accorded to Messrs. Cannell & Sons, Swanley, for one of the most splendid collections of *Zonal Pelargoniums* ever seen at any show, and a most attractive stand of *Salvias*, the scarlet and white *Mons. Issanchon* attracting much attention; to Messrs. Perkins of Coventry for charming wreaths and crosses; and to Mr. Holmes of Lichfield for an excellent group of plants. Messrs. Pope & Son had a very attractive stand of *Zonal Pelargoniums*, very small plants, with fine trusses; and Messrs. Richard Smith & Sons contributed a diversified group of variegated shrubs and Conifers. The Show was admirably managed by Mr. Redfern, the Secretary, Mr. Latham, and other members of the Committee; and although the day was not fine there was a large attendance of visitors.

BATH.—NOVEMBER 22ND.

A correspondent sends us the following extract from the *Bath Chronicle*:—

Two years ago, after having ceased to be held for nearly half a century, the exhibition of Chrysanthemums, Primulas, stove and greenhouse plants, cut flowers and fruit, was revived by that energetic local attraction association—the Bath Floral Fête and Band Committee. It was then held at the Pump Room, and was such a success that it was decided not only that a second show should be held, but that more space must be obtained for the display of the exhibits and the accommodation of the large number of visitors. Consequently last year the Assembly Rooms were brought into requisition, and the Show proved a most satisfactory one. The third Show was held at the Guildhall, it being impossible to secure the Assembly Rooms. The Show this year was a good one, and the event may now be considered as well established, and one that we may look forward to with pleasure each succeeding November. The Exhibition was very much better than the two previous Shows. The entries were very numerous and varied, and much difficulty had been experienced, in the small space at command, in displaying the exhibits to the best advantage. The banqueting room, council chamber, and even the vestibule of the Guildhall, were all metamorphosed into so many crowded green-

houses. Most advantage was taken of every available space; and notwithstanding the difficulties of want of room, &c., the plants were tastefully and ingeniously arranged, with a happy combination of colours, while due regard had been paid as much as possible to the requirements of the spectators. The Chrysanthemums were, as a whole, of good quality, notwithstanding the fact that the season has been by no means a particularly favourable one. Upon entering the Guildhall the plant in the vestibule that at once attracted the eye of the visitor was Peter the Great, a magnificent plant shown by Mr. R. B. Cater of this city. This specimen measured 6 feet in diameter and 18 feet in circumference. It was almost apparent to all that this plant was destined to take premier position, and so it proved. Mr. Cater was also a successful exhibitor in other classes. Mr. Thomas Jolly of Oldfield Park took first position in Class 6, and won several other prizes with his fine exhibits. Mr. John Bradner of Bristol was again to the front in many classes. His collection of six plants in magnificent bloom took first honours, thus repeating his success with the same plants at Devizes on Tuesday. The groups of Chrysanthemums were of exceptionally good quality. Primulas were grand, and those best competent to judge considered them as near perfection as any to be found this season. The premier position with this particular plant was taken by Mr. G. Garraway of Swainswick with a fine lot of highly coloured specimens. The cut blooms, bouquets, and outdoor foliage received considerable attention, and deservedly so, from the visitors to the Show. These exhibits were arranged on each side of the council chamber. Among the specialities may be mentioned the blooms of Pansies and Carnations which Mr. H. Hooper of Widcombe Hill exhibited, they being of particularly fine quality. Handsome groups of greenhouse plants were exhibited at each end of the banqueting room by Messrs. Cooling & Son and Mr. Drummond, who in this class took first and second positions in the prize list respectively. On the middle table in the same room were arranged many choice specimens of fruit. The Grapes were the principal feature, the Duke of Beaufort (gardener, Mr. Rutland) and Mr. James Chaffin again keenly contesting for the premier place. His Grace took the first prize with four bunches, consisting two of Muscats and two of Black Alicante. Closely following and taking the second prize were two bunches of Gros Colman and two of Black Alicante shown by Mr. Chaffin. In the class for three bunches of black Grapes Mr. Chaffin showed some well-ripened bunches, which took the first prize, the Duke of Beaufort being next with a lot that were larger, but hardly so well coloured. Mrs. Mellor of Westbury-on-Trym secured the first place for Muscats with some well-finished and highly coloured specimens. The Duke of Beaufort's bunches took the second prize. Apples and Pears were shown in abundance, and of the first quality considering the unfavourableness of the season for these particular fruits.

NORTHAMPTON.—NOVEMBER 22ND AND 23RD.

For eleven years the above Society has been encouraging the cultivation and improvement of the Chrysanthemum, and their efforts have been very successful. On this occasion the spacious Corn Exchange was filled with plants, cut blooms, Primulas, dinner-table decorations, fruit, and vegetables. The general quality of the various productions was satisfactory throughout, and from the taste shown in the arrangements the effect produced was remarkably good. Much credit is therefore due to Mr. Draper, the Hon. Secretary, Messrs. Gulliver, Archer, and Starmer, who worked hard to bring about such a pleasing effect.

The schedule comprised sixty-five classes, four silver cups as prizes of the respective value of five, three, and two guineas, with substantial money prizes as second and third prizes. For six large-flowering plants, for which one of these cups was offered, there were four competitors, the plants of medium size, foliage robust, and well furnished down to the rim of the pots. The plants were trained in free style, somewhat like Roses in pots, which makes the Chrysanthemum look more graceful than when the plants have been subjected to very rigid training. The first-prize collection from Mr. S. Ingram, gardener to W. Butlin, Esq., Duston House, was remarkably good both in foliage and flower. Mr. Woods, gardener to J. Phipps, Esq., Cliftonville, gained second honours, and T. Sheppard, Esq., J.P., the third.

It was hoped by the Executive that the valuable silver cup offered for twenty-four cut blooms would have induced some of the metropolitan growers to contest for it; but as no one outside Northampton entered, the contest lay between two local growers—an amateur (Mr. Fowkes), and Mr. Walter, gardener to Roger Eykyn, Esq. It is to be regretted that no other growers competed, for the cup was a handsome one, and the Executive deserved more exhibitors for such a valuable prize. Another year, if a cup is offered of the same value, there will probably be growers from beyond the radius of Northampton competing for it. However, the two collections staged were extremely good; that to which the first prize was awarded was remarkably even, each bloom being of fair size, neat, and of good form. They comprised such well-known varieties as Queen of England, Golden Empress of India, John Salter, and Princess Teck, and which have been repeatedly named in your reports of other exhibitions. Mr. Walter's collection had a few larger flowers than was in the cup stand, but he had several inferior, and consequently gained the second place. Both collections were remarkably fresh.

For four plants, large-flowering, open only to amateurs, six or

seven collections were staged, some of them highly creditable. Especially was this the case with the collection to which the cup was awarded to Mr. F. W. Henman, Great Houghton; and as we were informed that the grower was a shoemaker, and that he grew and bloomed the whole of his plants without the aid of any glass, we cannot but commend him for the style in which they were finished. The plants were neatly trained, and many of them bore good flowers. We were informed that the way he bloomed them was as follows: On all favourable occasions the plants were stood out of doors by day and brought in again by night, and in bad weather they were placed in the rooms of the house. Mr. Henman was a large prizetaker, and all his plants were grown in this way. Plants of Lady Harding, Mr. Howe, and Chevalier Domage were very creditable examples, and gained first honours in a collection of four single specimens, or for a single reflexed flower. Mr. R. Sear, Cowper Street, and Mr. J. Arnsby, Lower Thrift Street, were other successful amateur growers. Several fairly good plants of Japanese Chrysanthemums were exhibited, both in the classes for six and four; Mr. Green, gardener to Mr. Shoosmith, Mr. Woods, and Mr. Crisp sharing the principal honours.

The cut bloom classes throughout were well filled, and the winning stands contained good flowers; but there were some which did not come up to the customary standard. Especially was this the case in the Japanese forms, for which good prizes were awarded; but as this variety is yearly becoming a favourite we look forward for better and more even collections here another season.

Primulas were extremely well shown, as also were the fruit and vegetables.

WIMBLEDON.—NOVEMBER 23RD.

The annual autumn Exhibition of this Society was held at the Lecture Hall, and both as regards the number and quality of exhibits there was an encouraging improvement on former shows. The hall was well filled, a table down the centre bearing the cut blooms, which numbered about four hundred. These may be said to have been the great feature of the Exhibition. The competition in the various classes for incurved and Japanese blooms was very strong, nine competitors coming forward with twelve incurved and eighteen Japanese respectively. The quality of the flowers shown may be imagined when we state that Mr. C. Gibson, gardener to J. Wormald, Esq., Morden Park, who has been almost as invincible as Mr. Harding, had to take second place for twelve incurved; Mr. Woodgate, gardener to Mrs. Hammersley, Warren House, Kingston Hill, taking first prize with a fine even stand, Alfred Salter, Lord Wolseley (a sport from Prince Alfred), and Princess of Wales being particularly neat. Mr. Strong secured the third prize, his stand being only a point inferior to Mr. Gibson's. For twelve Japanese Mr. E. Beckett, gardener to J. P. Currie, Esq., Sandown House, Esher, was an easy first with blooms of superb quality, his Triomphe de la Rue de Chatelet, Boule d'Or, Thunberg, and Comte de Germany were especially fine. Mr. Gibson, who was second, had grand flowers, but as may be imagined his best blooms were past. Mr. Strong was third, his blooms being very fresh but smaller than the preceding. Mr. Strong, Mr. Woodgate, and Messrs. Mahood & Son, Windsor Nurseries, Putney, were placed in the order named for six incurved blooms; and for six Japanese Mr. E. Beckett was again first, Mr. Strong and Messrs. Mahood & Son on this occasion running him very close.

There were three entries for groups, Mr. Newell, gardener to E. Saunders, Esq., Fairlawn, Parkside, Wimbledon, being adjudged the premier award for a tastefully arranged and well-flowered group. Messrs. Mahood & Son and Mr. G. Stevens, St. John's Nursery, Putney, were second and third, their blooms being not nearly so fresh as those in the first-prize group. Amateurs' groups were well shown. Mr. G. Dove, Hartfield Road, and Mr. E. Collins, Pelham Road, Wimbledon, taking first and second places. There were several entries for six cut blooms in the amateurs' division; Mr. H. A. Rolt, Maud Villas, Mr. E. Collins, and Mr. A. Moore, High Street, being placed in the order named.

Among the groups not for competition, Mr. J. Lyne, gardener to A. Schlusser, Esq., Belvedere, had a grand display on the centre of the platform, about thirty plants of Calanthes in the best health being included in the group. Mr. Lyne also sent six specimen Pompons, which were much admired. In the class for three trained specimens, large-flowering varieties, Mr. J. Bentley, gardener to Sir T. Gabriel, Edgecombe Hill, was first with creditable examples of Peter the Great, Dr. Sharpe, and John Salter. Messrs. Mahood and Son were second (a pyramid of Mrs. G. Rundle being cleverly trained) and Mr. G. Stevens third. Mr. Wood, gardener to S. Nicol, Esq., Curry Hill, was first for Primulas; Mr. Beckett second; and Mr. Elliott, gardener to the Rev. C. J. Wynne, Wimbledon School, third. Mr. Beckett was also first for table plants.

Among the miscellaneous exhibits were two fine groups shown by Mr. D. S. Thomson, The Nursery, Wimbledon, and Mr. Runnacles, gardener to Mrs. Schuster, Cannizaro; fine bunches of Grapes and a collection of fruit by Mr. Alderman, gardener to C. Czarnikow, Esq., Mitcham; six Coleus, six double Primulas, and a model flower garden by Mr. Logan, florist, Copse Hill; boxes of large and small-flowered Anemone Chrysanthemums by Mr. Gibson; blooms of Lord Wolseley, the bronze sport from Prince Alfred, by Mr. Orchard, Coombe Leigh; a stand of large-flowered Anemones by the same exhibitor; a stand of Japanese blooms by Mr. Beckett; a collection of Apples by Mr.

Haines, gardener to Mrs. Jones, Clock House, West Hill; a box of Pears and collection of fruit by Mr. Goodyear, gardener to W. Vant, Esq., Grove House; a stand of twenty-four "undressed" incurved blooms by Mr. G. Harding, gardener to T. D. Galpin, Esq., Putney Heath; and a model bee hive by Mr. Smith, Cyprus Cottage, Wimbledon.

STAINES.—NOVEMBER 23RD.

Presumably with a similar object in view, and with similar chances of success to the Walton and Weybridge Society, a Chrysanthemum Society has this year been formed on the Middlesex side of the Thames, embracing the districts of Staines, Egham, Ashford, and Laleham, and the efforts of the projectors have been so far successful that the first Exhibition, held on Thursday last in the Staines Town Hall proved, though of moderate extent, sufficiently satisfactory to encourage hopes of considerable progress in future years. H.R.H. Prince Christian accords the Society his patronage as President; the Vice-Presidents include more than a dozen of the leading gentlemen in the neighbourhood, while a strong and practical Committee, with the courteous and experienced Secretary, Mr. T. J. Rawlings, evidently intend rendering their show a credit to the district. The first exhibition of a society like this can be considered as little more than an experiment, and it is only when two or three have been held that the capabilities of the growers can be fully perceived and provided for accordingly in the schedule. Some little time, too, is needed to give the local growers confidence, and induce those who have hitherto been non-exhibitors to enter the lists with their neighbours and test the respective merits of their productions side by side. It was not, therefore, to be expected that the competition would be very keen, especially as the prizes were moderate—indeed, when the schedule was first issued the amount of the prizes could only be stated in a few classes. Though, however, the contributors were not so numerous as they may be expected to be another year, yet the plants and blooms were sufficient to fill, without crowding, the commodious hall devoted to the Show, and these being arranged with excellent taste constituted an effective display.

The groups of Chrysanthemums formed the leading feature, eight being placed round the hall, four on each side. The class was provided for, a group arranged for effect in a half-circular space 10 feet by 5 feet, the quality of the plants and blooms, as well as the style of arrangement, being taken into consideration. Mr. Thatcher, gardener to H. L. Bunnell, Esq., Thorpe, secured the chief honours with a most meritorious group both in arrangement and in the quality of the plants and blooms composing it. An even sloping bank was formed, the blooms being abundant, large, and the colours clear and bright. Dwarf healthy plants formed the margin and imparted a suitable finish to the appearance. Mr. Hutchings, gardener to E. H. Ashby, Esq., Westbourne House, Staines, followed with a free graceful arrangement, his plants being most profusely flowered, especially prominent being *Sœur Melanie* and *Julie Lagravère* in fine condition. Mr. H. Craile, gardener to G. F. Yeo, Esq., The Hythe, Staines, took the third position, having fresh healthy plants, and fairly well flowered. Mr. H. Jemmett, gardener to H. C. Paice, Esq., Egham, and Mr. G. Riddick, gardener to W. Paice, Esq., The Limes, Egham, were awarded the fourth and fifth prizes. Two handsome groups not in competition at the sides of the proscenium were also noteworthy, both containing remarkably well grown plants. That from Mr. McNichol, gardener to W. Burchell, Esq., Laleham, comprised freely flowered examples of Chrysanthemums, with a pretty margin of Roman Hyacinths and Selaginellas alternately. Mr. Sims, gardener to W. B. Eastwood, Esq., had a greater diversity of plants in his group, including besides Chrysanthemums, well-grown Bouvardias and Poinsettias, with Palms, Ferns, and similar fine-foliage plants.

In other classes for plants several collections of vigorous neatly trained specimens were staged. Mr. E. J. Sims, gardener to J. N. Pimm, Esq., The Mansion, Staines, had the best four standards, most creditable examples of *Fair Maid of Guernsey*, *St. Patrick*, *Venus*, and *Refulgence*, the heads even and the blooms good. Mr. Craile followed with smaller but praiseworthy specimens. For a pair of standards Mr. J. Cox, gardener to J. F. Mieville, Esq., Duneroft, Staines, won the premier prize with *Mrs. G. Rundle* and *G. Glenny*, neat, healthy, and well flowered; Mr. Jemmett taking the second place. For the best single specimen standard Mr. Thatcher took the lead with *G. Glenny* in fair condition, Mr. Riddick following closely with *Her Majesty*. Mr. Sims had a neat pair of standard Pompons, *St. Michael* and *Mr. Murray* being the varieties.

Cut blooms were fairly represented, as, though they were not large, they were mostly neat and compact, fresh and bright. In the open class for twenty-four incurved Mr. Thatcher secured the chief prize with a creditable collection; Mr. Gray, gardener to Griffith Thomas, Esq., Park House, Englefield Green, taking a similar position in the district class. Mr. Hutchings exhibited the best twenty-four Japanese, and Mr. Riddick the best twelve, all good blooms. In other classes Messrs. Cox, Thatcher, Hutchings, Sims, and Riddick were the prizetakers.

Miscellaneous plants comprised some good examples of Zonal Pelargoniums, Primulas—the first-prize collection of the former from Mr. Sims being extremely healthy—*Vesuvius*, *Henry Jacoby*, and *Wonderful* being represented by vigorous specimens flowering most profusely. Primulas and Cyclamens were well shown by Messrs. Thatcher, Riddick, and Jemmett. *Mignonette* was also largely shown, the leading collections from Messrs. Riddick and Spring-

thorpe comprising neat specimens, healthy, compact, and freely flowered.

Fruit, including Grapes, Apples, and Pears, were contributed by Messrs. W. Mareham, gardener to the Countess de Morella, Virginia Water, Sims, Hutchings, and Thatcher, who won the chief prizes. Vegetables were also fairly represented, Messrs. Springthorpe, Belcher, and Thatcher securing the prizes.

Messrs. Smith & Larke, Kensington, contributed some ornamental china and glass stands filled with flowers, and tastefully arranged on tables at each end of the hall.

THE LIVERPOOL HORTICULTURAL ASSOCIATION'S SHOW.

FRIDAY, NOVEMBER 24TH.

It was unfortunate for the above Society in many respects that the Exhibition had to be postponed for a few days on account of the Assizes. It was very disappointing to several strangers who travelled long distances to see the Show on Tuesday and returned without seeing it, while many exhibitors were much inconvenienced by the alteration of the date. Notwithstanding this drawback, however, and the drenching rain which fell at intervals during the day, the attendance was good, and the Show, as far as the exhibits were concerned, was a great success, and undoubtedly superior to the two previous shows held by the Society. There was a falling-off in some of the classes, especially those devoted to stove and greenhouse plants, although the Crotons staged by Mr. W. Mease were wonderful examples of cultivation. The Chrysanthemum plants were not so good as usual, but the incurved blooms were magnificent. The blooms of Japanese varieties showed a marked improvement in both quality and quantity over past years. Some one thousand blooms were entered for competition, and out of that number 886 were staged with scarcely a bad flower amongst the whole.

Chrysanthemums in Pots.—These on the whole were scarcely so fine as on previous occasions. This refers principally to the closely trained large-flowering varieties, but the Pompons shown by Mr. C. Finnigan were superb, and the same applies to the pyramids. In the class for six large-flowering kinds Mr. C. Finnigan, gardener to W. Burnyeat, Esq., Huyton, was the chief prizewinner with *Mrs. Dixon*, *Prince of Wales*, *George Glenny*, *Hero of Stoke Newington*, and *Golden Empress of India*; Mr. Gowan, gardener to J. Cunningham, Esq., Moseley Hill, was the other only exhibitor. For four plants Mr. S. Whitfield was first, and Mr. C. Finnigan second best. The last-named exhibitor was first in the class for six Pompons, and staged very fresh profusely flowered plants of *Mrs. Hutt*, *White* and *Golden Cedo Nulli*, *Aigle d'Or* good, and *St. Michael*. Mr. S. Whitfield was the other competitor. For four plants the same exhibitor was again first with similar varieties, except one named *Snowball*, a pretty small pure white-flowered variety. Messrs. J. Hurst and W. Bustard were placed equal third. For one standard (trained) Mr. E. Green was first with a good specimen of *Mrs. Dixon*. The same exhibitor and Mr. Gowan were the prizetakers for one pyramid. Both staged remarkably neat examples.

Cut Blooms.—Incurved varieties were the feature of the Exhibition, and the blooms throughout the various and numerous stands were of large size and substance, possessing a depth and breadth of petal seldom seen, combined with good form and fresh colour. The competition was in many instances very close, more especially in the class for twenty-four blooms. There were three exhibitors. Mr. F. Roberts, gardener to W. D. Holt, Esq., West Derby; Mr. G. Mease, gardener to W. Nicol, Esq., Aigburth; and Mr. T. Leadbetter, gardener to R. N. Dale, Esq., Bromborough Hall, were the prizetakers in the order named. The first and second stands were so close that Mr. Roberts only secured his position by one point, his weakest bloom being *Queen of England*. This box contained grand blooms of Mr. Howe, *Golden Empress*, *Empress of India*, *Incognita*, *Princess of Wales*, Mr. Bunn, *Mrs. Heale*, Mr. Cullingford, *Jardin des Plantes* very fine, *Barbara*, *White Venus*, *Hero of Stoke Newington*, *Refulgens*, *Princess of Teck*, *Bronze Jardin des Plantes*, and *White Beverley*. Mr. Mease had grand flowers of *Miss M. Morgan*, *Mrs. Halliburton*, *John Salter*, *Emily Dale*, *Novelty*, *Queen of England*, *Princess of Wales*, *Mrs. Heale*, and *Hero of Stoke Newington*. Mr. Leadbetter had a grand bloom of *Eve* and Mr. Howe. For eighteen blooms there were six exhibitors, and the competition was again similarly close. Mr. J. Jellico, gardener to F. H. Gossage, Esq., Woolton, obtained the premier award, having splendid examples of *Pink Venus*, *Lady Slade*, Mr. Bunn, *Princess of Wales*, *Empress of India*, and several others, the same as those named in the previous class. Mr. F. Foster, gardener to J. Brancker, Esq., Wavertree, second with neat but rather flatter blooms. Mr. J. Warrington, gardener to T. Bright, Esq., Aigburth, was a good third. In the class for twelve blooms, from which exhibitors in the two previous classes were excluded, there was great competition. Mr. Brantingham, gardener to S. Still, Esq., Cloughton, took the lead with remarkably fine blooms, followed closely by Mr. G. Burden, gardener to G. Coekburn, Esq., Oxtou; and Messrs. W. Todd, gardener to J. W. Cropper, Esq., Aigburth; and R. G. Waterman, gardener to A. Tate, Esq., the last two being placed equal third. In the corresponding class for twelve blooms the prizetakers were Messrs. T. Leadbetter, G. Mease, Foster; Mr. F. Roberts, an extra prize, five competitors staging blooms. Altogether this was the finest exhibition of incurved flowers we have ever seen.

Japanese kinds were more numerous and superior to those exhi-

bited at the Society's previous shows, but there is still room for improvement. In the class for eighteen varieties Mr. G. Mcase was just first with a grand stand of blooms, having Curiosity fine, Fair Maid of Guernsey, M. Ardene, Elaine good, Soliel Levant, The Khedive,

Criterion, Madame C. Audigier, Apollo, Bouquet Fait, and Ethel. Mr. F. Roberts was a close second, having good blooms of Bronze Dragon, Alba plena, Hiver Fleur, and Bismarck. Mr. W. Wilson, Gateacre, third with small but very neat flowers, La Nymphe,

Fig. 84.—NARCISSUS ALBICANS. (See page 501.)

Striatum, and Exposition de Toulouse being very good. Mr. J. Jellico took the lead in the class for twelve blooms with similar to those already mentioned. Mr. Brantingham and Mr. R. G. Waterman were

the remaining prizetakers, the competition being exceedingly close, four collections being staged.

For twelve Anemones, not less than six varieties, Mr. Jellico was

first with good flowers of Gluek, Bijon, Lady Margaret, Madame Goderaux, Louis Bonamy, and Acquisition. The same exhibitor was first also for twelve reflexed flowers, showing King of Crimsons in grand condition, Lilac and Golden Christine, Chevalier Damage, Dr. Sharp, and Mrs. Forsyth. Mr. A. R. Cox was second with smaller blooms, the last-named exhibitor being first for twelve Pompons, not less than six varieties to be shown, with foliage and stems as cut.

Stove and Greenhouse Plants.—In the class for six plants, not less than three in flower, there were only three competitors. Mr. W. Mease, gardener to C. W. Newmann, Esq., Wyncote, Allerton, was well ahead with grand examples—*Centropogon Lucianus* about 7 feet through, the best specimen of this plant we have ever seen exhibited. Mr. A. R. Cox, gardener to W. H. Watts, Esq., Allerton, second, showing a good *Croton angustifolius*; and Mr. E. Thrupp, gardener to J. Walmsley, Esq., Wigan, third. For four plants, not less than two in flower, the same exhibitor was again first with grand *Crotons Williamsi* and *majesticum*, highly coloured and about 6 feet through, the flowering plants being a large pot of *Calanthe Veitchii* and *Azalea amœna*. Mr. J. Hurst, gardener to W. B. Bowering, Esq., second, his best plant being *Phoenix rupicola*. For three Palms or Cycads there were only two exhibitors. Mr. Thrupp took the lead, followed closely by Mr. S. Whitfield, gardener to J. T. Cross, Esq., Beechwood, Aigburth, second. For one plant the last-named exhibitor was first with a grand specimen of *Kentia australis*, followed by Mr. E. Thrupp. *Epiphyllums* were good and profusely flowered. Mr. P. Barber, gardener to Mrs. Barnsley, Aigburth, took the lead in the class for three plants, followed by Mr. J. Vaughan, gardener to R. Coltart, Esq., and Mr. J. Bustard, gardener to J. Lewis, Esq., in the order named. For one plant the competition was keen. Mr. Barber and Mr. E. Green, gardener to J. Woolwright, Esq., Aigburth, were placed equal first. Messrs. Vaughan and Thrupp were the remaining prizetakers.

Primulas were excellent, seven exhibitors staging for the prizes offered for six plants. Mr. Brown, gardener to G. Webster, Esq., Upton, was first with the most compact, well bloomed, and good coloured specimens; Mr. E. Green, second; and Mr. J. Phythian, gardener to D. Walker, Esq., Forest Lawn, West Derby, third. Mignonettes, as usual, were good; Mr. W. Evans, gardener to Mrs. Lockett, took the lead with well-grown standard plants, the other prizetakers being Messrs. J. Hurst and Bustard.

Table plants were shown in the best possible condition, the plants being very small and very neat, especially the first-prize collection of six plants staged by Mr. G. Park, gardener to R. A. Farrington, Esq., Wigan. His best plants were *Croton angustifolius*, *Pandanus Veitchii*, *Geonoma gracilis*, and *Dracaena Guilfoylei*. Mr. S. Agnew, gardener to Mrs. Watts, was a close second, and Mr. E. Thrupp a good third. Mr. E. Green took the lead for four Poinsettias, and Mr. Phythian for good pans of Roman Hyacinths.

Ferns.—There were only three exhibitors in the class for six stove and greenhouse varieties. Mr. J. Stephenson, gardener to Mrs. Horsfall, was well first, showing well *Adiantum excisum* nearly 4 feet through, *A. formosum*, *A. farleyense* good, and a grand *Davallia Mooreana*. Mr. J. Gore, gardener to T. Holder, Esq., second with good plants, having a very fine *Cibotium regale*; and Mr. A. R. Cox the remaining prize. Mr. J. Gore took the lead for one Tree Fern with *Dicksonia antarctica*; Mr. G. Leadbetter, gardener to T. S. Timmis, Esq., Huyton, second with the same variety; and Mr. J. Phythian third with *Alsophila australis*.

Oreheids were well and numerous shown for the prizes offered in the four classes devoted to them, and few, if any, exhibits in the hall attracted greater attention. For three plants, distinct, Mr. J. Wilson, gardener to J. E. Reynolds, Esq., Sandsfield Park, West Derby, was first with well-flowered plants of *Dendrobium heterocarpum*, *Odontoglossum Alexandræ*, and *O. Londesboroughianum*. Mr. W. Moss, gardener to W. Holland, Esq., and Mr. J. Edwards, gardener to S. Walker, Esq., Liverpool, were placed equal second, the former showing well *Lælia anceps* and *Odontoglossum Halli*, and the latter *Oncidium crispum* and a well-flowered plant of the lovely *Masdevallia Tovarense*. For one plant Mr. J. Edwards took the lead with a good variety of *Odontoglossum Alexandræ* with fourteen flowers, followed by Mr. J. Wilson and Mr. Gore, the former showing the same variety. For two *Calanthes* Mr. W. Moss was first with grand pots, and Mr. J. Stephenson for one plant.

Bonquets were not numerous, but those shown were good. In the nurserymen's class Mr. C. Rylance, Ormskirk, took the lead, followed by Mr. G. Downes, Florist, 97, Lodge Lane, Liverpool. In the corresponding class Messrs. J. Agnew, G. Leadbetter, and W. Evans were the prizetakers in the order named.

Mr. J. Phythian was first in the class for one epergne or vase for table decoration, but these exhibits need no further notice, the whole being too heavy.

FRUIT.—The display of fruit was large and remarkably good considering the season. In the open class for twelve dishes, distinct, Mr. J. H. Goodacre, Elvaston Castle, Derby, took the lead with two fair Pines; Gros Colman Grapes, large berries and well coloured; Gros Guillaume, well coloured but small berries; and the same applies to the bunch of Alicante, while Mrs. Pince and Golden Queen were good; a small fruit of Read's Hybrid Melon, Beurré Diel and Glon Moreau Pears, and two good dishes of Apples. Mr. Hannagan, gardener to R. C. Naylor, Esq., Hooton Hall, followed closely, two collections only being staged. There were four exhibitors in the

class for six dishes, Pines excluded. Messrs. Hannagan, W. Mease, and W. Evans were the successful exhibitors, the former showing good Muscat of Alexandria Grapes, Beurré Diel and Duchesse d'Angoulême Pears, with King of the Pippins and Ribston Pippin Apples. The second exhibitor had good Durondeau Pears and Grapes. The last-named exhibitor had good Pears and Apples, but the Grapes were inferior to those in the first and second collections. For two bunches of black Grapes, Muscat flavour, Mr. J. Kelley, gardener to Messrs. Reynolds & Co., Garstang, was first with Mrs. Pince, good bunches, but rather defective in colour; Mr. W. Roberts, gardener to T. Harrison, Esq., Gateacre, second; and Mr. J. Stephenson third, both staging the same variety, but smaller in the bunch. There were fourteen competitors in the next class, and Mr. F. Ferguson, gardener to Mrs. Patterson, was first for two bunches of black Grapes with Gros Guillaume; Mr. W. Lewis, gardener to T. Hardy, Esq., Kimberley, Notts, with Gros Colman with very fine berries and grand colour; Mr. W. Wilson, Gateacre, the remaining prize with the same variety. For two bunches of white Grapes, Muscat flavour, Mr. G. Middleton, gardener to R. Pilkington, Esq., Rainford Hall, was first with well-finished Muscat of Alexandria; Mr. W. Roberts second; and Mr. F. Elcock, gardener to W. H. Dixon, Esq., Hooton, third. There were seven exhibitors. In the class for two bunches, any other white, there were six lots staged. Mr. Wallis, Keele Hall, first with grand well-coloured examples of Golden Queen; Mr. W. Mease second with White Tokay; and Mr. J. Hurst third. For four varieties of Grapes, distinct, there were eight competitors. Mr. W. Lewis secured the premier position with Gros Guillaume, large bunch and well-coloured berries; Gros Colman, good; Alicante, and Muscat Hamburg. Mr. J. Wallis a good second, showing smaller bunches but well finished; Mr. C. Finnigan taking the other award.

In the open class for eight dishes of dessert Pears Mr. Goodacre staged a very fine collection, which deservedly placed him first. The varieties were Gross Calabasse large and fine, Marie Louise, Beurré Diel large, Beurré Clairgeau, Doyenné du Comice, Duchesse d'Angoulême, Napoleon, and General Todtleben. Mr. Hannagan second, having good dishes of Glon Morceau and Hacon's Incomparable. Mr. J. Lowndes third, having a good dish of Easter Beurré. Mr. W. Mease was first in the corresponding local class for four dishes with Marie Louise, the best dish of this variety in the Exhibition, Beurré Bachelier, and Beurré Diel; Messrs. Hannagan and J. Lowndes second and third respectively. For one dish of ripe fruit (local) Mr. W. Evans was first with Beurré Diel, Mr. Hannagan second with Marie Louise, and Mr. Mease third with Winter Nelis, sixteen dishes being staged. In the open class for one dish of stewing Pears Mr. Goodacre was first with large and fine fruit of Catillac; Mr. J. Kelley followed with the same variety, and Mr. W. Gardiner, gardener to S. E. Shirley, Esq., third.

Apples were remarkably good throughout. There were six competitors in the class for six dishes of dessert kinds (open), Messrs. Hannagan, Gardiner, and Goodacre being the successful exhibitors, the first-named showing Blenheim Pippin, King of the Pippins, Golden Reinette, Fearn's Pippin, and Ribston Pippin. The second collection containing grand dishes of Adams' Pearmain, Cox's Orange Pippin, and Baxter's Pearmain. In the local class for three dishes Mr. S. Whitfield was first with Wyken Pippin, Blenheim Pippin, and Ribston Pippin; Messrs. W. Evans and Hannagan second and third. For one dish (local) the prizetakers were Messrs. Foster, Lowndes, and S. Whitfield. For eight dishes of culinary kinds (open) Mr. Hannagan was first with grand dishes of Alfriston, Warner's King, Dumelow's Seedling, Greenup Pippin, Hawthorndean, Yorkshire Greening, and Cox's Pomona, good. Mr. W. Gardiner second, having Cox's Pomona, Blenheim Pippin, and Dumelow's Seedling very fine. Mr. Goodacre was awarded the remaining prize. Five collections being staged. In the local class for four dishes Mr. T. Johnston, Higher Bebbington, was first with Warner's King very large, Alfriston, King Apple, and Rylance's Surprise very good; Mr. Hannagan being second, having a good dish of Mère de Ménage. For one dish the prizetakers were Messrs. Johnston, Whitfield, and Evans.

Miscellaneous Exhibits.—Mr. Swan, gardener to W. Leech, Esq., Oakley, Fallowfield, contributed plants of a new hybrid *Dendrobium* named *Leechianum*, raised between *D. nobile* and *D. heterocarpum*. This variety had flowers of a very large size and were very striking, for which a first-class certificate was awarded. Messrs. R. P. Kerr & Sons, Aigburth Nursery, contributed a very fine table of small decorative plants, including Palms, Chrysanthemums, Ferns, Roman Hyacinths, double Primulas, Ericas, and Cyclamens; the plants of the latter being fully 18 inches through, and well flowered. The Horticultural Company (John Cowan), The Garston Vineyard, a similar group, with choice *Crotons*, *Dracenas*, *Nepenthes*, *Calanthes* of sorts freely intermixed. Messrs. Cannell & Sons, Swanley, Kent, a quantity of Zonal Pelargonium blooms in grand condition, also a box of *Salvias*, which was much admired, the varieties being *Bethelii*, *splendens*, *Hoveyi*, *rutilans*, *Mons. Issanchon* and *Pitcheri*. The above collections were very highly commended by the Judges. Messrs. J. Dickson & Sons, Newton Nurseries, Chester, sent a box of *Euonymus radicans variegata* Silver Gem (new), *Cupressus Lawsoniana* Silver Queen (new), also a collection of *Pernettyas*. Mr. C. Rylance, Ormskirk, a collection of Apples; and Mr. W. Lewis a large highly finished bunch of Gros Guillaume Grape, for which an extra prize was awarded.

The Chairman, Mr. Richardson, Curator, Botanic Gardens, the Secretary, Mr. Glover, and the Committee are to be congratulated upon the able and thoroughly successful manner in which the arrangements of this fine Exhibition were carried out.

SILKWORMS AND SILKWORM REARING.—20.

(Continued from page 461.)

AMONGST our native insects which have become more rare of late is the handsome moth to which has been given the appellation of the "Emperor" (fig. 85), although it is by no means the largest British species of the tribe, nor, indeed, can it be said to be the most beautiful. Yet this moth, *Saturnia Carpini*, certainly does offer to the eye a pleasing combination of colours, its eye-like spots suggesting its kinsmanship to the large foreign *Bombyces* that have recently passed under our notice. It is to heaths and patches of straggling wood that the caterpillar (green, with black or pink warts), has generally been attached, and the clearing of ground for cultivation during the last fifty years has not favoured the increase of *S. Carpini*, which is now confined to a few localities. The cocoon is of silk, and rather curiously shaped, but it could not be turned to any use; I doubt whether it could even be carded.

This insect I mention, however, because the larger *Saturnia Pyri*, native of some districts of France and of other countries with a warmer climate than ours, has been placed amongst the possible producers of a textile silk. In bulk it far surpasses our "Emperor" (fig. 85), and, as may be imagined, the brown or grey of the wings shows up strikingly the complex spots by which they are adorned. The caterpillar or silkworm is very large, of a light green tint, studded over with dark blue tubercles, from each of which rise seven radiating hairs. It is not difficult to rear, feeding upon Apple, Pear, Plum, Ash, or Elm during July and August, and forming its cocoon in the latter month or September. This is of brown silk, in texture very strong, which might be made useful by carding it if produced in sufficient quantity. The moths emerge to lay their eggs in May or June, there being but one annual brood. A few attempts have been made to keep these upon the Plum in the open air, but our cold nights are rather against them, and in spite of their hairs they also fall a prey to the irrepressible sparrows. One observer has noted that the birds seem to like these foreigners quite as well as our native caterpillars, excepting indeed *A. Cynthia* and *Prometheus*, which were regarded with dislike, seemingly, by birds, though they did not escape spiders. These destroy some seasons many young caterpillars of various species.

There is an insect named *Ceratocampa imperialis* which has been placed amongst the silkworms. It is an American species, and in its moth state remarkably beautiful, and of interest to those who experiment in caterpillar-rearing, though the cocoons are not of ascertained value. In expanse of wing it is from 4 to 6 inches, the males being smaller but more showy. The colouring is unlike that of the moths familiar to us in these islands, for the yellow ground is covered with small deep brown dots, and there are numerous spots or patches of red, with a purplish gloss upon them. It had been stated in the "Naturalist's Library" that the rare caterpillars of this species are seldom reared successfully, and if they reached maturity they generally died soon after entering the chrysalis stage; but M. Wailly of Clapham reports favourably as to those he had in 1881. Eggs laid during July produced young worms early in August; these were kept in a house under glass, but well ventilated. Their growth being slow would account for their passing through as many as six changes of skin, two beyond the usual number amongst silkworms, and it was about the middle of October when they ceased feeding. M. Wailly describes the caterpillars as varying much in colour, from yellow to nearly black; they exhibit five horns, which are studded with sharp points and forked. As the caterpillars increase in size these horns become shorter; they are not apparently used for weapons of offence. In habit this insect is not unsociable while in the larval stage, since M. Wailly remarks that "they crawled over each other's backs without showing the least sign of spite or animosity, even when they were in sleep, in which case larvae are generally very sensitive and irritable." The cocoon is made beneath the surface of the earth, and the chrysalis reposes therein until the following summer.

In addition to what has been previously stated with reference to *Attacus Yama Mai*, the Japanese silkworm of the Oak, and to *A. Pernyi*, the mountain species of North China, the following facts should be here noted ere concluding. A rather successful method of treating the newly hatched *Yama Mai* worms has been that of placing them under large bellglasses having a few openings in the dome, the food being kept fresh by putting small branches of Oak into saucers full of sand covered with paper. Any that may drop off the branches can without much difficulty be removed from the paper, and if kept out of the direct sunshine the leaves remain undried for several days. In this arrangement the branches must necessarily be cut short, but when these silkworms are fed upon branches plunged in water they must be cut long, otherwise the foliage would absorb some water into its natural juices, and this proves highly injurious to the worms; yet, as already shown, they do not object to—in fact, rather like—moisture apart from the leaves. The Oak being a somewhat backward tree in most seasons, in anticipation of the hatching-out of *Yama Mai* some naturalists have placed young Oaks in pots, and by protecting them through the winter have brought them into leaf rather early, putting the worms upon them with a covering of gauze. But forcing Oaks by artificial heat has not been found to answer.

Fig. 85.—*Saturnia Carpini*.

There is a risk, however, of losing some through the getting chilled if the worms are kept out of doors before June is well advanced.

Attacus Pernyi was reared several times in the open air some years ago, but the summer of this and of last year did not seem congenial to the worms when they were exposed upon Oak bushes to the changes of the weather. Near Colchester about ten years since a naturalist liberated a large number of fertile females in a somewhat retired wood. Subsequent investigations disclosed a few of the silkworms there, the progeny of these, and several were left upon the Oaks to attain their full size. No moths were obtained afterwards, or worms discovered the next season. The young *Pernyi* do not hatch so soon as *Yama Mai*—generally towards the end of June or in July, when there is abundance of Oak in good condition, a circumstance much favouring their rearing with success, and they evidently suffer little from diseases.

Hereafter it is possible that much may be attempted in the way of crossing one species with another. As yet such experiments are in their infancy. *Attacus Roylei*, the Himalayan species of silkworm, also a feeder upon Oak, shows affinities for *A. Pernyi*, and a hybrid breed has been obtained from the two. The worms have all the good qualities of the North China parent, and the cocoon is preferable to that of *A. Roylei*, where so much of the strength of the spinner is expended upon the loose outer cocoon that the inner is thin and poor. From the hybrid has been got a compact cocoon and of better colour than that of *A. Pernyi*. We may yet be able to pair some species with the Japanese *A. Yama*

Mai, which will render this excellent yielder of silk less difficult to rear in confinement.—J. R. S. C.

KITCHEN GARDEN.

Forcing Department.—Attention will now be needed to ensure a liberal supply of Asparagus, Seakale, and Rhubarb. For Asparagus, pits capable of holding sufficient fermenting material to preserve for some time a temperature of from 70° to 80° are useful, and the pits should also be furnished with hot-water pipes, and have moveable lights, so that at suitable times an abundant supply of fresh air can be afforded, as without this the flavour will be very inferior. In order to have a supply at Christmas a bed composed of leaves and stable litter should be made now and trodden down firmly. Place 2 or 3 inches depth of light rich soil on the surface, and at the temperature above indicated the roots should be introduced, spreading them out and mixing light soil amongst them. Water with tepid water, and cover the crowns with finely sifted spent tan.

Seakale in quantity can be forced in this way, but a lower degree of heat is needed than for Asparagus, and light must be excluded so as to secure well-blanching heads. This with Rhubarb is most readily forced in the Mushroom house; fresh roots being introduced at intervals according to the demand will afford an uninterrupted succession.

Where Chicory is used for salads roots should be introduced to the Mushroom house, potting them in large pots, or planting in light rich soil kept moist by watering as needed with tepid water. The tops should be cut off an inch from the crown, but not so close as to injure the growing point. It is necessary that light be excluded to secure well-blanching heads.

Make an occasional sowing of French Beans according to the space at command, earthing up those sufficiently advanced, and supply weak tepid liquid manure to those in flower and podding. Keep them near the glass, and ventilate freely when the weather is favourable. Mustard and Cress must be sown at intervals according to the demand. Ventilating frames which contain Radishes, Cauliflowers, Lettuces, and Endive, tying up or covering the last named to effect the blanching.

FRUIT HOUSES.

Peaches and Nectarines.—The house containing the earliest trees having been closed artificial heat may now be commenced, turning on the heat in the morning for an hour or two so as to raise the temperature to 50°, opening the house at that temperature, allowing a free circulation of air through the house, but not to lower the temperature, allowing an advance of 10° to 15° from sun heat, and close early in the afternoon, damping the trees at the same time if the weather be bright. Syringing the trees should only be resorted to on fine mornings and afternoons. Fire heat will only be necessary at night to keep the temperature from falling below 40°. An application of tepid liquid manure to the roots of weakly trees in inside borders will greatly assist the swelling of the buds and strengthen the blossom.

The lights should be placed on the house intended to be started early next year, and the ventilators kept open day and night excepting when the temperature falls to 40°, when they may be closed. As the trees become denuded of foliage in the late houses thoroughly cleanse the house, and if the trees are infested with scale it may be removed by syringing with water at a temperature of 160°. Remove the loose surface soil down to the roots, and supply fresh loam to which has been added a sprinkling of half-inch bones and some charred refuse. See that there is not any deficiency of moisture at the roots of trees in inside borders, for if allowed to become dry now it is likely the bloom buds will fall when they should be swelling. Keep the houses as cool as possible by free ventilation.

Vines.—In houses that were closed early in the month the Vines are now starting, and if the terminal buds are taking the lead the stems should be brought down to a horizontal position or below it. The parts that are not breaking freely should be syringed with tepid water three or more times a day, and when they have made an inch or two of growth the rods or canes should be secured in proper position. Turn over the fermenting material and add some freshly prepared material to be worked in as the turning proceeds. The inside border must be examined down to the drainage, and if any of the soil be dry repeated waterings of weak liquid manure or water at a temperature of 90° must be given until the whole of the border is thoroughly moistened through. The outside borders must, if they have been covered with fermenting material, be attended to so as to maintain the heat in them at 80° to 90°, and if lights or shutters be placed over all but not resting on the material, with a sharp incline to the front to throw off the water, it will add considerably to the endurance and regularity of the heat in the fermenting materials. When the weather is mild admit air for a short time. The night temperature should be kept at 60°, falling 5° on cold nights, 65° in the daytime on cold and dull days, 5° more in mild weather, and 10° rise from sun heat.

Houses of Vines to afford ripe Grapes in May must be closed at once. The outside border should be covered with some dry material and shutters or lights to throw off rain or snow. Fermenting materials may be used in quantity, but they are positively injurious if allowed to become cold and wet when the Vines are in active growth. If some sweetened fermenting materials—Oak or Beech leaves with a third or fourth of stable litter—be introduced to the house, and formed into a bed about 2 feet in height, and turned over occasionally, and fresh material added as the heat declines, it will save fuel, induce a good break from the moisture-laden and ammonia-charged atmosphere generated by the fermenting materials. The house and Vines should be damped two or three times a day. In dull weather the moisture given off by the fermenting materials will be sufficient, and even where they are not employed less moisture will be needed in dull weather than in bright sharp weather. Artificially the temperature should be kept at 55° at night, 5° less on cold nights, which should likewise be the artificial temperature by day, upon which an advance should be made from sun heat to 65°. The inside borders must be rendered thoroughly moist by repeated waterings.

Figs.—The first batch of trees in pots for forcing early should now be attended to, in order to destroy any insects which now exist in embryo and will infest the trees at a more advanced stage. The trees should in the first instance be brushed over with soap and water, and afterwards with an insecticide, care being taken not to rub off the young fruit. Very little pruning will be necessary provided the trees have been regularly pinched-in or stopped during growth, but if thinning or shortening the shoots be necessary to keep the trees symmetrical—it should be attended to. A slight warmth at the roots is a great aid for early-forced trees in pots. The trees may be stood on pedestals of open brickwork in the positions they are to occupy, bringing them near to the glass, as free exposure to the light is absolutely essential to success, and the trees should not be overcrowded. Oak or Beech leaves, with a fourth of stable litter, should be thrown into a heap, damped if necessary, and being turned over a few times be placed in the bed and brought up about the pots, but care must be taken not to allow the heat around the pots to exceed 70° to 75°. The soil must be rendered thoroughly moist by repeated watering or immersing in tepid water. The house should be closed, and a start made at the close of the present or early in next month to have fruit ripe by the close of April or early in May, damping the trees and available surfaces in the morning and early afternoon in bright weather, but when dull the moisture given out by the fermenting materials will be ample. At the commencement 50° to 55° by artificial means must not be exceeded, and 65° from sun heat, at and above which ventilate freely.

The trees permanently planted out and intended for early forcing must be untied from the trellis and pruned, thoroughly cleansing the house, and dressing the trees before securing them to the trellis.

The old mulching material should be removed from the border, and fresh material supplied to the extent of 3 inches thickness of partially decayed manure. Later houses should also be cleansed, and everything needed done, so that a start may be made at the proper time. Ventilate freely in favourable weather, closing during the prevalence of frost.

PLANT HOUSES.

Orchids.—Most of the occupants of the East Indian house will now be resting; and though less moisture must be provided, it must not, nevertheless, be entirely withheld; but as the temperature in the morning is rising, as it should by nine o'clock, water must be sprinkled over the paths and between the plants, and any plants requiring water must be given enough to keep the sphagnum damp. All watering and syringing must be completed before noon, so as to insure the house becoming dry before the temperature is lowered, for a cold and wet atmosphere is provocative of disease. During warm foggy weather the houses should be kept comparatively dry, the ventilators being kept close, and no more opening of the doors allowed than is absolutely necessary; but a little air may be given on fine days to prevent the temperature rising too high. Cattleyas and Dendrobiums except such as are on blocks or newly imported, should not receive any water at their roots. Any plants of *Dendrobium nobile* that have completed their growth early may now be placed in the East India house, and if damped lightly on fine days they may be had in flower by the new year. Very little water should be given at the roots until they begin growing. Let all plants coming into flower or producing their spikes be thoroughly exposed to the light, otherwise they are likely to become blind or the buds to drop before expanding. *Pilumna fragrans grandiflora* is one of the most desirable Orchids, flowering during the winter months. Plants in flower may be removed to a drier atmosphere. *Miltonias* may be repotted, shallow pans being most suitable for their growth, being well drained, as they require liberal supplies of water.

The Pleiones that have flowered and require larger pots should have all the old material removed from their roots. They will thrive in almost any light compost, equal parts of turfy loam and peat, also leaf soil, old cow dung, or peat and sphagnum. The pots or pans should be well drained, placing some sphagnum or rough peat over the potsherds. Bring the compost to within half an inch of the rim of the pot, place the pseudo-bulbs an inch apart, covering the old roots with half an inch depth of the compost, watering very lightly until the roots start into growth. To grow *Vanda cærulea* satisfactorily it should be placed in the Cattleya house. It thrives well in lumps of fibrous peat with the whole of the soft matter shaken out of it, the fibre being loosely worked in amongst the roots in a basket. It likes plenty of light, and should be suspended about a foot from the roof, and needs very little water at this season. *Odontoglossums* requiring larger pots may be shifted, taking care not to disturb the roots more than can be helped. They succeed best in equal parts of fibrous peat and sphagnum, with a free sprinkling of sand, thorough drainage being indispensable, as they require a very liberal supply of water. The period at which any plants commence growing is the best time to repot them. Plants of these that are growing freely require a good supply of water—a good damping overhead on fine mornings with a syringe or fine rose, using tepid rain water for the purpose. *Anætochilus* will now require careful treatment. Where grown in frames or under bellglasses a little ventilation must be provided, and the glass kept clean, in fact wiped inside every morning. Very little water will be required the next three months, just sufficient being given to keep the sphagnum a little moist. Slugs are great devourers of these plants. They should be sought for every night.

THE BEE-KEEPER.

ODDS AND ENDS.

The Sulphur Pit.—Many years ago I condemned the practice of killing bees by sulphur, spoke and wrote of the great value of bees

in autumn taken from honey hives, and of the easy and simple process of driving them from one hive to another. Since that time many thousands of swarms have been saved and profitably utilised. The other day a letter was received from a bee-keeper in Aberdeenshire which touches this matter of driving. The writer says, "It is now twelve years since you first taught us how to drive bees; my first attempts at this work were comical enough, but now I can handle bees with ease and without fear. And in this locality we can get women, wives, servant maids, and little lassies to drive bees from hives and neatly take their honey; men of all classes can of course do this work." For this little picture of Scottish life in Aberdeenshire we are indebted to Mr. Shearer of Cairnie. Probably no man in Great Britain has saved so many bees from the brimstone pit as Mr. Thomas Addey of Epworth, Lincolnshire. For many years, during the months of August and September, he has travelled over a large tract of country, gathering up the condemned bees, and selling them as an article of commerce. One year he told me he took three hundred swarms. One autumn I had more than 100 lbs. of bees in twenty swarms from Mr. Addey. Every pound of bees includes about five thousand, so that in the 100 lbs. I got five hundred thousand bees in one season to enrich and strengthen my hives. One season a Somersetshire bee-keeper ordered 10 stones (140 lbs.) of Mr. Addey, and I believe he obtained them. This year I have bought 40 lbs. of Mr. Addey and 40 lbs. from another bee-keeper; many other apiarians are supplied with driven bees from Epworth. Mr. Addey informs me that he visited the Lincoln Bee Show this autumn, and there saw something that so disgusted him that he hopes never again to see anything like it. I presume he refers to the manipulating processes seen in the bee tent, which waste and destroy so many lives.

Of the 80 lbs. of bees I bought in October last, 40 lbs. were used in strengthening my stocks, and 40 lbs. were used in creating fifty more stocks. Swarms thus saved and put into empty hives and fed with sugar syrup invariably become my best stocks; they always do well, and can be trusted for early swarms. The six now created are models of perfection. My experience with such stocks rebuts the thoughts and statements of some writers that bees cannot live without pollen. Though our models of perfection have little, if any, pollen in them, I can predict with all the possible certainty that they will be healthy and strong in numbers for five months to come. If such excellent stocks can be created from bees in October, and weak hives made strong, why kill them by sulphur?

Do bees remove eggs from one cell to another?—Yes, certainly. This I have known and witnessed for fifty years. I have often seen eggs laid by queens before being removed from their hives set in other cells after their removal, and have known such eggs become queens, thus proving that they were not the eggs of fertile workers. Queen-excluders, then, so much talked about at present, cannot be of much use? No, they are valueless; for if bees determine to breed in any part of a hive queen-excluders will not prevent them. Last September a correspondent of a journal wrote that one of his hives lost its queen when the combs were filled with honey, brood, and eggs. He removed a frame of honey and gave the hive a frame of empty comb in its place. The hive was examined four or five days after, when there were found several queen cells on the empty sheet of comb. As it contained no eggs when placed in the hive he saw that the bees must have taken them from one comb to another. Eight queen cells were erected and filled on the empty sheet. He adds, "There can be no mistake about this, for I took the empty frame from my honey room where it had been laid six or seven weeks." If more evidence be wanted it may be found in the fact that in many instances—I might venture to say in all instances of breeding in supers—the bees first prepare the cells for the reception of eggs; and experienced men on examining supers can tell where the eggs will be deposited. Bees are the masters and determine these matters themselves without consulting queen or queen-excluders. It will be well for bee-keepers to remember these facts.

Are young queens better than old ones?—Yes, in the sense that a young horse is more valuable than an old one; for though an old horse may be able to do as much work as a young one it decreases in value every year. As queen bees live four years only, they decrease in value year by year. But is it not true that old queens lay fewer eggs than young ones? If so, at what age do they begin to lay fewer eggs? The prevailing idea that the first year of a queen bee is her best may be correct; at any rate I have no disposition to question it, but we know that some queens are very prolific and remain fertile till they reach the allotted span of life, and till within a few days of their end continue to fill their hives with brood. Some queens fail sooner and become less prolific in the third year of their age, and during the breeding season their abdomens seem less expanded than younger queens. As queens advance in age their abdomens become darker in colour; and in

their fourth (last) year very dark, and somewhat contracted and tapering. Their wings and legs often decay before death.

Though very few queens fail to lay eggs enough for ordinary-sized hives, even in their third and fourth years, it is desirable to have young queens in all hives. Some seasons in Great Britain are unfavourable for swarming, and in such seasons few swarms are obtained. The queens in non-swarming stocks are of course a year older and of less value. If a bee-keeper has twelve stocks and takes no notice of the age of his queens and leaves all to chance and fate he will, perhaps unknown to himself, sustain great losses in the death of all his queens every four years, at the rate of three deaths every year. Are some young queens better and more prolific than others of the same age? In the nature of things there must be good, better, best, and doubtless there is a difference in the fecundity of queens as there is in the case of hens and other birds; but after a lifetime of experience and close observation I have no hesitation in stating that fertilised queens seldom fail to lay eggs enough for all purposes—that ninety-nine young queens out of every hundred lay more eggs than the bees require or have room for.

Some American and English writers on bees go, in my opinion, too far in their remarks on unproductive and bad-breeding queens. Through life our queens have been wonderfully productive, and now I have no fear of ever having bad queens or a bad breed of queens in future. But is it not a fact that some hives thrive better and become full sooner than others standing beside them? Yes, and very few bee-keepers of note have failed to notice the fact that one hive, at first not the most promising in the apiary, overtakes and outruns all the rest. This is a very common occurrence, but who can explain the cause or give satisfactory reasons for the difference? Some writers hastily come to the conclusion that the prosperous fast-going hive has a better queen than the rest—that one queen is prolific and the others are not so prolific. Such conclusions are often mere guesses and remain unsupported by fact and argument. Take a hive of slow progress—one that loiters on the way and gathers less honey than others standing beside it. At last it swarms, and the swarm and old queen get an empty hive to fill. Now everything seems to alter; the bees work as fast as they can, and soon fill the hive with combs and the combs with brood. In about three weeks the swarm-hive becomes as full of brood and honey as the mother hive was at the time of swarming. The same queen and bees now do more work than they did in the old hive—three times as much work is done in the new hive. All this happens in hundreds of instances, and some people too hastily blame the queens and say they are unproductive. If the queens are at fault in the old hives before swarming, why are they not at fault in the new hives after? And why do swarms in good seasons so often overtake and outrun non-swarmers both in breeding bees and gathering honey? The cause of hives not prospering is far more likely to be found in their internal condition rather than in their queens being poor egg-producers. It is not just to cast the blame of bad luck and bad management on queens whose marvellous productiveness so seldom fails. However, the question of slow-moving and non-productive hives, viewed from a practical point, is one of great importance and cannot be too deeply pondered; it is a question for all bee-keepers, and its solution will enlighten and help all apiarists. Meanwhile let all aim at having hives with young sweet combs, young queens, and strong with workers. These are essential conditions of success. The owner of an apiary of such stocks has nothing to fear; on good pasture and under sunny skies the results of his efforts will be highly satisfactory.—A. PETTIGREW.

THE ART OF BEE-KEEPING.—No. 3.

(Continued from page 464.)

NATURAL HISTORY.

Much assistance can likewise be given to the *building* instincts of the bee, for it must be remembered that the material from which those marvellous combs are built are not gathered by the bees, as many suppose, but are elaborated from their own bodies at much expense of time, and money, and tissue. To produce the eight little scales of wax which may be seen protruding from the wax pockets under the abdomen, and which together would form a pellet less than a grain of mustard seed, the bee must gorge itself with honey and hang in a semi-dormant state for about twenty-four hours. With half or two-thirds of the bees of a large swarm thus gorged and inactive at one time, anyone can see that wax is really an expensive substance both to the bees and the bee-keeper. Happily, recent inventions have now made comb foundations of pure wax so easily and cheaply obtained that no modern bee-keeper thinks of allowing his bees to produce all the wax required for their combs, or to build these of a kind and shape detrimental to the colony and inconvenient for management. With bar frames

and sectional supers comb foundations are a great boon, and the more liberally they are used in an apiary the more profitable will they be.

One other instinct, equally strong in queen, workers, and drones, must not be lost sight of, that of *locality*. On first taking flight from its hive every bee "marks its location" by making the circuit of its hive in ever-increasing circles, until its position with regard to surrounding objects is thoroughly apprehended. After that it sallies forth apparently heedless as to its location, but never fails to find its way back from whatever distance it may have flown to. As bees have been known to fly in search of honey to a distance of over five miles from their hive the acuteness of this instinct is remarkable. Should the hive be removed during its absence the bee will return to the old spot and probably perish; a remove of a foot or two will even cause it great confusion. The bee-keeper should thus be careful in regard to all needful alterations about his apiary. All removals should take place during the winter months, and even then only with great precaution, unless the distance to be covered be several miles. Small distances may be covered in summer by easy stages of a foot or two daily. Bees likewise mark their location anew after settling or being hived as a swarm, and this gives us an easy way of effecting removals at any season with small loss. We simply reduce the bees to the condition of a swarm by first driving or shaking them into an empty box or skep, and preferably in the evening, and afterwards run them into the hive in its new location. But the loss of a few bees through heedless removals is as nothing to the loss of queens that often takes place through hives being removed or altered in appearance during the period of a young queen's virginity. At this time she flies on every fine day, but she only once thoroughly marks her location. We have known such to be lost as a result of the substitution of a bar-frame hive for the skep from which she had previously flown. Instead of returning to the new hive she entered the nearest skep and was killed. Various plans are adopted to lessen the risk of such losses, such as disguising by means of a sack or branch the old hive for a few days before making the change, and similarly disguising the new one. The similarity and closeness of hives in an apiary is for the same reason a frequent source of loss both of queens and bees; consequently attempts should be made by means of shrubs or palings to break up the monotony of all large apiaries, and hives that are to be near each other should differ in design and colour as much as possible.

Many other facts in the natural history of his bees must be taken into account by the bee-keeper, such as their liability to get chilled and perish when tempted out of their hives by untimely feeding or handling; their habit of gorging themselves directly they are alarmed or disturbed, rendering them amiable in temper, but in winter tending to induce distension and dysentery; their excessive fondness for sweets and the apparent rapidity by which whole colonies are made aware of their presence in accessible places, making it dangerous at certain seasons to leave honey or other sweets anywhere within their reach; their baffled rage when such tempting supplies suddenly fail, leading them not unfrequently to attack men and animals viciously, or to force their entrance into weak hives for purposes of robbery; the habit they frequently develop of looking out and preparing a place where they may settle as a swarm, generally a roof, hollow tree, or untenanted hive in a neighbour's garden; and the mysterious power of communication by which the few scouts make the swarm aware of the existence of such a retreat, to the amazement and discomfiture of the bee-keeper, who ought to have known how to prevent the loss that comes so suddenly upon him. He ought to know that bees recognise each other chiefly by the sense of smell, and take precautions accordingly when uniting stocks or introducing strange queens; that gorged bees are not only harmless towards the operator but towards their own kind, and in this condition may be safely united, one stock or swarm with another; and that at least first swarms are generally in this gorged state. He should at all times be prepared to discover that in the best regulated communities accidents will happen; that queens may die or become hopelessly crippled at any period of their age, and leave the stock to perish unless he comes to its help with a new queen or the means of rearing one; that under the influence of the excitement of a first fine day in spring both bees and queen may desert their hive bodily; that combs may break from their fastenings owing to intense heat or want of ventilation; or that foul brood—that greatest of bee-keepers' scourges—may at any time be imported from the apiaries of careless neighbours. Above all he should make himself thoroughly acquainted with what ought to be the normal state of a healthy colony at every season of the year, that he may regulate his management accordingly, and likewise what are the conditions as to natural supplies in his own neighbourhood at any season, what are the main sources of honey and pollen when these become available, and what assist-

ance he may be able to give by sowing seeds of honey-producing flowers, or by feeding to bridge over any gaps in the natural supply.
—W. RAITT, *Blairgowrie*.

(To be continued.)

TRADE CATALOGUES RECEIVED.

N. Davis, 66, Warner Road, Camberwell, London, S.E.—*Catalogue of New and Old Chrysanthemums*.

S. Dixon & Co., Anton Street, Hackney.—*Catalogue of Chrysanthemums and Roses*.

Dickson & Robinson, 12, Old Millgate, Manchester.—*Catalogue of Forest and Ornamental Trees*.

* * * All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Coloured Plates of Orchids (*W. T.*).—Perhaps Mr. B. S. Williams, Upper Holloway, can give you the information required.

Celery for Exhibition (*E. C.*).—If you require large heads, which are usually coveted by exhibitors, Wright's Grove Red and Grove White will afford them under good cultivation. We have seen many heads of these varieties 9 lbs. in weight. The seed can be had from any nurseryman or seed firm of repute either in London or the provinces.

Roman Hyacinths and Narcissuses (*Silopian*).—If you can grow the plants after flowering in a light house, so as to produce stout healthy foliage, and keep it green as long as possible, then mature the plants under the influence of sun and air, they will flower pretty well another year if planted in a border, but usually the room and time thus occupied are not profitably employed, since fresh and good bulbs can be produced so cheaply. When not forced so early they are much more easily prepared for flowering another year in the open ground.

Kangaroo Vine (*Kittie*).—The plant to which you refer under the above name is *Cissus antarctica*, a member of the same natural order as the Grape Vine. It is a native of New South Wales, and was introduced to this country at the close of the last century. It is frequently seen in some of the London parks, especially at Battersea, where it is planted to climb over old stumps and tree stems in the subtropical garden.

Pear Trees Cankered (*F. G.*).—The wood that you have sent indicates either that the soil needs draining or that it contains something that is injurious to the roots. Probably an excess of moisture and a deficiency of calcareous matter have caused succulent growths which have not matured, and hence their decay. Drain the land, and replant the trees slightly above the general level of the ground rather than below it, placing fresh loam round the roots, with an admixture of lime rubbish and wood ashes. Cut off the affected parts, keep the growths thin, and in all probability the trees will recover.

Adhatoda cydoniæfolia (*H. W.*).—You will find an excellent engraving of this plant on page 543, December 15th, 1881, when the following cultural and descriptive particulars were given:—This plant is easily cultivated, and is worth a place in any collection of plants, and what adds to its value is that it blooms at a season when flowers are scarce. Perhaps its only objection is that it has rather a straggling habit of growth, but the way to overcome this objection is to train it under the roof or up a pillar; in such positions it appears quite at home. The best time to propagate it is in spring when it has commenced growing. The cuttings strike very readily in a little bottom heat, and should be potted as soon as rooted in a light rich soil. As soon as the pots are filled with roots the plants must again be potted, and when established the tops may be pinched to induce them to branch. After this they may either be grown on in larger pots, or planted out in a border in the stove and trained up a pillar or under the roof. *A. cydoniæfolia* is a native of Brazil, and therefore requires a stove temperature or an intermediate house."

Grapes for Autumn (*J. R., Bury St. Edmunds*).—There is no Grape that possesses "all the advantages and good qualities of the Black Hamburgh." A free-bearing and good-setting Grape, as likely to answer your purpose as any other, would be the Black Alicante. Although not of high quality the bunches are unusually good and the berries fine, assuming a purplish-black colour and fine bloom, giving them an imposing appearance. By planting in the warmest house, and starting as soon as you can consistently with being able to maintain a night temperature of 60° to 65° during the flowering period, the Grapes will follow the Black Hamburgh, and continue firm throughout the winter. You might try a Vine of Madresfield Court. It is a splendid autumn Grape, and if the berries do not crack you will probably increase it. It follows the Black Hamburgh, but does not keep nearly so well as the Alicante.

Potting Pelargoniums (*Donegal*).—Your Madame Thibaut that is now fading had better not be cut down and repotted now. Place the plants in a light position, and only give water sufficient to prevent the leaves drooping to any

great extent. As they are turning yellow they will probably decay gradually and fall in the course of a month or two. At that time, say in February, the stems will be hard, and the plants may then be cut down, still keeping them rather dry. In March they will have commenced fresh growth, and when the young shoots are an inch long turn the plants out of the pots, shaking nearly all the soil from their roots, and repot in pots of the same size or smaller, draining them well, and using a compost of turfy loam with a third of very old decayed manure or leaf soil, with sand to keep the whole porous, and afford the plants a light position in a house having a genial temperature. They will then, if watered judiciously, produce strong and healthy growths, and in time fine trusses of flowers. If cut down now the growths will be weak, because produced in the dull months.

Propagating Clematises (*Idem*).—Clematises are not readily increased by cuttings, or, at least, it is seldom that amateurs succeed in striking them. Short stubby shoots about 5 inches long, rather firm, but not hard, taken off close to the stem from which they spring and inserted in sand, covered with a bellglass, and the pot plunged in gentle heat, is the manner in which we have succeeded. Plants of the choicer varieties are increased by grafting them on roots of the freer-growing kinds established in pots and placed in a propagating pit. You will find full particulars on the propagation and culture of these plants on page 349, vol. ii., third series, the issue of May 5th, 1881. If you do not possess this number it can be had from the publishers in return for 3½d. in postage stamps.

Various (*Idem*).—Roses in the open air cannot be expected to continue flowering much longer. The unopened buds will be destroyed if not protected, and they cannot be preserved if the frost is prolonged and severe. Against slight frosts you may protect them by such means as you have at disposal or can devise. There is no Rose proof against the attacks of aphides. Dwarf crimson China Roses, such as Fabvier and Cramoisie Superieure, are pretty in pots in small greenhouses. A good very dark Hybrid Perpetual Rose is Louis Van Houtte, Senateur Vaisse having more scarlet and very bright. Petunias in pots will flower a second year. The plants must not be cut down closely now, but long shoots may be shortened. It is well to raise young plants in the spring from cuttings, which strike readily in a heated frame.

Apples and Plums for Market (*J. E.*).—You will find Damsons profitable fruit, and we should plant those in the hedgerow, leaving the meadow for the standard Apples. The Farleigh or Crittenden and the Prune are the best Damsons for market. The new large Bullace is useful, coming in after the chief crop. Early Apples as standards will pay you best. Good showy Apples must be provided to suit the market, such as Worcester Pearmain, Ecklinville Seedling, Lord Suffield, Cox's Pomona, Cellini, King of the Pippin, Small's Admirable, Stirling Castle, and Duchess of Oldenburgh. If any of them succeed in your locality better than others you should plant those in quantity. You will, however, succeed much better on the cultivated ground. Plums and Apples succeed well together as dwarfs, the Apples on the Paradise stock. Plant in alternate rows 8 feet apart, with Gooseberries between, which pay well if gathered green. The following Apples do well as dwarfs, supplementing those enumerated above: Irish Peach, Cox's Orange Pippin, Warner's King, Ribston Pippin, Dumelow's Seedling, Betty Geeson, and Mannington Pearmain. The last four are late varieties, but well worth growing. The following Plums do well as dwarfs: Rivers' Early Prolific, Belle de Septembre, Prince Englebert, Prince of Wales, The Czar, Sultan, and Victoria, all of them being good for market. Early Prolific comes in before the market is glutted, and Belle de Septembre after.

Seakale Boxes (*Melton*).—We are not aware that any firm makes what you require, and we would rather purchase pots than wooden covers for placing over the crows, as heat does not pass through wood so well as through earthenware. Still, boxes have been used successfully by Mr. Gilbert of Burghley, and

Fig. 86.

the annexed figure of one of his will enable you to make any number of a similar kind. They are simply four boards nailed together without dovetailing. They are a foot wide at the top, increasing to 18 inches at the bottom for covering the root. In height they vary from 18 to 30 inches, according as they are required for Seakale or strong-growing Rhubarb.

Pruning Trees (*A Twenty-years Subscriber*).—The length to which the shoots of newly-planted trees should be shortened depends very much on the roots. If they are well rooted you may remove about one-third or a little more; but if the roots are not numerous, or have been much cut in digging up, then shorten the shoots to half their length. Just as the sap is moving in the spring

is a good time for pruning the trees. Pyramids shorten similarly—that is, the leading branches; the side growths from those branches prune to one or two buds. If in the course of two or three years the trees grow too strongly you can check their luxuriance by root-pruning.

Pine Leaves Decaying (*F. C.*).—We shall be glad if you can quote the page on which we recommended liquid manure of the nature you describe diluted with half water, as unless it was advised under exceptional circumstances and special conditions there must have been a misprint, which needs rectification or explanation. If your Pine plants are not very large and the pots small, also crowded with roots, the stimulant would be too strong, and by checking root-action would lead to results similar to those indicated. Although water may not have lodged in the crowns we suspect it has accumulated at some time or other in the axils of the leaves, and thus aggravated the evil of which you complain. If you had informed us of the age and size of the Pines, the size of the pots, and whether filled with roots or not, together with the bottom and top heat to which the plants are subjected, in all probability we should have better comprehended the state of the plants and the best treatment to adopt under the circumstances. If you do not possess Mr. David Thomson's work on the Pine Apple, published by Blackwood & Sons, you will do well to procure it. It is a small volume, in which is recorded the experience of one of the most successful cultivators in Great Britain, and could not fail to be of service to you.

Cutting Down Vines (*Idem*).—If we remember rightly the Vines are very small, and we advised you to cut them down, with the object of producing strong fruiting canes another year. You had better place them in a cooler house. A Pine stove is certainly not the proper place for them at this season of the year, as their growth will be excited while rest is needed. When the leaves have fallen from at least two-thirds of the length of the cane, and the others are quite yellow and ready to drop off, cut down the Vines to a bold eye as near the soil as possible. The incipient growths to which you refer must be trimmed off, and the canes severed at a prominent bud that has not produced growth. Winter them in a perfectly cool place, and in the spring, when they commence growing, they will probably be better for being shaken out of the pots and the roots placed in fresh soil, as we apprehend the present pots, being large, are not filled with roots to the extent that is desirable, otherwise the canes would be as thick as your finger, short-jointed, hard, and studded with bold eyes, in which case cutting down would not be required. In all probability the variety to which you refer is the Black Muscat of Alexandria, a richly flavoured Grape, but not easy to produce in satisfactory condition.

Grape Vagaries (*M. D., Inverness*).—The first matter that perplexes you is that the Grapes in No. 1 division of your range, which is heated with eight rows of 4-inch pipes, are little, if any, earlier than those of the same kind (Black Hamburgs) in divisions Nos. 2 and 3 that are heated with four rows of pipes, all the Vines being started at the same time—namely, about March 1st. Our reply on this point is that the heat afforded by the eight rows of pipes is needlessly, and even injuriously high, and that the necessarily lower temperature in the other divisions is ample for ripening Black Hamburgs. When more heat than is requisite is maintained the growth of the Vines is unduly excited, which leads to debility sooner or later—that is to say, the Vines will fail to properly finish their crops sooner than others will that are grown under somewhat cooler treatment. That this is so your own Vines testify, as you say those in No. 1 division are "always ill coloured, better in No. 2, and pretty decent in No. 3." This indicates that the fire heat in No. 1 is excessive, drying the atmosphere unduly, and just as the artificial heat decreases in the range the Grapes improve. The Vines in the hottest division will start into growth the quickest, and will make a greater extension of growth before root-action commences than in the case of the others, to the certain disadvantage of the former as affecting the colouring process. Or, to put the matter in other words, the Vines in the cooler divisions will finish heavier crops than the others that are overheated can do, simply because the growth in the cooler structures is more steady at the first, and there is not the same delay in free root-action. The colouring of Grapes is not a question of ventilation so much as of support. If ventilation were the chief factor in colouring Grapes, then the crops in your three divisions would be finished alike, inasmuch as ventilation is similar throughout. The difference in the condition of the produce is entirely a question of support. The crop in the first house is too heavy, of that we have no doubt. But you may say it is not heavier than the weight of fruit in the others. It may not be, but the Vines are weaker, and 10 lbs. of Grapes on a debilitated Vine are far more exhaustive than twice that weight would be in the case of a strong and vigorous Vine. You must either reduce the weight of Grapes where the berries do not colour, or increase the root-action and the supply of food, for the want of colour is evidence of the want of support. We will now refer to your next perplexity, which you state as follows:—"A conservatory joins vinery No. 1, and a shoot of the Black Hamburg was taken through and trained, for affording shade, under the conservatory roof, this structure being kept as cool as possible all the summer with air on night and day. The same Vine that gives light brown Grapes in No. 1—the house with eight rows of pipes—in August, gives jet black Grapes in the conservatory in October, very sweet, and their skins are leather compared with their fellows in No. 1," and you conclude by saying "there are some things no fella can understand." This, however, is not one of them. If you consider for a moment you will perceive that nearly two months elapsed between the brown Grapes and the black Grapes ripening. All this time the Vine was increasing its roots, and we do not hesitate saying that they had at the least twice the food-absorbing power early in October that they had early in August. This is the simple solution of the problem of the brown and black Grapes on the same Vine. Very naturally you ask how you can have black Grapes in the vinery instead of brown, and suggest that you will owe us a bunch or two if we can inform you how to produce them next year. At once procure some fresh turfy loam inclining to be heavy instead of light. To each cartload add half a bushel each of bone meal and half-inch bones, also, if procurable, two or three bushels of wood ashes, mixing all well together, then remove much of the inert and ungenial soil from the roots, and place them in the fresh compost. If you notch some of them and shorten others you will find fresh roots form more readily, and take possession of the new soil. Keep the Vines cool, and let them start naturally in the spring; let the crops be lighter than before, ripen the fruit in September instead of August, and we think you will be able to send us a bunch of really black Hamburgs. If we have not made the matter clear to you, please write again.

Names of Plants (*H. W.*).—The plant is *Adhatoda cydoniaefolia*. See reply above. Seeds of the *Hierochloa borealis*, also known as *Holcus borealis*, could doubtlessly be procured from any of the principal seedsmen.

A Weak Hive (*Olyseus*).—As the hive which you have just bought contains only a small handful of bees and about 15 lbs. of honey it will probably

die during the winter. The bees in such cases generally perish in a cluster from cold. If the hive has three small seams of bees it may be preserved by closing the door and taking the hive into a house or room and keeping it there till spring, say end of February. You are probably right in thinking that mice have had access to the bees. They are great pests, and destroy many hives by killing the bees in autumn and winter. The doors of all hives should be contracted to keep them out. Feeding would not now cause the bees to breed.

Balance Sheets of Bee-keeping (*W. T. Garnett*).—We do not remember the numbers in which these appeared; but in the "Handy Book of Bees" (second edition) Mr. Pettigrew states that from 1870 to 1874 his profits were £220, after deducting the expense of 10s. per hive annually.

Making Mead (*A. Keeling*).—There are several methods of making mead, the following being recommended by an authority on the subject as simple and good:—To a gallon of water put 2 lbs. of honey and 1 lb. of sugar; boil for an hour, put in the whites of four eggs to clarify, and skim it quite clear whilst boiling; then put it into a clean tub, and let it stand for a week, putting in a toast with honey to make it work; then tun it, put in the peels of three or four lemons, let it stand for a month, and then, if it is not sufficiently fine, put in more honey, and let it stand longer.

COVENT GARDEN MARKET.—NOVEMBER 29TH.

THE character of the trade remains the same as recorded last week.

POULTRY AND PIGEON CHRONICLE.

NEGLECTED PASTURES AND WASTE LANDS.

(Continued from page 490.)

FROM quotations and observations we have endeavoured to make it apparent that the earthworm is a very valuable assistant to the farmer in every attempt which he may make to form or improve by renovating or manuring either old or new permanent pastures. There are, however, some operations of worms to which we may not have alluded, but which are fully treated of in the work written by the late Mr. Darwin. In it is an important allusion which had escaped our notice, and which has not generally received that attention which it deserves—namely, whether or not some of our most pungent and, we may almost say, caustic manures which we employ may prove to be destructive or distasteful to this valuable but humble assistant. We recollect that couch with earthy matters adhering to it proved to favour their operations more than fresh and active manures, like strong box or stall-made manure and town or farmyard dung.

Some reference is now needed to neglected pastures which first came under our notice about ten or twelve years ago, as illustrating valuable points. We had known this farm for more than forty years as consisting of a strong clay loam resting upon strong

yellow, or what we term beeswax, clay. It has during the past thirty years been fairly well tile or pipe-drained, and has borne fair crops of Wheat, Oats, and Clover when the seasons were favourable. It was always very heavy tillage, but during the past twenty-five years it has nearly all been chalked with a heavy dressing of upwards of 30 tons per acre, and greatly improved thereby. This statement is made with the view of showing that the basis favourable both for tillage and pasture had been laid by draining and chalking. For many years this was farmed on the old four-course system of Wheat, Oats, Clover and grass, and a winter and summer fallow. As the farm was unsuited for sheep-feeding, a dairy of cows had been kept, and in its management about ten or twelve years ago some of the fields only needed for hay crops with mixed Clovers and Rye Grass were left to become pasture and fed entirely by cows. Very little grass food was obtained, and, never receiving any manure, the Clovers died out and were succeeded by the *Carex* or Carnation Blue Grass, with some other worthless sorts, amongst which was the Black Bent, and Fiorin or Water Grass. But what made the land lie colder was that it was left in ridges $8\frac{1}{2}$ feet wide, the same as it was laid when in tillage. This circumstance alone did injury, and seriously impeded the prospect of obtaining a permanent turf, especially as it was fed off by dairy cows living only upon what they could obtain in these fields and some poor meadows, without ever obtaining any cake or corn, and in the winter time getting but little else besides straw or inferior meadow hay.

About seven years ago, however, a change of tenantry occurred on the farm, and the present tenant, a most enterprising and practical farmer, inaugurated an important change in the management of these neglected pastures. An improved method of feeding the dairy cows was also adopted, which were not only largely increased in numbers, but were of the improved Guernsey breed, and maintained especially for butter-making purposes, and assisted during summer and winter by 4 lbs. of cotton cake daily, in addition to a full bite of the best grass in summer, with a liberal allowance of Mangolds and good hay in the winter. They were expected to be beneficial, and proved profitable in two ways—first by yielding a large quantity of the best butter, and secondly by leaving valuable dung both on the pastures and in their stalls. When inspecting this farm with the present tenant about five years ago we advised him, in addition to his liberal mode of feeding the cows, to adopt a plan which had succeeded with us on various estates as to the manuring, and the plan has been carefully carried out by applying yearly about 4 cwt. of bone superphosphate per acre, and by each alternate year applying a liberal dressing of not less than 18 or 20 tons per acre as a compost of earth and farmyard dung, with some ashy town dung mixed together in the following manner. The earth obtained from various sources, such as roadside earth, couch, bank and border earth, and the proceeds of trenching in the meadows and ditches, and carted at all leisure times to large heaps made just within the fields or at the side of the roads contiguous to the pastures where it was intended to be applied, and each heap when made had a quantity of dung laid upon it of about one-third of its bulk, which was immediately turned up together and carefully mixed, and allowed to remain to amalgamate and decay, in readiness for laying out on the pastures, which was done in the early autumn on part of them in each year as the compost became ready and sufficiently decayed and commingled. We viewed this farm in the spring of 1879, before the plan of manuring had been continued long enough to show its effect; but on going over the farm again in the last week of the month of May this year 1882 we were greatly astonished to find a most extraordinary improvement on all the pastures which had been treated as before described, those which had been manured longest showing the best results; for upon two fields which had been the longest under treatment, although no seeds of any kind for renovating purposes had been

sown since the Clovers, &c., had died away, yet there were some of the heaviest crops of the best herbage we had ever seen, composed of Yellow Suckling, permanent Red Clover, and various kinds of useful pasture grasses. The weight of the crop for hay we estimated at 2 tons per acre of the finest quality, for the grasses were so thick on the land that they could not grow coarse. This was the result entirely of the feeding of cattle with cake and the dressings of composts especially adapted for the purpose in every way. Not only were the dressings of rich manuring value adapted for strong soils, but were also effective in setting the earthworms to work, a matter of the highest importance upon this otherwise impervious clay soil. At the same time, the earthy compost we consider eminently useful in encouraging the appearance and growth of the best grasses indigenous to the soil, and this we regard as most encouraging to the home farmer.

In the stocking and cropping of these pastures no sheep had ever been allowed to graze upon them, and dairy cows only had fed thereon after the hay was cleared. It must also be borne in mind that for the three years previous to our last visit hay crops had been carried off in each year, yet the improvement was as we have stated, which is a striking illustration of the wisdom of saving the grass for hay, and feed the aftermath only. But after the new grasses are thoroughly established we do not object to graze with cattle and take a crop of hay in alternate seasons.

In concluding our remarks we must urge the great importance to the home farmer of selecting each kind of seed separately, and endeavour to make himself acquainted with the shape and characters of them, so that in his own interest he may be able to examine and understand, after having ordered the kinds of seed which he requires, whether he has obtained them, and that he may then have the satisfaction of making his mixtures of seeds in his own way. We read in the *Journal of the Royal Agricultural Society of England* just issued that mixtures of grasses for permanent pastures have been brought before the notice of the Seed Committee of the Royal Agricultural Society, and examined by their consulting botanist, Mr. W. Carruthers, F.R.S., which had been purchased as containing the kinds and proportions of seeds recommended by a practical authority in the Society's *Journal*, and have been found to contain a large proportion of Rye Grass, Yorkshire Fog, and other worthless grasses. Nothing can show more forcibly than these facts the actual necessity of the home farmer having all his seeds required delivered separately, in order that he may not only scrutinise them as to their genuineness, but also have the opportunity of mixing them in such proportion of sorts as his soil and climate may render necessary in his own judgment and experience, or in accord with the experience of the most practical men.

WORK ON THE HOME FARM.

Horse Labour.—In nearly every district in the kingdom the seed-time for Wheat has been greatly delayed; even upon the hill farms and lightest soils the work of much Wheat-sowing has still to be done, and what has been done for the most part was succeeded by heavy rains in the night or day after seeding, which we know is much against the prospect of getting a regular plant of Wheat. When, however, we consider the condition of the heavy flat-lying soils in any district, seeding the land with Wheat in a satisfactory manner has been impossible unless done in September, and unless we get an immediate change of fair weather without frost but little Wheat will grow on such soils this year. It may be stated that we never had any reason to regret it when in the months of February or March we have sown what is called April Wheat. It has a bearded ear and yields a coarse strong sample of Wheat in the grain. We have obtained enormous crops of straw which is generally very stiff and strong, being well adapted for thatching farm shedding, ricks of hay and corn, and for sale in the towns for littering horses and cattle in stalls it is much valued; the yield of grain, however, is sometimes disappointing as to quantity, for the heaviest crops of straw seldom reach 40 bushels per acre. The horses have been fully employed where the land is high and dry by carting and heaping for store the crops of Mangold and Carrots, also in ploughing the stubbles to remain during winter. Upon the strong-land farms, however, the work for the horses for some time has been almost nil as

connected with land and its seeding, the ploughing and pressing. Drilling simultaneously has also been done at intervals upon lea ground with the press drill, which is made to deposit the seed in the grooves made by the rings of the presser, and when the harrows follow immediately after the work is securely done, and in case of change of weather, may be left at any period of the day. It is sometimes found to answer a good purpose in sowing by hand on the surface where the sheep have fed off roots, and plough it in shallow, and one advantage of this mode of seeding is that the corn does not become rootfallen and break down when in ear. The odd horse or mule will find full employment now to cart hay, straw, and roots for all the cattle and horses, they being now nearly all under cover except a few store stock. Earthing the cattle pens, pigsties, and similar work can now be done at odd times.

Hand Labour.—Pulling Mangolds is still being continued, also making up and covering in the store heaps. The meadows must be trenched, and water meadows will now be in flood and must have attention. Work in woodlands, too, will be going on, such as planting Firs for Hop poles, cutting underwood, Elm, and Ash timber; also hedging and ditching in the open districts. However, where dead fences are made of underwood and rods from the hedgerows creosote has been used with good effect by steeping the rods in liquid creosote, and the fence, it is said, will last double the time when so treated.

Live Stock.—We are approaching so near to the Christmas markets that the bullocks which are forward enough should be sold, in order to participate in the high prices which are likely to prevail. The same may be said of sheep which are fat enough, either of ewes, wethers, or tegs; they should all be sold, for they will very probably be dearer than we have ever known them. In the statement we made of the detail of feeding the early lambs last week we could not find space to finish our comments upon the subject as we wished to have done, and will now resume it by stating that first-class hay is of much more importance to this kind of stock than for wethers and older animals. We, therefore, in our practice always grew hay for the purpose, being composed of the finest and softest grasses, such as White Dutch and Yellow Trefoil Clover, without Rye Grass; for although the Trefoil comes into bloom earlier than the Dutch, that we do not regard, for when we have a full crop the Dutch makes the best hay when cut in grass just before it comes into bloom. We have obtained in a season or two the best hay made by Dutch alone, but it is too great a risk, as it takes much time in making, and we therefore mix Trefoil with it, enabling us to make the hay in three or four days' less time, and we always like to make it during the May month, without so much regard as to quantity per acre, our object entirely being to secure the best possible quality. When we have been deficient in the quality of our lamb hay the quality of the lambs has generally been disappointing. We have always been very particular where the ewes were fed on Mangolds at the troughs. It was our usual practice to so manage as to prevent the lambs from eating with them, as our best lambs were always made whilst eating white Carrots or James's Intermediate Red Carrot, because whenever the lambs are allowed to eat Mangold, especially after they are nearly fit for the butcher, the wether lambs are sure to suffer from stoppage of urine. We therefore always feed the lambs first in the morning; they will then draw away from the ewes into their own feeding fold in advance, and be shut in whilst the ewes are being fed.

POULTRY AND PIGEONS

POULTRY NOTES AT BIRMINGHAM SHOW.

THE annual gathering at Bingley Hall is looked forward to by many fanciers as the event of the year. The old birds are better through their moult than at the Palace, and some old faces which are to be seen nowhere else turn up at Birmingham with a regularity which says much for their faith in this old-established institution. This faith is in nowise misplaced. Although the authorities at Bingley Hall are inclined to be conservative, one good result of this spirit is that improvements, though they may have been tardily introduced, are steadfastly maintained. All the good results of a long experience were thus reaped in the Exhibition which opened on Saturday last. The penning arrangements were admirable. The awards were speedily made known. The wants of the birds were carefully attended to. Saturday was a clear bright day, and the additional windows in the roof constructed previous to the last Show made the light thoroughly satisfactory for judging, except just in the first row of Class 1. As last year, the awards are printed throughout in the catalogue by the side of the entries, which is a great help to those who want to refer to them quickly. Formerly it was necessary to turn continually from the entries to a list of awards like an appendix at the end of the catalogue.

Brahmas continue to head the list, from which position they some years ago displaced *Dorkings*; they filled 429 pens. The prize birds in these varieties were almost in every case priced at prohibitory sums, but we heard of various private sales at which birds changed hands at high figures. The 10 per cent. commission charged on sales

effected through the office causes many such private transactions to take place. Mr. Gibbins' cup Dark pullet, priced at ten guineas, fell to the hammer for sixteen guineas. The selling class birds in very few cases fetched more than their catalogue prices, an exception being the Rev. T. C. Peake's pair of Dark pullets priced at two guineas, which fetched five guineas. In the Dark variety there was a curious reversal of the Palace awards. This may be partly accounted for by the fact that the position of some of the birds as to height of pens and light was different, but we cannot allow this as a sufficient explanation. The old cocks (36) were on the lower tier, and looked much better. Lady Gwydyr's bird, which looked yellow in the strong light at the Palace, and was there unnoticed, here had the benefit of a position in the first row, which, as we have already noted, was rather dark. His size and shape here carried him to the front, and he took the cup for cocks and cockerels. He was somewhat closely pressed by second (Comyns), a medium-sized bird with a very graceful outline and broad cushion. Third (Norris) occupied the same position at the Palace, and is a fine bird, but now shows a little white in tail: h.c. (McMorland), the Palace cup-winner, here shows a lack of cushion; 1 (Sir H. Thompson), unnoticed on account, we believe, of a blind eye; and c (Norris) not quite fit yet, were also very first-class birds. Cockerels numbered fifty-one; they were as a class much better than at Sydenham. First (Lady Gwydyr) was a fresh one, very good in most points, but slightly deficient in fluff and cushion, and a trifle narrow in tail. Second, the Palace winner, and fifth were both shown by Sir Henry Thompson; we much preferred the latter. Third (Pritchard) we much liked at the Palace, where he was v.h.c. Fourth (Taylor) a large bird of good profile, but narrow-tailed and with slightly curved toes: h.c. (Adey) the Palace third, here looking a little brown on wingbow. Mrs. Bagshaw showed an extremely well-built cockerel, rather wild, and a shade too dark on wingbow. Mr. Norris's two very young unnoticed chickens will be heard of hereafter. In hens, which were a fine class, there was another reversal of the Judge's decisions at the Palace: Mr. Mitchell's h.c. hen at Sydenham here went up to cup. She is a large bird of a good type, moderately feathered, but hardly as fine in markings as we like. Second at the Palace held the same position here. Third (Taylor) large and shapely, but wanting clearness of ground colour and distinctness of marking. The Palace first hen here descends to v.h.c.; the light being stronger brought the brown into relief, but the same cannot be said of the Palace third and fourth, which are here only h.c. and unnoticed; they are grand in colour, with fine and clear markings. Pullets again seem to have struck the Judge very differently; they were sixty-three in number. The winner (Gibbins) was but v.h.c. at the Palace, and that was about her true position. The Palace winner, on the other hand, came here undeservedly down to v.h.c. Second (Sir H. Thompson) stood sixth at the Palace, while second and fourth there (Lingwood) here became third and fourth. We doubt if fifth (Ashworth) was even amongst the forty-five noticed birds at the Palace, and we prefer the Sydenham award. There were many good pullets in the class. In the Light classes, though the Judges at Sydenham and here were different, the awards were much more uniform. Cup, second, and we think third for cocks, went to the Palace birds, all good ones and well placed. 91 (Norris) and 103 (Percival) were also grand specimens: the former had a neater comb than most, and both had fine foot feather without a superfluity of hock; 107 (White), the Palace winner of last year, grand in all points but comb. Bad combs seem to be rather abundant in the Light classes this season. In cockerels, which were a good class, the Palace award was confirmed as regards Sir H. Thompson's cup bird; second (Lucas) very stylish, but far too long in leg; third (Breeze) shapely, but rather small; fourth (Ive) good in all but comb, and too much black in hackle; fifth we did not care for. Mr. White stood first and second with two very large well-feathered hens, not quite free from the prevailing fault of colour, which to a greater degree affected third (Lingwood), and more or less all the good birds in the class. The cup went undeniably to Mr. Nettlefold's Palace winning pullet in fine form. Even this beautiful bird is not quite free from the shade of buff on wings. Second (Morgan) and third (Mitchell) held, we think, the same position at Sydenham, fourth there being fifth here, the intervening bird being a well-marked pullet from Mr. Lucas's yard. 329 (Thorn) was a great bargain for six guineas, as if properly shown she could not fail to make her mark.

Dorkings filled about 280 pens. The Judge evidently considers white feet a highly important point. The cup for cocks and cockerels fell to the lot of Mr. Butler Smith's Dark cock, the cup bird claimed at the Palace for £20. Mr. Smith secured no less than five firsts in the Dorking classes—namely, the cup already referred to, first for Coloured cockerels, in the selling class, in the Coloured Dorking hen class, and in the Silver-Grey Dorking hen class. Mr. Cranston stood second for Coloured cockerels with a good all-round bird; Messrs. Smyth being second in hens with a bird which we rather preferred to first. She was perfect in colour, feet, and legs. The Palace winner was in this class only very highly commended. The Rev. Herbert Peel took the cup for Coloured hens and pullets with the pullet which held the same position at the Palace. She is very good in colour, with white feet, but with rather small toes, and the fourth and fifth toes not very well divided. Mr. Hulse and Mr. Cranston were the other winners in this class. Neither bird is perfectly white in feet, but we thought the third best in this respect. We specially admired Mr. Cranston's grand old Silver-Grey cock, a very model

of a Dorking, though past his prime. The Silver-Greys generally were superior to those at the Palace. The winning cockerel (Mulligan) was a good all-round bird though slightly ticked on breast. We noticed a failure in depth of colour on breast in the hen and pullet classes. The cup here went to Mr. Smalley for a pullet of pure colour though hardly as clear on feet as we could wish. In the variety classes most of the prizes went to Whites, which we thought very inferior.

Cochins numbered over four hundred pens. In the Buff classes Mr. Tomlinson carried off three out of the four firsts—namely, those for cockerels, hens, and pullets. He also took third for pullets. His winning hen and pullet were models of Cochin shape; the latter held the same position at the Palace, but has improved since then, being now more even in colour. The other winning hens were also grand birds; and Mr. Proctor's second-prize pullet is, we think, the bird which held the same position at the Palace, and which we much admired there. We could not endorse the cockerel awards of first and second; both are tricolor birds, a type which we hoped had been banished from the prize lists. Mr. Proctor's fine cockerels which we have previously commented upon stood third and fourth, and once more did not get their due. Mr. Percival's grand old bird, which won the cup at the Palace, here took the cup for best Buff cock or cockerel, and the cup for the best Cochin in the Show. The cup for Partridge cocks and cockerels went to Mr. Tomlinson for an old bird, good in most points though rather small. We almost preferred on this latter account Mr. Nettlefold's winning cockerel, whose chief fault was coarseness of texture of comb. The Palace cup cockerel was here if we mistake not only v.h.c. He now shows a patch of brown under his throat. A great feature of the Cochin classes was the extraordinary beautiful Partridge pullet to which the cup went, the only exhibit sent by her owner, Mr. Thorpe, hitherto little known in the poultry world. She is strikingly large and massive, with splendid feathering, and her marking is throughout nearly perfection. Her only fault is one wing being slightly slipped. Priced in the catalogue at £30, she was run up to thirty-four guineas at the auction. The winning hen was also a really fine bird in all points, though not so exceptionally well marked as the pullet. In Whites as usual Mr. Darby is amongst the winners. In cocks, however, he is beaten by his own champion of last year, which has twice since then changed hands at high figures, and here takes the cup for Whites. He stands second with a bird which is not quite out yet, but may later on take premier position. The grand old Palace cup hen is here to the front once more, though showing signs of wear. The cockerels are not so good as we have seen them in former years though the prizewinners are of considerable merit, and the same remark also applies to the pullets. The first (Darby) is beautifully shaped and in splendid condition, but wants size. We could not understand why Mr. Chase's pullet was passed over. In Blacks nearly all the firsts fall to Mr. Darby, though we must say that we do not think his present birds quite so magnificent as his Blacks of a few years ago, notably those which he sent to the Paris Exhibition in 1878.

Langshans had forty-seven entries in four classes. The winning cock (Oliver) was large and glossy, but wanted depth of chest. The first cockerel (Bush) was extremely brilliant in feather, though carrying a somewhat large tail. The cup went rightly to the first-prize hen (Mrs. Bennett), a really fine bird. We only remember to have seen one better, and that, if we remember rightly, came from the same yard. Hens and pullets alike show a waviness of comb which is somewhat of an eyesore to a fancier's eye.

Crève Cœurs were again not numerous, but, as at the Palace, the winners were of very good quality. Captain Turner again took three firsts, but the cup was awarded to a very beautiful pullet shown by Dr. Jackson.

Houdans had not as liberal a prize list as at Sydenham, and showed a falling-off in numbers, being only seventy-four as against ninety-six. Here we think the Birmingham Committee might fairly show more liberality. The cup again went to Mr. Marx's grand bird. Second (Wingfield Stratford), and third (Thomas) were also good. In cockerels Mr. Thomas's bird which we admired at the Palace was justly placed at the top of the list; second went to the Palace third (Mrs. Lane). In hens our selection at Sydenham (Turner) was rightly placed over Mrs. Lane's winner there, which here came third. The winning pullet also came from Mr. Turner's yard. The Houdans were on the whole good classes, though hardly so even throughout as at the Palace.

La Fleche had here two classes, but were not particularly good. Mr. Calvert and Mrs. Ricketts each won a first.

Spanish were neither so numerous or so good as at the Palace. The cup went to an old cock (Street), somewhat smoother in face than we have seen lately. The same exhibitor also stood first with a good hen, and with a pullet of nice quality of face though somewhat narrow over the eye. The winning cockerel (Wheadon) though good was not up to some we have seen this year.

Andalusian cocks and cockerels were the poorest classes we remember to have seen. The winning cockerels, though good in other points, had combs which were too heavy to be carried properly. The hens and pullets were better. Mr. Boissier and Mrs. Wilson respectively were the winners with birds very even both in ground colour and lacing. The seconds were equally good in lacing, but somewhat mixed in colour.

Leghorns were shown in pairs, an arrangement which apparently did not suit the exhibitors. The Palace winning Brown hen mated with a fair cock was in the first-prize pen. There were only five entries. Whites were more numerous, having twelve pens. Here again the Palace hen stood first, her companion being, we believe, the third cock. Mr. Fraser's beautiful cockerel here looked out of sorts, and was thrown by an inferior mate.

Minorcas had but three entries. Mr. Boissier's chance was spoiled by the ill treatment his pullet received from her companion.

Polish, though with two extra classes, fell some fifteen short of the Sydenham numbers. The beautiful White-crested were weakest, having but eight entries in four classes. This is indeed a pity, for they are about the most beautiful of the Polish varieties. Messrs. Partington, Unsworth, and Evans Broad showed good birds. Mr. Huish headed the list in Golden-spangled cocks and cockerels with two fine crested birds, probably father and son; they had much general resemblance to each other, and a common fault—a tendency to roundness of back. The difference in position perhaps contributed to the discrepancy between the awards here and at Sydenham. The winners in these two classes there were here passed over. The Palace cockerel especially was much admired for his beautifully coloured crest. The winning hen had a very distinctly spangled breast and large crest; second laced, but failing somewhat in parts. Both winning pullets had good crests and were well marked. In Silver cocks the Palace winner was again passed over. First (Adkins) wonderfully spangled on breast, with a fine crest, but rather dark at base of hackle; second same position at Sydenham. The cockerels were well selected and good in all points. The cup for the breed went to the first hen (Huish). This award we could hardly endorse, as the marking, though very distinct, was a something between spangling and lacing, and failed on the hackle. Second (Adkins), though rather too dark, had a good crest and well-marked tail. The first pullet (Adkins) was a beautiful crested bird of the medium type of marking; second only moderate.

Black *Hamburgs* by far pass the other breeds in numbers, in fact they nearly equal the other four put together. The class for cocks was not a good one. In cockerels Mr. Copeman took the cup with a very neat bird in brilliant condition, though slightly stained in lobe. The same exhibitor stood first for hens, and cup, second, and third for pullets, with very good birds; Mr. James Long being second in the hen class with a bird of the true type in brilliant condition. The cup Golden-pencilled cock (Cannan) was a wonderfully fine old bird, slightly stained in lobe. The first-prize Silver-pencilled cock (Fielding) had a pure white lobe and good comb and tail. Mr. Fielding's winning Golden-spangled cock was rather dark on breast, and with a pink tinge on lobe, but well deserved his position. The cup Silver-spangled cock (Ashwell) was a beautifully spangled young bird, perhaps a trifle too dark on breast and somewhat defective in colour of lobe. The Golden-pencilled cup hen (Fielding) was very finely marked throughout, as was also the first-prize Silver-pencilled hen (Beldon). The winning Golden-pencilled hen (Beldon) failed a little in wing-marking, whilst second was too dark in breast. The cup Silver-spangled hen (Mrs. Harris) was dull in colour and somewhat sooty in tail, and might, we thought, have given place to second (Beldon), a very good all-round hen.

Plymouth Rocks were shown in pairs. They looked better than at the Palace. First went to Mr. Bradbury for a nicely barred pair, though the cock was rather light in colour of legs. Second (Astley), the cock bad in comb, with a nicely marked hen.

Sultans and *Silkie*s were small classes. The winning pens in the former were rather yellow. The class was not as good as we have seen it. Mrs. Rickett's h.c. pair were the best in colour, though the hen was somewhat deficient in crest. Mr. Darby and Mr. Woodgate stood respectively first and second in the Silky class with good pairs. The Countess of Dartmouth showed a red-combed pair; but these did not seem to be admitted to competition.

Game were numerous represented, and were of much higher quality throughout than at the Palace. Black-breasted Reds of course made large classes. The cockerels numbered sixty, and the pullets fifty-seven. Captain Heaton is the hero of the season in this breed. His Black Red cockerel is the winner of three cups, including the challenge cup for this year, and he also took the challenge cup for pullets. His winning cockerel is a very perfect bird, though he might be a trifle larger and more powerful-looking in head. Second here goes to the same exhibitor, while of the rest we preferred 1540 (Lyon), passed over we believe through some error. Mr. Smith is a most able, painstaking, and conscientious judge, but his movements were, we thought, somewhat hampered by there being so many present during the judging. We think that at Birmingham some means should be adopted of excluding visitors from the classes which the Judges are actually engaged upon. The cup Brown Red cock (Brierley) and the first cockerel (Warner) were wonderfully good birds, while the cup Duckwing cock (Carless) was remarkable for his very beautiful colour. The winning Pile cock (Lyon) was of good type, though not perfect in head. The cup Black-breasted Red hen (Brierley) was a wonderfully good old bird, and took the cup over Captain Heaton's pullet, in consequence of the latter, though splendid in style, having a dark eye. The class of pullets was a wonderfully good one. In Brown Red hens the winner (Brierley) was a notable bird; the same exhibitor's cup and second pullet and Mr. Mercer's third-prize one were excellent, and the class a remarkably good one.

Of the rest we may note Mr. Thomas's cup Duckwing pullet and Messrs. Mather and Brierley's winning Pile pullets, the latter especially being of very high quality.

Aseel were but small classes, and with the exception of Mr. Dutton's first-prize cock (a Black Red) and Mr. Bryan's winning hen (a Black) contained nothing worthy of special mention.

Malays were good classes throughout. Mr. Futeher was first in the cock class with a rich-coloured dark bird of hard feather, carrying his tail rather high. The cup for the breed went to a powerful-looking cockerel shown by Mr. Bailey, while Mr. G. Burnell was first in hens and pullets respectively with very typical birds.

The *variety* class had only seven entries. First went to Mrs. Muir's Scotch Greys, second to Mr. Beldon's Buff Polish, and third to Messrs. Fowler's Pile Yokohamas.

Some extremely small and trim *Bantams* are shown. The first Black Rose-comb and first White Rose-comb, the latter also winners of a cup, and both shown by the Messrs. Crowther, are some of the very best we have ever seen, and took similar honours at the Palace. In the *variety* Bantam class a striking novelty appears from Lady Dartmouth's yards—viz., a pair of Bantam Andalusians, very perfect miniature Andalusians. Had they been a size smaller they must have won, as they are they well merited their v.h.c. First here went to neat Cuckoos, and second to Tailless. In Sebrights the Rev. W. Serjeantson was first and second with well-marked Silvers. Game Bantam were, as might have been expected from the classification, but few in number, and with the exception of Mr. Scanett's winning Black Red hen and Pile hen were not of any special note.

We are surprised to see so few fancy *Ducks* where such liberal encouragement is given to them. There were but two pairs of Mandarins and four of Carolinas, with special classes for each breed. The Call Ducks are very pretty, specially Miss Lawson's first-prize Brown pair. In Ducks the Rouens were considerably heavier than either of the other breeds, the cup pair weighing 21 lbs. 14 ozs. as against 20 lbs. 4 ozs. for the first-prize Aylesburys and 14 lbs. 12 ozs. for the cup Pekins, while the first-prize Goose scaled 45 lbs. 3 ozs. Mr. Wykes' cup Cambridge Turkey cock, and Mrs. Williams' second-prize bird, which was a Bronze Canadian, each scaled exactly 38 lbs. 8 ozs. : Lady Rothschild's winning cockerel 26 lbs. 8 ozs., Mr. Wykes' cup hen 22 lbs. 4 ozs., and Mr. Kenrick's first-prize young hen 17 lbs. 4 ozs.

The Judges were—Mr. W. T. Addie, Game other than Black Reds and Game Bantams ; Mr. O. E. Cresswell, Dorkings, French, and Fancy Bantams ; Mr. Dixon, Polish, Hamburgs, Ducks, Geese, and Turkeys ; Mr. Leno, Brahmans and Selling classes ; Mr. Montessor, Aseel ; Mr. Smith, Black Red Game ; Mr. Teebay, Cochins and the remainder.

TREDEGAR POULTRY SHOW.

THIS Show was held at Newport, Monmouthshire, on Tuesday and Wednesday of last week, and is noteworthy owing to its excellency and the liberal and perfect way everything connected with it is conducted. It is projected regardless of expense or profit, and there is no committee attached to it. It is generally termed Lord Tredegar's Show, as that nobleman is the chief patron, offering liberal prizes. Everything is managed through the Tredegar estate office, under the superintendence of Colonel Justice, his lordship's intelligent, courteous, and energetic agent. The Show just held, which includes general farm stock, is the sixty-fourth, and it is yearly increasing in magnitude. In 1874 the whole of the entries only amounted to 669, and this year they reached the total of 1078. In the first year named poultry numbered 315 and Pigeons 62, and this year poultry had 579 entries and Pigeons 138 ; or showing further the interesting increase, poultry numbered 116 more this year than they were last time, and Pigeons seventeen more than on the last occasion. This result is highly gratifying ; but we are not surprised at it, as it only proved the advantage of dealing liberally and fairly with exhibitors and the public. Five shillings is the poultry entrance fee, and those exhibiting for this reasonable sum have a chance of winning £2 and 30s. as the ordinary first prizes ; £2 specials in many of the classes, as given by Lord Tredegar ; and another £2 given by Mr. Cordes, late M.P. for Newport, for the best bird in the Show. Apart from this, and differing widely from most societies, an admission ticket is sent to every exhibitor. Besides this generous treatment every exhibitor has the list of awards posted to him gratis on the day of the Show. Altogether this Show is more worthy of support than any other we know, and it gives us much gratification to observe its substantial progress.

For many years the Show has been judged by Mr. Enoch Hutton, Pudsey, Leeds, and that gentleman again officiated in a most satisfactory manner. This year's Show merited a very lengthy report, as the quality of the exhibits throughout was unusually good, but space forbids us dealing with them fully.

Game altogether were grand, and the special prize for the best cock in the different classes of this breed was gained by Mr. J. H. Jenkins, Mountain Ash, with a very smart Brown Red. The special in the hen classes went to Mr. C. W. Brierley, Worcester, for a very stylish specimen of the same sort. The same exhibitor was well forward in several of the other Game classes ; and Mr. A. W. Evans, Newport, and Mr. R. W. Warner, Shrewsbury, had prize birds of merit.

Spanish were not numerous, nor were the specimens in these classes good. The best cock came from Messrs. Wingfield & Davies, Worcester, and the best hen from Mr. J. Bolton, Bristol ; Lady Allsopp, Hindlip Hall, Worcester, was highly commended in both classes for birds extra good in head and face qualities.

Dorkings were fine, Mr. Butler Smith taking first in both classes with a young cockerel and an old hen. The latter gained the special in the Dorking classes, and she deserved this distinction, as she was of immense size and true in colour. Hamburgs were very numerous, Mr. S. Fielding, Trentham, taking the chief share of the honours here.

Cochins made a grand show, the first-prize cock in the Buffs from Mr. W. Cannan, Leeds, being very deep and sound in colour. Old birds were mostly the winners in this class, the young ones not appearing to be so forward this time as we have seen them. In Cochins any other variety Mr. A. E. Ward, Sale, Cheshire, was first with a White cock, which was awarded Lord Tredegar's £2 as being the best bird in the Cochin classes, and it was also awarded Mr. Cordes' £2 as the best bird in the Show, winning in all £6, and he deserved it, as we have never seen a more perfect specimen of a Cochin of any sort.

Brahmas are always strong here, and there was no falling-off this year. In Light cocks Mr. G. H. Wood, Bucks, had an easy win, his bird being a long way ahead of the second one, from Mr. S. W. Thomas, in condition. Mr. R. Mitchell, Bradford, had several prizes in both colours.

Polish and *French* were large classes, all the best exhibitors in the country having specimens here, and the chief prizetakers were Mr. H. Beldon, Mr. C. H. Huish, Mr. J. Rawsley, Mr. P. Hanson, Mrs. D. Lane, Mr. S. W. Thomas, Mr. C. Bloodworth, and many others.

Leghorns, *Minorcas*, and *Andalusians* were well shown by Mr. E. Gibbs, Mr. J. Hopkins, Mr. J. Hobbs, and Mr. E. Emery. In both of the variety classes Mrs. Muir, Margam, was placed first with wonderfully good Scotch Greys, the hen gaining one of the special prizes as being the best in several classes.

Ducks, *Geese*, and *Turkeys* made a splendid show, the size of many being most remarkable.

Bantams were numerous, and all kinds were represented. In the Game cock section no less than fourteen came in for a notice from the Judge ; but this breed did not win the two specials for Bantams, as these went to Mr. T. F. Felps, Ross, for small, smart, well-coloured Cuckoo birds.

INSECTS INFESTING CANARY.—An answer is given to a correspondent on above in *Journal of Horticulture*. Some years ago I read somewhere that if a white napkin were spread over the cage for a few nights the insects would be found upon it in the mornings, and could be destroyed. I continually try this plan, and with complete success.—H. T.

FERTILITY OF HENS.—Some months ago I wrote to your Journal an account of the laying powers of two old Dorking hens in my possession. They have laid on the average five eggs each week from March till the end of the first week in October, when they began to moult. They were seven years old last March.—MARIAN.

REMARKS.

- 19th.—Fine bright morning ; sprinkle of rain 2.30 P.M. ; fine afterwards.
 20th.—Fine early ; afterwards unsettled and showery ; fine moonlight evening.
 21st.—Very bright morning ; afterwards dull, but dry throughout.
 22nd.—Dull and rainy at first ; afterwards finer, with high wind ; much warmer.
 23rd.—First part of day calm and fair ; squally, with rain from 4.30 P.M. ; very mild.
 24th.—Showery in forenoon ; fine afterwards ; moonlight evening.
 25th.—Rain early ; fine greater part of day, then showery ; lunar halo 9 P.M.

Although there was slight frost on Sunday morning, the temperature of the week has been considerably above the previous one.—G. J. SYMONS.

GARDENING PAST, PRESENT, AND FUTURE.

IN these days, when so many landlords have been compelled to forego a great amount of their rents, and consequently are finding their incomes very much curtailed; when many are reducing their gardening establishments as much as they can, and when others are turning them into market gardens, it is not unnatural that the question of the decline of gardening should occur to anyone who considers the matter.

Some there are who assure us that gardening has declined very much indeed both in regard to the comforts and pecuniary rewards of many who follow the profession, and also in the amount of professional knowledge brought to bear on the numerous subjects that claim the attention of those who have made gardening their pursuit.

Now, I think it must be conceded that in many places the comforts and salaries of gardeners have suffered. Anyone who is at all acquainted with the gardening world must know of some place that has for years been a model in regard to the unstinted support and general encouragement held out to the gardener to enable him to command success in all branches of horticulture; but, alas! evil times have come, and we see curtailment in every direction, and the place becomes a worry and vexation. Any gardener who has been accustomed to receive encouragement and support must, of course, feel the change when it does come, and this constitutes one of the elements that go to form what we term "the decline of gardening." What a heartbreak it must be to many a man who has for years been in the habit of getting everything he required to enable him to keep a large garden in perfect order, to have to scheme as to how much work can be accomplished with the diminished number of his assistants! Seeing many things that he had previously taken pleasure in having in the best possible condition becoming eyesores from want of the attention requisite to keep them right!

Such is the case in not a few of the largest places in the kingdom, and it is much to be regretted. The number of smaller places owned by wealthy merchants, but who in many cases, after having laid out a considerable sum on a garden at first, grudge the annual amount required to maintain it as it should be, is considerable, and that such is the case is also to be regretted. Still, we can point to some of our large landed proprietors who are able and willing to afford what is necessary to enable a gardener to have everything as it should be; also to many other liberal-minded gentlemen who do not grudge the annual expense, and who take a rational

interest in their garden, and think it is not mis-spent money that is employed to maintain it.

As regards the question of the decline of the present race of gardeners in the matter of professional skill something can be said on both sides. In the cultivation of some particular plant or vegetable there may be a falling-off from what used to be; but, taken all in all, there is not much to justify the charge that the present generation is behind the last in professional skill. It is too much the fashion of some to be always reminding others of the "good old times," but I feel sure that very few of those who sing the praises of those times would care to revert to them.

The improvements in horticultural structures and heating arrangements have been very great within the last thirty years, and have been much in favour of gardeners of the present day. Compare the simple and effectual means of ventilating now-a-days with the innumerable sashes and pulleys that used to be required in the old-style ranges of glass, and which are still seen in remaining old houses in various gardens. Compare the old flues with the grand boilers and pipes we have now. These and similar improvements go far to make gardening in these days easier, and therefore honour is due to many in past times for the successful way in which they pursued their calling and overcame many difficulties that are now almost unknown.

It cannot be denied, however, that in not a few cases men claim to be considered first-rate gardeners who in reality have never thoroughly mastered their profession; and here there is ground for an appeal to all who earnestly desire to rise in their profession to remember that gardening is an art that requires a steady and devoted study, an attention to details that many fail to give, and at the same time a power of grasping scientific principles, which, when understood, are invaluable. Those who by intelligent study of books bearing on the subject; by continual attention to everything in any way connected with gardening; by practising the best known methods of cultivation; and by noting personal experience and comparing results with others; adopting others' plans when such are proved superior—those who do all this deserve to be, and in many cases are, eminently successful.

No man need take to gardening, if he has the slightest wish to succeed, unless he is prepared to throw himself with great earnestness into the profession. When a man does so he is on the road to success, and may some day become a recognised leader in horticulture. In spite of temporary clouds obscuring the horticultural outlook in some quarters, I feel sure that a brilliant future is in store for what should always be the most ennobling and elevating pursuit in life.—EXCELSIOR.

PLANTING ROSES IN WET AND HEAVY SOILS.

OUR soil here (Bedfordshire) is locally known as "gault," but, more properly speaking, it is, I believe, boulder clay. It is of a pale yellow colour and full of small white chalk stones, which on being burnt become lime, and is very tenacious and retentive of moisture.

I have often been asked, "How do you manage to plant Roses in such soil in wet seasons like the present." My plan is a very simple one, but it is rather laborious, especially as I plant about five hundred every autumn. This is how I do it. First of all I stretch a line across the bed (which has been

prepared some months before), and beginning at one end about 18 inches from the outside I dig a hole and cast into it a good big shovelful of old potting soil or road grit, and upon this I place my Rose, carefully spreading out all its roots. I then cover them completely with some more of this light soil, and fill up with the gault. I then go to the next hole, and so on until the row is complete. We never trample round the plants until the ground becomes tolerably dry, then we tread lightly round each tree and muleh. I ought to mention that we use planks to stand upon when doing our work, so as to avoid trampling on the beds as far as possible. Nearly all my Roses are on the seedling Briar, and have been obtained from the Oxford nurseries. During the last four years about two thousand, both Teas and Hybrid Perpetuals, have been treated in this manner, and not a score of them have failed. Shrubs do equally well treated thus.

I have a sad tale to tell about the Roses on the Manetti, about three hundred in number, planted in October, 1881. They were fine plants when they arrived, and the wood seemed ripe and healthy; but in the following spring I found that in spite of mulehing, good drainage, and careful planting, at least one-third had died. The soil is too heavy for the foreigner. It simply dies in soil which seems to give full life and vigour to our English Dog Rose. I am well aware that people will say, "Would it not be better to wait until drier weather before planting?" I cannot say I think so. I hold that all planting should be completed by the end of the first week in November, and I have never found that Briar roots placed in light porous soil take any harm.

Many of the blooms that I exhibited this year were cut from Roses planted in the previous October. I fancy some persons may doubt this. Let them try the plan.—W. H. J.

[We give prominence to this short but very suggestive and useful letter. The method of planting is an excellent one under the circumstances. We have proved the value of a handful of fresh soil placed round the roots of a small plant when inserted, and a spadeful or two used in the same manner with Roses, shrubs, and fruit trees when the natural soil has been heavy and wet. The little extra labour involved by this care in planting is amply repaid by the satisfactory results that follow; in fact, the difference between careful and careless planting is not infrequently a difference between achieving success and incurring failure. The question of the relative merits of stocks for Roses is to a great extent a question of soils, and on this subject the remarks of our correspondent are opportune and useful.]

LOW NIGHT TEMPERATURES FOR GRAPES.

THIS year I have given the Vines under my charge much lower night temperatures than heretofore with the most satisfactory results. I think it is only fair to those who have so strongly advocated low night temperatures that all who have given the system a trial should, for the benefit of others, state their successes and their failures. In the first place I may say that all our houses contain different leading varieties, about half of them being Muscats. Previous to this year during the flowering period they were kept at a night temperature ranging from 67° to 70°. This year they were kept from 55° to 60°, and all, including the Muscats, set well. After flowering the night temperature was 60°, or as near that as the outside temperature would allow; on dull days it ranged from 70° to 75°, and 80° to 90° with sun. One and all exceeded my expectation, for without exception they finished well, my employers remarking that they were the finest and best-coloured Grapes they had ever had. The Vines are heavily cropped; as a proof, four rods of Gros Guillaume have an average of 4 lbs. to the foot. The treatment in every respect was the same as in former years, with the exception of at least 10° lower night temperature. I am aware there is nothing exceptionally low in the above figures, still much higher is advocated by some. Let others give their experience on the subject. I am fully convinced that were lower night temperatures more general we should not see so many Vines infested with red spider, and badly coloured Grapes as is now too often the case.—G. S.

AUTUMN FLOWERS.—*Calendula officinalis* flore-pleno has lately been making a grand display as a border flower. The seed was sown in spring and the plants treated as annuals, and their large,

double, deep orange-coloured flowers are now admired by all who see them at this dull season. *Campanula garganica* as an edging plant is attractive, its pretty blue bells and dwarf compact habit being great recommendations. It may be had in bloom from early spring to late autumn. I find *Zinnia Haageana* a useful annual for bedding purposes and for borders; is of a deep yellow colour, continues in bloom till the frost cuts it off, and is not affected by the wet. *Chrysanthemum segetum* has a lively appearance as a border flower. Another of our native plants which ought to have a place in all collections is *Malva moschata alba*; it is for the border and wild garden as beautiful as useful, continuing long in flower. East Lothian Stocks sown in the spring, grown on and planted out in the summer, are fine in the autumn. Plants so treated only need to be seen to be appreciated. *Eucomis punctata*, now established with us as a border plant, though not of bright colour, is interesting. That grand old *Fuchsia Ricartoni* does us good service in all places where a hedge of *Fuchsias* is required. This is one of the best for that purpose. Grown as a pyramid it makes a grand object for plunging on the lawn, and fine for the shrubbery. *Achillaea compacta* has been very fine in the border with its great plate-like yellow heads of flowers.—NORTH YORK.

CHRYSANTHEMUMS.

IT is some years since I have seen a show of *Chrysanthemums*; and being in London on the day of the Borough of Hackney Show at the Aquarium I availed myself of the opportunity, and was the more glad to do so, inasmuch as I had seen in September the collection grown by my friend Mr. Heywood of Reigate; and as I knew that he was an exhibitor was anxious to see how he came off; and as I have grown the flower for thirty years in my small way, and used every year in old Mr. Salter's time to enjoy the pleasure of visiting his winter garden and seeing all the new varieties of those days as they were coming out, my impressions of the Exhibition may be worth recording.

Since the days I mention the dressing of *Chrysanthemums* has developed into an art, as in the case of the Carnation and Picotee, and those who are not adepts in it stand but a poor chance. Whether this is well I leave to others to judge. For myself I do not admire it, involving quite an artificial style of flower and an immense expenditure of time and trouble. As I looked along the long line of boxes my first exclamation was, "The dresser has been very busy here I should think;" and so I found it to be the case. On my observing to an exhibitor, "I should think that those flowers have had half an hour each expended on them." "Nigher three hours," was the quiet reply. But even with this drawback the sight was not easily to be forgotten. The varied colours, the large size, and the curious forms of the Japanese made a very attractive exhibition. But is the game worth the candle? I saw at Mr. Heywood's hundreds of plants in the most robust health, but carrying, perhaps, two, three, or four blooms; and yet when I spoke to his excellent gardener Mr. Ridout, and asked him why he was not in the larger classes, his reply was, "Twelve are as many as we could do well. I might have put up twenty-four, but some of them would have been indifferent blooms—at least not up to the mark;" and when I saw the stands to which no prize was awarded I truly felt it was a difficult matter to come in in such a race. Mr. Heywood was first, however, as I should have anticipated.

I was struck with the fact how little of novelty there had been of late years in the incurved or Pompon varieties. The old and grand flowers, *Jardin des Plantes*, *Gloria Mundi*, *Nil Desperandum*, *George Glenny*, *Lord Derby*, *Beethoven*, *Golden Eagle*, *Queen of England*, *Empress of India*, *General Slade*, *Mrs. George Rundle*, and such-like flowers are still the best in cultivation; indeed most of the novelties in this class of late years have been sports from flowers already well known. The same remark applies to Pompons. We cannot now beat with new varieties the fine old varieties *Cedo Nulli*, *Trevenna*, *Trophée*, *Bijou d'Horticulture*, *La Vogue*, *Mrs. Dix*, *Duruflet*, &c. Now and then one crops up, such as *Golden Madame Marthe*, but as a rule the older varieties still hold the foremost place. By-the-by, it is a great mistake to show cut blooms of Pompons unless, as in *Pompon Dahlias*, in bunches.

It is far otherwise with the Japanese section: indeed twenty years ago they were unknown. In looking back at a report of the Crystal Palace Great *Chrysanthemum* Show in 1861, reported in his usual racy way by good old Donald Beaton, there is not even a mention of them; and when the first "Ragged Jacks" were introduced there was an outcry amongst the regular florists as to their hideous untidiness, and a regret expressed at seeing them, for they would inevitably spoil the larger flowers if they were hybridised with them. Some of us thought otherwise, and hoped to see a good deal of novelty introduced to this favourite winter flower, but I think few expected the results which have been obtained. Such flowers as *Elaine*, *Fair Maid of Guernsey*,

Peter the Great, Mons. Crousse, Madame Audiguier, Père Delaux, King of Crimsons, Fleur d'Hiver, Baronne de Prailly, Criterion, Comtesse de Beauregarde, &c., fully justify all that was anticipated of them; and certainly it was impossible not to be struck with the immense size of some of those exhibited at the Aquarium. Some of them were 9 and 10 inches across. And they have another advantage: they refuse to submit themselves to the *friseurs*, or, rather, they can do little for them. Many of them, too, when grown to a moderate size are excellent for bouquets and vases—better, indeed, than the larger and more formal incurved varieties.

I was not particularly struck with the specimens in pots, and fancy that I have seen them better grown. It is difficult to avoid formality in training; and as in the large pot Roses, I am not sure, however wonderful they may be for their size and the multitude of blooms, yet smaller plants more naturally grown are to the general run of people more acceptable.

Surely it is one great advantage that this flower possesses over many others, that it is everybody's flower. From the palace to the cottage all may, and many do grow it. It thrives in the murky atmosphere of our great towns, and, moreover, at a season of the year when few other flowers, except in the case of the wealthy, are to be had. It is pleasant to go into a greenhouse and find it filled with floral beauty in foggy November or chill December; it is pleasant to go into an exhibition hall and find it filled with an attractive collection of flowers; and for these reasons I think the fashion for the Chrysanthemum is not likely to pass away, as has been the case with some other flowers.—D., *Deal*.

[King of Crimsons is neither a new nor a Japanese variety.]

THE CUCUMBER DISEASE.

MR. JOHN GADD'S communication on this subject (page 470) is interesting, and I must congratulate him on getting rid of the disease so quickly. At the same time I must tell him that if his plants had the particular disease I wrote about in the Journal for November 9th much severer measures would be necessary for its eradication. The affection he speaks of appears at the roots of the plant, and has often been described in this Journal. The disease I mentioned has not, as far as I know, been described anywhere; and although specimens have been sent to scientific men, nothing satisfactory has yet been made known concerning it. The roots in my case are not affected; the disease shows itself first in the fruits, and then in the foliage and branches. Exudation of a gummy substance from the fruits, stems, and leaves is the principal feature; the fruits also curl round and generally refuse to swell, while those which do swell have patches in them which are hard and bitter. Cuttings from my plants carry the disease with them for certain, and it is almost certain that seed would do so too.

Mr. Gadd did not even clear his house, if I understand him, but kept the plant he had raised from a cutting in it. My houses were cleared several times, scalded, fumigated with sulphur, lime-washed and painted, seed obtained from a healthy source, and all to no purpose. I therefore think Mr. Gadd was extremely lucky in getting free as easily as he did. I said in my former paper that nothing short of complete isolation and seed from a healthy source will suffice; since then I have had further testimony that the isolation to be complete must include the attendant and his implements, for a nurseryman of my acquaintance has told me that he has been trying the isolation plan this summer and failed. I asked him what he had done as regards the attendant and his tools. His answer was that he could not manage to have a separate man to look after a Cucumber frame, and he did not think it necessary. But if the disease is of fungoid origin, as I suspect it is, we can easily understand that if the attendant does not carry it from one lot of plants to another it is more owing to good luck than good management; and I would advise that any nurseryman who unfortunately has the disease in his plants, and cannot afford complete isolation for a fresh stock, should give up the cultivation of Cucumbers for one season. It cannot possibly pay him to grow diseased plants, and in attempting to make it do so he may be spreading the infection far and wide.—WM. TAYLOR.

EARTHWORMS IN NEW ZEALAND.—The following interesting observations form part of a communication from Mr. A. T. Urquhart to the Editor of the *New Zealand Journal of Science*, and appear in the September number of that periodical. In October, 1875, I dug a trench on some newly cleared land—a raised beach at Manukau Harbour. The section then showed about 4½ inches of black mould, and a horizontal layer 1 inch thick of burnt clay, wood ashes, small stones, and pumice lying on a brownish-green arenaceous clay. The vegetation cleared was the growth of some thirty years. A portion of the land was left undisturbed. Measurements again taken a few

days ago gave an average depth of 1¼ inch of turf, 5¾ inches of black mould, and there was no perceptible difference in the layer of ash. An angular block of Trachyte about 25 lbs. in weight, placed in May, 1875, had sunk 1 inch, allowing for the turf. As the results of some accurate calculations as to the number of worms per acre, Mr. Urquhart gives results so considerably higher than Henson's, that he would have hesitated to publish them were he not in a position to prove them. Henson, it will be remembered by the readers of Darwin on "Vegetable Mould," calculates that there are 53,767 worms per acre in garden mould, and above half that number in corn fields. Mr. Urquhart's estimates, founded on digging about a quarter of an acre, as well as by a large number of tests on various parts of the fields—some that were under pasture for over sixteen years—gave from four to twenty-six earthworms per each square foot. The alluvial flats, slopes, and richer portions of the upper lands would average eight to the square foot, or say 348,480 per acre. In the uncultivated Fern lands worms are scarce. In New Zealand worms not only leave their burrows but climb up trees in search of food, this chiefly in the night time, though often until a late hour on damp warm mornings.—(*Nature*.)

SCRAPS ABOUT FRUIT.

RINGER AND TOM MONTGOMERY APPLES.—These are quite distinct Apples. Tom Montgomery has been grown in this neighbourhood extensively for many years. It was said to have been a seedling of Tom Montgomery's, but some doubted this. It is the same Apple as has been mentioned repeatedly in your pages lately—viz., Early Julien. This variety was sent here with a number of others from the Royal Horticultural Society's gardens, and was recognised as Tom Montgomery, and when cut and tasted quite agreed in every respect with that variety. Ringer is an Apple of the Keswick Codlin shape, not so elongated, but a good hardy kitchen Apple.—AYRSHIRE AMATEUR, *Kilmarnock*.

THE PRUNE AND CLUSTER DAMSONS.—I have a dozen trees of Prune Damson, none of which have ever borne a heavy crop, and I believe this to be the case generally. Twice only have I seen it with a full crop—in the deep rich loam of Mid-Kent and in the equally good soil of the Chilwell orchards near Nottingham. The Kent trees were closely pruned espaliers, and the Nottingham trees were unpruned standards, which proves that in a really good fruit-growing soil it will answer, but without it it fails. Cluster Damson, on the contrary, answers as well in our poor thin soil as it does in the Kentish orchards. Its growth is singularly robust, free, and healthy, and the fruit, always abundant in all favourable seasons, clusters so thickly upon the branches as to quite hide them from view. There can be no question that it is the best of all Damsons for market fruit-growers.—EDWARD LUCKHURST.

PEAR BEURRÉ D'ANJOU.—This proves a really first-class Pear. The fruit is very handsome, of large size, very sweet and juicy, with a delicious acidity and pleasant aroma. The crop this year was full and fine, the first dish of it being ready for table the beginning of November, and the ripe fruit keeps so well that it will probably be good till Christmas. The tree is an espalier of the palmette verrier form; and although it is not a large tree now, it came so slowly into bearing that I have not hitherto been able to fully appreciate its great excellence.—E. L.

KITTATINNY BLACKBERRY.—Your correspondent (see page 474) should plant the Blackberry just mentioned in a favourable situation in the kitchen garden, say along his rows of autumn-bearing Raspberries, in rows 5 feet apart and 3 feet between the canes in the rows, and tie them to a couple of wires or pieces of string strained to small posts or sticks the entire length of the rows. This done, a good mulching of half-decayed stable manure should be placed between the rows; and next summer train the young canes or suckers proceeding from those planted now to the wires, one on either side the parent plant, cutting away all superfluous canes as the work proceeds, and in other respects treating them the same as summer-bearing Raspberries, for like them the Bramble bears fruit on the preceding year's shoots. I think the result will be such as to amply repay him for his trouble.—H. W. WARD, *Longford Castle*.

USEFUL PLUMS.—Plums that hang long on the trees are invaluable to those who have large provision to make for dessert and culinary purposes. No Plum in cultivation at this season stands higher in the estimation of cultivators than Coe's Golden Drop. When in prime condition the fruits are like honey to the palate, when partly shrivelled they are all that can be desired as a Plum. Reine Claude de Bavay under the same circumstances is a suitable companion to Golden Drop. They are worthy of all

care. They are both sturdy growers and good bearers on the wall in different aspects. They are not over-particular as to soil or situation, but should have liberal treatment. Coe's Late Red and Ickworth Impératrice are first-rate for tarts and preserving, hanging on the trees well into November, and are highly esteemed. They must, of course, be protected from birds, and as far as possible from drenching rains, so frequent at this season.—
PRUNUS.

LANE'S PRINCE ALBERT APPLE.—I observe that one of your correspondents asks for details respecting this Apple. My experience of it has been most favourable; indeed I have more than once told Mr. Lane, sen., that he ought to make more of this Apple, as the more it is known the better it is liked. It is curious that in another column of the same issue (November 23rd) this Apple is mentioned as having proved a great success at Mentmore. By the kindness of Messrs. Lane I have been furnished with an account of their Prince Albert, from which I have extracted some details. This variety was obtained from a seedling tree in the garden of Mr. Squire of Berkhamsted, and was sent out by Messrs. Lane a few years since. It has been in great demand during the past season, as those who have tried the tree are planting it in larger numbers. It is a culinary Apple, lasting until March. The fruit is somewhat large, of a greenish colour, with a tinge or flush of red on the side next the sun; the flesh is white. The tree is hardy and succeeds in almost any soil, but it fruits best as a pyramid, though it does well as a standard. It rarely, if ever, fails to produce a crop. Unlike many varieties that require to be grown on the Paradise stock for early fruiting, Prince Albert is described as producing fruit the second year after grafting when grown on the free stock. Those who wish to obtain this variety should plant pyramids as the best form of cultivation for this Apple.—E. BARTRUM, *Berkhamsted, Herts.*

IN answer to "A SUSSEX AMATEUR" respecting Lane's Prince Albert Apple, I can very strongly recommend it as a most excellent kitchen Apple, one that with me never fails to give a crop. My soil is in first-rate condition, as I never spare manure, and periodically trench or dig the ground two spits deep, burying the manure at the bottom of the trench, so that I have always plenty of soil for my trees to grow in and feed on. I have not tested the keeping properties of the Apple, as it has always been a favourite for the mincemeat, and it is then perfectly sound, but I have no doubt would keep to the end of January. I find it a very free grower, having some seasons to shorten the shoots back 2 feet.—GEORGE B. CLARKE, *Woburn.*

OF HUMUS.

(Continued from page 498.)

AS many soils contain very little humus, and the most barren soils often contain it in abundance, it cannot be said, as was formerly erroneously supposed, that the proportion of humus present affords a sure index by which we can judge of their fertility. With the more correct information we now possess on the part played by humus in vegetation, it can be asserted only that fertile soils are usually characterised by its presence in considerable quantities, though such presence may be sometimes injurious; and Liebig appears to me to have spoken unadvisedly when, in his "Familiar Letters," he wrote that it is without action if the fixed mineral constituents serviceable to plants are absent from it." On the contrary, it will appear from other numerous and well-weighed statements of his, that the presence of humus, quite independently of any mineral substances it might possess, has a most important influence in increasing and maintaining fertility. For one proof of this I have only to refer to my last letter, in which the absorptive properties of humus for vapour of water (1) are dwelt upon. And this valuable function of absorbing water is an indication that humus possesses other and, as Ville maintains, more useful properties—"It fixes ammonia in the soil, so as to prevent its being carried off by rains."

Ammonia may exist in the soil in three conditions—(a), as gaseous carbonate of ammonia; (b), as ammonia physically condensed on the surface of the particles of soil, as happens when charcoal is exposed to this gas—a property apparently dependant on its porosity; (c), as ammonia chemically combined, which takes place whenever it comes in contact with the acids formed during the decomposition of animal or vegetable substances.

The experiments of Boussingault and Lewy have shown that in most cases the gaseous ammonia existing in the soil is minute in quantity, and it would appear from their investigations that the physically and chemically combined ammonia also (b and c) is present in the generality of soils in small amount; but still these

three causes of storage in fertile soils must exercise an important influence, and Liebig concludes that "soils which contain much vegetable matter absorb more ammonia and retain it more firmly than soils which are poor in decaying vegetable matter"—in other words, as they contain a greater or less per-centage of humus.

It may be remarked here that the degree of decay which the inorganic matter of a soil has undergone must materially influence the question whether the ammonia which is stored by a soil is physically absorbed or chemically combined. As the condition of pure humus is more nearly attained, so the quantity of ammonia absorbed (b) will be greater; whereas, during decay and the formation of the acids of the humus group, the quantity of ammonia combined chemically (c) may be the more important. The composition of humus is very complex in its chemical character, and the knowledge possessed of it is confessedly incomplete. Even the results of the analyses of many of the bodies which are supposed to be generated as the decay of humus proceeds, such as ulmin and ulmic acid, humin and humic acid, are not in all cases accordant. "Either several distinct substances have been confounded under each of the above names, or the true ulmin and humin and ulmic and humic acids are liable to occur mixed with other matters from which they cannot be or have not been separated."—"How Crops Feed," S. W. Johnson.) Berzelius discovered that there were two other acids existing in the acid liquid from which ulmic or humic acid has been separated, and these bear the names of apocrenic acid and crenic acid respectively. Mulder remarks that "in every fertile soil these acids (apocrenic and crenic) always occur together in not inconsiderable quantities. When the earth is turned over by the plough two essentially different processes follow each other—oxydation, where the air has free access: reduction, where its access is more or less limited by the adhesion of the particles, and especially by moisture. In the loose dry earth apocrenic acid is formed; in the firm moist soil, and in every soil after rain, crenic acid is produced, so that the action or effect of these substances are alternately manifested."

While the precise constitution of all these substances may be a matter of doubt therefore—and may remain so while the difficulties of procuring them in a pure state are unconquered—their existence in the soil, their production by humus, and "their importance in agricultural science are beyond question." If, also, it cannot be said to be proved that humus is absorbed by plants, the evidence in the matter is in the favour of its nutritive functions. "While no one denies or doubts that the last products of the destruction of organic matter—viz., the carbonic acid, ammonia, nitric acid, and water, together with the ingredients of ashes, chiefly nourish agricultural plants, no one can deny that other bodies may and do take part in the process." But although crops on the farm are rarely raised without the concurrence of humus, or at least without its presence in the soil, it is by no means indispensable, as I have already observed, to their life or full development.

In the decay of vegetable matters buried in the soil many other acids than those above named are produced; but as many of these can exist only temporarily as the results of fermentation and decay, and for the most part pass into carbonic acid, we now turn to the influence of carbonic acid in the soil. "Up to the present," Ville says, continuing his remarks upon humus, "these functions have not appeared very important, but now the utility begins to be evident. It absorbs the oxygen of the air, and afterwards undergoes a slow, inappreciable, but real combustion. It thus becomes a source of a gradual but uninterrupted formation in the soil of carbonic dioxide, which is less useful on account of the carbon it furnishes to vegetation than for the solvent power which it exercises with regard to certain minerals, and especially calcic phosphate and limestone." "We shall prove the truth of this fact by a very simple experiment. Grow two plants in calcined sand, one with the aid of humus and the other without, giving to both the same quantity of chemical manure. In both cases the yield will be exactly the same, but analysis will show that there is more calcic phosphate in the crop obtained by the aid of humus than in that grown by the sand alone. Humus, therefore, helps to supply the plants with phosphate."

"Humus can in certain cases produce a still more useful effect, for in a measure it increases the yield. This happens when the humus is associated with calcic carbonate.

"To prove this we will make four fresh experiments. In the first place we will grow some plants in calcined sand, the soil being provided with nitrogenous matter, and all the necessary mineral matters which must be employed in these conditions with the exception of calcic carbonate. If 22 grains of Wheat are sown the crop will weigh from 307 to 337 grains. This yield is

not altered by adding humus. Add humus to the sand and the crop does not change; substitute calcic carbonate for humus and still there is no change; add at the same time both humus and calcic carbonate and the yield is increased in weight to 475 grains. These facts being practically of fundamental importance I subjoin the following table:—

	Nature of Soil.	Yield Grains.
1.	Normal manure—calined sand.....	337
2.	„ „ limed sand.....	337
3.	„ „ sand and humus.....	337
4.	„ „ sand with lime and humus.....	475

Ville gives the name of normal manure to “a mixture of phos-

phate of lime, potash, lime, and a nitrogenous material.”—
INQUIRER.

(To be continued.)

BECKETT HOUSE, BERKS.

CHARMINGLY situated within a mile east of the Shrivenham station of the Great Western Railway is Beckett House, the picturesque residence of Viscount Barrington. It is a fine stone building in the Tudor style; was erected in 1829 from drawings made twenty or thirty years previously by the Hon. Thomas

Fig. 87.—BECKETT HOUSE.

Liddell, and stands on a slight eminence in the midst of its own beautiful and well-kept grounds, a grand feature in which is an extensive sheet of ornamental water immediately in front of the mansion, and extending from east to west of it, and which is stocked to repletion with a variety of aquatic birds, including wild ducks, which, flying hither and hither in the sunshine, add not a little to the characteristic beauty of the place. The banks of this lake, for such we shall call it, are planted with such flowering trees and shrubs as Lilacs, Laburnums, Guelder Roses, Syringas, &c., and in spring their flowers fill the air with their perfume, thereby adding sweetness to the pleasure that a stroll through these beautiful grounds at any time affords the visitor.

Adjoining the west front of the house and communicating with the interior of it is a handsome conservatory, 55 feet long, 25 feet wide, and of proportionate height, and having a tessellated tile floor. A house of this size takes a large quantity of plants to fill it. At the time of my visit (August) the centre was filled with two large plants of *Dicksonia antarctica*, surrounded with smaller plants of Palms, *Ficus elastica*, Acacias, *Abutilon Boule de Neige*,

Begonia semperflorens (a very free-flowering variety), &c., *Dracæna Veitchii* forming a background, and grouped with well-flowered plants of *Pelargoniums*, *Fuchsias*, *Begonias*, *Hyacinthus candicans*, *Caladiums*, *Eucharis amazonica*, Ferns (among which were a few fine specimens of *Adiantum cuneatum*), &c., all of which were arranged with good taste and to the best advantage under the immediate supervision of Mr. W. Meads, Lord Barrington's energetic head gardener. Planted out at one end of this house is a very large specimen of *Camellia imbricata* in fine condition, and from which ere long expanded blooms may be cut by the hundred. The back wall is completely covered with *Ficus repens* and Lemons, the pillars being embellished with climbing Roses, *Plumbago capensis*, *Heliotrope*, and Oranges, the ripe and ripening fruits of the latter, together with the Lemons, being very effective when contrasted with the numerous foliage and flowering plants by which they are surrounded. The front and roof are draped with well-flowered shoots of *Trachelospermum jasminoides*, *Jasminum grandiflorum*, *Habrothamnus elegans*, *Passiflora Imperatrice Eugénie*, and *Tacsonia Van Volxemii*, the shoots of which

intermixing and depending gracefully give to the whole a natural and perfect finish.

Descending from the conservatory to the terrace, whence fine views of grassy slopes, noble trees, and charming vistas are obtained, one of the latter—due west, with the church in the distance, whither a broad walk or drive leads first over the ornamental bridge which spans the lake within 60 yards of the mansion, and is built on a series of arches—being especially worthy of passing notice. In the immediate vicinity of this bridge are fine masses and trees of Yew (*Taxus baccata*), Weeping Birch (*Betula pendula*), Purple Beech (*Fagus purpurea*), &c., which I may add are effectively reflected in the pellucid waters in the foreground, and, together with the masses and variety of colour in the flower garden, and the expanse of rich green lawn close by, make a picture which for beauty of outline and variety of subject has few, if any, superior to it in the country.

The flower garden, which is geometrically laid out and capitally kept, is situate opposite the south and east fronts of the mansion. The beds were well filled with select varieties of plants, which were flowering profusely, and the combined effect of which fully demonstrated that the colours had been judiciously arranged; and the same may be said of the carpet hedging, which was very effective, and confined to a bed 90 feet long and 10 feet wide, running east and west in the direction of the low wooden foot-bridge, which is about 100 yards south of the one referred to above, and from which pretty peeps of scenery both under and above the latter are obtained—scenery which the pencils of a couple of fair artists were at the time assiduously transferring to their sketch books. Although the flower garden cannot be said to be a large one, it is stated that forty thousand plants are required for its embellishment every year. Before leaving the flower garden and grounds I may remark that they contain a few good Coniferae, including *Cryptomeria elegans*, *Taxodium distichum*, *Wellingtonias*, also some fine specimens of Elm and Beech; and at the west side of one of the bridges already mentioned, and which we cross to get to the kitchen gardens, is a summer house designed by Sir Christopher Wren which is said to contain a choice collection of old china, and to be two hundred years older than the mansion.

Leaving the flower garden and proceeding in a south-westerly direction, we come to the kitchen gardens, passing on the way thither several interesting spots, and which, together with Mr. Mead's cottage and the glass houses, are situate a short distance to the right inside the Shrivenham entrance to the park; in which I may remark are some fine trees, walks, and glades, through which pleasant peeps of distant scenery—including "White Horse Hill," six miles off—are obtained, and the branches of spreading trees prevent their being seen from the carriage drive.

The kitchen gardens, in three divisions, cover an area of 4 acres. The soil is a sandy loam inclining to clay, resting on a bed of the latter, and they are well and judiciously cropped with vegetables and fruit trees, which are also grown in this department, and, like trees in the generality of places this year, thinly cropped. Nearly two thousand heads of Celery are grown in beds containing four rows each.

Glass Department.—The first range we entered consists of two vineries planted with Black Hamburgh and Muscat of Alexandria, which were carrying good crops of average-sized and well-finished bunches. The next we came to is a span 90 feet long, and in three divisions, and running east and west, the first division being used for supplying winter Cucumbers; the second for stove plants, including Orchids for decorative purposes, the roof of this compartment being draped with well-flowered plants of *Stephanotis floribunda*, *Clerodendron Balfourianum*, and *Bougainvillea glabra*; and the third division, south side, was about to be filled with good varieties of winter-flowering Pelargoniums (250 plants), and the north side with such good free-flowering winter plants as *Bouvardias*, *Pentas carnea rosea* (a perpetual-flowering plant), *Begonias*, *Eranthemums*, *Gesnerias*, *Justicias*, *Lihonias*, *Poinsettias*, *Primulas*, *Cinerarias* (two hundred plants of each), and *Cyclamens*. This division during the summer months, while the winter-flowering plants are being grown-on in pits and frames, is devoted to the culture of Tomatoes and Cucumbers. Leaving this range we entered another span, which is devoted to the growth of Azaleas, &c., for conservatory decoration, and close by are three pits for Strawberry, Melon, and early Tomato culture, and in one of which I noticed a fine hatch of *Amaryllis* Sir John Franklin (fifty large hulbs) just coming into flower for the embellishment of the conservatory, and for which purpose this variety as grown by Mr. Meads is admirably adapted. A short distance northward of this house is a Peach case 100 feet long, and planted with the following excellent and well-tested varieties—viz., Peaches: Royal George, Grosse Mignonne, Bellegarde, and

Barrington; Nectarines: Elruge and Hardwicke Seedling, all in fine condition and carrying good crops of large handsome fruit. Tomatoes President Garfield and Dedham Favourite are grown in pots along the front of this case, their growth being restricted so as not to exclude any light from the Peach and Nectarine trees, which are planted and trained in the usual way against the hack wall, which is somewhat low.

Frame Ground.—A brick pit and sundry frames on hotbeds are used for the production of early vegetables and Violets (*Marie Louise*), which, as in most places, are in great demand at Beckett, as evinced by the fact that a cold pit 100 feet long and three four-light frames are devoted to their culture. Chrysanthemums (two hundred plants in 12-inch pots), Tea Roses, Tree Carnations, Eupatoriums, *Salvias*, *Richardias*, &c., which are now doing good service in the conservatory, were also located in this quarter; and a short distance off are situated the summer and winter Mushroom houses, fruit-rooms, and potting-sheds.

In concluding this notice of the gardens and grounds attached to Beckett House, over which Mr. W. Meads has presided during the last seven years with credit to himself and satisfaction to his employer, I may be allowed to state that Lord Barrington's kindness in throwing open on many occasions his park and grounds for fêtes and flower shows, &c., is highly appreciated by the residents of the surrounding districts; and for the good of horticulture and the community at large I would here express a hope that those occupying a similar position to Lord Barrington may, upon the perusal of these notes, be induced to follow the good example thus set by his lordship.—H. W. W.

[Accompanying these notes were two photographs, but our excellent correspondent will, we think, admit that neither of them is quite equal to the engraving which we had prepared in 1873, and which has certainly not been seen by many hundreds who have become readers of the Journal since that time, including possibly the present successful gardener at Beckett, Mr. Meads.]

DEW IN HOTHOUSES.

YOUR correspondent "CASUAL" quotes a part of the following sentence from me which occurs on page 447 of No. 1781:—"The temperature does not decrease so rapidly as that outside, owing to the presence of a warming apparatus and the screen of wood-work, glass, and foliage, which checks radiation, so that what is generally called the dew-point is not actually reached," and argues from this that I imagine the dew-point both indoors and out is at some fixed point of the thermometer. I do not understand how the passage will bear this construction.

The word "generally" is used because I am at that time speaking of dew-formation as it occurs from a falling temperature (the rules for finding out the point at which this occurs may be seen in any text book on the subject), as distinct from that which takes place with a rising temperature, and which is of the most importance to gardeners, but is not enlarged on in any text book I have seen.

Let me assure "CASUAL" that it is of little use for a man to commence indoor gardening till he has a slightly better knowledge of the subject than I am given credit for possessing. Your correspondent acknowledges that he does not understand the second conditions I mentioned under which dew is formed (not by different laws, mind), and I am obliged to come to the conclusion that he equally fails to understand what I meant to convey in the sentence quoted. I am as much disappointed about this on my own account as on his, for I always endeavour to be clear if I cannot always be correct; and if I have not made my meaning clear to practical readers I shall be happy to return to the subject, and will do my best to answer any queries which may be sent to me through the medium of the Editor, but I do not care to fill pages of this Journal unnecessarily with elementary matters, such as may perhaps be found better explained in school books than it is possible for me to explain them.—WM. TAYLOR.

POTATO STARCH.—The average consumption of Potato starch in the United States is estimated at from 8000 to 10,000 tons, and careful computations place the product for this year as follows:—Maine, 4000 tons; New York, 2500 tons; other sections, 500 tons; total, 7000 tons. These figures may be increased so as to bring the total up to 8000 tons, but it is not likely to go above that amount. In addition to the factories mentioned above there are five located on Prince Edward's Island, whose product for this year is estimated at 12,000 tons. This starch will probably find a market in Canada, and very little, if any, will come to this country. In addition to the 7000 or 8000 tons which will be the yield of our own factories there were at the beginning of the season 2000 tons on hand in small lots which had been carried over from last year, some of it being several

years old, but still in good condition. It takes 250 bushels of Potatoes to make a ton of starch, and its manufacture, which is very simple, is as follows:—After being thoroughly washed and freed from dirt the Potatoes are reduced to a pulp by means of a grater. The pulp, placed in a sieve, is washed by streams of falling water, the starch being carried through the sieve into a proper receptacle, and the fibre washed away as waste. The starch is carried with the water passing through the sieve into a stirring tank, in which it is washed from the finer particles of waste, and, being heavier than water, sinks to the bottom. It is then further cleansed in other tanks by washing and stirring, until the water is clear and is drawn off. The starch is then removed to a kiln, where it is dried and rendered fit for market.—(*American Cultivator*.)

LYGODIUM SCANDENS.

THIS is not a new Fern, but it is much rarer than it should be, especially with those whose gardens are small and space under glass limited, for it may be made to add another charm, and more fully furnish small indoor ferneries that even now, though crowded, are in some respects bare. The plant is a climber, and either in pots or planted out may be trained over a wall, up a pillar, or over bare and otherwise cheerless-looking rafters. It is nearly hardy, but it is far best to grow it under glass in a cool shady structure. Hardly anything need be said of its cultivation, for it is so easily grown that it would be difficult to understand under what condition it would fail to grow. Either in pots or planted out, if the soil is at all sweet, it is sure to do well, and it is just such plants that are wanted, especially by amateurs.

The fronds grow indefinitely, and so they are termed climbing. In winter they turn brown, and it is best to cut them down, when, as spring approaches, others will start. These may be trained to thin string and carried in any direction the cultivator may choose. As a pot specimen when trained on a balloon or pyramidal trellis it is by no means to be despised, for when well grown it is hardly second to any greenhouse species grown, and, indeed, much more imposing than most. For many purposes it is very useful for cutting, the fertile portion being very neat and beautiful. Its worst enemy is thrips, to which it is by no means subject unless grown in an atmosphere too hot and too dry.—SINGLE-HANDED.

INSECTICIDES.

IT may be assumed, without fear of contradiction, that gardeners do not love insects, although some by their industry and ingenuity teach lessons and astonish us; yet we are so solicitous for the well-being of the plants under our care that we cannot see them injured, even by the most instructive insect. Nevertheless, I do not think that the bulk of our craft love insecticides; at least one of the most noteworthy not very long since in the *Journal* admitted his dislike to them when giving advice as to the destruction of red spider by painting the hot-water pipes with a solution of sulphur. He then naïvely adds that as soon as possible it is washed off.

However, since insecticides are a necessary evil it is as well that we should know a few of those which have the least faults attending them. The proper qualifications of a good insecticide are that it should kill without injury to the plants, that it should be cheap and easily procurable, that it should not be unpleasant to the smell nor in appearance when applied. Without any one of these qualifications an insecticide will never become popular. Let us, then, examine a few, such as good cultivation, sulphur, Dalmatian powder, paint, limewash, and potash.

I place good cultivation in the first place, as, although not killing insects, yet with healthy robust growth they are abolished; consequently by care and attention, and knowing the wants of the plants, the use of any other insecticide is reduced to a minimum. Perhaps a better title for it would be insectiphobia.

Sulphur I place second, as undoubtedly the fumes or sulphurous acid are most deadly to all insect and animal life too; but the common practice of painting the pipes with a solution is not, I think, the best way to proceed. A better plan is to use sulphurous acid (not sulphuric, which is quite a different article), which is simply the fumes of sulphur pressed into water, which, when exposed, throws off the sulphurous acid. The method of using it is to pour out in plates or shallow pans placed on the staging or walks. It has these advantages over sulphur paint—that the work is done equally well without the risk of injury to tender plants, for if the paint be applied too strong and the piping overheated great damage may be done, even the destruction of a houseful of plants. Not only so, but the labour is trifling in comparison. The morning after the plates of acid have been put down, all the fumes having evaporated, the liquor remaining is only water, and may be emptied out, whereas the other unsightly stuff has to be washed off the piping.

Dalmatian powder is another good insecticide, but I do not remember having seen it commented upon in the *Journal*. I use it in two ways—sprinkling on the soil and for syringing. As a dressing on the soil it is best applied before it is brought under glass, about an ounce to the bushel. What pests it does not kill it drives away, leaving the soil in an excellent condition for potting or otherwise used, free from woodlice, worms, &c. I use it principally for destroying woodlice. For syringing 4 ozs. may be infused in a quart of boiling water, allowed to settle, and the clear liquor used; half a pint to an ordinary watering can full of water applied with a syringe and not washed off, taking care to wet the under side of every leaf. Two to three doses of this will be found very useful.

The next two insecticides will, I doubt not, meet the same objection as the first I named; but properly used paint and limewash are insecticides of the first order, as well as preservatives and ornamentors of our greenhouses. When paint is being applied I would advise every plant that can be moved to be put out, all the ventilators opened night and day two days at least before commencing to drive out all damp. Commence with a thin coat, adding plenty of turpentine, which is most deadly to insects; and to combine remedies as the doctors do, instead of using the ordinary dryers use paraffin oil, which not only serves the same purpose, but used in this way is very beneficial. I think it is not sufficiently well known that this common oil may be used in this way, and many times at a distance from town would save considerable time in waiting for the ordinary dryers. The second coat should be applied thick to stop all cracks, which effectually imprisons all eggs which may be deposited there. Limewash, too, ought to be applied thickly on all new work for the same reason, and care should also be taken to have new slacked lime, if possible while it is hot. I would here strongly urge upon all gardeners to advise when new work is being put up that it should be plain, for it is only in such structures that we have a fair chance to master our insect foes. In ornamental structures there are so many out-of-the-way places for them to multiply that we are forced to risk the displeasure of the æsthetics and plead for plain houses.

Lastly, a few words about potash. I use it for cleaning the glass, swilling all wood and brickwork everywhere, in fact, inside, and find it useful both for cleansing as an insecticide; and I am inclined to think it has another good property—that is, a good dressing for the soil. I have used it as strong as one ounce to the gallon of water for syringing glass over plants, and it has not injured the leaves, but I imagine improved them. However, I would not advise its use in this way, at least not carelessly, but used as I have described it gets into every crack and crevice, dealing certain death to the insect tribe. I would strongly advise all who have not had a thorough experience of them to be very cautious in their use of insecticides and note carefully their results, as many are more dangerous than useful. Paraffin, for instance, when applied to plants in any form whatever kills the insects; but how often does it close the pores of the leaves and make the plants unhealthy, and as a consequence more liable to future attack from their insect pests!—HORTUS.

PLANTING SHRUBS.

IT occasionally falls to the lot of gardeners to carry out changes in grounds necessitating, amongst other work, the transplanting of shrubs. I had a hint on the subject the other day which may be worth bringing to the notice of gardeners and others who have not paid much attention to this subject. We have had several weeks of this kind of work, and a gentleman visiting mentioned this as, to him, a curious fact. Some two or three years ago he had bought in a number of good-sized ornamental shrubs and young trees, and lately his attention had been called to some of these which had been blown over, and the balls were in the same condition as when planted, no roots having passed into the surrounding soil. In my opinion these shrubs had been placed into holes cut to fit the size of their respective balls as nearly as possible. The harm would be greater through the soil having been hard or clayey, so that the plants, though surrounded with soil on every side, were practically isolated from it. Planting when the soil was too wet would also conduce to a similar result. It will be conceded that if a plant costs a large sum to purchase that it is worth a little care to secure its succeeding when planted.

Of the many hundreds of shrubs which have passed our hands this autumn it would be impossible for one to blow over in the condition of those noticed. In every case the hole has been at least twice the width of the ball of the plant inserted, sometimes larger, and with the exception of extra large plants a liberal

dressing of good soil or leaf soil was given to each plant. In addition to forming a large hole in the first place, when the plant is being placed in the workmen dig round the edges of the pit and loosen the surrounding soil still further. It is also well to take out the soil to one depth, and not merely to cup it out; while the ball of the plant, if very firm and hard, should be made so that the roots will spread out. In firming the soil do not tread on the roots, but round them.—B.

A CORRESPONDENT informs us that in connection with the Boston Ornithological Society recently held was a show of CHRYSANTHEMUMS and PRIMULAS, which attracted much attention. The Chrysanthemums in pots were very good, and the prize collections contained many fine specimens of some of the newest varieties in cultivation. The cut blooms were very good. Several boxes of handsome Japanese varieties were much admired, and the Primulas were quite an attraction. The Show altogether was a success, and another year may bring a greater number of contributors.

— A CORRESPONDENT, "P.," sends the following:—"Query to gardeners of twenty-five years ago. What is the difference between the variety SNOW'S WINTER WHITE BROCCOLI and VEITCH'S SELF-PROTECTING BROCCOLI? Snow's Winter White Broccoli of twenty-five years ago and the variety sent out now called Veitch's Self-protecting Broccoli appear to me identical. I am quite sure that the Snow's Winter White of the present day is very different from that grown twenty-five years ago."

— MR. M. TAYLOR desires to know "which is the BEST HARDY AMERICAN BLACKBERRY, and also if any firm makes a speciality of them," as they are not kept in nursery gardens about his district. Probably the Parsley-leaved Bramble and Kittatinny are as hardy and prolific as any, and those who possess stocks would do well to advertise them.

— MR. JAMES McBEAN, Cook's Bridge, Lewes, writes as follows:—"In the last issue of the Journal and in the report of the BRIGHTON CHRYSANTHEMUM SHOW I observe your remarks on table plants to the effect that 'the second-prize collection was in the opinion of many far before the first-prize lot.' By many, however, the second-prize lot were considered far too large, and more adapted for grouping; and when six plants are wanted for table decoration it is seldom we use pairs. The first-prize plants were well cultivated, with plenty of foliage, and nearly all of a size, the varieties being distinct."

— WE are reminded of the closing weeks of the year by the receipt of a packet of very beautiful CHRISTMAS CARDS from Messrs. Eyre & Spottiswoode, the Queen's printers. The cards of these publishers improve in artistic merit every year, and those now before us furnish many examples of designs and execution which can hardly be surpassed.

— "PRO BONO PUBLICO" wishes "to call the attention of nurserymen and seedsmen to one or two matters of importance connected with LABELLING. Having lately had several fruit and forest trees and shrubs from nurserymen, the names having evidently been written by some kind of lead pencil, which when exposed to the rains and the atmosphere have become faint, and in several cases quite illegible, which has caused great inconvenience, particularly with fruit trees. These names have, I presume, been written by what are called the copying lead pencils. I have used one of the pencils in question myself, and had very

nearly lost many names until I luckily discovered the error in time. In previous years it has been the custom of some seedsmen when putting up and labelling the seeds to stick the name of the seeds over the string, and when the string is cut the name is torn off with it. This may appear but a trivial matter, but it is liable to cause mistakes, and sometimes much inconvenience."

— "M." writes:—"The MILDNESS OF THE WEATHER here in North Pembrokeshire has permitted us to gather the following Tea Roses from the open garden all through November:—Niphotos, Cheshunt Hybrid, and Gloire de Dijon. On Nov. 28th I gathered in one of our plantations a fine spike of Foxglove. Primroses, red Ribes, and other common plants have been flowering freely. Not having been cut at all by frosts, the clumps of Schizostylis coccinea have been grand this autumn with their masses of crimson spikes, and the Chrysanthemums have had almost as fine blooms in the open border as under glass. Of some forty varieties of the latter we have now in bloom, by far the most beautiful is Lady Talfourd, with large flowers as well shaped as a good Dahlia; colour pink, petals quilled and incurved."

— WRITING ON TAR v. MEALY BUG, a correspondent, "C. M.," observes:—"Mr. Pettigrew in his interesting article on Culzean Castle, on page 390, says that 'Mr. Murray informed him that the Vines were at one time very much infested with mealy bug, but that by dressing them with a mixture of coal tar and clay he had entirely eradicated the pest without the slightest injury to the Vines.' I should like to try Mr. Murray's receipt if I knew in what proportion to use the tar, also if it is the ordinary gas tar used for asphaltting paths, &c. I suppose it would be necessary to paint the Vines completely, covering the eyes or buds. I should be glad to know if I may use the mixture freely without fear of injury, as I would prefer to use the ordinary mixtures if there were any probability of the tar causing the Vines to break badly in the spring." We shall be obliged if gardeners who have practised this plan will record their experience on the subject.

— VALUABLE illustrations and diagrams of some of the most INJURIOUS OF THE INSECTS that prey upon our food crops are about to be issued by the Royal Agricultural Society of England. The drawings of the insects have been most carefully executed by Miss E. A. Ormerod, Entomologist to the Society, and show the insects in their various transformations, and also the nature of their attack. The series of six large sheets contain beautifully coloured illustrations of the common aphid or green fly, the large white Cabbage butterfly, the wireworm, the daddy-longlegs, the Turnip fly, and the Beet fly. Each is exhibited on a largely magnified scale in the caterpillar, chrysalid, and perfect insect state, and are also shown life-size. A short account of their habits, methods of prevention, methods of destruction, &c., is printed at the foot of each sheet. These illustrations are admirably adapted for the use of teachers in rural schools, who by their aid can readily impart a useful knowledge to our agricultural population of some of the most destructive of insects, and thus enable them to combat more successfully the insidious attacks of these terrible pests.—(*Journal of Forestry.*)

— MESSRS. LETTS, SON & Co. confer annually a great boon on the public by the issue of every conceivable form of DIARY AND MEMORANDUM BOOK. Their energy and enterprise seem never to fail, but rather to strengthen by age. We have received a packet of these valuable annuals, with specimens of various forms, all of which are more or less indispensable to somebody. It is not only as diaries that these are useful, but they contain much information which people are in everyday want of ready to hand and easy of reference. We commend the diaries of Messrs. Letts very highly to all who require one, and a diary is a record which everybody ought to keep.

— REFERRING to SUTTONS' GREEN CURLED SAVOY Mr. J. Clarke, Brynkinalt, writes—"This Savoy may undoubtedly be termed the mainstay of our kitchen gardens for winter use. It can be planted in almost any soil with success, but where extra large heads are in demand the soil can hardly be too rich or the situation too good. Where medium-sized heads are required I usually plant 15 inches apart each way. I have a grand crop here now, about 1500 plants, all with heads of useful size, large enough for any purpose. I usually plant in different aspects, so as to insure a good supply successively, which with the above variety I find no difficulty whatever to maintain. Growers for market purposes will do well to give this variety a trial."

— WE regret to learn that after a long and useful career the monthly horticultural periodical, "THE GARDENER," published by Messrs. Blackwood & Sons, ceases with the issue for December. Under the editorship of Mr. David Thomson the valuable practical instruction contained in this work has been welcome to many gardeners in Great Britain, but in this fast age a month was too long for them to wait for gardening information however sound it might be.

CARROT AND PARSLEY DIFFICULTIES.

I HAVE been very much troubled this last season by Carrots and Parsley proving a total failure here. Seeing my first sowing of Carrots a failure I prepared another bed in a different part of the garden, and mixed the soil, which is very black and stiff, with sand and soot, but with no effect, for as soon as the seedlings were about an inch above ground they quickly disappeared. I tried them a third time, with a similar result. The attack was made by a little white worm. I have many times seen Carrots destroyed by this insect, but I have never seen a failure like my own this last season. Parsley came up freely and grew for a short time, when it turned quite yellow. On examining some of the roots I found numbers of this little destroyer. However, after about two months it started and grew a little. Both crops are greatly in request here. Of the former crop I obtained none; while of the latter, the season was far advanced before I had any. The soil is very heavy and black, and I think very unsuitable for the culture of the Carrot. I have learned several good lessons from your correspondents, and I shall feel much obliged if some of them would state their experience of such failures and their best mode of destroying this pest.—J. C.

FRUIT-GROWING ON CHALK SOILS.

As I have previously stated when writing upon this subject, in soils of an extremely chalky nature successful fruit-growing is far from being an easy matter, inasmuch as such soils are deficient in those chemical elements which are necessary to the production of high-class fruit, as well as to the longevity of the trees themselves; indeed, in some districts it is absolutely impossible to accomplish anything which has the least semblance of success without much trouble and expense. The practical man who has to contend with such soils as are here alluded to knows only too well the ailments and chief characteristics of the majority of young fruit trees after they have been planted two or three years. Only once allow the roots to get a firm hold of the subsoil, and let them remain there undisturbed, then you will experience the mortification of seeing the leaves assume that yellow sickly appearance which is a sure forerunner of poor crops and also of premature death. This applies principally to Peaches and Nectarines; but even such fruits as Apples, Pears, Plums, Cherries, and Apricots do not grow in that luxurious way which they do on most other soils.

From the foregoing it must not for a moment be supposed that success is impossible. For many evils there are remedies, and so there is for the one we are now dealing with. We must, however, confess that our remedy is rather a costly and laborious one, but on the other hand we would venture to assert that the cost would not be thought too much when success is the result. With Peaches and Nectarines I would strongly recommend the under-mentioned plan. Take out the soil to a depth of 18 inches or 2 feet; concrete and drain the bottom; at a distance of 4 feet from the wall on which the trees are to be grown build up from the concrete to

the ground level a 4½-inch wall—here there is ample space for the roots of good-sized trees. The top spit of soil and a shovelling should be cast on one side, to be mixed afterwards with the new compost, the latter to consist entirely of good turfy loam, the best that can be obtained in the locality. With this there should be incorporated a little well-decomposed stable manure, together with a light sprinkling of half-inch bones. The turf should be chopped into rough pieces, and the whole of the compost be turned over several times before being wheeled to the border. As the work of filling the border proceeds tread down the soil firmly. Plant young healthy trees, with their roots not more than 6 inches from the surface, and give a good mulching of half-decayed manure.

By many this plan will be thought to be rather an expensive one, and so it is, I admit; nevertheless there need be no apprehension as to the successful results which will ensue. Money well spent and work well done will redound to the credit—aye, and often to the pleasure—of anyone as long as they live. The following varieties may be relied on in districts like those to which these remarks are applicable:—*Peaches*: Early Louise, Early Rivers, Early York, Royal George, Dr. Hogg, Sea Eagle, Barrington, George IV. (a good old sort, now seldom seen), Prince of Wales, Walburton Admirable, Late Admirable, Salwey. The last-named is worth growing on account of its lateness, and although it is not one of the best-flavoured Peaches it is not to be despised if allowed to stand on a shelf in a vinery for about a week after being gathered. *Nectarines*: Rivers' Orange, Elruge, Violette Hâtive, Pine Apple, Victoria, and Pitmaston Orange.

Apricots, Plums, and Cherries are not so fastidious as to soil and situation as Peaches and Nectarines. They never appear to be quite at home in soils where there is an excess of chalk; those who would succeed with them would therefore do well to trench the ground 2 feet deep, and let the new compost consist of two parts turfy loam, with one part peat and one part well-decomposed manure, this to be worked in with the top spit and a shovelling of the old soil. It is also essential that where these are grown the borders should be well drained. Of Apricots no other sorts need be grown than the following three: Moorpark, Hemskirk, and Breda. Plums: Coe's Golden Drop, Green Gage, Ickworth Impératrice, Jefferson, Peach, Reine Claude de Bavay, Pond's Seedling, Victoria, Washington, White Magnum Bonum. Cherries: May Duke, Black Tartarian, Elton, Early Red Bigarreau, White Heart, and Morello.

We shall now refer to Apples and Pears by simply stating that the compost recommended previously will also suit these; the ground also should be trenched to a depth of not less than 2 feet. If it is necessary to point out one thing more than another with regard to Apples and Pears, it is as to the system on which they ought to be grown. Where the best results are desired, by all means commence with young trees, and grow them as pyramids or dwarf bushes. By so doing, and lifting them periodically, say about every three years, far better returns will be had than by allowing them to grow into large trees, inasmuch as other crops can be grown profitably between the rows without detriment to the trees themselves, and in nine cases out of ten it will be found that the crops of fruit will, in quality and quantity, be such as to give the greatest satisfaction. I can confidently commend the following sorts of Apples—viz., Early Red Margaret, King of the Pippins, Cox's Orange Pippin, Margil, Old Golden Pippin, Blenheim Pippin, Keswick Codlin, Lord Suffield, Mère de Ménage, Cox's Pomona, Alfriston, Warner's King. Pears: Jargonelle, Citron des Carmes, Beurré Giffard, Williams' Bon Chrétien, Comte de Lamy, Seckle, Marie Louise, Beurré Clairgeau, Easter Beurré, Winter Nelis, Doyenné du Comice, and Beurré Bachelier. With regard to the compost recommended for Peaches and Nectarines, a small quantity of peat ought to be used. I have always found the greatest possible benefit accrue from a judicious use of peat in fruit culture on chalk soils.—ET CÆTERA.

TYDÆA MADAME HEINE.

WHERE decorative flowering plants are required during the autumn and winter months few are superior to Tydæas. When well grown and cared for they will occupy the same place in our stoves in winter as Achimenes do in our conservatories during summer. There are now numerous varieties, and many of them exceedingly beautiful, but requiring considerable care to have them in the best condition during the winter. Many of the varieties are really more adapted for summer flowering, and it is next to an impossibility to retard them sufficiently to have them in full beauty during the dullest months of the year. This is very marked in those kinds that form underground stems, and thus allow of being dried off after flowering the same as Achimenes.

Some will not endure this drying system, for they really are what I feel justified in terming evergreen varieties, and do not form underground stems, but are perpetuated by striking the young shoots that are produced near the base while the plant is in active growth. *T. Madame Heine* is of this type, and a true winter-flowering variety. It is of a sturdy habit of growth with green foliage, and flowers most profusely from November onwards. By inserting cuttings at intervals a succession of flowering plants can be had the whole winter. I have grown many varieties of *Tydæas*, and after three years' experience with the above variety have concluded to discard all others for winter, as the stock of this variety can be increased so rapidly.

The cuttings strike almost as easily as *Coleuses* if placed in heat, kept close, and shaded from strong sun. They may safely be placed singly in small pots when inserting them, as with ordinary attention every one will root. Any light soil will suit this *Tydæa* well.—SCIENTIA.

WINTER-FLOWERING PLANTS.

AN abstract of a paper read before the Young Gardeners' Mutual Improvement Society, Royal Gardens, Kew, by Mr. Garrett, foreman of the flower garden department.

To supply cut flowers and decorative plants during the winter months is a very important part of the gardener's duties in all establishments. Foliage plants are numerous, and are used largely for decorative purposes in winter, but ladies must be continually supplied with cut flowers for various purposes. Flowering plants must also be interspersed amongst the foliage and Ferns in the mansion as well as the greenhouse or conservatory. This continual supply is the great feature that has to be thought of, and the point where many gardeners fail, often at a time when a greater supply than usual is required for some special purpose. Requirements vary considerably in different establishments according to the tastes or wishes of proprietors, and such wishes have to be studied by the gardener.

The great secret in having flowers in winter is the careful selection of useful plants for the purpose, and good cultivation in the previous spring and summer. If sowing seeds or propagating plants is delayed too long in the spring or summer, the flowering period will be delayed in a corresponding degree. If the plants are well grown in the summer and receive proper attention, their successful flowering will be insured, but injudicious treatment in winter may render previously well-prepared plants useless. Where a gardener has a knowledge of what is required, it is the best and safest plan to select the best varieties of certain plants that suit his purpose, and grow a quantity of those that are certain to succeed. Collections are necessary for exhibition, and sometimes for other purposes, but selections are much more profitable generally.

EUCARISES AND GARDENIAS.

Stove plants and Orchids flowering in winter are rather limited, but there are a few that are indispensable. Two of the most beautiful of the former are *Eucharis amazonica* and *Gardenias*. These, from their powerful perfume and beautiful appearance, are greatly valued. They require a good rest in a cool frame or house during the early autumn to ripen and prepare them for flowering when introduced to heat. *Eucharises* do not require repotting often if they are in good health and the pots are well drained. Plants that are unhealthy are uncertain for flowering purposes. Probably the most important part of *Gardenia* culture is keeping the plants clean. If they are allowed to become much infested with scale or mealy bug the best plan is to prepare young plants, and keep them clean and throw the old ones away. The points of the shoots are always first attacked by mealy bug, and the buds being there are so much injured by the cleaning process as to be of little use when expanded. They can be grown in pots or planted out as may be convenient.

ORCHIDS.

Orchids last a long time, and some of them will bear much rough treatment; indeed, much more than many other good plants that are not nearly so much valued. A few are happily useful for winter-flowering, and are therefore very acceptable. *Cypripedium insigne* is largely grown, and will last a very long time as flowering plants, or in a cut state in water. Many other *Cypripediums* flower at this time of year, but probably none are so plentiful as *C. insigne*. *Zygotopetalums*, *Calanthe Veitchii*, *C. vestita* and its varieties, *Lycaste Skinneri*, and *Masdevallias* are the most useful in quantity for winter-flowering that I am acquainted with.

CHRYSANTHEMUMS.

Probably the most popular flowering plants for all purposes during the months of November and December are *Chrysanthemums*. A selection of a few distinct and useful sorts of these is preferable to a large collection. There are, however, several distinct forms, ranging from the small Pompon and Anemone-flowered to the large incurved, reflexed, and the curious Japanese section, all possessing a considerable degree of merit. They are propagated at different times from about the end of November until the following May, and much later

than this for small plants. Where large bushy plants are required the size of the flowers must be to a certain extent sacrificed, as the largest flowers are obtained from plants that are only allowed to bear a very limited number. As far as my experience goes it is better to propagate about the middle of February and grow the plants without a check, repotting as required until they are in 8 or 9-inch pots, which are sufficiently large for most purposes. An open airy position exposed to the sun, but not too much to high winds, should be selected for their summer quarters, when they will require constant attention and plenty of water if good plants are to be obtained. Liquid manure should only be supplied in moderate quantities until the buds are formed, when it may be given frequently. Stopping should not be practised on large plants after the middle of July. Small useful plants for stages or decorating may be obtained by placing four or five cuttings in small pots early in August. When they are rooted place them into 48-sized pots, and stop them once. They will flower about the same time as the larger plants. Neither should be subjected to fire heat if it can be avoided, as this invariably causes them to lose their lower leaves, especially in the autumn.

CARNATIONS.

Tree Carnations are not more difficult to grow to good-sized plants than *Chrysanthemums*, yet it is very seldom they are found in quantity. Probably their merits are not sufficiently well known. If they are grown principally in two or three distinct varieties scarcely anything can rival them as cut flowers for glasses or almost any purpose. *Belle Rose* and *A. Alégatière* are good red varieties, *La Belle* and *Purity* whites, and *Miss Jolliffe* a distinct perpetual-flowering variety of a pink or flesh colour. These are all distinct in growth, and are the best to be grown for plenty of flowers that I have seen. It is very important they should be propagated in the month of February to begin flowering in the autumn as large plants. When propagation is deferred later than this the plants will not flower so early in the autumn, neither will they attain the same size. They are best grown in frames until about the beginning of June, when they may be placed in the open air until the end of September. A house with a temperature of 50° to 55°, and air on all favourable occasions, will suit them all the winter. They generally do well in a soil composed of fibry loam, with a little leaf soil not too much decayed, and plenty of charcoal. The pots must be well drained, as Carnations of any sort will not succeed if the soil is allowed to become soddened.

BOUVARDIAS.

Bouvardias are extremely useful winter-flowering plants if prepared for that purpose, and are generally much admired. They strike freely in spring—about the end of March or beginning of April is early enough—and may be grown in pots, or planted out in frames as soon as established. I have found the best results from the latter practice, although the plants are not always so compact as when restricted in pots. They require to be frequently and evenly pinched until late in the summer to prepare them for flowering in winter. If planted out they will bear being transferred to pots about the middle of September, and will, if kept close for a short time afterwards, scarcely feel any check. A few standard single varieties are *elegans*; *Vreelandii*, or its larger form *alba grandiflora*; *Maiden's Blush*, and *Leeiantha*.

POINSETTIAS.

Poinsettias are very showy plants previous to and at the time of flowering. The flowers themselves are inconspicuous, and do not open until some time after the scarlet bracts surrounding them appear. To have dwarf plants in small pots they must, when growing, be plunged in ashes or some other material in light frames, where they can have plenty of air, and, except in the hottest summer weather, be fully exposed to the sun. When they are intended to be grown in small pots with one head of bloom, the middle or end of June is generally early enough to insert the cuttings, as they cannot be kept dwarf if propagated too early. They succeed best if inserted singly in small pots, as the roots are not injured so much when repotting. They are easily grown if proper attention is given them, but are among the first to suffer if neglected. The flowers form and the bracts change their colour about the beginning of November, when more heat may be applied, and if the plants are supplied with a little liquid manure it will help to develop and deepen the colour of the heads of bloom. The old *P. pulcherrima* is still the best for general cultivation. Its variety, *P. p. alba*, is sometimes grown, but is only useful as a variety. The so-called double form named *plenissima* was highly spoken of when distributed, but it does not seem to have been cultivated so much as was expected. If the plants are placed in a cooler temperature when the heads are developed they will keep good for six or eight weeks.

BEGONIAS.

Some of the autumn and winter-flowering *Begonias* are very effective when well grown, and are useful for supplying cut flowers, although some of them will not last very long in water. Their free-flowering habit will, however, compensate for this in a considerable degree, as the removal of one lot of flowers will often cause the plant to break, and so produce a quantity more. It is important to propagate them early in the season to have large plants by the autumn. Some of the best are *Weltoniensis*, *insignis*, *Knowsleyana*, *semperflorens*, its variety *rosea*, and *Ascotensis*. The new and distinct

Begonia socotrana promises to be a good winter-flowering variety by its appearance at the present time in the *Begonia* house at Kew.

PRIMULAS.

The single and semi-double forms of *Primula sinensis* and *Cinerarias* may be flowered in the autumn and winter by sowing the seeds sufficiently early in the season in March or April, and growing them when established in frames facing the north during the hottest weather. *Primulas* require a little heat in the autumn to assist them in opening their flowers, and to prevent their damping at the collar. The old double white variety, *P. sinensis alba plena*, still holds its own amongst the newer double kinds. It does not produce seed, and consequently has to be propagated by cuttings, which should be inserted in May or early in June.

Cinerarias are best when kept in cold frames up till the time of flowering. If they are subjected to fire heat they so soon become infested with green fly.

Salvias are useful for conservatory decoration in winter, but they are not of so much use for cutting, as their flowers so soon fall. The scarlet-flowered varieties may, however, be used with great effect as cut flowers by gaslight or for dinner-table decoration where they are only required for one evening. A very promising new decorative flowering plant for winter is *Impatiens Sultani*, as it is in flower nearly all the year round. If so it will be a valuable acquisition.

Among other useful plants which I can only mention now are *Plumbago rosea*, *Justicia speciosa*, *Linum trigynum*, *Euphorbia jacquiniæflora*, *Sericographis Ghiesbreghtiana*, and *Zonal Pelargoniums*.

(To be continued.)

PRUNING GOOSEBERRY BUSHES.

SINCE reading "LANCASTRIAN'S" remarks on the above (p. 477) I have carefully examined those bushes I have pruned and those I have not, and asked myself the question, Have I pruned too hard? Doubtless few prune so hard as I do, and yet I have pruned closer than ever this year. Still, I do not think any bushes the same size could carry a greater crop or better-sized fruit than these have done. Many visitors have remarked the heavy crop and splendid fruit.

It is an old saying, "Old notions die hard." This will apply here, for being taught that way of pruning the Gooseberry, and generally with the best results, why should we alter? I shall certainly try the other practice with some bushes I have in a young state, and note the difference. In the latter method there would be a considerable saving in labour, which is a great consideration to the hard-worked gardener. I should be pleased to see others give their experience on this subject, for, unlike the Apple or Pear, we seldom fail to get a good crop if birds can be kept away. I am lucky in this respect, having my Gooseberry quarter covered in with wire netting, and am ever anxious to gain experience, so as to increase produce with the least amount of labour.

While writing on this subject may I ask someone to explain why I lose one or two bushes most years when not more than from five to seven years old, while small branches on several wither and die from midsummer onwards? Last year I gave a heavy mulching of manure from the cowyard, but I am sorry to add that it has not had the desired effect. The soil is light, resting on a gravelly subsoil, and well drained.—S. J. A.

TRILLIUMS (AMERICAN WOOD LILIES).

THESE lovely flowers belong to the large, varied, and beautiful Liliaceæ, a family perhaps as attractive to the botanical and horticultural student as any we are acquainted with. Nor is this surprising when the numerous floral gems which it includes are taken into consideration; and there is no doubt the objects of these remarks are among the more interesting genera of the family. The character of the floral envelopes is particularly striking, the outer series of the perianth being green and foliaceous, while the inner one is coloured, representing the calyx and corolla in the dicotyledonous plants. They are extremely pretty, or at least the greatest number of them, some being curiously coloured and not very attractive. There is much written now by cultivators as to what hardy flowers should and should not be grown. But most of the *Trilliums* please everybody. Take for instance the lovely *T. grandiflorum* with its large white flowers and graceful habit. I have always known it to be admired, and rightly so, for it is one of our best hardy flowers. Not so useful as many other things for supplying cut flowers. Do not be misled. These are not the plants for that purpose. They are better adapted for border decoration in clumps sufficiently large to reveal what their decorative merits really are. They are grand for intermingling with hardy Ferns and Orchids, and with treatment such as is suited for these plants they will flourish.

It is necessary, to grow *Trilliums* well, that they should be

treated liberally. Granted that they will thrive fairly, especially *T. grandiflorum*, in ordinary border soil, yet they do far better if the soil is well prepared and a proper position selected in which to plant them. The common term applied to them is instructive—viz., "Wood Lilies." They are all natives of North America, inhabiting woody and low-lying damp positions where there is an abundance of vegetable matter. Plant them in a partially shaded position where they are not exposed to the hottest sunshine, as the flowers will last much longer. The soil I have found most suitable for them is a mixture in equal parts of good yellow loam, peat, leaf soil, and sand of a good depth, with a cool and damp position. If they are liberally supplied with water during the growing season large rhizomes are made for the following season, and they readily establish themselves, fine clumps being soon formed. The present is a fitting time to plant or divide them, as they are now in a dormant condition. But the sooner it is accomplished the safer, as the roots would be quite established before winter arrives. If there is any doubt as to the effect of the winter upon the roots, the safer plan will be to protect the crowns by covering the soil with leaves, bracken, or ashes during the winter, removing the same early in the spring, as they start into growth early in the year. Some of the varieties I know are not quite hardy in the north, or it would be safer to say that from some cause they disappear during the winter. This may be from excessive moisture. In that case it would be advisable to protect them with a bellglass. I am not aware that *T. grandiflorum* suffers in any part of the kingdom.

I have intimated above that they are all natives of the States of North America. One species, however, is found in Eastern Siberia, and I think one in Japan, but they both also occur in North America. The species and varieties described below are all under cultivation, although some of them are uncommon. But they can all be secured from good dealers in hardy flowers in this country, as well as from some North American dealers whose speciality is the collecting of the native plants. I have described the different kinds somewhat minutely, as there is much confusion among growers of them as to their proper nomenclature.

T. cernuum.—Stem about 9 or 12 inches high. Leaves sessile, broadly ovate, 2 to 4 inches broad; flower stalks short, recurved; petals white, ovate-lanceolate, one-half to 1 inch long; stamens shorter than the stigmas. This is well figured in "Curtis's Botanical Magazine," plate 954. It occurs from Newfoundland to Mackenzie River. It flowers with us in April and May, and has been known in this country ever since 1758. It is a very pretty and easily grown species—one of the earliest to bloom.

T. erectum.—Stems 6 to 12 inches high; leaves broadly or roundish ovate, sub-acuminate, from 3 to 6 inches wide; flower stalk longer than the flower, more or less inclined; petals ovate or ovate-lanceolate, three-quarters to 1½ inch long, very variable in colour—brownish-purple, white, or greenish, or tinged with pink. A very variable plant, known under the various aliases of *T. rhomboideum*, *T. foetidum*, *T. pendulum*, and *T. purpureum*. It occurs from Canada to North Carolina, Tennessee, and Missouri, and it flowers in this country during April and May, and was introduced about the same time as the last. There is a figure of the plant in the "Botanical Magazine," plates 470, 1027, and 3250.

T. erythrocarpum.—Stems 9 to 12 inches high, or less; leaves ovate, acute, or acuminate, 2 to 6 inches long; flower stalk erect or slightly inclined, often longer than the flower; petals ob-lanceolate or ovate-lanceolate, acuminate, wavy, three-quarters to 1½ inch long, white, reddish-purple at the base. Known also under the names of *T. undulatum* and *T. pictum*. It is well figured in the "Botanical Magazine," plate 3002. It occurs from New Brunswick to Wisconsin and Georgia, frequently on high mountains or cold damp woods. It flowers here in May and June, and does not appear to have been introduced until 1811. It is a very pretty species, and easily grown.

T. grandiflorum.—Stem from 9 to 18 inches high; leaves broadly rhombic-ovate, from 2 to 4 inches wide, blunt; flower stalk usually erect, longer than the flower; petals ob-lanceolate, often very broad at the base, 1½ to 2½ inches long, white, or more or less tinged with green. Known also as *T. rhomboideum* var. *grandiflorum*. It is also figured in "Curtis's Botanical Magazine," plate 855, erroneously under the name of *T. erythrocarpum*. It occurs from Vermont to North Carolina, and west from Wisconsin to Kentucky. It is the most handsome species in cultivation, having been introduced about the beginning of the present century, flowering during June and July.

T. nivale.—A much dwarfer plant, from 3 to 6 inches high; leaves ovate or ovate-lanceolate, blunt, 1 to 2 inches long; flower stalk short, erect, or slightly inclined. Petals oblong or ovate-oblong, blunt or acute, half to 1½ inch long, white throughout. It

is a very pretty little species, much smaller in all parts than all the others except *pusillum*, which I think is not under cultivation in this country. It flowers in April and May. Found from Western Pennsylvania to Kentucky, Iowa, and Wisconsin.

T. ovatum.—Stems 6 to 12 inches high, erect; leaves broadly ovate, bluntish; flower stalk erect; petals lanceolate or sometimes oblanceolate, sometimes very narrow, white or tinged with pale purple. This really appears to be a narrow-petalled form of *T. grandiflorum*, which it very closely resembles in habit and appearance. It is also known under the names of *T. obovatum* and *T. californicum*, and it is found from British Columbia southward in the coast range to Santa Cruz, California. It flowers in May and June, and is very easily grown. Introduced early in the present century.

T. petiolatum.—Stem very short, scarcely produced beyond the basal sheath; leaves ovate-elliptic to sub-reniform, 3 to 5 inches long, with petioles equally as long or even longer; flowers without a stalk; sepals erect; petals narrowly oblanceolate, 1 to 2 inches long, dark purple. This is very distinct on account of the stalked leaves. It flowers in April and May, and grows well in most places, but the dull colour of the flowers renders it unattractive. It has been cultivated in English gardens since 1810.

T. recurvatum.—Stems short, but longer than the last; leaves petioled, ovate to ovate-oblong, acute, usually so at both ends; flowers sessile; sepals recurved, acute; petals oblong-lanceolate, narrowed to a claw at the base, three-quarters to $1\frac{1}{2}$ inch long, brownish-purple. Known also as *T. unguiculatum*, and it occurs from Wisconsin to Indiana and Arkansas. There is a variety of it named *lanceolatum*, which has sessile leaves and narrower petals. The typical form flowers here in April and May, and is of more recent introduction.

T. sessile.—A very variable plant, from 4 to 12 inches high; leaves sessile, broadly ovate, or even rhomboidal in form, cuncate or rounded at the base, 2 to 5 inches long; flowers sessile; sepals spreading; petals narrowly lanceolate, more or less acute, one-half to 3 inches long, brownish-purple or rarely greenish-white. Known also under the names of *T. viride*, *T. discolor*, and there are forms under the names of *Wrayi*, *Nuttallii*, and *angustipetalum*. The variety *Wrayi* has greenish-white petals, and was figured in the "Botanical Magazine," plate 3097, under the name of *T. discolor*. The plant is found naturally from Pennsylvania to Wisconsin, south to Florida and Alabama, and the forms are more or less local in their distribution. It is easily grown, and flowers in this country during April and May, and has been known since 1759, and was figured (typical form) in the "Botanical Magazine," plate 40.—N.

GRAPES FOR SEPTEMBER—INFORMATION WANTED.

DURING the last twelve months your pages have teemed with valuable matter on Vine culture. Mr. W. Taylor's experiences proved extremely interesting to me, as also have other communications, especially those on manure. The leading article on page 469 contained some valuable hints, and I hope will not be lost sight of by your contributors.

May I be allowed to ask a few questions? First, I may say I have to give up growing those thick-skinned varieties, as no Grapes are required here after Christmas; I must, therefore, grow for flavour and appearance. Why is not the Black Muscat more grown? What are its faults? Will it succeed best grafted? If so, on what stock? Is not this considered the best black flavoured Muscat grown? Will some experienced and successful grower give me a hint on its cultural requirements? Many Grape-growers give the Duke of Buccleuch a bad name; not so the writer of the article above referred to. Will this succeed grafted, or better on its own roots? The house I want to renew is a span, the border all inside. How would the four following kinds succeed, providing the Muscat Hamburg is amenable to ordinary cultivation?—Muscat of Alexandria, Muscat Hamburg, Duke of Buccleuch, Madresfield Court. I must exclude the Frontignans. Would the above four thrive in one house? What four or five kinds would your Grape-growing correspondents recommend me to grow to be ripe about the middle of September?—J. E. R. I.

CAPE COWSLIPS (LACHENALIAS).

AMONG neglected bulbous flowers we may fairly, as I think, class these quaint denizens of South Africa; and yet when well grown, as they were by the late Rev. Mr. Nelson of Aldborough or by Mr. Ollerhead, whose baskets of *L. luteola* were ever a sight to see and remember, few spring flowers can be more useful or beautiful. There are at least fifteen or twenty known species, perhaps many more not yet discovered; but that not generally

seen in gardens is *L. luteola*, which, being very variable in its coloration, has obtained many names. This plant is that most often seen under the name of *L. tricolor*; and Mr. Nelson once wrote me that it was grown in the windows of sundry flower-loving dames in his parish far better than in many good gardens. *L. pendula* is a distinct species with broad Tulip-like leaves.

L. tricolor and *L. quadricolor* are highly coloured varieties of the *L. luteola* type, but more rarely seen. *L. aurea* is a golden-flowered gem, but rather more difficult of culture than most others.

L. Nelsoni, a hybrid raised at Aldborough between *L. aurea* and *L. luteola*, is one of the most robust and floriferous of the whole group, bearing long stout spikes of rich apricot-coloured drooping bells, which dangle from the gracefully arching stems in a most attractive manner.

Lachenalias are properly speaking greenhouse bulbs. Too much of heat or of moisture, especially when at rest, is death to them. Their growth begins in October, at which season they are best potted, selecting the bulbs into sizes so as to insure equality of bloom. Good sandy loam suits them if on a well-drained bottom; and when in full growth, say from this time onwards until February, regular waterings and an occasional sprinkling of Clay's fertiliser or other hardy manurial stimulant is most serviceable in promoting strength of leafage and flower spike. Our plants generally bloom in February, and the spikes remain fresh until April or even longer. Indeed, of all the bulbous flowers I know, none endure fresh and fair in blossom so long as do these. Soon after flowering the leaves turn yellow and fall, and water should be gradually withheld; then, when all the leaves have dried off, place the pots in a sunny frame or on an airy shelf in the sun, and give no water until the bulbs are again turned out and repotted in September and October. Few bulbs have a more decided season of growth and season of rest, and if this is duly observed and the plants encouraged when growing all will be well. They increase very fast under good culture. *L. Nelsoni*, indeed, seems to increase in a most remarkable way, every bulb throwing up five or six offsets every season, all of which bloom the next year. Our engraving was made from some grand spikes which Mr. Nelson sent last spring shortly before he died, and long may he have a monument in all true gardeners' hearts as the raiser of *Lachenalia Nelsoni* and several beautiful new Daffodils.—DUBLINENSIS.

THE KNOWFIELD NURSERIES, CARLISLE.

HAVING a few hours to spare lately in the old border city it was but natural that they should be spent in the nurseries of Messrs. Little & Ballantyne, which both by their extent and the variety and excellence of the stocks of hardy ornamental deciduous trees, evergreen shrubs, and Conifers, also of fruit trees and Roscs, are famed far beyond the district in which they are situated.

We are reminded at the very threshold of the great railway terminus of the existence of a seed and nursery trade of considerable magnitude by the new and extensive stores that have just been opened. This great building, which is one of the most complete of its kind in the country, is an index of the character of the firm—namely, well-established, yet active as with the vigour of youth. This structure is 100 feet long by 40 feet wide. There are seven floors of the dimensions named replete with every convenience for the conduct of an extensive agricultural and garden seed trade—lifts, speaking-tubes, steam engines for driving the seed-cleaning mills, stores, offices, &c., with a siding from the railway at the basement entrance, and telephone connection with the nursery. It is indeed one of the finest trade erections of the city, and certainly merits notice here.

The nurseries are upwards of a mile distant. The site being elevated and the stock exposed to the breezes from the Scottish hills assumes a sturdy and hardy habit of growth, which is necessary for enduring the severity of the winters in the north of England, as well as in the widely extending district "over the border." The extent of ground under cultivation exceeds a hundred acres. The approach to the nursery and residence of the proprietor, Mr. Watt, is rendered attractive by the wide borders on each side of the long drive, the fronts of which are formed into panels of choice Conifers in a small state, such as variegated Yews and Cypresses, *Retinosporas*, *Thuias*, and *Cryptomerias*, with choice Hollies, and a background, too crowded, of specimen Pines and choice deciduous trees. Amongst these was noticed the Snakebark Maple, *Acer striatum* or *pennsylvanicum*, with its curiously marked branches, and many fine varieties of Oaks and other trees too numerous to be particularised.

An interesting portion of the grounds is that devoted to choice specimen Conifers. One of the first that arrests attention is *Pinus Balfouriana*, a handsome conical specimen, possessing somewhat the habit of *P. cembra*, but very distinct by the white inner surfaces of the leaves and their dark exterior, also by their tufted arrangement at the ends of the branches. On this account it is commonly called the Fox-tail Pine, and the name is certainly appropriate. The plant, which is about 6 feet high, is reputed to be the finest specimen of its kind in this country, and it received the lion's share of attention

Fig. 88.—CAPE COWSLIPS—*a*, LACHENALIA PENDULA; *b*, L. NELSONI; *c*, L. LUTEOLA.

amongst its congeners at the Edinburgh International Show. Its hardiness has been satisfactorily proved, as it has passed without injury through a winter where the mercury of the thermometer fell 10° below zero. Near it was a compact specimen of the Korean Pine, *P. koraiensis*, attractive by its pleasing mixture of silver and green. It is worthy of a front place in all collections. The Weeping *Wellingtonia* cannot be passed in silence. There are many varieties that assume more or less of a pendant habit, but none so marked as this, many of the young growths pointing directly to the earth, as if they had been tied down; indeed, the drooping character is as pronounced as that of the Mountain Ash, and perfectly healthy. It is a distinct novelty, decidedly elegant, and the first-class certificate awarded to it a few years ago by the Royal Horticultural Society was not a mistake. *Abies amabilis*, the true form, was massive and fine, and *A. concolor violacea*, a glaucous variety, is very distinct and highly promising; while *A. Englemannii glauca* was extremely attractive, and should be planted wherever Conifers are grown. *Pinus sylvestris fastigiata*, which originated in this nursery, is perfectly dissimilar from the old Scotch Fir, the habit being more like that of the Irish Yew. Another plant of this habit, *Podocarpus coriacea*, ought to be more largely grown, being massive in appearance and very hardy. In effective contrast was Fisher Holmes and Co.'s Golden Yew, a fine ornament for small lawns, rockwork, and prominent positions that it is desired to render attractive with plants of this nature. For similar positions several varieties of *Cupressus Lawsoniana* represented here are admirably adapted, *C. L. lutea* and *C. L. alba spica* being both distinct and pleasing by the pale golden tint of the former and the chaste silvery hue of the latter; and similarly compact and worthy of note are some of the forms of *Juniperus virginiana*, notably *aurea variegata* and *glauca*. *Abies Alcoquiana*, one of the finest of the Japanese Spruces, is admirably represented, and the sturdy *A. polita* arrests attention by its stout and strong needle-like leaves. It also hails from Japan, and its hardiness has been quite established, while it is undeniably distinct and ornamental; and the same may be said of the beautiful *A. Veitchii*. *Retinosporas* are largely grown, all the forms being represented, and they are increasing in popularity yearly, as they deserve to do, for no Conifers surpass them either in elegance or hardiness. *Thuja dolabrata* is also growing in favour, its bold Lycopod-like sprays giving a very handsome appearance, and it thrives well in moist positions. *Thuja occidentalis lutea* is extremely effective, being quite hardy, and of a brighter golden hue than *T. Vervaeiana*. Passing with brief mention many fine examples of the valuable *Thuias gigantea* and *Craigiana*, we leave the Conifers, and glance at other departments of the nursery.

It is extraordinary to see the number of Larches that are raised here. Some 3 or 4 acres were occupied with beds of seedlings. In these there must have been millions of plants, the greater number raised from Perthshire seed, a few beds from Tyrolean seed not being nearly so satisfactory. Mr. Greig, the experienced manager, says the trees from native or Scotch seed ripen their wood better than the others, and do not start into growth in spring so soon by ten days, and thus escape injury by frost. Larger transplanted trees in various sizes were extremely clean and fine, three-year-old stock being 4 feet high. Scotch and Spruce Firs are also provided on a correspondingly large scale, and there are large breadths of the sombre yet useful Austrian Pine. Many thousands of plants of the Corsican Pine, *P. Laricio*, are raised and regularly transplanted. It is only by this practice that the trees can be removed with safety, and the labour entailed necessarily enhances the price, otherwise the Pine which grows so freely would be more extensively planted, as no evergreen tree grows so quickly, and none is so seldom attacked by rabbits.

The collection of hardy deciduous trees and shrubs is varied and fine. Amongst the Oaks, *Quercus pedunculata nigra*, which originated here, is conspicuous by its deeply lobed and very dark foliage; *Q. austriaca sempervirens* is one of the best, and *Q. panonica* has very large green nine to ten deeply lobed leaves, and is very distinct and fine. The Aucuba-leaved Sycamore is a variety of promise, the leaves being mottled with gold somewhat like the common Aucuba, but the spots are smaller and more numerous. Van Geert's Golden Poplar appears to flourish well, the golden hue being very marked and the growth healthy. Another tree of value deserves notice—namely *Populus fastigiata gigantea*. This is probably the quickest-growing of all trees adapted for sheltering screens, and not having a great spread of branches. It is far more robust than the old Lombardy Poplar, and has larger leaves; it is, moreover, said to be quite hardy, which is a great advantage, as miles of country in the northern counties have been practically denuded of Lombardy Poplars during the past severe winters, hundreds of grand towering specimens having been killed or injured beyond recovery. Those, therefore, who contemplate planting trees of this habit should make a note of the variety above mentioned.

Rhamnus alpinus is ornamental by its rich green, deeply ribbed, Laurel-shaped leaves, 6 inches long and 3 inches across. Acers were very telling among the lighter foliage, especially *A. platanoides ginnula*, with leaves like *Ampelopsis Veitchii* in shape and colour; *A. p. purpurea* being strong and good, and *A. colchicum rubrum* free and very fine. Amongst Privets *Ligustrum amurense* is in great demand, being hardy, upright in growth, with dark stems and green leaves. The two variegated deciduous shrubs, *Cornus alba variegata* and *Philadelphus coronarius variegatus*, were highly attractive, and

ought to be more frequently seen in shrubberies. The leaves of the former are green, clearly margined with white, a free-growing bush, having a better effect than half the variegated stove plants; while in the leaves of the other shrub (the Mock Orange) creamy white prevails, especially when grown in a rather shaded position. The yellow-berried Guelder Rose is distinct and not common, and the old silvery-leaved *Shepherdia argentea* grows like a weed in the nursery.

Evergreens of all kinds are grown in numbers, but only mentioned for observing that of Laurels the variety *rotundifolia* is the finest and hardiest, this being the place for testing their frost-enduring powers. *Causasia* is also hardy, and of a darker green; whilst *latifolia* is noticeable by its very long foliage. Of *Rhododendrons* there is a very extensive collection, all the leading most hardy varieties being included. In one enclosure a shrub of each variety has its name inscribed in bold letters on deal labels 2 or 3 inches wide. The names are written in pencil on wet paint, and thus really impressed; then marked over with printers' ink. Why? Not many people would guess. Because the wasps nibble at the lead until they clear it all off, while they do not touch the inked letters. Truly we live and learn.

Fruit trees in varieties suited for the north are carefully cultivated, and of Roses there were large and very numerous stocks, seven hundred thousand on the Briar and Manetti, with a few on the de la Grifferae stock, being raised annually; and here may be noticed a singular fact—on the plants of the two former not a speck of mildew was to be seen, while every plant on the latter was more or less affected with the mealy parasite, squares of each being side by side on the same kind of soil. The growths on both stocks were equally strong, and in that respect perfectly satisfactory, but the foliage in one case was a fresh bright green, on the other in some instances white as a miller's hat; but fortunately only a few comparatively were worked on the de la Grifferae for experimental purposes.

On the herbaceous and alpine grounds we cannot dwell, and it must suffice to say the collections of plants are large, this department evidently receiving careful attention; yet just two beds must be particularised—one a mass of Hyacinths (*Galtonia*) *candicans* with stems 5 feet high, an inch in diameter, the majority bearing fifty flowers; the other a mass of *Lobelia fulgens ignea*—a forest of fiery spikes of the same height as the *Galtonias*. It was difficult which to admire most, the purity of the *Galtonias* or the richness of the *Lobelias*. A mixture of the two grown as these were would create a sensation, and this hint may possibly not be lost. The able and enterprising managers of the London parks are ever seeking to produce fresh floral effects, and they might do worse than test the merits of this suggestion. We noticed also a superior strain of single Dahlias.

The glass structures in the nursery are filled with plants that are most in demand, including the best varieties of Azaleas, Camellias, Begonias, Zonal Pelargoniums, and others which need not be enumerated, but *Statice Butcheri* demands notice. It is apparently intermediate between *S. Holfordi* and *S. profusa*, but decidedly more effective than either, and undoubtedly a valuable summer-flowering decorative plant. The nurseries throughout were in excellent condition, and nothing could exceed the courtesy that was extended to—
A VISITOR.

EARLY WHITE GRAPES.

AS your pages are open to a fair discussion on horticultural matters I hope you will allow me space to bring to the notice of the readers of your Journal White Frontignan Grape. The Sweetwaters are receiving their share of attention, and deservedly, as they are easily grown and highly appreciated; but I think the above-mentioned Grape should be more generally grown. Some may object to the smallness of the berry, but the flavour is unsurpassed by any you may bring before it for early forcing. It bears well, and remains fruitful as long as the Black Hamburg. Although it is not such a showy Grape as Buckland Sweetwater, it is more decided in good qualities in many ways, as Buckland will not bear the trying ordeal of early forcing as well for a long number of years, having a disposition "to miss showing," especially when becoming old, the bunches become fewer in number and smaller, the berries less, and the setting more irregular. The same may be said in a greater or less degree of any Grape becoming aged, but there are more reliable sorts in this respect than Buckland Sweetwater. A good early Grape should hold a reputation for being first-class. Such a one we have in the Duke of Buccleuch, which is winning for itself the favour of all the best Grape-growers in the country, judging from the high position it has taken at different shows—a sufficient guarantee of the fitness of this Grape to be chosen as one of the best early forcers. Good cultivators no doubt do not need to be told this. The strong and early ripening of this Grape gives it a double advantage for early forcing, and nothing but mismanagement in the cultivator's hands could hinder a good crop being obtained. In addition to being a good early forcer the Duke has proved itself to be to some extent a good keeper, as I have seen it hanging quite fresh and plump in the

middle of January, having been ripe for more than six months.
—NORTHERN.

MAXILLARIA PICTA.

THREE properties are possessed by this plant that ought to recommend it to everybody. It is extremely easy to grow, it flowers freely at midwinter, and it is sweet-scented. Some, whose olfactory nerves may be more delicate than usual, may consider that the scent is rather too pronounced, and certainly a plant of moderate size will perfume a large house and a few blooms be quite sufficient for any ordinary room, but when not overdone the smell is delightful. Just now (November) it is here highly prized both for its odour and its beauty. In a floral arrangement when scent may be absent it will make up for the shortcomings of all the rest, and, as we have said, a few blooms are sufficient.

Two years ago a rather large potful of it in neglected condition came into my possession, and this was broken up into three and potted in a mixture of equal parts fresh sphagnum and charcoal, surfaced with growing sphagnum, and thoroughly well drained by having the pots half filled with potsherds. The plants have not been touched since, but as they are now grown solid they will have to be broken up at next potting time; otherwise they have had the treatment of ordinary stove plants, except that they have cost much less trouble, for beyond watering nothing has been done, and the reward is that from three plants in 8-inch pots we have a handful of flowers every week for a couple of months simply by retarding one and pushing one forward.

A few years ago we had only to say that a plant was an Orchid in order to frighten people from having anything to do with it; and though the old feeling is not quite removed yet, most gardeners are now aware that many Orchids are very easy to cultivate, and none more so than this.—S.

AN AMATEUR'S HOLIDAY.

ONCE again the holidays have come and gone. As usual, happy meetings took place with former friends among the flowers, and new acquaintances were formed, some of which seem already old. I may be able to present some things of interest to your readers respecting the shows, the gardens, and more fully the nurseries I visited.

Besides the more prominent exhibitions in Scotland I saw a number of "locals," and many things in these that would have done credit to any show. From these smaller displays, better than from the others, we learn with pleasure something of the extent to which gardening is prosecuted among our working classes in Scotland. We know what an important part the "kail-pat" plays in their families, and at some of these smaller shows collections and separate exhibits of vegetables were met that were not surpassed at any of the leading exhibitions. While in an amateur's garden I was amused by an old lady—by-the-by, she demurred good humouredly to my styling her old, and I promptly and humbly apologised. Bustling forward she exultingly challenged my friend, who had shortly before defeated her at their village competition, to produce the match of a fine Cauliflower she had with her. No hero of Tel-el-Kebir could seem prouder of his laurels than was the cheery old body—I again beg her pardon: she was only somewhat over eighty!—satisfied that she had triumphantly vindicated her assertion that she would beat the victor yet.

At one of these "locals" the best collection of annuals I have seen was shown by an amateur; at another Roses were scarcely inferior to any I saw elsewhere; at a third a neighbour of my own staged Gladioli that would have made their mark at any exhibition. But I do not think the display of flowers was such as to mark this as a really good flower year. I found a deficiency throughout in those flowers especially that bloom in spikes. Phloxes, for instance, were nowhere first-rate, and really good Antirrhinums were rare. Dahlias and many other flowers were scarcely to be seen in perfection either on the tables or in the garden. At the opening of one show I was surprised to hear it stated that in the district, which has long been noted for its florists, the Tulip had at one time been predominant. This had been succeeded by the Auricula, that in turn by the Pansy, and that now all of these had been superseded by newer and more beautiful flowers. And this where the memory of Lightbody is yet green! I thus translated the look of indignant protest on the face of a friend: "What ho, there! Campbell and Jeffrey and Gair. Treason in camp!"

Of the leading shows I saw in Scotland I would mention three as the more notable—the Rose Show at Helensburgh, where the collections of the Messrs. Dickson of Belfast and of Newtonards, with that of Mr. Smith, Stranraer, and others, the Pinks from Paisley, and the Pansies combined to form a fine display. What a glow those Roses from Ireland have! The usual joke was passed with the Messrs. Dickson about the desirability of getting hold of their varnish pot; but it seems it cannot be imported into Scotland. One bloom—an Alfred K. Williams—in one of their stands recalled and almost justified the words of a living writer: "If there were only a single Rose here and there upon earth, men and women would pass their years on their knees before its beauty." An ardent lover of the Rose informed

me that he and a brother rosarian, at a show in England shortly before, had loyally doffed their hats to the queen—in the person of even a superior bloom of the same variety.

The Glasgow September Exhibition maintained its established fame. The usual variety of florists' flowers was to be seen, and in most cases of capital quality. I would, if making exception at all, do so in the case of some of the Gladioli. In an extensive class including some really fine spikes not a few decidedly poor ones were observable. The Roses, too, owing to the weather were, with a few exceptions, not of much merit. The Pansies, as at the preceding Pansy Show in the same place, were beautiful. But why was such laxity in the naming of these observable? Where a card is laid down with the names exhibitors ought to adhere to one system of numbering. Here one did so by rows in order from back to front, and there another from left to right. I know that mistakes were made by those who could not check themselves by coming upon known varieties, and thus those who supply such orders are likely to be unjustly censured. This need not be.

The International at Edinburgh was too vast for me to say much upon now. Besides, on most of the exhibits I do not claim the ability to pass an opinion. Here again the Roses from Ireland were pre-eminent; and Mr. Dickson's blue ribbon, which I was pleased to see for the first time actually displayed on his stand, was another addition to the trophies of Belmont. Here, as elsewhere, Phloxes were poor. Some good Asters were present, especially a stand from East Linton. Hollyhocks, for some years conspicuous by their absence from our autumn shows, again made their appearance. Dahlias showed the effects of an unfavourable season and of frost on nights immediately before the Show. I take it as a matter of course that the Pentstemons of Messrs. Downie & Laird's collection carried all before them in both classes. Gladioli were well represented, and the same three exhibitors who at Glasgow the week before secured the first honours in their respective classes carried off the palm. But here again reprehensible carelessness in naming occurred, suggesting the probability of intending purchasers being misled. In one stand for instance—I need not say not a winning one—a variety did service under three different names. I would bespeak a little consideration in the placing of a flower that when properly shown vies with the Rose itself in attracting attention. I know that it is difficult to cope with every exigency and to meet every requirement in appropriate staging, but to give Gladioli a background of windows with, in the case of Glasgow, strong light falling upon them in front, does not do them justice. Were the object to discover defects if such existed, which they only too readily disclose in any circumstances, the end was fully attained. Happily the best flowers could stand even the severe test to which they were subjected, and visitors will find them out and throng to admire them even when they are shunted into a recess unworthy of them, and where less attractive objects would be doomed to comparative neglect.

At the risk of seeming invidious I would mention the grand Paneratum for which Mr. Souza, Touch Gardens, near Stirling, was awarded the first prize for the best greenhouse plant—a sample of the high-class culture which is noteworthy in every department of these gardens. The symmetrical Lapageria about 8 feet in height from Mr. Robertson, Springbank, Stirling, showed what skill can achieve even with comparatively restricted facilities.

In closing these random remarks I may state that all over the season four flowers stand out to be distinctly remembered—the Rose at Helensburgh already referred to; in another place a bloom of Thomas Mills; a spike of Gladiolus Camille, as seen in perfection on the first evening of the International; and another of Ondine, seen in the garden from which came the prize eighteen. Than these last two noble flowers I do not think it possible in all Flora's wide domain to find anything more captivating or more imposingly beautiful. I will next crave indulgence for some notice of gardens I was privileged to visit.—A NORTHERN AMATEUR.

ABUTILONS FOR WINTER.

FEW plants are more useful for various decorative purposes at this season of the year and onwards than Abutilons. Few plants have been more improved of late years than these, and instead of plants that become several feet high before they produced a flower, and then sparingly, we have those that flower profusely when only a few inches high, and in comparatively small pots.

To grow Abutilons for producing flowers in large quantities they should be planted out against a pillar, rafter, or where they can cover a wall. I think they show to greatest advantage against a pillar with their stem kept clean until they attain the desired height, and then the head can be allowed to form. Naturally they are of upright growth, but can be trained with but little care and attention to droop their branches in a downward direction. Standards grown in large pots or tubs would be very effective in large conservatories amongst Palms and other foliage and flowering plants. These plants possess one great advantage over many others in flowering almost the whole year; in fact they will do this if properly and liberally treated. When plants have attained a fair size in either pots or tubs they require liberal feeding and rich top-dressings frequently to keep

them vigorous and healthy, otherwise the foliage turns sickly, the wood becomes hard, and the flowers few in number. I do not, however, believe in keeping them growing and blooming year after year without giving them a season of rest. This opportunity should be seized when their flowers can best be dispensed with, and this undoubtedly will be during summer in the majority of gardens. If rested and well cut back during summer, and a portion of the soil removed from their pots or tubs and replaced with rich loam and manure, they will start again freely into growth and produce flowers in abundance during the whole winter and spring.

It is not so much of large plants that I am writing as of those of a suitable size for decoration in 4 and 5-inch pots. These plants can be grown well, and a succession of flowers produced through the whole year by striking batches of them. They are, however, most useful during autumn, winter, and spring. These are greenhouse plants, and thrive well under greenhouse and cool-frame treatment during the summer months. They will not flourish so well in the greenhouse during winter as in a house that is kept a little warmer. Under cool treatment during the winter their growth is remarkably slow—that is, in such houses where Azaleas, Epacris, and other plants are accommodated, and only frost excluded. They do fairly well in conservatories where the temperature is not allowed to fall below 45° by night; but better, and continue to grow and flower with greater freedom, in an intermediate house where the temperature is maintained between 50° and 55°, according to external conditions. We give a number of our plants stove treatment, and very beautiful they are when arranged amongst other flowering and fine-foliage plants. While they are benefited by a certain amount of heat stove treatment is really too warm for them; they grow too rapidly, and in consequence become drawn, which soon spoils their beauty for decoration. In an intermediate temperature where air can circulate amongst the plants when favourable they grow more slowly, and continue to flower freely for a long time.

To maintain a succession during winter and spring two batches should be propagated, one in July and the other towards the end of August or early in September. It is useless to propagate for this purpose earlier, as the plants only become tall. The cuttings should be inserted in thumb pots, as every one will root if placed in close handlights in Cucumber and Melon houses, and kept shaded from strong sun. As soon as the young plants are rooted they must be gradually accustomed to cool treatment; in fact, we generally have ours in a cold frame by the time they are ready for 4 or 5-inch pots, which is the size employed here, and the only shift the plants get after they have filled the small pots in which they are rooted. This batch we grow in cold frames as long as the weather will allow us to do so without checking the plants. Growth from the time of rooting is slow, and the plants are sturdy and strong with fine foliage down to the rims of the pots. By the time the plants have to be housed they are showing abundance of flowers, and average about 4 feet in height. To have large foliage at the base and down to the pots, it is necessary that the wood selected for cuttings be well furnished with good foliage when inserted in the small pots. If small side shoots are employed the foliage for some time will be small, in fact the base will never be furnished with bold large leaves. We give preference to good strong cuttings, such as can be obtained by removing the end of leading shoots, and then the plants are well furnished from the commencement. They seldom lose their foliage in the operation of rooting if judiciously treated.

The plants employed in the stove are generally those propagated in September, which are not so forward as those rooted a month earlier, and are very useful in the stove after many of the earlier winter-flowering plants are past their best. This batch are small and dwarf to commence with, and continue to flower well on into spring before they become too leggy. As soon as they reach this condition they are at once cut down, and the strong tops again rooted. It is a good plan to root a number together in 5, 6, or 7-inch pots, and keep them during the autumn in an intermediate temperature in readiness to be potted any time about Christmas, so that they will be in good condition for replacing those in the stove when cut down. By so doing no gap is occasioned where a continuous supply of their flowers are required either for cutting or the plants for decoration.

While growing Abutilons must not suffer by the want of water, and when the pots are full of roots liberal feeding must be resorted to. Stimulants should be given every time watering is necessary, by which means the plants are kept in a healthy vigorous condition.

Abutilons are not particular about soil, and will do well in almost any compost that is rich. Good loam to which is added one-seventh of manure, with sufficient sand to keep the whole

porous, will grow them well. There are many varieties worth growing, but the following are good and useful for decoration in small pots—Boule de Neige, Fire King, Violet Queen, Aurelia, L. Van Houtte, and Marshal.—SCIENTIA.

ARAUCARIA BIDWILLI.

My thanks are due to Mr. J. Smith for his particulars concerning the introduction of *Araucaria Bidwilli*, as they remove what now appears to be an error of very long standing. Professor Dyer is responsible for the statement that one of the two plants of this *Araucaria* brought home by Mr. Bidwill was purchased by the Duke of Northumberland for one hundred guineas, as, when cones were produced by the specimen at Kew, he exhibited them before the Royal Horticultural Society March 5th, 1873, also before the Linnean Society, and included the above particulars in some remarks upon the history of the species. These observations were quoted in the *Gardeners' Chronicle*, the *Journal of Horticulture*, and *Nature*, but the "other paper" referred to by Mr. Smith attributed the purchase to the Duke of Devonshire, though not in 1872 as Mr. Smith states, but in 1873 and subsequent to the meeting of the Royal Horticultural Society mentioned above, and it is, therefore, doubtless simply an incorrect rendering of the original statement. The particulars I gave I have repeatedly heard mentioned at Kew, and, as far as I am aware, the published statements had never been corrected until Mr. J. Smith cleared the matter up. Professor Dyer is, however, so noted for scientific accuracy that it is impossible to understand how he could have been led into so strange a mistake. Perhaps he can explain it.—L. CASTLE.

CHRYSANTHEMUM SHOWS.

SOUTH SHIELDS.—NOVEMBER 29TH AND 30TH.

THE above Show was held in the Free Library Hall, Ocean Road, under circumstances that augur well for its future prosperity and permanency. The Society has received an amount of support and encouragement from the local tradesmen and gentry that was never anticipated. Last January a few gentlemen, including Mr. Thomas Binks, Mr. Adam Hope, and Mr. John Wright, formed a committee. Others soon followed, and before the day of the Show they had £100 collected. They offered £60 in prizes this year; hope next year to offer £100 at least. In framing their schedule they made Messrs. Cannell's catalogue the standard as regards the classes of the flowers. This arrangement was found to answer well, and gave great satisfaction.

The Exhibition was publicly opened by J. P. Wardle, Esq., Mayor of South Shields. He was also supported by J. T. Etringham, Esq., the President of the Society. The Show was considered very fair, and better than ever was seen in Shields before, many of the exhibits equalling those at metropolitan shows.

For the group of Chrysanthemums, fine-foliage and other flowering plants, Mr. Henry Smail, gardener to J. C. Stevenson, Esq., No. 1, Westoe, was deservedly first. His collection comprised Chrysanthemums, Palms, Zonal Pelargoniums, and Coleus, all neatly margined with Ferns. Mr. East, florist, Westoe, and Mr. Whiting, gardener to E. Walker, Esq., Shot Tower, Newcastle, took the remaining places.

For six large-flowering Chrysanthemums the Society offered £3, £2, and £1 respectively for first, second, and third. Mr. Corbett, gardener to W. N. Liddle, Esq., Bernwell Hall, was first with neat trained specimens of Mrs. Dixon, Mrs. G. Rundle, Julia Lagravère, &c. Mr. Blanchard, gardener to Dr. Gibb, Sandford Lane, Newcastle, was second with fine plants that might have been improved by a little more training. Mr. Smail third with smaller but very even plants. For three large-flowering specimens Mr. Corbett was first with Argend, Mrs. Dixon, Mrs. Rundle; Mr. Smail was second with similar varieties; and Mr. Allen, gardener to Henry Wilson, Esq., Westoe, was third. Mr. Corbett was first with Pompons, remarkably fine specimens, including Cedo Nulli and others. For four Japanese Mr. Blanchard was first with Elaine, James Salter, Peter the Great, and Fair Maid of Guernsey.

In the miscellaneous plants class Cyclamens, Primulas, and Zonal Pelargoniums were well shown, and in a collection of greenhouse plants Mr. Smail staged some very well-grown Camellias.

Cut Blooms.—For twelve incurved Mr. Brown, gardener to Mrs. Joicey, Whinney House, Gateshead, was first with good varieties of Mrs. G. Rundle, Fulgore, Mrs. Dixon, &c. This exhibitor also took first for twelve reflexed, twelve Japanese, and twelve bunches of Pompons. These included the chief varieties in each class. Mr. Annison took first for six incurved, six reflexed, and six Japanese. Messrs. Wilson, Allen, and Whiting also showed well in these classes. Three stands of Japanese, incurved, and reflexed blooms not for competition were kindly sent by Mr. Milner, gardener to Mr. Newall, Ferndene, Gateshead. These were by far the best among the cut flowers, and were much admired. Mr. Watson, Fenham, Newcastle, Messrs. W. Fell & Co., Hexham, Mr. W. East, Westoe, and Mr. W. Marshall, Florist, Mariners Cottages, South Shields, exhibited stands of plants for decoration, including stove and greenhouse and con-

ferous plants. Amongst cut blooms Mr. Garret, Hindley House, Stocksfield-on-Tync, sent a superb collection of Zonal Pelargoniums. There was a stand of Primulas from Messrs. Cannell & Son, Swanley, Kent, and some Mignonette trained pyramidal shape from South Shields and Westoe Cemetery.

CHESTERFIELD CHRYSANTHEMUM SOCIETY.

NOVEMBER 23RD AND 29TH.

The above Society held their first annual Show last week in the assembly room over the Market Hall, a room admirably adapted for the purpose; and although it was considered late by several exhibitors, owing to the Committee not wishing to clash with any other shows in the immediate neighbourhood, it was pronounced to be by competent judges and growers the best show in the district. T. P. Wood, Esq., well known for his liberality, accords the Society his patronage as President. The Vice-Presidents include several of the leading gentlemen in the town. The arrangements were carried out under the superintendence of Mr. J. Hall (Hon. Secretary) and an influential Committee, of which the most prominent are Messrs. W. M. Hewitt, W. Slack, C. Auckland, and R. W. Proctor, and several of the leading gardeners in the neighbourhood, including Mr. J. H. Clements of Whittington.

There were no money prizes, but in lieu of them first, second, and third-class certificates of excellence were awarded. The President paid for the use of the rooms; Mr. Eastwood, one of the Committee, lent boards for tables, &c.; Mr. J. K. Swallow lent cloth for covering the same; and after the expenses, which cannot amount to much, are paid, the proceeds will be handed over to the Chesterfield and North Derbyshire hospital.

The plants, which included large-flowering varieties, Japanese, and Pompons, were not quite so good as we like to see. Although well bloomed, the majority of them were too high on long naked stems. One collection, however, exhibitors in future might advantageously imitate. This was six large-flowered plants staged by Mr. R. W. Proctor, and deservedly placed first in a strong class—the plants from 3 to 4 feet high, with beautiful fresh green foliage down to the rim of the pots, and every flower almost fit for a stand in the cut bloom class.

Cut blooms were the chief feature of the Exhibition. Mr. Tree, gardener to J. R. Swallow, Esq., was deservedly first for twenty-four large-flowering varieties, as was Mr. J. H. Clements. The Judges considered them equal, but all the local florists considered Mr. Tree the winner, as did most of the leading gardeners. The blooms shown by Mr. Tree were neat, clean, fresh, and well put up, and one old florist remarked that they might have all come out of one mould, so neatly were they incurved. Among the best flowers of Mr. Tree's were White Beverley, Beauty, Mrs. Dixon, Jardin des Plantes, Yellow Beverley, George Glenny, Mrs. G. Rundle, Empress of India, Lady Slade, Golden Empress of India, and Golden Queen of England. The best blooms in Mr. Clements' stand were Virgin Queen, splendid, and Prince Alfred, good; several of the others bad centres. This exhibitor and several others made a great mistake in setting their blooms down too low. For eighteen blooms, large-flowered varieties, Mr. R. W. Proctor was an easy first, his best flowers being Golden Empress of India, Red Dragon, Empress of India, George Glenny, Lady Slade, Lord Derby, and Prince Alfred. Second, Mr. J. Marsden, made the same mistake mentioned above, and some blooms looked dull. Twelve large-flowering varieties, Messrs. Hall and Auckland had some very neat blooms. We also noticed an excellent stand of Japanese and incurved exhibited not for competition by T. P. Wood, Esq., and a stand from Mr. Gosling quite equal to anything in the classes for cut blooms.

In the class for six Primulas the competition was very keen, Mr. R. W. Proctor ultimately winning, being very closely pressed by Mr. Frith, gardener to J. P. Jackson, Esq., J.P., Stubbin Edge; third prize going to Mr. Reynolds, gardener to W. G. Turbitt, Esq., Ogston Hall. In the class for three Primulas Mr. Parker, gardener to Mr. C. Markham, Tapton House, took the lead.

There was a grand display of Grapes and stove plants, kindly lent by the following gentlemen:—His Grace the Duke of Devonshire, Messrs. A. Barnes, M.P., Ashgate; H. A. Fowler, Whittington; J. B. Barrow, Ringwood Hall; W. B. Smith Milnes, Dunston Hall; F. Swanwick, Whittington; J. Britt, Chesterfield; Fletcher & Son, Chesterfield; R. W. Proctor, Chesterfield, who also lent a good collection of evergreens for the staircase. Mr. C. Shentall, fruiterer, had a very good table of fruit. Mr. Ewing, Sheffield Botanic Gardens, and Mr. Stephens, gardener to Sir John Brown, Sheffield, were the Judges.

THE COMET.

A WRITER in the *Times* some years ago (the *Times* cruelly printed the letter) stated that the name was derived from the word "comma," "because a comma is a dot and a tail." I cannot hope to make any equally erudite addition to useful knowledge, but yet I desire to call attention to what is being said of the late comet, which it seems before long may present some phenomena which will have very practical interest for a horticultural journal. It is stated, on apparently good authority, that the brilliant visitor alluded to was none other than the comet of 1688, which came back in 1843. This, if

true, is a very startling and perhaps formidable statement. That comet's period of revolution was thus given as of 175 years, instead of which we had it back in 1880, its period having been diminished to thirty-seven years. This is attributed to the sun's attraction (through a too near approach) having availed to suck it in towards it. And now the 1880 comet is back in two years instead of thirty-seven! At this rate, we are told, a very few months more must see it with a spiral motion dashing into the sun!

Some little time ago the general idea was that a comet falling into the sun—through the mass of matter cast in, besides the heat generated by impact—would cause an outburst of igneous force possibly sufficient to destroy all life on the earth's surface, if not to bring about the general conflagration. Of late Mr. Proctor and others console us by the idea that a comet had so very little solid substance that the effect on the solar central furnace is hardly likely to be great. We will hope that is so. But if the next year really is to bring such phenomena, and even a slight increase of heat be produced, we may have reason to be deeply thankful for the 6 or 7 inches of rain in October, which were registered all over the country.

A pleasing and scrupulously veracious American writer has described a spell of heat in which ducks were roasted and fell fit for the table in flying from pond to pond. Perhaps we need hardly anticipate this. Still, various questions may arise as to show fixtures in prospect of such a decidedly "early season," and it will not be amiss if the subject be ventilated beforehand.—A. C.

HARDY FRUIT GARDEN.

THE unusually wet weather this autumn has not been favourable to the ripening of the wood of fruit trees, but as the leaves have now nearly all fallen, planting should be proceeded with as the weather permits. It is a mistake to defer operations of this kind any longer than can possibly be avoided, as, although the trees are apparently dormant through the winter, there is a certain activity going on which causes the wounds to heal or callus, even if fresh fibres are not actually formed. This gives autumn-planted trees a considerable advantage over those planted later, the latter not having time to form fibres before the rapidly swelling buds are making demands insufficiently supplied, and the consequence is they will break weakly. Although it is important that planting be done early, it is undesirable to carry on transplantation whilst the ground is wet and unfavourable for working, or when frost prevails, as during frost much injury is done to the roots by the vessels being ruptured through an undue expansion of the moisture they contain. To avoid the roots becoming frozen after planting, a good mulching of partially decayed littery manure will serve the double purpose of keeping out the frost and assisting to keep the heat in, also maintaining the soil about the roots more uniformly moist.

In planting the choicer description of stone fruits, such as Peaches, Nectarines, although it may not be necessary to entirely form new borders, it is always advisable that old borders should be deeply stirred; but if trenching be resorted to, the subsoil must not be brought to the surface. Stirring the hard under stratum or subsoil will admit of percolation of water through the soil readily and the passage of air, and with drains to carry off superfluous water there will be no fear of the trees thriving satisfactorily. A few barrowfuls of fresh turfy loam to plant the trees in will afford a good rooting medium for them, and give them a better start than compost rich in decaying material. Calcareous matter is absolutely essential to the cultivation of stone fruits, and soils deficient in this should have some old mortar rubbish or chalk mixed with it.

Pears, Apples, and especially bush fruits, are greatly assisted in their growth by being planted in richer material; but even in their case it is necessary not to afford manure in such proportion as will induce a gross sappy growth, but what manure is employed should be thoroughly decomposed, well mixed with the soil, and not brought into direct contact with the roots. In planting standard trees, where time will not permit trenching to be done for these at once, it will be

well to get the trees in at once at the proper distances by digging or trenching large holes, and leaving the trenching of the space between to be carried out at some future time. The disturbance of the soil about them will be a great gain by the decomposition of the freshly turned ground; and whatever is needed to improve its texture can be readily applied, whether it be clay to render sandy shallow soil more tenacious and moisture-holding, or road scrapings, old mortar rubbish or ashes, to render heavy and wet soils more open.

Although Gooseberries, Currants, and Raspberries are allowed to stand many years on the same ground, even after they have ceased to afford full crops of large fruits, it is not a good practice, as fresh plantations are always more profitable, and a thorough system of rotation of crops should be carried out in the fruit department as in other departments of the garden. Where plantations of the above are giving indications of being worn out by the decay of the bushes wholly or in part, or from affording indifferent crops, fresh plantations should at once be formed, and when these come into bearing equal to the demand the old may be destroyed.

FRUIT HOUSES.

Pines.—During this and the following month the plants will require considerable time and attention in the several departments. The temperature in the sucker pit should be 55°, in the successional pit 60°, and in the fruiting house 70° at night, which under very adverse circumstances may be allowed to fall a few degrees. In the fruiting house the temperature must be raised 5° to 10° higher in the day, being guided by external influences; but in the other compartments a similar rise will not be necessary, except in the case of successional which are expected to show fruit, when they should have the temperature raised as indicated for fruiting plants. Great care will be needed in watering, particularly in the case of plants plunged in beds where there is but slight bottom heat, as under such conditions plants in small or moderate-sized pots will not require much water, and should only be given when absolutely necessary, and then in a tepid state.

FLOWER GARDEN.

Contemplated alterations in lawns and pleasure grounds should be carried out as long as the weather continues mild, completing those sufficiently advanced by laying the turf; but if the weather be frosty the groundwork should be proceeded with, deferring the turfing until mild weather. If there is to be any re-arrangement—replanting trees and shrubs—it is desirable to commence in a systematic manner the groundwork being completed before any planting takes place. The greatest mistake in planting is striving too much to produce an effect at once, as in a very few years the shrubs become so crowded that a thinning of one-half has to be effected, which may spoil the whole of the arrangements. The position of each specimen, or those that are to remain as such, should be arranged, and the whole of these planted first, the spaces being then filled in any manner calculated to produce a pleasing variety for present effect; only it is undesirable to employ tall-growing trees, which are much better planted in the arboretum or for grouping in park scenery. Still, many of the Coniferæ and others that develop into large trees are very beautiful in a young state, and they are used in ornamental borders. In planting shrubberies it is well to make a departure from the prevailing fashion of late years of giving preference to evergreens to the almost total exclusion of flowering deciduous shrubs, some of which are very beautiful.

Except the almost constant work of sweeping and rolling little remains to be done in this department at present. Any gaps in Box edgings should now be made good. Where the soil is suitable for the growth of Box it is unrivalled as an edging plant, but in sandy soils or those lacking calcareous matter it often turns brown, which greatly detracts from its appearance. Where this is the case the edgings will be greatly improved in colour by working in a good quantity of chalk when relaying. Christmas Roses are much appreciated and in great request for cutting. Handlights placed over them will greatly assist the flowers and improve their colour. There is always great risk in digging herbaceous borders, especially at this season, unless the positions of bulbs and plants are indicated by stout hard wooden pegs; but, except in the case of such things as are

well known, it adds much to the interest of plants to have them properly named. Bad weather will afford an opportunity of providing pegs or labels for such plants as require them renewed. The borders should now be mulched with well-decayed manure, leaf soil, or the reduced refuse from the rubbish heap, which will not only enrich the soil but form a suitable protection against the severity of the weather. Keep a sharp look-out against the depredations of mice amongst bulbs.

Ere winter sets in in earnest plants of doubtful hardiness should receive the needful protection. Some dry leaves placed about their crowns and some fern over, with a branch or two of Laurel or Spruce to prevent their blowing about, form a good protection for Bambusas, New Zealand Flax, *Chamærops Fortunei*, Pampas Grass, and many others; and those of doubtful hardiness against walls should have the roots similarly protected, affording in addition to this for *Magnolias* or *Ceanothuses* a double covering of mats tacked in front of the trees in severe weather. Roses of the tender kinds against walls may be treated similarly. Beds of Tea Roses must either now be lifted and laid in a pit to which protection can be given in severe weather, and from which they can be transferred in spring to the quarters for blooming, or they may be left in the beds protected with a good thickness of leaves kept from blowing about by some litter or fern, and in severe weather some dry hay or fern woven in about the heads will materially assist them to withstand sharp frosts. Hybrid Perpetuals should be well mulched over the roots with littery manure, and with this they are comparatively safe, as with the roots protected they will bear more cold than those not so protected, and in the case of dwarfs they will start from the base if the tops are cut off to the line of mulching.

THE BEE-KEEPER.

THE ART OF BEE-KEEPING.—No. 4.

(Continued from page 511.)

THE QUEEN BEE.

WHILE a worker bee is developed from the egg in twenty-one days, a queen takes only sixteen days—viz., three days in the egg, five as a larva, and eight in the sealed state. What makes this difference remarkable is the fact that the eggs from which both are developed are originally alike—*i.e.*, the same egg may produce either a worker or a queen, according to the way the bees treat the larva that hatches from it. No one has yet solved the mystery in which this transformation is enveloped. All we do know is, that the larva intended for a queen is furnished with an excessive quantity of rich food called royal jelly, and provided with a much larger cell than that of a worker, and which is placed in a perpendicular instead of a horizontal position. It is a knowledge of this remarkable power possessed by the bees that enables the bee-keeper to have queens raised at will. Usually queens are raised only when swarming is intended, or the old queen becomes nearly exhausted, or meets with sudden death. But if queens are wanted at any time the bee-keeper may almost invariably cause a number of them to be raised by simply removing the old queen. In this case the bees generally select young larvæ to be transformed into queens, and thus the latter may be ready to hatch in twelve, or even ten, days from the time of removal of the old queen. As, under such circumstances, the first hatched princess usually destroys all her rivals before they issue from their cells, the bee-keeper who desires to save more than one must be careful either to remove, or cage in wirecloth, such cells as he wishes to make use of, and that about the ninth or tenth day. Such sealed cells may be given to other stocks having no queens, as when artificial swarms are made, and thus one stock may do all the queen-rearing needed in even a rather large apiary.

The knowledge of these facts renders artificial swarming possible, since the bees left in a stock from which a queen and swarm have been taken will either raise a new queen for themselves, or accept a royal cell reared in another stock. Artificial swarming was practised ages ago by the natives of the eastern Mediterranean shores, though the knowledge of how both stocks came to have queens was not possessed by them. In our own country it does not appear to have been practised before the end of last century, but followed the discoveries of Shirach and Huber already referred to. Bonner indeed tells us he practised it even before he heard of Shirach's discovery. But his practice was in some respects faulty; and this is not

surprising, since neither he nor Huber knew anything certain about the fecundation of queens. This was left for Dr. Dzierzon and Baron Berlepsch of Germany to unfold about thirty years ago. Since then queen-rearing has been carried on with the certainty of a science, and has indeed attained considerable proportions as a special commercial pursuit both in Europe and America.

Let us now briefly notice the peculiarities of the queen (fig. 89) thus strangely produced. In appearance she differs greatly from her sisters the workers (fig. 90). She is about a third longer in body, and is altogether a more strongly fashioned creature, with the exception of her jaws and trunk, which are not so well developed. Her colour is a shade lighter, especially on the legs and under side of the body; and her wings are shorter in proportion to her size, and generally appear closely folded along her back. This latter peculiarity, as also her more slender outline, enables beginners at a glance to distinguish her also from the drones (fig. 91). Not being intended for foraging she is not provided with the spoon-shaped cavities on the hind legs, which the workers possess as pollen baskets, and she differs materially in other points of anatomy, but specially in having her ovaries largely developed. These last exist in the workers, but only in an embryo state.

In instincts she also differs greatly from the workers. She has no building or provident instincts, and when once fertilised never goes abroad unless to accompany a swarm. She devotes herself solely to the work of laying eggs, which she leaves entirely to the care of the other bees; and her temper is so different that no provocation will induce her to use her sting unless against a rival queen. In this case, however, her antipathy manifests itself in

Fig. 89.
Queen.

Drone.

determined attempts to kill any rival, and extends even to the unhatched tenants of the royal cells. Only in the somewhat rare case of a young queen hatched for the purpose of superseding one that shows failing powers do we ever find two queens living peaceably together in the same hive.

The queen is the centre of attraction in every colony. If suddenly removed or lost the bees manifest great uneasiness. They rush about the hive, outside and in, and at intervals unite in giving expression to their grief in a doleful hum. If brood or eggs be left they will in the course of a few hours settle down as if resigned and commence the work of providing a successor, but if this be impossible they will be found in an excited state for weeks after. Experts can generally tell by the sound produced on slightly disturbing a hive whether it be queenless or not.

The queen is recognised by the other bees mainly by her scent, and outside the hive they may be seen to follow her trail as hunting dogs track game. A strange queen is recognised as such at once, and only accepted by bees that have fully realised the loss of their own queen. It is thus necessary to use precautions in introducing a strange queen to a colony, the most approved method being to confine the new queen in a wire cage until the bees become reconciled to her presence, which is sometimes at once, but generally within twelve hours or so. Cases, however, occur in which she will be attacked whenever liberated, even after being caged for a whole week. The behaviour of the bees at the moment of liberation will generally satisfy an experienced bee-keeper as to their intentions, hostile or otherwise; but we recommend that in all doubtful cases an inspection of the hive be made an hour or two afterwards. If all is quiet no further anxiety need be felt, but if the peculiar angry hum of discontented bees be heard an inspection of the combs will often reveal the poor queen encased in a mass of excited bees, in which case she must be freed by means of smoke, or by tossing the knot of bees into a vessel of water and again placed in the cage.

Queens mate on the wing, generally when about five days old, though sometimes sooner; and their fecundation is sometimes delayed by adverse weather and other causes until they are from two to four weeks old. They seem then to become incapable of fertilisation, and in many cases settle down to egg-laying as if all were right. In such cases, however, only drones will be produced from the eggs, in accordance with what is known as *parthenogenesis*

—that is, of virgin birth. Such cases are not at all rare, and must be promptly dealt with by destroying the unfertile queen and replacing her by a fertile one, or by joining the stock to another in healthy condition.

The best of queens may, after laying many hundreds of thousands of worker eggs, suddenly begin to lay drone eggs *in worker cells*, a sure sign that they are becoming worn out. Such also should be replaced. Under purely natural conditions queens will live and do well for four years, or even more; but under the stimulating influences of modern management fully carried out they may be induced to lay as many eggs in two years, and soon after begin to fail. Experienced bee-keepers therefore endeavour to avoid all risks by renewing queens every two years, and all should keep a register showing the age of every queen in an apiary.

While on this point it may be well to remark that queenless stocks will occasionally develop one or more *laying workers* or pseudo queens. These cannot be distinguished from the other workers unless caught in the act of laying, and are not, therefore, easily got rid of. It is unsafe to attempt the introduction of a proper queen where a fertile worker is present, as the latter generally succeeds in retaining her place as mistress. For our own part we do not care to fuss with such colonies, as they are usually weak and composed of aged bees of little value. If still numerous we unite them to another stock, caging the queen as a precaution until the fertile worker may be supposed to have been despatched by the bees of the healthy stock.

When once fecundated a queen remains fertile as long as she is capable of laying worker eggs. This fact accounts for the purity of all the bees ever produced by an imported queen of any foreign race—that is, if a queen begins to produce only yellow bees she will do so as long as she lives. If mated with a drone of another race her worker progeny will be of a mixed character, though her drone offspring will, according to the Dzierzon theory, follow the mother. Her fecundity is amazing, it being well known that she can continue to lay for many weeks at a time from two thousand to three thousand eggs a day. Much appears to depend upon the way she is treated by the workers, it being quite easy, by stimulating the latter, to cause an increase in the daily deposit of eggs by the queen; but at no period of the year can she be said to lose the power of laying, as brood may be found in some hives every month of the year.

The peculiar character acquired by certain stocks of bees is largely by inheritance, and may be altered by changing the queen. Thus peculiarly energetic or good-tempered stocks may become indifferent workers or acquire a vicious temper; thus also by careful selection and breeding of queens much may be done towards improving the less energetic races. The introduction of new blood by means of queens imported from Italy and the east has latterly become a favourite practice with many bee-keepers, but the results hitherto attained do not warrant us in advising beginners to incur any expense in this direction. We consider our native bees to be at least equal to those of any foreign race, and advise all to learn to develop to the utmost the capabilities of these before attempting experiments with the pretty foreigners.—W. RAITT, *Blairgowrie*.

(To be continued.)

TRADE CATALOGUE RECEIVED.

Henry Boller, Woodfield Road, Harrow Road, London, W.—*Catalogue of Succulent Plants (Illustrated)*.

** All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Glass for Vinery (E).—If you reflect for a moment you will perceive how unfair it would be for us to recommend any particular dealer for supplying any article connected with the garden, and if you had read the Journal atten-

tively you would have observed that we have repeatedly said we do not nor cannot recommend dealers through our pages. 21 oz. thirds will be suitable, or 16 oz. seconds will do very well if the sashbars are not more than 10 inches apart. You can obtain the other particulars you require by consulting our advertising columns and writing for price lists.

Destroying American Blight (*B. J. Elliott*).—You say you have heard of tar being used for this purpose, but you cannot remember by whom nor in what manner it was applied. Mr. Speed, the able gardener to the Duke of Devonshire at Chatsworth, recommends the following as an infallible remedy. Take a pint of gas tar and mix with it a pint of dry powdered clay. Form the whole into a paste by adding by degrees a gallon of warm soft water. If this is applied with a brush during winter it effectually destroys woolly aphids, and indeed all insects, while it does not injure the trees.

Wiring a Vinery (*A Constant Reader*).—A distance of 18 inches from the glass is suitable for stretching the wires, these to be 10 inches apart, and stretched from end to end of the house across the lights, and not from the bottom to the top of the house in the direction of the sashbars. Mr. Luckhurst has found that suspending the rods a foot or so from the wires is a good plan, and we have no doubt whatever that it is, as there is then less danger of the laterals being broken by bending them down to the wires. In the large vinery at Longleat the trellis is 3 or 4 feet from the glass, but 18 inches suffices in ordinary structures, and you may rely on this distance as being safe.

Tomatoes in Vineries (*F. W.*).—Some of the finest crops we have ever seen were grown against the back walls of vineries before the Vines were established, and we have seen very useful crops in these positions even when the Vines were fully grown, and the Tomatoes had only glimpses of sun, as the foliage of the Vines almost entirely covered the roof of the house. Tomatoes in a house with Vines do no harm whatever unless they are planted in the Vine border or the growths crowded amongst the Vine leaves, and no sensible man would do this.

Storing and Ripening Medlars (*A Subscriber*).—Medlars may be treated in every respect similar to dessert Apples. If stored eyes downward on shelves in a dry room, or the fruit room, they will ripen naturally; but ripening may be hastened by placing fruit in a box or basket in a warm room. With us the Dutch Medlar ripened some time ago, and this is the largest variety. The Nottingham is later, of better quality, and is now eatable. The supply of either sort can be prolonged by gathering at intervals, and by artificially ripening of a part of the crop when this happens to be gathered all at one time.

Prices of Grapes (*J. M.*).—As you are well aware, the price of Grapes depends not on the quality of the fruit when cut from the Vines so much as on its condition when it reaches the market. We are well aware of the accuracy of your statement, and we are also aware from other letters on the same subject which reach us from time to time complaining of the low prices that fruit has realised, that it would do more harm than good to publish what you have written with the best intentions. We have to recognise the fact that hundreds of cultivators of Grapes cannot produce such high-class fruit and place it in the market in such good condition as you can and the celebrated grower to whom you refer. Grapes of very superior quality occasionally realise considerably higher prices than those published, but they in no sense represent the general tone of the market.

Forcing Rhubarb (*R. Watson*).—You have adopted the method which is generally pursued in forcing Rhubarb, and if you maintain a temperature of about 60° in the pots, crowns will start in about a fortnight, and stalks be ready for pulling in a month. Some varieties of Rhubarb do not force so well as others, and the crowns do not start so quickly into growth in November as during the early months of the year. Many persons obtain early Rhubarb by digging up the roots and packing them in Mushroom houses, or placing them in pots or tubs under the stage of a plant stove or in any warm place such as a cellar or stable.

Roses for Exhibition (*H. S. P.*).—The following are twenty of the best Hybrid Perpetuals:—Marie Baumann, A. K. Williams, Alfred Colomb, La France, Baronne de Rothschild, Charles Lefebvre, Marquise de Castellane, Duke of Edinburgh, Etienne Levet, Marie Rady, Capitaine Christy, Louis Van Houtte, Dr. Andry, Ferdinand de Lesseps, François Michelon, Madame Victor Verdier, Marie Finger, Comtesse d'Oxford, Mons. E. Y. Teas, and Madame G. Luizet. Six good Tea Roses are Catherine Mermet, Maréchal Niel, Souvenir d'un Ami, Marie Van Houtte, Souvenir d'Elise, and Devoniensis.

Eupatorium odoratum (*W. J. M.*).—This very useful plant is easily grown, and its abundant supplies of white fragrant flowers are most valuable at this time of year. To obtain large specimens the plants should be placed out in a border during the summer, being lifted and potted in autumn; and after keeping them close for a day or two until they have recovered they can be transferred to the greenhouse or conservatory, or any similar structure. Turfy loam, a little leaf soil, and well-decomposed manure form a suitable compost, and if the plants are retained in pots occasional supplies of weak liquid manure will be beneficial. This plant is readily increased by cuttings of the young growths treated like ordinary softwooded plants.

Pit for Growing Gardenias (*F. H. F.*).—A half-span is the most suitable. The width should not be less than 10 feet inside, which will allow of a border at the back 2 feet 7½ inches wide, divided from the pathway by a 4½-inch brick wall, then the pathway 2 feet 6 inches wide; and with a 4½-inch wall to form the side of the front border, the latter will be 4 feet 1½ inch wide. The walls forming the sides of the pathway should be 2 feet 6 inches high, the top course of bricks laid in cement, or have a stone or coping. If bottom heat be sought it should be furnished by hot-water pipes. Two 3-inch pipes will be necessary for the front bed, disposed a foot from the walls all around, and covered with thin slabs of stone or slate, so as to form a chamber a foot deep, which will leave 18 inches minus the thickness of the stone or slate covering. One 3-inch pipe will be sufficient for the back border, placing it up the centre. The covering of the chamber should have the joints left open, and have 3 inches of rubble on the chamber covers; and if the plants are to be planted out have the rough of the compost placed over the rubble, and then fill in with soil for growing the plants, than which nothing answers better than turfy loam, with a tenth of sand incorporated and a twentieth of charcoal broken up small. If the plants are to be grown in pots cocoa-nut fibre refuse may be employed in place of the compost as a plunging material for the pots; and if the borders are to be used as spaces for fermenting materials, to give bottom heat in place of the hot-water pipes, the depth should be increased a foot by excavating the bottom. The back wall should be 6 feet 6 inches high, the front 5 feet, and the height of the house from the centre of the path 8 feet, to the under side of the ridge. Ventilation need only be provided by the back lights, which should open the entire length of the house. No side lights are necessary, and it would be advisable for appearance to sink the house 2 feet in the ground, so as to have less wall

outside. For top heat three rows of 4-inch pipes will be necessary, taking one along the front of the house, and the other on the path walls, or they may be placed at the sides of the pathway.

Carnations in a Cold Frame (*Idem*).—Souvenir de la Malmaison and other tree Carnations may be wintered safely in a cold frame, the pots being plunged in ashes, and protection given over the lights at night in frosty weather. The plants, however, will not flower until June, at least onrs do not, and we have some in cold pits to succeed those grown in heat. The plants probably become drawn and weak in the greenhouse from their not having a light position and sufficient ventilation. The soil may also be too light, Carnations liking a rather strong gritty loam enriched moderately with old well-decayed manure, and should be potted rather firmly to induce a rather short-jointed growth and free disposition to flower. To have Carnations flowering in winter they require a temperature of 50° by artificial means, and all the light possible, with air upon all favourable occasions. It is little use attempting to grow Carnations in a house shaded by climbers or other plants and inefficiently ventilated.

Grape Failures (*M. D.*).—When you admit growing too heavy crops you admit everything; still you say, "Other cultivators have black Hamburgs in July and August, and why cannot I, in a house with plenty of pipes for heating?" You can have them if you regulate the crop in accordance with the strength of the Vines, and you cannot have them if you do not do this. The earlier Grapes are ripened the lighter the crops must be, because there is not nearly the root power for supporting the crop in July that there is, say, a month afterwards, and that extra month of root-extension in good soil makes all the difference between brown and black Grapes, the system of management in other respects being good. Soot is an excellent manure for Vines. But this is not the sole cause of your Vines showing so many bunches; the chief cause is probably the thorough ripening of the wood consequent on its being made early and having the best and longest portion of the summer in which to mature; nor is the number of bunches that show any criterion that the Vines are not overcropped. Their profusion indicates fruitfulness; but if you leave your usual crop on one Vine and have a reduced crop on another of equal strength you will find the Grapes on the latter will finish better, but the following spring both Vines will show the usual number of bunches if the wood of both is alike strong and matured. You are adopting the right course in providing fresh and good soil for the roots, as the better the Vines are supported the heavier crops they will perfect; and unless you either increase the root-action and food-supply, or reduce the weight of Grapes, you will not have well-finished produce even if the management as regards temperature and ventilation be the best in the world.

Pereskia aculeata (*Sigma*).—The plant of which you send a fragment is *Pereskia aculeata*, a member of the natural order Cactaceæ, and a native of the West Indies. It is chiefly grown as a stock for Epiphyllums, which are grafted on clean stems of the *Pereskia*, varying in height according to the uses for which the plants are intended. For plants in pots a height of 6 inches to 1½ foot is sufficient; but we have seen the stems taken to a height of 8 feet or more before grafting the Epiphyllums upon them. In this case the stems have been trained to the wall of a house, and the heads arched over a walk, the suspended Epiphyllums having thus a fine effect when in flower. The *Pereskia* itself is of little value except as a curiosity, and is easily grown, though seldom seen in flower. A compost of loam, sand, and small pieces of broken bricks, with a little well-decomposed manure, suits it well, and the temperature of a stove is the best fitted for it. Water must be carefully supplied during winter—indeed, very little will then be required; but whilst growing a larger quantity is needed. When your plant is large enough we should advise you to graft an Epiphyllum upon it, which you may easily do by cutting the stock to the required length, and then cut the upper part of the stem to a wedge-like point, taking a piece out of the base of the scion so that it will fit evenly saddle fashion upon the stock. This may be then secured with a piece of matting, and a union will soon be effected.

Culture of Fittonias (*Idem*).—When in good condition these are very attractive plants, and the silver-veined leaves of *F. argyoneura* are much valued by some persons for table decoration, either at the base of vases or in dishes containing fruits. They may be grown in baskets or pans, the latter being preferable, as they can then be placed in the stove or intermediate house on the stages under the shade of the taller-growing plants, and this appears to suit the *Fittonias* admirably. They also succeed well in small borders beneath the stages when not too near to the hot-water pipes, and while imparting a neat and pleasing appearance to what is often an unsightly part of the house they also prove useful in affording a bountiful supply of sprays or leaves for decorative purposes. Peat and light turfy loam, with a little sand and leaf soil, constitute a suitable compost, supplying good drainage when the plants are grown in pans. *Fittonias* can be readily increased by cuttings inserted in sandy soil in slight bottom heat. The "Greenhouse for the Many," price 9d., post free 10d., or Johnson's "British Ferns," price 3s. 6d., post free 3s. 9d., both published at this office, or Mr. B. S. Williams' "Select Ferns and Lycopods," price 5s., post free 5s. 5d., would suit you.

Tomatoes in Frames (*Nil Desperandum*).—You will experience no great difficulty in securing an early and continuous supply of Tomatoes in your three-light frame. Supposing you have another frame placed on a hotbed and utilised for propagating and other purposes in the spring, this would be the place to raise the plants. Earley's Defiance will be found the most profitable variety for your purpose, and seed of this or Conqueror—another large free-fruited variety, should be sown early in March thinly in an 8-inch pot or pan. Keep the seedlings near the glass, and when in rough leaf pot off singly into 5-inch pots, or in pairs in 6-inch pots, sinking them carefully up to the seed leaves in the rather light and previously warmed soil. Shade from bright sun, apply water carefully, and keep the plants near the glass. When well established they will require all the light and as much air as can safely be afforded. In this manner sturdy plants will be obtained ready for planting out in the frame early in May. Not much bottom heat is required, but a slight hotbed should be formed in order to give them a good start. We should not fruit them in large pots, preferring to plant out. A few days prior to planting cover the whole of the bed with about 1 foot of soil, consisting, if available, of two parts of turfy loam to one of half-decayed stable manure. Dispose about five plants in each light, these being planted in a sloping direction and pegged down, so as to be equally distributed about the bed. Continue to train till the frame is thinly filled, afterwards the points may be allowed to turn up, and these and a few laterals will furnish abundance of clusters of fruit, which will ripen better if staked up. Thin out each cluster to about six fruits. Closely rub or pinch out all superfluous growths, give abundance of water, varying with liquid manure when in full growth, and plenty of air on all favourable occasions; but do not syringe the plants nor throw off the lights during showery weather. The disease will not affect them if the foliage is kept dry, and by attending to the above directions there will be no necessity to replant during the season. You ought to commence gathering fruit early in July. Mr. Iggulden's treatise on Tomatoes, which you can have

from this office post free for 1s. 1d., contains a chapter on frame culture, besides other useful information on the subject. In reference to your other question, about 25 tons of rich manure would be a good dressing, giving, if needed, a sprinkling of nitrate of soda and superphosphate of lime in the spring or early summer when the crops are in a growing state.

Names of Plants (W. J. M.).—Eupatorium odoratum is the plant of which you sent a spray without leaves (see above), the other we cannot recognise from the specimen sent, all the flowers having closed. (*Sigma*).—*Pereskia aculeata*, see reply above. (*C. D., Wales*).—Without more definite particulars we cannot tell to what *Chrysanthemum* you refer; probably, however, it is *C. carinatum*. Seed flowers of the *Aquilegia*, the leaf alone is not sufficient.

COVENT GARDEN MARKET.—DECEMBER 6TH.

OUR Apple market is now very quiet, being principally supplied from Canada, samples reaching us in good order, and generally fine. Hothouse Grapes are in good supply, and coming in better condition. Kent Cobs firm.

POULTRY AND PIGEON CHRONICLE.

THE LEICESTER BREED OF SHEEP.

THE rise and progress of this breed of sheep is one of the most important histories in connection with our long-woolled sheep stock. The old Leicester breed was a large coarse sheep, possessing an abundant fleece with only a fair disposition to fatten. The Dishley or new Leicester, which for many years has quite supplanted and superseded the parent stock so as to be denominated the Leicester, is probably, with reference to its origin, the most artificial of any, having been moulded, as it were, by the master hand of Bakewell, obedient to certain principles which he believed to be correct, and which the experience of subsequent years has fully justified. Mr. Bakewell commenced the improvement of the Leicesters probably about 1750. In the year 1760, when the first letting of his rams was held, the first animal let for the season only made 16s., and it was not until about twenty years afterwards that Mr. Bakewell obtained a remunerating price for his sheep. It was then stated to have been only ten guineas; it, however, afterwards rapidly increased, so that in 1786 he realised three hundred guineas for the use of one ram let for the season. But three years afterwards, in 1789, he obtained for the letting of his rams the large sum of 6200 guineas, but the number let is not recorded. Still he must have been handsomely repaid and rewarded for his long-continued and untiring exertions under difficulties and opposition beneath which most men would have abandoned their pursuit as hopeless.

There were, as we may suppose, strong traits in the character

of Mr. Bakewell which, we are told, were quaint, but decided and peculiar. It is related of him that when he received a summons to show one of his horses in London to George III., His Majesty looked much more at the man than the horse. His management of vicious animals is said to have been remarkably effective. A horse which was sent to him as irreclaimable soon followed him like a dog up and down the Loughborough corn market, and a bull, which arrived at Dishley under the escort of six cows and a man on horseback with a nine-foot spike, was reduced to submission by a system of starvation, sleeplessness, and scratching at the tail head, which was supposed to go on for three or four consecutive days and nights. The memoirs of the old Leicestershire worthy have never been published, but his sayings, such as "Money wears but three lives," "Consume half the corn you grow with beasts, or lay out half its price in cake," "Rise with the lark and to bed with the lamb," are still preserved with his essays in a MS. book at Dishley. The essays are short and take a wide range, for which we cannot find space, but we need scarcely say were highly suggestive and characteristic of the man.

The sources from whence Mr. Bakewell derived his breed cannot be accurately ascertained. The old Lincoln, the Teeswater, and the Warwickshire have each been named, and it is said that other sorts of long-woolled stock have also been employed. There is no doubt that Bakewell was not particular as to the source so that he could obtain the desired qualifications. He was very uncommunicative on this point, and the knowledge of the real origin was lost with him. It is probable, however, that the foundation of his breed was the best existing specimens of the old Leicester breed, for we are informed that Mr. Bakewell found by selecting smaller and more compact animals that he produced an earlier maturity and a greater disposition to fatten, which more than compensated in his breeding plans and objects for the loss of weight and diminished size. Thus by systematically and unremittingly carrying out his principles—viz., to attain as near as possible perfection of form, style, and type, he at length produced an animal which far surpassed all others of the period in the before-mentioned qualities, comprising, as it has been well observed by Mr. Culley, one of his admirers, in the same apparent dimensions greater weight than any other sheep, with an earlier maturity and a greater tendency to fatten, a diminution in the proportion of offal, and the return of the most money for the quantity of food consumed.

We can easily imagine even in those days that this system could not be carried out without rapidly extending the improved breed, and of course improving the flocks of other sheep-breeders to a vast extent, and inducing other parties to seek a participation in the advantages of the system. Accordingly its advocates and promoters formed themselves into a club, denominated the Dishley Society, with the object of extending their breed, preserving it pure, and benefiting and protecting themselves. This Society was established by Mr. Bakewell, and a code of laws was adopted extending to thirteen clauses, for which we cannot find space in our notice, but must refer the home farmer to a work in which they appear by Mr. W. C. Spooner, M.R.V.C., "On the Structure, Economy, and Diseases of Sheep." Every farmer should possess this work, which is sold at a moderate price. We need scarcely say that these rules were laid down for the purpose of jealously guarding and preserving the purity of the breed, and the benefit of the members, and it was undoubtedly by strict attention to these rules and the principles adopted by Mr. Bakewell that the Leicester sheep continued to improve and to be introduced into one county after another, especially in the grazing districts of the midland and north-midland counties. Their merits were sufficiently tested at that time by the fact that they invariably bore away the prizes when competing with other long-woolled sheep at the shows of the Smithfield Club and other societies.

The various points which distinguish the Leicester sheep may be thus correctly described:—The head should be hornless, long, small, tapering towards the muzzle and projecting horizontally forwards; the eyes prominent, but with a quiet expression; the ears thin, rather long, and directed backwards. The neck full and broad at its base where it proceeds from the chest, but gradually tapering towards the head, and being particularly fine at the junction of the head and neck; the neck seeming to project straight from the chest, so that there is, with the slightest possible deviation, one continued horizontal line from the rump to the poll. The breast broad and full; the shoulders also broad and round, and no uneven or angular formation where the shoulders join at either the neck or the back, particularly no rising of the withers, or hollow behind the situation of these bones. The arm fleshy through its whole extent, and even down to the knee; the bones

of the legs small, standing wide apart, no looseness of skin about them, and comparatively bare of wool. The chest and barrel at once deep and round, the ribs forming a considerable arch from the spine, so as in some cases, and especially when the animal is in good condition, to make the apparent width of the chest even greater than the depth; the barrel well ribbed home, no irregularity of line on the back or the belly, but on the sides, the carcase very gradually diminishing in width towards the rump. The quarters long and full, and, as with the forelegs, the muscles extending down to the hock; the thighs also wide and full; the legs of a moderate length; the pelt moderately thin, but soft and elastic, and covered with a good quantity of white wool, not so long as in some breeds, but considerably finer.

These various qualifications as above stated were obtained and preserved by the great and long-continued attention which was paid by Mr. Bakewell, and assisted by the members of the Dishley Society, to the selection of individual animals, and mating the ram with the ewe so as to correct the faults or deficiencies either may possess, and thus, by carefully and progressively getting rid of faults, gradually approaching to perfection, which, though it may be rarely or never reached, should yet be the constant aim of the breeder.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—This is very much in arrear, especially in the loamy and strong-land districts, and the seedtime for Wheat has been greatly delayed; nevertheless, all that is possible should be sown with Wheat between the present time and the 1st of February whenever the weather proves open and favourable. This matter should not be delayed for want of manure; for although enough box or yard dung may be available, it would be well to reserve it for early root crops, such as Mangolds, Carrots, and Cabbages, because in those cases, even where the land will bear the casting of dung on to the land for Wheat, the delay attached to it may be fatal to the Wheat-sowing, for it often happens when the seedtime is unusually late that a day lost cannot be regained. The storing of Mangolds has now been nearly completed, and should be finished as soon as possible, or as soon as horses can be spared to cast it to the store heap. In the meantime the Mangolds may be kept in small heaps, covered with greens or refuse and damaged straw. When the Wheat land is all seeded ploughing and fallowing for roots may be continued. It is especially desirable that land intended for Potatoes should now be ploughed, and in those districts where female labour is available women may be employed at all favourable weather in forking out bunches of couch, bents, and Onion grass, either before the land is ploughed or afterwards, in all open weather when the grass, &c., can be seen, especially in the spring before ploughing and planting, which saves delay—a matter of great importance connected with all early spring crops. It often happens where women cannot be obtained for light work that it cannot be done by the men, and therefore more horse labour is required, which causes delay, and frequently the best seedtime is lost in consequence, besides the difference between cost of extra horse labour and light hand labour. At all leisure times the home farmer should remember that cartage of earth and earthy materials may be carted together in readiness, not only for earthing the cattle pens, &c., but also for making composts of earth and manure, such as yard or town dung, to be sooner or later applied to the pasture land.

Hand Labour.—In many districts more work is on hand than labourers can be found to execute. It is also increasingly difficult to get a good day's work done for a good day's pay. It is, therefore, very desirable that the home farmer should have nearly all his work done by task; at least, as much as is possible. This applies with still more force in female labour, for in any light work the women will do as much work as the men and earn as much money. In all piece and task work where the women can really earn good wages in field labour they may be induced to take their part or share in the light easy work on the farm, whereas if they are only employed or offered day work they would remain at home, as they do now in various parts of the kingdom. Upon all farms where much stock is kept either of sheep or fattening cattle there is always an abundance of light work adapted for them to do which really is not done in a satisfactory manner, or not done at all, where men only are available.

Live Stock.—The feeding of the in-lamb ewes is now a very important part of the business of the home farmer, for not only is it necessary to prevent the ewes eating large quantities of Rape and Turnips on the fallow surface, which makes bad lying for them, but it is essential to the health of the ewes and the success of the fall of lambs that they should have a run upon healthy grass, either pasture or old lea; and when the grass becomes bare and short it should be supplemented by Cabbages drawn out on the driest land, which may be appointed for their night lair. Another point is, that after the extremely wet autumn which we have gone through many flocks are breaking down with the foot rot or epidemic lameness, from which sheep have suffered so much in bygone seasons. In order to assist the home farmer in curing any lame sheep suffering from either of the above causes we give the remedy we used for more than forty years with great success. Recipe—Take 3 ozs. of nitre, 3 ozs. of blue vitriol, 3 ozs. of gunpowder. These should be reduced to a very fine powder, and well mixed with

half a pound of hog's lard; it will then keep for use. In the case of young lambs more lard should be used with it. But having the best remedy is not sufficient; it must be properly applied. Where the sheep break down lame continually they should be looked to daily, and those which are lame should have the paste rubbed in between the hoofs the first day it is discovered. If by any chance the disease should extend under the horn of the foot it should be carefully cut away as far as suppuration exists and without making the foot bleed. If it should bleed through accident in cutting it is best to let the bleeding subside before applying the remedy, which has in our case been so successful that we never lost 6d. per head by lameness since we have used this remedy. But many farmers with a large flock will not encounter the cost of continual labour by the shepherd and men under his direction, and in consequence have confessed to us that their losses on some occasions of condition in the animals has amounted to more money than their cake or corn bill. The Dorset and Somerset Down ewes will now begin lambing in a few days, and the course of management as directed lately for the horned ewes and their lambs will apply equally well to the Down ewes and lambs, with this exception—that the lambing fold will require to be placed in a carefully littered yard or fold, and it should be on ground with a slight inclination of the bottom or floor, in order that the water may drain away and give them a dry lair; whereas in the lambing fold for horned ewes we seldom use anything but a fold shifted daily on a piece of dry and sheltered pasture or old lea ground.

FARMING NOTES.

CATTLE.

PREPARATIONS are fast being made for the coming winter, and we are already looking forward to another year, for Michaelmas to farmers is practically the end of the year, the harvest being past, the season of growth almost at an end, and the year and its results lay open before us like a book written large, clear, and unmistakable. No time could therefore be better for a retrospective glance over its pages and to store up its most useful lessons.

Genial spring weather induced an early and abundant growth of grass that proved a great boon after the small hay crop of last year, and with hay at £7 a ton a cold late spring would have been disastrous for dairy farmers and breeders of cattle. So forward, however, was the grass, that by March 15th we were able to throw open the whole of the yards and to turn lean stock as well as cows upon the pastures—no light matter when it is remembered how frequently we are unable to do this till the end of April or beginning of May. It is true enough that much cattle is to be seen out upon pasture throughout winter whenever the weather is open, but it is a sight to be deplored, an outcome of hard times pointing with no uncertain hand to straitened means, and a struggle with dire adversity which can hardly result in good, for such cattle but too often are in a state of semi-starvation. It is far better to confine cattle entirely to the yards from the time that legitimate autumn-grazing is over till a full bite is to be had in spring. Let me explain what is meant by autumn-grazing. By the middle of October the yards are littered and all the cattle are driven in at night, but for weeks afterwards while the weather continues mild and open, and herbage is still plentiful, they are let out upon the pasture by day. For example, a mixed herd of steers and heifers of various ages varying from twenty to thirty months now occupy nightly two yards opening upon a run of 40 acres of sound upland pasture in four plots opening into each other, well sheltered with belts of timber and with plenty of snug corners, over some part of which they roam and graze daily, inevitably finding out where the grass continues sweet and abundant. The dairy cows have a similar run, but younger stock are confined to a small enclosure of a couple of acres with a cosey yard and lodge. It may be thought upon what is literally a hill farm early driving to the yards is unnecessary, but it should be remembered that the rainfall of October is generally great—in this locality it exceeds that of any other month—and it is accompanied by occasional frosts and a fall of 10° of temperature, to all which it must be unwise to keep stock constantly exposed. On the 21st of October I was out upon the pastures in a pouring rain, and found puddles of water in every slight hollow of the surface, so that a beast could hardly have found a place to rest upon at night, and yet it is no uncommon thing for cattle to be left out upon low-lying marsh land throughout October exposed to the wet and to every wind that blows, for there are hardly any sheltering trees or hedges there. That such exposure proves hurtful, sometimes fatal, is certainly not to be wondered at.

It is part of the experience of many a landlord to have appeals for forbearance when Lady-day comes round and rents are due. "I have plenty of lean stock," says the defaulter, "but it is in such poor condition that if I sell it now it will be at a loss." What is the cause? Overstocking the yards in autumn with a

view to making large manure heaps; winter pasturage to help out the fast-dwindling ricks of fodder, resulting in a wretched low condition, for which subsequent months of high summer-feeding barely atones. Surely it is much better in every sense to reduce the head of stock now well within the scope of our means, and to feed sufficiently well to maintain a sleek healthy condition throughout winter. Breeders of first-class stock claim to make every beast gain £1 in value for each month of its existence; but those of us who have to maintain a dairy cannot do so profitably, but we may realise very respectable sums for beasts kept over two winters and sold off the grass to the butcher early in the following autumn if they are always kept up to a reasonable standard of condition.

That lean stock fared hard very generally last winter there can be no doubt, for most of it came to the early fairs in very poor plight, and yet what prices were asked and given! It was no uncommon thing for £14 or £15 to be obtained by dealers for lean, very lean, steers of twenty months at the May fairs. Who after this can say that the British farmer is wanting in courage? But the prudence of giving so much is certainly questionable. It was no longer ago than the preceding autumn that beasts of three years old were to be had for a similar amount, and those who were so fortunate as to buy then must certainly have had a good time this year. Some beasts of that age bought for that sum were ripe for the butcher in May, and were then closely approaching a dead weight of 100 stone of 8 lbs. They might have been killed much sooner, but were brought on slowly for the sake of the manure, which from well-fed beasts of that age is the very best form of farmyard manure.

When cattle are turned out upon the grass in spring they eat so ravenously that there is considerable risk of the stomach becoming overcharged and unable to act. Excessive fermentation then soon follows, gases are generated which cannot escape, the stomach becomes distended almost to bursting, and the hoove-stricken animal will soon die if prompt measures are not taken for its relief. Going down to the farm one morning I saw a young Kerry cow standing alone at some distance from the other cows, and I at once went to it, for however quarrelsome cows may be they always keep together if they are well, and when one is seen to leave the others and keep aloof it should always be examined. The cow in question was not in calf, and yet I found its stomach unusually large. It was neither eating nor ruminating, and had a heavy dull look. I at once suspected it to be suffering from hoove, but as it was my first case I proceeded with caution, and some time was lost in watching the development of symptoms which soon became clear and unmistakeable. The proper remedies were applied and the cow was saved. It was a favourite, and I was sorry to condemn it, but knowing the probability of lingering debility it was fattened as its milk gradually failed, and eventually handed over to the butcher.

The utter ignorance of the cause of hoove and its remedy that exists among men who have had charge of stock for many years is really surprising. In the case of the Kerry cow the bailiff actually told me that he had seen it upon a bank feeding with its face to the wind, which he had no doubt had blown down its throat and caused the hoove. Mr. Youatt's description of its symptoms and effects is so clear that I append an extract. "The animal gradually becomes oppressed and distressed. It ceases to eat; it does not ruminate; it scarcely moves; but it stands with its head extended, breathing heavily, and moaning. The whole belly is blown up. This is particularly evident at the flanks, and most of all at the left flank, for under that the posterior division of the rumen lies." "The animal cannot long sustain this derangement of important parts. Inflammation is set up, and the circulation becomes seriously and dangerously disturbed by this partial obstruction. Affection of the brain comes at last, characterised by fulness of the vessels, hardness of the pulse, redness of the conjunctiva, and protrusion of the eye. The tongue hangs from the mouth, and its mouth is filled with spume. The beast stands with its back bent, its legs as much as possible under him, and he gradually becomes insensible, immovable; he moans, falls, struggles with some violence, and, as death approaches, some relaxation of the parts ensues, and a quantity of green sour liquid, occasionally mixed with more solid food, flows from the mouth and nose."

It by no means follows, however, that a hitherto healthy beast need die of it; only let it be taken in time, and remember, if the animal when first observed is moaning, not a moment is to be lost. The gas removed, preferably by a probang; but if that cannot be had, then recourse must be had to a trocar, or even to the rough-and-ready old method of stabbing the left flank and thrusting in a piece of elder to let out the gas. The acid fluid arising from excessive fermentation removed by the stomach pump and warm water, and Youatt's dose of 1 lb. Epsom salts,

1 oz. caraway powder, and half an ounce of ginger be given, and the most violent symptoms will soon disappear and the stomach begin to resume its proper functions once more. Of course a veterinary surgeon should be called in, but one is not always to be had at once, and it is all-important to know what to do.

Another cattle disease which has given me some trouble, but has in no case proved fatal, is Red Water. Hardly a year passes without one or more cases of it; but it has always been attacked with promptitude, and the beasts recover.—EDWARD LUCKHURST.

THE SMITHFIELD CLUB SHOW.

THE Exhibition which opened in the Agricultural Hall on Monday last is in every way a great success. The number of classes was slightly increased, the total value of the prizes in cups, medals, and money exceeding £3000; and there was a slight increase in the number of entries, as last year they were 503, this year 524—namely, 251 cattle, 187 sheep, and 86 pigs, while in quality the Show must rank as one of the finest if not the best that has ever been held. The list of prizes having been published in the daily papers we shall only record the winners of the breed cups and champion prize. After long and close examination the best steer in the Show was decided to be Mr. Lewis Lloyd's Hereford, and the best heifer Mr. Stratton's grand shorthorn. These prizes are £50 silver cups, to be won once only by the same animals. Next came the contest for the 100-guinea Champion Plate given by the Agricultural Hall Company, by agreement with the Club, and the Club's gold medal to the breeder. For a long while the chances seemed to be equal between the best Hereford, Devon, crossbred, and shorthorn. Then the number was apparently reduced to Mr. Stephenson's handsome iron-grey crossbred and Mr. Stratton's shorthorn. The shorthorn Lillian eventually received the coveted decoration (red and green), having won for her owner, who is also breeder, a £20 first prize, a £30 silver cup, a £50 silver cup, the champion plate and gold medal. She weighs 16 cwt. 3 qrs. 8 lbs. The heaviest beast in the Show, which gains no prize, and weighs 23 cwt. 1 qr. 22 lbs., belongs to Mr. T. C. Lucas of Horsham.

The machinery and implement department is also very extensive, both the galleries being closely packed, besides a large number of the heavier machines and engines on the ground floor. Such firms as Messrs. Clayton & Shuttleworth, Lincoln; Barrows & Stewart, Banbury; John Fowler & Co., Leeds; R. Hornsby & Sons, Grantham; Ransomes, Head & Jefferies, Ipswich; and the Reading Ironworks Company, contributed a great variety of excellent samples of all the most important agricultural machinery.

The exhibition of roots by the leading seedsmen is not quite so large as usual, but the roots generally are distinguished by moderate size and most excellent evenness of form, far preferable to the enormous coarse examples that have been sometimes seen there. Messrs. Sutton & Sons, Reading, as usual had a fine display well arranged, with large photographs of their warehouses suspended in front. Magnificent examples of the Champion Swedes, Berkshire Prize and New Golden Tankard Mangolds were noteworthy amongst the varieties represented. Messrs. J. Carter & Co., High Holborn, had a similarly attractive display, comprising large but even Swedes and Mangolds, with sample boxes of lawn Grasses. Imperial Prize-winner, Pomeranian and Mammoth Prize Swedes, White Globe Turnips, and Tankard Yellow Globe Mangolds were of unsurpassable quality. Messrs. E. Webb & Sons, Stourbridge, had a most tastefully displayed stand, and the quality of the exhibits is certainly very high. Imperial Swedes, Champion Yellow Globe, Mammoth Long Red, and New Kinver Globe Mangolds were amongst others represented in the finest possible condition. Other firms, such as Messrs. T. Gibbs and Co., Down Street, Piccadilly; Harrison & Son, Leicester; Rayn-bird, Caldecott & Co., Basingstoke; John K. King, Coggeshall, Essex; and Alfred Hall & Son, Westbury, Wilts, also staged smaller but meritorious collections of roots and seeds.

At the annual general meeting, held on Tuesday morning, it was announced that the Prince of Wales has consented to be President for 1883, and the Earl of Jersey for 1884. Sir W. Gordon-Cumming was elected Vice-President in the room of the late Lord Chesham. The Prince of Wales and the Duke of Edinburgh were made Vice-Presidents. Sir Brandreth Gibbs, for the fortieth time, after highly complimentary speeches, was re-elected Hon. Secretary, and a hearty vote of thanks was passed to Mr. Walter, M.P., the retiring President. The newly elected members of the Council are Messrs. J. B. Booth, H. Gorringer, J. Hornsley, F. N. Jonas, H. Fookes, A. Croskill, T. Brown, and Colonel Luttrell. The report of the Council was read by Sir Brandreth Gibbs, and passed unanimously.

THE POULTRY CLUB. MEETING AT BIRMINGHAM.

A MEETING of the Committee of the Poultry Club was held at Bingley Hall, Birmingham, on Monday, November 27th, at 4 P.M.

There were present the Hon. and Rev. F. G. Dutton (in the chair), and Messrs. O. E. Cresswell, A. Darby, C. F. Montessor, and A. Comyns.

THE DISQUALIFICATION OF THE DARK BRAHMA COCK AT THE PALACE SHOW.—The Secretary reported that he had written to Mr. C. Davenport Jones, a member of the Club, in reference to the disqualification of the fourth-prize Dark Brahma cock exhibited by that gentleman at the Palace, and as to an allegation in the pages of the *Stock-keeper* that the wings of the cockerel also shown there by the same gentleman had been tampered with. It appeared that the fourth-prize cock was disqualified in consequence of both his wings having been observed after the adjudication of the prizes to be tied up with string. Mr. Jones stated as to this that the string had been put on simply and only for the purpose of keeping the bird's wings in proper position during his moult, and had been by an oversight left on by his poultryman in his own absence from home when the bird was sent to the Palace Show. He denied that the cockerel's wings had been tampered with by himself or any person with his knowledge, and stated that up to a short time before the Banbury Show the bird was out at a run at his gardener's cottage, and was not seen by him from the time he was quite a chick until just before the Banbury Show. He further stated that the man who attends to his birds, an ordinary gardener, and not a regular poultryman, assured him he had not, neither did he know of anyone having drawn a feather out of the bird. The bird was examined, on Mr. Jones's behalf, by Mr. E. Morgan of High Street, Hastings, Mr. F. C. Davis of Southampton, and the Inspector of the Royal Society for the Prevention of Cruelty to Animals at Hastings; and in the opinion of these gentlemen the bird had not been tampered with in any way. The bird was, at the request of Mr. Jones, examined by a Sub-committee of the Poultry Club on Wednesday, November 22nd, and the following was the report of that Sub-committee:—

"A special meeting of the members of the Committee residing nearest to London was convened on Wednesday, November 22nd, 1882, at 47, Chancery Lane, so that the cockerel exhibited by Mr. C. Davenport Jones at the Palace, and reported on in the *Stock-keeper* as having been trimmed, might be examined. This was done at the request of Mr. Jones. There were present—Messrs. T. W. Ams, J. C. Fraser, C. F. Montessor, and A. Comyns; Messrs. Leno and Tegetmeier, both of whom had examined the bird at the Palace, also kindly attended for the purpose of identifying the bird.

"A very careful examination of the wings was made. It was found that several of the lower secondaries of the left wing were but partly grown, while one was entirely missing, and that the upper primaries of the same wing were also but partly grown. The remaining feathers, both primary and secondary, of this wing were, with one exception, fully grown, as also were all the feathers of the right wing. The lower secondaries of the right wing were somewhat curved, which tended to prevent the primaries from going properly under the secondaries.

"Those present came to the conclusion that the state of the left wing could only be accounted for on the supposition that the partly-grown feathers and missing feather had been removed some time since to allow the primaries to slip under the secondaries, and thus get rid of the defect of a slip-wing."

It also appeared that Mr. Leno, who judged the birds at the Palace, and Mr. Tegetmeier, who, at Mr. Leno's request, also examined the bird at the Palace, agreed with the conclusion arrived at by Sub-Committee. Mr. Leno, who had at the Palace, in the first instance, highly commended the bird, subsequently, and before concluding the judging, discovered that the wing had been tampered with, and so entered it in his judging-book, intending to pass the bird over on that account, but had inadvertently omitted to remove the h.c. previously entered in his judging-book.

The following was the decision of the Committee:—

"The Committee can form no opinion as to whether the string was left on the fourth-prize Dark Brahma cock at the Palace Show accidentally or otherwise; but the Committee have reluctantly come to the conclusion, from the evidence before them, that the left wing of the Dark Brahma cockerel—pen No. 533—h.c. at the Palace Show, had been tampered with.

"They accept Mr. Jones's assurance that he had no personal knowledge of the transaction, but are compelled to come to the conclusion that his poultryman could not have been equally innocent. They, therefore, call upon him to discontinue the employment of such man in connection with his poultry as provided by Rule 21."

The Secretary was directed to communicate with Mr. Jones as to what action he intended to take in the matter.

DORCHESTER SHOW.—A complaint as to the withholding of prizes at this Show having been under the consideration of the Committee at a former meeting, the Secretary now reported that he had, as directed at the previous meeting, written to the Secretary of the Dorchester Show on the 18th November, asking an explanation of the withholding of prizes in certain classes, but that he had as yet received no reply. The Committee thought that some further time for an answer should be allowed to the Dorchester Committee before any definite action in the matter was taken, and the Secretary was directed to write again to the Secretary of the Dorchester Show.

NEXT MEETING.—The date of the next meeting was fixed for Wednesday, December 13th, 1882, at the Charing Cross Hotel, at 2 P.M.—ALEX. COMYNS, Hon. Sec., 47, Chancery Lane, London, W.C., Nov. 29th, 1882.

CHICKEN VACCINATION.

DR. D. E. SALMON stated in his Montreal address that he had discovered vaccination to be a curc, or rather a preventive, of chicken cholera. The vaccine matter is procured by diluting the

blood of a cholera-infected fowl in about the same way Pasteur obtains the attenuated virus with which he protects sheep against anthrax. A New York report of this address says:—"As a standard he has used a virus diluted 1 to 10,000. This produced a local lesion in some cases, which appeared in a few days, and this in two or three weeks was followed by fever. All such fowls were afterwards exempt from the disease, even if inoculated with strong virus. Some chickens were susceptible to a virus as weak as 1 to 75,000, and by such inoculation were rendered proof against attack. Fowls not susceptible to a weak virus proved to be so to a stronger. Thus by grading the strength of the vaccine, which was easily and quickly done, all fowls could be successfully inoculated, and so rendered safe from these fatal innocerophytes. We need much more experimentation to determine whether there are still better methods to attenuate the virus, and whether we can protect against danger from other contagions, such as Texas fever or pleuro-pneumonia, not to speak of various human diseases, by the use of a similarly attenuated vaccine, which may be easily secured by diluting the blood of an individual diseased or dead of any of these contagions. Pasteur is at present busily engaged in this direction."—(*The Prairie Farmer*.)

OUR LETTER BOX.

Farming (Marian).—For a young man studying agriculture we cannot recommend any better work than Morton's "Encyclopedia of Agriculture." In addition the student should peruse the articles on any particular subject published in this Journal during the past five years for practical directions.

Improving Pasture (Waver).—You state that you have unfortunately succeeded to 20 acres of land covered with a mat of couch grass, and ask for information as regards its treatment to bring it into sweet pasture on the lines recommended by Sir J. B. Lawes. We think that is not a question to be considered how many sheep should be kept per acre, but a question of feeding by a large flock of sheep if you possess one, in order that the couch may be eaten down as bare as possible. The sooner the better. The sheep to have 1 lb. of cake each per day in the meal state mixed with a few cut roots, and be penned in a close fold at night time, to be shifted on to fresh ground every day, the fold to be made on the poorest part of the field with the least couch upon it. But it should be remembered that unless a large flock is now kept it would not pay to buy sheep at present prices for the treatment of 20 acres of land only, besides which regard must be had to the future treatment of the field. The nature of the soil has not been stated, but the first treatment to eat down the couch is the most important, and if this cannot be done with profit by sheep it may be done equally well by young cattle or dairy cows. After the couch is eaten down close the land may then in the spring be dragged with Howard's self-lifting harrow in order to obtain a little loose earth to receive the seeds for renovating. The seed to be per acre 10 lbs. of white Dutch Clover, 10 lbs. of Cocksfoot, 10 lbs. of Meadow Foftail, and 10 lbs. of Timothy Grass, without any annual grass seeds, only adding 10 lbs. of Paecy's Perennial Rye Grass, to be sown in the month of March, and the land after a good bite of grass is grown to be fed with cattle only, but no sheep to be allowed to feed thereon, as they eat out all the best grasses and Clovers to the injury of the pasture, the cattle to be allowed 4 lbs. cotton cake each per day. If the soil, however, is very light or sandy 5 lbs. of white Clover and 5 lbs. of yellow Suckling should be sown instead of 10 lbs. of white Clover, but the grasses as named to be sown, also let the soil be heavy or light. But the process of obtaining a pasture or turf which would supplant the couch would be very slow unless manures were used; therefore we advise in February in each year 4 cwt. of bone superphosphate should be sown, and if it is light soil 1½ cwt. of nitrate of soda per acre in addition. These annual applications, if supplemented by dressings of earth and manure composts occasionally, would much sooner produce a good turf. We must desire our correspondent to carefully peruse and study the contents of the series of articles just completed on "Neglected Pastures and Waste Lands."

REMARKS.

- 26th.—Generally fine, sprinkle of rain in afternoon.
 27th.—Very bright sunny morning, afterwards showery; moonlight night.
 28th.—Fine, bright, and cold.
 29th.—Rain early; damp day, with drizzle.
 30th.—Fine throughout.
 Dec. 1.—Thick fog early; hazy throughout.
 2nd.—Dark foggy morning; thick all day.
 Cooler, with much fog on the last two days.—G. J. SYMONS.

SMALL v. LARGE FRUIT BORDERS.

AT the outset I may as well state I am fully aware that much I shall write upon this subject will be at variance with the theories and practices of others. This knowledge, however, is no deterrent, simply because some at least of these "old hands" cannot, if they would, disprove some of the facts I shall adduce in support of my arguments. We learn as much from failures as we do from successes; at all events such is my experience. Unfortunately some of these mistakes that are made are on too large a scale to rectify, or at any rate those responsible have not always the courage to admit their errors and profit by them, but leave others to point them out.

I propose to divide my subject into two sections. In the first I shall endeavour to prove that we make unnecessarily large and expensive borders for such house-grown fruits as Grapes, Peaches, Nectarines, and Figs; and in the other that we do not take sufficient trouble with them—in fact, do not do justice to such wall fruits as Pears, Apricots, Peaches, Nectarines, Plums, and Cherries. With the latter I anticipate no great difficulty, but the former will not, I fear, prove so convincing to others as I am anxious it should.

It is a curious fact, but true nevertheless, that in some places the Vine and other house-grown fruit borders are constantly being pulled to pieces and remade, this being either the work of one man, or more often of a fresh gardener on taking charge. Such frequent upsets, besides being expensive, are likely to prove annoying to the proprietor, who mentally vows that no more vineries nor Peach houses will he build. In other cases, when making and remaking large Vine borders, so great an extent of good meadow land is robbed of its thin and fertile surface soil without any attempt being made to renovate it by those responsible, that the owner is easily convinced by the steward or bailiff how wrong he was to sanction such a proceeding. No more turf worthy of the name will this gardener be allowed to cut. Another gardener insists upon buying so many loads of turf, besides bones, manures, and unlimited draining material, in this manner contriving to make the border cost nearly as much as the house. If the result generally justified the outlay it would not so much matter, but, unfortunately, it does not; the success is far from being permanent, and the work of border-making is recommenced.

I maintain these large borders were wrongly planned, and of this I have had ample proof. It seems a prevailing idea

that Grape Vines require an inside border to the full extent of the house, with probably a border of the same width outside, and most of us know what one or both means. If these borders were eventually taken full possession of by the roots it would be a different matter, but they seldom are, and I may say in some of these cases nobody knows where the principal portion of the roots really are. I have worked for days removing a large inside border, and have found the remains of old horses—these at one time being considered valuable additions to the Vine borders—but found no roots worth preserving, especially near the burying places. They were all outside and far away through the regular outside border and well established in the ordinary garden soil. In another instance there was a large outside border, which, like the preceding, was not walled in, and had not been much disturbed for years. It had been, so I was informed, annually well manured and otherwise attended to, but on examination I could find no active rootlets, these again being at the extremities of the old roots across a pathway into the vegetable ground, and fully 20 feet from the stems. In each case (I could give more such) if a small border had been formed, say about 9 feet wide, either inside or outside, and walled-in, much labour, room, and expense would have been saved, continuously heavy crops would easily have been secured, and great anxiety avoided.

Large borders as a rule result in uncontrolled root-action, whereas in a small border we know exactly where the roots are, what we have to deal with, and work accordingly. Large quantities of manure, liquid and solid, are annually thrown away on these large borders; but the network of roots in a limited border absorb all and repay for the supplies of rich food given them. Fresh turf may contain sufficient fertility for young gross Vines and other fruit trees at the commencement; but this is soon exhausted or washed away, and in deep borders the roots are out of this and away, too often downwards, before those in charge become concerned about their whereabouts. Now Vines or trees in narrow and comparative borders, like plants in large pots, almost command attention, and, added to this, the roots in these are easily kept alive and the border easily maintained in a fertile state.

If water is scarce then let this border be outside of the house, but if plentiful—and remember abundance of water is required—then let it be inside, as being still more under control. The inexperienced especially should not attempt a combination of the two unless they are certain of being able to maintain sufficient moisture inside, as the roots inevitably make for that most congenial, this generally being the moist outside border. Let those in charge of such combinations test the truth of this assertion, and either correct or corroborate it. There is no doubt much depends upon the intelligence of those in charge; but I believe I may safely assert there are more of us who could better manage small borders than large. Given a small border full of roots, and the Vines can be made wonderfully productive by a mere tyro; but the same man would fail with a large and unmanageable border.

Let me advise those contemplating planting Vines or fruit trees under glass to form neither wide nor deep borders. They can make no mistake about a border for Peaches, say 6 feet wide and 30 inches deep, the bottom being concreted and covered with 9 inches of drainage material; and for Grapes about 3 feet wider, and in other respects similar, unless they

eventually neglect to top-dress and to otherwise feed the Vines liberally. The second part of my subject must be postponed.—W. IGGULDEN.

ABOUT DECORATIVE PLANTS.

IN many gardens the demand for small decorative plants is rapidly increasing, and large specimens in consequence are being discarded. Large plants are noble and beautiful when well grown and arranged where they can be seen to the best advantage; but they occupy too much room in gardens where thousands of small decorative plants are required. The object a few years ago when a plant was obtained was to repot it and grow it into a specimen; but now, if likely to prove useful, they are divided, and a stock obtained as rapidly as possible for decoration. It is very seldom that large plants are found in any number in gardens where decorative plants are largely grown, for it is impossible to arrange them so as to keep them in good condition, and at the same time present an effective display. But where small neat specimens are grown they are much more attractive, and can be removed and changed at will.

A few years ago fine-foliage plants were largely grown for table and room decoration, and many valuable old flowering plants were discarded to make room for them. But the fashion has changed, and flowering instead of fine-foliage plants are now in great demand. Perhaps there never was a time in the whole history of horticulture when flowers and flowering plants were in such constant demand for the many and varied forms of decoration.

Those cultivators who have both flowering and foliage plants to produce know the extra care and labour needed in producing the former. If we take the Cyclamen—one of the most lovely and useful plants that can be grown either for cutting or the various forms of decoration—we shall find they are on cultivators' hands at least twelve months. This length of time must elapse from the sowing of the seed before they are ready for the purposes for which they are grown. The same may be said of the single and double forms of Primulas, which are indispensable during the winter. It would not be difficult to enumerate many others—such, for instance, as Mignonette, Zonal Pelargoniums, Heliotropes, Celosias, and many more that take the same length of time, or nearly so, to have them in the best condition and in full beauty at this season of the year.

How is it with fine-foliage plants? If we take small Palms we shall find they do not entail half the care and labour to keep them in good health and condition for several years without even the trouble of repotting. They certainly must not be grown in too high a temperature, or they soon become too large, and will require occasional supplies of liquid manure. Crotons and Dracænas are easily produced, as good tops can be taken, rooted, and ready in a few weeks for purposes of decoration, and the same may be said of many other fine-foliage plants.

The length of time required in production is by no means the only matter to be considered. Where flowering plants only are used in rooms double the quantity have to be grown than are necessary with foliage plants. These then require proportionate house room in which to grow the plants. In how many gardens do sufficient suitable houses exist in which to grow decorative plants well? Low houses and heated pits should be liberally provided in all gardens where the demand for small well-grown decorative plants is large; but on the contrary, we often find a very limited quantity of suitable plant houses, and vineries and Peach houses have to be filled with plants. This necessitates constant removal of the plants from house to house, and not unfrequently is the means of red spider and thrips establishing themselves upon the Vines or Peach trees. I have in two instances had leaves of whole vineries to sponge, in one through red spider establishing itself upon a Tea Rose which passed unnoticed, and from it to the Vines, and in the other through thrips. I am certain that mealy bug is introduced into vineries chiefly through turning them into plant houses. It is surprising the success that attends plant-growing under such difficulties; but it is impossible to produce them in the same excellence as if proper houses were provided in which to grow them.—W. BARDNEY.

SUTTONS' READING EXHIBITION BRUSSELS SPROUTS.—Through the kindness of a friend, who sent me a few plants in the early part of the year, I have been enabled to grow the above variety for the first time, and have much pleasure in bringing the same before the notice of those of your readers who take an interest in kitchen gardening, and strongly advise them to procure a packet of seed of it in the spring—i.e., if obtainable. Last year the crop of seed proved a failure, hence it is that this season it is only in the hands of a favoured

few. The plant grows to a height of about 18 inches, and is studded with large handsome sprouts as hard as bullets, which are of excellent flavour. Taking all points into consideration it may appropriately be described as being a very superior variety, and is worthy of special commendation.—J. HORSEFIELD, *Heytesbury*.

PLANTING, PRUNING, AND TRAINING FRUIT TREES.

THIS is a matter in which looseness both in teaching and practice is apt to creep in, to the injury of the trees, and consequently to the subsequent loss of the planter. Those of us who assume to be teachers of gardening must be heedful of this, and take especial care to show why the method of culture we recommend is the best. It is not enough to dogmatise, and say Do this or that, in these days of keen intelligent inquiry into cause and effect. We cannot enter too minutely into details when treating of the culture of any crop, but fruit trees which may remain where we plant them for two or three generations merit especial care, particularly at the outset.

Will those who advise the training of trees horizontally tell us why they do so? Why, too, are we so frequently advised to refrain from pruning a newly planted fruit tree till the sap is in motion in spring? I am still a good many years on the right side of fifty, yet I have lived long enough to see a large number of fruit trees planted in that best of all soils for fruit-growing—a deep fertile loam, trained horizontally, attaining full development in size, form, and fruitfulness, and then gradually becoming more and more vigorous in the top branches at the expense of the lower ones, till they were comparatively worthless and were cut down to be replaced by palmette verriers and cordons. I am not wont to favour rigid rules of culture, but in fruit-tree management there are two or three rules that must be enforced as strictly as the laws of the Medes and Persians. One of them is that, whatever be the form of a fruit tree, all its branches must point upwards, either vertically or at a sufficiently acute angle to induce a prompt and free flow of sap and a sufficiently equal distribution of vigour through the tree. Now, after a horizontally trained tree is brought into fruit-bearing it never does this. Hence the undue vigour of its upper spurs; hence, too, its condemnation and the substitution of palmette verriers, with the end of every branch not only pointing upwards but upon a common level, so that in a full-grown tree the tips of the lower branches are as high as the pair at the top of the stem. Surely no one after seeing a full-grown palmette verrier could ever dream of reverting to horizontal training; for the improved form so thoroughly exemplifies the equal distribution of vigour, and is so handsome withal, that it excels all other modes of training.

Turning now to my second question, which is of even greater moment at this season of the year, and which, I may repeat, is, Why are we so frequently advised to refrain from pruning a newly planted fruit tree till the sap is in motion in spring? The advice so clearly bears caution upon the face of it that "For safety" is the only answer we can imagine. This answer naturally leads to the question, Is it, then, dangerous to prune when planting—say in autumn? I emphatically assert that it is not; only take care to select healthy young trees in full vigour, see that the transplanting is well done, and prune at once, not simply because you may do so with impunity, but because it is decidedly the best for the trees. To wait till the sap is in motion certainly involves a loss of time as well as of vigour. The bud to which we prune contains the germ of a branch which it is important should be as robust as possible, and yet we are advised to weaken it by leaving other buds above it to waste the first flow of sap and then be removed! Is not this rather like doing a thing because somebody said it was right, without inquiring if it really is so? Never let us forget that it is the swelling bud which attracts sap from the circumjacent tissue and causes it to flow, and not flowing sap which forces the bud into growth. It was upon some standard Apple trees that I proved the fallacy of waiting till spring before pruning, and the matter was discussed in the Journal about thirteen years ago. Since then I have planted a considerable number of all sorts of fruit trees—Apples, Pears, Plums, Peaches, Nectarines, Apricots, Figs, and Cherries, and have pruned when planting with invariable success, the first year's growth always being as sturdy, stout, and strong as could be wished.

It is, however, by no means intended to imply that time'y pruning was the sole or even the primary cause of this success, for careful transplantation is even more important. Mark the term! I use it intentionally, because young trees often sustain injury from an undue exposure of the roots to the air. The lifting and packing is sure to be well done by a good nurseryman,

and it should be the planter's care to unpack them and cover the roots thoroughly with fine soil as soon as he receives them. Planting cannot always be done at once, nor need it be pressed on till a favourable opportunity offers, if the roots are only so protected from the drying shrivelling action of the air.

Plant only in soil that you know to be fertile. Do not mind not having that "sweet upland loam," which we would all get if we could. It cannot be too often repeated that soil which will grow good vegetables answers equally well for fruit, only take good care there is enough of it. Never plant in a shallow soil because of the great risk—in many sorts the certainty of canker and premature decay. Every tree should have a station 6 feet square and 2 feet deep. Excavate a hole of that size. If the sub-soil is of a close heavy texture likely to retain much moisture, lay a 2-inch pipe drain across the middle of the bottom, and connect it with the nearest drain or outfall; then ram hard a 4-inch layer of broken stones all over the bottom, and fill with good soil, from which remove every particle of roots or pieces of wood, decaying wood being a nidus for fungus, which spreads to the roots and destroys the tree. Remove all bruised roots with a clean cut, spread out the others evenly and at full length; pack the soil closely among them and trample it firmly, taking care that the surface of the station about the collar of the tree is 6 inches above the common level to allow for its sinking. Secure the tree firmly in its position by stakes or wires; fasten a weather-proof label with its name and date of planting to it; cover the entire surface of the station with a mulching of any rough litter—then, and not till then, may you consider that you have done all that is necessary at the time of planting. Do not put off the naming, as is so often done; enter it also at the same time upon its place in the garden plan, and then if a label is lost you can always replace it correctly.—EDWARD LUCKHURST.

SERICOGRAPHIS GHIESBREGHTIANA.

THIS plant has long been known and valued by gardeners as a winter-flowering plant for the warm greenhouse, but I believe it is not generally known that it is a most valuable plant for covering the back walls of vineries or other fruit houses.

We have here three plants, each about 6 feet high and the same in diameter, trained over the back wall of a lean-to vinery, the roof of which is quite covered with the Vines. They are planted out in a narrow border, which is separated from the Vine border by a stone-flagged pathway. The growths they have made during the past summer are very strong, much more so than we ever see them when grown in pots, and they have throughout the summer been very ornamental with their ample Laurel-like foliage of a dark and glossy green. During the whole of last month they have been one bright glowing sheet of scarlet, as from near the ground to the topmost points they are quite covered with long spikes of *Salvia*-like scarlet blooms.

Although the house is kept quite cool, as the Grapes are now all cut and the Vines at rest, yet the blooms expand freely and last well when cut. We find them most useful for arranging with *Chrysanthemums*; and although we are cutting them in quantity nearly every day, the display is yet as bright as at first owing to successional spikes taking the place of those cut. The ladies here are much pleased with it, and are proud to show it to their friends and visitors.—W. K. W.

CRAB v. PARADISE STOCKS FOR APPLES.

DWARFING stocks have been for a long time recognised as suitable for Apples; nevertheless, I feel sure that the Crab stock has been banished from some gardens when it would have been better retained. In my own case I am planting young trees budded on the Crab, as I find almost without exception that the stocks used by nurserymen do not live in this soil. The only exception I can name is Ecklinville Seedling, which does well; but even such popular kinds as Lord Suffield and Stirling Castle continue in health for a few years only. One of the very worst is Hawthornden, which will not grow at all. Our soil is rich and light, with a substratum of gravel near the surface. It would be interesting to know the experience of others with soils of a similar character.

The plan adopted to remedy this disappointing state of things has been to purchase stocks of the common Crab at this season, grow them on for a year, cut them down, and bud on the young wood of the following year. We have old and healthy trees on a free-growing stock, and expect that young trees on a free stock will do as well now as they did half a century ago. The best Apples for the particular garden should alone be propagated, no matter whether the name is known or not. When a gardener is expected to keep an average daily supply of, say, half a bushel Apples for

four or five months, it does not so much matter knowing the names of fifty varieties, as it does to know the half-dozen sorts that are practically sure to yield a crop year after year and enable him to meet such demands with ease.—B.

LINARIA VULGARIS VAR. PELORIA.

THE plant, of which a flowering spray is represented in fig. 92, and which is referred to in the article on page 552 as growing in the gardens at Keir, is an example of a peculiar phenomenon

Fig. 92.—*Linaria vulgaris* var. *Peloria*.

that is occasionally observed in flowers, and is termed *Peloria*. This consists in the transformation, or, according to some botanists, the reversion, of what are usually irregular corollas to a regular form. For example, in the *Linarias* and *Antirrhinums* the corollas, as is well known, have commonly a two-lipped form, to which the term "personate" is applied, the chief difference between the two being that the corollas of the *Linarias* are furnished with a spur at the base and those of the *Antirrhinum* are without this appendage. In the case of the variety *Peloria*, however, this two-lipped form quite disappears, the upper part assuming a conical shape with the extremity five-cleft and sharply revolute, the base

being furnished with five spreading spurs, giving the flowers a totally different appearance. The species itself is an attractive plant, but this variety is superior to it, as the flowers are produced so abundantly that they form a dense spike 6 to 9 inches or more in length, and of an extremely pleasing yellow colour. As a garden plant it is much appreciated both on account of its peculiarity and its beauty, and as it is readily increased by its roots a stock can soon be obtained. Occasionally fine specimens may be seen at exhibitions where classes are provided for hardy plants, and they form some of the most effective for such collections.

Though not very common, this *Linaria* has been long known both to cultivators and botanists, and in the sixth fasciculus of Curtis's "Flora Londinensis" are given some interesting particulars concerning the history of the plant, as follows:—"The earliest account that we find of the *Peloria* is in the first volume of the 'Amœnitates Academicæ' of Linnæus, published in 1749. It there forms a distinct thesis or dissertation written by Daniel Rudberg, who enters minutely into the history of the plant, describes it fully, and illustrates it by an engraving. The plant appears to have been first discovered in the year 1742 growing in a province of Sweden about seven miles from Upsal by a botanical student named Zioberg, who gathered a specimen of it, and placed it in his herbarium as a plant he had not met before." Professor Celsius observed this specimen, and called the attention of Linnæus to it, who secured plants for the Botanic Gardens at Upsal. Linnæus, it is said, at first considered it a new genus, but further examination proved that it was only a variety of *Linaria vulgaris*, or *Antirrhinum Linaria* as it was then termed. Plants of the variety *Peloria* have been found wild in several parts of Great Britain, but it is very rare.

DEW IN HOTHOUSES.

I AM much obliged to Mr. Taylor for his offer to answer queries on this subject privately; but I am not at present seeking information in that way, and I feel sure you will not think I am occupying your pages frivolously in returning shortly to a subject on which Mr. Taylor has said "his whole theory and practice of giving air is entirely based," and which he says he is quite alive to the importance of. I think the subject is both interesting and important; and the question is not one of answering elementary questions, but whether the theory laid down by Mr. Taylor to your readers is the correct one. If I misunderstood Mr. Taylor on the subject of the dew-point, and he means what I mean and explained on that point, then it seems he does not differ from "W. Y.," who, he said, was right on the subject of dew outdoors but wrong on dew in hothouses. Mr. Taylor makes it appear that the cause of the production of dew under a rising temperature is distinct from that which takes place from a falling temperature, which is not the case. In both cases the cause is a lowered temperature coming in contact with a warmer one and producing condensation. To assert anything else is contrary to the text books and only tends to confuse the reader. Neither do I think Mr. Taylor is at all correct in teaching that "a dew deposit in any way is one of the things we have to guard against" with a few exceptions in the case "of decorative plants that have not very soft foliage," &c. This idea of Mr. Taylor is to me quite new as well as directly opposed to the teachings of Lindley and others, who have pointed out that the absence of dew in hothouses was not an advantage but one of the distinct drawbacks of artificially heated glass houses. Speaking of dewing in hothouses, Lindley advocates it by every practical means, observing that "in this as in all things else the operations of Nature should be imitated with all the exactness possible." Dew on Vines, Peaches, or plants at night is one of the most satisfactory signs I know of, especially when the plants are growing, but it is never seen hardly except after hot days when pipe heat has been dispensed with during the night, when dew is always condensed or deposited on the leaves.—CASUAL.

THE subject of dew on plants in houses has been lately discussed; but the question of the deposit of dew on the leaves of plants in glass structures, and more particularly on Grapes, rests on one simple fact. All cultivators of the Vine under glass must have observed that when air is not admitted sufficiently early dew will be deposited on the berries, and more especially when the temperature inside is not obtained artificially; and if air is not then admitted very carefully scalding of the foliage and rust on the berries will be the result. If the temperature is artificially raised internally the foliage, fruit, and every object in the house is of the same temperature, and moisture will not then be condensed. Mr. Taylor evidently understands the question of dew-formation, and his practice is to raise the inside temperature early

in the morning, admitting air also early, so that no dew shall be deposited. This appears to be the whole of the argument, and, so far as my knowledge goes, is all that Mr. Taylor professes. My opinion is that much of the scalding of which we frequently hear complaints and see examples is due to too low a night temperature being maintained, and that the fires are not pushed on rapidly enough early in the morning, the sun then acting on the Vines with increased power however early the ventilators are opened.—JOHN GADD.

ROSES FROM CUTTINGS.

I HAVE tried three methods of Rose-growing, and now give the results of my experiments.

1. On the 29th of July, 1881, I inserted in a bottomless box cuttings from Gloire de Dijon, Coupe d'Hébé, Duke of Edinburgh, Princess Louise Victoria, Marie Baumann, Madame Moreau, Miss Ingram, and Xavier Olibo. I covered the box with a sheet of glass and made it air-tight. I kept it closed for fully a month, and then opened it in fine weather and supplied water as was necessary. I kept on the glass during last winter. The cuttings of Miss Ingram and Xavier Olibo all failed; of the others 40 per cent. have succeeded, and these are now well-rooted plants.

2. On the 1st of November, 1881, I planted out in the open air a number of cuttings from twelve varieties of Roses. I protected them with litter during the winter, and watered them in spring when necessary. From these I have very few plants, and only of three kinds—Gloire de Dijon, La France, and Duke of Edinburgh. Only 11 per cent. of those slips succeeded.

3. On the 30th of November, 1881, I inserted under a hand-glass cuttings from Camille Bernardin, Sir Garnet Wolseley, Thomas Mills, Duchess of Edinburgh, Gloire de Dijon, and of these 90 per cent. have succeeded.

But, notwithstanding my many failures, I am happy to say that from these slips I have at this time (1st November) a goodly number of excellent well-rooted plants, and I have tried all the three modes this season again.

I may add that the soil is rich loam, and that I mix a good quantity of river sand with it.—AMATEUR, *Strathbogie*.

CULTURE OF HORSERADISH.

THE present being a good time to prepare for next year's supply of Horseradish, I offer a few remarks which, if followed, cannot fail to bring some first-rate roots, young and tender, the produce of one year's care; and instead of having to dig perhaps a rod of ground to find one stick that is presentable, the first may be taken with the certainty of its being good. Prepare a portion of ground large enough to grow one year's supply by trenching, or, what is better, double-digging, and apply a dressing of decayed manure as the work proceeds, and let it remain rough on the surface exposed to frost till March, which will be the month for planting. It is often said that any corner will grow Horseradish, but experience teaches that open ground will grow it best, and when well managed a few rows of Horseradish look well in any garden, whereas on the old corner principle it is generally overrun with weeds, and will, if the old saying be true, give trouble for seven years.

To prepare the sets take the long side shoots, any size up to the size of the little finger, and from 8 inches to 1 foot in length, then with an old blunt knife carefully scrape off the little side roots to within an inch or two of the bottom, rub them with an old piece of cloth, tie the roots in bunches of two dozen more or less, and bury them in soil or ashes in the bunches level with what will be the crowns, then when planting time comes examine them and break away any growths they may have made except two or three at the crown. If properly done there will be no roots but those on the portion left for that purpose at the bottom. By this method we not only get it straight but rootless as well, consequently it can be easily scraped for use, and being of one year's growth is young and tender. The sticks will vary from 1 to 2 inches in diameter, according to cultivation.

In March mark out the number of rows required from 15 to 18 inches asunder, and dibble the roots in 15 inches apart in the rows, or, better still, with the spade dig out a trench the required depth and place them at the side by the line, filling the trench firmly, just covering the crowns. Keep them free from weeds, and lift the roots any time after the leaves have died; prepare sufficient side shoots for the next year, and lay the remainder in to be used as required.

I may add that an article on the culture of Horseradish appeared in the *Journal of Horticulture* four or five years ago. Since that time I have grown mine on the principle there recom-

mended with great success. It may appear that much preparation is required, but in practice it is not so. A man can soon prepare the sets, and it takes but little time to plant them, and if done well success is certain.—S. J. A.

BOUVARDIA ALFRED NEUNER.

It is questionable if any new plant of recent years has more fully sustained the character given it when first sent out than this Bouvardia. Those who have grown it will be able to say that a word too much has not been said in its favour. The merits of the single forms are well known for purposes of button-holes and bouquets, but this beautiful pure white double form surpasses them for such purposes. It is very free-flowering, and I do not think any single form in cultivation is superior to it in this respect. It is of robust growth and good habit, and will, without doubt, become one of our most popular winter-flowering plants. The flowers last a long time after they are fully expanded, both in a cut state and upon the plant, and on this account are valuable for cutting. Those cultivators who have white flowers to produce during winter and have not grown it may safely obtain it at once, so as to raise a stock for another year. It is worth a place in every garden.—SCIENTIA.

WINTER-FLOWERING PLANTS.

(Continued from page 527.)

AN abstract of a paper read before the Young Gardeners' Mutual Improvement Society, Royal Gardens, Kew, by Mr. Garrett, foreman of the flower garden department.

HARDWOODED PLANTS—ERICAS.

So far I have referred only to plants that are more or less soft-wooded, except those that were selected from the stove and Orchid houses. In addition to these there is a considerable variety amongst hardwooded greenhouse plants that flower in the autumn and winter, and as these are totally distinct in their growth they require very different soils and treatment. Many hardwooded plants are annually killed by overwatering after being newly potted, and others meet with a similar fate from being allowed to become too dry. Careful treatment as regards potting and watering are absolutely necessary for the successful cultivation of such plants as Ericas, Epacrises, Azaleas, Eriostemons, Chorozeas, and many others. Ericas are supplied in the greatest quantity in autumn and winter in two varieties—namely, *E. gracilis autumnalis* and *E. hycmalis*. These are probably grown as well in the neighbourhood of London as anywhere. Several extensive growers, who know exactly how to treat them, grow and supply them annually by the thousand to nurserymen and salesmen at a cheaper rate than the latter could grow them themselves. An enormous number is also grown annually to supply Covent Garden Market. Another cause of failure with many hardwooded plants is caused by insufficient care in potting. They should never have their stems buried below the surface of the soil, neither should the balls of soil be dry when repotted, or they will not be soaked through without saturating the new soil. Although water must be applied sparingly after repotting in spring, the plant will bear a copious supply when established in the summer, but much depends on the strength or the variety of plant as to whether it will require little or much. Ericas and Epacrises begin to flower early in autumn, and will last a long time in a cool house where fire heat is seldom used except for keeping out frost.

AZALEAS.

Azaleas mostly flower after Christmas, but if the plants are well ripened and forced a little each year some of the early varieties will flower some time before this. Those with white flowers are extremely useful for cutting if the plants are large enough to allow of it being done. Two of the best for forcing are *A. anemonæflora plena* and *A. indica alba*. *A. amœna* is generally the first to flower amongst the coloured ones; it will force well, and is very bright and pleasing.

CAMELLIAS.

Camellias invariably flower well in winter if supplied with plenty of water and air on all favourable occasions. A place is found in many gardens for planting them out either in a part of the conservatory or against back walls in other houses; they are much better treated in this way, and do not require attention so often in watering, &c., as when grown in pots or tubs. The old white variety *C. alba plena* is one of the best and is generally the first to flower.

BULBS.

We have yet another class of plants that are extensively grown, and are amongst the most beautiful when forced early—namely, Dutch bulbs and Lilies of the Valley. The earliest consignments of bulbs are received from Holland about the middle of August. If potted soon after their arrival and carefully forced the early Roman Hyacinths, Double Roman, and Paper White Narcissus will begin to flower by the end of October, and if successional batches are potted

and brought on in the same way these beautiful sweet-scented flowers may be had the whole winter. Most of the large-flowering Hyacinths arrive later, and it requires a much longer time to get them in flower. Lily of the Valley is imported in quantity about the end of October as clumps and also as single crowns. The single crowns imported from Berlin are the best for early forcing; those from Hamburg, which are larger and are much grown, will not force well until later in the season. They require potting lightly and plunging in a bottom heat of about 90° to start them. As soon as they commence growing the crowns should be kept in a little cooler temperature to assist the leaves to come with the flowers, leaving the pots still in the bottom heat. A small frame purposely for them affords the best means of treating them in this way. The flowers often appear when early forced without the leaves, and sometimes this cannot be avoided, but if the leaves can be had at the same time they are almost equally valuable with the flowers.

Early Tulips, especially the Duc Van Thol varieties, may be had in flower by the end of November, and are always much admired. The first pots of bulbs in flower are always looked forward to with much interest and pleasure, as they seem to bring with them many of the beauties of spring to brighten some of the duller days of winter. While on the subject of bulbs the American Tuberose must not be omitted. The bulbs of these are imported, I believe, about February, and should be potted in batches and grown in frames in the summer, introducing them to a little heat as their flower spikes advance in growth. When the bulbs commence growing the numerous shoots on them should be reduced to one to form a flower spike, and naturally the best one should be selected. The flowers may be taken singly from the stem and used for buttonhole or other bouquets. Being highly perfumed and pure white they form worthy companions to the Gardenia and Eucharis.

The flowers of the Christmas Rose (*Helleborus niger*) are very useful for cutting purposes. The plants flower in the open air in winter, but are very much improved if placed in a house where there is a little heat. Good clumps produce a quantity of flowers which command at times a high price in the flower market, especially if they have expanded under glass or protected from the weather in some other way.

VIOLETS.

I now come to the last, but by no means the least in point of merit or usefulness, of the winter-flowering plants. What may be justly termed universal favourites at any time in the year, when even only a few can be obtained, are Violets. These are found in almost every garden where there are a few frames, but in many cases the plants are small and infested with red spider, consequently the flowers are small both in size and quantity. Violets for winter must be started as young single plants in May in a piece of prepared ground, and be kept watered and syringed freely to have good plants by the end of September, when they should be transferred to their winter quarters in frames where a little dung heat has been previously prepared. Fire heat is very injurious to them, and should be avoided if possible, as the plants are so subject to the attacks of spider. They require plenty of ventilation on sunny days or when the weather is mild. One of the worst enemies to Violets grown in the neighbourhood of London is fog. So far from flowering, the plants will scarcely exist if exposed to many London fogs. If they are in frames as advised and a fog is expected, the best plan is to close them and keep them so until it is past. This will sometimes cause the plants to damp, but of the two evils the least must be chosen. Some of the single Violets are very hardy, and will do well outside in the country except in severe winters, but most of the double varieties require glass protection to open their flowers satisfactorily. The best double variety for winter that I have seen is Marie Louise. The old Neapolitan is perhaps the sweetest scented, but it does not flower much before spring, while Marie Louise is much hardier, and begins to flower as early as August or September, and continues in favourable weather until the plants begin to grow in spring. Violets are in great demand in all private gardens, hence the importance of giving them special attention.

POTTING, SOILS, AND MANURE.

A few words in conclusion on the subject of potting as applied to the plants I have mentioned. Some of the principles may be extended to all plants, according to their growth and requirements. This may seem somewhat elementary, as most gardeners, even the younger members of the profession, think themselves proficient in this important branch. Plants, however, by their sickly appearance often tell a different tale. Wherever fibry loam can be obtained it should be used in a large proportion for all plants of the softwooded class that have to remain in the pots for any length of time. Neither peat nor sand is necessary after they are established and ready for the final potting if a little leaf soil and plenty of charcoal can be obtained. In many places this cannot be obtained in quantity, but in many others it is not used when an application would bring a plentiful supply. Soils that quickly decompose should be limited with this class of plants, as in my opinion it is better to supply a plant with liquid manure as it is required, or some of the artificial manures, of which Standen's and Clay's fertiliser are two good forms. Loams are very variable in different places. In the neighbourhood of London it is difficult to get soil with much fibre in it, consequently something lighter has to be mixed with it to keep it from clodding

and becoming sour. Charcoal and leaf soil not too much decayed are the best ingredients I have found for the purpose. All the plants should be well drained. With hardwooded plants it should be remembered when potting that they generally have to remain twelve or more months before being again repotted, consequently good drainage is of the first importance. Good peat, with a limited quantity of sand and firm potting, are the principal requirements of most plants of this class. The roots are small, and the plants generally of a slow-growing nature, consequently their requirements are very different from those that are softwooded and of much quicker growth.

Much more might be said on potting. I have only made a few remarks on it as far as regards the plants I have referred to. Young gardeners should watch the results of different methods of practice in the cultivation of useful plants, and be prepared in their turn to pursue, according to circumstances, that method which has proved to them the best.

ODONTOGLOSSUM HALLII.

ABOUT three years ago I obtained a small pseudo-bulb of *Odontoglossum Hallii*, which has grown and flowered so well that I am induced to give some particulars of its size now and the treatment it has received, for it certainly is the most vigorous plant of the kind that has come under my notice. In the short time mentioned the small pseudo-bulb—about the size of a Broad Windsor Bean—has increased to half a dozen, each from 3 to 4 or 5 inches long, and from 2 to 3 inches broad. The spikes are being produced just now, and the foremost, which is hardly so vigorous as one or two which are only developing, is fully 5 feet long, and is showing twenty-seven blooms. The leaves are about a foot long, and the whole plant occupied a 6-inch pot. These dimensions may, for aught I know, be far from uncommon, but are much above that of any plant I have hitherto seen, and I have seen many examples in the collections of even famous growers. Moreover, the pseudo-bulbs and spikes have increased yearly at an extraordinary rate, not merely in size but in numbers. In fact the number of breaks have doubled yearly, to say nothing of the increase of size. The hope, therefore, is not unfounded that by another season the pseudo-bulbs may be stronger and spikes more vigorous still.

The treatment has been very simple. It has had a mixture of charcoal and fresh sphagnum, half and half, for a root medium, and has been kept confined at the roots, as I believe most Orchids should, for it seems that the soil does not become sour. So well have the roots liked this treatment that they have always been healthy and have filled the pots. The plant likes a constant moistness about the roots, at least when there is no sourness, even after the pseudo-bulbs have fully grown. If the flower-spikes come up the growth ceases; but if these do not appear, no sooner is one set of growths made up than another set appears. When this happens to a *Cattleya* weaker growths are the result, but not in the case of the majority of *Odontoglossums*, which really do not want a resting season as long as they are not subjected to a too high and dry temperature. Advantage may be taken of this fact to increase the strength and bulk of such, for when kept growing by steady moisture and moderate shading for a season or two small healthy plants gain strength and size to a wonderful extent. When this object is gained it will be found that a little stinting for water just as the pseudo-bulbs near completion, coupled with exposure to all the light possible short of scorching, will insure a free and a vigorous inflorescence. Though we say a "little stinting," it is not meant that water should be withheld so as to cause them to shrivel. This is often done to insure maturation and rest, but it only secures exhaustion.

Can any of your readers tell me if my plant of *O. Hallii* has attained full strength?—SINGLE-HANDED.

OF HUMUS.

(Continued from page 521.)

I FINISHED my last letter with an account of an interesting experiment by Ville which strikingly illustrated the solvent effect of humus upon carbonate of lime, and the consequent results on the yield of Wheat produced by its presence in conjunction with this mineral. Its effect upon the so-called insoluble phosphates through the carbonic acid which it generates was, it may be remembered, fully shown in my letters on the value of phosphate of magnesia. In fact, there can be no doubt whatever that decaying organic remains in the ground do afford long-continued, if feeble, sources of carbonic acid; and we can, when this truth is impressed upon our minds, better understand why it is that land exhausted by cultivation should, when putrescible vegetable and animal remains are added to it, regain its fertility in a comparatively short time, and how it comes to pass that the use of "farmyard manure

in the time of fallow will promote the process." And here let me add a word from this point of view in favour of sewage manures, which from the most unbounded faith in their fertilising properties have declined to so low a point that farmers can hardly be persuaded to cart them away when they can be had gratis. These manures are at all events characterised by a large proportion of highly putrescible organic matter, such as, in the case of earth-closet manure, appears, from the recent correspondence in your columns, to command the favour of horticulturists to an extent at least quite equal to anything I should contend for. To my mind it is clear that the chemist ought not to ignore in his returns the value of such organic matter, which at present he virtually does. To aid in bringing about a more reasonable mode of valuation is the object of these letters.

The following table, extracted from the analyses of Boussingault and Lewy, of the air found in the interstices of different soils containing varying amounts of decaying vegetable matters, will assist us in a correct appreciation of the influence which humus confers by furnishing copious supplies of carbonic acid in the soil. The figures give the proportion of carbonic acid found in ten thousand parts of air, and it will be seen that the soil is incomparably richer than the atmosphere in this active solvent, by which, as Liebig tells us, "the fixed elements of food are rendered soluble and capable of being distributed in all directions." Indeed, having his mind directed very powerfully to the important influences of this gas, he goes so far as to say, "We know of no other way in which the earthy phosphates are dispersed through the soil than by means of carbonic acid and water," which is, of course, saying more than he could with precision assert; but it shows the extent to which his mind was impressed by their action, and yet the substance which yields this solvent is not to be allowed a value in estimating the value of a manure! But we will proceed with the promised table.

	Carbonic acid in 10,000 parts of air by weight.
Ordinary atmosphere.....	6
Air from sandy subsoil of forest	38
" " " " surface soil " "	130
" " " " " " vineyard	146
" " " " " " old Asparagus bed	122
" " " " " " " newly manured	233
" " " " " " pasture.....	270
" " " " " " rich in humus	543
" " " " " " sandy field (dry weather) }	333
" " " " " " newly manured }	
" " " " " " " (wet weather) }	1413
" " " " " " newly manured }	

It appears clear from the foregoing remarks that humus must assist materially in bringing into solution both phosphate of lime and carbonate of lime. But this is not all. The original sources of supply of the potash, soda, and silica found distributed in soils are the feldspaltic rocks. The soda and lime feldspars are often exceedingly durable. The decomposition of feldspar, when it does yield, consists in the breaking-up, through the action of the atmosphere, of the hardy glassy mineral into kaolinite (a hydrated silicate of alumina) and soluble substances which are removed by water. The hydrated silica when newly set free from combination is quite soluble in water, and together with the alkalis, when much water has access during the decomposition, is dissolved out. Thus 100 parts of potash feldspar, in being converted into kaolinite or pure clay, has removed from it 41.8 per cent. of silicic acid and 16.9 per cent. of potash. The high importance of carbonic acid in a soil containing undecomposed silicates is therefore apparent, and the bearing of the table just given on this question can also be readily understood. S. Johnson, from whose work the figures given in the above table are extracted, after remarking upon the fact that the carbonic acid originates in large part by oxydation of organic matters, adds that this is strikingly demonstrated by the increase of its quantity resulting from the application of manure and the supervention of warm wet weather. "It is obvious," he says, "that the carbonic acid contained in the air of the soil, being twenty to a hundred or more times more abundant, relatively, than in the common atmosphere, must act in a correspondingly more rapid and energetic manner in accomplishing the solution and disintegration of mineral matters."

"The vegetable and animal remains in a soil seem," Liebig says in his "Natural Laws of Husbandry," page 80, to "exercise a remarkable influence upon the diffusion of silicates. The experiments made on this point show that the absorptive powers of an arable soil for silicic acid is in an inverse ratio to the amount of organic remains in it; so that a soil rich in such remains will, when brought into contact with a solution of silicate of potash, have a certain amount of silicic acid unabsorbed, whereas an equal bulk of soil poor in organic remains will take up the whole of the silicic acid in the solution. The incorporation of decaying vegetable and animal matter will, therefore, in a soil containing

disintegrable silicates, first of all accelerate the decomposition of the silicates by the action of the carbonic acid generated in the process of decay; and then, as these substances diminish the absorptive power of the soil for silicic acid, as soon as this acid has passed into solution it is distributed through the soil more widely than would have been the case had these substances not been present."

But even yet we have not exhausted all the beneficial influences on the growth of plants which the carbonic acid resulting from the decomposition of decaying vegetable matter and humus exert; but the consideration of these further influences I must postpone to another and concluding letter on humus.—INQUIRER.

(To be continued.)

COAL TAR AND CLAY v. MEALY BUG ON VINES.

IN answer to your correspondent "C. M." I beg to inform him that Mr. Murray's recipe for destroying mealy bug on Vines is equal parts of coal tar (common gas tar), clay, and water thoroughly incorporated by frequent stirrings until the whole mixture becomes of the consistency of cream. It can then be applied freely to cover the bark and buds, and the filling-up of all holes and crevices, without fear of it doing the slightest injury to the Vines. I had the early house of Vines here painted with the mixture yesterday, and I feel confident, after Mr. Murray's experience, that it will destroy the mealy bug and do no injury to the Vines.—A. PETTIGREW, *Castle Gardens, Cardiff.*

IN reply to "C. M." on page 524, I have to inform him that it was common gas tar that was used here, about a fourth of tar to equal quantities of clay and water, one man keeping it well stirred during the time that another man was applying it to the Vines, rubbing it well over all the cane, eyes included. We had some Lady Downe's more affected with bug than any others, and were prepared to remove them in spring if they suffered from the treatment we gave them. In their case the tar was used much stronger than the quantity given above, but the dressing had not the slightest ill effect, as the eyes broke as freely as those on the other canes in the same house. We paint all the wires and rafters in the vineries with paraffin oil, as it is no use trying to get rid of mealy bug on Vines by cleansing the Vines only.—DAVID MURRAY, *The Gardens, Culzean Castle.*

GRAPES FOR SEPTEMBER.

YOUR correspondent, "J. E. R. I.," asks some questions about Grapes which I venture to reply to. In the first place, there can be no doubt that the Muscat Hamburg is a Grape of splendid quality. Its chief fault is that it sets badly, but with adequate attention in regard to artificial impregnation this can be overcome. I would crop it lightly, give it a Muscat temperature with plenty of air, when such can be given without cooling the house too much. I would rather have it on its own roots than on any other stock, though it does well on the Black Hamburg with the extra attention above referred to.

In regard to the Duke of Buccleuch I would advise your correspondent to try it on its own roots, if such a course is convenient for him; if not, he need not hesitate to graft it on the Black Hamburg or a Muscat, as I have had it on these stocks and found it do remarkably well. The border being all inside in the house is much in favour of the Duke. If "J. E. R. I." simply wants Grapes for the table, and especially if they are not to be subjected to packing and travelling, he might safely plant the four kinds he mentions—viz., Muscat of Alexandria, Muscat Hamburg, Duke of Buccleuch, and Madresfield Court. These varieties, if started about the middle of February and generously treated in regard to heat and judicious ventilation, should be in good condition for the table by the middle of September.

I would advise that the Duke and Madresfield Court be planted together at one end of the house, and if possible a watertight division put in the border, so that they could be treated to less water at the roots than the other two; but they could be kept drier than the others without such a division. This is one of the essential points in the successful cultivation of the Duke and Madresfield Court. When they are given too much water cracking is almost sure to result. Let the directions that have already been given for the cultivation of the Duke be followed, such as always maintaining a succession of young rods. In pruning leave three or four eyes, selecting the most fruitful shoot when such can be decided upon, rubbing off the rest. A touch with a feather when in bloom is an attention well repaid in the case of the Duke as well as the Muscat Hamburg. Should the Duke show signs of

cracking, notwithstanding careful watering, a nick with a knife on the laterals the bunches are on between the bunch and the main stem is of great assistance in stopping the evil. Success with any Grape can only be attained by giving Vines all the conditions favourable to them. Good borders, and keeping them so with good cultivation, are needed to be permanently successful with any variety of Grape. Taking it for granted that "J. E. R. I." is both able and willing to supply these essentials, I have no hesitation in advising him to plant the four kinds mentioned. They combine so many good qualities that the difficulties that attend their cultivation should not deter anyone from growing them. They can be made to do perfectly well in the same house, always remembering about the watering of them.

There are other Grapes that "J. E. R. I." might grow for use in September. What says he to the grand old favourite Black Hamburg? Surely he does not esteem it lightly. He might have it, Foster's Seedling, and Buckland Sweetwater for September use, but they are deficient in flavour when compared with the first mentioned varieties. Some growers lay great stress on the necessity for lean-to houses for Muscats. My experience is that either lean-to or span-roofed structures can be made to produce first-rate Grapes. I would advise "J. E. R. I.," if he plants the four high-class Grapes and is successful with them, to use the Duke and Madresfield Court, first allowing the Muscats to have a little longer time to ripen.—VITIS.

[This article is written by one of the most experienced and successful cultivators of Grapes in Great Britain, and we quite agree with him on the merits of the varieties recommended when all of them are well grown.]

AT a General Meeting of the ROYAL HORTICULTURAL SOCIETY, held on Tuesday last, Geo. F. Wilson, Esq., F.R.S., in the chair, the following candidates were unanimously elected Fellows, viz.:—Colonel Beddome, General Duke, Mrs. General Duke, Arthur George Grote, Henry W. W. Nutting.

— "W." observes:—"There is now a fine display of GREENHOUSE RHODODENDRONS of the Princess Royal type in bloom in the Handsworth Nurseries, Sheffield. Four or five large houses are quite filled with specimen and half-specimen plants, all in the most vigorous health, and more or less covered with large trusses of bloom. The stock of plants at these nurseries numbers many thousands.

— "IN the same nurseries Orchids are now grown in very large numbers. There is also a fine display of CYPRIPEDIUMS in flower, including the new *C. Spicerianum*. In one of the cool houses there are upwards of a hundred plants in bloom of *Masdevallia tovarensis*, the pure white blooms of which are most valuable made up into sprays, wreaths, &c., for ladies' wear, also as buttonhole flowers for gentlemen.

— "IN a house filled with Pelargoniums, Regal and French varieties, I noticed a large group of a variety called MADAME CHAS. KÖNIG, every plant of which is now flowering freely, and as the blooms are pure white without any markings whatever they are most valuable for cutting. Mr. Williams, the able indoor foreman, tells me it is the most free and continuous-blooming of any variety; in fact, while the plants are growing freely it is never without blooms."

— MR. G. G. KERTICE writes:—"Allow me to correct an error into which your correspondent has fallen in connection with the CALANTHES AT THE MANCHESTER SHOW which obtained a first-class commendation. They were exhibited by my employer, John Allen, Esq., of Oldfield Hall, Altrincham, and not by Messrs. Dickson, Brown & Tait, as reported in the Journal of November 23rd, 1882."

— A CAREER of great promise has been brought to a close by the sudden death, which we regret to announce, of Mr. JOHN SADLER, Curator of the Edinburgh Royal Botanic Gardens, which occurred on Saturday last, the 9th inst. Although Mr. Sadler had been unwell for some time nothing serious was apprehended until Thursday last, when for the first time he was unable to leave his bed. The cause of death has been certified as disease of the kidneys. Mr. Sadler was born at Gibbeston, Fifeshire, in 1837, and was consequently only forty-five years of age. His connection with the Royal Botanic Garden commenced in 1854, when, at seventeen years of age, he entered as junior assistant. He eventually became chief assistant to Dr. Balfour, Professor of Botany. This position he continued to hold until 1878, when he was appointed Curator on the death of Mr. M'Nab. He was also Curator of the new Royal Arboretum for Scotland. He acted for twenty-one years as Secretary to the Edinburgh Botanical Society, and was also Secretary of the Scottish Arboricultural Society for nineteen years, and on his retirement from these offices was presented with a gold watch and appendages, and a purse of a hundred sovereigns; also with a timepiece bearing a Latin inscription written by the late Sir Robert Christison, Bart., and a purse containing seventy-one sovereigns. He was a Councillor of the Royal Physical and the Royal Caledonian Horticultural Societies; President of the Edinburgh Fungus Club; a member of the Scottish Alpine Botanical Club, and Edinburgh Naturalists' Field Club. He was examiner in botany to the Edinburgh University Local Examination, and also for many years lecturer on botany in the Royal High School of Edinburgh. In 1869 Mr. Sadler was awarded the Neill prize of £50 by the Royal Caledonian Horticultural Society. Added to his industry and ability Mr. Sadler possessed an urbanity of demeanour which won for him hosts of friends, and his loss is deeply mourned by all who knew him. He leaves a widow and seven children, with whom much sympathy is felt in their great bereavement.

— A CORRESPONDENT, "REFULGENS," writes as follows on BUSH CHRYSANTHEMUMS AT LIVERPOOL:—"It is evident to anyone visiting the Chrysanthemum Show at Liverpool that the strong point of culture in the neighbourhood is the production of incurved blooms and closely trained specimen Pompons. I was surprised to see such poor examples grown and shown as bushes. They were the more conspicuous to me after seeing the fine plants that have been staged at Manchester during the past two or three years. The Manchester plants display a very high standard of cultivation. They do not average 3 feet in height, and are furnished with bold green foliage to the base, and each shoot terminates with a large well-formed flower that would not disgrace an exhibition stand of cut blooms. I hope this hint may induce the exhibitors of bush plants in Liverpool to exert themselves to grow and show these plants in creditable condition, so that this portion of their exhibition may not be the weakest feature as it has been during the past two years." [Our correspondent should show them how to do it, as he is a successful exhibitor.]

— A CORRESPONDENT writes:—"PHALLENOPSIS AMABILIS and P. SCHILLERIANA are quite at home and growing splendidly on blocks of wood in the stove at Wyncote, Allerton, under the charge of Mr. W. Mease. The pieces of wood are about 1 foot in circumference and about 18 inches high, and are stood on the trelliswork over a tank of water. The plants have been placed on the top of the wood with a little sphagnum moss, which is growing freely, and the roots are clinging to the wood, and could not possibly be doing better in any other position. The foliage is remarkably fine, and the flower spikes conspicuous for their strength."

— It will be useful to record the names of the SYNONYMOUS ROSES bracketed in the National Rose Society's catalogue, and

concerning which it was resolved at the annual meeting (see page 555) that only one of those too-much-alike varieties would be admitted in stands exhibited at the shows of the National Society, or those of Societies affiliated with them. The varieties are as follows:—*Hybrid Perpetuals*—Charles Lefebvre, Marguerite Brassac, and Paul Jamain; Duchesse de Caylus and Penelope Mayo; Eugénie Verdier and Marie Finger; Maréchal Vaillant and Avocat Duvivier; Marie Rady and Comtesse de Choiseuil; Maurice Bernardin, Exposition de Brie, Ferdinand de Lesseps, and Sir Garnet Wolseley; Monsieur Boncenne and Baron de Bonstettin; Prince Camille de Rohan and La Rosière. *Teas and Noisettes*—Adam and President; Chromatella and Cloth of Gold; Devoniensis and Climbing Devoniensis; Madame Bravy, Alba Rosea, Josephine Malton, and Madame de Sertot.

— ON the 11th inst. a meeting of the members of the DUNDEE HORTICULTURAL SOCIETY was held to consider the proposal in reference to holding an INTERNATIONAL SHOW in 1884. Provost Moncur presided, and there was a good attendance. It was stated that a number of gentlemen had guaranteed a fund to the amount of £125, which it was thought could be easily doubled, and it was agreed that not less than £1000 should be given in prize money. The proposition was duly seconded, and carried unanimously. We trust the project will be successfully carried out.

— A CORRESPONDENT has sent us three fruits of GENERAL GARFIELD TOMATO of enormous size and very ugly, not with the object of recommending the variety, however, but to show that outdoor-grown fruits approaching ripeness on the eve of winter will ripen when cut and hung in a warm room. He had preserved many bunches in this manner, and has now a good supply of Tomatoes. Those sent to us a fortnight ago have changed to a much brighter scarlet colour in our office, and they are of fair quality. This variety is described as requiring too much room, and is not sufficiently prolific for many cultivators.

— MR. G. J. SYMONS, F.R.S., 62, Camden Square, London N.W., requests us to publish the following note on BRITISH RAINFALL:—"I am just preparing to issue to all the observers of rainfall known to me blank forms for the entry of their records for the year shortly about to close. This staff now exceeds two thousand; but still, as they are not unfrequently rather clustered, there are many parts of the country where additional records are needed. I have no doubt that records are already kept in many places unknown to me, and I shall be glad if you will allow me to invite communications from anyone who has kept an accurate record, and to supply either those already observing or contemplating doing so with a copy of the rules adopted by British observers, and with all necessary blank forms—all, I may perhaps as well add, free of charge, as our greatest requirements are ample and accurate records." We shall be glad if those of our readers who are able to do so will co-operate with Mr. Symons in the work in which he has been so long, industriously, and usefully engaged.

— RELATIVE to TABLE PLANTS at the Brighton Aquarium Show, "AN OLD DECORATOR" writes:—"I believe it was quite as great a surprise to your correspondent to find himself placed first as it was to many others who visited the Show, numbers of whom expressed the opinion as published by your reporter. As to the attempted disparagement of the second-prize collection, I can say, after many years' experience in floral and table decorations, they were just the size I should select, as I should be extremely puzzled what to do with the very small plants staged by your correspondent." Another correspondent says the remarks in our report were quite justified, and our reporter assures us that the dissent of several persons against the awards were expressed very forcibly, while he "put the matter in the mildest possible form."

— RELATIVE to the WEIGHTS OF PEARS, it may be interesting to some of our readers to state that in the autumn of 1879 half a dozen Pitmaston Duchesse Pear trees in 9-inch pots were purchased, and grown on in the same pots under the care of Mr. William Bremner, gardener to Miss Wrigley, Wansfell, Windermere. There was a good crop, the three heaviest weighing 29½, 26½, and 24½ ozs. respectively.

— IN reference to MANURE FOR CHRYSANTHEMUMS, "B." writes:—"Last year I wanted a large supply of flowers; the pots were crammed with roots, and in order to carry them over the flowering season a mixture of manure and loam was applied to the surface of the soil. A little sulphate of ammonia was dissolved in the water given to them. This season similar treatment has been given the plants, and I am highly pleased with the results. In a root-crammed soil, such as that occupied by free-rooting plants, there is nothing fresh left for the roots to take to. The slight surface-dressing I imagine supplies this want to some extent, and to the benefit of the plant. With regard to a good late white I would be glad to have advice. We have had a bountiful supply of Elaine, and a later batch of the same to last till Christmas. Just now Fair Maid of Guernsey and Fleur de Marie are commencing to unfold their earliest blooms. Both, however, possess faults; the former not being so pure in the white as desired, and the latter wanting in the quality of floriferousness. Does anyone know a late variety with the good qualities of Elaine? I am glad to see La Nympe coming into notice. I recommended it highly a few years ago for furnishing purposes. Julia Lagravère is another kind well worth attention to the burdened flower-producer. Where a bronzy hue is liked, as it often is by ladies, General Bainbridge should be grown as the best. This kind is very productive of side shoots, which under good cultivation afford good blooms."

— "J. H. T." writes that "when being shown through the very fine and well-managed gardens at Knowsley Hall I was quite delighted with a very fine specimen of that grand old plant, LUCULIA GRATISSIMA, planted out against the back wall of a conservatory, covering a space of about 10 square feet with upwards of a hundred of its rose-coloured large terminal cymes of fragrant flowers."

— THE WEATHER IN THE METROPOLITAN DISTRICT has been quite of a wintery character during the past week. There have been no such falls of snow as have occurred over a wide extent of the country; indeed, the ground has scarcely been covered, and then only for an hour or two on the 6th inst., the greater quantity melting as it fell. Fogs have been prevalent, and sufficiently dense and prolonged to do considerable injury to Orchid and other flowers, and the ground has been hard with frost. Yet the mercury of the thermometer has not fallen below 22°, or 10° below freezing; but this occurring on several consecutive nights, and no thaw following during the day, has quite put a stop to planting and ground work generally, and much of this work remains to be completed. The weather yesterday (Wednesday) was much milder.

— "J. H." writes on STRAWBERRIES IN DECEMBER:—"At Chalcot House Gardens, Westbury, there is at the present time in one of the houses the best crop of ripe Strawberries of Vicomtesse Héricart de Thury it has ever been my good fortune to see at this time of the year. The batch consists of several dozens of plants growing in 7-inch pots, each plant carrying from thirty to fifty fruits in different stages of development. Those I had the pleasure of tasting were of good flavour and fair size, the largest weighing nearly half an ounce each. The plants were forced in the spring, and after having had a rest of a few weeks were shaken out and repotted in good turfy loam and well-decomposed manure, nothing further being required afterwards other than giving water when

necessary. The highly satisfactory results obtained reflect great credit on Mr. Davies the gardener."

— AT the next meeting of the METEOROLOGICAL SOCIETY, to be held at 25, Great George Street, Westminster, on Wednesday the 20th instant, at 7 P.M., the following papers will be read:—"Popular Weather Prognostics," by the Hon. R. Abrcromby, F.M.S., and M. Marriott, F.M.S.; "Report on the Phenological Observations for 1882," by the Rev. T. A. Preston, M.A., F.M.S. Mr. J. S. Dyason, F.M.S., will exhibit (1) a series of typical clouds in monochrome, and (2) a series of sketches of clouds in colour made in June, July, and August, 1882. As the list of officers and Council for the year 1883 will be prepared at the next Council meeting, it is requested that those Fellows who wish to suggest names for the new Council will send them in before the 20th instant.

CHRYSANTHEMUM KING OF THE CRIMSONS.

ALTHOUGH certificated a few weeks ago this is not a new variety as many suppose it to be. It has been in the neighbourhood of Liverpool probably about fifteen years, and I have known it for at least a dozen years. It is a handsome dark reflexed variety that might have been lost had it not been brought to the front this year. It has not been very largely grown about Liverpool during the past few years on account of the rage for incurved varieties, and very few collections include it at the present time, though undoubtedly it is one of the richest and best in cultivation for the conservatory and general decorative purposes.—W. BARDNEY.

YOUR editorial criticism on this flower on page 519 reminds me of the reply of the pert young lady in *Punch*, who when told to call a black beetle a cockroach because it was neither black nor a beetle, replied, "Oh! it is neither a cock nor a roach." However, let me say I did not write without authority, for in the catalogue of Mr. Davis of Camberwell, a large metropolitan vendor of Chrysanthemums, I find it classed under the new Japanese varieties with this observation:—"This magnificent variety, although not new, has on account of its scarceness been seldom offered to the public, although it is well known to the northern growers. In habit of growth and shape of flower it is similar to Julia Lagravère but three times the size, and the colour a most brilliant crimson—real crimson. It is called a reflexed flower, but it is quite as much a Japanese as Elaine, Triomphe de Nord, and many others highly recommended."—D., Deal.

[It would be interesting to know how long Mr. Davis has grown King of the Crimson, and whether he has produced blooms that warrant him in saying the variety is "quite as much a Japanese as Elaine and Triomphe de Nord." Good blooms of the varieties mentioned are out of place in a stand of reflexed flowers, while King of the Crimson has never been included in a stand of Japanese, nor, we venture to say, never will be without spoiling its effect or risking its disqualification. One of the finest blooms of the variety in question that has been exhibited was staged by Mr. Molyneux at Kingston in his first-prize stand of reflexed varieties. We grew King of the Crimson eighteen years ago, and that is our authority for saying it is not new, and the same experience has taught us it is a true reflexed and not a Japanese variety; indeed, we shall not be surprised to hear that it was raised long before the Japanese forms were known in this country.]

MUSCAT OF ALEXANDRIA GRAPES.

I WAS much interested with Mr. Bardney's account of the Muscats at Knowsley Hall. From what he says of them they must be very fine, and when in such grand condition will be a source of pleasure to all who are fortunate enough to see them.

A house of Muscats finished as these at Knowsley is something to be proud of at any time, and more especially in these times of comparatively sunless summers.

I can, however, hardly agree with Mr. Bardney when he suggests that the success attained with these Muscats is to be attributed to the roots being nearly all in sand. Of course nothing is better for making roots multiply, but if nothing else is supplied than sand poor results will assuredly follow. When spread on the surface of a border of good strong material sand is very beneficial, for if some of the roots are laid in it they rapidly increase in numbers, and then take possession of the loam, &c., that forms the border.

I have sometimes seen Muscats treated in the way Mr. Bardney refers to in regard to removing leaves to allow the sun to shine directly on the bunches. Such treatment often results in one side of the bunch being scorched into a brownish colour, and some of the berries reduced to raisins. I have invariably found that Muscats colour well under a considerable shade of leaves when not too heavily cropped, kept free from spider, given a good amount of heat, and fair ventilation.

The cool treatment has failed with me several times, and I have learned to consider it "penny wise and pound foolish." The difference between a house of Muscats such as Mr. Bardney describes, and one wherein the majority of the bunches have a green appearance, and shrivelling and shanking abound, is so great that any extra attention and outlay are amply repaid when a thoroughly finished crop is secured.—VITIS.

NORTHWARDS—KEIR.

Now that the autumn shows are over, and there is somewhat less pressure on the space of the Journal, I will endeavour to record a few memories of the past that were impressed during a pleasant week in September among the hills and gardens of "bonnie Scotland."

Leaving the great show at Edinburgh my first resting place was, through the kindness of Lady Susan Melville, in the old home of the Stirlings. The Stirlings of Keir date back from an early period. History records that in the reign of James VI. the Laird of Keir, Sir Archibald Stirling, had charge of the young Prince Henry in Stirling Castle, and in the reign of Charles I. and II. Sir George Stirling took an active part in those turbulent times, fighting as a Royalist under the Duke of Montrose. The last owner of Keir was Sir William Stirling-Maxwell, Bart., who assumed the latter name on succeeding to the Pollock estate. He died in Venice in 1878, but left behind him a monument of his accomplishments in literature and his taste in art in the library and chaste adornments of the mansion, with the beautiful and skilfully planted grounds surrounding. Three years previous to his decease his first wife, Lady Anna Maria, met with a dreadful accident by fire, which terminated fatally, and her two sons were placed under the guardianship of her sister, the distinguished lady above mentioned; the present Baronet, Sir John, being now about sixteen years of age. Under these circumstances Keir, as regards the high keeping of the grounds, is naturally not quite the same as when the late Baronet, who would appear to have made their planting and adornment a prominent occupation of his life, provided so liberally for the maintenance of every department of this fine estate. But let no one imagine that the pleasure grounds of some 60 acres, and containing thousands of Conifers, have run wild, or that the gardens are no longer enjoyable. On the contrary, a fair allowance is granted by the trustees to Mr. Russell, the gardener, whose twenty years of supervision have afforded him that experience which enables him to apply the means to the best possible advantage; and Keir is enjoyable still, and enjoyed by great numbers of visitors, for the grounds are generously opened to the public on one or two days a week throughout the summer; and the word "Salve," cut in the stonework over the gates, greets all comers with a "welcome"—this, it may be stated, in the unfortunate event of there being any readers less learned than the writer, being the English equivalent of the Latin inscription.

To describe in detail the various features of the grounds were impossible; they are far too numerous, diversified, and intricate, while the number of specimens, Conifers especially, almost bewilders; therefore nothing more will be attempted than a portrayal of the general character of the surroundings of this ancient Scottish home.

Only a mind at once fertile and original could have conceived the plans, and the possession of wealth executed them, that have resulted in work so prominent and unlike what is usually seen in gardens. *Keir* or *Caer* signifies a fort or castle, and this indicates that the position is elevated. In one respect it is, as it overlooks the Carse of Lecrop and Stirling; but higher still are the adjacent Ochils, notably Bencluch and Demyat, whose purple summits reach the clouds, while Ben Lomond, when thrown in relief by the setting sun, is seen towering majestically in the far-off distance. But the mansion though high is not on a lofty craig; it is reached by an easy gradient from the Bridge of Allan, about two miles distant. Some portions of the grounds quite close to the house are high above it, and it is this bold rugged surface-configuration that has afforded scope for the ingenuity that has been exercised by Sir William in contributing to their attractiveness and accessibility.

The first feature that arrests the attention of the visitor is the wealth of Conifers—Araucarias in hundreds, Irish Yews like sombre sentinels in thousands, Cupresses not only surrounding the

house as if with a forest, but trained up the building, producing an unique effect. The next feature is the masonry—admirably executed balustrades, with sunken paths flanked with Ivy-covered walls, terraces, vases, tunnels, bridges, and flights of steps leading from the lower to the higher portions of the grounds; yet there is nothing incongruous, as every part appears to have been designed for an useful purpose, and executed ornamentally, while the numerous trees, shrub-clad rocks, and evergreen hedges more than counterbalance the cold effect that masses of stonework too often produce. Then fine glades, avenues, and groves of Conifers with noble timber trees and charming vistas abound; indeed, at every point and turn there is something to admire.

The engraving shows Keir when the trees near the mansion were younger than they are now; but the Cypress-striped walls are apparent. The plants, now trees, employed, were brought home by Sir William when travelling in the East. On that account the species has been called *Cupressus orientalis*. This, however, is a fancy term, the true name being doubtless *C. sempervirens*, *Linn.*, or *C. fastigiata* of De Candolle—the Upright Roman Cypress, found in the south of Europe and Asia Minor. The specimens under notice are from 25 to 30 feet high, 18 inches in diameter at the base, tapering to the top. Being slightly cut occasionally they are close, round, and smooth, and, planted 4 to 5 feet apart on each side of the windows, have a remarkable effect.

The lawn in front of the house is crowded with splendid tapering specimens 40 to 50 feet high of the fastigate form of *C. macrocarpa* and *C. Lawsoniana*; indeed, they have obstructed the view so completely that it has been found necessary to remove some of them. The horizontal form, *C. Lambertiana*, is also represented, but not so numerously. This plantation of Cupresses extends round the western side of the building, and past it for a long distance, forming also a beautiful sheltering screen for the flower garden; many handsome specimens of *Thuioyses*, *Junipers*, *Araucarias*, and other choice lawn ornaments being interspersed with the Cupresses, a vase here and there of scarlet *Pelargoniums* appearing to have a more than usually bright effect in contrast with the great depth of surrounding foliage, and imparting cheerfulness to what would otherwise be a rather sombre picture.

On the opposite or eastern side of the flower garden is a wall 12 or 14 feet high and 400 or 500 feet long, covered from base to summit with *Cotoneaster microphylla*, not closely clinging to the surface, but in semi-wild luxuriance, the lower branches falling and rooting in the gravel walk, and affording young plants by the thousand. This wall supports the higher ground, and above the top of it runs an embraured hedge of Portugal Laurel, which has a striking effect. In the lawn space thus enclosed in a frame of deepest green there is not much danger of having flower beds too bright. These beds are simply four rows of large circles, two on each side of the lawn, linked together, and chiefly fitted with the brilliant *Tropæolum Vesuvius*, a small yellow floriferous *Viola*, and an effective dwarf *Ageratum Queen Victoria*. The alternations of the three colours as viewed from the mansion had a most pleasing effect, and not at all too bright for the position.

Near the end of the flower garden, distant from the mansion, is a bowling-green and tennis-ground of a decidedly out-of-the-way kind, and singularly striking. It is simply an oblong dish of considerable magnitude, the sloping sides of lawn being 8 or 10 feet deep. In this there is nothing remarkable; but along the top of what may be termed the upper terrace is a hedge of Golden Queen Holly cut square to the height of about 4 feet, and at intervals of about 6 feet the growth has been permitted to extend, and this in turn has been cut to form spires, square in form to correspond with the base, and tapering in a point some 10 feet high. Parallel with this extraordinary hedge, on a lower terrace, is a similar hedge of Yews. The appearance of these spires of foliage—gold and deepest green—arranged with almost mathematical precision is remarkable, beautiful alike in colour and stateliness, the general effect of the enclosure viewed from either above or below being probably unequalled in its way by any lawn-tennis ground in Great Britain.

We have yet to ascend to the higher grounds. Returning to the mansion two grand old centenarians attract notice—a Sycamore and Chestnut. These are reputed to be some four hundred years old, and are supposed to have been planted at the time of the erection of the mansion. They are still healthy and cared for, the great gaunt limbs of the former being supported by iron bands. But we pass on. The upper grounds are reached by flights of steps conducted up the face of rugged natural rocks, amongst which *Araucarias* and *Cupressus luxuriante* and spring from a groundwork of trailing plants and Ferns. Near the foot of the steps are specimens of *Cupressus Lawsoniana fastigiata*, planted by the Queen of Holland and the late Lord Beaconfield, and there

are other memorial trees planted by learned and notable visitors to Keir. Reaching the summit a straight terrace-walk and avenue of Irish Yews extends northwards, with an embasured hedge on the left as a dividing line between the upper and lower portions of the pleasure grounds. Parallel with this, but still higher, is another walk of a similar character, with at intervals memorial urns and entablatures in memory of departed friends. The upper walk leads to the kitchen garden, which is entered by massive gates from original designs by Sir William, the lower conducting to a range of glass, 300 feet long, erected against the kitchen garden wall, and facing the pleasure grounds. From here is, or was, seen what was for years regarded by many as the pride of Keir, a grand old Araucaria, a noble specimen about 50 feet high, excellently furnished and very handsome; but it fell a prey to the ruthless storms of the past few years, having been uprooted, laid low, and replanted three times—its fate was sealed, and it is probably now removed to give place to a younger specimen, of which there are plenty of beautiful examples in the grounds. Before another is planted the rock will be excavated to afford a

greater depth of soil, and had this been done originally the noble tree referred to would have doubtless yet been standing where it has stood so long and been so greatly admired. In this part of the grounds, too, which is of a less formal character, some fine Larches are prized, not so much for their size, which, however, is considerable, but because they are considered to rank with the oldest in Scotland. The oldest, as being the first introduced, are at Dunkeld, and the "story goes" that when the original trees reached their destination it was found a few were missing, and as the consignment passed Keir it is supposed that by accident or "otherwise" the missing trees found refuge there, and there they remain. Be this as it may, they are noble specimens, and worthy of being prized by the family.

"Vistas" have been mentioned as a feature of Keir. There are several worth note, but only one can be particularised. The rock on which Stirling Castle stands rises rugged and bold out of the centre of a low flat plain, and this commanding old fortress is an historical landmark, of which there are so many, but none more pronounced, in this romantic district. Well, from the umbrageous

Fig. 93.—KEIR HOUSE.

recesses of the Keir pleasure grounds a tunnel has been cut through the trees, pointing directly to and on the same level with Stirling Castle. This is the terminal point—nothing else is seen, nor nothing else is wanted, for no terrestrial telescopic view can be imagined more interesting. "But why mention it?" some may say, "there is only *one* Stirling Castle, and the view cannot be imitated or reproduced!" True, but the question suggests itself—Are there not other hidden objects, historic or picturesque, that with a little thought and labour might be revealed and brought within the range of vision, adding greatly to the interest of the site from which they might be viewed? There are many, but not thought of. Let one example be given; it may perhaps be called a child of Keir, for it is scarcely conceivable that any other spectacle could have led to it. Most persons have heard of Lincoln Cathedral, and those who have seen it will grant there are few edifices of the kind that are externally more imposing. Four miles from Lincoln is the residence of Mr. Alexander Leslie Melville, a near relative of Lady Susan Melville, this residence being enclosed with plantations, but on or about the level with the grand old building mentioned. From the front doorstep of Longhills Mr. Melville has produced what, to an artist, is worth a journey to see; for he will see in the far distance, as if through

a living telescope—and he will see nothing else—Lincoln Cathedral clear and well defined. It is a charming picture, nothing on the estate being half so attractive to visitors, and yet it has cost little to produce. The trees were at one end, the building at the other, and only the woodman's axe and the artist's eye were needed to do what has been done so well; yet for years this matter was never thought of, and possibly never would have been but for the example referred to by Sir William Stirling Maxwell. The Keir and Stirling Castle vista, therefore, is worth mentioning, as, peradventure, it may induce others to consider if something of the same kind cannot be effected, and thus make some of the beautiful homes of Albion more admired still by their owners, guests, and visitors. Let the matter be pondered over by those who are interested in striking landscape effects, and who are seeking to reveal features of interest and beauty near, yet hidden by something that could with advantage be removed.

"Avenues," too, have been mentioned. There are Deodar avenues, mixed Pine avenues, Cypress avenues that have not yet been alluded to at Keir; nor can they be more than mentioned. There are specimens that merit notice that must be passed—*Pinus monticola* 40 to 50 feet high; *P. insignis*, one of the few examples of mature age that have survived the late severe winters

of the north; *Abies Morinda* 30 to 40 feet, with its elegant weeping branches; *A. Webbiana*, bearing its grand purple cones, but the growths injured, nearly always, by spring frosts, which spoil the symmetry of the tree; and in similar condition is *A. Pindrow*, the Indian Silver Fir. These must be passed, but a curving avenue of Lawson's Cypress may be followed, because it leads to something worth notice near another entrance to the grounds. On each side of the gates here Irish Yews were planted several years ago, and are now amongst the most striking ornaments of the pleasure grounds. They are 10 to 12 feet high, but only the lower portion to the height of 3 or 4 feet are of the typical form, the remaining 5 or 6 feet being the Golden Yew in splendid colours, and by a little timely pinching the fastigate character of the Irish Yew is maintained throughout. Very little trimming, however, is needed for effecting this, as the stock appears to have a decided influence on the scion or grafted portion, and renders its growth conspicuously upright and close. These Yews, like golden pillars on dark pedestals, are splendid objects. They were obtained from the continent, where they are prepared in larger numbers than in the nurseries of this country. In Mr. Charles Van Geert's interesting grounds at Calmpthout, a few miles from Antwerp, numbers of Irish Yews are grafted with various golden forms, some upright, some weeping; and years hence when they have developed their character they will be admired wherever they are, as these noteworthy Keir examples are admired now, and it seems almost a pity there are not more of them.

Many other fine examples of various Conifers must be passed, and the concluding note on the pleasure grounds have reference to a characteristic example of the taste of Sir William in the disposition of the grounds. In front of the Yew Temple is the following motto in Box edging:—"Homo quasi flos egreditur et conteritur," which may be freely interpreted—"Man like a flower passes away and is spent." The letters are large, 2 or 3 feet high, and clear, sloping outwards, forming the outer rim of a large circle. Mottoes of the same character abound at Keir indoors as well as out, especially round the cornices of the rooms; but these can be no further alluded to here, nor can the Fern dells and cascades, the deep ravines and bowery wilderness walks, and only a line or two can be devoted to the glass structures and kitchen gardens.

In reaching this department to the mansion we pass through a tunnel of masonry—not a mere low narrow archway, where persons must stoop to save their hats and squeeze in passing to guard their elbows from abrasion—but a work of magnitude, through which a load of hay could pass if needed; and the road, if the curve to the left is followed, ascends and twists corkscrew fashion until the higher level of the garden is reached. This is a large walled enclosure. The fruit trees, old and large, on the walls seldom bear; but the late owner prized the trees as trees, caring little whether they produced fruit or not: therefore they had to remain, and in all probability will remain for some time, because he cherished them. Vegetables are grown the same as other vegetables in other gardens, and that remark must suffice, the marginal flower borders containing old-fashioned plants, one of which, because seldom met with, demands notice. The flowers are so singular and attractive that everyone who sees it wants a spike and a slip: but for particulars see the figure of *Linaria vulgaris* var. *Peloria* on page 543.

A span-roofed range 200 feet long is devoted to plants, but they are not so much prized as formerly, nor is there the same time devoted to them; but there are several good Orchids and Ferns, with other plants for yielding flowers for cutting. The vinery range, 300 feet long, is, as above stated, outside the garden. During the last few years nearly the whole length has been replanted, and heavy crops of excellent Grapes are now produced. By special desire the Black Hamburgs were obtained from the Hampton Court Vine; but one original Vine, now some eighty years old, was retained in the house. On the young Vines fruiting it was found that the Grapes were not nearly so rich as those of the "old sort;" so some grafts of this were attached to the younger Vines, and on rods of both sorts of the same age and side by side there is a marked difference in the quality of the fruit, the old Keir variety being far superior to the new comer both in firmness of flesh and richness of flavour. Whether its superiority will be maintained under other conditions remains to be proved, and with this object a young Vine has been sent to the Royal Horticultural Society's gardens at Chiswick, where it will be compared with other varieties of the Black Hamburg that are there established. It only remains to say that old Peach trees in this range bear heavy crops, that young trees of newer varieties are planted, and a grand plant of Gloire de Dijon Rose on the back wall of one of the houses gives thousands of blooms annually; and that

the cordial welcome accorded me by Lady Susan Melville and the young laird, with the extreme kindness of the trusted persons in charge of the establishment, Mrs. Cairns, Mr. Sadler, and Mr. Russell, rendered my visit peculiarly enjoyable, and the recollection of it now constitutes one of the brightest of the sunny memories of the year.—J. WRIGHT.

LIBONIA FLORIBUNDA.

THIS is one of the most serviceable decorative plants for this season of the year that we have in cultivation. Anyone having an ordinary forcing pit or hotbed to enable them to strike the cuttings early in the spring, with a cold frame to grow them in through the summer months, can have useful plants of one summer's growth fit for room-decoration during the dull months of winter. The cuttings root freely, and the plants make rapid growth when properly attended to.

The compost suitable to strike cuttings in is loam, peat, and silver sand in about equal proportions, and the same compost will do equally well to grow them in afterwards. We have plants at present of two years' growth, which are flowering most profusely, and are admired by all who see them. This plant is well known, but often very badly managed by being kept in too high a temperature. Our best plants at the present time were out of doors on a bed of ashes all the past summer.—LEADENHAM.

ROYAL HORTICULTURAL SOCIETY.

DECEMBER 12TH.

THE last meeting of the year was not largely attended either by members of the Committees or by exhibitors; and with the exception of the plants from Holloway, the flowers from Swanley, and the Apples from Elvaston there was comparatively little of special note.

FRUIT COMMITTEE.—Harry J. Veitch, Esq., in the chair. Three bunches of Gros Colman Grapes were sent from Chiswick, the berries large and the colour good. They were brought to show the difference in flavour from different houses, those from the conservatory being extremely good, while some bunches from another house were much inferior in flavour. A cultural commendation was awarded to Mr. Hudson, gardener to H. J. Atkinson, Esq., Gunnersbury House, Acton, for fine handsome bunches of Black Alicante Grapes extremely well coloured; also two good Pine Apples, Lord Carrington and Smooth Cayenne, large, even, and well ripened. A vote of thanks was awarded to Mr. Mann, gardener, St. Vincent's, Grantham, for a dozen dishes of Apples in very good condition; Warner's King, Blenheim Pippin, Worcester Pearmain, Lord Lennox, Pike's Pearmain, and Bramley's Seedling being particularly fine. Two seedling Apples were also sent by Mr. Mann, one named Grantonian and the other Baron Wolseley; the latter considered not superior to others, the former to be kept at Chiswick and brought again in April.

A bronze medal was awarded to Mr. Goodacre, The Gardens, Elvaston Castle, Derby, for a collection of about eighty dishes of Apples comprising a large number of varieties, the fruit mostly in excellent condition and of fair size. Very notable were Nelson's Glory, Golden Noble, Blenheim Pippin, Alfriston, Waltham Seedling, Lady Henniker, Court Pendu Plat, Hollandbury, Warner's King, and Ecklinville Seedling. Mr. Gilbert, The Gardens, Burghley, Stamford, sent a dish of a small Apple, which was determined to be the Early Nonpareil. Messrs. J. Dickson & Sons, Newton Nurseries, Chester, exhibited two seedling Apples named Favourite and Masterpiece, both of which were passed. Mr. H. E. Eckford, The Gardens, Boreatton Park, Shrewsbury, sent six dishes of seedling Potatoes, concerning which no opinion was expressed. Messrs. Thomas Laxton and Sons, Bedford, sent some seedling Apples; one, a cross between Nonpareil and Stamford Pippin, being considered promising. The others were passed.

At the conclusion of the meeting Mr. John Lec proposed a vote of thanks to Mr. H. J. Veitch for his services as Chairman during the past year.

Messrs. James Carter & Co., High Holborn, offered prizes for a collection of twelve varieties of vegetables, three competitors appearing and staging very creditable examples. Mr. H. Marriott, Prospect House, Skerbeck, Boston, took the lead with clean specimens of Golden Globe Onions, Carentan Leeks, Veitch's Autumn Giant Cucumbers, Maltese Parsnips, Improved Magnum Bonum Potatoes, Perfection Brussels Sprouts, Silver Ball Onions, Major Clarke's Red Celery, Long Surrey Carrots, Golden Queen Onions, Perfection Beet, and Jersey Lily Turnips. Mr. E. Summers, gardener to the Earl of Scarborough, Sandbeck Park, Rotherham, was awarded the second prize for a good collection.

FLORAL COMMITTEE.—Mr. B. S. Williams in the chair. A vote of thanks was accorded to Messrs. H. Cannell & Sons, Swanley, for very beautiful and tastefully arranged collections of single and double Pelargoniums, Salvias, and Heliotropes. A basket of the new double blush *Bouvardia* President Garfield was also shown, the blooms being similar to Alfred Neuner in form, but of a delicate pale pink hue.

Among the double Zonal Pelargoniums the following were very notable:—General Campinon, very dark scarlet; Lord Mayor, bright pink; Gambetta, rich scarlet; La Quintinie, white; and Henri Cannell, purplish crimson. The best of the single varieties were W. B. Miller, deep scarlet; Eureka, white; Eurydice, purple-pink, white centre; Guinea, very brilliant scarlet; Dr. Orton, intensely dark scarlet; Kate Farmer, salmon scarlet, very large; Constance, pale pink; and K. Greenaway, good pink, white centre. The Salvias included the brilliant blue S. Pitcheri, the scarlet S. splendens Bruantii, the mauve S. leucantha, the purple S. Bethelli, and the scarlet and white-striped S. Mons. Issanchou. A vote of thanks was accorded to Mr. James Waddell, Shenley House, Stony Stratford, for two plants of a sweet-scented variety of *Odontoglossum Alexandrae*.

Mr. B. S. Williams, Upper Holloway, was awarded a silver medal for extensive groups of Primulas and Cyclamens, representing his special strains. Red and white Primulas, with white, rose, purple, and crimson Cyclamens, were shown in very satisfactory condition; the plants healthy, the flowers large, and the colours bright and clear. A vote of thanks was accorded to Mr. Todman, gardener to G. Connell, Esq., Bushy Down, Tooting Common, for a collection of seedling Pelargonium flowers and two hybrid Azaleas. Of the latter, one named Mrs. Tom Corbett had white flowers, larger than the amœna type, but smaller than the indica varieties, the President Goodheart having flowers of similar form and size, but bright red in colour. As early-flowering varieties requiring very little forcing these are very useful.

First-class certificates were awarded to the following plants:—

Chrysanthemum Duchess of Albany (Jackson & Son).—A Japanese variety, with narrow irregularly cut florets, bronzy yellow, blooms full and of great size.

Chrysanthemum Ceres (Jackson & Son).—Also a Japanese variety, with white florets something like Elaine, but much larger and the bloom looser.

Acroclinium roseum flore-pleno (J. C. Schmidt, Erfurt).—A double form of this well-known plant, of a most delicate soft rosy hue.

Acroclinium album flore-pleno (Schmidt).—Similar to the above, but the blooms are pure white.

Pescatorea Vervaeii (Vervae & Co., Ghent).—An unattractive Orchid, with flowers of moderate size, the sepals and petals white, tipped with purple; the lip of a similar purple colour.

Cosmos bipinnatus var. parviflorus (Royal Horticultural Society).—The flowers individually are not so attractive as the species, being of a rosy purple tint; but the chief merit of the plant consists in its floriferousness, which renders it useful for decorative purposes. The plants were shown in pots, and a second-class certificate was awarded for it.

SCIENTIFIC COMMITTEE.—Sir J. D. Hooker, K.C.S.I., in the chair. Some discussion took place with reference to the reports on losses of plants during severe winters, compiled by the Secretary. Much regret was felt at the reply from the Council that the Society is unable to publish it, as great disappointment has been expressed by many of those who, at considerable trouble and pains, had contributed to the reports.

Fasciation.—Dr. Masters exhibited a specimen of fasciated flower heads of *Helichrysum*, or "Everlastings." He also exhibited from Mr. Veitch a flowering stem of *Eucharis* provided with a leafy bract—a very unusual condition. This being the last meeting of the year a vote of thanks was offered by Mr. Maclachlan, and seconded by Mr. Grote, to the Chairman, which was responded to by Sir J. D. Hooker.

LECTURE.—The Rev. G. Henslow illustrated by several examples the power of plants to render themselves attractive with bright colours independently of, or in addition to, the corolla. This was principally attained by means of the bracts. A beautiful series of Salvias, exhibited by Mr. Cannell, showed how the bracts and calyx, both being unusually green in flowers, could become brilliantly coloured, and so intensify the beauty of the spray. An *Acroclinium*, a kind of "Everlasting" from West Australia, showed how the bracts of the involucre surrounding the florets could mimic a true flower. In this plant the chaffy scales interspersed amongst the florets contributed to that same effect. Bracts might thus either enhance the general colouring of an inflorescence, or actually assume the appearance of a flower. Mr. Henslow further illustrated this by dried specimens and drawings of *Poinsettia*, *Lycesteria*, *Epiphyllum* on the one hand, while *Bupleurum*, *Cornus*, *Darwinia*, and *Euphorbia jacquiniæfolia* were exact imitations of true flowers on the other.

CELERY IN WINTER AND SPRING.

WHERE a regular and good supply of vegetables has to be maintained throughout the winter Celery must be grown in quantity for daily use, and during the next three or four months it will require some attention to keep it in a sound fresh state. It is a well-known fact that there are innumerable rows of Celery destroyed every winter through damp and frost, but the chief cause of this is having the plants too forward. In many instances the seed is sown in April and May, the plants are turned out in June and July. By October they are fully grown, then decay commences with the first wet or frost. I have nothing, however, to say against having Celery ready in autumn, but it is through

expecting the autumn stock to keep up the supply throughout the winter and spring that the mistake is made. Winter and spring crops should be grown specially for those seasons. The seed for these should not be sown early, as if good plants are placed in the trenches in August that is quite early enough. Earthing up those late crops should never be done until the plants have made considerable progress, as one of the chief sources of decay in winter Celery is earthing up too much, and at this season it is much better to use sand or ashes for this purpose than the soil.

Apart from growing winter and spring Celery in trenches, equally good and sounder heads may be secured by planting out on the level ground and never disturbing the earth around them, but blanch the stems by placing refuse ashes between them. One of the finest pieces of winter Celery I have seen was treated in this way, and the blanching material was chiefly shavings and mortar rubbish. The shavings protected the plants from the frost, and there was not one in fifty decayed. When anything of this kind is used for blanching, or even sand and ashes, it is rarely necessary to add any other protection in severe weather; and this is an advantage well worth attention, as there is nothing more liable to cause the centres of tender blanched Celery to decay than having the tops covered with straw or fern. Our Celery for autumn use was earthed up finally early in October; that for using in the new year has just had the last application of ashes placed round it; and the latest spring plantation has had nothing round it yet, but the growth is robust, and so hardy that severe weather will do it little or no harm. About one month before it is wanted some blanching material will be put about it, and it will then turn out much sounder and better flavoured than if earthed in autumn. Red Celery has always proved better able to resist the weather, and not so liable to become spongy in the stems as the white varieties, and I recommend red Celeries alone for midwinter and spring use.—A KITCHEN GARDENER.

CUNNINGHAMIA SINENSIS.

SIMILARLY to the Araucarias recently noted, *Cunninghamia sinensis* may be considered as a living memento of the earlier ages of the world, and the striking resemblance borne by this Conifer to one species of *Araucaria*, *A. brasiliensis*, has given rise to some confusion which may be easily removed. First as to the names with which this *Cunninghamia* has been doubtfully honoured, and the history of its introduction. Under the cognomen *Pinus lanceolata* we find some of the earliest references to it, one of the most noteworthy being in Aiton's "Hortus Kewensis," where it is recorded that the plant was first received at Kew in 1804 from China, having been introduced by the Directors of the East India Company through Mr. William Kerr. *Belis jaculifolia*, *Cunninghamia lanceolata*, and *Araucaria lanceolata* are some of the other titles which it has received at the hands of different writers, the first generic name being rejected as too much like *Bellis*, and the last name is of garden origin. The accepted generic name was given to "Commemorate the merits of James Cunningham, an excellent observer in his time, by whom this plant was discovered, and in honour of Mr. Allan Cunningham, the very deserving botanist who accompanied Mr. Oxley in his first expedition into the interior of New South Wales, and Captain King in all his voyages of survey of the coasts of New Holland." The specific name formerly adopted (*lanceolata*) referred to the shape of the leaves, while that now accepted (*sinensis*) denotes the native country of the tree.

As already stated, in habit this *Cunninghamia* closely resembles *Araucaria brasiliensis*. The leaves are tapering and 2 or 3 inches long, but they are less rigid than those of the *Araucaria*. The cones, too, are quite distinct, those of the *Cunninghamia* being of a reddish tint, the scales regularly and deeply serrated. It is rather curious that when these were first observed they were considered to be excrescences or galls caused by the attacks of insects. The tree attains a height of 30 to 40 feet in China and Japan, but it is seldom seen so large as that in England; indeed, for many years it was grown under glass, as too tender to endure exposure in the open air. According to Loudon, however, "in 1816 a plant was turned out into a sheltered part of the pleasure ground at Claremont, where it continued to live without protection, and, though injured more or less by severe winters, it was in 1837 18 feet high, the diameter of the trunk 7 inches, and of the head 16 feet. This height it had not exceeded in 1841 in consequence of the top being frequently broken by heavy falls of snow." In 1828 there were plants of this *Cunninghamia* at Dropmore, then about 10 feet high, having been introduced in 1823 and only slightly protected, as was also *Araucaria imbricata*, which, though believed to be hardy, had not been trusted out of doors without

protection. Plants had also been raised from cuttings and were succeeding well not only at Dropmore but elsewhere, as in Loudon's "Gardener's Magazine" for 1827 Mr. Stewart Murray, Curator of the Glasgow Botanic Gardens, wrote as follows:—"In this garden were two plants of *Cunninghamia lanceolata* 2 to 3 feet high, struck from cuttings several years ago, and although in very luxuriant health, the tops still retained the appearance of a branch which even when tied up to a stake always seemed as if endeavouring to regain its horizontal position. During the winter of 1825 I loosed the top of one from its stake, and fastened it down in quite a horizontal direction. In about six weeks afterwards a very vigorous shoot made its appearance from below the surface of the earth in the pot. When the shoot had attained the height of 8 or 9 inches I cut away the old top entirely, and at this

time the plant is nearly 2 feet high, furnished all round with three tiers of regular horizontal branches. One year after I repeated the experiment upon my other plant, and with similar success."

It is regrettable, however, that few handsome specimens of this Conifer are seen in gardens, and unfortunately severe frosts often greatly injure its appearance, browning the foliage without killing the tree. Still some good examples are included in a few collections, amongst which may be mentioned Dropmore, and the Duke of Hamilton's estate, Brodick Castle, Island of Arran. Rev. David Landsborough informs me that a specimen said to be over twenty-five years old is still living in the last-mentioned garden, and has never been protected, and though browned by the winter of 1880-81 it was not otherwise injured. Quite recently there

Fig. 94.—*CUNNINGHAMIA SINENSIS*.

was also a large tree fully 30 feet high at Aberpergwm, Neath, the seat of Mr. Williams, and several others have been noted in the Journal. Small specimens 6 to 10 feet high are very attractive, and in a sheltered position they are decidedly handsome, the growths assuming a pleasing purplish tint. In pots for conservatories or planted in winter gardens it is well worth a little attention to insure healthy growth. A substantial but not too heavy loam is the best suited for it, and it may be increased either by seeds or cuttings. The engraving (fig. 94) represents a tree of good size, and shows the habit well.

It may be added that *Cunninghamia sinensis* is found in the south of China, and that it is cultivated in Japan, where some specimens have been observed of such a size as almost to lead to the belief that they were natives; however, that appears is not

the case, as wild specimens are not found in Japan now. This is the only species known, as *C. selaginoides* and *C. cupressoides* are now referred to the genus *Athrotaxis*.

In reference to the history of *Araucaria Bidwilli*, which has recently been discussed, Professor Thiselton Dyer writes me as follows:—"The remarks I made with regard to the *Araucaria* in the temperate house at Kew were on the authority of Sir Joseph Hooker, who tells me that he repeatedly heard the story from his father, Sir W. Hooker. There seems to be no doubt that there was a specimen at Syon, but as they could not afford the space for its development that we are able to give it I understand it became unhealthy and was thrown away. We have two trees in the winter garden not very different apparently in age or size. Mr. Smith's letter may refer to one of these and Sir Joseph's anecdote to the

other. The two stories may not, therefore, disagree." I suggested this explanation to Mr. Smith some time since, but he states that there is no doubt the specimen he took there was the first, and that others were not received until some time afterwards.—
L. CASTLE.

NATIONAL ROSE SOCIETY.

ANNUAL GENERAL MEETING.

ON Thursday last, December 7th, twenty-two members of the above Society assembled at the rooms of the Horticultural Club, Ashley's Hotel, Henrietta Street, Covent Garden; and considering the extremely unfavourable weather the muster was uncommonly good, including the following:—Dr. Robert Hogg, Rev. H. H. D'Ombraïn (Hon. Sec.), Rev. Alan Cheales, Rev. H. A. Berners, Capt. Christy, E. R. Whitwell, B. R. Cant, Cecil E. Cant, G. W. Piper, Arthur Turner, Charles E. Cuthell, H. H. French, George Paul, E. Wilkins, W. J. Grant, W. Farren, George P. Hawtrey, J. D. Pawle, John Laing, C. F. Hore, H. Appleby, G. Prince, and E. Mawley (Hon. Sec.). Dr. Hogg took the chair at 3 P.M., and the proceedings were commenced by Mr. E. Mawley reading the circular calling the meeting; and on the proposition of the Chairman the minutes of the last annual meeting were taken as read. After Messrs. B. R. Cant and J. D. Pawle had been appointed scrutineers of the ballot for election of officers and Committee the Rev. H. H. D'Ombraïn read the following report and financial statement.

IN presenting this Report the Committee have much pleasure in expressing their satisfaction with the progress that has been made by the Society during the past year. The Exhibition held in the conservatory and arcades of the Royal Horticultural Gardens in July besides being, all things considered, the best Rose show which the Society has yet held, was also as regards the number of exhibits unquestionably the largest exhibition of the kind ever seen in this or any other country. The Exhibitions at Bath and Darlington, both of which were attended by a very large number of visitors, were also in every way successful.

The Committee record with pleasure the completion of the Society's "Catalogue of Exhibition Roses." This undertaking, although more arduous and costly than was at first anticipated, will no doubt prove of great service to their members as well as to others interested in Rose culture. In order to show the general approval with which this Catalogue has been received, it need only be stated that the demand for it has been so much larger than had been thought probable that almost all the extra copies printed for sale have been already disposed of.

In the course of the year a question of a somewhat difficult nature was brought before the Committee—viz., as to the meaning of the term "amateur" as used in the Society's schedules. After careful consideration the conclusion was come to, that as it would be almost impossible to draw up any precise definition which would equitably meet every case that might arise, it would therefore be better for the Committee to decide on each case that might come before it upon its own merits. For the guidance of exhibitors they wish it, however, to be clearly understood that in their opinion no person who traffics in either plants or flowers ought to be considered an amateur.

It is a source of much congratulation that the Committee are enabled to announce, that notwithstanding the removal of their principal Exhibition from the Crystal Palace (in the neighbourhood of which they have a large number of subscribers) to South Kensington, the list of members shows a larger increase than in almost any previous year.

Financial Statement.—It will be recollected that the Society commenced the past year with a balance in hand of £97 9s. 4d., and that it was thought likely that this amount would be very considerably reduced by the unusually heavy expenditure anticipated in the current year. Owing, however, to the increased number of subscriptions received, there still remains a balance in the Treasurer's hands of £53 3s. 4d.

The Committee cannot refer to the subject of finance without expressing their deep regret at the loss the Society has sustained in the death of their esteemed Treasurer, Mr. William Scott, who had almost from its first establishment so zealously acted in its behalf. This death having occurred after the last annual general meeting had been held, temporary arrangements were made with his assistant, Mr. George Lambert, for the fulfilment of the duties of the treasurership until a new Treasurer should be elected. They now with pleasure announce that this office has been accepted by Mr. T. B. Haywood, President of the Reigate Rose Association, a gentleman well known as a successful rosarian, and one to whom the Committee entrust the financial interests of the Society with entire confidence.

Affiliated Societies.—The arrangements made with regard to affiliated societies last year appear to have given very general satisfaction. Several new societies having during the year become affiliated, there are at the present time no fewer than twenty-one societies wholly or in great part Rose societies in connection with it; and the Committee are happy to state that as the rules and regulations of the National Rose Society have been adopted by most of them, its influence has in this way been considerably extended.

Arrangements for 1883.—As the Exhibition at South Kensington was so great a success, the Committee have felt justified in again entering into negotiations with the Council of the Royal Horticultural Society for holding their metropolitan show at the same place and on similar terms in 1883. Several towns have solicited the Committee to hold their provincial meeting in their midst—viz., Sheffield, Manchester, Birmingham, and Sutton Coldfield; and after due consideration Sheffield has been selected, owing to its priority of application, and to the very hearty and liberal manner in which the Society was welcomed there in 1881. The invitation to again hold an exhibition at Darlington next year was with some reluctance declined, the Committee considering that the northern and midland growers would have an opportunity of exhibiting at the Society's provincial show, which it had previously been arranged should take place at Sheffield in the next county. So as to meet the wishes of exhibitors residing in the southern and south-western counties, arrangements have been entered into with the Royal Southampton Horticultural Society to hold a third exhibition there early in the season.

Members' Privileges.—Members subscribing £1 will be entitled to two private view tickets and also to four transferable tickets, admitting at the same time as the general public. Those subscribing 10s. are entitled to one private view ticket and also to two transferable tickets admitting at the same time as the general public. All these tickets are available for either one of the Society's exhibitions.

To exhibitors pass tickets will be given with their show cards, enabling them to leave and return to the place of exhibition at any time during the day.

The Committee, while again tendering their thanks to the Local Secretaries for their valuable aid, would impress upon them and their members generally, that although much has been done, yet that much remains to do, especially in endeavouring to increase the number of members, of whom there are at present only 390; and they would earnestly appeal to all their friends to work heartily and energetically for the Society in the coming year. They also desire particularly to thank Mr. E. R. Whitwell for having so successfully carried out the details of the late Darlington Show, and Mr. R. B. Cater, who contributed so much towards the success of the Bath Exhibition.

BALANCE SHEET FOR THE YEAR ENDING 30TH NOVEMBER, 1882.

RECEIPTS.		£	s.	d.
Balance in hand and at Bankers 30th November, 1881.....		97	9	4
Subscriptions received	273	9	0	
Donations to Society	5	0	0	
" Special money prizes	4	0	0	
Affiliation Fees and for Medals from Local Rose Societies	36	15	0	
Entrance Fees	10	0	0	
From Bath	105	0	0

Examined and found correct.

GEORGE P. HAWTREY, } Auditors.
GEORGE PAUL, }
GEORGE LAMBERT, Hon. Treasurer, pro. tem.

The Chairman submitted the above report to the meeting, and it was proposed by Mr. E. R. Whitwell and seconded by Mr. George Paul, that the report and financial statement be adopted, printed, and circulated, which was carried. Some discussion then took place as to the advisability of reprinting the Catalogue of Roses issued by the Society, the first edition of which is very nearly exhausted; but it was finally concluded that it would be inadvisable to adopt this course until a sufficient time had elapsed to warrant the issue of an entirely new edition. It was, however, unanimously resolved that the paragraph in the above-mentioned catalogue to the effect that two or more Roses bracketed together in that list as too much alike should not be exhibited in one stand, should apply not only to all the National Rose Society's shows, but also to the exhibitions of societies affiliated to the parent Society during the ensuing year. The paragraph in the Report in

*Exclusive of the special prizes presented by members and others.

reference to the meaning of the term amateur was also considered satisfactory. Several localities were named, but no decision was come to as to where the Society's provincial Exhibition in 1884 should be held. The members present were, however, requested to make it generally known that the Society were seeking a suitable town in which to hold a Rose show in that year. Letters were read from G. Baker, Esq., Vice-President, T. B. Haywood, Esq., Hon. Treasurer, and the Rev. J. A. Williams regretting their inability to be present at the meeting. Cordial votes of thanks were then proposed and carried unanimously to the Chairman, Dr. Hogg; the Honorary Secretaries, the Rev. H. H. D'Ombraim and Mr. E. Mawley; the Treasurer during the past year, Mr. G. Lambert; the Committee; and the Horticultural Club for the use of their rooms, which brought the proceedings to a close.

The following is the list of Committee and Officers elected for 1883. Those preceded by an asterisk are new members. *President*: the Rev. Canon Holc. *Vice-Presidents*: George Baker, the Hon. and Rev. J. T. Boscawen, James McIntosh, the Mayor of Sheffield. *General Committee*: H. Appleby, R. N. G. Baker, *Rev. H. A. Berners, Rev. H. B. Biron, *R. Bloxam, T. F. Burnaby-Atkins, Rev. J. B. M. Camm, B. R. Cant, R. B. Cater, Rev. A. Cheales, Captain Christy, J. Cranston, H. Curtis, J. Cutbush, C. E. Cuthell, C. Davies, Rev. E. L. Fellowes, *H. H. French, Rev. J. M. Fuller, Rev. F. H. Gall, T. Gravely, *Rev. R. C. Griffiths, T. B. Hall, G. P. Hawtrey, *J. Shirley Hibberd, R. Hogg, LL.D., C. F. Hore, *J. House, J. Laing, M. T. Masters, F.R.S., W. Mount, G. Paul, W. Paul, J. D. Pawle, Rev. J. H. Pemberton, Rev. E. N. Pochin, G. Prince, T. F. Rivers, W. Robinson, J. Sargent, *A. Slaughter, J. Tinsley, A. Turner, C. Turner, H. J. Veitch, *J. Wakeley, E. R. Whitwell, *E. Wilkins, *Rev. J. A. Williams. *Auditors*: G. P. Hawtrey and George Paul. *Hon. Secretaries*: the Rev. H. Honeywood D'Ombraim, Edward Mawley. *Hon. Treasurer*: Thomas Burt Haywood.

In the evening the fifth annual dinner of the Society was held and well attended, Hon. and Rev. J. T. Boscawen in the chair, Dr. Hogg occupying the vice chair.

GROWING CHRYSANTHEMUMS FOR EXHIBITION.

A FEW years ago I searched every book and paper I could obtain on horticultural subjects to gain some information upon growing Chrysanthemums for exhibitions, but to no purpose, as I could find nothing beyond the ordinary cultural directions. What we want is plain pithy articles showing how such grand blooms as those exhibited at Kingston, Liverpool, and elsewhere, are grown. What are all the ingredients used in potting and top-dressing, and when is it done? What kind of liquid manure is used, when commenced and when left off? What importance is attached to ripening of the wood, if any? when and how should it be accomplished? What different culture do the Japanese require? do they require heat after being housed? I find all these points require attention. Will some of the great exhibitors, or others who understand the subject, give their experience on the proper culture of the Chrysanthemum. Another question—As varieties are very numerous, could not an election be taken of, say, thirty-six incurved and thirty-six Japanese, after the manner of the Rose election? and, like Roses, are not some of them too much alike to be shown in one box as distinct?—J. L.

KITCHEN GARDEN.

ALL work should be advanced as much as possible at this period of the year. During the prevalence of frost wheel out manure and composts and spread it at once, so that any worms or grubs it may contain will be destroyed by exposure to the frost. No opportunity should be lost of turning any vacant ground, so that it may be well pulverised and friable for receiving the seeds or plants in spring. Sufficient wintry weather has already been experienced to necessitate vigilance in regard to tender vegetables. A portion of the Celery crop should likewise be covered with straw or litter, so that the daily supply can be lifted as required. The remainder of the Celery crop must be fully earthed up as a means of protection. Although it will be necessary during very severe weather to cover

frames containing Endive, Lettuce, Parsley, and Radishes, the frames should be opened whenever the weather will permit, and so also should handlights containing Cauliflower plants.

FRUIT HOUSES.

Peaches and Nectarines.—With the buds swelling in the earliest house gentle fire heat may be provided. To admit of a free circulation of air by day and at night the house must be entirely closed. No addition must, however, be made to the general range of temperature, which should still be kept at 50° to 55° by day and 40° to 45° at night, with an advance to 60° or 65° from sun heat. It is best, however, to err on the safe side, particularly through the early stages, making up for any lost time when the fruit has passed stoning. Old trees and those that have been forced for a number of years will endure more heat than those not previously subjected to the forcing process. Much also depends upon the position of the roots; as with these inside, as all early-forced Peaches ought to be, and kept near the surface by rich top-dressings, forcing may be carried on more quickly and with less risk than when they are outside, where, however well protected, they must necessarily be liable to checks from sudden depressions of temperature. Syringing the trees, walls, and paths must be regularly attended to daily, but the trees must not be kept constantly wet, the afternoon syringing being performed in time so that the trees become dry before dark. Fermenting materials on inside borders must be frequently turned for the purpose of obtaining atmospheric moisture, and to maintain a genial heat.

Continue pruning and tying in succession houses, and proceed with late houses in that respect as opportunity offer. Lay in the wood sufficiently thin to admit of the full development of the foliage, leaving it its full length where the space will allow. Gross sappy shoots should be cut out, and provision made for a good supply of young shoots in such trees and those extending by cutting them back to firm well-ripened wood.

Figs.—Pay attention to the leaves that have been placed loosely about the pots, and if the heat does not exceed 75° they may be pressed firmly down and more introduced from the reserve heap, which should be kept in readiness for use as needed. Where the trees in pots are not large they may be placed on the fermenting materials; but when the trees attain a good size the pots should be supported on pedestals of dry bricks, so that the necessary turning and additions of fermenting materials can be effected. The night temperature should still be kept at 50°, with an advance of 5° to 10° more by day in mild weather; but as the fermenting materials will be almost, if not quite, enough to secure this without artificial heat, yet it is not advisable to dispense with this entirely, as a gentle heat in the pipes will prevent condensation and otherwise produce conditions favourable to frequent damping of the trees and walls of the house.

Complete whatever may be necessary in getting the succession house ready for closing, and proceed with the pruning of the trees in later houses. Cut out the old shoots that have reached the extremity of the trellis, and shorten spurs, leaving, however, sufficient wood for bearing without crowding the trees. Train and tie-in on the fan system, leaving plenty of room for the extension of the new growths, as Figs that have plenty of leaf space produce the best-coloured and finest-flavoured fruit. Clear the wood thoroughly of insects by repeated washing of strong softsoap water (8 ounces to a gallon), and if there be scale add half a wineglassful to every gallon of spirits of turpentine. A soft brush must be used for the young wood, as the young fruits are easily disfigured, the more forward being liable to be destroyed if due care be not taken.

Cherry House.—If the house and trees have been thoroughly cleaned forcing operations may now be proceeded with, maintaining 40° as the night temperature and 50° in the daytime by artificial means, which should not be exceeded in either case for the present. If the sun raise the temperature to 55° ventilate at that temperature, and do not allow the heat to rise above 60° without full ventilation. The border should be mulched with partially decayed manure 3 inches thick, as that prevents evaporation and keeps the soil uniformly moist. If the soil is dry supply tepid water repeatedly, but frequent syringings will not be needed.

Cucumbers.—Severe weather with little sunshine renders sharp firing necessary to maintain a suitable temperature, and care is needed, as the air is often so dried as to be injurious to the health of the plants. Thinning the fruits must be attended to, overcropping soon exhausting the plants, removing at once all male blossoms and any damaged leaves. Very little if any stopping will be required now, except the growths of vigorous plants. See that the plants do not suffer from insufficient supplies of water, but be careful not to give too much. Atmospheric moisture must be sparingly given, but an ungenial condition of the atmosphere should be avoided by damping available surfaces occasionally.

PLANT HOUSES.

Pelargoniums.—The earliest cut-back, large-flowered, and other varieties that were first shaken out and placed in smaller pots will now have taken root freely in the fresh soil, and should at once be moved into the pots in which they are to flower. Large pots are not necessary, as the best specimens can be had with heads of bloom in 8-inch pots. The aim should be to have the soil full of roots before spring, and then supply them with liquid manure. The soil must be rich turfy loam, with a fifth of thoroughly reduced manure incorporated, and a little sand, ramming it well into the pots, for if potted loosely the plants have a tendency to produce too much foliage with few roots and flowers. Place the plants near to the glass, keeping them well tied out to form the plant for which they are intended. If simply wanted for decoration they only need the shoots tied out so as to admit the light amongst them, for if allowed to assume a close erect position they become drawn and weakly.

Calceolarias of the earliest-sown plants should now be removed into larger pots; those 7 or 8 inches in diameter will be large enough for general decorative purposes, but if wanted to be grown large they should have another shift later on, as it is not advisable to give them too much root space at once. The plants cannot have too much light, and should be kept cool and moist, frost, however, being excluded. *Humea elegans* also should be shifted into larger pots as they require it. They also need to be kept cool and moist and free from aphides, these and Calceolarias having the foliage injured by too strong a fumigation with tobacco. Cinerarias should be regularly supplied with liquid manure, shifting any needing more root space before they become very much rootbound.

If a few plants of *Cytisus racemosus* be placed in a house with a temperature of 50° artificially they will soon come into flower and be very useful for conservatory decoration. A few more *Epacris* placed in a house with a similar temperature will come into flower shortly, and succeed those that were similarly treated earlier in the autumn. Varieties that have a tendency to bloom early, as these not only flower in a lower temperature, but keep fresh much longer either on the plant for conservatory decoration or for cutting. The varieties of erect habit usually are disposed to flower earlier than the branched sorts, of which there are now many fine forms in shades of colour from white up to crimson.

Where greenhouses are kept furnished with flowering plants damp will now have to be guarded against by means of gentle fires, as the condensed vapour depositing on the blooms will cause the petals to be spotted and the buds to decay. Whenever fires are resorted to for expelling damp a small chink of air should be left on at the same time, in order to allow of the escape of superfluous moisture. Primulas should now be carefully watered, especially the double varieties, not wetting the crowns, which induces decay.

THE BEE-KEEPER.

BEE LORE.

WE have sometimes been much amused, oftentimes sore perplexed, by the many and various superstitions concerning bees. In all parts of England, Scotland, Wales, and Ireland certain curious myths are religiously believed and held sacred by old-fashioned bee-keepers. Many of these are widespread, others

are local to a few counties and unknown elsewhere. As we before remarked, some of these superstitions are amusing and can be traced their origin; whereas others perplex one greatly to know how they can have arisen.

The all-prevailing custom among villagers and farm labourers of ringing bells, beating pots or kettles, and otherwise making as much noise and hubbub as possible when a swarm issues, was in vogue in very early ages. Since we do not believe that the noise has any effect whatever in causing the swarm to settle, we can only suppose that the institution of the custom was for the purpose of giving notice to neighbouring bee-keepers that the operator on the bell, drum, or kettle claimed the rising swarm and identified it as his own. "Habit is second nature" says the proverb, and the habit in question holds sway over the rural bee-keeping world for long centuries after the cause for and establishment of that habit has been forgotten. By an old law of the time of Alfred the Great a bee-keeper is permitted to follow and to secure his swarm if on another's property; but he must keep the swarm in sight, and that his neighbours may know he is following it he must ring a bell as he pursues it. The bell-ringing is now oftener replaced by yelling and the beating of a kettle or rattling of fire-irons, and the bee-keeper is not so much intent on calling his neighbours' attention to the fact that he is following his bees, as on charming the swarm and causing it to alight seduced or terror-stricken by his rough music.

The law of Alfred evidently explains the origin of the custom, although, as we said above, the habit prevailed centuries before that law was made. Virgil refers to the tin-can music in his fourth *Georgic*. Plato, Pliny, Varro, and Columella all speak of it, and attribute the settling of the bees either to fear or joy; while Aristotle is not certain what the effect is which the beating of brazen vessels has on the bees. We believe that a violent concussion of the air affects a swarm. A gun fired near a hovering swarm seemed to cause it to pitch suddenly, but we intend to make further experiments and make the result known.

Who has not heard of the bees who would never thrive unless the hive were anointed with a concoction of beer and treacle or sugar? Tom Clodpole has some bees in his garden which never do well unless the carcase of a dead cat dangles from a pole close to their hive. Another sapient skepist always places his manure heap as handy as possible to his honey-gatherers. Nothing will convince him that it is unnecessary or even prejudicial to so combine, as Samson did, the strong and the sweet. Whence shall we trace this deeply seated belief? Are Tom and his sapient brother right, and are we wrong? The solution lies in a nutshell. Bees require salt, which they obtain from various natural sources. The decomposition of the dead cat, the heating of the manure heap, are two generators of salt; and the bees, unheeding or disregarding the hideous and the filthy, seek and find what they require and carry off the pure salt to their hives. Thus the countryman is right so far as his knowledge guides him, his manner of application only is wrong. In early spring, before honey is distilled in the flowers, we give the bees the requisite small quantity of salt with their artificial food. Once let the earth bring forth her floral treasures, and the salt will be found by our insect friends in sweeter laboratories than the carcase of a cat or a manure heap.

But what shall we say of Mrs. A, who has kept bees nearly all her life, and that life a tolerably long one? We are almost afraid to tell of her recipe for dressing a hive to receive a swarm. However, at the risk of revealing a secret, and perhaps of shocking some reader with a very delicate constitution, the secret must come out. Many a swarm of bees had she lost before she was told of the magic "dressing." We might perhaps laugh at her when we heard what it was; but although we seemed to know how to get bees out of a hive (we had just driven some condemned bees), we should never know how to be sure of keeping bees in a hive unless she gave us her recipe. Since using it she had never lost a swarm. And what was the potent remedy? We hope the printer will put it in very small type. "A little bit of pig dung about the size of a nut!" "Just stick it in the middle of the crown of the skep, and the swarm won't never leave it there." So says Mrs. A, and she must know, for she kept bees long before many of us new-fashioned bee-keepers played with our rattles. How shall we explain this curious perversion of the sense of the nectar-scenting bee? Only by saying it is a proof of the old saw, "There's no accounting for tastes."

There are still living among us the bee-keepers who will never sell a swarm, as such an action would certainly bring them bad luck, and others who tell all great afflictions to their bees. They would expect to lose a beloved sister, father, or mother if the bees were not duly informed of brother Tom's death. We generally find that such of our bee-confiding friends are very misty as to

their knowledge of the natural history of the bee. They do not believe in the queen bee, but, like Virgil of old, believe that a king governs the community, and that what they tell to the bees on the alighting board is whispered into his majesty's ears. When a hive dies from want of sufficient food or from queenlessness it has invariably succumbed to "them wopses." One old lady bee-keeper has reasoning powers so sparsely developed that she said (and indeed she was not joking) "she always left her bees till long after Michaelmas before she took 'em up, eos them bluebottles is all over then, and the honey ain't got no maggots in it!"

It is a common mistake for certain hives of bees to be accredited with collecting a more or less excellent kind of honey than their fellow colonies. Even by those who are expected to be better informed, one is often asked such a question as this—"Your yellow-banded bees make much better honey than the common black ones, don't they?" The fact is overlooked that bees do not make the honey, but only collect and store it. Of course there may be times when bees from one particular hive work more during a flow of a special kind of honey, and thus store it in greater quantities than a neighbouring hive may do. The one hive may, from particular circumstances, just at that time be unable to send forth many gatherers; and although it may perhaps later on become stronger than its strong neighbour, yet it may just miss a harvest of the best kind of honey, and at the end of the season may be weighty with an inferior kind gathered later in the season. How easily, then, hive No. 1 may get a good name as the collector of a superior kind, and hive No. 2 a bad name as the storer of very poor stuff.

There is another very curious superstition which holds sway in some parts of the country, notably in Hertfordshire. The country folk believe it to portend the greatest ill luck to themselves and their bees when a swarm settles on dead wood. We knew a labourer who had for many years kept bees, and who had not been induced to part with a swarm for money. We persuaded him to sell us a strong swarm, and he was heard to say that his bees had never done so badly as they did that year. Matters, however, reached a climax the following spring, when his first swarm, a fine strong one, settled against the pales of the garden fence. He was heard by a friend who was passing to bemoan his ill luck, and to take the gloomiest of views for the future well-doing of his bees and his family. Returning some time after, our friend found the beautiful swarm a soddened dead mass on the ground. This wise prophet of evil to come had sacrificed fifteen shillings' worth of bees to propitiate the dark fates who threatened him, and who had warned him by causing his bees to settle on dead wood! We believe that he was fully convinced that he had been only wise and prudent in what he had done; for that year, the year 1876, was a grand year for honey, and the bees he had left swarmed on living bushes and stored a heavy harvest. "When ignorance is bliss 'tis folly to be wise!" The same man, it may be noted, was afterwards just prevented by his employer from dealing summary destruction to the green fly on the fleshy leaves of a fine *Calla æthiopica* by sweeping them off with a birch broom. When the insect tribes were to be executed he stopped at no half measures. We will conclude this paper with an eastern legend.

The Queen of Sheba having failed to puzzle Solomon with many enigmas and trials of his wisdom, stood some distance from the king holding in each hand a bouquet of lovely flowers. Those in one hand were Nature's own product, the other bouquet consisting of the most cunningly worked imitations. It was impossible for the eye to detect which were natural and which artificial. Solomon applied to his courtiers and wise men to give their opinion, but they owned their inability to decide between the two bouquets. The wise king then commanded a casement of the cedar palace to be thrown open, and admitted some bees. Attracted by the sweet perfume of the real flowers the bees at once solved the mystery.—P. H. P.

FORMIC ACID AND HONEY.—Honey, according to A. Vogel, says the *Scientific American*, contains on an average 1 per cent. of formic acid. Observing that crude honey keeps better than that which has been clarified, E. Mylius has tried the addition of formic acid, and found that it prevents fermentation without impairing the flavour of the honey.

TRADE CATALOGUES RECEIVED.

Ant. Roozen & Son, Overveen, near Haarlem, Holland.—*Catalogue of New Gladioli, New Dahlias, and Miscellaneous Plants.*

Hogg & Robertson, 22, Mary Street, Dublin.—*Catalogue of Trees and Shrubs.*

Thomas S. Ware, Hale Farm, Tottenham, London.—*List of Single Dahlias.*

* * All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Address (J. C.).—The address of Mr. Peter Henderson is 35, Cortland Street, New York.

Work on Orchids (J. F.).—Mr. B. S. Williams' "Orchid Manual" would probably suit you. It is published by the author at the Victoria and Paradise Nurseries, Upper Holloway, price 7s. 6d., post free 8s.

Chrysanthemum Sport (W. A. W.).—We consider the variety sufficiently distinct from Guernsey Nugget to justify you in naming it. It is a great improvement on the variety from which it originated, not only by its great breadth of petal, but by the delicate yet distinct pink tint on the reverse side of the petals. This is very apparent under artificial light, and, as well-grown blooms will be incurved, will be the prominent colour. You had better endeavour to grow some very fine blooms, which we shall be glad to see, as we regard the variety as one of considerable promise.

Laburnums and Cattle (J. F. C.).—Laburnum seeds being poisonous we should not plant trees within the reach of horses or cattle, unless we had evidence that trees are growing in paddocks or parks where these animals are kept and have not been injured by eating the leaves or seeds. If any of our correspondents can adduce instances of Laburnums to which cattle have access not proving injurious to the animals we shall be glad to hear from them, or, on the other hand, if they can state any instances of cattle-poisoning by Laburnums.

Anemones (A Working Man).—We much appreciate your kind offer, and will accept what you express a desire to send. If you address a parcel the same as you addressed your letter it will reach us, but it will be well to write to us at the same time, informing us of the dispatch of the parcel to our office. If you pack them in a little damp hay or litter, to be closely rolled up in a piece of old sacking or similar material, and tied securely, they will travel safely.

Climbing Plants for a Porch and South Wall in Oxfordshire (A. C.).—The best of the Honeysuckles are *Lonicera flexuosa*, *L. brachyopoda*, and for its early fragrant flowers *L. fragrantissima*. These would answer admirably for your porch. Of very choice climbers for a south wall the best six are *Berberidopsis corallina*, *Escallonia macrautha*, *Ceanothus azureus*, *Jasminum officinale*, *Fremontia californica*, and *Ampelopsis Veitchii*.

Glass Wall Protectors (J. F. P.).—We think you will find the necessary details of the Peach-protector in the illustrated article published in No. 928 of the Journal, January 9th, 1879, pages 24 and 25; also in answer to questions called forth by that article on page 62 of No. 930, published January 23rd, 1879. If you do not possess these numbers they can be had from the publisher, price 3½d. each, post free.

Pruning Gloire de Dijon Rose (Cairney).—You are fortunate in having such fine growths. Shorten them at different heights, some from 2 to 4 feet, others from 5 to 8, and the remainder leave nearly their full length. If they are likely to crowd the wall you might take one down and train it across the others near the base, only shortening it slightly, and it would produce a bloom from every eye. So would any of the shoots if you do not object to training them in this manner. The lower buds do not break when long shoots are trained in a vertical position.

Adiantum cuneatum (H. S. P.).—This, we presume, is the Fern to which you allude, and which you state is now "at a standstill." It is better resting than growing at this season, and all you have to do is to water it judiciously to keep the fronds quite fresh, but not saturating the soil so as to cause the roots to decay, nor keeping it so dry as to cause incipient fronds in the centre of the plant to shrivel. A temperature of 45° will be suitable until February. At that time more heat and a genial atmosphere will promote fresh growth, and the soil being suitable (turfy loam, peat, and charcoal), strong fronds will be produced. Spring is the time for repotting, but as you say nothing about the size of the plants nor pots they are in, we are unable to give you any useful particulars on that point.

Spiræa japonica (Idem).—The proper time for dividing the plants is after they have flowered in pots, say about May or June, and it is then a good plan to plant them out in rich soil in the garden. They may be also grown in pots during the summer, but this plan involves more labour in watering than if planted out. If plants having strong crowns are taken up and potted in the autumn, placed in gentle heat, and judiciously watered, they will grow and flower freely in due time. Tobacco smoke is injurious to the foliage of these plants.

Gloxinias (Idem).—The corms may be wintered safely in a temperature of 60°, keeping the soil dry. In the spring sprinkle them occasionally, and as soon as growth is apparent shake them out and place the corms in small pots in a compost of peat, loam, and leaf soil, surrounding them with sand, and apply water with great care. Before they are rootbound shift into larger pots, using stronger and richer soil, and keep them in a warm house but shaded from the midday sun, and they will grow vigorously.

Gooseberries for Profit (A Farmer).—We doubt if you will find it advantageous to carry out your project of purchasing the "celebrated Lancashire kinds," first because the trees are more costly than established sorts that are

grown and sold by the thousand by nurserymen; and secondly because they do not always bear freely. For gathering green we doubt if you will find any to surpass Whitesmith and Lancashire Lad, the latter a red variety, and good also for preserving. Crown Bob bears heavy crops of fine fruit, but in all soils the trees do not grow freely. Early Sulphur is one of the best for affording ripe fruit as soon as possible; while for late use and general preserving purposes the Red Warrington has few if any superiors. If any of our readers can name more profitable sorts to grow by the hundred or thousand than those we have recommended we will readily publish the names with any particulars of the varieties that are furnished.

Conifer Hedges (*T. Wilkinson*).—There are few if any Conifers that will form a more beautiful hedge than *Thuia gigantea*, usually sold under the name of *T. Lobbi*. It is hardy, retains its bright green colour throughout the winter, and is close yet elegant in appearance. *T. occidentalis* is cheaper and makes a good hedge, but in light soils is apt to get thin at the base. We have seen ornamental hedges of the *Cedrus Deodara*, *Abies excelsa*, and *Cupressus nutkaensis* (often sold as *Thujopsis borealis*), and good compact fences of *Cupressus Lawsoniana*; but the firmest, closest, and most durable of Conifer hedges are those of the Yew, but it is of somewhat slower growth than most of the other trees named, and its dark colour may not suit your taste. In planting to form hedges young trees should be inserted from 1 to 2 feet apart according to their size, the ground being trenched and manured to promote free growth.

Spray Diffuser (*S. Hoskins*).—There are several appliances for distributing insecticides in the form of spray. One of the most serviceable of these has been advertised by Mr. Wells, Earlwood Nurseries, Redhill. We have nothing to add to nor detract from the following remarks that we published last year relative to this handy little garden appliance. It is much less of a plaything than some spray-distributors that we have seen, and is used precisely the same as a pair of bellows. An insecticide of any kind, and of approved strength, if placed in the reservoir can be distributed far more economically than through a syringe, and is often more effectual, as the spray adheres to the foliage like dew, which is not the case when liquid is applied through a syringe. Any insect-infested plant in a collection can easily be dressed with the aid of this implement, and it will be of even greater value in destroying thrips and other insects on Vines where the Grapes are colouring. For this purpose this spray-diffuser will be of substantial value, as a large vine may be dressed in a very short time without injuring the Grapes by placing the nozzle between the bunches and covering the foliage with, to the insects, deadly dew.

Inarching Vines (*J. D.*).—The information you require is not given in either of the works to which you allude; but you will find different methods of propagating, including inarching, in our "Vine Manual," which can be had from this office post free for 3s. 2d.; if you also send 3½d. to the publisher and ask him to send you No. 617 of the *Journal of Horticulture* you will find the details of an excellent method of inarching or bottle-grafting, which can scarcely fail to be of service to you. The particular method that is best to adopt can only be determined by circumstances; but we think you will have no difficulty in accomplishing your object. If we can render you any aid we will readily do so on receiving particulars of your case, and the means and material at your disposal.

Weeds among Fruit Trees (*W. K.*).—"Water Grass" is very common on such soils as yours, and where the land is under cultivation can only be got rid of by frequent tillage and cleaning. We do not think any special manure will destroy it. Practically we do not think there is any difference between English and foreign bones, and as those that you have used have answered well, you cannot do better than continue them; then lime, we think, will not be needed. There is no better manure for fruit trees than bones.

Jacobæa Lily Culture (*Subscriber*).—The following extract from our "Greenhouse Manual" will answer your inquiry, except, as you have only one bulb, we should place it in a small pot and plunge this in a larger, as the soil in the smaller pot could be kept in a more equable state of moisture than if the pot were exposed. *Sprekela formosissima*, or *Jacobæa Lily*, has narrow Amaryllis-like leaves; flowers rich crimson, on stems about a foot high. It is an old favourite, and without forcing, or in the greenhouse, it flowers about June, earlier or later according to temperature. With forcing it may be had in flower from February. It has one great defect—namely, that of flowering either before the leaves are produced or when there are but few of these. Like many others, the beauty of the specimen is greater when there is a mass of bulbs in a pot, half a dozen or more not being too many for a 6-inch pot. They succeed admirably in a compost of fibrous loam two parts and one part of leaf soil, and should be covered to the neck. Drain the pots well and place them near the glass. From the end of September to April keep the plants dry on a shelf; in April gradually moisten the soil, having previously examined the drainage and put it in order, also removing the surface soil and giving a top-dressing of fresh. When the flower scapes appear water copiously, and after fresh foliage is made give very liberal supplies up to September; then place the plants on a shelf near the glass and lessen the supply of water, but not so as to cause the foliage to become limp, and after September keep them dry. If the plants are required to flower, say, in April or earlier, they may have the drainage put in order, removing any old soil that comes away freely, and be top-dressed, placed in a bottom heat from 70° to 75°, and a top heat from 55° to 60°, and they will soon start into flower. Just before the blooms expand the pots should be gradually withdrawn from the hotbed before removal to the greenhouse or sitting-room. Avoid too large pots and potting over-frequently. After the removal of the old soil the pot should just hold the roots without cramping, while allowing of a little soil all round. No harm will result from the bulbs being left in the pots until the latter split; on the contrary, the plants are never so healthy nor so free-flowering as when they are in this state. If they should be enfeebled in growth repot them in a smaller-sized pot.

Vine Border—Garnishing Grapes (*Idem*).—Your Vine border will not require any further covering. Garnishing fruit is a matter of taste and the materials at command. Some use green and variegated Holly, sprays of Conifers, or any other evergreens; others prefer the foliage of stove plants, such as Coleuses and Fittionias. Not knowing your resources we cannot give a more explicit reply.

Pinus Lambertiana (*C. M. A.*).—In its native habitat, California and Oregon, this is the tallest of all the Pines, often reaching a height of upwards of 200 feet. In Veitch's excellent "Manual of the Coniferae," it is stated that "In England *Pinus Lambertiana* thus far shows no indication of rivalling the gigantic dimensions of its parent in California. Although introduced fifty years ago, there are few specimens that exceed a height of 50 feet; its growth in all soils and situations is very slow, especially during the first years from the seed. It is, however, a handsome tree of erect habit, with branches short and slender in proportion to the height of the trunk, the lower ones spreading, those higher up with the ends inclined upwards, and the highest ones ascending and generally

well furnished with foliage distinguished by its bluish-green tint. To insure a good specimen of this noble tree it should be planted in a situation sheltered from winds blowing from the north, north-east, and east, and a clear space having a radius of not less than from 20 to 25 feet should be allowed for it." Dr. Hogg, in his "Vegetable Kingdom," states:—"The timber of *P. Lambertiana* is white, soft, and light, and produces an abundance of pure amber-coloured resin, which, when the trees are partly burned, acquires a sweet taste, and in this state is used by the natives of the Rocky Mountains as a substitute for sugar. The seeds are eaten either roasted or pounded into coarse cakes, for use during the winter season."

Fruit for Market (*Vectis*).—It is next to impossible for us or anyone to give categorical replies to all the questions you have submitted. Your first query we answer in the negative. The prices represent the current retail value of the different articles enumerated in the lists, and in most cases the probability is that a less amount would be returnable by a salesman disposing of the same class of goods, after deducting commission. Your second question we answer in the affirmative, yet conditionally—namely, assuming the soil and district to be favourable, and sound judgment and good management are exercised, the investment we should expect would prove fairly lucrative; or, in other words, some persons might employ the sum named in the manner you suggest profitably, while in other hands and under differing circumstances the returns would not be satisfactory; and, further, under any circumstances some time must necessarily elapse before any substantial return would be available from the culture of hardy fruit. The first half of your third question we answer without any qualification. It is not at all likely that planting railway embankments will affect the fruit supply of this country, but that the American yield will affect it more or less is quite probable; still, by growing the best market varieties and producing fruit of high quality you ought not to fear a competitor who has to send his goods nearly four thousand miles to market. Your fourth question depends wholly on the skill and aptitude of the cultivator. The safe plan would be to combine both forms of culture, as the former would give immediate returns, and in the meantime the latter would grow into profit, and, the seasons being favourable, would increase in value yearly. As to glass copings, you must avail yourself of the experience of cultivators in your own district; in some places they answer well, in others they fail occasionally. In reply to your fifth and last question, we think you would act more wisely by extending your present business if it is profitable, than by running the risk of establishing another near London. The nearer you come to the metropolis the greater is the value of land and the cost of labour; and further, you would lose a week in the maturation for market purposes of your crops, as we suspect the season in your district is quite a week earlier than in Surrey, Kent, or Middlesex, which is a point of great moment. We know nothing about your local rates for the transit of goods, but we know that both fruit and vegetables are sent much further distances with profit to the cultivators than you will have to send if you decide to cater for the London market. In growing fruit, &c., for market some persons succeed where others fail. If you have succeeded in a small way you will have gained experience that may warrant you in extending the scope of your operations; but if you have not had a fair return for the outlay already incurred you will do well to act cautiously. It is one thing to be "very fond of gardening," but quite another matter to practise it successfully as a means of procuring a livelihood. Endeavour to thoroughly understand the whole matter, and to see your way clear before investing money that you cannot afford to lose, and do not put all your eggs into one basket until you have learned by experience which basket to choose.

Names of Fruits (*J. L. B. C.*).—The delay that has occurred is the consequence of your not having complied with the request at the head of this column. No. 2 is Alfriston; 4, Bess Pool; 5, Cellini; 7, Moss's Incomparable. The others we cannot name, some of them were decayed when examined. (*T. E. P.*).—Hughes' Golden Pippin. (*E. Bartrum*).—Warwickshire or Wyken Pippin.

Names of Plants (*E. Y., Norfolk*).—All the plants you name would be admissible in a class for greenhouse plants. The one of which you send flowers and leaves is *Chrysanthemum pinnatifidum*. (*X. Z.*).—1, *Selaginella Wildenovii*; 2, *Brainea insignis*; 3, *Asplenium dimorphum*; 4, *Adiantum macrophyllum*; 5, *Blechnum brasiliense*. (*W. R.*).—1, *Maranta arundinacea*; 2, *Tradescantia zebrina*; 3, *Tradescantia Warscewiczii*; 4, *Fittouia argyoneura*.

COVENT GARDEN MARKET.—DECEMBER 13TH.

TRADE quiet. Market largely dependant upon Canadian Apples, which are reaching us in good condition. Common qualities of Grapes principally off the market, and good samples are in full demand at firm rates.

POULTRY AND PIGEON CHRONICLE.

THE LEICESTER BREED OF SHEEP.

(Continued from page 538.)

It was the custom formerly, as it is now in various places, for the sheep-breeder to set aside the most promising of his ewe and ram lambs for the purpose of breeding, and this with the occasional exchange of animals of the same blood with other known breeders (an exchange which when guided by discretion) had up to Bakewell's time constituted the only source of improvement or preservation deemed requisite. But Mr. Bakewell introduced the novel plan which, although at first sight may appear selfish, yet perhaps has tended more to the improvement of stock than any other system yet invented. After he had established his own flock, and had fully tried and proved its superior qualifications, instead of selling his rams he offered to let them at a certain price. The advantages of this plan are self-evident; it enables the breeder who wishes to improve to do so at a moderate price. This plan at present is not discontinued by ram-breeders, but is kept within very moderate bounds as to numbers, but not so as to price, for in case the breeder possesses a few extraordinary animals he obtains a high price for the letting, and still retains them in his own possession and for use in his own flock. He also sells a larger number, thereby obtaining a large income from them in each year, and still preserves the best of his standing flock for future maintenance of the breed.

It is curious to note that with all the peculiar restrictions by which the members of the Dishley Club, or as called by some Bakewell's Club, in 1796 (the year after Mr. Bakewell died), no less than sixteen English counties were in communion with the Club, including the border counties. After the Dishley Club disappeared a club was started in Lincolnshire; the flockmasters connected with it met at Lincoln and drew up the rules ("for the benefit of the public") ostensibly. They were framed somewhat after the Lincolnshire model, and bound over the members not to show at a market, or let more than a hundred rams, or serve ewes at less than five guineas each unless sixty were sent. When Mr. Bakewell's flock was sold it went into the hands of Mr. Smith of Dishley, and passed from him to Mr. Honeybourne. It was, however, finally dispersed amongst Messrs. Stubbins and others, with whom we notice the name of Mr. Barford of Foxcote, to whom we shall specially refer further on; also to Mr. Phillip Skipworth the elder, whose purchase of ewes laid the foundation of the celebrated Aylesbury flock, the property of the late Mr. Torr of Shorthorn renown.

We cannot pass over without special remarks another era in the history of the Leicester breed, in which Sir Tatton Sykes made his first purchase of ewes, comprising half a score at ten guineas each, of Mr. Sandy. The Baronet loved a small thrifty sheep, but he did not look for a very lengthy style of fleece, preferring a closer shorter coat than was usually grown by the Leicester sheep. He liked also to feel for the cloven back in a ram as the best index of good firm flesh. Only grass, Turnips, and hay were used in maintaining the flock, as cake, corn, and peas found no place in his fold stores. In his earlier days at Mr. R. Colling's sale he gave as much as 156 guineas for a shearling ram "Ajax." When the Cotgrave flock was dispersed in 1844 he went up to a hundred guineas for a three-shear ram considered the "pillar of the flock." For some years before his death the worthy Baronet would allow no rams to be used which were not

of his own breeding. His letting of rams of the Hedmere flock in September, 1862, was his fifty-ninth and his last, but the prices made were not high. He never would prepare anything for show, hence they did obtain show prices; but the Hedmere flock has gone well to the fore since his death, both in the hands of Lord Berners and Mr. Borton, at the Royal Agricultural and the Yorkshire, as well as the Christmas shows.

Since that time the breed has been still further advanced; some of the evils which crept in with the earlier improvements, such as weakness of constitution, sterility, and inferiority of wool have been to a greater or less extent amended, and at the present day the breed remains the most perfect of any of the long-wools as respects the carcass, and, in the opinion of its advocates, though disputed by others, the best adapted and most profitable for fertile pastures. While there is no long-woolled breed but what has obtained some improvement from a cross with it, the Leicester as regards its peculiar qualities has derived no advantage from a cross with others; but its unrivalled qualifications can only be retained by preserving the breed pure and untainted. The late Mr. Sanday, to whom we have previously referred, was one of the celebrities of the same period, for at five shows he won all the first prizes, and according to the Steward's report of the Royal Agricultural Society's meeting at Worcester, where he showed for the last time, he however won fifteen first prizes, seventeen seconds, and three thirds for rams; eleven firsts, ten seconds for shearing ewes; besides eighteen high commendations in fourteen years. His sales in 1862-63 produced £5378 12s. 6d., including an average of £19 12s. for 173 rams; the highest price was 140 guineas obtained for a three-shear, being the gold medallist at the Battersea International Meeting of the Royal Agricultural Society of England in 1862.

At the period we have last referred to the sheep-breeders in the counties of Devon and Cornwall had for years been good customers to the Leicester breeders, and have reared first-class animals on their own account. Mr. George Turner of Barton, Devon, had for a series of years been a successful breeder and exhibitor of pure Leicester sheep both at the Royal and the Bath and West of England Shows. The importance of this breed of sheep is forcibly illustrated by the improvement of sheep stock in Ireland. What the native sheep were like before the introduction of the pure Leicester is told with great fidelity by Mr. George Culley when he visited that country many years ago. None of the original breed that we can hear of is left, and those who may wish to see what the Leicester cross has done have only to view the eighty to one hundred thousand sheep which are annually shown at Ballinasloe Fair, than which probably no other fair in the United Kingdom can produce such a level array. The top lots, two-year-old ewes and wethers, are really wonderful sheep, and yet they have not tasted a pound of cake or any artificial food. Still, a pure Leicester flock is not suited for Ireland, as the climate is too wet for them, and they become delicate in constitution; in crossing, however, the Dishley stock "nicked" exactly with "the original natives."

We must give a few words upon the last of the old-fashioned Leicester breeders, Mr. Valentine Barford of Foxcote in Northamptonshire, whom we had the pleasure of meeting and seeing his sheep at the Royal Society's meeting at Northampton in 1847 if we recollect rightly. He was a man of sturdy self-reliance, and possessed a flock which was generally believed to be the only one in the kingdom which could present an "unbroken pedigree from the time and stock of Bakewell," and reared upon a farm which he and his father before him had held under the Dukes of Grafton for more than a hundred years. One of the principles of rearing and feeding of sheep by Mr. Barford was to select animals from his own flock only, and never to use any artificial food. They were, however, distinguished by great symmetry, were always healthy but small; nor was their fecundity impaired, although they were "bred in-and-in," as it is commonly termed. Before concluding the subject we must allude to the "Barmshires," or, as some call them, Border Leicesters, which are peculiar to the border counties of Roxburghshire, Berwickshire, and Northumberland. These sheep, and the high estimation in which they are held, is best shown by the large sums yielded by the rams at their annual lettings; for although they are not pure Leicesters they have considerably more of this blood than of any other, and are well adapted for crossing with the long-woolled breeds of ordinary stock in Lincolnshire, Durham, and other counties; and it is said that when the Border Leicester rams are mated with the various stocks of long-woolled ewes that the produce is more hardy, and give excellent quality and heavy weights at an earlier age than the pure breed on either side. Thus we must admit that the original pure Leicester, as reared by Mr. Bakewell, proved a great acquisition to the sheep stock of the kingdom.

WORK ON THE HOME FARM.

Much time has been spent in horse labour lately in carting and storing the Mangold crop, which is now generally completed; and on those farms where the couch has been carefully heaped in readiness for the purposes of bottoming the farmyard or flooring the cattle and pig pens, it has been almost the only work which could be done with advantage and without displacing other more important work on the home farm during the stormy weather of the past three or four weeks. Still, at some drying intervals a few acres of Wheat have been sown in fair condition as regards the face of the land in burying the seed and finishing the work; but with the weather which has since been deplorably wet it is impossible to say how much seed will perish, especially upon some irregular and mixed soils.

Hand Labour.—Men have lately been employed in various ways, such as filling the couch into carts for purposes as above stated. We have lately employed some of the men to examine the draining on meadow land, where the appearance indicated partial stoppage of the pipes. The same has been done on the arable land, and at the same time where a new or fresh drain is required it has been marked out for doing the first opportunity. On some fields on the mixed soils there will, after such a succession of wet seasons as we have had, be a few bunches of couch left; but this work may now be done by either women or old infirm men by using the three-grained fork. This, however, should not be delayed, but ought always to be done before the roots are fed off, as, after the sheep have trodden it into the land, it is difficult to see it, and more so to lift it without leaving portions in the land. It is also desirable wherever Mangold, Carrots, Cabbages, or any roots have been removed from the land that it should be looked over, and any grass and Docks, &c., forked out before attempting to plough or seed the land.

Live Stock.—The dairy cows will now require much attention in various ways, for on pastures which are low-lying the tread of the cattle is very injurious for either early grass or to lay up for hay next spring. The cows in milk should, therefore, get some of the Drum-head Savoy Cabbages in their pens or stalls night and morning, with a run during the daytime on very dry pasture or old lea ground. They should have also at the mangers 3 or 4 lbs. of decorticated cotton cake, and chaff of sweet Oat straw mixed with meadow hay. But one thing must not be forgotten—that every animal should have access to rock salt in their manger, as it is a great assistance in keeping up the flow of milk. The horned ewes and lambs have done well lately, although the weather has been so wet, with the exception of an increase of foot rot and epidemic lameness, for as the lambs run on to a fresh fold every day they can find a clean lair in it, whereas the ewes when fed in troughs with cut roots will find clean food; yet in lying back they have space enough to choose a lair, and in dirty weather like what has prevailed lambs will choose their lair in advance, but run through the lamb gate to suck, and return again to their fold. The tegs or hags, as they are called, if properly trough-fed with sufficient roots and hay, with cake in addition, will be doing well; but in the event of any misfortune by loss of the root crops from frost, &c., it may reach a disaster, as so much money is invested in their cost.

TUSSOCKS AND MOLES IN PASTURES.

WE have a field of old pasture which until this year has been good fine grass land, but this autumn the greater part of it is becoming covered with coarse tussocks of useless grass, of which I enclose a specimen. The field was dressed with lime and earth a year and a half ago. It is grazed, and at haymaking time any parts that seem to require it are gone over with the scythe. Our neighbours assure us that the cause of the deterioration of the field is moles, of which there certainly are many traces both old and recent exactly in that portion of the field which is now covered with objectionable tussocks. Is it likely that this is the true reason, and what do you recommend us to do?—ROBESTON.

[When the tussocks of coarse grasses prevail on old pasture land they often indicate that the land is too wet on the surface, although not requiring to be drained; yet on strong clay soils the surface may be relieved of superfluous water by a few open trenches, which are undoubtedly beneficial. These tufts of coarse grass may be cut up with the turf-cutter, and either burned or used for litter in yards or cattle pens. If burned the ashes may be spread with benefit on the land where the tussocks prevailed. There is another cause of tussocks. Frequently in sheep-feeding the animals will eat out the white Dutch Clover and finer grasses, causing them to die out, and as the cattle refuse the coarser sort of grasses they will then form into tussocks, which sheep and cattle will both refuse. If, however, such grass land were fed off by cattle only, the finest grasses and Clovers would be likely to hold their own against the encroachments of tussocks, especially if manured. We do not think that moles would produce the coarse grass unless it is indigenous to the soil thrown up by them, in which case it would be advisable to trap the moles and prevent them throwing up any subsoil. Our opinion tends to the belief that the moles may be allowed to work even with benefit if the hills thrown up were spread about once or twice in a week. In

the month of July or August 10 lbs. of permanent white Clover seed may be sown and chain-harrowed in, and if the land is strong 4 cwts. of bone superphosphate may be applied per acre. If, however, the land is gravelly or sandy white Clover and yellow Suckling may be sown in admixture, and 2 cwts. of nitrate of soda or 3 cwts. of best Peruvian guano applied per acre. We incline to the opinion that constant feeding has impoverished the land, and if sheep have not been grazing thereon that the best Clovers and grasses have died; therefore, in the case of fresh seeds being sown and manure applied, it may be well the next summer to take a crop of hay to encourage the growth of the best grasses and newly sown seed plants. But at any rate, when the tussocks have got possession they must be removed before any better grasses will have any chance to get a footing. It is a good plan in pastures to employ an old man with a barrow at low wages to continually attend to and remove twice a week all the droppings of the cattle to a heap of earth made to receive them, and form a compost to apply as manure to the pasture in the winter. The same man may then at intervals spread the molehills.]

POULTRY AND PIGEONS

SUNDAY POULTRY SHOWS.

A LONG list of poultry shows which either extend over Sunday, or, which is practically the same thing, close on Saturday night, draws our attention to the subject. We have before animadverted upon this, as it seems to us, very inadvisable arrangement. The present is a fitting opportunity for again stating our objections to it. They are, roughly speaking, that the protraction of a show over a Sunday interferes with some of the special conditions which make any such exhibition useful and successful. We will give them seriatim.

1, The first object of every show is, of course, to enable the public to see and learn what good and pure-bred poultry are, and to enable fanciers to compare their specimens. The artificial restraint of a pen, and all the turmoil involved in an exhibition, confessedly do the birds exhibited no good, and are liable, if great care is not taken, to do them some harm. All experienced exhibitors know that much depends upon the length of shows, and know to their cost that long shows are very prejudicial, especially to young birds. We believe that few fowls suffer at all from occasional exhibitions at one-day shows, and probably not many from the ordinary two-days, but directly they are confined for three or four days it is far otherwise, and every day seems to add greatly to their fatigue. Now this being the case, it is obviously useless and mischievous to keep them confined during a whole day which, from the custom of this country, cannot be one of public exhibition. So much fresh air and exercise is lost to the birds, and nobody gains thereby. We must not, however, take it for granted that there is often absolutely no reason for the arrangement. There may be in particular places special obstacles to the only show-room being spared on other days than Saturday and Monday. This is hardly likely to be frequently the case. The ordinary reason, however, given for it is that shows on Saturday evening pay. The working classes, it is said, then have money, and spend it in coming to exhibitions which they otherwise would not enter. There is some truth in this, and nowadays, when the promoters of all such undertakings have much financial difficulty, it is not to be disregarded. We contend, however, that so detrimental is long confinement to exhibited poultry that even this inducement should not have weight with show committees. If people will not come to a show on other evenings than Saturday they are not likely to be a class who take real interest in it or are likely to be benefited by it.

2, Not only is confinement trying to poultry, but still more so are long journeys and exposure. All should be done that may make their transit to and fro as easy and expeditious as possible. Saturday nights and Monday mornings never favour locomotion, and have in our own experience often proved specially disastrous to travelling fowls. It is not long since we exhibited at a show which closed on a Saturday evening. There was a clause in the schedule to the effect that all exhibitors might have their birds fed and taken care of in the show room till Monday morning. We naturally signified our wish to avail ourselves of the permission. The birds ought, therefore, to have started on the return journey early on the Monday; great was our astonishment to find them before mid-day waiting at our station, very remote indeed from the place of show. They had been turned out on the Saturday night, had waited here and there through Sunday, and, needless to say, were none the better for their travels. This is

simply an instance of the evils almost certain to result from the close of a show on Saturday night.

3, One more condition of a well-managed show is that it should be carefully and scrupulously guarded while open to the public, and that before and after opening none should have access to it but those responsible for its management. It is easy enough to keep out intruders before the judges have begun their work or while they are engaged upon it—a policeman and a locked door suffice.

Experience, however, has shown us that it is by no means so easy to keep a show absolutely closed during a Sunday when it has already been open on other days, and more than this, that practically shows are never so kept. This or that fancier who "has no time in the week" craves special permission from his friend, a committeeman, just to look round on the Sunday afternoon; another acquaintance edges himself in at the same time; by degrees there is a regular assembly, hence not unfrequently scandal if not mischief. Some years ago we were exhibitors at a show advertised to close on Saturday night and to be rigorously guarded through Sunday. We stayed in the town at an hotel facing the show hall. It never occurred to us to ask even the favour of seeing that our birds were safe and well on the Sunday in the face of so apparently rigid a rule. During the afternoon, however, we saw divers people going in and out. The town is a garrison one, and the troops seemed much attracted by the crowing; they wandered about harmlessly, would that all the visitors had done the same! At last we too followed, to find that some dastardly individual had changed some of our birds, mutilated others, and turned an almost priceless cock loose to fight up and down the rows. We have exhibited now a long while and many birds, and are pleased to say that this is the only occasion on which we have ever for certain known any wilful and malicious damage done to our birds; but then with few exceptions we have not exhibited at shows extending over Sunday.

The fact of its being difficult to keep a show room strictly and absolutely closed is to our mind a very strong argument against any show being protracted over a Sunday. There may, as we have said, be exceptions to this as to all rules. If one is to be made we should certainly make it rather in favour of a show which begins with a Sunday than one which ends with it. The Crystal Palace and Birmingham are exceptional shows—exceptional in the number of visitors that attend them, and in the time that it takes to go well through them; they are exceptional, too, in the distance that exhibits are sent to them. For these reasons there is much to be said in favour of their duration, and of their closing on Thursday evening, and consequently beginning before one Sunday, to enable all birds to reach their homes, however distant, before another Sunday. We have never, therefore, hesitated to show at them, though we have often wished that Birmingham could be shortened by one day. To the committees of smaller shows who have not these valid excuses we commend for consideration our objections to Sunday shows before the opening of another year.—C.

NOVELTIES.

AMONGST recent inventions we note some of special interest to poultry-keepers.

THE THERMOSTATIC INCUBATOR.—This has been recently introduced by Messrs. Christy. It is a continuous heating incubator with a regulator, and is thus an entirely new departure for this firm, which has hitherto depended on hydro-incubators pure and simple, and similar incubators with outside circulating boilers, only requiring heat for an hour or two daily. The new incubator claims to require a minimum of attention. The regulator consists of a band made of two metals, which expand at different temperatures, and is said to be thoroughly reliable. Upon the metal which expands at the lower heat being affected, the metal band changes from a straight line to a curve; one end being fixed the other necessarily moves, and thus operates upon a rod connected with an air valve opening from the egg-drawer, and by increasing or diminishing the amount of ventilation keeps the temperature even. The entire bottom of the egg-drawer is perforated and exposed to the air, while the ventilating shaft rises from the centre of the top of the drawer. The bottom of the water tank is slightly domed so as to allow an even flow of air from all parts of the drawer. The lamp is a small one, and the expense of working the machine is thus kept low.

WHILE speaking of incubators we may mention a novelty in the way of a reason for parting with an incubator. The machine was that known as the "Fancier," which was first described in our columns by the designer, Mr. Comyns. An extensive breeder of Game Bantams had purchased one of these machines. We heard

that he was anxious to dispose of it, and upon meeting him at the Dairy Show we asked his reasons, whereupon he declared it was simply "because it hatched so many chicks he did not know what to do with them." We have heard many reasons for parting with an incubator, but this is certainly the first time we have heard this particular one advanced.

THE OVIFER.—This novelty, introduced by the Ovifer Company, 280, High Holborn, is, as its name indicates, an egg-carrier. Its principle will be readily understood from the accompanying illustration. It consists of three wire springs securely fastened to a metal plate. The egg is inserted between the springs, and is there lightly but securely held during transit. The ovifers are made in sets ranging from one to five dozen, and are constructed to fit in boxes and baskets of various sizes, so

Fig. 95.

that any desired number of eggs may be packed. We can recommend them as a convenient and safe method of packing eggs.

THE EGG-PROTECTOR.—This, which was brought out towards the close of last season by Messrs. Christy, we have now fully tried. It consists of a perforated metal egg-shaped box, rather larger in size than an egg. It is intended to be used for protecting eggs which are being hatched out from being crushed by the hen, while at the same time allowing sufficient space for the chicken to emerge from the shell. We saved the lives of a good many chickens with half a dozen of these egg-protectors during the latter part of last season. It is to be noted, however, that some few hens (about one in twenty was our average) will eject the egg-protector from the nest. A little care in this respect is therefore necessary.

SALES AT BIRMINGHAM SHOW.—Messrs. Smyths' second-prize Coloured Dorking hen was claimed at catalogue price, £25, the largest price we have yet heard of for a Dorking hen. The pair of Scotch-Grey fowls belonging to Mrs. Muir, which we noted as being first in the Variety class, were also claimed at the catalogue price—viz., eight guineas.

OUR LETTER BOX.

Buckwheat (A. B. C.)—We have no doubt you will be able to grow a good crop of Buckwheat, as the land is in fair condition. This crop does not require very rich land, or it is apt to throw too much haulm for yield of seed, but in case it is required to be used whilst green as a fodder crop the ground cannot be too rich. You speak of weeds on the land; if they are not couch grass they may be ploughed under with the skim coulter and injure nothing unless gone to seed. If the land is foul with couch, and Buckwheat is grown, it should be drilled in lines 12 inches apart, and hoed between. The seed required will be 2 bushels per acre.

REMARKS.

3rd.—Gloomy day; rain in evening.
 4th.—Fine and bright.
 5th.—Dull and cold; slight snow at intervals.
 6th.—Cloudy; slight snow.
 7th.—Fair, frosty morning. Snow commenced about noon, and continued rest of the day, lying about 2 inches at night, all the remainder having melted.
 8th.—Bright morning; gradual thaw; snow still on ground.
 9th.—Fine throughout; sunshine at intervals; slight fog in evening.
 Temperature still below the average, considerably so on the 7th, on which day a rather heavy fall of snow occurred; in and near London much of it melted; had it not done so, it would have been nearly 6 inches deep.—G. J. SYMONS.

DIGGING AND MANURING.

CAN anyone say whether the late very wet weather has made any converts among those who believe that the correct time to do all the digging possible is in autumn or early winter? Many must have found that too early digging is a mistake, especially where the soil is tenacious clay. Yet nearly every writer recommends turning vacant ground to the "ameliorating action of the weather." The phrase sounds well, but, unfortunately, the influence of the weather is not always ameliorating, but quite the opposite. The writer's conviction is that autumn and early winter digging is a great mistake, a cause of poor crops, and a monetary loss in many soils and districts. This is so exactly the reverse of what is generally held, that the position taken up will require to be vigorously supported and defended if converts are to be made.

It may be as well to commence at the beginning and ask and answer the question why we dig. The simplest answer to this question is, That without digging we could not grow crops. Digging breaks, and so pulverises the soil as to allow of plant roots extending and collecting their food from the soil. Moreover, in digging plant food is added and dug in, when the roots of the plants will find it. Now those who advocate autumn and early-winter digging do so because they hold that when it is done thus early the winter's frosts further tend to pulverise and break up the particles, thus making a still better root-medium. Well, I simply deny that such occurs. Do not misunderstand me. Decidedly the surface of soil that is exposed is broken up, but there is still a surface left to the action of the frost though ground is left undug. Moreover, those who turn up their soil in early autumn never have more than one surface exposed; those who wait till late winter and early spring have an opportunity of exposing two. But early digging does not result in a finely pulverised soil in spring, for—especially after such seasons as we have passed through—the rains of winter solidify the soil much more than any frost opens it. Frosts, indeed, only open and produce a surface tilth very suitable for sowing seeds in or for young plants, but so far as the body of the soil is concerned they have less effect than may be supposed.

Heavy clay soils after much rain, when dug in autumn, are often nothing more than a sea of mud in early spring, which only solidifies when drying winds come, and remain so long wet that it is often far into spring before it can be either re-dug, forked, or otherwise mechanically pulverised. Soil that is left untouched, on the other hand, but is solid save for cracks

and worm channels, such as most clays are at the end of summer, are comparatively waterproof, and instead of becoming putty-like mud, as they would if dug, remain comparatively dry. Then when thrown up, possibly in large clods, late in winter or early in spring, rain does not convert them into mud, for between the clods the rain escapes, and every wind dries the pieces till they are like the masses of lime that come from limekilns, and so easily reduced to powder whenever fairly moistened. When this occurs the lumps may be very finely pulverised by the fork, and a seed bed secured surpassing that produced by the winter's frost; while, instead of a solid body beneath, there is a friable fertile soil.

As often as not we are told that by the pulverising action of frosts and thaws plant food is liberated and made ready for the succeeding crop. To this we may reply, Is only dry ground acted on by frosts and thaws? The answer, probably, will be that roughly dug ground presents a greater surface. But we ask, Does frost only act on the surface? Then we may be told that the frost will penetrate deeper than if the soil were undug. The reply to this is that by leaving the soil untouched till late in the season the undug surface has all the advantage of the November and December frosts without being so liable to become waterlogged with the autumn rains, which wash the pulverised surface of dry soil level, so making the differences of surface extent not so great after all, but decidedly blocking the way for an easy passage of the rain downwards. Everyone knows what happens then. A dry soil by reason of its porosity sucks up much water. When solid it does not do anything like the same extent; and, moreover, an undug soil is full of worm channels and cracks by which the water escapes. If anyone doubts these facts let him, spade in hand, say in January, turn up after rain a piece of ground dug in October and a piece undug. But if we leave the digging till say January, February, or even March, we are enabled to expose first the undug and then the dug surface to the weather, and not only secure a better pulverised soil, but, so far as "weathering" will help the liberation of plant food, the spring digging surely secures the greater advantage.

There is another point, and it is this: when soil is so prepared that the surface water, instead of passing off by cracks, &c., is forced through the soil, and in its descent will carry off the nitrates so plentifully produced in autumn. The "liberation of plant food by weathering" is a parrot cry that means nothing at all by the majority who use it. It may be worth while to inquire what it is that weathering liberates. Not nitrogen, even on the most fertile soils, and hardly anything at all on soils that depend on manuring solely or nearly so. But even on soils of the most fertile description, all that can be liberated is just such matters as are not of very particular value, for the simple reason that they are likely not to be very deficient, and they are of such a nature as remain in the soil unless taken up by plant roots, and are not readily washed away; but, as we said, early digging does not secure a greater weathering. It tends, however, to the loss of what is of most value in the soil and in the market.

In manuring we add nitrogen, phosphoric acid, and potash. The phosphoric acid and potash are fixed in the soil, not so the nitrogen. Whether as ammonia or only organic matter, nitrogenous matters after the soil becomes warm in summer are speedily converted into nitrates. So long as the land is occu-

plied by a vigorous crop these are mostly utilised; but when, as in autumn, the land is bare they accumulate in the soil. These are very easily lost. Because of their solubility the soil cannot hold them, and in order to dispose of them the best plan is to dig early, and so secure the passage of rain through the body of the soil instead of by the surface and otherwise. These nitrates are very valuable, and supposing digging soil in autumn really was the best way of liberating plant food, which it is not, it would still be a great mistake.

The reasons given are surely enough to convince anyone that autumn tillage, unless in districts where the rainfall is limited, is wrong; but there is yet another. In digging, manure is generally added. Now, the most valuable part of really well-prepared manure is subject to waste when thus applied. Far better apply it later; indeed, manure to be applied profitably should be given at cropping time, or as shortly before as possible. In order to have the manure fit for this it must, of course, be well decayed; but, unless it is wasted in preparing, there is apt to be a loss in the use of any other. Fresh manure applied in spring does not give out its best qualities at the time it is wanted, but continues decaying all summer and autumn, and so a residue of nitrogen is left over that is apt to be lost. On the other hand, when manure is well made and forked or lightly dug into the soil the plants receive the benefit of it in their infancy, which is important, for a good start is a great advantage.

In many gardens crops might be raised profitably and the land improved by using no ordinary manure for a time, but only nitrogenous ones. As Liebig puts it, the strength of the chain depends on the weakest link. The weakest link in the fertility of soils long manured is certain to be nitrogen, because while the rest of the necessary elements are not liable to loss by drainage this is. The consequence is that there may be an actual surplus of everything else, there may be and often is a deficiency of nitrogen. Those, therefore, who are short of manure need not hesitate under such circumstances to give no manure at all to many things except a slight dressing of sulphate of ammonia or nitrate of soda during the growing season. This treatment often works wonders on "worn-out" flower beds. Such manures are also of much value in the vegetable garden, and greatly help the growth of many vegetables. For fruit trees they are not so suitable, chiefly because they are apt to cause too much growth of not a satisfactory character.

Much manure might be saved in gardens if "green manuring" were resorted to. If vacant plots were sown in autumn with Mustard or Rape thickly the nitrogen, otherwise lost, might be saved by being reorganised. As such green crops would save what would be otherwise largely lost, digging them down would be quite equal to an application of extraneous manure, and as they decay readily would become speedily available for immediate crops. Such have been proved of much value on the farm, but as the richer soil of the garden is much more liable to loss because of its richness, they would likely prove of even more value in the garden. Be this as it may, autumn digging certainly contributes to the loss of what we should all try to save.—SINGLE HANDED.

CHRISTMAS.

CHURCH AND HOUSE DECORATION.

CHRISTMAS is coming; and it will be welcomed more heartily than any other festival of the whole twelve months, not because it is the last of them, but because it is the recognised season of social gatherings and family reunions throughout the land. More true geniality, kindly greetings, and friendly intercourse prevail just now than at any other time; and though Christmas and its doings are like an oft-told tale, yet the heart warms to this subject, for at the very mention of it a host of pleasant memories crowd upon the mind, and the writing of a Christmas note once more is certainly no unpleasant duty.

Evergreens, symbolical of the perennial freshness of true friendship and sincere affection, ought always to predominate in Christmas church decoration. So abundant are they, and so varied in form, that combined with the dried flowers of "Everlastings" they suffice for all the requirements of good taste for such a purpose. A quiet tone of refinement should pervade our embellishment of such a building, and I must own to a feeling of antipathy for scriptural texts in large white letters on crimson cloth and all such theatrical

display. In the little church which I help to decorate the reading desk, lectern, pulpit, and seats are left untouched; a fringe of Moss and Ferns runs along at bottom of the front of the chancel seats; a richer fringe of clusters of Holly berries in circles alternating with broad stripes of Laurustinus flowers in sand is made from each side of the chancel steps to the pulpit and reading desk. The broad window sills are carpeted with Moss, upon which are crosses, double triangles, circles, and monograms of Golden Queen Holly, berried Holly, variegated Ivy and Box, Osmanthus, variegated Vinca, Diplopappus, and flowers of Laurustinus. The font alone is an exception, and has bunches of Violets upon Moss around its base, and the basin covered with Moss, upon which stands a floral cross of white flowers, Camellias or Marguerites, with a few flowers at intervals in the Moss around the base of the cross.

There are many large churches with pillars and wide bare spaces in the nave where a more liberal use of evergreens is called for. Wreaths for the pillars and trails around the doors are never more chaste than when done well with Ivy. Mixed wreaths are often very handsome, and may safely be employed when there are plenty of young people to make them. Groups of Palms springing out of mossy mounds give beauty and warmth to any bare spaces where they can be conveniently arranged, but other plants in pots are uncalled for at this season of the year.

In house decoration a much more florid style may prevail. Plants in pots cannot be too abundant in all the accustomed places. Violets and Mignonette should "scent the air with sweet perfume;" cut flowers, renewed frequently so as always to be fresh and bright in vases. To these the evergreens form our Christmas addition in the guise of sprays, wreaths, trails and festoons, just as may appear best in keeping with the furniture and permanent decorations. As a rule very little is required to be done in this direction, except in old baronial halls where armour and trophies of the chase give mutual facilities for evergreen decoration.

Berried Holly is abundant this Christmas; so, too, are the bright scarlet berries of *Iris foetidissima*, and the equally beautiful clusters of *Skimmia japonica* berries. *Cotoneaster Simonsii* has been very gay, but the birds are so fond of its scarlet berries that most of them disappear before Christmas. Moss, sometimes difficult to procure, is not so this season, as might be expected after so wet a year. Some old lodges thatched with Heather have the whole of it clothed with a soft bright green mossy carpet.—EDWARD LUCKNURST.

DEW IN HOTHOUSES.

ALLOW me to assure "CASUAL" and all whom it may concern that I have never knowingly made an offer in this Journal to answer queries privately, and that letters asking for information privately on subjects which appear in its pages are not answered. Any letter sent to the Editor breathing a genuine spirit of inquiry is sure to be duly attended to by the men best qualified for the subject which he has at command, but certainly will not be answered privately, as that is against all the rules of public journalism, and notice to that effect is printed every week at the head of the first column containing answers to correspondents. It is well it should be so. All questions have two sides to them, and when queries are answered publicly there is a chance for errors (which the best of us are liable to fall into) to be corrected. The answers to correspondents is a very strong point in this journal. They do more, perhaps, in an educational point of view than all the rest of its pages together, and I for one seldom fail to gain a lesson from their perusal, for I invariably read most of them through, and if I find anything I disagree with or cannot understand I make a note of it.

Once more, then, I have failed to make myself intelligible to "CASUAL," and if I have been as unintelligible to other readers I must of late have become less clear than I formerly had the credit for being. Allow me to say now as clearly as I can that there is no dispute as to the real cause of dew. It is always caused by the condensation of vapour on surfaces which are colder than the air containing that vapour. It is produced naturally in unheated houses as well as in the open air during certain conditions of the atmosphere, which are well understood. In our heated houses we can produce it at will almost independently of outside weather, and some of the lessons a young gardener has to learn are when this dew would be beneficial and when it would be injurious, as well as how to make it or prevent it. Your correspondent is perfectly right in following Dr. Wells as to the cause of dew-formation; for although there is much to be learned yet on the question of dew as to its chemistry and its effects on vegetation, the theory of its formation is clear enough, and cannot be materially altered; but when he quotes Dr. Lindley as an authority on horticulture he is not on such safe ground, for in matters horticultural we have been travelling fast. Lindley's time, like our

own, was transitional, the so-called facts of to-day being disputed to-morrow, and intelligent practical horticulturists to-day would be as likely to be guided in their operations by Zadkiel's Almanac as by much of the theory which Dr. Lindley taught, although he lived only a few years ago, and was one of the best men of his generation.

Your correspondent is still wider of the mark when he adds a bit of his own home-made theory. I see no use discussing the matter further with him, and indeed should not have noticed his last communication had it not been necessary to remove the impression that I was open to answer queries privately.—WM. TAYLOR.

ROSE MARÉCHAL NIEL.

VISITORS who have attended the various Rose shows held since the year 1878 must have noticed how few blooms have been exhibited of Maréchal Niel compared with the numbers they had been accustomed to see previous to the above date. It is a well-known fact that from the time of its introduction to this country no Rose made a finer display on the exhibition table than the one we are now considering. What magnificent blooms of this Rose were then placed in competition, having sometimes a class devoted to it, at others carrying all before it in classes for yellow Roses! but wherever shown in quantity it invariably caused an "obstruction," through arresting the attention of the visitors, who stopped to admire the glorious Maréchal Niels; also with what effect it told when shown in association with others, be they Hybrid Perpetuals or Teas!

Now in the majority of instances this Rose is comparatively rarely seen, and the honours in the classes for yellow Roses fall to *Perle des Jardins*, *Jean Ducher*, and others—poor substitutes for Maréchal Niel. Can this falling-off be attributed alone to the severe winters of 1879 and 1880, or is the constitution of the variety weakened in any way to account for it? Mr. G. Paul estimates its sale in the country at fifty thousand per annum (*vide* "Rosarians' Year-Book," 1882, page 59). It has been grown on stocks of various kinds, planted in every conceivable position at all likely to contribute to its well-doing; yet out of doors in the majority of instances it has proved far from satisfactory of late years.

One thing against its longevity is its predilection to canker, and when this malady takes hold of a plant there is little hope of its ultimate recovery; and, further, I am of opinion that this disease can be transmitted from plant to plant by propagation, either in the form of cuttings, budding, or grafting—hence the cause of so many serious losses from this disease, and hence the necessity of greater caution being exercised in propagating from thoroughly sound and healthy plants only. I am now alluding to out-of-door plants, as it is well known there are many places where this grand Rose is well grown under glass; but the blooming period of those is, as a rule, over before the Rose shows commence, while even under glass in some instances it has not proved a success, canker alone being the cause of disappointment. Frequently after the plant has made excellent growth for a season or two, and looks most promising, to his great disappointment the following season the foliage turned yellow and sickly, and the plant, struggling to put forth its flowers, drooped and died.

No other Rose that I am acquainted with which grows with such vigour as does the Maréchal when in good health is such a victim to so dire a disease. Can anyone suggest a remedy for or preventive of this great evil?—OXONIAN.

INSECTS INFESTING CARROTS.

SEEING that one of your correspondents finds it difficult to procure Carrots through the attacks of insects, I beg to advise him to try applications of gas tar. The first application could be given in September, and the ground well trenched to the depth of 2 feet, if the soil is suitable at this depth to be brought to the surface. If not, add a little quicklime in each trench after the first spit is taken off. This must proceed with the work, and fork it up with the bottom. Let the second dressing be given in February, choosing a time when the surface of the ground is dry; and if a dry day follows give the surface a good raking. Ten days before you intend to sow the seed draw the drills somewhat deeper than usual, and run the third lot of gas tar in these. Mix the seed in a liberal quantity of burnt earth and sand before sowing. I have been very successful in extirpating the insects by these dressings; the Carrots quite enjoy

it, and turn out fit for any exhibition table.—JOHN MACKAY, *Hammersmith.*

COLLECTIONS OF SEEDS.

IF I remember rightly, some letters appeared in our Journal a short time ago regarding the boxes of vegetable seeds as sent out by seedsmen, which showed that the writers were not altogether pleased with their purchases. For twenty years I made out my own list, which amounted to about a pound. Three years ago, by the advice of a friend, coupled with a little laziness, I bought a guinea collection. When it arrived I went carefully through it to see what advantage there might be, and found, provided the packets were the same size they would have been if ordered as usual, a gain of something like 30 per cent. in my favour. This looks very well; but I was obliged to buy certain sorts which were deficient, although there were enough of those valueless to me to sow a good portion of the garden. The reason why seedsmen prefer collections is, I imagine, because they grow certain sorts, not only for their excellence, but also for their prolific qualities. We find in nurserymen's

Fig. 96.—Pear Josephine de Malines.

catalogues—"Our selection, 6s. a dozen; purchasers' selection, 9s. a dozen." Now it has struck me that if we were to send up our wants somewhat in this way—Broad Beans, one quart in two varieties; six quarts of Peas for succession; 6 ozs. of Carrot for succession; 4 ozs. of Onions in two sorts, &c., vendors would be able to allow 15 or 20 per cent. off catalogue prices. I should like to know what Messrs. Carter & Co., Messrs. Sutton, and other large seed merchants think about it, as well as amateur and professional gardeners.—C. T. H., *Dorset.*

PEAR JOSEPHINE DE MALINES.

WE figure this fruit with the object of drawing attention to what we consider one of the finest winter Pears in cultivation. It should be planted in all gardens where late Pears can be grown. In the south the trees bear well in the form of pyramids, but are finer from walls, and a tree is worthy of a good position everywhere. Its time of ripening varies greatly. We have had it firm until April, but sometimes it ripens in December. In the cool fruit room at Chiswick it is ripe now, and no Pear in the collection is more delicious. On the question of ripening we append

the following timely and suggestive letter from "WILTSHIRE RECTOR:"—

"Having lost my whole gathering of these Pears last year, owing to my not looking at them until after Christmas, as they are not due until February, I thought I would at any rate be in time this year, and so examined them in the middle of November, when I was surprised to find that some were almost ripe. I brought them at once out of the cold fruit room into a cupboard in a room where there was a fire, as I felt sure they did not need any greater heat such as I apply each year to Bergamotte Esperen. My surmise was right. From that time (November 16th) until now I have been eating them daily, none lost from over-ripeness, but coming to table in rotation, and I never tasted this Pear of finer flavour. I quite endorse Mr. Smee's opinion that 'Josephine de Malines is, of late Pears, unrivalled in juiciness and flavour.' But I add this note of caution—Watch your Pears, or you may lose them altogether. If you trust solely to even the best of catalogues or manuals that tell you this Pear is in season from February to May, still there may come years when their period of ripeness is November to late in December. I would ask, Have other fruit-growers noticed this change of season, and what can be the reason why a Pear should be ripe three months before its time in spite of its being kept, as I have said, in a cold fruit room?"

[We suspect it will be difficult to explain the matter, but shall be glad if a solution is forthcoming. There is, however, this satisfaction—the fruit is excellent at whatever time it ripens, and few persons can err by growing Josephine de Malines.]

WINTER v. SUMMER PRUNING.

I MUST confess to having been educated in a somewhat antiquated school of gardening, especially as regards pruning. The custom was to prune hard in winter with a view of imparting vigour to the trees, and particularly to the fruit buds or the spurs; whilst those trees that produced fruit on last year's wood, such as Peaches and Nectarines, were cut in very sharply, out of a length of 2 feet or more barely a third of it was left after pruning for producing fruit or to insure growth for future crops. Summer-pruning was little practised. True, an attempt was made to shorten the forerights some time after midsummer, and the disbudding of Peach trees was of course attended to, yet the chief of the pruning had to be done in winter. The trees seemed to like it in so far as their power for making wood were concerned, giving a crop of shoots in summer quite equal to that removed at the previous winter pruning, and the trees had (as "JOHN BULL" so forcibly brought before your readers in a recent volume) a grand appearance—fine trees covering I know not how many yards of wall, and in good seasons bushels of fine fruits were looked for as a certainty. "This, of course, was long before the Quince and Paradise stocks had come into vogue," some may say; but it was not, for there were then those, but not in such numbers as we find them at the present time, and yet there were dwarfs, Apples on Crab stocks bearing as freely as giants in the adjoining orchards; therefore we may dismiss the supposition that gardeners some few years back knew little of the restrictive as opposed to the extension system. In their bushes, espalier, and wall trees they practised the former, and it is doubtful whether the old practitioners were not right in allowing a fair amount of summer growth. An excess of summer growth deprives the fruit and wood for future bearing of the light and air essential to their development, as root-action is thereby stimulated and the supply of nutriment is out of proportion to the demands; but a moderate summer growth maintains a healthy reciprocal action between the roots and head—the fruit swells freely, and the bloom buds are thoroughly developed. Trees on the restrictive system are, in the case of vigorous examples, in no better plight than those allowed to make an excess of summer growth, as no amount of pinching will transform the unduly vigorous growths into fruit buds. Root-pruning may, close pinching will never do so. A moderate extent of new growth annually appears necessary for maintaining the trees in health and fertility, and it does not matter whether the superfluity be removed during growth or when the trees are at rest.

But I shall be asked if there is really no difference between winter pruning and summer pruning. My answer must be, Decidedly none. An over-luxuriant tree is not to be brought from a barren to a fruitful state by either winter or summer pruning. A vigorous tree pruned hard in winter is a mass of strong spray in summer, and on one closely summer-pruned clusters of growth break again quickly after stopping. The remedy in both cases is identical and threefold. First, extension, so as to bring the head into action with the roots; secondly, root-pruning, so as

to limit the supply of nutrition proportionate to the head; and thirdly, re-grafting. All of these are effectual in restoring unfruitful trees, especially the last—a practice by no means so common now as it was in old times, when if any tree had outgrown its space, and for want of room giving nothing but unfruitful growth, it was headed down and re-grafted. How often do we see trees which require extension to render them fruitful allowed to remain year after year without anything being done to rectify the evil, whereas re-grafting would restore them to fruitfulness in nearly as little time as root-pruning, and assuredly with greater certainty, no trees producing such fine fruit as that upon the wood of the first years of fertility.

Winter pruning and summer pruning are identical. Both mean the removal of parts not necessary to the symmetry of the trees, and as regards fruitful trees serve no other purpose whatever, as is evidenced by trees left to assume their natural form in orchards. If there is any advantage to the crops of fruit it must be obtained more from the winter than the summer pruning. The value of foliage in enhancing the size and quality of fruit is exemplified in trees both on the dwarfing and free stock which have attained an age that very little if any growth is made beyond that necessary for the formation of spurs or fruit buds. This may not be the result of age naturally, but by the food supply not being in excess of the requirements of the tree for fruit-production, for the less are the supplies of food the greater will be the effort on the part of the tree to fruit. These trees are yet the most disappointing of all. The blossom is very profuse and beautiful, but not unfrequently they do not set a single blossom. Why? The balance between the head and roots is so even that support is not forthcoming equal to the demands of the blossom, simply because there is no leaf or wood-bud growth to excite the action of the roots or to draw up sap for the expanded blossoms; or it may be that the blossoms are imperfectly developed in embryo in the previous autumn, and this, too, from a deficiency of alimentary matter. If there is a good set of fruit many drop in stoning, and the spurs thereby liberated give the tree strength enough to perfect the fruit remaining and form fruit buds for next year; but if all the fruit remain, the tree is so weakened by the year's crop that very few, if indeed any, of the spurs develop into fruit buds, whilst the fruit, unless thinning has been resorted to ungrudgingly, though great in numbers is inferior in both size and quality.

The remedy in their case is to prune to induce the production of fresh wood—increased supplies of nutrition by lessening the number to receive it—through well thinning out the clustered spurs; which, by affording more sap than can be appropriated by the fruit-bearing parts, will cause wood growths to be made, alike benefiting the present and future crops. Heading-down, either for re-working or training up fresh growth, will be attended by similarly favourable results. The great aim of pruning is to preserve the symmetry of the trees and make them adaptable to certain positions, but to think that pruning ever was instrumental in causing barren trees to become fruitful is a mistake.

Winter pruning may consist in thinning out the spurs and cutting back any that have grown so as to be at a distance from the base, which will admit more air and allow space for fresh growth, increased vigour, and finer fruits. In the case of trees neither too strong nor too weakly it will not be needful to cut back the summer shoots, stopped or otherwise, and not terminated by a fruit bud or a spur for forming one to a bud at its base. To prune trees in winter that make too much wood, and in consequence are unfruitful, is erroneous. Extension is needed, not curtailment, the head being left intact if space permit, and the roots pruned instead of the branches. How frequently do we see pyramid and bush trees cut into fashion and out of fruiting, which is left to themselves would convert the previous year's growth into fruitful buds, and give a heavy crop the following year. Once get a tree into bearing, and it will give little use for the knife; thinning, shortening back, and the removal of superfluities or irregularities will be all that is necessary, performing this in winter if the trees need vigour, in summer if too vigorous.

This brings me to the point I started from. Everybody has, or ought to have, a garden, and what garden is without its Gooseberries? I had a quarter of Gooseberries, beautiful bushes, making splendid shoots every year, which were spurred-in every winter, and they bore splendid crops of grand leaves, the shoots armed with glorious spines. The scantiness of crop was attributed to too rich soil, but the manure was given as usual, and the only thing laid aside was the knife; not a shoot was shortened nor one thinned out. The result was nearly every bud produced one or more berries, and by the time they were fit for tarts it caused some anxiety as to how the fruit was to be gathered, the shoots were so close and the spines so menacing. The heads were the

usual straight sticks disposed around the stem, and these had become quite closed up. These bushes happened to be those from which dessert fruit was taken and none gathered for tarts. The weight of fruit opened the heads, there were no longer any fear of difficulty in gathering. Every bush had to be staked and tied with tar band. This has been repeated every year since, and the only use now found for the knife in that quarter is in thinning old growths and encouraging new.—G. ABBEY.

CHRYSANTHEMUM KING OF THE CRIMSONS.

WHETHER this variety of Chrysanthemum should be placed in the reflexed or Japanese section is one of those questions that is not likely to be settled to everyone's satisfaction by simple argument. I have never attempted to force King of Crimson into the Japanese section. In my catalogue I give what I consider a full description of the flower (in the body of my catalogue it will be found classed as a reflexed); and in remarking that it is as much a Japanese as *Triomphe du Nord*, &c., I think the six blooms shown by me at the Aquarium fully justify. They were very generally admitted to be superior to many of the so-called Japanese, and it seems strange that the Judges should give a certificate for it as a Japanese, and the Royal Horticultural also, without it having some qualification to that distinction. It was very natural that "D., Deal," in making notes on the Show should follow the Judges' classification. I would rather have had it certificated as a reflexed, for my opinion is not that we should add such varieties to the Japanese, but place them all in the reflexed class, and so keep the classes more distinct. Now that we are about to have an election of the incurred varieties perhaps it will be followed by the same with the Japanese, which would afford a good opportunity for making a division of the two types. New varieties would then follow more in their proper class, especially as reflexed flowers are coming to the fore.

That King of the Crimson is not new we all agree. I heard of it many years ago, though I never had stock of it till Mr. Molyneux, a famed Hampshire grower, brought it from Liverpool some four years since, and kindly gave it me to send out, so that it is to Mr. Molyneux that thanks are due for King of the Crimson being again placed in commerce. It is a magnificent flower, and ought to have been seen at our large public shows long ago.—N. DAVIS, *Warner Road, Camberwell.*

KING OF THE CRIMSONS was grown by the late Mr. J. B. Whiting at the Deepdene, Dorking, about the year 1850. It was grown there for several years, but discarded to give place for *Julie Lagravère*, which has a much better habit for specimens; therefore, to my knowledge King of Crimson has been in cultivation for over thirty years, and is certainly not a Japanese variety. Several varieties of recent date have crept into the Japanese section, such as *Duchesse de Gerolstein*, *Illustration*, &c., that are poor reflexed varieties, and in no way like the true Japanese type.—J. BROWN, *Great Doods, Reigate.*

THE CUCUMBER DISEASE.

THIS curious disease appears to baffle cultivators in different parts of the country, and I felt much interested in both Mr. Taylor's and Mr. Gadd's remarks concerning it, as I, with many others in this part of the country (Hunts), have suffered by it. With me its appearance is similar to that described by Mr. Taylor, the fruit being inclined to curl and covered with numerous gummy exudations. I also notice in the young stems and leaves before the fruit are attacked small dark spots, as if it is some kind of fungus, as I have no doubt it is.

My experience of it dates from May, 1881. In a span-roofed house about 30 feet long we had been having a good supply for the previous three months, when I noticed small black spots on the tips of the fruit, causing them to curl and not develop satisfactorily. I had heard of the disease being within a few miles from here the summer previous, though I had not seen it, and at once concluded it was the much-dreaded pest. The plant first infested was cut out and burnt, but in a few weeks all the plants were diseased. All the small fruits as soon as noticed were cut off, for, like Mr. Taylor, I could not well afford to remove them until I could raise a stock from a new source. This was done. Young plants were raised in a house where Cucumbers had not been grown for four or five years, and then planted out at the end of June in dung frames, two large new three-light frames being employed for the purpose, newly painted. But to my alarm, as soon as the fruit appeared the black spot and gummy exudations followed, and only about a dozen clean Cucumbers

were cut from these two frames. These were situated about 30 yards from the Cucumber house. Again new seed was obtained from another source, and the plants placed out in a span-roofed pit that had generally been used for small miscellaneous greenhouse plants, but with the same result—no good Cucumbers again that year.

Not only were Cucumbers so affected, but Vegetable Marrows also, one bed near the frames above alluded to being the first to show it; then another in the kitchen garden towards September, and 70 or 80 yards from it. Melons did not have a trace of it, although growing in the next house to the Cucumbers. Of course all the growth was cleared and burnt as soon as possible, and all the soil taken out of the house and frames was wheeled as far away as possible. Sulphur and tobacco powder were burnt, and paraffin used freely about the walls, glass, and woodwork, and not a Cucumber plant or any plant of the Cucurbitaceæ family was in the garden from the end of October till the following March.

This year we have been a little more fortunate, having cut six times the quantity of fruit, but not so early in the year by two months. It, however, made its appearance in September both in Cucumbers and Vegetable Marrows, and a bed of about thirty plants of the Stockwood Ridge Cucumber in a favoured position as to soil and aspect in the kitchen garden, more than 100 yards away from the others, also had it badly, not a good fruit being obtainable from them. With these I did not notice it till after a week or two continuous rains we had about harvest time. I had also noticed that with plants in frames and houses dull wet weather favoured its spreading more rapidly. Raising the temperature of the house 10° by fire heat checked it considerably, but failed to stamp it out.

Although in Mr. Gadd's case soil is noted as the primary cause of the disease, one singular case came under my notice this season where a friend had been cutting good Cucumbers for two months up to May. They were then infested with this disease, and the plants were cut off level with the soil; new plants obtained from a fresh source, and planted in the same material that the diseased plants had been growing in, were watered and top-dressed as required, and no disease appeared all the rest of the summer, although within 50 yards a bed of Vegetable Marrows were growing attacked badly with it, the gardener going daily to it, and in and out of the Cucumber house several times during a day.

Another man not far from here, who sends Cucumbers by the hundred to market, had a few plants affected by this disease last spring; but he told me that raising the temperature considerably by fire heat checked the evil, although it did not cure it. The cost of extra fuel in weather when it is reasonable to suppose it could be dispensed with is a serious item for the market grower, increasing the cost, and thereby reducing the profits.

This subject cannot well be too much discussed in the gardening press, as any cure for this most troublesome pest would be a boon to many gardeners, their employers, and the general public.—A. HARDING.

GARDENING PAST AND PRESENT.

A RETROSPECT is always pleasing when it traces a steady advancement, and nothing shows this in a higher degree than gardening. We do not need to go back to the gardens of antiquity to see this, for it has had full proof in our own day. Gardeners love their profession, and an old gardener is never better pleased than when relating to the juveniles of his craft the incidents of his bothy days, and how differently work was done then. Instead of rising at four o'clock on a dewy morning to mow the lawn with scythes, as our fathers did (aye, and some of the first of modern gardeners), we see the machine drawn by a pony in all the glory of leather boots, leaving a surface so smooth that it outrivals the best carpet.

But herbaceous plants shone the brightest in the past. The taste for them is reviving, but it will be long ere we see them firmly reinstated in their rightful place. Modern taste allows them because they are fashionable, and so they are bought and planted. I do not write this unguardedly, for I have seen excellent collections proving little better than an eyesore. In old gardens the herbaceous border was a centre of interest, and there were few gardeners but what possessed an herbarium of their own collecting. The introduction of so many tropical plants has lessened the interest of the herbaceous border, and placed it in the houses, but even those who most love the old style will own this is a great step of advancement. Good though the pleasure grounds of the past were, how much better are those of the present, with the many ornamental trees and shrubs that collectors have sent us from all quarters of the globe!

Grape-growing, always an important branch of gardening, never before reached such a state of perfection; but where now are the Pine Apples that used to have so much attention? Except in a few establishments they are not grown, and in the weekly calendars of the gardening papers, where they so long held the place of honour, they are seldom mentioned. Kitchen gardening has been always well done, but I question much if ever better vegetables were grown than now; at least there were not so many varieties to assist gardeners in lengthening their season.—J. MACDONALD.

AIGBURTH BRUSSELS SPROUTS.

A YEAR ago your esteemed correspondent Mr. Iggulden remarked that the above much-praised variety had, with him, in good soil, grown too strong, and produced sprouts so large, open, and coarse as to be unacceptable, and asked correspondents who had grown it on poor soil to state whether the produce was satisfactory. As far as I can remember no one replied, presumably because all who had had fared similarly to Mr. Iggulden. That was what was done here; but this year plants were put out early on very indifferent soil, but still the results are unfavourable; so much so, in fact, that it never will again be grown here. The imported will be again resorted to, although a per-centage of such also comes useless. The fact seems to be, that Brussels Sprouts tend to revert to the type from which it sprang.—S. D.

FLOWERS OF THE PAST SEASON.

WITH me the past season has not been one of the most favourable for plants in the flower garden; and being reminded of the approach of another season, I wish to say a few words respecting some that have exceeded my expectations.

Gaillardia plectrantha Lorenzana.—Seeds of this were sown in heat, grown on as required, and planted out at the usual time, proved an acquisition both for beds and borders. It produced its variously coloured flowers through the summer until the frost stopped them. It is of dwarf habit, and was much admired by all who saw it.

Linaria reticulata aurea purpurea.—Another very choice dwarf annual. Its beautiful flowers are very attractive, and with care in cultivation it proves a useful plant for beds and borders. If intended for bedding, the plants should be pricked out singly and moved with a ball to their destination; but I prefer placing them singly in small pots. It seems to be at home everywhere in a garden.

Papaver umbrosa.—One of the richest crimson flowers we possess. It is treated as an annual, the seed being sown in the autumn and the young plants thinned to a few inches apart. It stands through our ordinary winters sown in spring, and we have a continuous display through summer and late autumn.

Verbenas.—I find these are much better grown from seed than from cuttings. The seed should be sown in heat in early spring, and grown on. Planted out at the usual time I had a splendid bed of mixed colours of all shades. I intend in the future to rely on seed for my supply. By so doing I shall economise time and space. Through the winter of late years I have found it a difficult matter and almost impossible to succeed with plants and cuttings through the winter.—P. U.

OF HUMUS.

(Continued from page 547.)

It is apparent from the facts cited in the letters which I have already addressed to you, that humus if not a direct food for plants (on which some obscurity still rests, high authorities ranging themselves on opposite sides on the question), there can be no doubt whatever that the functions performed by it in aiding the nourishing properties of other manurial constituents are most important. In the words of Liebig humus, as well as chloride of sodium, nitrate of soda, salts of ammonia, &c., "besides the action peculiar to their elements, perform also a kind of digestive function comparable to that of the stomach in animals, and in which they may partly replace each other. These substances, therefore, act beneficially upon those kinds of soil only in which there is a defect, not in quantity, but in the form and condition of the nutritive elements. They may, accordingly, in this permanent action be replaced by a mechanical comminution, or exceedingly fine pulverisation of the soil.

"The term 'manure' is commonly used to designate all matters which, applied to a field, will increase the amount of its future produce, or when the land has been exhausted by cultivation will restore its capability of yielding remunerative harvests. Manuring

agents act partly in a direct manner as elements of food, and partly, like common salt, nitrate of soda, or salts of ammonia, by enhancing the effects of the mechanical operation of tillage, so that they frequently exert as favourable an influence as the actual increase of the nutritive substances in the ground."—(Liebig's "Nat. Laws of Husbandry," p. 131.)

"For corn and summer plants, in order to obtain a maximum of produce, the presence of organised matter in the soil is of the utmost value. By the addition of sawdust the effect of the mineral manure was strikingly augmented, and it appears to me to be clear that the chief cause of this increased action must be looked for in the carbonic acid formed by the decay of the wood, which in this case acts not nearly so much as a source of carbon as by its solvent power for the earthy phosphates, and by converting into bicarbonates the neutral alkaline and earthy carbonates, and by rendering the silicates soluble. This carbonic acid is the condition furnished by Nature for the passage of these necessary parts of the food of plants into their organism, for the earthy phosphates and carbonates are only soluble in water when the water contains carbonic acid. The carbonic acid contained in rain water is obviously not sufficient to bring into the soluble form, which alone is fitted for assimilation by vegetables, the proportionately large amount of mineral substances absolutely necessary for a maximum development in summer plants, such as grain, during the short period of their growth. It is well known how great is the effect produced in this way even by moderate rains; and we may easily calculate how greatly this action must be increased by the addition of carbonic acid, whereby the solvent power of rain water for these mineral substances is augmented a hundred, nay, a thousandfold. The carbonic acid of ordinary spring water, which often retains in solution such considerable quantities of inorganic matter, proceeds from the same source—namely, the decay of organic matter in the soil."

"If to one acre English we add 8950 lbs. (about 4 tons) of the ashes (or of the ingredients of those ashes from other sources) of Wheat, Potatoes, &c., this large supply only suffices to give to the soil of the whole surface, to the depth of one foot, these materials in the proportion of 1 grain to each cubic foot. This is much less than is contained in a cubic foot of tolerably fertile soil; but, on the other hand, much more than is required for one crop. But since only that part of the manure acts which is in contact with the fibres of the roots, it is easy to see why so much must be given at first. It would appear, then, that in many cases the chief effect of manure on our fields consists in this—that in consequence of the more abundant nutritives in the upper crust of the field, the plants during the first period of their growth push out ten times, perhaps a hundred or a thousand times, more root fibres than they would have done in poor soil; and that their subsequent growth is in proportion to the number of those organs, by means of which they are enabled to search for and assimilate the less abundant food in the deeper strata. This may explain how a quantity of the constituents of manures—ammonia, alkalies, and earthy phosphates—so small in proportion to the same matters diffused through the soil, increases the fertility in so remarkable a degree."—(Note, Liebig's "Fam. Letters," p. 512.)

And here we may fitly refer again to that last important office of carbonic acid to which I alluded briefly at the conclusion of my last letter (p. 546); and, as in my first letter on humus (p. 472) I objected to the interpretation which had been put upon Liebig's theory by S. W. Johnson, I will call the attention of your readers particularly to the mode in which Liebig expresses himself, when it will be seen that he carefully distinguishes between the insolubility which arises from the natural chemical insolubility of a substance and that attractive force which the soil, like charcoal, exercises, for example, upon colouring matter, and which "is about on a par with the feeble affinity of water for salts which are dissolved by it, but without alteration of their chemical properties." The matters attracted "merely lose their solubility in water." The surface attraction which brings this about is therefore termed by Liebig "physical attraction." "In this state of physical combination," he says, "the alimentary substances are manifestly in the most favourable condition to serve as the food for plants, for it is clear that the roots in all places where they are in contact with the soil will find the necessary substances . . . retained in the soil by so slight a force that the most trifling dis-solvent cause brought to bear upon them suffices to effect their solution and transference into the plants." "The evaporation of water from the leaves produces a vacuum within the plant, whereby a draught is created which powerfully assists the contact of the moist earthy particles with the cell wall (at the extremities of the root fibres). The cell and the earth are pressed against each other. Between the fluid contents of the cells and the nutritive substances physically combined in the earthy particles

there manifestly exists a strong chemical attraction which, with the co-operation of carbonic acid and water, causes the transference of the incombustible matters into the system of the plant."—(*Liebig's "Laws of Husbandry," p. 71 and p. 86.*)

In this action of carbonic acid we have my last argument in favour of the manurial action (using the term in its widest sense) of humus, and I am unable to see anything more than an apparent verbal contradiction between the two theories of humus to which S. W. Johnson calls attention (see p. 473).

In conclusion I have only to sum up the various modes in which humus exhibits its agricultural value.

1, As an absorbent of moisture, which materially increases the fruitfulness of a soil.

2, By attracting and physically fixing ammonia, which would otherwise be washed away.

3, By chemically fixing ammonia by the aid of the acids which are generated as its decomposition proceeds.

4, By providing a long-continued, if feeble, supply of carbonic acid, which helps to distribute the phosphates, &c., which are imperfectly disseminated through a soil.

5, By assisting, through the disintegrating influence of the carbonic acid which it generates, in breaking down hard insoluble substances containing potash and silicic acid, &c.

6, By supplying carbonic acid to bring about the transference into the organism of the plant of the food with which the rootlets come into contact.

I would ask, then, whether these properties are not of sufficient importance to justify our agricultural chemists in allowing some money value for humus as such?—INQUIRER.

FRUIT AND JUDGING AT EDINBURGH.

MANY times previously I have contributed my thoughts in regard to some rule being authoritatively laid down in order that judging at horticultural shows might thereby be rendered more uniform. Let me premise that with grumblers I have slight sympathy, and not so much because they may not have some reason for their fault-finding, but because they seem to be satisfied with that one privilege and seldom take any other step to secure a more excellent way. It is well known to an exhibitor before he stages his produce that his exhibits risk being submitted to no better tests than the likes and dislikes of some person not better able to judge than himself.

At Edinburgh one of the things that pleased me most was the courtesy of the Secretary, next the attractive groups of plants staged for effect, and next very fine collections of Apples. With the Grapes I must own that I was somewhat disappointed. I could not get away from the thought that Grape-growing "with the lions" had not advanced since the Manchester show some ten years previously, though perhaps it might be quite as true that, generally, Grape-growing had progressed. At the show, save pairs of bunches, I could not find one perfect stand. In the collections it was plain that great difficulty had been experienced to secure bunches of uniform merit. The staging, too, was faulty. I once previously was anxious to show at Edinburgh, but on examining the schedule I discovered that Grapes must be exhibited on stands not higher than 6 inches at the back, and I refused to submit to any such foolish rule. Uniformity is desirable, and especially in the staging of Grapes grown by various competitors, as this secures a sameness being all but impossible. Had the Committee carried out the spirit of the rule that I have condemned by having had sloping boards fixed, padded, and covered, and requested that each exhibitor removed his Grapes from his own stands to the uniform stand provided, then I think the Grapes would have made a most magnificent display, which otherwise they failed to do. And this change would have included other desirable conditions, which it is unnecessary at present to further particularise.

Unfortunately, I took no notes at Edinburgh, but from memory I shall just run through the few stands of Grapes, and then I shall again propose a system of judging which if followed out would, I think, not only secure merits being more uniformly recognised, but form a source of increased interest to exhibitors, also to others interested, and do much to allay grumbling, as exhibitors would then see the reason of being passed by. On the evening of staging, after only a glance, I concluded that chief honours would be secured by either Mr. Kirk or by Mr. McKelvie, and that Mr. MacIndoe and Mr. Hunter would have a sharp run for third place. After a more careful examination next day the judgment I had arrived at I considered had been hasty; and that, though there was not much advantage to boast of, still that the awards arrived at by the Judges were justified. Had Mr. Kirk picked his stand of twelve bunches for his six I think undoubtedly

he would have won the six; but this he failed to do, and lost the prize. Mr. Hunter's Gros Colman and Golden Champion in his twelve were superb. Here he decidedly surpassed Mr. MacIndoe, as did Mr. MacIndoe surpass him where they again showed the same varieties—Gros Guillaume and Trebbiano. Next, Mr. MacIndoe staged two fine bunches of Black Hamburgh and in fine condition, whereas Mr. Hunter staged two equally fine bunches of Muscat of Alexandria, but which were past their best; and here it was that I think the award was gained, as Mr. MacIndoe's Mrs. Pince decidedly required time, whereas Mr. Hunter's better-ripened Alicantes were not at all such handsome specimens as he has previously exhibited. Mr. Kirk's pair of Muscat of Alexandria were decidedly weak, as were his otherwise handsome bunches of the Duke of Buccleuch weak, they having so many stoneless berries. Great credit was, I think, due to Mr. Kirk for his staging less showy bunches and depending on higher-class Grapes; but there the matter ends, as we have no rule that prefers one variety of Grape to another when equally well grown. Of Mr. McKelvie's exhibits I find that my memory does not justify further criticising them, though I well remember that with daylight my first very high opinion was partly modified.

Regarding awarding the Veitch Memorial medal to Mr. MacIndoe's two magnificent bunches of Gros Guillaume, I much regret that I could not agree with the judgment. That probably more credit was due to the ability that presented to us such produce I readily admit, but a weak spot that may reasonably be passed over in a collection when presented to us in a single exhibit I quite as earnestly contend judges are not justified if they ignore it. With the poor quality of the Grape as already alluded to, there being no recognised classification of merit, judges have nothing to do, but for such an award the nearest to perfection was necessary, which these bunches were not, as they had been cut some weeks too soon, and that this award was necessary to justify the other award I do not for a moment admit. The stand was undoubtedly first, but when closely examined this lack of finish was discernible enough, and there were other pairs of black bunches certainly without a fault. Mr. Hunter's Gros Colman, Mr. Johnstone's Alnwick Seedling, and I know at the time I examined other pairs of black bunches without a weakness visible. Had I had the giving of the prize the many meritorious exhibits that were otherwise necessarily passed by, in any of them where I could have discovered an equal justification, they would have been remembered. When it rains it frequently pours I grant, but enough is the more excellent way for all that.

Next, as to my suggested rules of judging. I contend they are plain, easily understood, and if the system does not promise to supersede the present system, then pray let others who are interested point out where they fail. On each exhibit I would lay cards similar to the following—

COLLECTION OF SIX DISHES OF FRUIT.

Fruit admissible.	Points allowed by Committee.	Points awarded by Judges.
1 Pine	10	9
2 Grapes	8	8
6 Peaches	6	5
6 Nectarines	6	—
6 Figs	6	6
1 Melon	6	6
6 Plums	4	2
6 Pears	4	3
6 Apples	4	1
1 quart Strawberries	4	—
1st card		40
2nd card		41
3rd card		38
		119

Judge's Name—A. B.

N.B.—The Judges are requested not to compare their cards or to add up the points. This duty will be performed by the Secretary, and by him the prizes awarded accordingly.

And not that I stipulate for the points I allow, for I am not in any way wedded to any particular allowance of points; generally what is made beforehand is fair. Each judge would then take one card, and after seeing the number of points allowed by the Secretary for fair specimens of each exhibit admissible, then on the blank space they would fill up according to their individual judgment, put their initials or names to the card, and then pass on till all was judged. We have a plurality of judges to prevent

oversight; by my system, in addition to this guarantee, we would secure to each exhibitor really what was each judge's opinion. More I dare promise: this opinion within the reach of all, as the judging cards would continue to lie on the exhibit, would be an attraction and a boon highly appreciated. To follow judges about the show requesting their reasons for their award is at all times a most unpleasant proceeding, yet I think it is but fair that an exhibitor should be reasonably satisfied when he, and probably friends, fail to discover the reason why other exhibits are placed in a higher position. My pleasure at witnessing this grand Show had much of its lustre obscured by my coming into contact with gardeners who stand high in their profession who were making loud complaints regarding the judging. My cards undoubtedly would tend to mitigate this most regrettable state of things, as judges would then not only have to give their opinion on every separate dish or plant, but leave such opinion to a following searching criticism.—JOSEPH WITHERSPOON.

ODONTOGLOSSUM HALLI.

IN reply to the letter signed "SINGLE-HANDED," as to whether his plant of *Odontoglossum Halli* has attained its full strength, I may say I have two plants of that *Odontoglossum* three years old. One has one lead, the bulb measures $6\frac{1}{2}$ inches long and 5 inches in circumference, the leaves $24\frac{1}{2}$ inches long by $1\frac{1}{2}$ inch broad. This measurement is from the last growth, which is considerably stronger than any previous growth made. The plant is grown in a 7-inch pot in a compost of broken crocks, peat, sphagnum, and charcoal. It has an abundant supply of water all the year round, and is showing a flower spike as thick as a goose quill. The pseudo-bulbs are glossy, vigorous, and healthy, and though the plant is grown in a low temperature all the year round nothing could look healthier. The other plant has two leads and is showing spikes, and is almost as strong as the first. I have some plants of *O. cirrhosum* almost as good, but the pseudo-bulbs instead of being long are rounder or obtuse.—A. J., *Leek*.

IN accordance with a frequently repeated request for an ELECTION OF CHRYSANTHEMUMS we have taken steps to procure returns from the chief growers and exhibitors throughout Great Britain. The incurved varieties have been selected first, and all who wish to take part in the election should apply to the Editor at once for a form, which has been prepared to aid in carrying out the object in a convenient and systematic manner.

— MR. F. C. PAWLE, Northcotes, Reigate, desires us to notify that the Reigate Rose Association have fixed their Show next year for Saturday, June 30th.

— RELATIVE to the POISONOUS NATURE OF LABURNUM SEEDS "P. L." writes:—"During the time I was journeyman at Harewood House, the Earl of Harewood's near Leeds, several swans were poisoned by eating ripe Laburnum seeds falling into the lake. That was either in 1868 or 1869, and his lordship then had all the Laburnum trees cut down that were near the lake."

— MR. BROWN of Great Doods recommends the following as late WHITE CHRYSANTHEMUMS:—"Princess of Teck, very good; Mrs. Kaims, creamy white; Blonde Beauty, blush white. The above are incurved varieties. The following are Japanese—Meg Merrilees, lemon white, very useful; Sarnia, pinkish changing to white, very good and late; Ethel, very fine late white; Bouquet Nationale, beautiful fringed white. The above varieties are all good if well grown, and will flower until the middle of February if grown naturally and not thinned for show blooms."

— MESSRS. H. CANNELL & SONS of Swanley exhibited several plants of the new DOUBLE BOUARDIA PRESIDENT GARFIELD at the last meeting of the Royal Horticultural Society,

and though the Floral Committee did not honour the variety with a certificate, such a recognition would have been well merited. The flowers are double and similar to Alfred Neuner in form, but they are of a pale rosy shade, varying slightly in depth of tint, though perfectly distinct from the pure white of the other double variety.

— THERE appears to be considerable room for the employment of ELECTRIC LIGHTING IN CONSERVATORIES; and though at present only occasional public experiments have been made in this direction, there is no doubt that it will become more general. As an example of trade enterprise in this direction we recently observed that a florist at Brixton is lighting his show house, a conservatory of moderate dimensions, with a large electric lamp, which shows the groups of plants to excellent advantage. With Palms, Ferns, Dracænas, and Crotons are associated Poinsettias, Euphorbias, Cyclamens, Primulas, Tulips, and other bulbs, a tasteful display is produced that is much more effective at night than in the day during such dull weather as has recently prevailed.

— A CORRESPONDENT writes that "CHRYSANTHEMUM ROSA BONHEUR is one of the most useful grown. It does not exceed a height of 2 feet, and is therefore useful for stages. It is one of the Japanese kinds, and the colour is a bright pinkish lilac. Ethel is again useful as a very late white, though perhaps a cross with Elaine might produce something much better. These have flowered with a number of other good kinds in the Cambridge Botanic Garden. In that establishment a plan has been adopted this year by which a good display has been made without trouble or much labour. Instead of growing in pots some good clumps were carefully lifted of the Pompon kinds and placed on the floor of a greenhouse, where by a few stones the soil was kept together in a bed, so that no check was sustained by the plants, the result being a larger quantity of flowers for cutting, in addition to the extra display obtained. This plan is one that might often be adopted with advantage."

— "R. L." writes:—"THE VALUE OF WINTER-FLOWERING BEGONIAS is well exemplified in one of the houses at Orsett Hall, Essex, where numerous plants of the most useful varieties are flowering profusely, and Mr. R. Castle, the gardener, states that he finds them indispensable. *B. semperflorens* and its variety *rosea* are especially good; the large white blooms of the former and the rosy-tipped flowers of the latter variety are produced very freely, even by small plants in 60-size pots. These young specimens are very useful for decorative purposes, either in a warm conservatory or a stove. *B. fuchsioides*, with its pendant brilliant scarlet flowers, is similarly attractive, while *B. Ingramii* has been in excellent condition for two months and more, and plants are still loaded with blooms. *B. Frœbeli* is also well grown, and when bearing its deep scarlet flowers as freely as it is now it is unsurpassed amongst its allies. Good turfy loam forms the basis of the soil employed, and the healthy growth of the plants amply testifies that they appreciate their treatment.

— "IN the same gardens a comparatively rare plant is now flowering—namely, THE VIOLET-SCENTED TINNÆA (*T. æthiopica*), of which you gave an engraving in the Journal some time ago (February 3rd, 1881, page 94). This is not so remarkable for the beauty of its flowers as for its fragrance, which strongly resembles Violets, and in a warm house of moderate size one plant is quite sufficient to perfume the air most agreeably. The corollas are two-lipped, deep maroon, almost black, the calyx being large and light green, inclining to white. The chief defect of the plant is that it is liable to become straggling unless the growths are pinched-in to induce a sturdy and compact habit. It delights in a stove temperature and a moist atmosphere, with a compost of light loam, sand, and leaf soil."

— WRITING on the WEATHER IN THE SOUTH OF SCOTLAND

a correspondent observes:—"A snowstorm with fog and hard frost has since the 5th inst. stopped all outdoor work. Inland the weather has been much more damaging than in our district. From one place in Berwickshire we have heard that the coal supply was exhausted; and the roads to the railway station being impassable, they had to make the best of things until the roads were cleared. The weather previous to this outbreak was fairly good, consequently there have been both gardeners and farmers found in a state of unpreparedness. Many of the latter have neglected to secure Turnips, and we have even heard of Potatoes being as yet unlifted. The latter, owing to the railways being blocked, have risen to a very high price considering what had been realised of late years. The vegetable markets, which have been overstocked throughout the autumn, will now be scantily supplied, as the snow is generally over a foot in depth in the district. On the night of the 11th inst. the frost was intense, the thermometer indicating from 8° to as low as -4° Fahr., or 24° to 36° of frost." In another district of Scotland we are informed the thermometer a week ago registered as low as -10°, or 10° below zero.

— THE DOUBLE WHITE BOUVARDIA ALFRED NEUNER is becoming a great favourite with the florists and bouquetists in Covent Garden, and the flowers are now quite abundant in the windows there. It appears to be greatly appreciated for button-holes, and for this purpose the flowers are admirably adapted either associated with Rose buds, Violets, the single scarlet and pink Bouvardias, and similar flowers.

— "L. D. W." remarks:—"CHRYSANTHEMUM GOLDEN CIRCLE is a very useful Pompon variety that is not generally known. It is of dwarf sturdy habit, a profuse bloomer, and the flowers a very good yellow in colour. This variety retains its foliage well, and is not so subject to mildew as many varieties. It is admirably adapted for growing into small specimens for decorative purposes; or where naturally-grown bushes are in request, with a minimum of labour required in staking, this variety should have a place, as it will be found a grand companion to *Sœur Melanie*."

— GARDEN APPOINTMENT.—Mr. H. A. Mann, who has for the last nine years held the position of head gardener at St. Vincent's, New Somerby, Grantham (Mrs. R. Hornsby's), has recently been appointed to a similar post at Denton Manor near Grantham, the seat of Sir W. E. W. Gregory, Bart., M.P.

— "B." gives the following as three FREE-FLOWERING DOUBLE PELARGONIUMS:—"Few flowers are more charming during the winter season than a good double white Pelargonium. The best in all respects that I have had is *Candidissimum plenum*. The truss is not so large as some kinds, but is quite large enough, while it is a model as to form, and of the purest white. Like other double varieties it requires stove treatment during the winter. An occasional application of some manurial agent is also necessary to keep the plants floriferous. Old plants are much better than yearlings, which applies to other kinds as well. The most useful scarlet is doubtlessly *Wonderful*, the most floriferous of all doubles. This is a sort which I always think is seen to greater advantage during the winter months than at any other season. Of pink shades *Madame Thibaut* is the best. It is almost as free-flowering as *Eugène Bandouin*, and has a larger truss of pips. Both are good, though I prefer the former."

— WE have received some further particulars in reference to the second annual EXHIBITION OF PLANTS AND HORTICULTURAL APPLIANCES to be held at the AGRICULTURAL HALL, ISLINGTON, from March 15th to the 24th, 1883, which has already been announced in these pages. Special provision is made for plants, fourteen classes being enumerated in the schedule, the prizes in

thirteen being of equal value—namely, a gold medal value six guineas as the first prize, or money if preferred, and a silver medal value three guineas as the second prize, offered under the same conditions as the other. In the fourteenth class, however, which is for a collection of British and foreign fruits, the first prize will be a gold cup value £10, and the second prize a silver cup value £5. Classes are provided for collections of hardy spring-flowering plants arranged for effect, decorative evergreens and flowering shrubs, Hyacinths, Narcissus, Tulips, miscellaneous bulbs in flower and arranged for effect, Ivies, Hollies, bedding Pelargoniums, carpet-bedding plants, dinner-table decorations, window boxes, and hanging baskets. The value of the prizes offered may be expected to insure a keen competition, and if that be the case an extremely attractive show will result. The horticultural appliances will include exhibits from a number of the most important firms, comprising greenhouses, conservatories, frames, borders, heating apparatus by water and gas, summer houses, garden seats, vases, rockeries, implements, fancy boxes, flower stands, dried grasses and flowers, artificial manures, and insecticides. The Manager is Mr. J. H. Raffety, the Hon. Sec. Mr. Shirley Hibberd, and the Assistant Sec. Mr. W. A. Holmes.

— MR. BARDNEY writes:—"The plant of *LUCULIA GRATIS-SIMA* referred to on page 475 has about 320 trusses of flowers; the number mentioned by your correspondent only alluded to those fully expanded when he saw them. This is merely stated that readers of the Journal who do not know this beautiful plant may form a correct idea of its free-flowering habit."

— AN experienced cultivator writes as follows:—"The best BED OF HARDY PLANTS I have seen this season was a large one, the centre being composed of the two varieties of Pentstemons *Eclipse* and *Mrs. Sutherland Walker*, both being reddish shades of colour, and in habit branching and floriferous. These were planted about 3 feet apart each way, the ground beneath being covered with a carpeting of the dark purple *Viola Alpha*. A line of the yellow *Viola Sovereign* surrounded these, and another line of the dark-leaved *Ajuga reptans* divided this from the edging, which was a sloping band of *Sedum glaucum* rising from the grass of the lawn. So much depends on the way that these hardy flowers are treated that it may be advantageous to make a note of this. In the first place, both Pentstemons and *Violas* require very liberal culture. Both require to be strong plants when placed out. The Pentstemons were struck in the summer of 1881, not in the autumn as is generally the case. The *Violas* were merely old plants divided and planted early in spring. The results were that by the beginning of May the *Violas* were flowering freely and the bed a feature in the grounds. In June the Pentstemons were blooming, and continued with the *Violas* without break until the end of November. At their best not even the scarlet Pelargoniums could rival the Pentstemons in brightness. The summer work merely consisted in placing a short stake to each plant of Pentstemon, and in cutting the seeding spikes of these and the seed capsules off the *Violas*. I have some late spring-struck Pentstemons of 1882 potted for bedding purposes next season. These do very well, and come into flower even earlier than spring-struck plants of the preceding year."

— A CORRESPONDENT writes:—"There is at the present time a GOOD DISPLAY OF *CALANTHES* in one of the plant houses at Marston House, Frome. They are disposed in a bank of such Ferns as *Davallia Mooreana*, *Adiantum Farleyense* and *cuneatum*, and *Lycopods*, and are remarkably effective. The varieties include the drooping *C. vestita* and *C. vestita lutea*, and apparently three distinct forms of *C. Veitchii*. Of the latter the dark red form is decidedly the most valuable. The others are much lighter, one being tall and arching, and the other more erect,

sturdy, compact-flowering, and the flowers smaller, of a still lighter shade. They are grown in a light compost, consisting principally of sphagnum, rough peat, and charcoal, and were not dried off nor transferred to a lower temperature when the foliage was commencing to change colour. Even those who affect to despise Orchids generally must admit that *Calanthes* for decorative purposes have no equal during the dull winter months."

— THE "GARDEN ORACLE" for 1883 is now issued, and the fact that this is the twenty-fifth year of publication is in itself sufficient testimony of its value. In addition to usual calendrical matter and miscellaneous useful tables lists of the new plants and flowers of 1882 are given, together with selections for general cultivation. New and select fruits and vegetables receive similar attention, one of the most important features of this issue being a synoptical catalogue of garden Peas. Illustrations of new garden appliances are also given, completing a compendium of seasonable information.

LINUM TRIGYNUM.

THIS old inhabitant of our plant houses is not half so generally grown as it deserves to be for decorative purposes at this season of the year. When well grown no plant arrests the attention of visitors sooner than this. If I had the room to spare for a time at this season of the year I should have sufficient plants to entirely fill a house, or one side of it, and intermix with it plants of *Plumbago rosea* in 5 and 6-inch pots. The feathery sprays of the latter would rise well above the groundwork of yellow produced by the more bushy habit of the *Linum*.

Linum trigynum is generally placed in catalogues as a greenhouse plant, but when subjected to cold treatment its growth is remarkably slow, and few flowers are produced in winter. During summer it will thrive well under cool treatment, and I daresay in the more southern parts of the country would do outside for a few of the warmest months in a sheltered position. This, however, I cannot recommend, for I have never tried it, but know outside treatment will not do in wet, cold, northern localities. It is only during the hottest months of the year that I place our plants in cold frames.

Propagation is effected by cuttings of the young shoots, which are produced freely after the plants have flowered and been partially cut back. The most vigorous growths should be selected for the cuttings, being taken when about 2 inches in length, and inserted in sandy soil either singly or in a 5-inch pot, and placed in a vinery or any warm position under a bellglass. The cuttings will root freely and quickly in any warm close house with or without bottom heat; in fact, if the old plants are kept in a very warm moist atmosphere they will quickly throw out numbers of roots from the stems. This plant is rather strong-rooting, and must be potted singly as soon as the cuttings are struck, and grown in an intermediate house until they are ready for larger pots. When the young plants have commenced rooting in their first pots the points of the shoots must be pinched out in order to compel them to break back. Stopping the shoots must not be neglected when required in the early stages of growth. If the cuttings are rooted early in the month of April they will be ready for 5 or 6-inch pots in June, which are large enough for bushy decorative plants. Cool-frame treatment may be afforded during the two following months, or until the middle of September; after that date they must have a position where the night temperature will not fall below 50°. The shoots should be stopped about a fortnight before placing the plants in their flowering pots, and the plants rooting freely into the new soil before they are placed into cold frames. Care must be taken in preparing the plants for this shift, or they are sure to be checked for a long time in consequence.

Particular attention to watering and syringing is of the greatest importance in the cultivation of this plant. If once allowed to suffer by insufficient supplies they are sure to become infested at once with red spider. They can be kept clear of this pest if properly watered and syringed heavily twice daily. If this be done every morning and again early in the afternoon, and the frame closed while the sun is on it, with abundance of moisture, there need be but little fear of red spider troubling the plants. During their season of growth they should stand upon some moisture-holding material: nothing is better for this purpose in frames than coal ashes. Although abundance of water is required care must be taken for some time after they are first potted. Plants not infrequently are watered too freely when in this stage and the soil in consequence soured. When the pots are fairly

well filled with roots stimulants may be given freely every time watering is necessary. Once or twice weekly applications of clear soot water will be found very beneficial in imparting to the foliage a dark green hue.

Air must be freely admitted during the summer on all favourable occasions in order to ripen the growth as it is made, as upon this depends very much whether the plants flower profusely or not during winter. It is wise, however, to ventilate freely early in the season while the young plants are growing rapidly. They will stand without any apparent injury a close warm atmosphere during autumn and winter, but the flowers are over quicker, and do not possess that substance and brilliancy as they do when brought into flower in the temperature of an intermediate house. A little shading is necessary during the summer, at the same time every ray of light possible should be admitted to them.

The soil I have found most suitable is good fibry loam with one-seventh of manure, or a 6-inch potful of bone meal and the same quantity of soot to each barrowful of soil, with sufficient coarse sand to render the whole porous.—W. BARDNEY.

PLANTING ROSES—SPRING v. AUTUMN.

THIS question has now been so thoroughly well discussed that further remarks are hardly necessary, more especially as this season it has practically settled itself, for after having had an unusual amount of rain in October, November, and the early days of December, we are now having snow and sharp frost (10° at 4 feet from the ground), and planting is simply impossible; but I may be permitted, as the originator of the question, the privilege of a reply. I cannot but feel grateful for your many kind correspondents, most of them known to me, who have given us their opinions, and for the courteous manner (so becoming in the *Journal of Horticulture*) with which it has been treated. I am bound to say that the preponderance of opinion is against me, but whether facts are equally adverse is another matter. This can only be proved by further experiments, as sufficient evidence in favour of both systems has been recorded in the *Journal*.

It must be borne in mind that I did not write about what one might do with the transplanting or removing of plants which were already in the garden, where they would have no time to remain out of the ground, and where they could be moved at any time during October so as to make fresh roots before the winter set in, but to those which had come from a distance, which are never received from the nurserymen until November, and sometimes in December; and in my opinion it was, as I said, better to get these in the autumn (by no means to delay the order till the spring) and then lay them in, covering the roots with stable litter and then leaving them. Now in the opinions which have been given adverse to this plan it has been in many instances conceded that it was good for Teas, and indeed this is the advice which is given in some catalogues as to the winter treatment of this class. But I would desire to ask, Which is to be protected—the top or the roots? If the roots, which I hardly imagine to be the case, what difference can there be? They are budded on the same stock, and it is that and the junction which have to be protected. In fact, as I have more than once insisted, I do not believe that this difference in treatment in Teas and Hybrid Perpetuals is at all necessary in the northern parts of England or in the south of Scotland and Ireland generally. In the Midlands, where frost is so much more felt, or in the northern parts of the kingdom, the case is perhaps different. The newer varieties of Teas are so much hardier than many of the older ones, and some of the newer Hybrid Perpetuals have so much Tea blood in them, that they approach more nearly to one another than they used to do, and their treatment, therefore, becomes more assimilated.

As I look at my Roses heeled in and covered with stable litter I must confess to being more easy in my mind about them than those that are planted out, although the latter are protected about the roots with longish litter from the pigstye, for I believe that well-decayed stable manure is but a poor protector from frost; it is so sodden that I think it must hold much wet, and amongst other things that next season will, I hope, bring to us will be further experience on the system I have thus indicated.—D., Deal.

ASTROCARYUMS.

THE *Astrocaryums* are a genus of pinnate-leaved Palms, chiefly found in South America and inhabiting the regions on the upper Amazon, and frequenting the marshy districts in the neighbourhood of that and other rivers. Like the *Martinezias*, they are distinguished by an abundance of formidable spines, which thickly clothe the stem and leafstalks; but notwithstanding this character the species are mostly rather handsome when they reach a good size.

A fine example of *A. mexicanum*, a species which was introduced from Mexico in 1861, is grown in one of the houses at Endcliffe Hall, Sheffield, and is probably the first which has flowered and

ripened seeds in this country. The woodcut (fig. 97) shows a portion of this Palm, the spadix of flowers being sheltered under a large spathe covered with spines, which gives a most peculiar

Fig. 97.—ASTROCARYUM MEXICANUM - SPATHE AND SPADIX.

appearance to the plant. Seeds have also been matured, as the *Astrocaryums* are not dioecious like many other Palms, but both

pistillate and staminate flowers are produced on the same spadix, and fertilisation is thus readily effected naturally. The generic

name (*Astrocaryum*) refers to a character of the fruits in some of the species, which, when mature, split into six narrow portions, which spread out in a star-like manner and permit the inner portion of the fruit to fall out. Like many other Palms, these are not devoid of uses. For instance, *A. Murumuru* produces an edible fruit upon which cattle feed in its native country, and the fibre of *A. vulgare* leaves is employed in weaving hammocks and various other purposes.

The fruits of many species of Palms are invaluable in some tropical countries, the Date and Cocoa nut being remarkable examples of those useful in this respect; the Areca nut, too, is another noted production, while the Ivory nut is also the fruit of a Palm. One extraordinary character of Palms is the astonishing number of flowers produced by single plants. For instance, twelve thousand staminate flowers have been counted in one spathe of the Date Palm; but this number is far surpassed by *Alfonsia amygdalina*, as in one spathe as many as 207,000 flowers have been produced, and it is estimated that one plant has borne about six hundred thousand flowers. Several other similar examples have been observed, and the large specimen of *Arenga saccharifera* in the Palm house at Kew a few years since, which used annually to produce enormous quantities of flowers, has often attracted attention on this account.

At Endcliffe a grand specimen of *Seaforthia elegans* has been fruiting for a long time, the seeds falling and germinating in hundreds on the rockery at the base of the specimen, and these Mr. Stevens transfers to pots as they become large enough for removal.

GROWING CHRYSANTHEMUMS.

IN reply to your correspondent "J. L." (page 556) in reference to growing Chrysanthemums for exhibition, I should refer him to the *Journal of Horticulture* of December 29th, 1881—Mr. J. W. Moorman's excellent article on Chrysanthemum culture. By following the directions given there and selecting the right buds you cannot fail to have fine flowers and plants. But now that the subject is opened I think it would be interesting if some of our successful northern growers would give their experience in regard to crown and terminal buds—the varieties they have found to work best on these two buds, say the best twenty-four incurved and twenty-four Japanese. The selection of buds is but indifferently understood, and undoubtedly the secret of success lies not so much in stimulants as in disbudbing. I might state that Prince of Wales and its sport Mr. Corbay have done but indifferently on the crown bud about Liverpool this season.—C. WARING.

ROYAL HORTICULTURAL SOCIETY'S COMMITTEES.

THE reconstruction of the Committees of the Royal Horticultural Society for 1883 by the Council is as follows:—

SCIENTIFIC COMMITTEE.

CHAIRMAN.

Sir Joseph Dalton Hooker, K.C.S.I., M.D., C.B., F.R.S., V.P.L.S., Royal Gardens, Kew.

VICE-CHAIRMEN.

Geo. F. Wilson, F.R.S., Heatherbank, Weybridge Heath.
Col. R. Trevor Clarke, Welton Place, Daventry.
Rev. M. J. Berkeley, F.R.S., Sibbertoft, Market Harborough.

SECRETARY.

Rev. G. Henslow, F.L.S., Drayton House, Ealing.

Balfour, Professor I. Bayley, Hillhead, Glasgow.	Hogg, Robert, LL.D., F.L.S., 99, St. George's Road, S.W.
Bauer, F. O., Normal School of Mines, South Kensington.	Loder, E. Giles, Floore, Weedon, Northamptonshire.
Bennett, Alfred W., M.A., B.Sc., F.L.S., 6, Park Village East, N.W.	Lowe, Dr., Wimbledon.
Boseawen, Hon. and Rev. J. Townshend, Lamorran, Prohus, Cornwall.	Lynch, R. Irwin, A.L.S., Botanic Gardens, Cambridge.
Boulger, G. S., 144, Kensington Park Road, Notting Hill, W. [Kew.]	Masters, Maxwell T., M.D., F.R.S., Mount Avenue, Ealing, W.
Church, A. H., F.C.S., Royston House, Kew.	McLaehlan, R., F.L.S., Lime Grove, Lewisham.
Cooke, Dr. M. C., Herbarium, Kew.	Mangles, J. H., Valewood, Haslemere.
Crewe, Rev. H. Harpur, Drayton Beauchamp Rectory, Tring.	Moore, Thos., F.L.S., Botanic Gardens, Chelsea, S.W.
Elwes, H. J., F.L.S., F.Z.S., Preston, Cirencester.	Murray, G., Botanical Department, British Museum.
Foster, Dr. Michael, F.R.S., Cambridge.	Paseoe, F. P., F.L.S., 1, Burlington Road, Westbourne Park, W.
Gilbert, J. H., Ph.D., F.R.S., Harpenden, St. Albans.	Smith, Worthington G., F.L.S., 125, Grosvenor Road, Canonbury, N.
Glaisher, Jas., Dartmouth Place, Blackheath.	Strickland, Sir C. W., Bart., Hildenley, Malton.
Grote, Arthur, F.L.S., 20, Cork Street, Burlington Gardens, W.	

FRUIT COMMITTEE.

CHAIRMAN.

Henry Webb, Redstone Manor House, Redhill.

VICE-CHAIRMEN.

John Lee, 78, Warwick Gardens, W.
Sir C. W. Strickland, Bart., Hildenley, Malton.
H. J. Veitch, F.L.S., Royal Exotic Nursery, Chelsea, S.W.

SECRETARY.

Arehibold F. Barron, Royal Horticultural Society, Chiswick, W.

Blackmore, R. D., Teddington.	Mason, Major F., The Firs, Warwick.
Bunyard, George, The Nurseries, Maidstone.	Paul, George, Cheshunt, Herts.
Burnett, J., The Gardens, Deepdene, Dorking.	Paul, William, Waltham Cross, N.
Crowley, Philip, Waddon House, Croydon.	Rivers, T. Francis, Sawbridgeworth.
Denning, W., The Gardens, Londeborough Lodge, Norbiton, Surrey.	Roberts, J., Gunnersbury Park, Acton.
Ford, Sidney, Leonardslee, Horsham.	Rutland, F., Goodwood, Chichester.
Goldsmith, G., Hollanden Park, Tunbridge.	Silverlock, Charles, 412, Strand, W.C.
Hogg, Robert, LL.D., F.L.S., 99, St. George's Road, S.W.	Smith, J., The Gardens, Mentmore, Leighton Buzzard.
Howeroft, Mr., 14, Tavistock Row, W.C.	Stevens, Zadok, The Gardens, Trentham Hall, Stoke-on-Trent.
Killiek, Lewis A., Mount Pleasant, Maidstone.	Sutton, Arthur W. (Sutton & Sons) Reading.
Lane, John E., Berkhamstead.	Weir, Harrison, Weirleigh, Brenebley, Staplehurst.
Laxton, Thos., Bedford.	Willard, Jesse, Holly Lodge Gardens, Highgate, N.
Lyon, S., The Gardens, Sundridge Park, Bromley.	Woodbridge, John, The Gardens, Syon House, Brentford, W.

FLORAL COMMITTEE.

CHAIRMAN.

Rev. H. Harpur Crewe, Drayton Beauchamp Rectory, Tring.

VICE-CHAIRMEN.

B. S. Williams, Victoria Nursery, Upper Holloway, N.
Geo. F. Wilson, F.R.S., Heatherbank, Weybridge Heath.
Shirley Hibberd, 15, Brownswood Park, Stoke Newington, N.

SECRETARY.

Arehibold F. Barron, Royal Horticultural Society, Chiswick, W.

Ballantyne, H., The Dell Gardens, Egham.	Hudson, James, The Gardens, Gunnersbury House, Acton.

AUCHENDRANE.

AUCHENDRANE, which is beautifully situated on the classic banks of Doon in South Ayrshire, is the seat of Sir Peter Coats, a gentleman well known for his large-hearted benevolence and for the lasting benefits he has conferred on his native town of Paisley. Few of the wealthy of any country have been so generous in considering the wants of the people and ministering to them. Sir Peter a few years ago presented the town of Paisley with a building for a free library and museum at a cost of about £20,000, and recently provided additions to the buildings at a further cost of £12,000. This is only one (though it is the most conspicuous) of his public acts of generosity; but few will ever know of the many private acts of charity bestowed by him on the poor and needy.

When visiting the International Flower Show at Edinburgh in September last I took the opportunity of spending a day with my much-esteemed friend Mr. Currie, the head gardener, and through the kindness of Sir Peter of having a day's salmon-fishing in the Doon.

The principal entrance to Auchendrane has been well chosen at a point on the Ayr and Maybole turnpike road, distant from Ayr about five miles and close to a bridge that crosses the Doon. The approach on each side is tastefully planted with large clumps of Rhododendrons and other flowering shrubs, which grow luxuriantly here, and flower freely during the season. The mansion is pleasantly situated on the right bank of the Doon, and secluded from the public road by plantations. It is a modern building, standing on an eminence high above the rapid-flowing river. The house commands a fine view of a richly wooded valley. The mansion and grounds have been greatly

improved of late. The property possesses rare natural advantages, but much has been done to improve it since it came into Sir Peter's possession. It is rare to find within so small an area so much of what constitutes the charm of a residential estate. By judicious arrangement a large extent of pleasure ground has been formed and flower gardens laid out, while ornamental trees and shrubs have been skilfully planted in suitable places for effect. Pleasant winding walks have been made through the woods and along both sides of "bonny Doon," these being connected by means of a light and graceful bridge spanning the river. Lawn tennis and other recreation grounds have been laid out amid charmingly picturesque surroundings. Artificial ponds have been constructed on the banks of the river, in which experiments have been carried on in the artificial hatching of salmon fry. The mansion is artificially lighted by means of gas manufactured from paraffin oil on the estate. The gas, I understand, is better than that from coal, and its manufacture is free from some of the disagreeable effects incident to ordinary gas-making.

The kitchen and fruit gardens, vineries, Peach and plant houses lie to the left of the mansion on a somewhat higher level, and are screened from it by a plantation of trees and shrubs. The gardener's house, a substantial new building, stands on a commanding position close to the kitchen garden. It is commodious (with rooms upstairs and down) and well fitted with bath-room and every other appliance calculated to give health and comfort. The forcing and plant houses stand all together in a large block. Some are span-roofed and some of them lean-to, and each house is divided by a glass partition, and connected by a door to the next, so that a person entering the first house can pass through all the others without the necessity of going outside.

The first house in the range is a span-roofed plant stove 60 feet long by 22 feet wide, with raised bed in the centre for standing the plants on. It contained choice climbing and other plants. The climbers are planted out in the borders and trained over the roof; treated in this way they do well. I have seldom seen better-grown plants of *Allamanda Hendersonii* and *Bougainvillea glabra*. They were flowering most profusely, and I was informed that they had been so for months. The centre bed and side stages are filled with large Palms, Ferns, Crotons, *Dracænas*, *Eucharises*, *Cycas revoluta*, and a general collection of stove plants. A small but choice selection of *Odontoglossums* and other Orchids filled a portion of one of the side stages, all of which were clean and healthy.

The second house is a half-span-roofed vinery 50 feet in length. It was planted some two years since with from two to three Vines each of the following varieties:—*Gros Guillaume*, *Lady Downe's Seedling*, *Alnwick Seedling*, *Black Alicante*, *Gros Colman*, *Black Hamburgh*, and *Foster's Seedling*. The Vines were bearing from one to two large bunches each of nicely finished fruit. They have made strong canes this year, and to judge from their health and general appearance they will produce some fine fruit next year. The portion of back wall in this house forming the half-span is covered with Vines of *Gros Colman*, which were bearing a heavy crop of medium-sized bunches and large finely coloured berries.

The third house contains Melons, Figs, and plants. The Melons are planted out in a border in the usual way close to the front lights, and trained over one side of the roof. The plants occupy a stage on the other side, and the Figs the end wall and centre of the house. *Auchendrane Hybrid* and *Strathsfeldy* are the varieties of Melons generally grown here. Mr. Currie informed me that good crops of Melons and Figs were obtained annually from this house, and that the same atmospheric treatment seemed to suit both fruits. The fourth house is an early vinery—a lean-to—20 feet long by 14 feet wide, planted with *Black Hamburgh* and *Foster's Seedling*. The fruit was all gathered some time before my visit, and the Vines were in good condition for forcing early next year. The fifth house is an octagonal greenhouse 24 feet by 24 feet, and 18 feet high, the roof of which is gracefully draped with climbing plants hanging down in long festoons of flowers. These consisted of *Passiflora*, *Tacsonia*, *Bignonia*, *Lapageria*, *Acacia*, and *Maréchal Niel Rose*, the latter worked on the *Banksian Rose*, and seemed to do remarkably well on this stock. The interior of the house was filled with large *Camellias* and a general assortment of healthy well-grown plants.

The sixth house is a late vinery devoted entirely to the culture of *Gros Guillaume*. The Vines looked as if they were well cared for; they were vigorous and clean, and bearing a good crop of highly finished fruit. In passing I might say that Mr. Currie informed me that none of the Vine borders were ever allowed to become dry at any time, and that they were freely watered at all stages of the Vine's growth when they required it, which had the effect of keeping the leaves in a green and healthy state, and allowed of the canes getting thoroughly ripened before the foliage fell. The seventh house is devoted to Azaleas. It is a light and graceful structure, well adapted to the growth of plants of this kind. The inside is fitted up with stone stages for placing the plants on; and part of the rafters here, as is the case in most of the plant houses, is covered with climbing plants, which give a finished effect to the house. At the time of my visit the Azaleas were undergoing a thorough syringing with a mixture of paraffin and water previous to being placed in their winter quarters. They were large pyramidal-trained plants from 6 to 8 feet high and well set with flower buds. The eighth and last house in this block is a small Peach house some 50 feet by

9 feet, which calls for no special comment. All the houses were neat and orderly and scrupulously clean.

At one time all the houses here were overrun with myriads of ants. They had increased in numbers to such an alarming extent that they ate and destroyed the best of the fruits, and if they had not been exterminated they would soon have destroyed all the plants in the houses. Mr. Currie tried every means he could hear or think of to destroy them, but to no effect. The case became serious, and it was just a question of whether the ants or the plants would have possession of the houses. If the ants could not be destroyed they would be obliged to give up growing plants and fruits. Under these conditions Mr. Currie became desperate, and determined to flood the houses and borders with cold water and drown them out, even if it did injury to the Peach and Vine roots. After repeated and continuous flooding he succeeded in destroying every ant in the houses.

Immediately behind the houses are the young men's rooms, potting sheds, stokeholes, seed room, &c. An aviary has recently been erected on a level plot of ground between the gardens and the mansion. It is an ornamental building, and contains a choice collection of foreign birds of beautiful plumage. Attached to the aviary at each end is a small span-roofed greenhouse and a span-roofed plant stove, each 20 feet in length. The greenhouse contained good specimen plants of *Fuchsias*, *Pelargoniums*, and others, besides an assortment of plants for cutting bloom from. A fine selection of the best *Abutilons* were grown in this house and trained up the rafters, which produced a constant supply of flowers to cut from. A little heat is kept on during the winter, as the demand for cut flowers here is great at all times. The plant stove contained neat little plants for table decoration. To the side of this house is a rustic cool fernery, which looks well, but it is found to be too much shaded and dark for the proper growth of Ferns, and will consequently be altered from its present state.

There are two kitchen gardens of moderate size intersected by gravel walks. One is in front of the forcing houses, and the other in front of the gardener's house. The ground in both is undulating. The soil is a light clayey loam, which produces good crops of vegetables and fruit; but the fruit crop, as far as Apples, Pears, and Plums are concerned, has been a failure this season, as in most other places. Besides fruit and vegetables great quantities of *Carnations*, *Dahlias*, and other flowers are grown in the kitchen garden to cut from during the summer.

The flower garden lies a little to one side of the mansion on a broad lawn immediately above the Doon, from which a fine view can be had "of hill and dale, of wood and lawn, and of rock and river" in a most enjoyable atmosphere, away from the smoke and bustle of town life.—A. PETTIGREW, *Cardiff*.

CHRYSANTHEMUM SŒUR MELANIE.

I SHOULD have replied earlier to the remarks of your correspondent Mr. C. Orchard, but was anxious to obtain as much accurate information as possible before doing so. I have obtained flowers of *Sœur Melanie* and compared them with the variety grown in this neighbourhood under the name of *Souvenir de Malanche* (not "Melange," as written on page 475 and 500 by your two correspondents), and am fully satisfied that they are identical. I found this variety here seven years ago, and its value then well established about Liverpool. Mr. Glover, late gardener at Lea Hall, Gateacre, obtained it about twelve or fourteen years ago from Mr. Morse of Dursley, by cuttings through the post, under the same name as it is now known by in this locality. I also find it is under the name of *White Trevenna* in some gardens. Some six or seven years ago, if my memory serves me right, the name *Souvenir de Malanche* appeared in Messrs. Cancell & Sons' catalogue. Now the question arises, which is the correct name of this variety, and how long has *Sœur Melanie* been in the market? If the latter name was only given about three years ago, there can be no doubt that it is an old variety under a slightly altered name.—WM. BARDNEY.

[*Sœur Melanie* and *White Trevenna* are quite dissimilar, and undoubtedly distinct varieties.]

ABUTILONS.

IN a recent issue of the *Journal* Mr. W. Bardney commented on the usefulness of *Abutilons* as winter-flowering plants, giving some valuable directions concerning their culture; and the attention he accords them they well deserve, for their utility is beyond all question, few plants continuing in flower over so long a period of the year, and requiring comparatively such little trouble to ensure their success. A few years ago the present race of hybrid *Abutilons* was quite unknown, and the past ten years have witnessed the production of nearly all the varieties now so highly appreciated in many gardens. Such species as *A. striatum*, *A. venosum*, and *A. insigne* have been long known, and these, with the distinct *A. vexillarium* or *A. megapotamicum*—a later introduction than the three former—had become well-

established favourites before any attempt had been made to raise a dwarf compact-habited race of plants. Cultivators upon the Continent took the lead in this direction, and amongst the forms which made their appearance at the beginning of the past decade *Boule de Neige*, which is still the best white variety, stands pre-eminent, possessing all the qualities of a really useful plant, compact yet vigorous in habit, very floriferous, the flowers well formed and pure white. The parentage of this I have been unable to ascertain, but together with *A. Darwini* it has proved the source of the present race of *Abutilons*. The last-mentioned species, it may be observed, is a native of Brazil, whence the late Mr. C. Darwin obtained seeds which produced the first plants grown in this country. The flowers are of good size, orange colour with darker veins, and sharply three-lobed leaves; one remarkable peculiarity of the plant being that the earliest flowers are sterile with their own pollen, but readily fertilised with pollen from another plant. By crossing *Boule de Neige* and *A. Darwini* the hybrid *A. rosæflorum* was produced about 1874 at Holloway, and this was a most important and curious advance, the flowers being rosy crimson, very even in form, and abundant.

About the same time or shortly after Mr. George, gardener to the Misses Nicholson, Ripon House, Putney Heath, who has contributed more to the improvement of *Abutilons* than any other English horticulturist, had raised some seedlings which were considered as the result of an accidental cross between *A. Boule de Neige* and *A. Darwini*, as these were the only two grown together at the time, but it is now uncertain which was the seed-bearing parent. From the first batch thus secured four were selected and sent out by Messrs. Osborn & Sons of Fulham, representing rose, yellow, and orange shades. The best, however, was *Lady of the Lake*, with rose-coloured flowers veined with a darker tint, and this was honoured with a certificate by the Royal Botanic Society, Regent's Park, in 1878. Such satisfactory results from chance fertilisation induced Mr. George to try several careful crosses, from which were obtained other distinct and beautiful forms, several being distinguished by the high colours of the flowers. One of the most notable of these is known as *Swanley Red*, and Mr. George attributes the rich colour of this and some others to a cross he believes he obtained between one of the *Abutilons* and *Hibiscus Rosa-sinensis*, the former being the seed-bearing parent. These plants are sufficiently nearly allied to render this probable, especially as in some of the forms so obtained the foliage is very distinct from the other *Abutilons*, exhibiting some distant resemblance to the *Hibiscus*, and the habit is also suggestive of that plant, though the supposed hybrid does not follow it in the fugaciousness of the flowers. Another cross has been similarly tried—namely, between the variegated *A. Sellowianum marmoratum* and a variety of the hybrid type, the result in this case being that plants have been raised which produce their flowers in clusters at the end of a common peduncle, and are thus quite clear of the foliage—a character of great importance. The flowers at present, however, are susceptible of improvement both in form and colour, though the cross must be regarded as a step in the right direction, and will no doubt lead to another type of *Abutilons*. Several other experiments have been tried, but they will be referred to on another occasion. At present only a few of the best of the varieties can be mentioned.

The flowers of all the varieties noted below are distinguished by the rounded petals, the margin slightly incurved, giving a globular appearance to the flower. The habit is compact and strong, the flowers being produced in great numbers throughout the winter months. *Sir Garnet Wolseley*, deep scarlet, with darker veins inside; *Mrs. Garfield*, pale pink, dark centre, large open bloom; *Splendens*, dark scarlet, very handsome; *purpurea*, purplish crimson or magenta, very distinct; *Goldfinch*, light yellow with orange veins, open flower; *Emperor*, deep purple; *The Premier*, very large flower, rich rose; *Crimson Gem*, scarlet crimson; *King of Roses*, bright rose; *Cloth of Gold*, golden yellow, smooth even petals, very free; *The Bride*, pale pink, delicate, free, and good; *Eneantress*, rose with deeper veins, small neat flowers, extremely free; *Silver Bell*, white with rosy veins, flowering in small clusters; *Orange Gem*, orange scarlet, open flower; and *King of Crimson*, one of the best, of a fine crimson hue. *Brilliant* is very distinct from the above, being more bushy in habit, but not so dwarf as those mentioned below. The flowers are deep scarlet, not so well formed as the preceding, but produced so freely that the variety is unrivalled in a decorative point of view.

In addition to these Mr. George has a race of very dwarf *Abutilons* very close in habit, and scarcely exceeding a foot in height after two years' growth, and are, therefore, invaluable for decorative purposes. The best of these are *Vivid*, rich scarlet; *Pink Gem*, small flower, clear rosy-pink; and *Scarlet Gem*, very bright.

The method of cultivation adopted by Mr. George corresponds to a great extent with that advocated by Mr. Bardney, except that at Putney a lighter compost is employed—namely, a mixture of loam, peat, and leaf soil in equal proportions, with a little sand, and the condition of the plants indicates that this suits them admirably. One important point in their culture is keeping them near the glass, as this not only insures a greater compactness of growth, but increased floriferousness with brighter-coloured flowers. It is a mistake to have *Abutilons* in too low a temperature, about 55° to 65° being the most suitable during the winter months. Good plants can be grown from cuttings in from six to nine months, and plants so raised in the spring will flower freely the following winter, one or two pinchings improving the habit of the plants.—L. CASTLE.

ALLAMANDAS.

YOUR correspondent "M. M." on page 498 recommends an intermediate temperature for these plants. They certainly will do fairly well under cool conditions, for I have had them in conservatories for fully three months without any fire heat being applied. I have also kept them in a night temperature of 50° during winter, and the plants have continued flowering until February. It is, however, a mistake to suppose they will last as long and well as in a higher temperature. In a warm house *Allamandas* grow rapidly and luxuriantly, also flower abundantly, every lateral that is produced affording blooms. As soon as one lot of flowers are produced the shoot branches into three or four, which yield blooms when they have extended about a foot or little more in length. Under warm treatment ten times more flowers will be produced than is the case when grown cool, as the continuous supply depends entirely upon succession growths. With care and a knowledge of how to thin out the lateral growths the plants will flower as well at the bottom as the top if trained under the roof of a plant stove.

As regards soil, peat is unnecessary. The *Allamanda* delights to grow in a good rich loam, to which is added a seventh of manure, and the whole pressed into the pot as firmly as possible. The plants will thrive if grown in pots, and when these are full of roots guano water or any other liquid manure may be supplied not only weekly, but daily.—X.

WATERING PLANTS.

THE best of soil may be procured and the plants properly potted in it, and yet everything may be spoiled through the injudicious supply of water. Watering is one of the arts which cannot be taught in writing, and, indeed, cannot be taught at all. The judgment of the operator must be called upon to decide when water is necessary. I am being continually asked, "How often should such and such a plant be watered?" My invariable answer is, As often as necessary. This impresses on the would-be recipient of what is supposed a secret the necessity of understanding. A rule which may be generally adhered to is, only to give water when the soil in the pot is dryish, and yet not so dry as to cause suffering to the plant. It should be understood that soil which is kept continually wet is always cold and ungenial, and plants cannot thrive in soil which is in this state. Moreover, soddened soil soon becomes sour, and that destroys the roots. Root-bound plants are not easily injured with too much water, but soil which is not occupied with roots quickly becomes sour.

An experienced person knows by the appearance of a plant whether it is needing water or not, but even he may be deceived unless the watering has been properly done. Generally speaking a plant needs water when the pot it occupies sounds hollow when struck with a key, pocket knife, or similar heavy article, and when a plant really needs water it should receive enough. The spaces left in the pots for holding water should be quite filled, and this must be repeated until the water drains from the pots; no more should then be given until required again.

Although overwatering is a common evil, sometimes less than enough is given. This generally happens when insufficient space is left in the pots to hold the water. This point should always have proper attention. Sometimes it happens with those who have been warned against, or have seen the evil of overwatering. A plant may be dry or it may not, but a teaspoonful or so is given, and the surface of the soil is moistened; still the plants look flagged, so by-and-by another dribblet is given, and this goes on continually. The result is that while the surface is wet—often too wet—the soil where the roots are is dust dry, and so the plants languish. Sometimes when plants become too dry they cannot be moistened at all by ordinary applications of water.

The right thing in this case is to place the pots in water for some hours.

Rain water should be used if possible, and failing that the softest water procurable. It should never be used when lower in temperature than the house in which the plants grow. For this reason it is always best to have a cistern inside the house to contain it. Failing that it should always stand in the house for some hours previous to using.

LIQUID MANURE FOR PLANTS IN POTS.

When plants become rootbound they require shifting into larger pots, so that fresh nourishment may be afforded them. In many cases this is not practicable, and in all cases it is desirable to grow as large plants as possible in the smallest-sized pots. In that case top-dressings of rich material become necessary, and also feeding by means of liquid manure. Top-dressings are not always applicable, but in most cases liquid manure may be applied with advantage. The simplest kind of liquid is when a salt, such as sulphate of ammonia or nitrate of soda, is dissolved in the water. Such substances are cleanly and inoffensive, and are, therefore, preferred by many; but unless the soil contains something substantial in itself these will fail after a time, although they will promote luxuriant growth at first. For plants which are to occupy the pots for only a few months and then be thrown away they are very suitable, but otherwise they are not so good as dung or guano water. The latter is made by dissolving half an ounce or more of guano in a gallon of water. Liquid manure such as this should only be applied by inexperienced persons once or twice a week, for too much may do considerable harm. Good liquid manure may be made by steeping cow, sheep, deer, horse, or other animal manure in a cask of water. The water becomes highly impregnated with manurial matter, and is, when properly diluted, very useful. When liquid manure is made from animal manure the clear water only should be drawn off and used, for when thick it destroys the porosity of the soil. It is only the salts and gases of the manure which are dissolved in the water which are beneficial. Suspended matter is worse than useless.

Urines make good liquid manure, especially when used with those prepared from manures. Pure urine should in all cases be diluted with six or eight times its bulk of water when used for plants in pots; when used in a stronger state it is almost sure to destroy the points of the roots.

Soot is useful as a liquid, which may be prepared by placing the soot in a bag and suspending it in the water, so that only the salts which it contains may mix with the water. The chief substances of value found in soot are carbonate and sulphate of ammonia.—N. B.

CULTURE OF DRACÆNAS.

DRACÆNAS are very useful plants, especially as they are well adapted for house decoration; and as most gardeners have much of that kind of work to do, these remarks may be of use to those not acquainted with its culture and propagation. Where any old plants have become too tall the tops can be taken off, turned out of their pots, and have most of the roots removed. The stems and roots may be then laid lengthways in cocoa-nut fibre, over a little bottom heat. They will produce scores of little plants, which, when strong enough, must be separated from the main stem and potted singly in small pots, in equal parts of turfy loam, peat, and leaf soil, with a little powdered charcoal and silver sand. They must be kept in a brisk moist heat close to the glass. Plants in 32-size pots make useful plants for decorating, but if large plants are required they must be shifted into larger pots before their roots become matted. They must not be kept in too moist an atmosphere during the winter, or the foliage will damp. When the plants are required for house decoration they should be grown in a drier and cooler atmosphere about a fortnight before using. Varieties of the terminalis and gracilis type are the most useful.—Y.

GRAPES FOR GENERAL CULTURE.

AS A Grape-grower of many years' practice, and one as familiar with both new and old varieties as most people, nothing has surprised me more than the prominent advocacy of doubtful varieties of Grapes for general culture which has lately appeared in the pages of the *Journal of Horticulture*. I do not by any means hold the Editor responsible for all that appears, but when we see it stated in a leading article that "everyone" should plant early houses exclusively with such Grapes as the Madresfield Court and the Duke of Buccleuch, it is impossible to absolve the Editors from a certain amount of responsibility in the matter, not to speak of the fact that these two sorts, and another equally doubtful—the

Muscat Hamburg—have also been advocated for a main September supply as well. I believe I am correct in reference to the leading article which appeared a few weeks ago signed "HONI SOIT QUI MAL Y PENSE," for I have not the number by me now; I sent it away to a friend, who replies, "I doubt if he could get one good gardener of repute to endorse his advice to plant a whole early house each of the Duke of Buccleuch and Madresfield Court, to the exclusion of the long-tested and tried Black Hamburg, which his statements amount to, for not one garden in a hundred needs three early vineries."

No one who understands the wants of private gardens would advise the wholesale planting of doubtful fruits of any kind, and past articles in the *Journal* and other papers testify to the doubtful propriety of anybody, let alone "everyone," planting an early house each of the above two Grapes. One can only excuse the writer of the article in question on the ground of ignorance and rashness, until he points to successful examples of what he advises. The correspondence of the *Journal* must long ago have convinced its Editor how unwise it is to advise gardeners to commit themselves with their employers by rash ventures, knowing—as he should know—quite well that really excellent examples of the fruits he names are so exceptional that when they are produced they are at once chronicled as something unusual. We have two early vineries here, and I have no doubt my employer would allow me to plant them with any variety I thought best, but he would hold me responsible for the result; and if I had planted the whole 60 feet with the two sorts named for a supply all through May, June, and July, I can only guess what the result would have been, after having my own way in the erection of the vineries and formation of the borders, &c., and spent perhaps several years in an abortive experiment.—HEAD GARDENER.

[Admitting that our correspondent is an experienced grower of Grapes, and in his way a clever critic, we are the more surprised that he has missed the point of the letter which he criticises. The article on page 469 was *not* a discussion on and recommendation of "Grapes for general culture," but was a comparative estimate of varieties, and especially those "introduced during the last twenty years." No one knows better the value of the Black Hamburg as an early Grape than the writer of this estimate, and he would be the last to exclude it in favour of either the Duke or Madresfield Court if that were the question at issue. His experience is too great for that, and his success as a cultivator entitles him to express an opinion on all the Grapes he mentioned, for all of them he has grown well, most of them perhaps as well as they have been produced by any other cultivator in the kingdom. He can pass without notice the suggestion of "ignorance" that has been, we think, a little prematurely, not to say rashly, attributed to him. As to our unwisdom in committing gardeners, &c., we can endure either the joke or mild impeachment whichever our correspondent intended, and shall pursue our course as usual.]

THE GREENHOUSE AND ITS INMATES.

(Continued from page 450.)

CHRYSANTHEMUMS.

THESE are invaluable for decorating the greenhouse and for furnishing cut flowers during the darkest, dullest time of the year. Cuttings should be struck in spring on a hotbed, and afterwards transplanted into boxes in good loam and decayed manure 4 or 5 inches apart. Pinching must be attended to for the purpose of inducing a bushy habit. When the plants become too large for their position in the boxes they should be transferred into 6-inch pots, using the same kind of soil. Previous to this they should be grown in a cold frame. By May they should be placed out of doors in a sheltered place, plunging the pots in ashes. Stopping the shoots will be necessary at intervals up till June. Shifting must also be attended to, and abundance of water given to prevent the plants flagging at any time. As the pots become filled with roots liquid manure should be given occasionally. Staking must also be attended to, or winds will break the shoots. It is the practice of exhibitors to thin the flower buds as soon as they can be seen. If extra fine blooms are desired the practice may be resorted to, but for ordinary purposes it is seldom practised. The plants should be housed by the beginning of October, or at least before frost injures them. Should mildew appear at any time the affected parts must be dusted with flowers of sulphur; this will destroy it. While under glass they are somewhat liable to attacks from green fly. Syringings of soapy or tobacco water will prevent their appearance; smoking will destroy them when they do appear. After the flowers decay the shoots should be cut down to the surface of the pots, and the roots stood in any cool place safe from frost, and exposed to light until the necessary number of

cuttings have been furnished by them. The shoots from the base form the best cuttings.

Many possessors of small greenhouses do not grow these plants because they require much room. To such I would recommend the Pompon varieties. If there is only space for half a dozen plants I advise the growing of White Cedo Nulli, and, if variety be wanted, Yellow and Lilae Cedo Nulli. These may be grown and flowered in 6-inch pots if supplied twice a day with water and the tops pinched repeatedly. Under this treatment plants 15 or 18 inches high and as much across will produce between one hundred and two hundred blooms in November and December. Dwarf plants of tall kinds are often produced by layering the flowering shoots of tall plants into pots containing prepared compost in August or early in September. The following is a selection of good varieties:—*Show varieties*—Yellow: Jardin des Plantes, George Glenny, Mrs. Dixon. White: White Globe, Empress of India, Mrs. Rundle. Lilac-purple: Prince of Wales, Lady Hardinge, King of Denmark. *Pompon or Small-flowered varieties*: Bob, crimson; General Canrobert, yellow; Madame Marthe, white. Cedo Nulli varieties are all good. *Japanese*: Kri Kang, rosy-lilac; Elaine, white; The Cossack, crimson. *Anemone-flowered*: Gluck, yellow; Fleur de Marie, white; Prince of Anemones, lilac and yellow; Quilled Queen, white; Golden Queen, yellow; Empress of India, white. *Reflexed*: Julie Lagravère, deep red; King of Crimson, rich crimson; and Sœur Melanie, white.

CACTUS JENKINSONII.

Like many others of this class, this is a handsome plant when in flower. Its wants are very few: fibry loam, pieces of sandstone, and charcoal suit it. Plenty of drainage must be given, and from the time it finishes its growth until signs of fresh growth appear in spring very little water need be given. Ordinary greenhouse temperature all the year round and a sunny position suit it admirably.

CALLA ÆTHIOPICA.

The Lily of the Nile, as this is popularly termed, is an old-fashioned but indispensable plant, and one exactly suited to the amateur. Good drainage, good loam, leaf soil and sand, and plenty of water, with ordinary greenhouse treatment during the winter months from October to May, and planting out in a sheltered spot where it will be exposed to the sun during summer, is all that is needed to enable it to do well and reward the cultivator with plants which are worth growing, although they never flowered, but are doubly attractive when they produce their curious vase-shaped pure white spathes. Large specimens may be had with little trouble, but small plants in 6-inch pots are preferable for ordinary work. They should be divided at planting-out time if necessary, and potted, and then stood in the shade for a week or two before removing them to the greenhouse in September.—J. H.

(To be continued.)

HARDY FRUIT GARDEN.

WHEN the weather is unfavourable for ground work, or too cold for ordinary pruning to be done, orchard trees should have attention in thinning. The chief object with standard trees is to keep the centres thin and open and the branches from crossing each other, which will not only preserve the symmetry of the trees, but admit more light and air greatly to the benefit of the fruit. It is necessary to bear in mind that a large reduction of the head will cause a quantity of young shoots to arise in the following season, and should not be practised except in the case of weakly trees. A sharp saw and a keen eye exercised judiciously will soon improve the trees in the most neglected orchard. In some localities moss and lichen seriously affect the health of the trees, in which case scrape the trunks and main stems with a blunt hoe-like instrument, and then wash them with a strong salt brine, or paint them with limewash. The smaller branches may be reached by employing a syringe.

Where bullfinches are troublesome a good syringing with a mixture of water, lime, and soot will help to prevent their attacks. Pruning Gooseberry and Currant bushes is objected to at this season on

account of the havoc birds sometimes make with the buds, particularly near towns or buildings; but as most of the mischief is committed by the birds when the buds are swelling in spring, it is questionable whether it is not preferable to prune now and proceed as above advised. In pruning Gooseberry bushes it is advisable to distinguish between those that make much wood and do not bear freely, and those that make little wood and fruit abundantly. Very little pruning should be practised in the first case, merely thinning out in the centre, otherwise leaving the bushes intact, whilst the second description may be spurred in closely as regards the side shoots, shortening extensions as desired. Red and White Currants usually bear freely enough on spurs, hence the spray of last summer's growth should be cut hard back to the base. Black Currants should have the old growths well thinned out, and straggling branches and those too long cut back to young growths at the base. This will keep the bushes well furnished with strong young wood, which affords fine fruit plentifully.

Pruning wall and other fruit trees should be proceeded with as weather permits. Thinning and shortening back any spurs projecting too far from the wall should be practised more generally than it is, as it not only adds greatly to the appearance of the trees, but improves their vigour and health, as old spurs from their contracted bark do not admit of a free circulation of the sap. Old Pear trees still endure very hard pruning, breaking again regularly if the trees are healthy; but Apricots, Cherries, and Plums are not to be depended upon in that respect, yet they may safely be cut back to a single eye, which is necessary to keep the spur alive and assist it in becoming fruitful. Extensions should as far as practicable be trained in their full length, cutting away, however, any unripened shoots to firm wood, and any leading shoots may be shortened to originate growth to the required positions for filling vacant space. If the trees are not entirely loosened from the wall and re-nailed or tied, they should be examined carefully, renewing any shreds or ties that are worn out, loosening those too tight, as well as nails likely to cause injury to the branches or shoots drawn and replaced, so as to allow of the unimpeded swelling of the growths and the free flowing of the sap.

Young trees are frequently cut back severely, which is advisable when the trees are ill furnished as a provocative of vigorous growths for furnishing properly from the base, and in the case of trees that have the shoots imperfectly ripened. Then it becomes a necessity; otherwise to cut a young tree hard back is only to encourage strong growths, which from their grossness rarely ripen well. Trees left with their branches entire, properly laid in and trained, cover double the space and bear in half the time, as the more top the more roots and the less probability of the trees producing strong gross shoots. Healthy young trees always break freely, and afford plenty of young shoots to choose from without having the tops reduced, and come into bearing quickly, besides avoiding canker, gum, or other ills.

FRUIT HOUSES.

Vines.—A Grape room is as important for the keeping of Grapes during the next five months as the house in which the late fruit is grown, and to ensure the good preservation of the Grapes the room must be well ventilated, dry, and free from frost; indeed, it should if necessary be provided with artificial heat, so as to maintain a temperature of 45° to 50°. Freedom from dust is also essential. Racks for holding the bottles should be fixed in the walls, so as to maintain the bottles in a slanting position; and now the wood of the Vines is ripe the Grapes should be cut with some wood both above as well as below the bunches, and a few pieces of charcoal placed in the bottles along with clear rain water. The Vines should then be pruned and dressed. Gros Guillaume, Gros Colman, and Alicantes do best on the long-rod system of pruning, but Lady Downe's is so free that it succeeds well if pruned to a good eye. All glass, woodwork, and pipes must be well washed, removing the loose soil and mulching from the inside border, and replace with fresh loam with some bone meal intermixed.

In houses which have been closed the Vines are in various degrees of development. Where the buds are breaking freely a night temperature of 60° should be maintained, and 65° by day, allowing an advance from sun heat to 75° before giving any air, and then be

careful not to cause a sudden reduction of temperature. As the growth advances increase the temperature gradually to 65° by night, and when in flower a night temperature of 70° may be maintained. Disbudding should be done when the shoots are about an inch long, reserving the strongest and best-placed near the base of the spur; and in the case of short-jointed young rods it will be necessary to remove some of the buds, so as to keep them 12 to 15 inches apart on each side of the rod. In disbudding it is well to bear in mind that Black Hamburgs, Frontignans, Sweetwaters, and Muscadines produce finer bunches from young rods than on old spurs; hence, where the Vines give only small bunches a young rod should be originated from the base of each Vine, training these for the first season between the older ones, and at each annual pruning the spurs on the old rods should be cut away as far as the young rods are intended to bear, and in the second or third season the old rods may be cut out. In this manner the house is furnished with young vigorous wood, to the permanent advantage of the Vines, and without loss of crops.

PLANT HOUSES.

Roses are never more valued than during the winter months. To insure this it is essential to have a good supply of Tea varieties carefully prepared in summer, and to prevent interruption in the supply it is necessary to have a light well-ventilated house to grow them in, as they will not come on quickly enough in an ordinary greenhouse temperature; 50° at night and 5° more in the daytime is however, quite enough for them. Let them have a light position with ventilation upon all favourable occasions, but avoid subjecting them to currents of cold air after they have made young leaves, as they will be liable to attacks of mildew.

Plants of *Stephanotis floribunda* that are not too vigorous in growth produce the greatest quantity of flowers, and as the flowers are valued for cutting and are very useful in winter and early spring. Plants that have made an early growth, been well exposed to light, and kept somewhat dry for a time, will be furnished with a quantity of well-ripened shoots that have shown flower spurs in autumn, having them now fresh upon the plants. Such subjected to a night temperature of 65° to 70° and 5° more by day, will soon develop the flowers. If the soil be dry give a good soaking, but do not syringe them much. Plants having the wood well ripened but not furnished with bloom spurs should be syringed once a day; they will commence growing immediately, and the wood being well ripened will show bloom at the second joint of growth. Plants in small pots should not be repotted now, but supplied with liquid manure, deferring potting until after flowering, when it can be done before the summer growth is finished.

Bougainvillea glabra produces a quantity of flowers for cutting, and is an excellent companion to *Stephanotis* both as regards variety of colour and duration. Plants that have had the wood well ripened, kept dry, and rested for about a couple of months, on being well soaked at the roots will commence growth immediately, and be in bloom in about eight weeks. All the weak shoots should be cut out, as the flowers are only produced from the strong wood.

THE BEE-KEEPER.

ODDS AND ENDS.

Hiving Swarms.—It is fortunate for bee-keepers that swarms on leaving their parent hives generally alight on trees, bushes, or hedges, and remain there for a while; but nobody can tell why or for what purpose they alight on such places, nor how long they would remain there if left to themselves, but wise and experienced bee-masters hive their swarms as soon as possible after they settle in clusters. The position and surroundings of swarms determine the mode of hiving them. If a swarm settles in the thicket of a hedge a hive is placed over and as near to it as possible, that the bees may run up and into it. If a swarm alights on a branch of a tree and hangs from it the bees are easily shaken into a hive. If an apiary is surrounded by lofty trees swarms often alight near their tops and are inaccessible. Last year I had many swarms

that alighted on the tops of trees beyond the reach of the longest ladder in the neighbourhood. In such cases the branches had to be cut 10 and 12 feet below the swarms and gently guided down to the ground, and there the bees were hived. When swarms settle on the trunks of thick trees it is often difficult to hive them, as they may decline to run into hives propped up or tied above them. If the swarms are near the ground and will not run into hives we sweep the whole swarm to the ground and place a hive over them. In all large apiaries a few pieces of comb well cemented to a small board tied to a long stick or pole should be kept for use in hiving swarms. By holding this board so as to touch the swarms as soon as they settle the bees begin to cluster round the combs, and by making well-known sounds entice their companions to leave the branches. By using such boards swarms in almost every conceivable place may be reached, carried to the apiary, and there hived. These boards should have a few small pieces of comb cemented on both sides.

The Size of Hives.—This is a point of great importance but difficult to determine. How many eggs do queen bees lay? Are the hives capable of enlargement? Is the apiary managed on the swarming or non-swarming principle? Is it run or comb honey that is aimed at? Queens have been known to lay three thousand eggs in a day, but two thousand may be considered a fair day's average production of eggs in the height of the season. If hives are small half the eggs laid by the queens cannot be set or utilised. There is not room for them, even if not a cell were used for honey and pollen. In good honey seasons about half the combs are used for honey and pollen, thus contracting the breeding spaces in hives of considerable dimensions. Small hives, then, are a mistake, and may be considered outside the sphere of intelligent and thorough-going practice. A gentleman in the neighbourhood of Wrexham wrote a few weeks ago to ask if 16-inch hives were not too large for that locality. We answer that if honey or profit be the object sought hives less than 16 inches are too small for any locality. A gentleman at Wimbledon told the readers of the *Journal* that he took 100 lbs. of run honey from a 20-inch hive one season. Hives 16 inches wide and from 12 to 14 inches deep, containing from 2000 to 3000 cubic inches of space, are what I generally use and recommend. They are small enough in good seasons and large enough in bad ones. In honey seasons these capacities are not so great as their capabilities: they have to be enlarged by supers and ekes.

Can a District be Overstocked with Bees?—Yes, however rich the pasture may be. But very few districts, if any, in Great Britain are overstocked. In poor localities bee-keeping does not pay, and few hives are kept there. In better places for honey, where bee-keepers are well instructed and successful, we have seen the list of apiarians enlarged and the number of stock hives increased, but many beginners on being stung once or twice become afraid of bees, sell their stocks, and give up the trade. Many more people would keep bees but for their stings; but probably if bees had no stings their number would rapidly decrease, their treasures are so coveted by men, vermin, or small animals, and their bodies by birds. That we have honey bees at all amongst us is probably owing to the fact that they have stings and know how to use them. The question of over-populating a district with bees is a difficult one to deal with. Some American apiarians reckon that from 100 to 150 hives are enough to keep in one place, and if more are kept the pasture would be insufficient. The bee-keepers of this district (Bowdon) have about one hundred stock hives; in my native place (Carlisle, Lanarkshire) about the same number were usually kept, but I have not heard complaints made in either place about overstocking. In both places strong hives in honey weather gather 5 lbs. each per day. But it is reasonable to say that the fewer hives are kept in a given place the richer the pasture will be, because fewer visits will be made to the flowers. Bees go a mile and a half from home for honey and work over all the fields, orchards, and woods within such circumference. If bees have not flowers enough within a mile and a half of their hives they should be removed to other pasture two or three miles distant. Large apiaries should be at least three miles apart. The introduction of Alsike Clover and the quantity used in Cheshire instead of the red Clover has greatly improved the pasture of bees in this neighbourhood, and probably in others as well. Unfortunately we have no Heather near Bowdon, the Glossop Moors being twenty-five miles distant, and Delemere Forest about twenty. Heather is so rich in honey, and yields it so fast to bees in August and September, that it is all but impossible to overstock a good Heather district during these months.

Under-feeding or Spare Diet.—We have been told that on the gravestone of the late President Lincoln it is stated that "no man ever regretted eating too little." This may be true or otherwise,

but it is well known that many hives of bees which have not been utterly destroyed from want have suffered much from not getting food enough. During the last ten years we have had so many unfavourable seasons for honey, that almost all bee-keepers have had to feed their stocks to keep them alive. In the year now passing away feeding has been the chief concern of the apiary. If we be favoured with a run of good seasons for honey in future, and I hope we may, we cannot expect the run to be unbroken. Bad seasons may come and feeding may be necessary, and it may be well to point out the dangers of inattention to feeding in time of need. Bees that are half fed do not prosper. Is it reasonable to expect bees to breed when they have not food enough for themselves? If the honey cells become empty breeding is stopped. In such a crisis hives suffer severe relapses, and often do not recover from them for weeks. For a hive full of bees and brood much food is required. Brood is heavy and can't be reared without much and substantial materials. During inclement weather artificial food should be administered liberally. All the bees of a large swarm cannot get a taste or breakfast on or out of a pound of syrup. A few weeks ago a bee-keeper in this place wrote to Epworth for bees to strengthen two stocks. He had a reply to this effect, that Mr. Addey would not send less than 20s. worth of bees. The Bowdon gentleman did not want so many, and he asked if I would take half of them. I consented, and the bees came. The day following I got my share, which were in a state of starvation. I instantly gave them a pie-dishful of syrup, which was soon taken. In removing the dish I saw at a glance that half the swarm was still unfed and starving, and while I was preparing more food all the bees left the hive as a hunger swarm. Pressed by hunger they had resolved to cast themselves on the world before the food was administered. This hunger swarm was speedily hived and well fed, and is now one of my pet stocks. Let bees be kept free from the discouragements of poverty.—A. PETTIGREW.

TRADE CATALOGUES RECEIVED.

James Carter & Co., 237 and 238, High Holborn, London.—*Vade Mecum for 1883 (with coloured illustrations).*
S. Dixon & Co., Hackney.—*Catalogues of Chrysanthemums, Roses, and Miscellaneous Plants.*

* * All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Address (H. T. H.).—We thought everyone interested in flowers knew that Mr. Cannell's establishment is at Swanley, Kent. The address has appeared in our advertising columns probably fifty times during the past twelve months.

Anemones (A Working Man).—The parcel has arrived, and we are obliged by your kind attention in this matter.

Seedling Apples (Cosmyne Moore).—Although the varieties may be serviceable in your district, inasmuch as they may be free bearers, yet neither of them possesses sufficient merit for placing in commerce. No 1 is of fair quality, but No. 2 is very soft in the flesh, and has a peculiar musty flavour.

Admission to Exhibitions (R. O.).—Fellows of the Royal Horticultural Society and others having tickets have admission both to the Shows at South Kensington and to the Gardens at Chiswick. Persons are also admitted to the Shows by payment at the turnstiles, the prices on the respective days being announced in advertisements. Your other question will be answered next week.

Inarching Vines (J. D.).—If you have read what we recommended you to obtain last week, and require further information that you will specify, we will readily aid you, but we cannot give in a short reply such full details as you will find recorded in the number of the Journal we quoted (617), which can be had from the publisher, price 3½d. post free.

Chrysanthemum Sport (W. A. W.).—The large blooms are comparatively worthless. It is only by retaining the character of the smaller flower with broad incurved petals that the variety can be regarded as good. A further trial is evidently needed before the true value of the sport can be determined.

The Oldest Rose Tree (Curio).—One of the oldest Rose trees of which

we have any record is one that is described as being trained upon one side of the Cathedral of Hildesheim, in Germany. The root is buried under the crypt, below the choir. The stem is a foot thick, and half a dozen branches nearly cover the eastern side of the church, bearing countless flowers in summer. Its age is unknown, but documents exist which prove that the Bishop Hezilo, nearly a thousand years ago, protected it by a stone roof, which is still extant.

Cypripedium insigne (R. G. W.).—Our opinion of the flowers and leaves you sent is that the plants from which they were taken must be in excellent condition; such vigour could only be produced by the best cultivation. It is not uncommon to see twin flowers produced by vigorous plants, and some regard that as a distinct variety, but unless liberally treated the flowers only come singly.

Gathering Mushrooms (H. C., Hemel Hempstead).—It is not necessary to fill up the cavities that are formed by pulling up the Mushrooms; on the contrary, some growers make them larger with a knife. See the notes and illustration on page 169 of our issue of August 24th of the present volume. If you do not possess that number a copy can be had from the publisher in return for 3½d. in stamps.

Stocks for Vines (T. A., Derby).—All the varieties you name make good stocks, and you need not hesitate in carrying out your plan; but we should place Gros Colman on one of the Muscats. The Muscat forms a good stock for most Vines. For information on inarching see our reply to a correspondent last week, also in our present issue.

Painting Wire (Idem).—In those districts where galvanised wire is injurious to trees the coat of white paint is beneficial; and if the wire in your case has had any noxious effects, by all means paint the wire as you propose.

Climbers for Wall (R. C.).—Most of the plants you name are not sufficiently hardy for your district. There are no evergreen plants that cling to the wall except Ivies, and the variegated forms are highly attractive. Crataegus pyracantha is an excellent plant for walls, and we know many examples 30 feet high. Cotoneaster Simmondsi is good and effective. The common white Jasmine would succeed, and the Honeysuckles named last week are also quite hardy.

Ivy for Walls (Arbor).—There is no climbing evergreen that will be so suitable for your purpose as the common Ivy, and though we have known many walls covered with Ivy to which cattle had access we have never known them injured by eating the foliage. The leaves have a bitter taste but are not poisonous, as they have been employed in medicine as a dressing for cutaneous eruptions. The berries have an acidulous, resinous, and puugent taste, and are said to be purgative and emetic. They contain a principle called pederin, which is similar to quinia.

Temperature for a Greenhouse (F. J.).—Provided the temperature does not fall below 40° early in the morning the plants which you name will be quite safe, but to insure that it must be from 45° to 50°, according to the weather, at ten o'clock at night. As a rule a night temperature ranging between 40° and 45° is the best for ordinary greenhouse plants in winter, allowing a rise of 5° from fire heat alone in the daytime. During bright days the house will often be warmer than that without fire, but judgment must be exercised in providing artificial heat sufficiently early in the afternoon to prevent the temperature suddenly falling too low and involving hard firing to increase it. Damp is often injurious in greenhouses, and it is a good plan to occasionally heat the pipes on a bright and mild day so that the top ventilators can be freely opened for the dissipation of moisture. Provided there is no danger from damp you will do well not to use any more fuel than is requisite for preventing the temperature falling below 45° to 40° at night, nor should it exceed by fire alone 45° to 50° during the day.

Preparing Manure for Mushrooms—Site for Beds (W. G.).—When manure is prepared in large quantities, amounting to upwards of three or four cartloads, it may be prepared quite as well in the open air, as if preparing it for an ordinary hotbed, as in a shed; but with small quantities a covered place is advantageous—indeed, often indispensable. The space under a bridge, boarded-up at each end, would be very suitable for growing Mushrooms; and if room could be found for a heap of fermenting materials in preparation for successional beds, the heat thus imparted would be sufficient, and the atmosphere would be in the best condition for the crops. Heat thus afforded would be far better than that provided by any apparatus.

Gladioluses Growing Prematurely (W. N.).—As the corms have produced roots from 1 to 2 inches in length, and top growth is commencing, they had better be potted, as if they remain where they are they will spoil, and removed to a dry room the roots will shrivel. As you have no frame or greenhouse the pots had better be stood on a hard base, or on ashes, impervious to worms, in the open air or in a very cool cellar, and cover them 3 or 4 inches thick with cocoa-nut fibre refuse. The growth will then be slow and sturdy, and in March, or when the weather is favourable, the plants can be turned out of the pots and planted carefully in the garden. The soil, if moderately moist, as it should be when used, no water will be needed until the pots are withdrawn from the fibre. This material is very cheap and useful in gardens. Pots 3 to 4 inches in diameter will do, according to the size of the corms.

Specimen Chrysanthemums (T. M., Ch shire).—The cuttings are best inserted singly in small pots, which may be done now, or when sturdy cuttings can be had. After they are well rooted repot them into 48-size pots, but do not stop them until they are 6 inches high. Be very careful when you stop them only to just take the smallest point out, so as to get as many shoots as possible. If stopped roughly, pieces about an inch in length being removed, only a few shoots will be produced, and consequently time lost. Place a small stick to each plant to keep the main stem erect. After the shoots have grown about 4 inches take the points out again. Place a piece of twine under the rim of the pot to tie the shoots down to. Be careful in tying that they do not break away from the main stem, as they are apt to do if not prevented by placing a tie round the base of each shoot to the main stem or stick. It is of importance that the plants be kept in a free-growing state always. Repot as required, and apply water carefully yet sufficiently. A 12-inch pot will grow a large specimen. As the shoots from each stopping attain a length of about 6 inches take the points out and keep the shoots well down in the early stages of the plant's growth, when the after-training will not be difficult. The last stopping should be done about the end of June. Each plant should carry sixty good-sized flowers, consequently you will require sixty shoots. Remove all suckers as they appear till after the flowering period. Some societies are very particular in having a clear stem from the rim of the pot to the first tier of branches. After the plants have been disbudded and the blooms are commencing to expand finally tie them into the required shape. Some growers take those plants that have been grown on the single-stem system for large blooms, and cut them down to about

12 inches. After they have broken well on the stem shake them out, and place them in small pots, and stop and repot as recommended for cuttings. The plants often come stronger under this system, but are apt to throw up suckers frequently, which should be removed. We shall shortly publish further notes on Chrysanthemum culture that will probably be useful to you.

Pines Unhealthy (F. C.).—We thought we had never advised the liquid manure which you have given to the plants. Weak guano water is very different from the decidedly strong applications that you have afforded. You have no doubt given it too strong by half, and also probably more often than it was needed, even if it had not been strong. So far as we understand the state of the plants, they have been overwatered, overfed, and, according to the temperatures you submit, underheated. If you refer to page 512, November 30th, you will find the proper temperatures advised for such plants as yours. The bottom heat is correct, but the top heat is at the least 5° too low for plants kept so moist as yours have apparently been. It is only when plants have been prepared by skilled cultivators that they can be kept healthy in a temperature of 55° and falling as low as 50°. Raise the temperature to 60°, and little water given once a fortnight or less frequently will suffice for the next two months, especially if the pots are plunged. Provided you can maintain the present temperature at the roots there is no necessity for introducing fresh leaves and the attendant slugs. The small work we advised would be of great service to you in your efforts at Pine culture. No one without seeing your plants can tell whether they are likely to fruit or not in the spring. They probably will not, and if they do the fruits will be small. If the Passiflora cuttings are in a pot remove it to the greenhouse; if in the open ground, cover them with a handlight and protect from severe frost.

Autumn and Winter-flowering Heaths (R. L. B.).—Three of the most useful Heaths for your purpose are *E. hyemalis*, *E. gracilis autumnalis*, and *E. melanthera*, which are quick-growing, easily increased plants, and flower most abundantly. Their value is indicated by the fact that many thousands of these Heaths are now sent to Covent Garden Market, as there is a good demand for plants of moderate size in 48-size pots. Of the dwarf compact *E. gracilis autumnalis* numbers of plants are grown in 60-size pots, and prove valuable for decoration as a margin to groups or in the front rows of stages. A small spray of this plant is shown in the woodcut (fig. 98), the flowers being rosy purple. *E. hyemalis* has longer crimson flowers thickly clothing the branches; and *E. melanthera* has small bell-shaped flowers produced in great numbers of a lilac colour with black prominent anthers. All of these may be treated similarly, a compost of light fibrous turf and peat with sufficient sand to insure good drainage.

Fig. 98.

Planting and Pruning Apple Trees (W. Hawley).—Under the circumstances we do not perceive that you could have adopted a better method of planting than the one you describe, and by mulching you may keep a number of roots near the surface. Long manure is suitable during the winter, but in summer short manure placed over a sprinkling of bone dust or wood ashes will be more effectual in inciting root-action and affording food for the trees. Digging incautiously amongst fruit trees and permitting the surface of the soil to become dry in summer is certain to result in the roots penetrating downwards in search of moisture. In mulching it is important, in summer especially, that the material be spread

at the least 6 inches, and a foot is better, beyond the extremities of the roots, otherwise they will inevitably turn downwards when they reach the dry radius, and cannot be brought near the surface again without manipulative aid. Even with all the care you may take in mulching it may be necessary, and will probably be advisable, to lift the trees, say about every third year, and place their roots near the surface, but this can only be determined by the condition of the trees. It is not easy to give definite advice on pruning, but we do not hesitate saying that as much harm as good is done by the use of the knife. Skilled cultivators can and do prune to good effect, but the unskilled prevent the production of fruit in their efforts to produce it. It is better not to prune at all than to do the work as it is too often done by those who own, or are placed in charge of, fruit trees. If your primary object is to produce fruit, and not to train the trees to any particular form, and keep them to a certain small size, we should prune but slightly, only removing any misplaced branches and to prevent overcrowding, at the same time shortening the ends of any shoot here and there that marred the symmetry of the trees. This may be done at any time when the weather is mild.

Sowing Fern Spores (F. R.).—The spore-bearing fronds should be carefully examined, and as soon as they appear to be approaching maturity—that is when the spore cases become brown, and before the spores are liberated, the fronds should be cut and placed upon a sheet of paper in a dry position, each species or variety separately, and the spore side downwards. It is, however, often preferable to place the frond upon the surface of the soil in the pot intended for the spores. The soil previously to being placed in the pans should be well baked or exposed to the action of fire sufficiently to consume all organic substances it may contain, also to destroy the spores of common strong-growing Ferns, which often overpower and either greatly injure or kill the weaker sorts. This process also serves to destroy any fungi that may be present, and which would otherwise prove injurious to the Ferns. The pots must be liberally drained, placing a large crock hollow side downwards at the bottom, then half fill with rough potsherds, covering these with a layer of smaller pieces, and on these may be placed the soil, rendering the surface firm and smooth. Water it

sufficiently to thoroughly soak it, and allow it to stand for a day or so before sowing the spores, which may be done as already stated, either by placing the fronds on the soil or by gently shaking the papers on which they have been lying over it. Each pot should then be covered with a piece of glass and placed in a pan containing about an inch depth of water, which will rise through the soil by capillary attraction, and keep it sufficiently moist, as watering on the surface must be avoided until the young Ferns appear. These directions must be carefully followed for all the delicate species and varieties; but there are some, such as the common Pterises, Adiantums, and Gymnogrammas, which require very little trouble, and germinate most readily. Spores of stove and greenhouse Ferns should be sown in a temperature of 60° to 65°; the hardy sorts can be sown in a frame or any cool house. There is great difference in the time required for the germination of Ferns: some species appear in a week or two, while others are several months, and instances have been recorded where Ferns have remained in the prothallus state for several years before fronds have been produced. You are probably aware that the prothallus is the small green cellular expansion which first appears after the germination of the Fern; and in the case of strong-growing species, if they are too crowded a few may be carefully removed with some of the soil attached, and placed in a large pan, as the space thus afforded often ensures a more rapid advance in those moved, and also in the others.

Raising Oranges from Seed—Grafting (Idem).—Oranges can be readily raised from seed, but you cannot insure obtaining plants that will resemble the parent variety, as, like so many other plants, they vary greatly from seed, and too frequently revert to a coarser and worthless type. However, as you only have seeds, there is no other course open to you. Light sandy soil is the best to sow the seeds in, just covering them, and place the pots in a stove or other warm house until the seeds have germinated. When several leaves are formed the young plants may be potted singly in small pots, and grown in a warm moist atmosphere, employing good turfy loam and a little well-decayed manure, similar treatment being needed as the plants advance. The difficult part is that you would have to wait several years before being able to judge the merits of the variety, as the Orange does not fruit in a very young state under cultivation. It is therefore usually preferred to obtain scions of small known variety, and graft these upon seedling stocks. This might be done in your case when the plants are two years old, and they may be either cleft or side-grafted, early spring being the best time for the operation. The stock and scion should be placed in a propagating house and shaded until they are united, when the plants may be removed to their old quarters, and heated as advised for the seedlings.

Forcing Seakale (Marton).—Pots are convenient but not "absolutely necessary," indeed in all probability far more Seakale is produced every year without the aid of pots than with them. A Seakale tub was shown in our columns a month ago, but even that appliance can be dispensed with. We have used open crates, and have seen fine Kale produced by inserting a few sticks slantingly round the crowns, bringing the points of the sticks together pyramid fashion, and covering with long litter previously to adding the fermenting materials.

Avocado Pear (J. Roberts).—Fruits of this plant may be occasionally seen in Covent Garden Market, but they are only introduced in small quantities and as a curiosity. The tree which produces them is *Persea gratissima*, specimens of which may be seen in the Palm house at Kew; but we are not aware that plants have produced fruit in this country.

Names of Plants (Keswick).—The specimen you have sent is of *Gnaphalium germanicum*, the common Cudweed, and may have been introduced in the manner you suggest. Grass and Clover seeds should be obtained from the best sources. There is nothing more costly than cheap seeds. (*H. M.*)—The spray bearing berries is *Ruscus aculeatus*, the Butcher's Broom; the other is *Euphorbia Lathyris*, the Caper Spurge. (*Stephanotis*).—1 and 2, *Adiantum Capillus-Veneris*; 3, *Asplenium cicutarium*; 4, *Selaginella caulescens*; 5, *S. cuspidata*; 6, *S. Martensii*. (*Bedland, Bristol*).—1 and 2, *Blechnum brasiliense*; 3, *Neprolepis davallioides*; 4, *Adiantum macrophyllum*; 5, *Rivina humilis*; 6, *Eupatorium odoratum*. (*A. B., Surrey*).—1, *Bouvardia longiflora*; 2, *Bouvardia Hogarth*; 3, *Eupatorium odoratum*; 4, *Abutilon vexillarium*; 5, *Selaginella Kraussiana*. (*R. O.*)—1, *Odontoglossum Alexandrae*; 2, *Cypripedium insigne*; 3, *Cypripedium insigne Maulei*. (*A. L.*)—1, *Adiantum Luddemianum*; 2, *Blechnum coreovadense*; 3, *Salvia leucantha*; 4, *Salvia splendens*.

COVENT GARDEN MARKET.—DECEMBER 20TH.

Our market has been well supplied with all classes of goods, prices remaining the same; and the extra demand for Christmas is well met by the supplies.

POULTRY AND PIGEON CHRONICLE.

MAXIMUM WEIGHT FOR AGE OF CATTLE AND SHEEP.

HAVING previously on the 20th of July last given an account of maximum produce of farm crops, we now propose to furnish an account of the maximum produce of farm stock. We shall illustrate the subject by examples and practices connected therewith from some of the best stock-feeders in various parts of the kingdom. This matter is of the highest importance to those engaged in the breeding and feeding of cattle for the home markets, and as at this period when the best specimens have lately been exhibited at numerous shows throughout the country, including Birmingham and the London Show in Islington Hall, and are sold chiefly for consumption at Christmas

The practice of feeding cattle for "baby beef" seems to have become prominent, and first mentioned in the home and southern counties. We find the first honourable mention is made by Mr. Henry Evershed, in reporting on the farming of Surrey and other counties in the Journal of the Royal Agricultural Society of England in 1854, states—"Of the example farm of Mr. Cyrus Ellis of Great House Farm, Hambleton, in Surrey, who was then a producer of young beef on a sand farm, he with others in his neighbourhood still continue the practice, for by the plan of early fattening Mr. Ellis avoids summering the cattle a third season; the calves are allowed to run out in the arable fields as soon as the Rye is ready for them, afterwards they get cake in the pastures. The fattening bullocks are started on early Turnips by the middle of September." It is further stated that if the animals are to attain the earliest possible maturity they must remain at all times in their sheds or boxes placid and undisturbed. They must not be turned out for exercise either in summer or in winter. The experiment was tried of keeping one lot in, and turning another on the best grass during the most favourable period of the summer. At the end of summer those kept under cover were worth about 30s. each more than those fed out of doors, the feeding having been the same except the difference in the fodder. There is no doubt about the value of this experiment and its results as to early maturity. It is unfortunately without any record of the weight of animals at a given age; still the early lesson thus laid before us is not without its value, as evidenced by several instances which we shall bring to notice, for Mr. Evershed, in writing his essay in the Royal Journal in 1878 on the early fattening of cattle, states, "That Mr. Joseph Blundell of Southampton set an early example in the production of 'baby beef' in South Hants in 1857, and read a paper on the subject before the Royal Agricultural Society, June 18th, 1862."

The following is his treatment:—"My calves are weaned at a few days old, fed with new milk at first, gradually introducing the skim milk, linseed cake meal and barley meal, with a little sweet meadow hay for a time in the rack allowed them, until they can safely take to green fodder, which they get in succession—first Rye, second Trifolium, third Clover, with a portion of old Mangold, then early Turnips. To commence the winter they get hybrid Turnips, Carrots, or Swedes, and lastly Mangolds, until the green fodder comes in again; being supplied with clean fresh Oat or Barley straw always in the rack whilst feeding either on green fodder or roots, the portion not eaten being removed for littering

the boxes daily. As soon as they begin to take green fodder they are allowed a small portion, say 2 lbs., of cake meal per day, mixed with the old Mangolds, which are cut with Gardner's Turnip cutter. As soon as root-feeding commences they get 4 lbs. of cake meal per day, and continue to receive this quantity until they are sold—at from eighteen to twenty months; having, however, during the last three months 1 lb. of bean or barley meal extra. But at no time after they once take to their green food are they allowed hay, as this would be found to absorb the profit and injure the health of the animals also, for since I adopted the method of straw-feeding I have never had an animal hoven or unhealthy. The quantity of roots given the first winter is 56 lbs. per day, the second autumn not more than 64 lbs. per day, the meal being always mixed with the cut roots. In this way each kind of food is more beneficial to the animals, and when only fed twice a day they have plenty of time to lie down and digest their food, and will return to the troughs with a good appetite, and will eat a good portion of clean straw." Mr. Blundell has frequently obtained prizes for young stock at the Easter cattle show of the Botley and South Hants Farmers' Club, and has published one instance of a first-prize Shorthorn heifer which he sold to Mr. William Lunn of Southampton, at eighteen months and three weeks old, weighing 98 stone 6 lbs., with a great weight of fat inside.

This selection of Mr. Evershed's is well calculated to induce farmers to excel its results if they can, and we shall show how far this has been since accomplished as we proceed to give further experience of cattle-feeders taken from his essay. Messrs. Drewitt and Son of Pickard's Farm near Guildford, who have furnished details of feeding, &c., say:—"When the calves are weaned they get whilst on grass 2½ lbs. of linseed cake each daily. In October they commence feeding in yards with the same allowance of cake, with one-third of a bushel of Swedes or Mangold daily, straw, and rough hay. After the second summer on pasture with the same quantity of cake they are prepared for the butcher, with 1½ bushel of roots daily, 5 or 6 lbs. of linseed cake daily for three months, and afterwards at the finish 5 or 6 lbs. of peas or barley meal in addition. At a little more than two years old useful Shorthorns thus kept nine of them were sold to Mr. Colebrook, butcher of Guildford; the heaviest steer was just 105 weeks old, and weighed 122 stones 2 lbs. At a sale of young common country-bred cattle fed by Mr. Stanford of Carlton Court, Sussex, seven Shorthorns were sold; the best animal of the lot was sold to Mr. Page of Partridge Green, which gave 8s. per week to the feeder, weighing 132 stones at one hundred weeks old. It is, however, considered a fair average weight for animals well fed from birth to yield 100 Smithfield stones of 8 lbs. at one hundred weeks old."

Although it is often stated that old beef as well as mutton is to be preferred, yet the quality of all meat, however, depends greatly upon management and the mode of feeding. The evidence of Mr. Port, the butcher of Ship Street, Brighton, who supplies a superior class of customers, states that some bullocks from Mr. Stanford's at Carlton Court, purchased on June 12th, 1874, at nineteen months and a half old weighed 100 stone 4 lbs., and that when slaughtered proved the most complete carcasses of beef, and the meat gave every satisfaction to the consumer, being very tender and of delicious flavour. Much more evidence of a similar nature is obtainable, but we have given enough to prove not only the advantage of making young beef to the feeder but to the consumer also. Still there remains the practical point of detail in feeding and the cost; for it will be noticed that in Mr. Blundell's mode of feeding, and the cost of the material and quantity allowed per day is much less than in the case of Messrs. Drewitt and Sons on their plan of feeding, or on Mr. Stanford's allowance for his young animals. There is, however, a further question to be considered, that of housing, because in our experience for many years when we desired to make young beef we always fed them at full head as calves, and continued such mode of feeding—namely, at full allowance of the best of food, but the animals were always on the straw in boxes or sheds under cover, which latter plan is the only way to obtain the full benefit of liberal feeding, for young animals in particular.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—Since our last statement there has been continued delay as far as preparing and seeding the land with Wheat is concerned. In many counties the reports state that not one-half of the land intended for Wheat has been sown, and that much which has been sown cannot produce an even plant, for the rains have been so heavy and continuous that much grain will perish in the land. The Wheat plant is, however, a very hardy one, and will bear various changes from frost to thaw, but heavy rains occurring immediately after sowing settles the ground over the grain on strong soils so

closely that the seed cannot germinate. Should there come a change of open weather to enable the sowing of Wheat to be again commenced, a larger quantity of seed (not less than 3 bushels per acre) should be sown, for when late sown the birds are sure to destroy a portion of the young shoots as they first appear above ground. The home farmer need not hesitate about sowing Wheat from this time until the first week of February on the dry soils of the eastern, southern, and home counties if a favourable season occurs, because if the land can be harrowed so as to bury the seed, the heavier and closer the land lies the better, for it prevents the growth of various weeds. The great objection to sowing Wheat late, especially in the latter part of February or March, is when the land is too dry and light, for then the land does not furnish a firm root-holding for the young plant, but it also favours the growth of numerous weeds, which are indigenous to some soils. If the season should still continue quite unfavourable for sowing the land with Wheat, the land may then be (especially on strong clay soils) sown with the black Tartar Oats. Drege, however, will give the greatest quantity of grain, and if the newly-selected white Tartar Oats are mixed with the long-eared American Barley the yield will reach the outside of produce, and the straw will be valuable fodder. If the land is sandy or gravelly Barley may be sown alone if the season be favourable. Still we think that Oats or drege offer the best substitute for Wheat, because we expect when the land is in good condition that as many quarters of Oats will be grown as sacks of Wheat, which at present prices will make as much money, and it is more likely to be the case when Oats or drege is sown upon land previously prepared or intended to have been sown with Wheat.

Horses have been lately employed in drawing out couchy earth or earthy composts on to the pastures without injury during frosty weather. When the weather has been wet the drawing of earth from various sources to heaps for future mixture with yard dung has been done, and has filled up the odd time with advantage if parties are prepared to make a good use of the earth hereafter. Not only do we recommend it for mixture with dung as compost for grass land, but we advise that it should be used at the bottom of all pens where cattle are housed, but also on the floor of the pig pens and cart-horse stables, sheep folds for lambing yard, breeding sows' yard, also the farmyard or cattle-yards, and also for use upon all sites for making dung heaps. The value of earth if properly placed as an absorbent of liquid manure and urine of animals is not sufficiently regarded by farmers in general, and the loss which has occurred in all old-fashioned farmyards during the late autumn rains has been very great. Before we can expect the home farmer to agree with us to the full extent in these matters he must accept our ideas as correct—namely, that every cubic yard of earth saturated with urine under cover will contain as much of the elements of manure as 2 cubic yards or cartloads of farmyard straw-made dung.

Hand Labour.—In all open weather let the women or old men go fork in hand and look over all land where lumps or bunches of Couch-grass or black Bents prevail, also the Onion-grass and Docks. All these, whether on the fallows or between the Turnips and Swedes, before feeding with sheep should be forked out and carried to small heaps first, and afterwards be cleared away with horse and cart the first opportunity. Some hands will be required in fine weather to attend the threshing machine, for we advocate the threshing of the greater part of the corn during the winter months, because the hands should not be displaced or taken away from important farm work in the spring or summer months.

Live Stock.—Much extra attention has been required during the prevalence of snow and frost. All young cattle of a year and half old intended for young beef should now be well fed under cover, so that they may be ready for sale from the middle of June to the middle of the month of August, as beef always sells well at that period, especially of light weights and nice quality. The Dorset Downs are now just lambing down, and will require the usual care, good lair, good food, both hay and Cabbage, but always with rock salt within reach, as it has been lately stated by good authority that even those ewes which had flukes in their liver have so far recovered after being fed with salt, iron, &c., in their mixtures of cake and roots that when killed have on examination of the livers proved that the flukes had been destroyed and expelled from the liver, which exhibited the injury done and the healed surfaces which had been affected by these parasites. The lambing folds should be carefully made in a dry sheltered position, on slightly sloping ground, but the shepherd and his assistant should be prepared for attending day and night with the moveable shepherd's house or van properly provided. It is in those cases where many twins occur that extra attention is so much required both by night and by day, the assistant and the shepherd relieving each other at night time.

INDIAN CORN CULTURE IN AMERICA.—Indian Corn is by far the most important staple crop grown by the American farmer. Under present acreage in this country, with a favourable season, the annual Corn crop should be fully 1,800,000,000 bushels. Though its market value per bushel is less than that of Wheat, yet the aggregate value of the Corn crop is nearly, or quite, double that of Wheat. It is not, however, as a grain raised for sale alone that the importance of the Corn crop is manifest to the farmer. Indian Corn is the basis on which is produced a large proportion of the pork, beef, and mutton of the

country, while the production of butter, cheese, and wool is more or less dependant upon the feeding of Corn. These facts are brought more prominently to public notice in years like the present immediately following a season of general or partial failure in Corn.—(*American Cultivator.*)

POULTRY AND PIGEONS

CHOOSING A DORKING COCK.

I HAVE been asked to give the points by which I would choose a Dorking cock. It is a question not very readily answered in writing, as there is much that would be more easily pointed out in the live bird than defined by the pen in words. However, I will try. First as to carriage. He ought to carry himself up like the old-fashioned Game cock, not the low horizontal way in which the present mongrel does—the so-called Dorking. His tail should be carried well up and should be large and full, the larger the better, with fine long sickle feathers. One with a good Dorking tail is very difficult to find: I have scarcely seen any of late in the show pen. Next, his head should be large and his eyes bright; and his comb large, upright, with long even spikes, finishing with a rounded lobe at the back, but not drooping towards the back of the head like that of a Cochin, as many of the show birds do, but being well up and relieved from the head at the back. A very excellent type of this form of comb can be found in Bewick's "British Birds," vol. i., in the engraving entitled "The Domestic Cock," which also shows the carriage of the true Dorking. The neck should be of moderate length and well set on the shoulders, which should be broad, though not square like the Brahma, which makes the bird to look better than he really is, but it should have a rounded fullness. The breast should be deep, thick, well forward, full and rounded, having much more meat on than appears unless handled. The back should slope well towards the tail, as should the breast and sides, falling as it were to a point, so that the bird carries but little offal, bearing small or no resemblance to the show Dorking of the present, whose back often rises if it is not straight; and the great thickness from the back to the belly shows only too clearly the quantity of offal that it carries, which makes it weigh the more: at the same time it is a vastly deteriorated fowl. The thighs should be neither short nor long, but large and full and strong; the legs rather short than long, but not very short like a Bakie or Dumphy. If they are too short the young fowls are apt to get overwet in the grass, which is prejudicial to their health and well-doing. The bones should be fine and by no means thick: a large-boned Dorking is a mongrel *without any doubt*, and is coarse in flesh as well as bone. The colour of the legs should be a whitish flesh colour, the scales looking soft and of fine texture. The whole of the feet, and particularly the toe nails, should be white. A dark toe nail is a sure sign of cross-breeding, and *one* so coloured should *never be bought to breed from* by the true Dorking fancier. The toes should consist of five in number, and be even, strong, straight, not lumpy or gouty; and the fifth toe should be as long or nearly so as the middle toe in front, but turned up and nearly if not quite touching the back of the leg. This is an important point to notice, as many of the prize birds, even cup-winners, show clearly by their short straight fifth toe their mongrelism. The feathers should lie close to the body, any looseness betrays a cross.

Again. Another great point to notice and to be *utterly* avoided is a red earlobe. This is a sure sign of Asiatic cross, and on no account should be tolerated. Jaques, writing of the true Dorking about twenty years ago says, "The earlobe should be of a beautiful white, resembling the mother of pearl." This to my mind is a most excellent definition of the colour. If the bird possesses the above qualities take it in your hand, and I have not the slightest doubt you will find that it has a clear white *thin* skin, with flesh of a fine texture and white, with white fat. It will be said, possibly, that I have not mentioned colour, nor have I. Get all the qualities I have stated, the colour is the last, the least, and the most *useless* consideration. The so-called Dark Dorking of to-day is not a Dorking colour at all, but is got by crossing, and has been one of the causes of the spoiling of the Dorking; but so long as judges give to colour as a point, and so long as weak-headed critics of shows write such nonsense as "Good bird, bad in colour," or "Good, but we did not like the colour of his wing," &c., the Dorking proper will not be seen at the shows. The colours of the Dorkings were chiefly the Dark Grey, the Reds or Bays with rose combs, the Speckled, the Cuckoo, the Browns, Mottles, and the Whites. The Grey were the hardiest and finest birds and truly beautiful, the cocks being slightly chestnut on the

wings. The Bays were light red or speckled on the breast with light red hackles striped with black; the saddle dark red, and the tail coverts orange, with the larger tail coverts black edged with red, and the tail black, with a green and purple sheen on it; these had rose combs chiefly, and were very beautiful and for table excellent. The old Browns were much like the Black-breasted Red Game in colour, but not so bright. The Speckles were of three kinds—Red Speckles, Black Speckles, and the three colours mixed. The last were in great repute and were often seen at the Birmingham shows of five and twenty years ago, but the Judges have set up a standard of colour of their own, and the consequence has been the loss of the old breeds and the triumph of mongrelism. If for no other reason than this I for one am truly sorry that poultry shows ever existed; but there are others which I do not care to mention and are quite beside the subject in hand.

In choosing the Dorking cock be sure to bear in mind these things. Never buy to breed from a bird with the *slightest* tint or sootiness on the legs or feet—no, not even a *dark toe nail*, nor one with bright red sides to its legs: this is another sign of the mongrel. Nor ever buy one with a red earlobe. No true Dorking ever had one. An experience of fifty years teaches me this. My readers can be guided or not by me as they like, I only write what I should do myself. And now as I am writing I may say I feel sure that there will be, there *must be*, a reversion to the true old type of Dorking, and the present mongrel will be swept away as though it never existed. Already people think twice before they give the prices asked, and about here they decline altogether the show birds that breed these sooty-legged chickens. So it will be until this grand table fowl is purged from the crossings and intercrossings, and it again becomes the table bird it once was—the finest in the world.—HARRISON WEIR, *December 11th, 1882.*

THE POULTRY CLUB.

A MEETING of the Committee of the Poultry Club was held on Wednesday, December 13th, 1882, at the Charing Cross Hotel, at 2 P.M. There were present Mr. O. E. Cresswell (in the chair), the Earl of Winterton, and Messrs. A. Comyns, S. Lucas, and C. F. Montrésor.

ELECTION OF MEMBERS.—The following new members were elected:—Mrs. H. J. Goodall, Melton Mowbray; T. Raines, Bridge Haugh, Stirling.

THE DISQUALIFICATION AT THE PALACE.—The Secretary reported that he had heard from Mr. C. Davenport Jones, who stated that he would abide by the decision of the Committee.

DORCHESTER SHOW.—A complaint as to the withholding of prizes at this Show, which had on several occasions previously been under the consideration of the Committee, was again brought forward. The Show was held under Poultry Club rules, and a subscription had been granted by the Committee in aid of the funds. It appeared that in the schedule published by the Committee of the Dorset County Poultry and Pigeon Society certain prizes were offered for competition without any condition as to the withholding of the same in case the entries should be below any specified number, the only rule as to withholding of prizes being the ordinary one, providing that "the Judge would be empowered to withhold a prize or prizes in any class in which there was not sufficient merit." It further appeared that when the Show authorities ascertained that the entries in certain classes were but few they instructed the Judges, and entered such instructions in the judging books, to the effect that as to these classes certain prizes should be withheld. Some of the Judges declined to follow these instructions except in cases where there was not sufficient merit, but at least one Judge followed the instructions and withheld certain prizes. He, however, awarded v.h.c.'s and h.c.'s in nearly every class in which prizes were withheld, thus clearly indicating that the prizes were not in his opinion withheld for want of merit. When the official list of awards appeared it became apparent that these v.h.c.'s and h.c.'s had been suppressed by the Show authorities, the only awards published as to such classes being the prizes actually awarded. This would seem to have been done to give colour to the withholding of the prizes as having been so withheld for want of merit, when they were in reality withheld at the arbitrary dictation of the Show authorities, acting in direct opposition to their own rules.

The Secretary of the Club reported he had written several times to the Secretary of the Dorchester Show, and had at length received a reply in the following terms:—

"Dorchester, 7th Dec., 1882.

"Sir,—I have the honour to acknowledge the receipt of your letters, and to inform you in reply thereto that the reason the Judges were instructed to withhold prizes in some of the poultry classes at the recent Show held in this town was owing to the very small number of entries. My Committee thought that as the competition was so very limited in some of the classes they were justified in curtailing some of the prizes, but upon further consideration they much regret having done so, as it has caused dissatisfaction amongst a few exhibitors, particularly with the President of your Club.

"I would respectfully remind those few exhibitors who have complained that, owing to the very heavy snowstorm during the Show held in January, 1881, my Committee had to pay no less than £60 out of their own pockets over it, and had the poultry exhibitors responded better to the very liberal prize list

offered them on the last occasion the Show would have been much more successful and satisfactory in every way."

The following resolution was passed:—

"That the Committee of the Poultry Club strongly condemn the action of the authorities of the Dorchester Show in directing the Judges, contrary to the rules published in the schedule, to withhold certain prizes irrespective of merit, and also in suppressing the v.h.c.'s and h.c.'s awarded by the Judge or Judges in these classes. That the Committee of the Club call upon the Committee of the Dorchester Show to publish an amended prize list, according as far as is now practicable with the prize list offered in their schedule and the rules printed therein, and to include in such prize list all exhibits to which v.h.c.'s and h.c.'s were actually awarded by the Judges. That in such prize list all the prizes offered by the schedule be awarded to the exhibitors in each class in the order of merit in which they actually stand in the judging book as far as is practicable, and that where in consequence of two or more exhibitors having been awarded v.h.c.'s or h.c.'s they have an equal claim to any prize or prizes, such prize or prizes be equally divided between such exhibitors. That the exhibitors be forthwith paid the amounts due to them respectively on such amended list as aforesaid."

The Secretary was directed to communicate this decision to the President, Vice-President, Chairman of Committee, Secretary, and Treasurer of the Dorset County Poultry and Pigeon Society.

STANDARD OF PERFECTION.—The Secretary reported that a large meeting of leading Game fanciers had been held at Birmingham during the Show for the consideration of the portions of the Game standard left unfinished at the Palace meeting. The further consideration of some questions connected with the standard was postponed.

ELECTION OF OFFICERS AND COMMITTEEMEN.—Instructions were given to the Secretary as to the annual election of officers and committeemen in place of those retiring by rotation on 31st December. The day on or before which nominations to the vacant offices are to be made was fixed for Wednesday, January 3rd, 1883. The following gentlemen retire by rotation:—The *President, the Secretary, and Messrs. T. W. Anns, O. E. Cresswell, *J. C. Fraser, Rev. H. C. Fellowes, R. E. Horsfall, Rev. E. H. Morgan, L. Norris, and G. Vigers. The President and those members of the Committee whose names are indicated by an asterisk do not desire to offer themselves for re-election. There will thus be several vacancies for which candidates must be nominated. Candidates may also be nominated for other offices and for places on the Committee to compete with those retiring members who offer themselves for re-election. Candidates must be members of the Club, and must be nominated with their own consent by at least two members. Nominations to be sent to the Hon. Sec. on or before January 3rd, 1883.

NEXT MEETING.—The date of the next meeting was fixed for Wednesday, January 17th, at Charing Cross Hotel at 2 P.M.—ALEX. COMYNS, *Hon. Sec., 47, Chancery Lane, London, W.C.*

WATFORD POULTRY SHOW.—The annual Poultry Show of the West Herts Agricultural Society was held in connection with the Exhibition of Fat Stock on December 12th and 13th at the Agricultural Hall at Watford. The building is one of the best in the kingdom for an exhibition of this kind. The cattle and stock are on the ground floor, while the poultry are arranged in tiers in the gallery which runs round the interior of the Hall. The number of entries was not quite so large as usual, but the quality of the birds exhibited was said to be superior to the entries at any previous show. The cup for the best pen in the show went to Light Brahmas of Mr. G. H. Wood: these, however, were closely pressed by Mr. Bartrum's cup pen of Dorkings. The cup for Cochins was won by Mr. Breeze, for Game by Mr. Ross, for Hamburgs by Viscount Grimston, Bantams by Mr. Flitt, and Mr. Huish secured the cup in the Any other variety class with Polish.

REMARKS.

10th.—Frost, thick fog throughout.

11th.—Misty, dull, and very cold.

12th.—Dull and cold.

13th.—Dull and foggy; gleams of sunshine in forenoon; warmer.

14th.—Dull and damp; fog in morning.

15th.—Dull and foggy.

16th.—Dull, but not much fog; considerably warmer; rain after 9 P.M.

An extremely uncomfortable week, sharp frost in the early part, almost constant cloud, and a great amount of very dirty fog.—G. J. SYMONS.

REPORTING PROGRESS.

IT is the custom for individuals in whatever sphere of life they may move to periodically look into those affairs which most intimately concern them, with the object of determining as accurately as possible their present position and future prospects. Similarly it is desirable to examine, as well as circumstances permit, those matters with which they are identified in the way of trade, or interested in as a pursuit that affords them wholesome health-giving exercise, from which they hope to derive pleasure and satisfaction. This custom is a safe and excellent one, and the natural time for carrying it out is towards the close of the year; this seasonable work accomplished, and not till then, can they properly report progress.

In reporting progress in the great industry of horticulture there is a tendency to take a view too limited for properly comprehending the subject. A year is but a short time for measuring the stages of advancement of that of which Nature is the author and man only the guide. Yet much may be done in a year, and that much has been done in that short period we have good evidence; but in order to understand the full import of the general progress that has been effected we must take a further backward glance: Let the old look back to the period of their middle age, and the middle-aged look back to the days of their early manhood, and carefully estimate the condition of gardening then with the appliances at the time, and then look at the position of the craft now. They will have seen changes occur—something advancing and something receding in accordance with natural laws or the fleeting fashion of the hour; but these are mere incidents in the life of that which is essentially diversified, yet which is gaining vigour with the lapse of years.

The decline of horticulture has been whispered by the timid. With as much reason they might bemoan the decline of civilisation or the decline of man. Not in this our day is there any substantial evidence of the decline of one or the other; the three are co-existent and progressing. In science, art, and industry real progress must be reported, and can this be so while that which is a combination of those great elements is receding? It is impossible. With a great and continuous "levelling upwards" in education, higher intellectual tastes and refined perceptions must be promoted; and under these circumstances there can be no permanent decline in horticulture, but progress must continue, and there is every probability that it will be greater in the future than it has been in the past. Granted that "bad times" is not an empty phrase, there have been times far worse; that "low rents" exist—there

have been lower; that "depressed trade" is not a vision—there has been far greater depression. These checks and changes are but little clouds in the nation's life, which through all history have been periodically recorded, and, like comets, come and go, no one knows why nor whence, nor exactly what is their mission. So sure as the human frame has its ailments, so sure will there be recurring impediments to the smooth progress of that aggregation of individuals of which nations are made. These obstacles may be, and must be, to some calamitous; and, on the other hand, they may be, as they have been, "blessings in disguise" as affecting the whole community. But admitting to the full all impediments, progress in horticulture must still be reported, and that of a remarkable kind. Evidence of this we were about to adduce when the following letter came to hand from one of the most experienced, successful, and enlightened of British gardeners. Referring to the somewhat discouraging views that have been enunciated as to the past, present, and future of gardening, our correspondent observes:—

There is, it is to be hoped, no necessity yet to sing dirges over the fortunes of our craft. Mutation to a great extent characterises all mundane affairs, and so do seasons of adversity; but such conditions should never cause despondency and gloomy forebodings to spring from the mind, for they may in the long run result in good to the cause we all have so much at heart.

Almost everything advances as do the tides—not by one continuous and uninterrupted flow of progress without surges that seem to bode nothing but retrogression, and gardening cannot possibly be shielded from similar influences.

Though I do not want hopefully to tell "a too flattering tale" of gardening, I think it has as yet kept step with the fortunes of old England, which have sometimes been chequered and uneven, but in spite of which progression of a very marked and substantial kind is the sum of its ups and downs.

Agricultural depression has recently put a drag on the wheels of her twin sister horticulture, and it may be in some instances "reversed the engine." But I am of the opinion that horticulture is not in such a bad way after all, and that "its streams are yet fresh, and its sunshine bright" when looked at from the standpoint of bygone experience.

Nearly half a century has passed since the writer took to "the spade" as a means of livelihood. Not a very long time to look back, but long enough to enable him to see at the far end of the vista a very different condition of gardening from what we have now. Many things have changed, and many have been discovered since then. Taking the case of what I shall term the operative gardener first. His position fifty years ago was very different to what it is now. I never had more than 9s. per week as a journeyman in Scotland, and 13s. without lodgings in England, and I had the fortune to be employed in some of the best gardens on both sides the Tweed. Under gardeners are much better paid now, and, I think, not so hardworked. Head gardeners' situations, which then yielded £45 and £50 per annum, have now risen to £70 and £80; and I know of several large places where the gardener's emolument was but little over £100, whereas now it is up to £200. So much, then, for the gardener.

As to gardening, it would take almost a volume to contrast its extent and condition half a century ago with the state and the dimensions it has now attained. Almost every old garden has widened and extended greatly; and though at present we see some retrogressive steps in the case of gardens owned by those who derive their revenue from land exclusively, that does not prove that horticulture as a whole is not making progress. What of the retired merchant class, and those who are still actively carrying on the wonderful commerce of the nation? Why, where there was one garden owned by this class fifty years since there are fifty now. Then the shopkeeper, not to speak of the merchant prince, was content to reside above his shop or store, and was innocent of a garden. Now in thousands of cases they have their villas in the suburbs or right out in the country, have their gardens and glass houses, and their gardener or gardeners as the case may be. So that, although in some of the more pretentious gardens of the nobles and gentry we witness what it is to be hoped is but a temporary retrogression, the horticultural wave is to be seen going forward at a far greater number of points than where it is receding. Of course, it is very undesirable that the gardens of

the great landocracy should show signs of any decay, but I am not certain whether the multiplication of the smaller gardens that has gone on so rapidly the last twenty years is not more desirable than the increase of the larger. It is at least a sign that the love for gardens and gardening is getting a deeper hold on the masses, and that, instead of its being confined to a few giant gardens, is developing into what may be termed the graceful twigs of the good old horticultural tree.

Market gardening, especially that branch of it which supplies choice fruits and flowers to the great centres of commerce and wealth, has of late years developed into wonderfully increased proportions, and these exotic commodities are now made use of to an extent never dreamed of in the memory of past generations. We need only go to Bexley Heath, the Tweed Vineyard, and similar establishments to see the immense factories that exist and have come into existence within the last ten or twelve years for turning out plants, Grapes, &c.; but we can also witness the vast multiplication of smaller concerns for the same purpose in various parts of the country. Nor can we fail to observe the marvellous extension and increasing richness of nurseries with the gigantic seed establishments that had no counterparts a generation ago, the tendency in these being to further extension rather than restriction—active life, not decay, being the manifest signs here.

If we take a glance at horticultural literature, progress there also is very apparent. The number of weekly papers almost exclusively devoted to horticulture has more than doubled, and their circulation more than quadrupled during the past generation, while their present character must also be regarded as improved. At all events the press is much more expensively conducted than formerly. It is not very long since a woodcut was a rarity in a gardening paper; now they teem every week with illustrations, though it may be doubted if they effect an amount of good in proportion to the expense they entail in production. But there is another branch of gardening literature that cannot be overlooked—the wonderful trade mediums that have come into existence during the past few years. Many of these are works of art, and are only produced at an expenditure of money, skill, and labour that is absolutely incompatible with a declining industry.

The character and capabilities of gardeners have been touched upon by correspondents. This is rather a difficult and invidious point to handle or illustrate by comparison. I do not believe in the progression of man individually. Solomon and his contemporaries were probably of as great intellectual grasp as any in these times, and there are not very many Homers, Platos, and Shakespeares now. Still civilisation has progressed, and so have the arts and sciences, and by what process of reasoning or comparison can we exclude the gardener from some share in the progress of that same civilisation? Probably the remuneration of gardeners has not advanced at the same rate as that of other classes, and so the tendency may be towards an inferior class only being enlisted in its ranks. As to character, from my own knowledge, conduct and behaviour in all ranks of gardeners were tolerated forty years since that certainly would not now be allowed. And it is generally admitted that the sphere of the gardener's care and anxiety has widened considerably, while many of the branches of the profession have improved, though perhaps some of them have been neglected. Gardeners of the past might be greatly puzzled to meet the requirements of families at the present day. Surely all the literature, the improved appliances, and the stimulus of competition has not been in vain, but must, as I think they have, result in the general improvement and spread of horticulture.

It might perhaps be difficult at this time of day to be the pioneer of any marked improvement in cultural matters. There are so many ardent workers in, and lovers of, gardening that surely the time has not yet come for writing *retrogression* on its path. No! unless the country recedes from its present position of wealth and greatness it would be rash to prophesy evil things of gardening.

I am of opinion that any marked improvement in practice must now arise, and be stimulated by widening the basis of what may be termed the science of the garden, such as its chemistry and physiology, and the horticultural press would do well to whistle for this wind to speed on the good old craft of horticulture. —DUM SPIRO SPERO.

Those are not the hastily written words of a youthful enthusiast, but are the well-considered expressions of one who has grown grey in advancing the work in which we are all interested, and which well and widely practised is fraught with benefit to all classes of the community. In what has been done in the past we rejoice in having had some share; and as to the future, with a widening field and ever-accumulating materials, we more than rest in the hope indicated in

the three closing words of our correspondent's letter, and look forward with confidence to the coming year. May it be prosperous to all.

DUKE OF BUCCLEUCH GRAPE.

I HAVE watched with considerable interest the controversy that has recently taken place both in the Journal and its contemporaries respecting the Duke of Buccleuch Grape. Some of the articles devoted to this subject have savoured too much of a passage at arms with quills, but what growers and intending planters really require is a thorough exposition of facts and practice which may enable them to form a correct estimate of the Vine under notice. Mere word-twisting and pulling to pieces of sentences that a writer might have used in perfect good faith will not give us the required information. Having had a fair share of success in growing and fruiting the Duke I venture to state my experience.

Some seven years ago I purchased the Duke with a number of other varieties for planting a new vinery, the price of the cane being half a guinea. The whole consignment was much knocked about in transit, but none received any permanent injury except the unfortunate Duke, which (and a fine cane it was) broke off close to the pot. However, I planted it along with the others, spreading the roots carefully. It made a vigorous growth during the following summer, even outstripping some of its companions which had been cut back in the orthodox plan to the first wire.

The second season I allowed four bunches on the Vine. The set was all that could be desired. The berries swelled to a great size, but became slightly spotted. It at once established itself as a favourite at dessert both from its noble appearance and brisk sweet flavour: the skin also is so thin it may be eaten with the fruit. This induced me to place a graft on a Muscat of Alexandria in the same house, which I had planted as a stock for any variety that might be specially approved of: but further of this graft anon.

The winter pruning consisted of cutting to spurs in the usual way and leaving about 5 feet of leading cane. Eight bunches showed, and—mark that—all on the leading cane, not one on the spurs. The set this year was not quite so good as the previous season, more stoneless berries having to be left at the thinning than I liked to see. This was also the case with some Muscats in an adjoining vinery planted at the same time.

The soil of the border—fibreless light black material, to which had been added about three cartloads of clay—had been dug from off the lime and ironstone; hence a sufficiency of the first-named mineral was considered certain, but the indifferent stoning of the berries gave me to understand that I was wrong in my calculation. I therefore applied half a chaldron of lime fresh from the furnace to a border 70 feet long by 14 wide. The lime was first of all placed in small heaps all over the border, then covered with the surrounding soil to the depth of a foot. Water was then poured on the soil; this was done to prevent any of the valuable properties of the lime escaping. The heaps were then spread over the border and forked in, so as not to injure any of the roots close to the surface. This application had the desired effect, for since that not a stoneless berry has been seen in our bunches. It sets as freely as its neighbour Foster's White. The spot also disappeared the following season. This latter malady I attribute to an excess of humus in the soil.

The barren aspect of the side branches consequent upon spur-pruning induced me the following winter to use my knife less freely. Several of the best side growths were left a foot to 18 inches in length; the others were cut-in to spurs just to watch their behaviour for another year. Result: Spurs barren, extension wood, a capital show of fruit. I had thus the Grapes evenly distributed all over the Vine.

Ever since I have experienced no difficulty in getting a good crop of Grapes every year with perfect setting and no spotting. The Grape, as most readers are aware, has a noble appearance: bunches 8 to 12 inches in length with proportionate width; berries $3\frac{1}{4}$ to 4 inches in circumference.

Respecting the graft on the Muscat of Alexandria, I have only to say that the bunches and berries are even finer than on its own roots, and the flavour is also slightly improved; the growth is more vigorous, with less pith and more prominent eyes. High feeding is in my opinion detrimental to its well doing, and as our borders are considerably above the surrounding ground level the roots have the full benefit of the sun. My Dukes are growing in a house planted chiefly with Black Hamburgs. They take about ten days longer to ripen, and I have up to this season succeeded in keeping the Grapes perfect as late as desired, but during the past summer many berries decayed before half the crop was cut.

This might have been caused by the crowded state of the berries, which had swelled more fully than hitherto, and owing to the thin nature of the skin splitting would ensue, and decay in consequence. The scissors will have to be used more freely in future, and a dry buoyant atmosphere maintained.

To sum up. I consider the Duke the finest white Grape in cultivation except the Museat of Alexandria, and, giving it ordinary Black Hamburg treatment and long spur-pruning, it cannot fail to please the most fastidious. What a grand sight a whole house of it must be at Clovenfords! while a Belgian gentleman who called here this summer on his return from Mr. Thomson's, exclaimed on seeing ours, "*Bon! Bon! Magnifique!*"

The respective merits of Foster's White and Buckland Sweetwater Grapes have also lately been discussed. Now I do not think it is fair to either Grape to judge them from only one point of view; for while Buckland Sweetwater is essentially an early Grape, fit to eat as soon as coloured, and even before that, Foster's White is practically of no use for dessert until weeks afterwards; in fact not until it has assumed that deep golden hue so much prized in Muscats, and that can only be obtained by long hanging and partial exposure to the sun. Hence if white Grapes are desired as early in the season as possible Buckland Sweetwater is the better of the two, with Foster's to follow; but both must make deep obeisance to the noble Duke.—A. WIPF, *Eastcliffe Gardens, Lincoln.*

ONCIDIUMS.

TROPICAL America is the home of the great family of *Oncidium*s; but though many of the two hundred or more species are found in tropical latitudes, yet some of them ascend to such great heights in the mountains that numbers of the most handsome can be safely included amongst what are termed cool-house Orchids. Still the greater proportion of them require warm treatment, similar to that afforded the East Indian species. Of those which are found at the greatest elevations, perhaps *O. Warscewiczii* is the most remarkable, as it has been observed growing upon Oaks on the mountains of Costa Rica 8000 to 10,000 feet above sea level, and there the temperature in the coolest season falls to 40° or even below it.

The *Oncidium*s are of epiphytal habit, and they are chiefly treated as such under cultivation; but there are some, especially the strongest, which succeed very well under culture in pots, and there are few which cannot be grown in baskets. As, however, the treatment required by these plants is so extremely varied, the

Fig. 99.—*Oncidium tigrinum*.

particular character of each species noted will be referred to under their respective names. One peculiarity of the genus is the enormous length the inflorescence attains in certain species, 10, 12, and even 15 feet being reached by *O. unguiculatum* and others. Yellow, too, is the most prominent colour, and the shades of this from the most delicate lemon to the deepest orange are very numerous. In a few purple hues are found, and perhaps one of the best known of these is the spotted *O. cucullatum*, the flowers of which contrast most strikingly with such types as *O. concolor* or *O. tigrinum*.

In the following notes the best and most useful species only are selected, as many of those known and some of those that have been introduced are comparatively worthless in a horticultural point of view, though interesting botanically.

Oncidium tigrinum.—The two species shown in fig. 99 and fig. 100 represent two distinct types, the large and the small-lipped

Fig. 100.—*Oncidium zebrinum*.

forms. Decidedly the most showy of these is the former, which is entitled to rank amongst the best of the whole genus. There are several varieties of this species, but that shown in the engraving—viz., *O. tigrinum* var. *splendidum*, is by far the finest. The lip is the most prominent portion of the flower, of a very bright clear yellow colour, the sepals and petals having a similar ground colour heavily barred with rich chocolate brown. It is said to have been found both in Mexico and Guatemala, and I believe first flowered in this country in Lord Londesborough's collection about twelve years ago. It produces a handsome branched raceme 2 feet or more in length, the flowers being 3 to 4 inches in diameter, and the lip often 2 inches broad. They are produced early in spring, and last for a month or more in good condition. A pot or a basket suits both the variety and the species very well, the temperature of the Cattleya house being most likely to insure its success. The typical *O. tigrinum*, which is also grown under the name of *O. Barkeri*, has been much longer in cultivation, having been introduced about 1840.

Oncidium zebrinum.—A charming species, but much rarer in cultivation than it should be. As already noted this is an example of the small-lipped *Oncidium*s, and it is curious that there should be similar characters in the genus *Odontoglossum*; for instance, *Odontoglossum vexillarium*, *O. Phalænopsis*, and *O. Roezlii* may be taken as species of the large-lipped section, while *O. cirrhosum*, *O. Halli*, *O. gloriosum*, and others come under the small-lipped type. The flowers of *Oncidium zebrinum*, as shown in fig. 100, are of moderate size, the sepals and petals white barred transversely with rich reddish purple, and are borne in a panicle that occasionally reaches, or even exceeds, 10 feet in length. Plants appear to have been introduced by several different persons, but the first to flower I believe was one in Mr. W. Bull's collection in 1872. It is a native of Venezuela, and succeeds best in a warm house.—L. CASTLE.

(To be continued.)

HELIOTROPE WHITE LADY.—This is an excellent variety, which will doubtless, when well known, be accorded a place in every garden

where fragrant flowers are in demand during winter. It certainly has not pure white flowers, and when allowed to develop naturally without the aid of heat they are heavily shaded. In a temperature of 50° during winter they are slightly shaded, but when grown in a house 10° warmer the flowers are nearly white. However, it is a beautiful light-flowered variety, and far superior to any other I am acquainted with for producing flowers in winter. It is a strong and robust grower, and every shoot, however small, will produce a large truss of flowers. This variety possesses one decided advantage over any other Heliotrope, and that is, it does not grow weakly during winter while in a temperature of 50° to 55°. If it can be kept in the temperature named it will continue growing and flowering the whole of the winter. Its compact habit admirably fits it for purposes of decoration. But I think it is even more beautiful when cuttings are inserted moderately early in the season, and grown on into small standards. Plants with about 18 inches of clear stem and then trained on small umbrella-shaped trellises, and freely pinched during the summer, will be found very attractive while in bloom during the winter in warm greenhouses or conservatories. Grown as small standards this plant forms an excellent companion to the varieties of tree Mignonette.—LANCASTRIAN.

PEAR PITMASTON DUCHESS.

I THINK we may prophesy that this Pear will soon become one of the most popular of all the varieties. In size and beauty it has no rival, and though its quality of flesh is not equal to a Marie Louise or a Doyenné du Comice, it runs those two fine varieties very closely, a little more sugar only being wanted to place it on a par with those two first-class kinds. We have it growing both on walls and standards, and also worked on the Quince and Pear stock. As grown on the Quince and trained to a west wall the sight when the crop is hanging is one to be remembered. On this stock the fruit is never so abundant, but the increased size and clearness of skin are remarkable in comparison with those grown on the Pear stock. On this latter stock fruit is produced more abundantly; but even if thinned to the extent of those on the Quince the size is much inferior, but there is no perceptible difference in quality of flesh. I have noted precisely the same variations with trees trained as standards and pyramids, of course the fruit being smaller on both stocks than from trees on the walls, though even in those positions it is rare that a fruit is of a less weight than 12 ozs., and from walls that weight is frequently doubled. We had dozens of fruits this year weighing from 22 to 28 ozs. The only fault it has is that when once it begins to ripen it is quickly over, a fortnight being the extreme length of time that it continues in good condition; but to some extent its season for use may be lengthened by gathering the fruit at intervals of a week or a fortnight—say a third of the crop about the middle of September, and the other at two different times between then and the end of the first week in October. Its hardiness, fruitfulness, and beauty are qualities that will eventually tend to its classification as the market Pear *par excellence*.—W. WILDSMITH, Heckfield.

CHRYSANTHEMUMS.

WHEN I read the remarks of that excellent florist, "D., Deal," at page 518 on the Chrysanthemum I could not help feeling the importance of anyone, however well versed he may be in a flower, following closely from season to season the improvements or otherwise which it attains. Your correspondent has evidently missed much by his non-attendance at Chrysanthemum exhibitions, for no flower, not even the Rose, has made such rapid advance and has become so generally grown as the Chrysanthemum. It cannot be called, like the Rose, a "clerical" flower, but it may truly be called a "gardener's" flower; and while it requires attention over a longer period than the Rose, it can be grown and flowered by everyone who has a glass house to protect its expanding blooms. The season of the year when it is in perfection also makes it doubly valuable, and I am safe in asserting that in large gardens where Chrysanthemums were little cared for a few years ago they are now grown in large quantities for home decoration and affording a supply of flowers. The Temple Garden was the only public place in London at one time; now all our public gardens grow them by thousands.

Dressing.—I must differ from your correspondent on this point, for the Chrysanthemum is not dressed so much as was formerly the case; the blooms are grown larger and of greater substance and solidity than formerly, and therefore naturally require less dressing. A great characteristic of the recent Kingston Exhibition, in which there were upwards of 1600 blooms staged, was the noticeable fact that very few boxes contained highly dressed blooms; in fact, a well-known prizetaker and expert dresser—viz., Mr. Rowe, formerly of Rochampton and now of North-

ampton, remarked that there was scarcely a bloom that could be said to be dressed; and I know it to be a fact that not one in ten that grow the Chrysanthemum can dress it. Some flowers it is almost impossible to improve; for instance, the six Princess of Wales exhibited by Mr. Molyneux at Kingston were simply perfection, and I should say that no art could have improved them. The trio of Rundle varieties, generally speaking, grow so perfect in form that they cannot be improved. Barbara, Prince Alfred, and others are generally of good form. The cup certainly may contract the florets towards the centre, but that cannot be said to be dressing.

There has certainly not been many novelties added to the list of incurved varieties for several years, except sports of these, which are in some cases acquisitions. The sport of Prince Alfred, and named Lord Wolseley, now in the hands of Messrs. Cannell and Sons for distribution, will be a very welcome addition. Then last year there was a very pretty golden amber sport of Eve, named Mabel Ward. In this way we obtain a few more improved varieties, but of new seedling incurved varieties we have none. I should think that the suggestion made in your last issue for a tabulated return of the varieties is a good one, and may be of even more service amongst the more rapidly increasing varieties, the Japanese.

Pompons.—I cannot too strongly endorse the opinion of "D., Deal," that these ought to be shown after the manner of the Pompon Dahlias at the Crystal Palace last autumn. When exhibited in bunches as grown without disbudding they are far more effective than are one, two, or three flowers too often laid flat upon the boards. Imagine the difference it makes in the effect of an exhibition, or even to the stand itself, if a bunch of three trusses is cut from 6 to 9 inches long bristling in flower buds from top to bottom, against three flowers resting flat upon the board.

Japanese.—The varieties of these have become so numerous that it is difficult to remember them all. A few magnificent varieties have been introduced during the last few years. In 1881 Messrs. Veitch & Sons contributed some extraordinary flowers, and I may mention Comte de Germany, Bend Or, Thunberg, and Kämpferi. Messrs. Jackson & Son are also large introducers, and to them may be given the credit of sending out many of the best varieties we now possess. Of these latest introductions I shall have more to say hereafter. Messrs. Dixon & Son are also large introducers.

The question has been raised whether King of the Crimson is a Japanese variety. It cannot possibly be placed amongst the latter unless we include Cloth of Gold, Chevalier Domage, and even Julie Lagravère in the same section. To Mr. Molyneux must be given the credit of again bringing this old variety to public notice. The first year he exhibited it at the Southampton Exhibition in 1880 I was particularly struck with its beauty, and I consider it regrettable that the reflexed varieties are not sufficiently encouraged. All exhibitions should include a class for them.

Mr. Molyneux, I believe, had the majority of his stock of cuttings in the first instance from Liverpool, and in that neighbourhood King of the Crimson had been known for many years. Triomphe du Nord is a very different flower: its florets are flat, and the whole flower has the character of a pure Japanese after the manner of Fulgore, only with broad instead of quilled florets.—J. W. MOORMAN.

NOTES ON PINE-GROWING.

SINCE the importing of Pines from St. Michael's assumed such dimensions many growers of Pines for market have given up the trade, and even many gardeners have in a great measure abandoned their cultivation; their employers being satisfied with the St. Michael's fruit, which can be had very cheap and looks remarkably well. To a real lover of a good Pine, however, the foreign fruits can never equal the home-grown fruits for flavour, and this has caused some who ceased the cultivation of Pines to begin again. These cases are not numerous yet, but still they show that the home cultivation may again become general.

Overpotting and overwatering are two evils that require to be guarded against in the cultivation of Pines. These two evils have been the means of many failing to produce Pines of first-rate flavour, and have in some instances ruined plants that otherwise would have been splendid. Good fibry loam, bone dust, charcoal, and a little soot make a good compound for fruiting plants in, watering—when watering is really required—with weak liquid manure. Ten and 11-inch pots are large enough; fruit 8 lbs. weight can be produced in these sizes of pots, which weight is heavy enough for anything; indeed, smaller fruits are more useful. This is one objection to Mr. Hunter's grand seedling, it throws such large fruit. Its extremely upright and very tall leaves make it rather awkward in a house. Anyone who has the

Queen, Smooth Cayenne, Charlotte Rothschild, and Black Prince is possessed of varieties that have every good quality.

The objection that used to be urged against Pine-growing, "that they took so long to produce a fruit," does not hold now-a-days, when we can produce them in the year from the time the sucker is potted on. The old system of growing the plants for two or three years has long been exploded.

Pine-growing, strangely enough, has been always considered a remarkably difficult part of a gardener's duties, but this is a great mistake. If a few simple rules that experience has shown to be right be adhered to, the cultivation of Pines is child's play compared to the growth of hardwooded plants or the management of a kitchen garden as it should be managed. Gentlemen who desire to have the fruit in its perfection must have them grown at home, and gardeners who are thus called upon need not tremble at the mention of Pine-growing, as I have seen some do, who

considered that there were some mysterious secrets connected with the cultivation of this noble fruit.—J.

MR. G. F. WILSON'S GARDENS.

Few names are more prominent in the horticultural world than that of Mr. G. F. Wilson, and his gardens are famed for the great collections of hardy, herbaceous, alpine, and bulbous plants that are grouped in a free and informal manner, which to many is so enjoyable. The annexed engraving from a photograph represents a portion of one of Mr. Wilson's gardens, which is being admired by the owner, his son, and Mr. Harry Stevens of the celebrated firm of horticultural auctioneers. The friends of these gentlemen will have no difficulty in recognising them, but for the information of others it may be stated that Mr. Wilson is the central figure in the view submitted. As the gardens in question were fully described in our

Fig. 101.—MR. G. F. WILSON'S GARDEN.

columns so recently as June 3rd, 1880, it is not necessary to enlarge on them here, as readers who are interested in the details will find them in the number quoted.

SELECT VEGETABLES.

THE selection of vegetables to be grown during the approaching year should no longer be delayed, and with the object of giving assistance at the present time in this important work these notes are written. Some of the varieties recommended for general culture in the following notes are new and others old, but individually or collectively they are capable of giving the greatest satisfaction.

Asparagus.—This is undoubtedly one of the choicest and most useful vegetables, and too much attention cannot be given to secure the best variety, as, unlike many other vegetables, when seed of an inferior sort is sown it cannot be changed again for a better the following season; but it may be three or four years after sowing before the mistake is discovered, and as long again before bearing plants of a superior variety can be raised. The Giant or Battersea is the smallest of our English varieties, one of the oldest and least worth growing. Reading Giant is a large superior sort which can be recommended. Next to this comes Conover's Colossal, which is also a sterling variety. The Purple

Argenteuil, so much grown in France, has been recommended by Mr. Laxton for cultivation in this country.

Artichokes.—Of the two distinct kinds of Artichokes, the Globe and the Jerusalem, the first is not a general favourite or a profitable crop to grow, but the other is a first-class vegetable deserving extensive cultivation. In Globes the green one is very much better than the one which produces purple heads. At first the green one does not bear so freely as the other, but when established it succeeds far better. There is only one variety of Jerusalem Artichoke, which produces the largest, most numerous, and best tubers when the plants are 2 feet or so apart.

Beans.—Amongst the hosts of dwarf French varieties Osborn's Forcing and Canadian Wonder are still the best. They are now generally regarded as standard varieties. Osborn's is the better of the two for forcing, and Canadian for the open air. In Runner varieties Sutton's Giant White and Carter's Champion are alike good: in fact there is no difference visible in them when growing, but the seeds are not the same colour. Mont d'Or is the name of what is termed the Butter Bean. It is a runner, and produces long narrow pods of a cream colour. It takes its name from the flavour it is said to possess, but although we have had it cooked in a variety of ways we never found the butter very prominent in texture or flavour.

Broad Beans.—These are equally as popular as the preceding.

Webbs' New Kinver Mammoth is the best Broad Bean we possess. Its habit is most prolific, pods enormous and flavour perfect. As a show Bean it is unique. Carter's Leviathan gave great promise, as its pods were very large, but they were not produced freely enough; but Seville Longpod is fully established in this class, and as a very early sort Beck's Green Gem deserves to be grown. The Windsor varieties are prolific, but the pods are too short to give satisfaction.

Beetroot.—Size of root should not be the first or only consideration here; but compactness and good colour are the points to secure, and having regard to quality alone Dell's Crimson is the best. The Egyptian Turnip-rooted is the best for early use or shallow soils. The Seakale variety is a good vegetable in the hands of those who know how to cook it.

Borecole or Kale.—This is an excellent winter vegetable, as no frost or severe weather will injure it in the south—in fact this improves the flavour; and of kinds there is no better than the Cottagers', Scotch, and Curled. Ragged Jack is the hardiest of all with me. The variegated-leaved Kale is most valuable for supplying leaves in winter for garnishing.

Broccoli.—These are of much importance, and the selection must be made with care, as of all vegetables none is more erratic than Broccoli. There are some, said to be autumn sorts, which do not head until far on in winter, and winter varieties so called are often of no use until spring. These results are sometimes brought about by the weather, but variety has much to do with it. Some years' experience and observation are required to secure the right sorts, and these we give below under three headings. Autumn: Veitch's Self-protecting. Winter: Osborn's Winter White, Backhouse's Protecting, Cooling's Matchless, and Leamington. Spring: Lauder's Late and Suttons' Queen. Veitch's heads from November to January, the others following; and Leamington does not come in until well into spring, when it is replaced by the two last-named, which are superb Broccolis. Suttons' Queen is a variety we would never be without.—A KITCHEN GARDENER.

(To be continued.)

RELATIVE VALUE OF STRAWBERRIES.

In a recent number of the Journal a correspondent, replying to someone who inquired which is the best Strawberry, states that, taking all things into consideration, he would grow Keens' Seedling in preference to any other one variety. This, no doubt, he finds best for his soil; but as showing how much Strawberries may be influenced by the soil they are grown in, I wish to state my experience in growing them on a poor heavy soil near Maidstone. On this soil Keens' Seedling grew vigorously, but fruited very poorly, while Vicomtesse Hericart de Thury or Garihaldi grew well and fruited very much more abundantly than Keens' Seedling or the other varieties I grew. Perhaps the following list may be of use to some of your readers situated on a similar soil, as the results were very carefully arrived at, and each of the fruits that were picked was weighed, and also the value of them noted according to their size, &c.

AVERAGE WEIGHT PRODUCED BY ONE PLANT.

	First year.	Second year.	Third Year.	Total.
1. Vicomtesse Hericart de Thury	Onnce. 1½	Onnce. 6	Onnce. 8½	Onnce. 15¾
2. Premier	1	1½	2	4½
3. President	0¾	1	2	3¾
4. Roden's Early Prolific	1	0¾	1¾	3½
5. Black Prince.....	0¼	1½	Not grown.	—
6. Keens' Seedling ...	0¾	0¾	2	3
7. Souvenir de Kieff...	0¼	0¾	Not grown.	—
8. Dr. Hogg	¾	1½	1¾	2¾
9. British Queen	¾	¾	Not grown.	—
10. Sir J. Paxton	0¼	None.	1¼	1½
11. Elton	0¼	None.	None.	0¼

The order according to the average money value of their produce is nearly the same, the value being reckoned at low market prices varying from 8*d.* to 2*d.* per pound, according to the size of their fruit and the time of its ripening; and again, the Vicomtesse is much before the others, showing that the berries were of good size compared with the others. Nos. 3 and 4 changed places, and likewise Nos. 7 and 8.

Elton will be seen to be decidedly the worst. The plants grew very large. They fruited the first year, probably only because their roots were shortened by transplanting. I think such sorts as Elton and Keen's Seedling would thrive on a light soil.

Here I have a different soil from that previously mentioned—a fertile medium loam, and not having been here long enough to

test the varieties myself, have to go by the experience of others, being indebted to Mr. J. Groom, late head gardener at Linton Park Gardens. This summer I planted twenty-four of the best varieties for comparison, and in time hope to state the result. I am planting 58,000 for market all of one variety—Sir J. Paxton. I would have planted a large proportion of the Vicomtesse, but could not obtain the plants in quantity, as it is now superseded by Sir J. Paxton on the soil—light, I believe—from which I am getting my runners. This shows which is considered the best variety in certain districts by those who earn their living by them. At the same time I do not suppose it has been tried against some of the newer and earlier varieties which have been grown in gardens.

All those of the above 58,000 we have as yet put in have been planted in a cut made by the spade, instead of a hole made by a dibber as has been recommended in the Journal for Cabbages and their tribe. We previously dipped them in liquid manure to sustain them until new rootlets were produced; and although we cannot plant them in such large quantities in the same manner as they could be planted in a garden, those planted in October and later have taken well, the large leaves not having died off, and new ones having made their appearance. In fact they seem as good, or better, than some varieties obtained from a nursery in July for my garden, planted in the same manner, but without the liquid manure, and which had to be watered afterwards on account of the dry weather. I have planted a few plants of twenty-four of the best varieties this summer, so I hope to be able to see for myself which I think best on this soil, and to state the results.—W. KRUSE.

BOUGAINVILLEA GLABRA.

THE above superb flowering plant is well worthy of a place in either large or small establishments. For growing in a pot as an exhibition plant, against a wall or up to the roof of either a stove or greenhouse, it has few equals. It is one of those accommodating plants that may be had in flower at almost any time of the year with those who know how to retard and forward it. When we take into consideration its accommodating character in every respect, the profusion of its somewhat uncommon-coloured flowers, their lasting properties and suitability for associating with other cut flowers, it is surprising that it is not more largely grown. It is of very easy cultivation; anyone who possesses a house with sufficient heating power to keep out frost may grow and flower it successfully.

It is not very particular about the soil it grows in. However, when grown in a pot it should have some good compost with an admixture of broken bones. When in a healthy growing state it should be liberally supplied with water, and when the pot is full of roots occasional supplies of weak liquid manure are very beneficial; as a stimulant I find diluted cow urine excellent. With those who have a stove temperature at command it may be kept growing and in flower almost continually. When, however, it is grown in a cool house it is deciduous and should be treated accordingly. Here, it is growing up the roof of such a house, and commences flowering about the middle of July, and continues doing so until October. In January it is pruned like a Vine on the short-spur system, and the growths untied and rearranged on the trellis again about 18 inches apart. It is not very troublesome as regards insects; green fly appears to be the only one to trouble it, and this can be easily kept down by fumigating with tobacco paper occasionally.—J. RICHARDSON, *Calverton Hall.*

SPRING v. AUTUMN MANURING.

It is an important question to cultivators whether manure for spring crops is best applied in autumn, winter, or spring, and as there appears to be much haphazard work in these applications a discussion of the matter may prove serviceable. For Potatoes especially it is often recommended to apply the manure in autumn, so that it may not be too fresh and rank at the time the sets are planted; and, again, it is frequently recommended to wheel manure on any ground which requires it during frosty weather, so that the ground itself may not be injured by trampling on it. Now in the matter of Potatoes I have no doubt it is a bad plan to place large quantities of rank manure close to the sets. Especially is this the case with some varieties which do not make a great amount of haulm. The old Ashleaf, for instance—(or, as I am told it ought to be called, the old Walnut-leaf, and certainly its leaf is more like that of the Walnut than the Ash, it being roundish at its extremity instead of pointed, as is the case with Rivers', Veitch's, and Myatt's Ashleaf)—becomes black and hollow in the middle if the soil in which it grows is a little too strong.

On the other hand, the Scotch Champion on my soil appears capable of taking up as much manure as a crop of Cabbages, and is invariably of the best possible quality, appearances in an uncooked state alone excepted, although I frequently see it black or hollow in the centre and spotted throughout when grown on light soils. Let me parenthetically advise anyone who has a piece of ground too heavy to grow other varieties of Potatoes to try Champions there, planting them at least 30 by 15 inches apart, and he may perhaps secure a heavy crop of good Potatoes and improve his land at the same time. Couch grass and other troublesome weeds are no drawback to this. If the soil is well pulverised and the Potatoes get a fair start they will take care the weeds are no more trouble. It is a capital cleansing crop for bringing neglected corners into cultivation.

It is remarkable this season that in this neighbourhood all the testimony I receive is in favour of the quality of the Champion as compared with other varieties, and many people regret they did not plant more of it. Now, although I shall continue to grow Champions for my main crop, having proved their suitability to my soil and to the palates of my employers, I do not advise them to be grown largely on light soils, as I attribute it entirely to the cold wet season we have had that their quality from light soils now is superior to that of other varieties. The same results were obtained after the still colder and wetter summer of 1879. It is to be hoped we shall not always have summers which are cold and wet, and when good seasons do come the Champion on soils which are dry or poor will not be of good quality.

But to the manure question. Is it not possible to apply it in spring in such a condition and in such a manner that it may not be too rank? I should say that when a manure is too rank for a given crop it is either because it has been applied in too large a quantity, or that its particles have not been sufficiently divided. A piece of rank manure as large as a man's fist is too large to place against a Potato set, and does more harm than good, but if powdered and distributed through a cubic foot of soil it might prove beneficial. I will return to this part of the subject further on; but first let me suggest some of the disadvantages likely to follow an autumn or winter application.

In the case of light soils much of the ammonia is lost during winter; and if this is the case, as there is seldom any difficulty about the cultivation of this class of soils in spring, it is certainly more economical to defer the application. In heavy soils perhaps there is not much loss of ammonia, but the addition of manure to them certainly makes them more retentive of water and a better harbour for slugs and worms, the cultivation being consequently delayed, and the crops run greater risks of damage. The plan of wheeling manure on the ground and leaving it in heaps is greatly to be condemned in a garden, as it makes it patchy and prevents a regular-looking crop being grown for years; while the other plan of spreading the manure over the surface and leaving it there must allow some of its valuable constituents to evaporate, and if the ground is heavy it will have the effect of keeping it wet, preventing aération and the action of frost.

Winter-digging on heavy ground is also a great mistake, but I cannot enter into that part of the subject now; and the next question is, If the manure is not to be applied in autumn or winter, how can it be most economically preserved and applied? This I will leave for another paper.—WM. TAYLOR.

[P.S.—Mr. Taylor sends the following supplementary note, written after receiving the *Journal* last week:—"Please state that my paper on manuring was in your hands before that from 'SINGLE-HANDED' appeared. I am delighted to see 'SINGLE-HANDED' coming out strongly again, and hope he is in a fair way for complete recovery. His article so well expresses the views I hold that I had to look at it twice before I could be sure I had not written it myself."]

LAWNS IN WINTER.

A GOOD lawn is attractive at all seasons, but more especially in winter, as then the surroundings are seldom so cheerful or attractive as in summer. Many parts which might be passed unnoticed then become conspicuous now, and good order should be the leading feature. It is now too late to try to improve the grass on lawns, and all that can be done is to keep them in as fine condition as they were in summer.

To sweep or walk much on grass when it is very wet will soon disfigure it. Some think they can clean the grass when the weather is too wet for working in the kitchen garden, but those who follow this plan will never have enjoyable lawns in winter, as much sweeping under those conditions destroys the close-grown velvety texture of the turf, and gives it a muddy unsightly appearance which it will retain until fresh growth commences

next spring. My advice in wet weather is, "Keep off the grass." When the surface is dry sweeping can be done quickly and effectively; then if the roller is run over the grass, the lawns in winter will be almost as beautiful and enjoyable as they were when at their best in summer.—J. MUIR.

RELATIVE to LABURNUMS AND CATTLE Mr. James Stott, nursery and seedsman, Alnwick, writes:—"I have had a field over twenty years with a row of Laburnum trees in it, which seed abundantly. Cows, horses, goats, and sheep are pastured in it, and have free access to the trees for shade. I have never seen any of the cattle eat them. The seed generally hangs on the trees till the young leaves appear."

— MR. W. WELLS, Redhill, Surrey, sends us flowers of two good late WHITE CHRYSANTHEMUMS, which he finds valuable at this time of year. One is named Miss Marchaux, an incurved bloom of moderate size but good substance, and pure white. The other is unnamed—an open bloom of a semi-reflexed character, full, neat, and of a clear pure white, very free, and extremely useful for cutting.

— RELATIVE to the COLOURS OF FLOWERS, "C. M." writes:—"I was much astonished to read in the *Journal of Horticulture* a statement of De Candolle's that 'blue and yellow being the two primitive colours of flowers, and always exclusive of each other, no blue flower ever changes to yellow, nor yellow to blue'—(*Journ. of Hort.*, p. 315, April 20th, 1882). What does the author of the article think about the Pansy (*Viola tricolor*), where you will find varieties of bright blue and bright yellow colours? Of *Hyacinthus orientalis* we see the same phenomenon. We very often find both colours in the same flower—for instance, *Torenia Fournieri*, some varieties of *Iris*, and in several varieties of Pansies, &c."

— RELATIVE to FRUITS and LOCALITIES an experienced gardener observes, and many will agree with him:—"I do wish writers in the *Journal* would at least name the county they write from when recommending fruits. Varieties of Apples and Pears which may be good with the writer, but perhaps not even be suitable if grown in another county. Something more is wanted than the bare recommendation. The time a variety blossoms is in my opinion of the greatest importance, and this information would give readers of this paper an idea if the same variety would be suitable for the locality in which they reside. If those who give us the benefit of their practice would give the information suggested and state the character of the soil their remarks would be of greater practical value."

— MR. C. PRINCEP of Walsall writes as follows on SILICA AND IRON FOR VINES:—"The correspondence having reference to the Vines at Knowsley Hall is of importance to all those connected with Grape-growing. I should be glad to know more of their history, border formation, and how supplied, beyond the information already given. Acting upon this, a portion of a vigorous and well-matured cane was dropped into the crucible, and the ash obtained (a portion of which I now forward), which in its fibrous state afforded unmistakable proof of the presence of iron. I think 'VITIS' has lost sight of that which is most important, the needful for their successful culture—viz., both silica and iron."

— "WHERE choice white flowers are in demand during the winter," writes a correspondent, "*JASMINUM GRACILLIMUM* will be found an invaluable acquisition. It is now to be bought at a comparatively cheap rate, and should, and indeed is, rapidly

becoming popular. It requires less heat than Gardenias, grows freely, and produces trusses of beautiful pure white and highly scented flowers at the points of the gracefully drooping branches, and each vigorous branch will produce more bloom at nearly every leaf-axil. I find cuttings strike slowly but surely in an ordinary moderately heated close propagating frame, and the stock will be increased as rapidly as possible."

— MR. F. W. BURBIDGE writes—"I am glad you propose an ELECTION OF CHRYSANTHEMUMS, in which I shall be pleased to join. The truth is, as in Roscs, we have far too many kinds too nearly alike. Will anyone say why we so seldom see old Crimson Velvet now-a-days, or if the new King of Crimson is its new form? Sœur Melanie I call a small Elaine; its white is pure. White Trevenna is not so white, shows a yellow eye, and is otherwise inferior. I had this year a seedling perfectly single, like a single Pyrethrum, and am very proud of it. Some day a single-flowered race will be valued. Of all reflexed vars. Progne is here the favourite, rich violet-purple, scented like Violets and Mignonette mixed. Ethel is fine now after Elaine, but its white is not so pure. In reflexed flowers the bright face of the florets is shown, and so they will always lead in colour. Incurved flowers show the backs of the florets only, and so are paler."

— THE following notes upon the LONDON NURSERIES AT CHRISTMAS briefly indicate the chief features at the dullest season of the year, and prove the value of Orchids for winter decoration, as in most of them these are by far the most notable amongst flowering plants. The great demands upon our space this week will not admit more than the briefest reference to them, and we must reserve detailed reports until another issue.

— IN Mr. B. S. Williams' rich collection of ORCHIDS AT UPPER HOLLOWAY, notwithstanding the recent fogs which prove so injurious to the plants, there is now a display of great interest and beauty for December, and the condition of the plants with the buds showing gives abundant promise of a still finer effect in a few weeks' time. Odontoglossums as usual at this time of year are well to the fore, some superb varieties of *O. Alexandræ* being very notable; some are pure white, and others heavily spotted and blotched, while all the best flowers are distinguished by their good form. *O. Pescatorei* and *O. gloriosum* are also good; *O. Halli*, *O. hebraicum*, and many others showing numbers of spikes. Cypripediums are attractive; the useful *C. insignis* being represented by several magnificent specimens. The varieties *Maulei*, *Chantinii*, and *punctatum violaceum* are flowering well, and a good opportunity is afforded for comparing them with each other. The two latter are precisely alike, and distinguished from *Maulei* by their darker lips and petals, and their much broader leaves—two well-marked characters. The lovely crimson-hued Cypripedium *Warneri* is in good condition and deserves a place amongst the best of the genus. *C. Roezli*, *C. Roezli alba*, *C. Harrisianum*, *C. villosum*, *C. Boxalli*, *C. Sedeni*, and many other well-known favourites contribute considerably to the beauty of the collection. *Lælia anceps* with its beautiful variety *Dawsoni*, *Lycaste Skinneri*, and *Maxillaria grandiflora* are flowering well, and the grand Cattleyas are showing abundance of sheaths.

— ONE other Orchid in the same nursery is particularly noteworthy—namely, *CÆLOGYNE BARBATA*, as it has been considered by some difficult to flower, though this does not appear to be the case at Holloway. Several plants there have three to five spikes of flowers each, and if the brownish lip is a disadvantage the plant is far from being unattractive when in such good condition. It is found that it succeeds best under cool treatment until the flowers are showing, when it should be removed to a warmer house to induce them to open, as otherwise they are liable to damp off.

— THE value of COOL-HOUSE ORCHIDS is admirably shown in Mr. W. Bull's nursery at Chelsea, and in one house alone there is now a display of Odontoglossums such as can scarcely be rivalled at this time of year. There are upwards of 140 spikes, the flowers on a large proportion of which are expanded, and the varieties are extraordinarily fine. *Odontoglossum crispum* is magnificently represented, and one of the varieties is the most handsome we have seen, although good varieties of this useful Orchid are now so plentiful. This has flowers of exquisite form $4\frac{1}{2}$ inches in diameter, the petals and sepals broad and beautifully fringed, white most delicately suffused with rich rose. Another handsome variety, named *roseum*, has smaller flowers, but is perfect in form and of a warm rose tint. *O. Pescatorei* is equally good, and one of the varieties deserves special notice, though all are fine. In this the flowers are rounded, pure white, with two dark purple spots at the base of the lip, which render the variety one of the most striking and handsome in cultivation. *O. odoratum*, *O. Rossi*, *O. baphicanthum*, *O. Cervantesi*, and many others are similarly fine.

— IN other houses are multitudes of vigorous Orchids, Cattleyas by thousands as healthy and promising as it is possible for them to be, *Oncidiums*, *Lælias*, *Cypripediums*, and scores of others; but perhaps there is nothing more remarkable than a grand lot of *ODONTOGLOSSUM VEXILLARIUM*—not in flower, of course, but in splendid condition, growing literally like weeds, and giving promise of a superb display next year.

— MESSRS. J. VEITCH & SONS have two great features in their Chelsea nursery—namely, ORCHIDS AND NEPENTHES, and at all seasons something of interest will be found if only those two of the multitudinous departments be visited. The Orchids claim first attention, and as usual the display well maintains the credit of the firm. The vast stock of Odontoglossums include all the best varieties obtainable, such as *O. Alexandræ*, *O. Andersonianum*, *O. blandum*, *O. Wilckeanum*, *O. tripudians*, *O. Rossi*, *O. nævium*, *O. maculatum*, and *O. deltoglossum*, being in strong force and bearing abundance of flowers. Cypripediums are admirably represented, not the least noteworthy being the favourite *C. Sedeni*, while *C. euryandrum* and *C. calurum* deserve prominent notice. A very handsome Cattleya—viz., *C. Dodgsoni*, is also in flower, the blooms being of great size; the sepals and petals large, blush white, and the lip tipped with rich rosy crimson—in fact it is one of the best of a handsome genus. *Maxillaria nigrescens* is a curiosity, and beautiful in contrast with the lighter-coloured forms, such as *M. grandiflora*. The sepals and petals are narrow and of an extremely dark rich reddish brown hue. *Phajus irroratus purpuratus* is a distinct variety with a rosy purple lip and white sepals and petals—a pretty contrast. The yellow *Oncidium cheiroporum* is in fine condition. *Lælia anceps* and *acuminata*, with *Angræcum sesquipedale* and *A. Chailluanum*, also attracting notice, the former by their rich crimson flowers, and the latter by their white wax-like blooms.

— IN the NEPENTHES HOUSE there is quite a forest of pitchers, probably some thousands of the most varied dimensions, some of sufficient capacity to hold a pint of water. The highly coloured *N. madagascariensis* and *N. Mastersiana*, with *N. Rafflesiana*, *N. Hookeriana*, the very distinct *N. Veitchii*, and the large *N. bicalcarata* and innumerable others, are in the best possible condition, and well indicate the value of such plants in a decorative point of view when judiciously treated.

— A GRAND variety of *ANTHURIUM ANDREANUM* is observable in one of the houses at the above nursery, the brilliant scarlet spathes being nearly 7 inches long by about 5 inches in breadth, and produced very freely. The superb *A. Wallichii* and *A. Veitchii*

are also in grand condition in the same house, the leaves of great size, and the former finely coloured.

— MESSRS. JAMES CARTER & CO. have now a good display of PRIMULAS AT PERRY HILL, but they are not yet at their best, and in the course of a few weeks will doubtless improve considerably. However, the merits of these carefully selected strains can even now be readily seen. Much attention is paid to these plants at Perry Hill, and, as a result, improvements are being annually effected, the colours being varied and deepened, the form of the flowers perfected, and the habit rendered more compact. Very notable amongst the most recent forms obtained is one with remarkably rich rose-coloured flowers, the deepest shade that we have seen. A handsome Fern-leaved white variety has also been selected, of extremely sturdy habit, the flowers large, beautifully fringed, and pure white, with a dark well-defined eye. The light rose and crimson, with the ordinary white varieties, are all meritorious in a high degree. The celebrated "blue" Primula Holborn Gem has its colour well developed, while a still further improvement has been effected in it, a form with much darker flowers having been selected. It is quite evident that we shall soon have a strain of really blue Primulas, as still greater advances may be expected.

— MESSRS. H. CANNELL & SONS' Swanley Nursery as usual contains a number of attractions, but specially noteworthy just now are the PRIMULAS, ZONAL PELARGONIUMS, AND SALVIAS, which occupy several large houses, and present a brilliancy that is most welcome at this season. Of the first named the noted varieties Swanley Red, Swanley Purple, and Swanley White constitute the bulk of the stock, but many others of the best strains are also grown, together with new and striking selections. The Zonal Pelargoniums both single and double are magnificent, and the varieties are so numerous, each possessing some special merits, that it is difficult to make a selection. However, some of the most effective are the following:—Singles: W. B. Miller, deep scarlet; Eureka, white; Eurydice, purple-pink, white centre; Guinea, brilliant scarlet; Dr. Orton, very dark scarlet; Kate Farmer, bright salmon; Constance, pale pink; and K. Greenaway, rose-pink, white centre. Doubles: General Campinon, dark scarlet; Lord Mayor, bright pink; Gambetta, rich scarlet; La Quintinie, white; and Henri Cannell, purplish crimson—with many others equally handsome. Of the Salvias the brilliant blue S. Pitcheri, the scarlet S. splendens Bruanti, the violet-mauve and white S. leucantha, the purple S. Betheli, and the scarlet and white S. Mons. Issanehou have for months past maintained a superb display.

— IN the outside borders at the above nursery CARTER'S PERPETUAL BLUE VIOLA is proving the appropriateness of its title by flowering most abundantly. This is said to be the result of a cross between Viola pedata and Viola Admiration, and has lavender-blue flowers of good size, possessing a slight but most agreeable fragrance. The latter quality, combined with its free and constant flowering habit, renders it a most useful variety, and one which will become a general favourite. In pots under glass the flowers come much larger and are extremely valuable for cutting.

— ONE of the finest and most interesting displays of Primulas perhaps ever produced may now be seen in the trial grounds of MESSRS. SUTTON & SONS at Reading. It is fine because of the distinct and superior strains, and the splendid culture that is represented—interesting because of the extraordinary character of many varieties that have been produced by crossing, not a few of which are grotesque in habit and colour, while others are strikingly beautiful. Ruby King, which occupies the whole of one side of a house, is a rich glowing mass of colour such as is seldom seen, the trusses being dense, bold, and brilliant. Perhaps their

appearance is the more striking by the contrasting effect of a mass of the charming white variety Pearl that occupies the other side of the structure—a perfect sheet of beautiful flowers. Reference to some of the newer varieties must be postponed, but the doubles, raised from seed, demand prompt mention. In form, richness, and chasteness of colours they are alike noticeable, and they, with the Cyclamens, which are of the very first order of merit both as to culture and condition, are faithfully represented in the new catalogue now being issued. Altogether the display is most meritorious—quite a museum of Primulas—and the firm deserve high commendation for the results that have been achieved.

— WE regret to learn that MR. WILLIAM HINDS recently died, after a very short illness, at the early age of thirty-eight. Mr. Hinds has held the position of head gardener at Roby Hall, Otterspool, Liverpool, and Canford Manor, Dorset, and he had been permanently engaged on the staff of the *Gardeners' Chronicle* during the past year. On leaving Liverpool he was presented with a gold watch as a token of the esteem in which he was held, and during his residence in the south his urbanity of manner and his assiduity in the fulfilment of his duties gained him the respect of many friends.

NOTES ON GRAPES.

THE various opinions expressed upon Grapes in your columns are undoubtedly very interesting, and quite necessary for the peculiarities of the different varieties being fully understood. A correspondent on page 469 has contributed an useful article on this subject, and I will endeavour to give your readers the benefit of my experience with the varieties there discussed.

Your correspondent begins with Madresfield Court. It is quite true, as he says, that the original recommendation of this being a grand late Grape was very misleading. In more than one establishment I know a whole house was planted with this variety for a late supply which ended in disappointment, and after ten or twelve years' cultivation it is found the most suitable place for it is the early vinery. It is very gratifying to find out the good qualities of this Grape. I have often seen Madresfield Court indifferently grown, and it has not been altogether satisfactory here, but after observing the bunches exhibited by Mr. Roberts of Gunnersbury at the Alexandra Palace two years ago, and the following year at the International at Manchester, gave me fresh courage; and with another trial I hope to succeed better. I feel sure if Mr. Roberts would detail his practice in producing such splendid examples as he exhibits, and how he prevents the berries cracking, he would confer a benefit on more growers of Madresfield Court than myself. Like many more I cannot afford a house exclusively for its cultivation, but have it planted in an inside border of our early house.

Duke of Buccleuch I planted nine years ago, but it has not always given me satisfaction, although I have had the finest berries I have yet seen of this variety. Its great fault with me is cracking at the last swelling, which greatly disfigures it. My employer prefers this Grape to all others we cultivate. It is more satisfactory grafted on the Black Hamburgh, but I have never been able to keep the fruit in good condition more than three months after ripe. I should be glad if "NORTHERN," who on page 530 states he has seen the Duke in good condition six months, would give fuller details of the treatment and conditions under which the fruit kept so well.

The most remarkable bunches of this Grape I have yet seen were in the third-prize collection of six varieties of Grapes exhibited by Mr. Kirk at the International Show at Edinburgh in September last. These were simply grand, although perhaps smaller in the berry than usually seen. I heard several first-class Grape-growers say they did not know there was the length of bunch to be had in the Duke as shown by Mr. Kirk. It would appear from a report by "T. B.," in a contemporary, that Mr. Thomson finds something else requisite besides giving the variety a house to itself, and if the report be correct Mr. Thomson bores a hole through the shoots between the rod and bunch—rather an extreme measure. I have not yet tried the gimlet dodge, but have twisted a piece of wire tightly round the shoot below the bunch with good results, and prefer this mode to notching the lateral, as practised by some growers to prevent cracking of the berries. The Duke is well worth whatever extra care it requires

to grow it in a mixed house of early Grapes. Golden Champion I can say nothing about yet, as, although I have it planted in an inside border, I have not yet fruited it.

Mrs. Pince's Black Muscat.—I shall never forget my astonishment with regard to this Grape in 1868 when that excellent cultivator, Mr. Taylor of Longleat, then the foreman at Garston Vineyard, showed me a house which one Vine had filled and was bearing twenty-six or twenty-seven bunches splendidly coloured and finished, and the Vine but twelve or fourteen months old. I made a short report of this in the Journal, which was pretty well criticised; but nevertheless Mr. Taylor corroborated my statement if my memory serves me right. But notwithstanding all opposition Mrs. Pince is still in existence, and is well worthy of cultivation. Like some others it has its peculiarities, and its worst habit is in failing to colour well; yet in some places it is good. The best examples of Mrs. Pince I have seen were grown this autumn by Mr. Hollingworth at Wood Seat near Rochester, the residence of C. M. Campbell, Esq., and had they been in competition at Edinburgh I question very much if both the Veitch memorial medals would have gone to Hutton Hall. Mrs. Pince colours better if grown in a lower temperature than is usually accorded to this variety.

Mrs. Pearson I have planted, but it has not yet fruited with me. It has proved a bad grower; in fact, where all other Vines have made very good canes this is but very little larger than when first planted seventeen months ago. I have not yet seen it very good at other places, and should like to hear the opinion of others relative to this variety.

Golden Queen is very different to the above, and I consider this will prove one of our best late Grapes. It is a good grower, very fruitful, and requires no special treatment that I am aware of to have it in good condition; its only drawback is that, like Gros Colman, it takes longer to ripen than many other varieties. Mr. Wallis grows it on the extension system at Keele Hall, and the bunches excel in colour the best Muscats of Alexandria I have ever seen. Nowhere have I seen this Grape in such excellent condition as at Keele. Whether Mr. Wallis has it grafted I cannot say, but I consider it colours better on its own roots.

Duchess of Buccleuch I do not grow, nor do I consider the variety worthy of a place, as the smallness of the berries detracts from what other good qualities it might possess as regards flavour.

Tynningham Muscat I prefer to all other varieties of Muscat, being finer in bunch and berry with me than any of them, and quite equal in every other good quality.

Alnwick Seedling I have grown three years, but as yet not to my satisfaction, as but few of the berries swelled, the majority being like Black Currants. I should have discontinued growing it but for the information recently given in this Journal as to its requirements, but am giving it another trial, when I hope to succeed better.

Gros Colman is a truly noble Grape, but requires a high temperature to finish it well. The foliage of this Vine is the most tender of any variety I know, being so liable to scorch or curl. I find this Grape very much improved when grafted on the Muscat of Alexandria. I have had no difficulty in keeping Gros Colman in bottles of water, but it requires a rather higher temperature in the fruit-room than is requisite for other varieties when kept in the manner indicated.

Lady Downe's is undoubtedly our best late-keeping Grape. With me it does not scald until it commences colouring, and to counteract this we admit more air and afford less atmospheric moisture. White Lady Downe's I once grew, but its flavour was so inferior that I did not consider it worth cultivation, so cut it down and grafted Foster's Seedling upon it. This, I consider, one of our best Grapes, and considerably superior to Buckland Sweetwater for an early vinery. Certainly it has not so fine appearance, but its other good qualities compensate for this; moreover, it is good for table use, and keeps well up to Christmas.

West's St. Peter's.—This is good and worthy of more extended cultivation. It is a thin-skinned Grape, keeps well, colours well, bears well, and is one of the best Grapes in cultivation for a sick person. It was a great favourite with the late Mr. Alport when gardener at Doddington Park, and I do not recollect to have ever seen it better grown than by that good cultivator.

Black Alicante is a very useful late Grape, and with me keeps as well, or nearly so, as Lady Downe's. Gros Guillaume, incorrectly called Barbarossa, is another good late-keeping Grape, but requires growing on the extension system to secure the best results. With me the bunches require support, as I have often found them part in the footstalk and fall to the ground when suspended in bottles of water.

The Muscat Hamburg is the finest-flavoured black Grape, and if it was more amenable to ordinary cultivation would be a universal

favourite. If planted in a somewhat stiffer soil than is usually recommended for Vine borders an improvement will be perceived. This also applies to Duke of Buccleuch. There is another Grape I should like to hear what Grape-growers have to say respecting its good and bad qualities, and that is the Golden Hamburg.—CHAS. ROBERTS, *Highfield Hall Gardens, near Leek.*

LAPAGERIAS.

LAPAGERIAS are among the few plants which succeed well with abundant root space. The method to follow with a plant established in a small pot as received from a nurseryman is at once to remove it into one 8 or 9 inches in diameter, draining the pot well, and employing as compost turfy loam and peat, with nodules of lime rubbish freely intermixed. After a time growth will commence, and in due time the pot will become full of roots, when they must be shifted once more into a larger pot at least 4 inches wider than the one to be set aside. This shifting must be continued if the plant is to be kept growing in a pot, as the more abundant the roots the stronger and more numerous will be the shoots annually thrown up from the base of the plant. It may be stated, however, that a 13-inch pot will, with occasional rich surface-dressings supplemented by waterings with liquid manure, keep a plant in good condition for several years, but not so luxuriant as if more liberally treated as to root space. Returning to the first start of our typical plant, this growth must be carefully trained on a string under the roof of the structure in which the plant is growing. Year by year the same care must be taken with young shoots which may be produced. To prevent overcrowding the first spindly growths should be cut off close to the soil, and all along the future of the plant should be studied by allowing at least 6 inches between each main growth. The above is the only certain mode of obtaining large blooms and plenty of them. It may be noted here that this plant is not particular as to aspect. It does well full in the sun, in the shade, or under conditions between these two; plenty of root-room, head-room, and water apparently being the conditions most favourable to its healthy growth.

Though I have plants growing in pots under conditions as above recommended, at the same time I would recommend even more space at the roots than can be provided by pots, and, in fact, prefer planting out in beds more or less restricted in size to the room at command. The progress a plant makes after being planted out is really astonishing, and the number of flowers produced for at least six months of the year is very great indeed. The compost should be of an open nature. Plants I have had to do with, put out in a soil in which Camellias flourished, made no progress until a different kind of compost was employed.

I have a large specimen which was planted out in a bed specially made for it seven years ago, the compost used being the older roots of *Lastrea dilatata*. This year the blooms have declined considerably in size, but this I expect to overcome by a thick dressing of rich material and occasional manurial waterings. These old plants seem to be very prolific of seed pods, which to anyone wishful of increasing stock would be the most ready means of doing so. In the case of the white variety this would of course be a risky way of promoting increase, as the plants resulting from such seed would require to be flowered before being sure as to colour. I have an idea that there are two forms of variety of the white Lapageria—one smaller than the other, and not so strong in growth or so large in the foliage. Perhaps some of your correspondents or readers are able to say if this is so.—B.

LIBONIA PENRHOSIENSIS.

AMONGST the most useful plants for winter decoration Libonias play a very important part. They are easily grown, and well repay a little extra trouble bestowed upon them. Your correspondent "LEADENHAM" (page 552) speaks very highly of *L. grandiflora*, and gives some cultural remarks respecting it. *L. grandiflora* is a great favourite with most people, being extremely useful for conservatory and room decoration. If your correspondent has not already tried *L. penrhosiensis* let me recommend it to him and others desirous to possess another winter-flowering plant, and in my opinion far surpassing *L. floribunda*. *L. penrhosiensis* is quite distinct from the latter both in foliage and flowers. The foliage is much larger, and has a beautiful polished surface. The flowers also are much larger than *L. grandiflora* and more highly coloured; instead of the yellow being so prominent they have a bronzy hue. In addition to the above it is decidedly more floriferous. The treatment recommended by "LEADENHAM" for *L. floribunda* will apply to *L. penrhosiensis*, but I find an occasional supply of liquid manure or Clay's

fertiliser given about twice a week when the plants are showing flower to be very beneficial. With us our plants have been in flower since the beginning of November, and will be very attractive for some time yet.—W. K.

A SPECIMEN CHRYSANTHEMUM.

ALTHOUGH Chrysanthemum shows are visited by thousands of persons who become familiar with the wonderful examples of culture that are staged, yet, nevertheless, by far the larger proportion of our readers have not had an opportunity of seeing these brilliant autumn tournaments, and some of them, as we know, have a suspicion that the descriptions of the blooms and plants are sometimes a little exaggerated. A photograph, however, does not exaggerate, and the engraving shows a dwarf-trained plant, one of others equally good, in a group at the late Kingston Show. The engraving represents as truly as a figure can do one of the magnificent specimens exhibited by Mr. C. Beckett, gardener to

T. H. Bryant, Esq., Glencairn, Surbiton Hill, and we are pleased to add a few particulars of a group which reflected the highest credit on the exhibitor.

The three largest plants each measured 21 feet in circumference, and most of the other specimens 15 feet. When staged they presented one sheet of bloom 60 feet by 20 feet, filling the entire end of the hall. Mr. Bryant's gardener has obligingly furnished us with an outline of his treatment, which is as follows:—"I insert the cuttings in December, and as soon as rooted keep them growing freely, and without a moment's check, till they are finished, supplying them with stimulants as needed. They are stopped periodically until the middle of July, and are then permitted to form and develop their flowers. These directions are very general, but very much depends on the judgment of the cultivator and his devotion to his profession. To be successful with any plant it needs constant attention early and late, the slightest neglect being fatal to success. I would add that special care must be exercised to keep the plants free from the many pests that

Fig. 102.—SPECIMEN CHRYSANTHEMUM.

are ever ready to attack them. I am proud to say that Mr. Bryant received the commands of H.R.H. Duke of Albany, and that I had the honour of taking the three largest and two smaller plants to Claremont. The Duke and Duchess expressed themselves very much pleased at having had the opportunity of seeing them, saying "they had never seen finer."

We have only to add that both Mr. Bryant and his gardener have good reason to be proud of such specimens. The plant being "tilted" the pot is necessarily hidden.

We regret that we have not space this week for an excellent paper on Chrysanthemum culture which was read at a meeting of the Wimbledon Gardeners' Society, and by request of the members sent to us for publication. It will appear in an early issue. We are obliged also to defer the publication of notes in answer to "J. L." on page 556.

BORDERS FOR HARDY FRUIT TREES.

At the commencement of my previous notes on fruit borders (page 541), I proposed writing a second paper on the subject,

which I now offer. What I shall attempt to demonstrate is that we do not do justice to our hardy fruit trees; in fact, in the matter of borders we go as much to one extreme as we do in the opposite direction when we form excessively large borders for house-cultivated fruits.

It is true every walled-in kitchen garden is provided with so-called fruit borders, but in how many cases do the trees have anything like the full benefit of them? In reality the choicest fruits do not receive as fair treatment as ordinary orchard trees, owing in this case to the shape of the trees or other causes hindering the digging and heavy cropping the borders devoted to the wall-trained trees have constantly to undergo. To all appearances in most gardens the vegetables and not the fruit trees are of primary consideration. Neither are gardeners altogether to be blamed for this, as they are bound to produce continuous and heavy crops of vegetables and small fruits from a comparatively small space of ground. As a consequence not only are the borders immediately in front of the trees closely dug and cropped, but the space at the foot of the walls is also utilised; at the same time, if gardeners must persist in this close cropping, they can at

any rate avoid planting such gross-feeding and comparatively permanent crops as Violets, Strawberries, Parsley, and herbs generally on these borders. The former, especially when planted at the foot of the walls, are very injurious, as they impoverish the border to a great depth; and a herb border near the walls inevitably impoverishes the land, yet both cases are by no means rare.

Quick-growing crops, such as Potatoes, Cauliflowers, Kidney Beans, Turnips, and Lettuces, are not so objectionable, especially seeing how frequently the ground for early crops of these is favoured with regard to heavy dressings of manure. The manure is very beneficial to well-established fruit trees; but unfortunately the frequent diggings have the effect of driving the roots of the trees down into the subsoil, and this, it is almost needless to repeat, is quite in the wrong direction. Under the system at present pretty generally in vogue, and which I must admit to a certain extent unavoidably prevails here, we may look in vain for the valuable fibrous roots.

The roots of most trees, and more especially, I think, of Pears, require but little disturbance to induce a downward tendency, and if active steps are not taken to prevent the misfortune becoming intensified the decadence of the tree will soon be seen. Not only have the wall trees under my charge rooted down into the cold subsoil, but the pyramids are in the same plight. Fruit trees of any kind with several roots 2 inches in diameter deep down into clay, and with but few if any surface roots, are certain to produce crops of cracked worthless fruits. In our case I should say the Strawberries, Gooseberries, Violets, and Parsley I found planted about the trees were the primary cause of this deep-rooting. These have been cleared off as much as possible, and according as we are able these gross roots are severally shortened, the trees raised, much clay cleared out, fresh soil added, and all medium-sized roots brought nearer to the surface. There I hope to be able to keep them, and eventually be able to point to crops of fruit equally as fine as those grown on trees and in the gardens at Ashton Court, which were treated in a very similar manner by Mr. Austin, the well-known practical gardener in charge.

It is really a blunder to begrudge a good Apple, Pear, Plum, Peach, Nectarine, Cherry, or Apricot tree a few feet of border room, say half the square feet of wall or ground the tree covers. If we gave it a thought we should remember the crop of one tree is oftentimes worth more than all the vegetables obtained from a considerable length of border. Eight dozen fair-sized fruits from a fully grown tree of either Peaches or Pears is not a particularly heavy crop, yet these are or were worth to the proprietor this season at least 32s., and would find a ready market at 24s. We should have to market a considerable quantity of vegetables to realise that amount. I say, Give the roots of the trees fair play and mark the result.

That the sheltered wall borders prove extremely or rather comparatively profitable vegetable quarters must be admitted. But I am under the impression if other open sunny spots were as well managed they would produce vegetables quite as early and equal in quality. Where are the earliest vegetables in any quantity grown that are sent to the London markets? Certainly not in walled-in gardens, but in the open fields. The designers of the majority of kitchen gardens make a radical mistake by forming the wall borders much too narrow, and this materially affects the system of cropping. Instead of being 10 or 12 feet wide (they are often narrower) they should be 20 feet wide, and of this a width of 5 feet at the very least ought to be devoted exclusively to the fruit trees. Under such circumstances the roots would be encouraged to remain near the surface, where the freely formed fibres would revel in the liberal top-dressings of manure they ought to receive when the trees were in full bearing. These favourable conditions would result in better ripened growth, more frequent crops of fruit of the best quality, and much less necessity for frequent replantings in order to replace trees prematurely dead or dying.—W. IGGULDEN, *Marston*.

MUSHROOM-GROWING IN SPHAGNUM MOSS.

THERE are now in full bearing at "Broomfield," Sheffield (the residence of B. P. Broomhead, Esq.), several Mushroom beds, which for quantity and quality of the produce I have not before seen equalled, except in the case of Mr. J. Barter's outdoor beds, which were figured in the Journal of May 4th, this year, page 359. Mr. Walker, the able gardener at Broomfield, tells me that the material of which these beds are composed consists solely of sphagnum moss imported from Germany, where it has been artificially dried and afterwards compressed by hydraulic power into cakes or bales of about 1 cwt. each, and which are sold as a patented bedding material for horses, &c. Mr. Broomhead purchased a quantity for use in his stables, where its merits are appreciated, as it speedily

and readily absorbs all the drainage and ammonia, and keeps the stable free from all unpleasant smells. Thinking it would be a good material for Mushroom-growing, Mr. Walker made up some beds with it, which have succeeded beyond his expectations. He says he has never before had beds which have been so quick in coming into bearing or so lastingly productive. He commenced gathering Mushrooms in five weeks from the making-up of the beds, and when I saw them he had been gathering from them every day for five weeks, and the beds then were quite covered with fine Mushrooms, which are very thick and solid. He also showed me a box which by way of experiment he had filled with moss which had not been used in the stables, but which he had saturated with stable drainage from a tank where it is collected. This upon being made up into the box heated very strongly, so that he had to wait a number of days for the heat to subside before spawning, but when I first saw it the spawn had run through it and Mushrooms were appearing apparently as thickly and as freely as upon the other beds. On a subsequent examination there was no doubt the experiment was a great success, as the box was crowded with splendid Mushrooms.—W. K. W.

INSECTICIDES.

UNDER the above heading in a recent issue of the Journal I read with considerable interest the able contribution signed "HORTUS." I beg, however, to differ from him as to the application of sulphurous acid in the manner indicated. Brimstone I have detested in any form from childhood upwards, when it was used internally, externally, and threatened eternally; and, in my opinion to subject *Abutilons*, *Coleuses*, *Poinsettias*, and other choice softwooded plants to the influence of an atmosphere charged with sulphurous acid fumes for twelve hours means sudden death. Sulphurous acid contains 9.2 per cent. of gas in suspension, hence I caution experimenters to first sponge themselves with the acid (which will soon evaporate), and note the condition of their respiratory organs. This simple process will, I believe, be conducive to plant-longevity. As to Dalmatian powder, it is a most valuable insecticide; but, again, I differ from your correspondent "HORTUS" as to its application. Let us trace its origin and see wherein its energies exist as an insecticide. It is prepared by grinding to powder the dried and expanded florets of a composite plant which grows freely in the sandy plains of Persia and Asia Minor, possessing when freshly prepared a pungent, aromatic, characteristic odour, and herein lies its power. It acts more as a repellant than a poison, and should be used like snuff—dry.

I have grown the plant and find the flowers inert, not possessing the qualities for which the exotic ones are noticeable; and I find negative results from its use in solution as suggested by "HORTUS;" indeed, a more effective solution can be prepared from any of our indigenous composite plants, such as *Camomile* or *Tansy*.

But if may be asked what practical suggestions I have to offer on the subject of insecticides; and although I am not entitled to a blue ribbon I shall place first and foremost water, and to satisfy readers of a bucolic tendency we will occasionally have it hot—say 140° Fahr., for some plants. Next I place tobacco, which I have diligently employed ever since I escaped parental control. But my object in writing is more especially to draw the attention of practical men to the employment (as insecticides) of the juices of plants of an acrid or poisonous nature.

It is notorious that certain plants are injurious to insect life. Take, for instance, the common Elder (*Sambucus nigra*), the Foxglove (*Digitalis purpurea*), while the whole order *Ranunculaceæ*, inclusive of *Aconites*, *Crowfoots*, *Hellebori*, and *Delphiniums*, possess acrid properties fatal to insect existence. Why not utilise these remedies?

Take, again, the immunity from attack enjoyed by the Scotch Fir and all the Cedar tribe of forest trees. From these we obtain wood tar and turpentine, so fatal to insect life and so invaluable to the entomologist. Would not an infusion of the bark of the *Pinus palustris* (*P. australis*) aid us? The seeds of the *Delphinium Staphisagria* have been used for centuries in the form of decoction to destroy lice in cattle, also rats; and quaint old Gerarde states that they were some time used in apophlegmatisant gargles, so with this character it is needless for me to refer farther to the power of the *Stavesacre* seed beyond saying that it is cheap.

As to Mr. Speed's remedy for American blight, may I suggest to him the use of wood tar in preference to gas tar? My process is this for standard fruit trees: First slake a peck of lime with water to the consistence of cream, and whilst still hot add one pint of the brown oil of tar. This when mixed forms a tar soap or emulsion, which annihilates the American bug wherever employed. Colour with soot if you like.

Finally, I must strongly recommend the soluble fir-tree oil, together with the spray-diffuser, which enables the operator to direct a spray of the vapour in every cranny, and without injury to the most delicate plant life. The spray-producer is especially valuable, as it carries its insidious vapours where the syringe would be ineffective.—W. LITCHFIELD, *Coventry*.

PEAR PRINCE NAPOLEON.

As a late Pear the merits of this variety are not perhaps sufficiently known. It is of comparatively recent introduction, having been raised from the seed of *Passo Crasanne* in 1866. Mr. Haycock, Barham Court Gardens, the grower of the fruit now figured, writes to us relative to this Pear:—"My experience with Prince Napoleon is that it is a most excellent late Pear, and one worthy of attention. It does not succeed here on the Quince, but grows well on the Pear stock. It makes rather thin weak short-jointed wood, and forms fruiting spurs very freely. It also succeeds very well double-grafted. I find *Beurré Hardy* makes a good stock for it, but I much prefer the Pear stock. The fruit is rather small, and very much like *Passo Crasanne*, but, though not so large, is a little longer;

skin dark brown russet. In use during January and February, and has a sharp brisk flavour—a quality that many people like."

Our description of Prince Napoleon is as follows:—Fruit unovoid in its outline, roundish or Bergamot-shaped, somewhat knobbed at the stalk and the crown. Skin entirely covered with rough brown russet, so much so as to leave the ground colour exposed like yellow speckles. Eye large and open, with long erect segments set in a deep, uneven, and knobbed basin. Stalk very stout, 1 inch long, inserted in a deep uneven cavity. Flesh yellowish, buttery, melting, sweet, and juicy, with a very high balsamic flavour, which to some may be unpleasant. It is really a strong *Seekel* flavour. A very fine Pear in the end of February.

AZALEAS FOR FORCING.

A FEW notes on some varieties of Azaleas that have been proved by the writer may be acceptable to some of your readers.

Narcissiflora.—A general favourite, which is invaluable for early forcing. Though the individual flowers are not particularly fine, the large quantity of them compensates in a great measure for this slight defect. No collection can be considered complete without some of this variety.

Fig. 103.—PEAR PRINCE NAPOLEON.

A. Borsig.—A very fine white, a good forcer and neat habit; the individual flowers much finer than *Narcissiflora*.

Iveryana.—Another good white, but it hardly forces so well as the previous two. *Madame Camille von Langenove* is a beautiful variety, semi-double, white striped with red. It proved with me a fair forcer.

Baron de Vriere.—A fine large white with small pink stripe. The only objection I have to this is that it sometimes flowers unequally, half the plant being in full bloom, and the other half with the buds hardly swelled. This has often perplexed me.

Apollon.—This has a handsome large flower, white with slight rose stripe; it also proved a rather unequal flowerer.

Bernard Andreas alba.—This is a superb kind, and should be in every collection. The rose variety is equally fine.

Raphael.—White, double, and in addition sweet-scented; it did not prove a very equal flowerer.

Flag of Truce.—Another double white; very large flowers, forcing very well.

Souvenir de Prince Albert.—A very free-flowering semi-double, rose and white; should be in every list.

Sigismund Rueker.—One of the very best, rose and white, large-flowered, and very profuse; should have a place in every collection.

Baron Ossey.—A very good forcer, flowering very freely; flowers not very large, and of a brownish crimson.

Madame Vander Cruysen.—This is a grand variety, forcing admirably, and flowering very profusely. The flowers are large, of a beautiful rose colour.

Rachel von Vornhagan.—Another variety in a great measure resembling the last mentioned, of a rosy red, and a very free flowerer. I consider the last two very splendid varieties for making a display, and all who wish for that should grow a large proportion of them.

Roi d'Hollande.—Red; a good free-flowerer, individual flowers not particularly fine.

Punetulata.—Dwarf rosy red, flowering very freely, and invaluable as a dwarf decorative flowering plant.

Jean Verreaene.—A beautiful variety, red and white; flowers very large. This is admired by all who see it, being a striking object among many others that are not mean rivals.

Comtesse de Flandres.—Rosy, very free flowerer, and good forcer.

These are some of the varieties that have been tried by me, and I have endeavoured to speak of them exactly as I found them. The descriptions in catalogues, though not meant to be deceiving, are naturally rather glowing, and in some cases the objects of

much laudation in catalogues prove far below the standard of merit assigned to them. It would be much more satisfactory for all concerned if nothing but the very plainest truths were employed in descriptions of plants. Vendors would, in the long run, profit by only praising what they could positively declare were good. The rage for new varieties of plants of all kinds is tempting, no doubt, to those who have to supply the demands of the public, and leads to the varieties being over-praised simply because they have some little novelty about them. Varieties that have proved good should not be placed aside for others whose chief recommendation is that they are "new."—A MARKET GROWER.

A BOUQUET DISSECTED.

To whom are we indebted for setting the latest fashion in ball-room bouquets? I make the inquiry, not because I am anxious to perpetuate the inventor's fame, but because I am so thoroughly disgusted with the style as to wish to hold them up to opprobrium. Call me uncharitable if you will, but when we see such monstrous bouquets as are now being borne in ball-rooms, who can help pitying gardeners who, at this dull season of the year especially, have to imitate a fashion initiated doubtless by those interested in the sale of as many choice flowers as possible? These "sweet things in the way of bouquets" average 45 inches in circumference, some in fact being 18 inches in diameter—this, be it remembered, being all flowers, as Fern fronds and papers are scarcely seen. In some instances nothing but Violets are employed, in others Violets in equal proportions with the choicest white flowers, while many white Camellias, Eucharises, Roman Hyacinths, and Gardenias are freely used.

The bouquet I contrived to secure when its owner had had enough of it was composed exclusively of Gardenias (thirty-six in all), Maidenhair Fern, much extremely dirty moss, wire in great quantities, the holder and twelve strong brass pins varying in length from 3 to 4 inches. Very little growth was cut with the blooms, but each, unless bunched as they sometimes were, had three or four wire stems bound together, the longest two only passing into the handle. They were arranged almost flatly, and a few blooms were bent over the side which was to be carried uppermost. The Gardenias were really bedded among the moss, this serving to keep them in position, and being freely damped also to preserve freshness. The bouquet was first placed in a collar of stiff brown paper, then in a wider strip of the same material covered with white satin and fringed with two bands of lace, the large pins securing these in position. The bundle of wires serving for a handle were then surrounded with soft tissue paper in such a manner as to fit tightly in a neat bouquet-holder, then more pins, and this too highly scented combination of the sublime and ridiculous was completed.

The only consolation in connection with the subject I can find at present is the thought, how wearied the proud bearers of these monstrosities must have felt long before the ball was at an end. At any rate this must have been the case if those as large or larger than my specimen, as this weighed in its entirety exactly 24 ozs.; and I should say the strongest of us would not care to carry such a weight near our noses for more than a hour at a time. Indeed they had to be left on the seats when a dance commenced, and for this reason alone I should say they will not long remain fashionable.—W. I. M.

GOOSEBERRY-GROWING FOR MARKET.

THE annual statement of the weights of the heaviest prize-winning Gooseberries is certainly very tempting, and I for one must plead guilty to having weakly yielded to an ambitious wish to see what I could do in that direction by planting the whole of them and many others. An answer to a correspondent on page 558 shows that would-be growers for market are also tempted by the "monsters." Nor can it be wondered at, for upon the face of it Gooseberry culture appears most simple, and one might reason that if certain sorts grow to so large a size under peculiar care and skill, surely they will be considerably above the common size under ordinary methods of culture. But in reality there is as much difference in Gooseberries as there is among Pears and Apples. Weakly drooping spreading growth, shyness in fruiting, poor insipid flavour, and premature fruit-shedding are all to be found among them. Warrington is undoubtedly the best of all, either for green or ripe fruit. In the green state it is ready for picking early, it ripens slowly, hangs long upon the bush in prime condition when ripe, and ranks in general estimation among our best late sorts either for jam or eating. It has been so useful to me for so many years that I consider it the best for any purpose.

Its habit of growth is excellent, and it is so sturdy and robust as to flourish in our poor thin soil where many other sorts planted near it have perished after a brief existence of a few years. In the valuable "Hints on Vegetable and Fruit Farming," published in the last number of the Journal of the Royal Agricultural Society, Mr. Whithead speaks of Warrington in unqualified terms of praise. That gentleman lives in the very heart of the Kentish fruit-growing district, and his opinion is most valuable. He recommends Whitesmith and Early Sulphur for picking green, and has a good word also for Lancashire Lad, Red Rifleman, Golden Drop, and Monarch. Of prize sorts he considers Roaring Lion, Leveller, Leader, Napoleon, and Careless good, but he only mentions them as garden sorts, profitable if grown with special care.

A brief extract of quantities and prices may usefully be given— "Directly the berries are large enough the bushes are picked over, and the largest are sent to market, when they make 3d. to 3½d. per lb., or even more at the beginning of the season, but the price soon falls to 2d. and 1½d. per lb., and even to 1¼d. per lb. An average crop from Gooseberry bushes in full vigour would be between 6500 and 7500 lbs. per acre, and the price between 1½d. and 2d. per lb. Occasionally, when the soil is well suited for these bushes, very large profits and quick returns are made. The expense would depend upon the amount of the crop in respect of picking, carriage, and salesmen's charges. The expenses in connection with the cultivation alone would range from £10 to £12 per acre, and all other charges in the case of an average crop would amount to £7 or £8 per acre." The bushes are 6 feet apart, or 1210 to an acre in some cases, and 5½ feet, or 1440 to an acre, in others. The ground is manured and dug in winter, and hoed once or twice in summer.

These interesting facts of what is done in Kent are important, and are safe data for the guidance of beginners in other parts of the country. The only question to which they give rise is, Could not Gooseberries be cultivated more cheaply? I have two rows of Warrington, which were planted twelve years ago, now in full vigour, and always bearing a full crop of fine fruit, among which there has been no digging for full half that time, probably longer. An annual surface dressing of manure is given in winter, and hoeing if weeds appear in summer, but digging would certainly do more harm than good, for the soil near the surface is crowded with roots. Nobody digs a Vine border for the same reason; why, therefore, should we dig a fruit plantation, provided the land is drained and rendered pervious to the quick passage of rain water before planting? —EDWARD LUCKHURST.

KITCHEN GARDEN.

Forcing Department.—It will be necessary to keep fermenting materials in a state of preparation for use in this department; and as a larger bulk than usual is generally required for the next two months, it will be found desirable to mix two parts tree leaves with one of stable manure, which will considerably increase the bulk, and the heat, although not so strong as in stable manure alone, will be more regular and durable. The Radishes sown last month in heat will be coming on for use, and should have free ventilation, or they will be liable to damp off; similar remarks applying to those sown later and Carrots, which must not be kept close, or they will become drawn. Only sufficient heat by linings should be afforded as to keep them gently moving. Frames of Potatoes must be freely ventilated on all favourable occasions, applying linings to the sides of the bed alike for safety from frost and to promote a steady growth. Fresh beds should be made and planted with sets previously started in heat as pits or frames become available. Maintain the supply of Asparagus by the introduction of fresh roots at intervals according to the demand, similar remarks applying to Seakale, Rhubarb, and Chicory, the last three forcing admirably in a Mushroom house or other place having a temperature of 55° to 60°. Mustard and Cress must be sown at intervals so as to maintain a successional supply. French Beans will likewise require to be sown at fortnightly intervals to maintain a regular supply, ventilating those advancing freely when the weather

admits, keeping them well supplied with tepid liquid manure, and earthing up those sufficiently advanced.

The early stores of Lettuces and Endive must be frequently examined, removing all decayed matter. During favourable weather ventilate freely, but during severe weather cover them securely, and keep them in the dark, or do not uncover so long as the severe weather continues. Cauliflowers and young Lettuce plants in frames or handlights must be frequently examined for the removal of decayed foliage, dressing the surface, and stirring the soil between the plants.

FRUIT HOUSES.

Peaches and Nectarines.—In the earliest house the flowering has already commenced. This degree of forwardness may not yet be attained by trees which have not been forced early in former years, and in this case it is not advisable to push them hard, but let the same conditions prevail as were indicated in our last calendar. When the flowers begin to expand maintain 50° at night, falling a few degrees when the weather is severe. Raise the temperature early in the day to 55° , and keep it between that and 60° during the day, the latter not being exceeded by fire heat alone; and this should be accompanied by a circulation of the air in the house, opening the top ventilators a little at 55° ; and as the temperature advances gradually increase the ventilation, having a free circulation top and bottom at 65° , closing for the day at 60° . Damp the surfaces in the house twice a day, ceasing to syringe the trees after the flowers expand, and leave a little air on at the top of the house constantly to prevent the atmosphere becoming stagnant. Dust the flowers with a camel's-hair brush when the day is fine and the house well ventilated to insure fertilisation. As the setting period during the dullest time of year is the most important throughout the whole process, the greatest care should be given to the requirements at that season.

The house containing trees intended to afford ripe fruit in June of such varieties as Royal George and Grosse Mignonne Peaches, Lord Napier and Elruge Nectarines, should now be closed. The inside border should have a thorough soaking with water at a temperature of 75° , and the outside border protected with a good thickness of dry leaves or fern. Syringe the trees and available surfaces in the morning and in the afternoon, so as to have the trees fairly dry before night. Ventilate freely from and above 50° , at which close the house, and employ fire heat only to prevent the temperature falling much below 40° at night.

PLANT HOUSES.

Forcing House.—In order to keep pace with the increased demand for flowers which prevails in most establishments almost every house is required. Stoves are crammed to the injury of the permanent occupants; and though numbers can be brought into bloom there, they are not nearly so good for decorative purposes as those forwarded in a house where the forcing is more gradual. A light airy house with beds for holding fermenting materials for bottom heat is a great aid in very early forcing, and if it have a partition so as to allow of one lot of plants being brought forward to succeed the other, and so on, the succession will be maintained with regularity. For most hardy plants 50° to 55° at night and 60° to 65° by day will be a suitable temperature after being kept in a house for a fortnight or three weeks in a temperature of 40° to 45° at night and 50° to 55° by day. Forcing hardy plants is much accelerated by syringing them in the morning and afternoon of fine days. Shelves should be provided so that Hyacinths, Narcissus, and Tulips will be near to the glass.

It is hardly necessary to direct attention to the many very beautiful plants that by gentle forcing contribute to the supply of cut flowers and plants for general decorative purposes. Foremost come Lily of the Valley, early in the season requires bottom heat. Lilac is indispensable. *Deutzia gracilis* is very graceful and effective, but is being rivalled by *Staphylea colehica*. The old *Viburnum Opulus*, or Guelder Rose, and the lovely *Laburnum*, with *Wistaria sinensis*, are a trio too seldom seen forced. *Spiræa Thunbergii* may be mentioned as a very graceful white-flowering plant. Clematises such as Miss Bateman, Fair Rosamond, The Queen, Albert Victor, Mrs. S. Baker, Vesta, Stella, Lord Londesborough, and Sir Garnet Wolseley, are charming.

Then there are *Rhododendrons*, with large heads of flower from the purest white to glowing crimson. *Azalea pontica* of the richest yellow and sweetest fragrance, the Ghent varieties being very beautiful. The *Azalea mollis* vars. force easily and have large trusses, being also very floriferous and very effective for any purpose. The Double Plum (*Prunus sinensis alba flore pleno*) is also useful, and the chaste *Kalmia latifolia* is always admired. Sweet Briar is always appreciated for its perfume. *Hoteia japonica* is not only an elegant and graceful plant, but its large white feathery inflorescence is very effective, and *Dielytra spectabilis* is a very graceful plant and useful for vases.

THE ART OF BEE-KEEPING.—No. 5.

(Continued from page 535.)

THE DRONE.

THE drones are the males of the colony, of which the queen and workers are the females, and they seem to be almost useless except for the purpose of fertilisation. As already observed, this takes place while the queens are on the wing, and is of such potency that the queen is rendered fertile for life. The limited observations seem to indicate that the drone dies immediately after mating. We know for certain that he leaves a mark of fertilisation, which any bee-keeper may observe who watches his young queens returning from their wedding flight. As queens are only reared by colonies in a normal state during the summer, drones are only produced during that season, and are starved to death or driven forth to die at the close of the honey season. The appearance of drones at other times thus indicates some abnormal condition of things—viz., a queenless stock, or the presence of an unfertilised or decrepit queen or fertile worker.

According to the Dzierzon theory, which is generally held to be correct, drones follow the race of their mother without respect to the nature of her alliance. Thus an Italian queen mated with an English drone will always produce pure Italian drones, though she produces mixed workers. This fact must be borne in mind by all who attempt to improve the race of bees by the introduction of foreign blood. For average bee-keepers, however, whose great aim is honey, the only concern in regard to drones is how to limit their production so as to be certain of reaping their one advantage without at the same time creating a host of useless mouths, at a great expense to the colony. And just here we must cross the ideas of those who cry out for a purely natural system of bee-keeping. In a state of nature one could never expect to find even two colonies within a yard of each other, or a score of them within the limits of a small garden. Let us suppose we should find one in every square mile—quite a liberal allowance. To make certain of a young queen meeting a mate during her short and rapid flights of a few minutes at a time, we should expect a colony in such circumstances to produce a large number of drones, and so it does. But when we crowd a country with hives so that dozens or even hundreds are found within a square mile, we are under no necessity for increasing the number of drones in like proportion. If those of a single hive were sufficient in a state of nature to patrol the whole neighbourhood they may be regarded as nearly sufficient still. And further, the production of drones is at great expense to the colony—they are gross feeders both in the grub and perfect state, and they bring nothing in. Drone traps, therefore, do not meet the case; prevention rather than cure is wanted. This we effect by the liberal use of worker-comb foundation, using sheets so nearly filling the frames that at most only a few dozens of drone cells can be built round their edges. Absolute restriction of drone comb is not advisable, especially where supering is resorted to, as in that case the queen in the exercise of a natural impulse to produce drone eggs will most probably deposit those in the supers and thus spoil their combs. It is observable, besides, that there is a vivacity and industry about hives that have a fair proportion of drones buzzing and bustling about their doorways, which is often wanting in those having no drones. On the whole we consider that we meet the case sufficiently by having, say, 50 out of the 1000 inches of comb in a standard hive with drone cells; a number sufficient for the production of four hundred drones every twenty-four days, which is the time required for the hatching of perfect drones from the egg. And we so arrange the combs that the drone brood is confined to the outside ones. Where early drones are wanted for breeding purposes we can usually obtain them by

inserting a comb containing drone cells right in the centre of the brood nest. Under such management drone traps, or the cutting-out of drone comb, become quite unnecessary.

BEE PASTURAGE.

Next to the natural history of the honey bee there is no subject on which bee-keepers should be so well informed as the pasturage from which the bees are expected to store their honey. This necessarily varies with each locality, and therefore any calendar of operations, such as is given in most bee books, is necessarily to be taken only as a general guide to management, which must depend so largely on local conditions. We would thus urge on all bee-keepers to construct for themselves a calendar suited to their particular circumstances, having as its basis the results of previous observations on the comparative value of the different sources of honey and the dates at which they usually begin to yield.

In these islands there are three main sources from which bee-keepers expect any considerable surplus, and these follow each other with but a short interval. These are fruit blossoms in April and May, Clover in June and July, and Heather in August and September. The later-flowering fruit plants, such as Raspberries, often fill the interval before the Clover blooms, and in many loca-

Fig. 104.—Stewarton Hive.

lities the Limes fill the interval before the Heather. Now, the management necessary to secure a surplus of honey in any locality must largely depend on which of these three great sources is the principal one in that locality. Dwellers in or near large towns will generally find that the fruit blossoms are the most productive, especially since it is becoming more and more the habit to cut down the Clover crops in such neighbourhoods for green fodder. In more pastoral districts Clover will take the leading place, and in moorland districts the Heather. Favoured districts are such as yield two of such harvests in succession, but few yield all the three. To take advantage of the fruit blossoms requires very special management, for at this time stocks are seldom found near their full strength. Those, therefore, who have little else in prospect must use every effort to have their stocks at their strongest thus early in the season. They must be stimulated to early and continuous breeding, and even then may have to be united two and two before they are fit to enter their supers. Once strong enough to do so they should be prevented from swarming till that particular harvest is over.

Owing to the honey from fruit blossoms being somewhat dark in colour and peculiar in flavour, those who have abundance of Clover in prospect seldom care to have it stored in supers. They welcome it, however, as affording the best stimulus towards getting strong stocks in good time for the more coveted Clover harvest, or towards getting through with such swarming as may be desired before the Clover blooms; for it ought to be a principle in modern management, now that we know how, to allow little or no weakening of stocks by swarming during the height of any honey yield of which a full advantage is to be taken. As far as the Clover season

is concerned this is most desirable, and, as there is time both before and after to make all desired increase there is nothing lost in the attempt. This matter of controlling or preventing swarms is the principal part of good management at this season, for stocks are then at their strongest, and it forces itself daily on the bee-keeper's attention. The various methods adopted to this end will be afterwards described, but we meanwhile press the principle on all who would take full advantage of this or any other shortlived harvest, that there ought to be no weakening of stocks by swarming or artificial division while it lasts. The best laid plans will often fail, and what seems a mania for swarming may take possession of many stocks which must in some degree be deferred to, since in such cases absolute repression will often produce a listless inactivity more to be feared than a certain amount of weakening through division.

A reference to his calendar will enable the bee-keeper to make due provision for the opening of the Clover season in strong stocks already, if possible, entered their supers. Attention to ventilation, doorway and storage room in advance of immediate requirements, will often carry him through the best part of it without much trouble, and a warning look at the date when the harvest closes will enable him by gradually diminishing the amount of super accommodation to insure that few if any unfinished sections will be left on hand.

The advent of the Heather season frequently finds stocks in a condition poorly fitted to take advantage of its extreme richness. Under ordinary management they are weakened by previous swarming, so that only the first swarms are usually in a position to yield any great surplus. Frequently also there is a spell of cold and wet weather after the Clover season which puts a stop to brood-rearing, leaving so many empty cells in the brood nest that the bulk of the Heather honey is stored there, rendering it difficult of appropriation and of less value. A knowledge of these things will guard the bee-keeper who hopes for Heather honey against the evils hinted at. He will take care to maintain his stocks in full strength right into August, and will take special precautions against having the central combs cleared of brood then. These remarks scarcely apply to purely highland districts, for there the conditions are naturally more favourable. Swarming is much later, and so also is the Clover harvest. Indeed the latter generally continues some time after the Heather is in bloom. Naturally, therefore, stocks in such districts are in a better position for taking advantage of this harvest than those in the low country, unless unlimited swarming has been allowed.

It may even be found profitable to take special measures to secure a surplus from sources even later than the Heather. In some parts of England, but more especially in Ireland, there are large quantities of Ivy which produce honey freely even in December. The general weakness of stocks and the usual approach of cold weather have, however, hitherto prevented more than a mere sample of this very peculiar but beautiful honey from being obtained.

The bee-keepers' calendar suggested should contain a record of the average dates at which stocks are found to be naturally at their weakest and strongest, when they, both with and without stimulation, usually commence breeding in the spring, or cease in the autumn, when natural swarming begins and ends, &c. Were these particulars entered after their dates in parallel columns with those regarding the pollen and honey-producing plants, and the beginning and ending of the various honey harvests, a valuable guide as to necessary management would always be at hand. To frame such a calendar here would be extremely difficult, taking into consideration the variety of circumstances belonging to each district in these islands, varying as it does so much in latitude and altitude as well as in the nature of its honey-producing flora.—WILLIAM RAITT, *Blairgowrie*.

(To be continued.)

THE STEWARTON HIVE.

I WITH others would feel much obliged if some of your bee-keeping correspondents would favour us with a drawing of the straw Stewarton hive spoken so much of lately in your valuable paper, and also details as to its management, and where it can be obtained.—FREDK. BULL.

The woodcut (fig. 104) may help your correspondent and others to form an idea of a straw Stewarton hive. The top roll of the hive is in wood, and the straw is sewed to it. The bars are let into the wood and level with the top of it. The interstices between the bars are filled with slides, which are moveable and run in grooves. Our intention is to dispense with the slides and use moveable straw lids instead, as the bees are apt to cement the slides to the bars. The lids will be easily lifted off and on the hives when supers are used. The supers will be made of wood 4 inches deep, and of course same width as the hives, and with bars across them 2 inches wide for honeycomb. In supering the lid will be simply lifted from the top of the hive to the top of the super. The hive is 15 inches wide and 13 deep.—A. P.

TRADE CATALOGUES RECEIVED.

Sutton & Sons, Reading.—*Amateur's Guide for 1883 (with coloured illustrations).*

B. S. Williams, Upper Holloway.—*Catalogue of Vegetable and Flower Seeds.*

James Veitch & Sons, Chelsea.—*Catalogue of Vegetable and Flower Seeds.*

C. Fidler, Reading.—*Catalogue of Seed Potatoes.*

Dickson & Robinson, 12, Old Millgate, Manchester.—*Catalogue of Vegetable and Flower Seeds (Illustrated).*

Frederick Roemer, Quedlinburg, Germany.—*Catalogue of Vegetable and Flower Seeds.*

Stuart & Mein, Kelso, N.B.—*Catalogue of Vegetable and Flower Seeds.*

Waite, Nash, Huggins & Co., 79, Southwark Street, S.E.—*Wholesale Catalogue of Vegetable and Flower Seeds.*

** All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

To Correspondents.—In consequence of the great pressure on our columns this week many valuable articles on a variety of topics have to stand over to a future issue. Correspondents must not conclude that the notes they have obligingly sent are not appreciated because they are not promptly published; on the contrary, they are prized, and the writers are thanked for their willingness to impart information. We shall always be glad to receive notes of interest from any of our readers.

Book (Penally Abbey).—The work you appear to require is Curtis's "Botanical Magazine," published monthly by L. Reeve & Co., 5, Henrietta Street, Covent Garden. It is edited by Sir J. D. Hooker, and gives coloured illustrations of new, rare, and interesting plants.

Cælogynes (S. M.).—Your plants are evidently in good condition, the foliage, pseudo-bulb, and flowers being quite satisfactory, but not extraordinary.

Chrysanthemums (G. Cole).—It is impossible for us, as we have many times stated, to name varieties of florists' flowers of any kind. Still, we have occasionally given the names of those we could easily recognise. Those you have sent are not typical well-developed blooms, and cannot be satisfactorily identified.

Saponaria calabrica (O. J.).—For early spring flowering the plants ought to be raised in the autumn by sowing the seed at the end of August or early in September. Sown in pots now, the plants grown in a light frame, and subsequently planted out, would be the quickest mode of attaining your object; or the seed may be sown in the open ground during favourable weather at the end of January or early in February.

Snowdrops in Pots (G. G., Yorkshire).—They flower well in pots, but will not endure much heat. The singles are better than the doubles for early flowering. The bulbs you have just received will not flower nearly so soon nor so well as established clumps would if now dug up, potted, and placed in a frame or house having a temperature of about 45°. They must have a light position, and be frequently sprinkled with cold water, the roots also being kept constantly moist.

Hambleton Deux Ans Apple (M. C. B., Hants).—This useful late-keeping Apple originated in Hampshire, and is now grown rather extensively in that county. If you cannot procure trees from a local source your only alternative is to write to some of those large general nurserymen who advertise fruit and other trees in our columns. We never recommend dealers. Such a practice would be manifestly unjust, since there are so many who equally well supply whatever is needed in gardens.

Hawthornden Apple (D. Johnson).—This deservedly popular and valuable Apple was raised at Hawthornden, a romantic spot near Edinburgh, celebrated as the birthplace and residence of Drummond the poet, who was born there in 1585. We have never learnt at what period the Hawthornden was first discovered. The first mention of it is in the catalogue of Leslie & Anderson of Edinburgh; but we do not think it was known about London till 1790, when it was introduced to the Brompton Park Nursery.

Heating Greenhouse (J. D. B.).—By all means have a small boiler and two rows of hot-water pipes, a flow and return, connected if possible along the front and both ends of the house, as, however good a stove may be, the heat cannot possibly be distributed so regularly as that from pipes heated with hot water and arranged as indicated. If the house is a lean-to and not more than 10 feet high at the back 3-inch pipes will suffice, but if a span roof or lofty you had better have 4-inch pipes.

Barbarossa Grape (Exhibitor).—You are certainly wrong in this matter,

as you may gather by the following description of the true Barbarossa, the fruit of which you have probably never seen. Bunches medium sized, shouldered. Berries slightly oval, or obround. Skin thin and delicate, of a grizzly colour, or pale red, covered with a thin grey bloom. Flesh delicate, juicy, sweet, and with somewhat of a Royal Muscadine flavour, but very much richer. Gallesio says it is "the king of dessert Grapes." The Grape which has been grown in this country for some years under the name of Barbarossa is a totally different variety. Its correct name is Gros Guillaume, and it is black, while the Barbarossa is, as its name implies, a rose-coloured or grizzly Grape.

Mushrooms in a Frame (Disappointed).—You have failed because you have acted quite contrary to instructions. Digging a deep square hole in the open ground, filling it with manure in September, inserting spawn and placing a frame over the sunken bed, is not what has been advised nor the way to succeed. You probably did not think when you were "improving on the outdoor system" of culture that you were providing what may be termed an earth cistern for collecting the drainage from the surrounding soil, thus chilling the bed and causing the spawn to decay instead of spreading and producing Mushrooms. In the summer the failure might not have been so complete. Outdoor beds of Mushrooms entirely above the surface of the soil and well covered with litter are now bearing prodigiously. You would have done well to have tried this method of culture before attempting to "improve" upon it.

Cutting Camellias (E. D. O., Wicklow).—When Camellias are quite healthy the flowers may be cut with a portion of the growth attached, not only with impunity but occasionally with advantage, as the plants frequently produce more growths than would have otherwise issued, and a closer habit is induced with a large supply of flowers. It is necessary to sever the shoots near a healthy bud, otherwise the buds will die back as you have stated. If there are no healthy wood buds below the blooms, but the only growing points are near them, that the flowers should be removed without cutting off any portion of the shoot. By examining the condition of the wood and studying the health of the plant you will we think, have little difficulty in deciding on the point you have submitted.

Heating Defective (R. P. O.).—The piping is sufficient in the lower house and the boiler probably sufficiently powerful, but you do not state its size. The fault we suspect is in the arrangement of the pipes, but it is impossible to indicate it from the very imperfect sketch before us. Cannot you send us a larger and better sketch, showing all the pipes and their connections, indicating also the flows and returns? Please say also if both houses are on the same level; and if they are not, the difference between the height of the pipes in the two structures. Your full postal address should accompany your letter. On hearing from you again the case shall have our best consideration.

Carnations Unhealthy (E. C.).—The Carnation leaves arrived so much shrivelled, the paper having extracted the moisture from them, that it is not easy to determine the cause of their discoloration; but we certainly do not attribute it to red spider, and we rather suspect that you have aggravated the evil by your free application of insecticides. They appear to have been attacked by a fungus, and a dry atmosphere and dustings of sulphur would have been the most likely means to effect an improvement, while additional moisture in an atmosphere probably already too moist would have an opposite effect. Defective root-action, especially if caused by over-watering, is an almost certain precursor of spot and fungus. Remove all the affected parts, apply water with great care, not wetting the foliage, providing a dry atmosphere, and your plants may possibly improve. You do not say whether they are young or old, or whether kept in a frame or greenhouse. If old and exhausted they will probably be of little further service, but if young they may with judicious treatment regain their lost vigour.

Libonias Unsatisfactory (Idem).—The condition of the plants indicate that there has been some error in treatment, but in what respect it is impossible for us to say. You say they had a "good shift" in June, but possibly it might have been a bad one. If the roots were much matted, and the soil they surrounded or permeated was dry when placed in larger pots, the shift was a bad one. If water was given too copiously immediately after repotting, as is not unfrequently the case, the shift was also unfortunate, and the plants would have been better left in their original pots and supported with liquid manure. Again, overdryness during the summer, if only for a day or less, causing the roots to shrivel, would lead to the premature fall of the leaves and the non-production of flowers. Torpid root-action is the main cause of the evil, but whether it is the result of over-watering or under-watering we have no means of knowing. Possibly there have been mistakes of both kinds, for we have often known plants allowed to get unreasonably dry and then made and kept unreasonably wet, as if to atone for the initial error; thus a double mistake has been made, and the plants have suffered proportionately. Plant them out in good soil and a warm sunny position next year, and note the lesson that Nature teaches in the cultivation of Libonias.

Culture of Calochorti (Idem).—They can be grown outdoors if you wish, but they will need protection during the winter, covering them with a layer of ashes 3 or 4 inches deep, but they must be planted in well-drained light soil or success cannot be insured. Frames are also suitable for them, the bulbs being planted out in sandy loam, and ventilation well attended to in favourable weather. In pots these plants are very uncertain; sometimes they grow and flower fairly well, and at others they are most unsatisfactory, whatever care is taken with them. Plenty of drainage and similar soil to that already mentioned are necessary for Calochorti in pots.

Gros Maroc Grape (Bute).—As you doubt that this Grape can be grown in a house with Black Hamburg you had better visit Mr. Rivers' nursery at Sawbridgeworth next year, and you will see it growing vigorously, and probably bearing freely, not only in a house with the Black Hamburg, but with a dozen other varieties as well. In that house it commences colouring quite as soon, if not sooner, than the Black Hamburg, and hangs until March. The bunches are not giants, but of good size, the berries being very fine and splendidly coloured. You will do well to remember that the Vine needs more room than the Black Hamburg, as it is a very strong grower; and we have no doubt whatever that, like Gros Guillaume and the Duke of Buccleuch, it will bear better on the long-rod system than by close spurring. But although it succeeds under the conditions named, we are not prepared to assert that its flavour would not be improved under a somewhat higher temperature, the same as is that of its relative Gros Colman. Both these Grapes were introduced from France by Mr. Rivers, and have been at Sawbridgeworth for nearly a quarter of a century.

Situations (A Young Gardener).—Your desire to succeed is a worthy one, and your efforts to obtain a situation under a gardener famed for his abilities is commendable. Whether your plan of operations will answer can only be proved by experience; but unless you can include copies of testimonials from those who can certify to your ability, industry, and general good conduct, we doubt if your letters will do more in the majority of cases than insure a civil answer. Most "fauned gardeners" are inundated with applications from young men,

but as a rule those are not placed on the list of candidates for vacancies in the absence of such testimony as we have indicated. Your letter is creditable to you, but we should not have been less favourably impressed with it had you sent your full name and address, and it is not impossible that this would have enabled us to have given you a somewhat different and not less useful reply. However, the hint we have given you may possibly be of some slight service. We know it would be of no use writing to the gardener your name.

Soil for Vines and Peaches (J. B.).—The soil of which you have submitted a sample will, we have no doubt, grow Vines and Peach trees well provided they are in other respects properly managed. We should have little fear of the traces of fungus doing any injury to the Vines and trees, as we have used soil of the same nature for Vine borders with the best results. Still, you will not err by attempting to destroy what little fungus there is, especially as you may improve the soil at the same time. We should turn it over, and on each layer spread a little fresh unslaked lime, simply breaking any lumps larger than your hand. A bushel will suffice for a cartload of soil, and the moist earth will cause the lime to "fall" in the course of a week or so, at the end of which time, if the heap is again turned over, it will be in excellent condition for use. A bushel of half-inch bones mixed with each cartload of soil will improve it for both Vines and trees; so also would an admixture of wood ashes, but neither of these additions is necessary, as the soil is sound and good.

Selection of Grapes and Peaches (Idem).—You ask for seven Vines suitable for growing in the same house for affording fruit from August till Christmas, three to produce white, and four black Grapes. The most easy and certain method for an amateur to produce a supply would be to plant one Vine of Buckland Sweetwater, two of Foster's Seedling, two of Black Hamburgh, and two of Black Alicante, the Alicante to have the warmest position. If we wanted seven varieties we should venture on planting one each of the following:—Duke of Buccleuch, Foster's Seedling, Muscat of Alexandria, Black Hamburgh, Madresfield Court, Alnwick Seedling, and Mrs. Pince, and by having the Muscat and two last named in the warmest position should expect to succeed in our object; but we hold out no kind of guarantee that either you or anyone else of whose cultural skill we have no knowledge would find this selection satisfactory. You must now decide for yourself in accordance with your experience and competency, on which important matters you supply no information. Of Nectarines we doubt if you could do better than plant Lord Napier, Violette Hâtive, Improved Downton, Pine Apple, Humboldt, and Victoria.

Planting Bulbs (C. B., Waverley).—It is fully late for planting Crocuses and Snowdrops, but all the others will do well planted now. It will be a good plan to do as you suggest, placing them close together on an inch or two of leaf soil or cocoa-nut fibre refuse in boxes, and covering an inch or so deep, placing the boxes in a cold frame—in fact, burying them, as, if their sides are exposed, the soil will become dry, if it does not get frozen. Try the Crocuses and Snowdrops also. When roots an inch long are produced replant very carefully so as not to break them in the border, surrounding them and covering the bulbs with leaf soil. If the ground is moderately dry you may plant the Tulips and Narcissuses in the border at once, but if wet treat as directed with the other bulbs. Questions reaching us on Wednesday morning can seldom be answered in the "next issue."

Tea-scented Roses for Beds (Novice).—Tea Roses do not like a strong soil, especially one overlying clay. This more particularly applies to a cold climate; hence if you attempt growing Tea Roses you must make sure of the soil being well drained, and add to it some gritty material so as to open its texture. The plants should be planted about 2 feet apart in the bed in the first instance, the distance being increased in the course of two or three years. In winter the plants will need protection during very severe weather; but it is preferable to take them up early in November, pot them, and keep them plunged in ashes in a cold pit, planting out again early in April. When in the pit the light must be kept off in mild weather. Gloire de Dijon, Gloire de Bordeaux, Abriote, Goubault, Homère, Julie Mansais, David Pradel, Madame de St. Joseph, Madame Lambard, Souvenir de l'Empereur Maximilien, Rubens, Marie Sisley, Madame Ducher, Le Nankin, Madame Margottin, Cheshunt Hybrid, Duchess of Edinburgh, Belle Lyonnaise, Vicomtesse de Cazes, Madame Trifle, Madame Berard, Madame Alexandre Bernaix, Letty Coles, and Marie Van Houtte have been recommended by a cultivator who grows Roses in some of the coldest districts in the north of Yorkshire.

Plants for Affording Cut Flowers (Blackheath).—If your greenhouse is such that you can plant out a number of climbing plants and train them thinly under the roof you will be able to obtain abundance of cut flowers from the following Roses:—Gloire de Dijon, Maréchal Niel, Lamarque, and Rêve d'Or are very suitable for the roof; while Tea Safrano, Niphotos, Isabella Sprunt, Perle de Lyon, and Souvenir d'un Ami can also be planted out if convenient and trained up the end of your house, or grown in pots in such quantities as you think will meet your demands. Hybrid Perpetuals may also be forced in pots, and you will find the following good and useful for the purpose:—La France, Général Jacqueminot, Jules Margottin, Duke of Edinburgh, Louis Van Houtte, John Hopper, and Coquette des Blanches. Lapageria alba and rosea, Clematis indivisa lobata, as well as other deciduous varieties, are also useful for the roof, and will do better planted out than if kept in pots. If your greenhouse is a lean-to you can have Camellias, Abutilons, Rhododendrons such as Gibsoni, Habrothamnus elegans, Tropæolums Ball of Fire or Vesuvius, and other similar plants to cover the back wall, growing them in large pots or boxes, which will give you abundance of flowers without taking up much room of the house. You will also find Azaleas, Epacris, Bouvardias Vreelandii, Hogarth, and the beautiful double white Alfred Neuner three of the best and most useful. Zonal Pelargoniums will be found invaluable, both single and double forms, the latter being the most serviceable for cutting purposes. Tuberosus Begonias would do well in the greenhouse, and be useful for cutting during the summer. Heliotropes, Mignonette, Cyclamen persicum, as well as single and double Primulas, the latter being indispensable where cut flowers are in daily request, as they will continue to produce them in succession for six months or more. Chrysanthemums are amongst the most useful of plants for supplying cut flowers from late summer until the month of January. The supply of flowers will not be sufficient to maintain during the summer months when quantities can be obtained from the outside; such, for instance, as Narcissus, Carnations, Phloxes, early and late-flowering Pyrethrums, Roses, and many others which will associate well with flowers from the greenhouse. For the winter supply quantities of Deutzias, Rhododendrons, Ghent and Mollis Azaleas, Lilaes, Spiræas, Guelder Roses, and other hardy flowering plants should be prepared for forcing into bloom in your heated pits. If these are suitable for the accommodation of stove plants you should grow in quantity Eucharis amazonica, Gardenia florida or intermedia, both being free-flowering varieties. Begonias of such sorts as insignis, nitida, nitida rosea, semperflorens grandiflora, Ingrami, Moonlight, Dregei, and weltoniensis you will find valuable for your purpose. Gloxinias raised from seed and grown in your heated pits, and

brought into flower in batches and placed in the greenhouse while in flower, would also be very serviceable. Euphorbia jacquiniæflora and Clerodendron fallax you will also find useful; the latter can readily be raised from seed. If your pits are sufficiently lofty, so that you can grow climbers thinly under the roof, you will be able to obtain a valuable supply of choice flowers from such plants as Allamanda Hendersoni, Clerodendron Balfourianum, Bougainvillea glabra, Dipladenia Brearleyana, and Stephanotis floribunda.

Names of Fruits (O. J.).—Pears: 1, Josephine de Malines; 2, Winter Nelis; 3, Marie Louise, fruit from a late bloom. Apples: 1, Golden Russet; 2 and 3 not known, probably local varieties. (William Heale).—2, Trumpington; 4, Besspool; 5, probably Old Golden Pippin; 6, Golden Noble; 9, Autumn Pearmain, well kept; 10, Autumn Red Calville. The others are under examination.

Names of Plants (J. H., Canterbury).—1, Davallia canariensis; 2, Hymenophyllum hirsutum; 3, Nephrolepis tuberosa; 4, Trichomanes radicans.

COVENT GARDEN MARKET.—DECEMBER 27TH.

The market has continued to be well supplied with all classes of goods, prices remaining the same; and the demand is well met by the supplies.

POULTRY AND PIGEON CHRONICLE.

MAXIMUM WEIGHT FOR AGE OF CATTLE AND SHEEP.

(Continued from page 582.)

HAVING given the weight for age of young cattle as far back as 1857 and 1869, we will now quote the weight for age of young cattle as exhibited at Islington, taking first a shorthorn steer, fed by Colonel Sir R. Loyd Lindsay, at 102 weeks old weighed 120 stone of 8 lbs. A cross-bred steer shown by Lord Lovat at ninety-one weeks old reached 108 Smithfield stones of 8 lbs. As these two young steers were the heaviest in the Show at weight for age in their class, we must compare these two animals with the two selected at the earliest period; and when we consider that those were only exhibited or slaughtered in country districts, it decides the matter in this way, that no more weight for age has been obtained now than formerly by the young cattle shown this year at Islington. The heaviest animal at Islington this year was shown by Mr. C. T. Lucas; at the age of 190 weeks it only reaches in weight 187 Smithfield stones. It will thus be seen in comparison with young animals it does not show so much weight for age, and scarcely justifying the keeping of adult cattle for feeding as profitable beef.

We will now show the curious and peculiar results of buying prize animals at one show and keeping them for another exhibition the following year. In the Scotch cattle contest this year we find

in Class 27 the cup steer of 1881 reappeared. He is now the property of Mr. J. Cridlan. It weighed in 1881 Exhibition 17 cwt. 1 qr. 21 lbs., and this year, 1882, it has only a record of 18 cwt. 1 qr. 12 lbs. But we find another instance in the cup heifer, a famous conqueror of the year 1881. She weighed at Islington 15 cwt. 3 qrs. 24 lbs., and was shown again in 1882 at Bingley Hall, Birmingham, when she weighed only 16 cwt. 3 qrs. —*i.e.*, she gained by a year's hard cramming 88 lbs., an increase which at beef prices will hardly give twenty pence per week to pay for keep which cost probably over twenty shillings. These are lessons which must teach those who are willing to learn, for it is evident that the Society which admits animals to be exhibited in this way sets an example which offers no advantage or credit to them, nor can any satisfaction be available for the exhibitor.

For the sake of contrast we will give an instance of keeping cattle on from one year to the next. Mr. James Crew occupying good grazing pastures of his own in the vale of Wincanton in Somersetshire. As near as we can recollect the period, he purchased two oxen of full age at Salisbury Christmas Cattle Market in the year 1854, and gave £64 for the pair of Devon oxen, and fed them on his own occupation on hay and water only, the produce of his own pastures, with a covered shed to run into at will during the winter until the grass came. They were then grazed for the summer, and hay-fed again in the autumn, without cake or corn, or anything besides the produce of his pastures in hay or grass. These animals were taken to Salisbury Christmas Cattle Show again the following year, and were sold for slaughter at £128. We have no record of the weights or increase, but give the account as an outside profit on the method of keeping and feeding just as Mr. Crew told us. We further believe that these oxen had been worked on the land for several years previous to the first purchase, in which case it is an excellent example of what may be done by others under similar circumstances.

In our business and correspondence with experienced men we are confirmed in the assumption that we do not now meet with oxen which weigh more than 210 Smithfield stones, and then only does it occur in the case of worked bullocks of from six to seven years of age, which can only be reckoned as 210 stones in 312 weeks. But when animals are in full condition and weight at from two and a half years to three and a half years of age they cannot be kept to a profit beyond the latter period after having been fed the whole time with full measure of best food. At these large Christmas exhibitions the feeder now gives no account of the kind of food used and the method of feeding; but years ago we recollect well, when we reported the shows held in Baker Street by the Smithfield Club, the food, &c., used was stated by the exhibitor of his cattle and sheep, and we think this is a serious omission in the present arrangements so far as the rising generation of farmers are concerned.

We will now proceed to the consideration of weights for age attained by sheep and lambs, and in relation to which we find a great revolution has occurred during the last twenty or thirty years. For instance, it is recorded that the long-wooled Lincoln sheep as wethers when fat have been known to reach the weight of 60 lbs. per quarter, or 30 stones the carcass, at three years of age, the mutton, of course, not being so valuable as that of the smaller breeds. We give an example. Mr. Clarke of Canwick in 1827 exhibited two wether sheep in Lincoln market. When slaughtered one weighed 32 stones 5 lbs.; the other 31 stones 2 lbs. At the same period the Leicesters and Cotswolds also reached as wethers heavy weights, but not so much at the same age as the instances we have given.

WORK ON THE HOME FARM.

Horse Labour.—Ploughing and sowing the Wheat land is now much behind, and on many farms in various strong-land districts in the western counties but little has yet been sown. This work must therefore be attended to, making the most of every day when the weather is fine, or even part of a day; for, in fact, the ploughing and sowing or drilling should be going on simultaneously, so that as fast as the land is ploughed the seed should be sown up close to the plough. This applies to land where roots have been fed off by sheep as well as land hitherto rendered impossible to work by reason of the succession of adverse weather, otherwise field work is nearly suspended. The ploughing, however, for next year's root crops and Potato crop may be continued upon all friable soils in the absence of rain; with these exceptions but little ordinary work can be done. Carting out manure to heap in the field where required either for next year's Mangold or Potato crop may be done, but some mellow earth should be placed as a floor to absorb the drainage from the heap. To prevent heat and waste afterwards the dung should be drawn by the carts, and when finished some matured earth should be laid over the top of the heap, which will prevent undue fermentation. Also repairing roads may now be done: shaping the bye roads of the farm may also be done, by digging and carting away to heap the

sides of the roads, so that the water may readily escape to the water table or outside of the roadway. When ordinary roadways through and about the farm, and between the fields are managed in this way no gravelling or other materials are required after the roads have been properly shaped with outlets for the water from them during the winter months in each year. Nor must this be considered an unprofitable matter, because if the earth and parings are removed every year to heap, the proceeds will be available for all purposes of mixing with and making compounds or compost heaps with manure for pasture lands, as well as for use as absorbent materials to be used at the bottom of pens where pigs, cows, &c., are kept, and in stables where cart horses are accommodated. Drawing timber, and the proceeds of the underwood grown in the coppices and hedgerows when made into different items for sale, such as hurdles, bavins, hoops, and hoop rods, &c., may now be proceeded with, so that such work may not interfere with important labour on the farm in the more busy times of the year. If frosty weather occurs manure may be drawn on to the young Clovers direct from the farmyard, both box manure and that from the pig and cow pens. Earth and earthy composts may also be drawn out and spread upon any meadow land which under ordinary circumstances would not bear the weight of the horses and carts.

Live Stock.—Preparations should now be carried on for the lambing season by getting a dead fold made on some dry spot and covered with earth, so that when the bedding of the fold is completed the urine may be absorbed, and preserved as long as the ewes are kept therein. A sheltered spot a little on the incline should be chosen for the position of the fold, and if it can be obtained near to the shepherd's residence so much the better; but when it is not made near to his cottage, the shepherd's van or moveable house in general use on most farms will accommodate the shepherd and his assistant during the lambing season. So long as frosty weather prevails Cabbages are the best food for the ewes before and just after lambing, and until common Turnips can be made available; but we do not like either Mangolds, Swedes, or Turnips cut and used for feeding ewes in troughs before or just after lambing, for we have known a great injury done by the ewes eating roots in large quantities at such times. The dry flocks, both tegs or hoggets, will now be doing well; for although the weather may be wet and the land dirty, if the food is cut and used as trough food, and if cake or corn is used for feeding let it both be reduced to meal and have it mixed with the cut roots, for in this way every animal gets its share of the cake, &c., as well as roots, but the troughs should not be overfilled and food left for the night. The great advantage, however, in mixing roots and meal at feeding time will be found in the health of the animals, because every one gets its fair share of the superior food, and as it enters the stomach together one material corrects the other, and prevents any laxative effect or other internal injury. The milch cows should now be housed when the weather is adverse; and unless the pastures are very dry they should not go into them, and avoid their treading by a little airing in the farmyard or home paddock, and be fed at the stalls morning and evening only. They are now generally coming forward to calving time; straw or inferior hay with a little decorated cotton cake in meal mixed with the cut roots will keep them in useful condition, because after the cows go dry and they are kept too highly they are apt to make fat internally, which frequently produces an adverse calving time.

POULTRY AND PIGEONS

CELEBRATED POULTRY YARDS.

MR. W. COOK AT WEST CHISLEHURST.

WE some time since reviewed a work called the "Poultry Breeder and Feeder," of which Mr. Cook is the author, and which is published at this office. This work has called forth some severe criticism from at least one quarter. We desired in the interests of fair play to see for ourselves what Mr. Cook has actually done in the direction indicated in his book—namely, the keeping of poultry simply with a view to egg-production, with little or no regard to fancy qualities. With this object in view we communicated with Mr. Cook, and asked his permission to visit his poultry yard. This was at once accorded, and on the 11th inst. we paid our contemplated visit.

The yard can hardly be called a celebrated one in the ordinary acceptance of the term, but we think it deserves to be so characterised on account of the wonderful results obtained by its owner in the very limited amount of space at his disposal. Mr. Cook's house is small, forming one of a terrace of similar houses, and the fowl yard occupies about half the garden, a piece of ground less than 20 feet square in fact. At one side is a well-built wooden fowl-house, lighted with a window, at the other side a shed boarded on two sides and part of the front; each of these structures is about 8 feet in length by 5 or 6 feet in width.

In this yard were twenty-six adult birds and some half a dozen chickens. Of the twenty-six birds half were hens and half pullets. A large Golden-spangled Hamburgh cockerel completed the stock.

At Mr. Cook's request we noted down the particulars of the various

crosses of which he had examples. They were as follows, the name of the male bird being in each instance given first:—Buff Cochin—Coloured Dorking; Partridge Cochin—Light Brahma; White Dorking—Light Brahma; Black Red Game—Light Brahma; Black Red Game—White Dorking; Black Red Game—Golden-pencilled Hamburg; Black Hamburg—Dark Brahma; Golden-spangled Hamburg—Partridge Cochin; Golden-spangled Hamburg—Dorking; Houdan—Dark Brahma; Houdan—Light Brahma; Houdan—Partridge Cochin; Houdan—Golden-spangled Hamburg; Houdan—Black Hamburg; Houdan—Minorca; Malay—Dark Brahma; Malay—Coloured Dorking; Spanish—Dark Brahma; Spanish—Partridge Cochin.

The owner pointed out to us the bird or birds of each cross as he named them; and we may say that, as we had previous knowledge of several of the crosses, and the examples pointed out to us corresponded in all respects with what we knew birds of these crosses to be, we were able in this way to verify the accuracy of Mr. Cook's information. All the birds were most healthy in appearance, and, with the exception of one or two rather old hens which were heavy in moult, had the appearance of being in full lay.

We noted down from the rough account book in which the laying results are kept the following figures:—The total for August from twenty-six birds was 494 eggs, for September 373, for October 219, for November 204, and for the eleven days of December which had elapsed 106. The December figure we thought specially worthy of note, as the day of our visit was the last, or nearly the last, day of the severe frost which had continued for more than a week, and which had entirely checked the laying of such of our own birds as were doing anything in that direction. We hope early in the year to be able to give the complete figures for 1882, but it is worthy of remark that during the period of four months of which we have already a complete return, and which are amongst the worst laying months of the year, each bird averaged fifty-three and a half eggs. Even if this proportion only were kept up throughout the year, each bird would lay 160 eggs.

These results are attained, not from what Mr. Cook believes to be the best crosses, but from a variety of birds kept to exemplify many different crosses, bred, however, from parents selected chiefly for laying qualities. The birds are treated in the way indicated by Mr. Cook in his book. They are fed on warm soft food in the morning, grain in the evening, and are given warm water to drink. In addition they are given at this season of the year, four or five times a week, some of the tonic powder specially prepared by their owner. This is mixed in their soft food. We noticed also crushed oystershells in the yard, and the birds were picking over a barrowful of horse manure thrown down to afford them employment and amusement.

As a further proof that Mr. Cook has gone very thoroughly into the matter of the laying qualities of individual birds, we may mention that he showed us a basket of eggs, being those gathered during the preceding couple of days, and pointed out to us the eggs laid by birds of most of the crosses which were represented in his yard. Many of these eggs were very fine, those of the Houdan crosses being perhaps the largest. At Mr. Cook's request we visited with him the house of a gentleman living in his neighbourhood who manages his poultry yard on Mr. Cook's method. This gentleman keeps a large school, including several boarders; and in addition to supplying the wants of the house he is enabled to spare, even at this season of the year, a considerable number of surplus eggs. We did not take note of the exact number of hens kept here. The yards were of small dimensions, extending merely across the end and a few feet down the sides of the garden of the large villa in which the gentleman resides. We estimate, however, that there were about thirty hens. Of these one lot consisting of Black Hamburgs were only just through their moult and had not recommenced laying. The others were crossbreds of various kinds, and from these there was a return, as their owner assured us, of from eight to twelve eggs per day. All the birds were in prime condition, which their owner attributed to the use of the powders already mentioned. He stated voluntarily that since using these and working upon Mr. Cook's method as to feeding, &c., he had had more than double the quantity of eggs from his fowls.

We have hitherto confined ourselves to an accurate statement of what we saw and of what we were told by the gentleman to whom we have just referred. We have done this because we desired to put the matter before our readers and allow them to judge for themselves. We now add some information gathered in the course of a long conversation with Mr. Cook.

He has for many years devoted considerable attention to the development of laying qualities in birds of various pure breeds. The birds of these breeds he is not now able to keep at his own place; they are distributed amongst the yards of friends in Chislehurst and Bromley, who supply him with eggs for hatching out birds of the pure breeds or crosses which he desires to have. In this way, though his own place is but small, he has been enabled to have more actual experience of various crosses than many people with large establishments could manage. The results of his experience are to a great extent given in his book. We questioned him, however, as to some matters upon which we thought a little additional light could be thrown, and he most kindly afforded us the fullest information on every point.

In his book, as we have already noted, he speaks much more of

Cochin than of Brahma crosses. Our experience has led us to believe that, other things being equal, a Brahma is superior to a Cochin for the purpose of crossing, more especially as regards the table qualities of the progeny. Mr. Cook entirely agreed as to this, and said that it was partly through accident that he had had so much more experience of Cochin than of Brahma crosses; and it was also partly in consequence of the Cochins which he first used for crossing being much better layers than the Brahmas, and thus giving a better laying result in the progeny. We also suggested that a Minorca was, in our view, preferable to a Spanish bird for crossing purposes. As to this Mr. Cook agreed with us, as, indeed, he has stated in his book, and it appeared that here also the employment of Spanish instead of Minorcas had been chiefly the result of accidental circumstances.

We further wished to have Mr. Cook's view as to what were for general purposes in his opinion the most profitable crosses. Here he again agreed with us that Houdan-Brahmas, Minorca-Brahmas, and Hamburg-Brahmas deserve to be placed at the head of the list. He has recently also made trial of Plymouth Rocks for crossing with Houdans and Minorcas, and has found the results of these crosses so far very good. The very best cross within his own experience for laying has been between Golden-spangled Hamburg and Partridge Cochin. These birds, in addition to their useful qualities, are handsome bright-coloured birds, which, as he said, greatly improved the appearance of a yard. He had in his sitting-room a stuffed specimen of a bird of this cross, one of five sisters remarkable for laying. He told us that in one week in December, 1879, he had from these five birds twenty-nine eggs, which, sold at 3d. each, made the return for the week 7s. 3d., a result certainly noteworthy.

In reviewing Mr. Cook's book we stated that we thought he had hardly given sufficient emphasis to the fact that the wonderful laying results recorded were from birds bred from strains specially selected for laying qualities. The author assured us he fully intended to give emphasis to that fact, which he considers of primary importance. He agrees with us, however, that even from parents of but indifferent laying qualities, provided they be of breeds which were originally good layers (before being spoilt for laying by being bred up to exhibition standard, &c.), much better results may be expected from the progeny of a first cross than from the birds of the pure breeds. Just as in the case of fancy characteristics a cross causes the birds to revert to original qualities undesirable from this point of view, so a cross between birds whose ancestors were good layers causes the progeny to revert to these good qualities, and to produce a result in eggs superior to that obtainable from the pure breeds themselves.

OUR LETTER BOX.

Earth Floors in Stables (R. O.).—You ask if nag horses are allowed to stand on earth floors throughout the day without litter of any kind. We say Yes, just as well and far better than when allowed to stand on pebbles or any other impervious floor, because it is so much softer and better for the feet. If the dung is cleared away the urine will sink quickly into the earth if it has been laid in quite dry and properly rammed down, and will not then sink so as to form puddles on the surface if in boxes 12 feet by 12 feet. Still, if in stalls where the urine always falls so much in one place it must be kept level on the surface by earth repairs. Cows should stand in pairs in double stalls 7½ feet wide, each cow being tethered to the corner of the stall or feeding manger. The feeding box at each corner should be 2 feet square at top, 1½ foot deep, and 1½ foot wide at bottom; but in order that each animal should feed in common upon hay or straw the space between the boxes should be used for that purpose, the manger being 2 feet wide, 2 feet deep, and 1½ foot wide at the bottom.

REMARKS.

17th.—Dull throughout, with sprinkle of rain at 3 P.M., and slight break in the clouds at 7 P.M.

18th.—Dull at first; day much finer, with clear sky.

19th.—Fine, misty latter part of day.

20th.—Foggy and dull, rather bright for a short time at noon.

21st.—Much finer, brighter day, moonlight night.

22nd.—Fine morning, misty afternoon, damp evening.

23rd.—Fine and bright.

Much milder than the previous week, and rather above the average temperature.—G. J. SYMONS.
