prize hive deserved a higher place; and Messrs. Blake, Blow, and Dines by no means obtained their deserts, as we considered the hives shown by these exhibitors to be second to none in their general utility, ease of manipulation, moderation in price, and solidity of material and workmanship. We regret that want of space forbids our entering more into detail as regards these excellent specimens of what a modern hive should be.

In Class 6, "For Framed Hives, price limited to 15s.," Messrs. Dines were *facile princeps* with their double-walled hive, affording every facility for harvesting comb honey in side sections and upper racks, their hive being remarkably cheap at 15s. Messrs. Best and Blow also well earned their position of second and third with hives of similar construction. We thought this an excellent class, there being twenty-one entries all of superior workmanship; indeed, for such hives a few years ago we must have paid from 30s. to £2 each, so good a work has the Bristol Association effected in the supply of really good hives at moderate prices during the few years of its existence. Mr. Blake obtained here a commendation, and several others might well have shared his good fortune, especially Messrs. Neighbour, Baldwin, and Green, the latter for a hive on the doubling principle for obtain-

ing extracted honey. It is a remarkable fact, especially worthy of notice, that in all the moveable-frame hive classes, the British standard frame, although established barely six months, appeared to be almost invariably adopted. Class 7, also, was a most superior class considering the low price of 10s. 6d. to which the exhibitors were tied down, and here again Messrs. Dines were successful, being closely pressed by Messrs. Blake and Best, Messrs. Baldwin and Abbott obtaining high commendations. Who would not invest so small a sum as 10s. 6d. in order to become possessed of a really good sound bar-frame hive for entering upon one of the most charming of all country pursuits, and, withal, a most lucrative one?

In Class 8, for amateurs, the fortune-favoured ones were Messrs. Benthall, Brooks, and Stewart, with hives which, to say the least, would have done credit to professional workmen. We particularly liked Mr. Stewart's hive, which comprised all the useful principles that we expect to find in a modern hive. With Class 9, "For the best Straw Hive for depriving purposes, price limited to 5s.," we come to the last of the hive classes. That there should be found in a straw skep class seven entries, whilst in former years one, two, or at most three have been the maximum, speaks well for the rapid strides now being made in apiculture. We must confess to a lingering fondness for the hive of our forefathers, and if, in this age of change, modern ideas can be united with and engrafted upon the old dome-shaped straw hive, why not? We should have here placed first the Messrs. Abbott's highly commended Pettigrew Stewarton Hive, as being about the best and soundest straw hive we ever saw, being extremely well wrought with strong oaken hoops at top and bottom, the diameter of the latter being slightly smaller, contracting the skep at bottom to prevent the falling of combs, on the old Grecian hive principle—a most excellent one; its arrangement also for procuring straight combs leaves little to be desired. To most of the specimens shown the modern sections, either were, or might easily be, adapted.

The conclusion of this report will appear in our next issue.

PRESTON APIARIAN SHOW.—We are informed that entries are wanted for the Great Bee Show to be held at Preston, September 6th, 7th, and 8th. For honey, three silver and three bronze medals, three certificates and money prizes to the value of £15, are provided. For driving, first prize 50s.; second, 20s.; and third, 10s. Apply to the Hon. Sec., J. P. Jackson, Esq., 31, Jermyn Street, Liverpool.

TRADE CATALOGUES RECEIVED.

Hogg & Robertson, 22, Mary Street, Dublin.—*Catalogue of Hyacinths and other Flowering Bulbs.*

James Dickson & Sons, 108, Eastgate Street, Chester.—*Catalogue of Bulbous Plants.*

Robert Veitch & Sons, Exeter.—*Catalogue of Bulbs and other Flower Roots.*

Dickson, Brown, & Tait, Corporation Street, Manchester.—*Catalogue of Dutch and French Bulbs.*

George Bunyard & Co., Maidstone.—*Catalogue of Roses, Hyacinths, and other Bulbs.*

Stephen Brown, Weston-super-Mare.—*Catalogue of Bulbs and Spring Flowering Plants.*

John Cattell, Westerham, Kent.—*Catalogue of Bulbs, Vines, Strawberries, &c.*

E. Webb & Sons, Wordsley, Stourbridge.—*Catalogue of Bulbs (Illustrated).*

E. Wilson Serpell, Plymouth.—*Catalogue of Bulbs.*

** All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Onions Failing (J. G.).—You had better sow again at once, taking care that you sow good seed this time; but in all probability the "sort that has

come up well" will afford sufficient plants, which if carefully transplanted in good soil will enable you to meet the demand for early Onions next summer. We have had the finest of crops by transplanting 4 inches apart in rows a foot asunder.

Beetles v. Strawberries (J. C.).—We are greatly obliged by your communications on this subject and the specimens you have sent; these shall be carefully examined and referred to with the publication of your letter.

Insects on Carnations (E. C.).—The flowers which you sent to us were seriously infested with the small black thrips, *T. cerealium*. They are very prevalent in some districts during the harvest period, and may be found in large numbers on Wheat, Rye, Grass, in fact on nearly all the cereals, also on Peas. It is not easy to prevent them attacking Carnations without more or less depriving the flowers of their beauty or perfume. Forceful and frequent syringings with pure water is a safe application and not ineffectual. A little pyraflin mixed in the water, or a solution of quassia chips, would also be useful in extirpating the insects.

Mackaya bella (Idem).—The principal object is to ensure the thorough ripening of the wood, which may be effected by placing the plant in a light position in the cool part of the stove, or in an intermediate house. It will only be necessary to cut out the weak growths, also removing any that are too crowded.

Peaches and Nectarines for Succession—Late Grapes (Subscriber).—The following will give a good supply of fruit over a very long period—Alexander, Hale's Early, Rivers' Early York, Early Grosse Mignonne, Old Grosse Mignonne, Royal George, and Bellegarde. A good later variety is Desse Tardive. We presume you intend growing them under glass, but you do not say so. If you require Nectarines, Lord Napier, Pine Apple, and Victoria are very good. You do not say how many varieties of Grapes you want, nor whether you require white as well as black varieties. The best and most useful decidedly late Grapes are Black Alicante, Mrs. Pince's Muscat, Alnwick Seedling, and Lady Downe's.

Grapes Splitting (Wanderer).—The Grapes sent in a flat round tin had been so shaken in transit through not having been firmly packed, as to arrive almost shapeless. The variety we think is Bidwill's Seedling, but we cannot be certain from an examination of such imperfect specimens. It is a very thin-skinned Grape and not worth growing. Probably if the Vine had been more heavily cropped the berries would not have split to the extent they have done. We should certainly not keep the Vine, as the space it occupies could be much more satisfactorily filled with a Black Hamburgh or other approved variety. The inferior character of the fruit is not your fault, but the fault of the variety.

Split Oak Fencing (Twelve-years Subscriber).—The best information we are able to afford on this matter is from a table in the "Gardeners' Year Book," under the head of "Fencing" on page 46. We find the price for 4 feet cleft oak pales, with two arris rails and oak posts 5 feet apart, fixed complete, per rod 37s.; pales 6 feet high with three arris rails, 55s. If a 1½-inch oak plank a foot wide is placed along the bottom, add 10s. This estimate is for the best material, and for fences such as are erected on gentlemen's estates in the country. We are informed that builders near London put up split oak fences 6 feet high at a cost of £1 per length of 3 yards, but we know nothing of their substance nor the materials that are used. You cannot do better than state your wants to a few of the principal builders in your neighbourhood, and ask them to furnish you with estimates for completing the work.

Propagating Lapagerias (F. C.).—Only a skilled propagator can strike cuttings of these plants. They are increased by layers, a shoot being laid on a bed of peat and pegged down at the joints, only half the leaf that is attached to each being visible above the soil. They must remain there a year, the bed being kept in a regular state of moisture the whole of the time. The plants grow freely in spongy peat and charcoal, the pots or beds being drained efficiently so that copious supplies of water can be given without making the soil sour. A cool greenhouse is suitable, and if not exposed to the full sun the plants appear to grow the more freely. We have seen them very fine on a north aspect.

Viscaria cardinalis (H. M.).—The above is the name of the annual of which you have sent flowers, and you ask if plants would "look well in a greenhouse?" Yes, if you can grow them as well as they grow in an open border; but you can scarcely do this in the summer, as the growths speedily become drawn and weak when the plants are placed in a warm house. We have had most attractive pots of Viscarias in the greenhouse by the following simple method of culture:—Sow the seed now in a shallow drill in an open position in the garden, and cover it lightly with fine soil. As soon as the seedlings can be handled thin them out, so that each plant stands separately an inch from the others. This thinning is important and cannot be done too soon. The plants so prepared will endure the winter safely, and when they fairly commence growing in the spring three can be placed in a 6-inch pot, using rich soil. Place the pots close to the glass in a very light frame, just protecting the plants from frost, and ventilate freely on every favourable opportunity, removing the lights during fine days in April, as the object must be to ensure steady and sturdy growth. Water the plants carefully at first, and copiously when the pots are filled with roots, giving liquid manure twice a week. By pursuing that treatment we have had beautiful masses of flowers in May, and the plants were much admired in the greenhouse. They must be kept in a frame until the flowers commence expanding. If you sow more than one row of seed the rows must be a foot apart.

Abutilon Thompsoni (P. D.).—This is an evergreen shrub with golden variegated or marbled leaves. Keep the plants rather dry and cool during the winter, prune in February rather closely, and continue rather dry up to March, when they may be watered more freely. When the young shoots are an inch long turn the plants out of the pot, remove most of the old soil from the roots, which may be trimmed a little, and repot in a size of pot that will hold the roots conveniently. Water carefully, but sprinkle the foliage with water twice daily, shading from bright sun until the plants have recovered, then afford a light and airy position, watering freely and shift into larger pots when good roots have been formed. A pot 2 inches larger in diameter may be given in April, and another shift in June. Stopping the shoots may be practised up to July, so as to induce the required habit of growth—bush or pyramid—tying out or down, and if this be done judiciously the plant will be ornamental to the end of the season. The foliage must not be allowed to flag for want of water during growth, whilst if the soil be made sodden it will not thrive. It is fine for covering walls and training to pillars in conservatories, also for flower borders. Sandy fibrous loam three parts, peat and leaf soil half a part each, with a free admixture of sand and pieces of charcoal. Cuttings of young shoots moderately firm strike freely in sandy soil in gentle heat.

Vines Unsatisfactory (F. J.).—The box arrived, but the lid and Grapes

appear to have been lost in transit. There was one leaf in the box much scorched, and this indicates that the ventilation has been defective. If the house is exposed to the early morning sun, and is not opened before nine o'clock, that would during hot weather account for the scorching and the unsatisfactory condition of the Vine. On bright mornings the top lights ought to be opened slightly two or three hours sooner. Possibly, too, you have not given sufficient water. Dig into the border to a depth of 2 feet, and if the soil is in the slightest degree dry give a heavy watering at once. The laterals should be thinly disposed so that the leaves of one do not overlap those of the other, and they should be stopped as frequently as is needed so as to secure the full exposure of the leaves to the sun. By adopting this practice, ventilating early and watering sufficiently with liquid manure if needed, the Vine, assuming that it makes fairly good growth, ought to bear useful Grapes. When the roof of a house is covered Vines on back walls seldom bear well. The Black Hamburgh foliage is very unsatisfactory, small, thin, and affected with mildew. Syringe with a solution of soft soap, and dust the leaves with sulphur. We feel convinced there has been some error in ventilation, if not in other points of management. Have you not a good practical gardener and successful Grape-grower near you who would inspect the Vines and give you advice thereon? If this course is practicable we think it advisable.

Forcing Roses in Pots (*A Constant Reader*).—You do not say whether you prefer Tea or Hybrid Perpetual Roses, but as you require them about Christmas you will have to rely upon Tea varieties for producing blooms at that season of the year. During winter "good blooms" cannot well be produced, but beautiful delicate buds may be had in quantity by growing such kinds as Safrano, Isabella Sprunt, and Duc de Magenta, which are only good in the bud at any season. The first two are decidedly the best for early flowering, and the first has the good character of unfolding its buds if cut in a very small state when placed in water. Niphotos, Catherine Mermet, and Rubens will form a good succession to the above, and flower profusely during the month of February. The best Hybrid Perpetuals are La France, Comtesse d'Oxford, Anna Alexieff, Jules Margottin, Alfred Colomb, Victor Verdier, Seneur Vaisse, Madame Lacharme, Magna Charta, Duke of Edinburgh, and Général Jacqueminot. The first three can be had in flower by the end of January, and the following three if started a little later will form a good succession; the remainder will bloom well any time during the month of March or April. The best way for you would be to obtain plants ready established in pots which are prepared in quantity, both Tea and Hybrid Perpetual varieties, by the majority of well-known nurserymen. These plants are not prepared and ripened sufficiently early to produce flowers at the time you want them. The Tea kinds might be obtained to produce flowers at Christmas if you obtain them at once and then keep them slowly growing, and to achieve real success they should be grown earlier each year and rested, when they will in a very short time flower almost naturally at the time you want the first batch to bloom. You will find a good practical article on producing Roses at Christmas in the Journal for December 25th, 1879.

Wiring a Vinery (*P. H. P.*).—We prefer having the wires stretched from end to end, parallel with the front and back plates. Galvanized wire will be safe provided it is well painted. In some districts it is injurious when not painted. The size of the wires is not material, this depending on the number of small rods that are screwed into the rafters or sashbars, the rods having eyes at the end for supporting the wires. In the large vinery at Longleat, where neither the Vines nor bunches are pigmies, the wire is not much thicker than a stout knitting needle, and the lines are 10 inches apart. They should be 18 inches from the glass if the height of the house permits; many Vines are injured by the foliage crushing against the roof. It is quite immaterial whether you plant five or six Vines; there is room for six, and the shade which they cast on plants does not depend so much on the number of the rods as on the laterals that proceed from them. If you have six Vines and the laterals are not nearer than 2 feet apart, you will, with good culture, obtain fine Grapes, while many kinds of plants will succeed in the house as well. The question of securing light for the plants is simply one of thinning and stopping the laterals.

Furnishing Orchard House (*I. E.*).—We can now quite understand your proposed arrangement, the plan making it quite clear. We have observed that owners of orchard houses have distinct objects in view. One cultivator requires the greatest bulk of good fruit, produced in the easiest manner regardless of the form in which the trees are trained, and of the varieties, provided what he has are good; the other finds much pleasure in testing varieties and systems, hoping also to obtain good crops. This is, as your plan suggests, the class of cultivators to which you belong. From that point of view your proposed method of furnishing the house is good, and we think it can be carried out successfully subject to one condition—namely, removing the trees, or some of them, in pots to a sheltered position in the open air to mature their fruit after it is set and the weather has become favourable. To leave all the trees in the house throughout the season would sooner or later result in overcrowding, and both the trees in pots and those planted out would sustain injury. The plan we have suggested of removing the trees in pots and plunging them in a warm position in the open air is practised with great success by Mr. Rivers at Sawbridgeworth, and he finds the plan in every respect satisfactory. The trellises across the back border, which we presume will be taken up to the roof, will shade the wall considerably; and instead of planting two trees at A, A, in your plan, we should prefer one placed in the centre of the space between the trellises to be trained as vertical cordons; you would thus have room for five trees exactly opposite the five trees in pots next the walk. These trees as they become large would undoubtedly shade the wall unduly, but we should prevent this by placing the trees outside in June, or when it would be safe and proper to do so, and by this plan you would insure a longer succession of fruit than if the trees remained in the house. For carrying out this plan successfully it is essential that the trees be not started into growth early in the spring.

Compost for Vine Border (*Amateur*).—We cannot do better than quote the reply to a correspondent last year who asked for a recipe for a first-class Vine border:—"As you require to know how to make a 'first-class Vine border,' we will state how the Vine borders at Arkleton were made, and append the results achieved by Mr. Dickson, the late gardener there. In the first place the borders rest on several feet of gravel, so that the important condition of perfect drainage is provided by Nature. The inside border is 14½ feet wide and 3½ feet deep; the outside border is of the same width and the same depth in front, and 2½ feet deep at the edge next the walk. The Vines are planted inside, and have free access to the outside border. The components of the soil are fibry loam of medium texture taken from an old sheep pasture, and to every twelve cartloads of turf were added two cartloads of old lime rubbish, one cartload of horse droppings, one cartload of charcoal, and 5 cwt. of inch bones. The turf was fresh from the field, mixed well with the other ingredients, and wheeled into the border without lying exposed. That may be taken as a first-rate recipe for a Vine border, judged at least by the following results, which are

certainly 'first-class.' In the year 1869, at the Edinburgh International Exhibition, the first prize was awarded to Mr. Dickson for a bunch weighing 16½ lbs.; in 1870 the first-prize bunch at the Royal Caledonian Society's Show weighed 19 lbs. 5 ozs.; in 1871 the first-prize bunch at the same Society's Show weighed 18 lbs. 7 ozs.; in 1872 the first-prize bunch at Glasgow weighed 19½ lbs. 6 ozs.; in 1873 at Manchester the prize bunch weighed 16 lbs. 1 oz.; and in the same year another bunch at Glasgow weighed 16 lbs. 10 ozs.; then came the bunch produced in 1875, weighing (by the Judges) 25 lbs. 15 ozs. We do not advise you to make the border its full width now. A width of 4 feet will probably be sufficient the first year, the front being supported with a wall of turf. If the soil is in the right condition as to moisture—that is, moderately moist but not wet—you may press it down slightly as it is placed in position, and it will not afterwards settle to do any harm. Making a border is only one element in Grape culture. If you would like fuller particulars of Mr. Dickson's practice you will find them recorded in Nos. 757 and 758 of the Journal, the issues of September 30th and October 7th, 1875. If you do not possess these numbers they can be had from the publisher, price 3½d. each." The most useful variety of Grape for an amateur is the Black Hamburgh, a Vine or two of Foster's Seedling being added if white Grapes are needed. The best time for you to plant Vines will be in the spring when growth is commencing; but the Vines should be had in pots this autumn, and be kept very cool during the winter. If the pots are plunged in leaves or ashes in a shed they will be quite safe.

Potting Liliams (*H. Jones*).—Pot them immediately after the flower stalks become yellow, and instead of taking the hulks quite out of the soil, turn the plants out with the ball entire. Remove the surface soil down to the crown of the roots, and cut the stalk or stems off at that point. Next remove the drainage and any soil that comes away easily. Clean the pot inside and replace the drainage with an inch of the rougher parts of the compost over it, work the soil carefully around the roots, and cover the crowns about an inch deep. The pot should be about three parts full, the remaining space being filled afterwards. We use a compost of two-thirds turfy loam a year old from decayed turves cut 3 inches thick, and one-third leaf soil or turfy peat, with a free admixture of sand.

Names of Fruits (*M. C. B.*).—The Peaches are not ripe. If the tree has small flowers the variety is Royal George; if large flowers, Early York. (*J. P. H.*).—The Apple is in all probability a seedling, and, although it may be useful and bear well in your district, has no commercial value. (*W. Watson*).—We seldom received fruits in a worse state by inefficient packing. The Apricot is possibly Brussels, the Nectarine is bruised beyond recognition.

Names of Plants (*C. S. D.*).—No. 1 is *Hypericum Androsæmum*. Its common name is Tutsan, which is thus quaintly explained by Gerarde—"The leaves laid upon broken shins and scabbed legs healeth them, and many other hurts and griefs, whereof it took its name Tout-sain or Tutsane—healing all things." The Welsh call it the "Blessed Groundsel" in reference to its reputed curative properties. No. 2 is *Potentilla argentea*, and No. 3 *Impatiens Balsamina*. (*Preston*).—The greenhouse plant is *Diplacus glutinosus*; the Orchid is *Maxillaria picta*. (*K. C.*).—We have many times stated that it is impossible for us to undertake to name varieties of florists' flowers, such as Zonal Pelargoniums. There are far too many so closely resembling each other, that the only satisfactory mode of determining the names of varieties is to compare them with those in a large collection. Florists from whom plants are purchased are usually able to supply the names of good specimens that are sent to them. All the petals had fallen from the trusses you sent to us; a little clear gum applied to the centre of each flower would have prevented this. The herbaceous plant is *Lychnis coronaria*. (*A. R.*).—1 and 2 are varieties of *Selaginella Martensii*; 3 is a *Begonia*, but, as we have repeatedly stated, we do not undertake to name varieties of the fine-leafage section. All *Selaginellas* are included in the order *Lycopodiaceæ*, and are correctly termed Lycopods, but not Lycopodiums. (*F. S.*).—*Achillea serrata* (Goose-tongue), an old garden plant now nearly lost, formerly grown in every cottage garden. (*H. J. G.*).—1, *Agrostis alba*, White Bent Grass; 2 and 4, *Agrostis canina*, Dog's Bent Grass; 5, *Festuca duriuscula*, Common Fescue Grass; 6, *Trisetum flavescens*, Yellowish Oat Grass; 7, *Glyceria fluitans*, Floating Meadow Grass; 8, probably an *Arundo*, a miserable sedge; 9, *Festuca pratensis*, Meadow Fescue Grass. If you send again we must ask you to submit better specimens. The others were not in a condition to be named, even if you had not exceeded the regulation number. (*F. L. P.*).—1 is *Phygelius capensis*, a native of South Africa, having been discovered in Caffreland about thirty years ago. It is included in the order *Scrophulariaceæ*; 2, *Plumbago Larpenæ*, also known as *Valoradia plumbagioides*, a Chinese plant. (*M. H. S.*).—*Scabiosa caucasica*.

POULTRY AND PIGEON CHRONICLE.

BREEDING HUNTERS AND ROADSTERS.

(Continued from page 189.)

It is no doubt true that breeding hunters and fast horses for profit can be best done on good grazing land; the home farmer must therefore, before commencing to breed horses for pace, consider the nature of the soil whereon they are to be reared, in order that the animals' health and beneficial growth may be assured as far as the soil can influence it. It is well known that sheep and cattle bred upon wet undrained land suffer from defects in their constitutions, having frequently diseased livers, defective feet, and that many animals, although well bred, often meet a premature death. Horse-breeding may therefore under similar circumstances be attended with many risks, which should be kept steadily in view. It should therefore be carried out upon land having a dry subsoil; the surface, moreover, should be fertile, abounding in carbonate and phosphate of lime. Upon this subsoil and this surface we have a right to expect full-sized healthy animals if they have been bred from sound parents. A very hot and dry surface with gravelly or sandy subsoil is not desirable, for these often produce animals with narrow contracted feet—a most serious defect in hunters, and roadsters especially. These observations, however, are more particularly applicable to stock reared entirely on pasture land after a certain age. Capital horses are, however, reared chiefly upon food supplied in their sheds and racks, having only for the purpose of exercise a paddock of good size and well fenced in connection. In this way the advantages are great and the risks less, for young animals so brought up are more docile and more easily broken in, and at the same time more free from accidental blemishes. We have frequently seen well-bred horses when allowed their range in pasture districts disfigured by blemishes, which in some cases may not injure their working powers, yet are sure to diminish their selling price.

Breeding horses, which is constantly resorted to by farmers, sporting men, and amateurs, all of whom have evidence to show that they can produce certain desirable qualities in the offspring which neither of the parents possessed. The mule may be referred to as an illustration on this point; for here we find the produce much superior in size, power, and action to the ass, whilst its powers of endurance under exposure to weather and privations exceed those of the class to which his dam belonged. This illustration is often taken as a defence for promiscuous intercourse, but the thoughtful business man will not be deceived, and still resort to his old and safe guide that "like begets like." Nor can mating the entire horse with the mare be carried out with success, as is frequently done in cattle-breeding—namely, to mate them so that the good points in one animal should cure the defects of the other in the offspring. But let it be borne in mind that in the case of horses, where perfection is the object to be attained, that both male and female in themselves should be as perfect as it is possible to obtain them.

The really good half-bred stallion—such as we used to meet with, with his large clean legs, well-defined knee, hock, and postern joints, with good head, shoulders, barrel, and hind quarters—is now become scarce. These horses when about 16 hands high formed a connecting link between the thorough-bred and the stronger classes; from such sires mares fit to breed hunters used

to be obtained, besides many of the most valuable horses in England for general purposes: but of late years, whenever such a stallion has appeared it has only been to be favoured with a few mares preparatory to his being exhibited, and then sold to go abroad. To find a really good half-bred stallion of this old stamp at five years old has been a rare occurrence during the past twenty years or more, even in the chief horse-breeding districts, such as Yorkshire, Shropshire, and Norfolk. Mares also of the stamp for producing hunters are at present very scarce, as may be inferred from the small number presented at exhibitions of general stock; yet with our climate, soil, and national resources the few good animals still obtainable for breeding would suffice for laying a foundation if we had a stud-book to encourage the production and recording stock of the right sort.

This scarcity of both stallions and mares is not likely to be altered unless we resort to the practice of former times, when Royal plates of £100 each were given for competition all over England for four-year-old horses carrying 10 stone 4 lbs.; five years old, 11 stone 6 lbs.; six, and aged, 12 stone, and decided in four-mile heats. The prizes then were a great inducement to breeders to rear animals of size and substance, and to keep them when obtained. As long as these Royal plates were given to horses carrying these high weights, strong thorough-bred horses were bred and kept, which, however, in the end broke down, and became the most valuable acquisition to breeders of horses in all parts of the country. Having become blemished they were no longer coveted by foreigners, and remained at home for the rest of their lives, helping to produce a race of horses with size, substance, blood, and action. On the rules and regulations of the Jockey Club will depend the extent to which good stallions in the future can be obtained. If two-years-old engagements were carried over to the third year, and indeed to the fourth year, the character of the blood horse would at once greatly improve. Again, modern steeple-chasing has drawn heavily on the supply of blood horses, adapted for country stallions. That sport, which formerly was intended to be a test for good riders across country, and also of the clever hunter, has to a great extent been the means of calling out the indifferent race horse to beat the horse really fit to be ridden to hounds, and therefore many good powerful blood horses have been converted into geldings which would have been extremely useful as stallions.

The eye is the best guide in estimating correct forms of the horse. Like the sculptor and painter, we cannot proceed far by measurement, although, like the artists, we can run our rule over one or two points, and then take in the details with the eye, commencing, however, with the feet, for the old saying is "No foot no horse," and then proceed to estimate the general outline and shape as adapted for our purpose. In Mr. Gamgee's essay it is stated—"When horses like Little Wonder and Daniel O'Rourke, that were sensibly under 15 hands high, are seen to outrun horses of 16 hands for the Derby, it is generally thought that the little horse has gained over the larger through his quicker movements, that more strides must be taken in one case than the other; or else that the lower horse keeps up the pace the longest, as is really the case, the larger horse being the weaker. But as regards the length of stride, the notion of the little horse having the shorter is very probably wrong, and when he has beaten the larger animal it generally is by his length of stride, and the same construction which gives that faculty confers the power to keep it up."

We must again refer to the giving of prizes, for we remember when a prize of £100 was given by the Royal Agricultural Society at Battersea, the best stallions were entered from all parts of the country; a Derby winner was entered to whom was awarded the prize. The object of the Society, however, was not obtained. It is not a winner of the Derby or St. Leger—a horse that will never be taken from his own stable door—that should come to an agricultural show, exhibit himself there, and walk off with the prize; but what is required is a good, strong, thoroughbred country stallion that is available for the use of the ordinary mares of the country. This prize did, it must be remembered, indicate a great fact, a hint suggestive of what may be done by the £100 prizes or Royal Plates being revived towards restoring our losses and bringing us back again to our original position. It has gone far to illustrate the great principle that such rewards are highly esteemed by the owners of valuable horses, and will induce them to keep and show them for such prizes, and it should be one of the conditions that such prizetaker should be available for mares at a moderate charge in his own district, for there surely is great need of them.

The country is so ill supplied with thoroughbred horses of the required stamp and type, that it is almost impossible to find a useful short-legged thoroughbred horse that can carry 12 stone across the country. This is a great loss, for with substance there

is no substitute for blood; there is no elegant carriage horse without it, no quick-stepping hack without it, and no fast-enduring hunter without a large portion of it. Our cavalry must feel this loss very much, for it ought not to be overlooked that blood gives pace, and that pace is power. In conclusion, we assert the remedy is in our own hands. Let Her Majesty's plates of £100 be re-established for high weights and long distances, let the princes of the realm throw their influence into the scale, and the nation would soon respond to the example. It is a national subject, and worthy of all the patronage which can be bestowed upon it. The agricultural societies of the United Kingdom should follow on with the Royal Agricultural Society, and call for weight-carrying thoroughbred stallions. We may thus recover what we have lost, and again obtain a sufficient supply of the description of horses so needful for doing good service throughout the country. We cannot conclude entirely without stating that for some of the ideas and plans suggested we are indebted, not only to J. Gamgee, sen., of the New Veterinary College, Edinburgh, but also to the Right Hon. John Evelyn Denison, both of whose essays in the Journal of the Royal Agricultural Society for the year 1863 will be found well worth perusal.

WORK ON THE HOME FARM.

Horse Labour.—In all cases where the Wheat stubbles are foul with couch the land should be autumn-fallowed; but the manner of doing the necessary tillage is important. Some farmers are never satisfied unless they plough the land deep the first time. Now in our experience this is wrong, for if the couch and black bent grasses are buried deeply it, as it were, doubles the work of cultivating to bring them to the surface again. In fact, they are not entirely brought up again, but the grass roots are divided and left in the land after much work has been expended. We have, therefore, always in commencing the work of autumn-fallowing, if done by steam power, cultivated long ways and cross ways, with the cultivating tines on, to the depth of the previous ploughings, and then comb out the lumps of couch, &c., with Howard's self-lifting drag harrow; we know of no other drag worth using in comparison with it for such a purpose. In case the work of autumn-fallowing is intended to be done by horse labour only we advise the raftering or half-ploughing, and after this turn the raftered furrows back again by what is commonly called back-stetching. This moves the whole of the surface; but it should not be raftered too deeply. After a drying day or two the land will work freely, and should be dragged across first, and then twice more, reversing the direction of the first work by transversing the direction of the dragging, which will then, if the weather has been favourable, have reduced the fallowed surface into a condition ready for the use of the roller and harrows. Much extra horse labour may, however, be saved by carting the couch away, although some earth may still be attached to it without continuing the tillage labour to reduce the grass into a state to burn, and which in the event of rainy weather succeeding cannot be done. After couch has been carted away to heap to rot or laid at once on to pasture land the fallow may remain until after Wheat-sowing has been completed; it may then be deeply fallow-ploughed to lie during the winter.

It is now time to arrange the acreage for green crops required now to be sown with seeds of Trifolium, Winter Vetches, Rye, and Winter Barley. These, however, should be sown on land quite free from couch. Previous, however, to seeding for the green fodder crops stubble Turnips should have been drilled with artificial manures upon land intended for Mangolds next year, so that they may be fed off by sheep or reduced by grinding and ploughed in as manure, which plan will wonderfully forward the tillage for Mangolds, and manure it also to a certain extent. We will suppose also that Mustard seed has been previously sown on the fallow break upon land coming in for Wheat, in order that the green crop of Mustard may be ploughed in before sowing the Wheat at about the middle of the month of October. In seeding for Trifolium, if a succession of spring and summer fodder is required, three sorts should be sown. The quantity of seed should be 25 lbs. per acre, especially as this year the seed is cheap. For earliest growth we like the early crimson variety; second early, the pink blossom sort; and for the latest use as green fodder up to a week or ten days in July we prefer the perfect white-blossomed variety as being the latest for green food we have ever grown. Too much seed cannot often be sown, for it has many enemies, especially the small white slugs, for we have known the first and second seeding carried away by them after seeding with 20 lbs. and 25 lbs. per acre respectively, and we have afterwards succeeded by sowing 30 lbs. per acre as late as November 13th. In sowing Rye we like the Giant or St. John's Day sort, and when it is saved for seed the bulk of grain will be greater than the ordinary variety, and the straw, which is very long and strong, is very much more valuable than that of any other cereal. Winter Vetches, too, may be sown so as to secure a succession, because the early sort, which is a small grain as compared with the ordinary variety, comes in for feeding a fortnight earlier—a matter of importance in some seasons both for cutting up as green fodder either for horses or cattle as well as for folding off by sheep.

Hand Labour.—Men will now be employed in hoeing the late Turnips. The women will be employed in forking out couch where there is but little either in the stubbles, or anywhere else in fact;

for a few shillings per acre spent in this way not only saves much horse labour, but it frequently forwards the seed time in the spring, also for the various crops; besides which, forking out couch can be done in any weather, whereas working it out by horse labour can only be done in favourable weather. Some men will now be employed filling manure cart from the yards and cattle boxes to be laid out and spread immediately on the lea ground intended for Wheat, and to be ploughed in as soon as possible, in order that the Wheat may be sown on a stale early-ploughed furrow.

Live Stock.—The ram sales are now nearly over of the Hampshire and Sussex Down flocks, but for the Shropshire Downs and all the long-woolled breeds the sales are on. The sales of all sorts have realised more money than those of last year, and we are pleased to find that the health of the flocks and freedom from lameness is very marked and decided as compared with many years past. The ordinary off-going flocks, either of horned Dorsets, Long-woolled, or of Down sheep, are all selling at very high prices, such as ought to make the home farmer and agriculturists in general ask themselves the question, Can they pay for fattening at such prices as they are now making? Let men of business make careful calculations as to the cost of fattening sheep or bullocks where not only hay is added to the roots for the purpose, but cake of either linseed or cotton sorts to be added also; and take notice also of the money invested, and the time before the money as regards manure obtained is returned, and the interest it gives for investment; and after having made fair calculations as to the facilities for obtaining artificial manures, ask the question whether manure cannot be bought cheaper than it can be made by cattle-feeding? We call attention to these matters because it is not only a matter of extreme importance, but of great interest to the home farmer. It also requires an intricate calculation to decide the matter without bias, and in perfect fairness as a matter of business; for why should parties blindly follow, without making such calculations as the case may require, an old traditional system of feeding stock, without reference to the peculiar circumstances by which the cases are surrounded, not only as it affects the profit on stock, but also the profit on the production of corn?

CROPS IN NORTH DURHAM.

THE fate of the fruit has long been known, but the hopes and fears of the success or otherwise of the harvest are now absorbing every man's mind, even to the exclusion of Egyptian matters. Two weeks of bright warm weather, following suddenly a two-months spell of showers, has made a wonderful change in the appearance of the country. Corn is rapidly changing its colour; and although a field or two has been cut, the harvest will not be general in this cold bleak country for a fortnight. The change has been so sudden and so marked that the farmer's especial trouble just now—and he always has one on hand—is that grain may be prematurely ripened, and the yield light consequently.

Potatoes are looking well, but from what we hear the yield will not be an average one in quantity, but quite up to, if not beyond it, in quality.

Turnips are a great success. The showery weather of late has benefited them in a most marked degree; and now that the land has got warmed by the hot sunny days of August, we may expect a more than average crop.

Mangolds are not much grown in this thin soil, and what I have seen of them are not looking at all well, though I am told that there are some excellent crops further inland, a statement which is most likely to be true, as Mangolds like the alluvial vales.

Beans are said to be the crop of the year, but not many are grown.

Hay is all harvested, and the aftermath, or "fog" as it is called here, is growing abundantly. Second crops of Clover are especially good—a great boon to the dairy farmers in this populous neighbourhood, where there is an almost continuous demand for green food.—PETER FERGUSON.

SCOTCH HARVEST PROSPECTS.—A Glasgow telegram says:—"Reports published concerning the harvest prospects in Scotland state that the hay crop is one-fourth above the average, that Turnips everywhere are a full crop, and that all kinds of grain are better in quantity and quality. Potatoes show considerable evidence of disease, which will increase if the weather is wet. It is estimated that the Scotch harvest, including Turnips, is five millions sterling better than last year."

CANADIAN AGRICULTURE.—The report of the Minister of Agriculture of Canada for the year 1881, states that the exportation of cattle through Canadian ports, principally to Great Britain, were 45,535 cattle and 62,401 sheep. A large importation of Clydesdales has been taking place, and the first-prize horse of this class at the late Reading Show has been forwarded to Canada. The export of phosphate of lime also increased from 12,000 tons in 1880 to 15,601 last

year, the value being 239,493 dols. The total emigration to Canada during the year was 47,991. The rapid extension of railways, particularly in Manitoba and the North-West, and the prosperous condition of the country generally, are also subjects of comment.

POULTRY AND PIGEONS

THE FATTENING OF POULTRY FOR THE TABLE.

WE will finish our articles on the fattening of poultry by giving a translation of a French author's directions for funnel-feeding. We have seen it practised on young Pigeons in Italy, and a very neat and rapid method of feeding it seemed, only in their case hard grain and water were given separately instead of a soft mixture as in this case.

"The third method," he says, "is funnel-feeding—*i.e.*, the forcible administration, by means of a funnel, of farinaceous food in a liquid state. This latter method is sure in the end to prevail generally, so simple is it, so easy, and so quickly performed. The fatterer procures barley meal, not crushed barley, for the meal must not have any husk in it, but must, on the contrary, be well sifted. This is mixed smoothly into milk and water in equal proportions. The paste must be of the consistency of clear pap just put on the fire, and there positively must not be more than half milk, for experience proves that if more is put in the fattening process stops at the end of a few days, and the bird soon dies.

"Next a funnel of white metal is got, which will hold as much as any chicken requires at a meal. The pipe of the funnel which goes into the bird's mouth is cut off diagonally; its edges are rounded back, and finished off with a little pewter mouthpiece to make it soft. A small ring is attached to the funnel just below the rim of its large end for the forefinger of the right hand. Its position is specially important, for while the head of the fowl is held in one hand, with the other the funnel must be properly inserted, which is quite easy when the ring is properly placed. The opening at the bottom of the funnel (which, as we have said, is cut off diagonally) must be turned towards the operator, and for this reason the ring must be fixed to the large end of the funnel somewhat to the right of the lower mouth as one looks upwards. Those who are well accustomed to it use the funnel without any risk, but people who are not used to it are in some danger of injuring the gullet. It is well, then, to put some indiarubber round the mouth, and so obviate all possibility of accident.

"All this is very simple, and I only dwell upon it just to explain it thoroughly, which is very important. The paste is put in a vessel, whence it can be easily taken up in a deep spoon. As soon as all is ready the bird is seized by the wings near the shoulders; its head is placed forwards between the operator's knees, so as to get tight hold of it without hurting or shifting it. It flutters a little the first time, but soon gets used to it. When it is quite quiet the right forefinger is passed into the ring, the left hand seizes the bird's head, its neck is stretched out, and its beak opened with the help of the right hand, which still holds the funnel. When the beak is properly opened they manage to keep it so an instant with the left hand alone, while the neck of the funnel is quickly put down the throat, care being taken not to hurt it. Then they take the paste and fill the funnel with it, but not to overflowing, the bird's neck all the while being stretched out. The spoon used for the paste is then replaced, and the right hand holds the bird's crop till it is perceptibly filled, which operation may be helped by the action of the hand. The crammed fowl is then replaced and another taken out.

"The quantity of paste which the funnel should hold and a chicken swallow is about one-eighth of a pint, but at the first meal not more than half that should be given, and the full amount not before the third day; after that more or less according to the bird's strength. The meals are regularly given three times in the twenty-four hours, at intervals of eight hours—*viz.*, at six in the morning, at two in the afternoon, and at ten at night in town houses; at four in the morning, at noon, and at 8 P.M. in farm houses. To facilitate the operation of funnel-feeding, and to obviate accidents from forgetfulness or intrusion, which tire and harry the chickens, there should be a proper apparatus, according to the number to be fattened, consisting of two, three, or four coops, closely barred, and more than ten birds should not be put in each. These are put in a quiet spot, in a stable or some other place, with equable atmosphere and away from draughts. There should always be one unoccupied. When all is ready the bottom of the coops is covered with clean straw, and as the cramming is carried out each bird after being fed is put into the empty one

that the last bird had been taken from. This is continued till everyone has been changed into the next coop, and the straw is changed every day while each is momentarily vacant. The straw must be changed every day, for good feeders and those who fatten for them never allow the birds to remain on their droppings, for it imparts a disagreeable flavour to them. The progress of each bird must be watched attentively, and anyone which stands still must be killed. Only those, too, must be selected for this treatment which are in good case and health, for it would be useless to put up weak chickens, which, instead of fattening, would sicken and die. The duration of the process is from fifteen to twenty days, according to the habit and breed of the chickens; after that the birds would only go back."

These directions seem plain and practical enough, and we hope before long to give the system a trial. The rule of cleanliness is much more in accord with our own ideas than that given by our French authority with his directions for cramming with balls.—C.

COOKED MEAT FOR FOWLS.—It is too much the practice to feed raw meat to poultry, under the mistaken idea that as the worms and insects which they seize with such avidity are uncooked so should be any meat given them by their owners. But the early worm which Biddy takes in her empty crop—soft, pulpy, and crushed by the bill before it descends the gullet—is one thing, and the coarse, dry, stringy, fatless flesh thrown to them "in the rough" and the tough is quite another, even if the carcass of horse or sheep so bestowed is not still more objectionable on account of disease. True, these nearly "dry bones" may serve to while away a weary hour in the monotonous life of the poultry yard, and happily the fowls may labour under the impression that they are eating something, and so they may serve a certain purpose in the poultry world; but for real aid and comfort to the fowls, save all your refuse meat and buy in addition "liver, lights, head, and all," as the old story runs, from the shambles, and boil all together for two hours or more. Then chop finely, and mix with meal in the water in which they are boiled. This dry rich mess, showing bits of meat like the raisins in plum pudding, will be a dish fit to set before any "queen of the (poultry) harem," and she and her maids of honour will pay you for it in more than words, as your egg basket, high with pearls, will show on many a succeeding day.—(Poultry Yard.)

OUR LETTER BOX.

Love Birds (C. S.).—A change of food is acceptable to the birds and beneficial. Canary seed, millet seed, Indian corn, and oats being varied according to judgment, crushing the larger seeds if needed.

Lucerne Irregular (Dr. Mackenzie).—We have no doubt that the strips of land spoken of on which the Lucerne is of "double growth" is caused by two old banks and ditches which formerly existed and intersected each other, and that the banks were levelled and the ditches filled with the loose earth and vegetable mould. This is the cause of the deeply rooting plant like Lucerne making extra growth in the second cutting, as the roots are now working in the deep and valuable soil. We have plenty of instances on our own land which illustrates in the same way the advantages to be derived from deeply moved soil. We have thrown down many old banks, and ever since it has been done we can tell by the crops where the ditches formerly existed; nor can we by any amount of manuring obtain the same benefit that will be derived from deeply moved soil, especially in those cases where rich vegetable mould has been buried in the subsoil.

REMARKS.

20th.—Cloudy day, with sprinkle of rain in afternoon; wet night.

21st.—Fine, bright, windy day.

22nd.—Fine bright morning; cloudy afternoon; wet evening and night.

23rd.—Dull at first; fine and bright during the day with high wind.

24th.—Showery and cool, bright intervals; moonlight night.

25th.—Wet cold morning; bright afternoon and evening; moonlight night.

26th.—Fine and bright, few spots of rain at times; heavy rain in evening.

Mean pressure and temperature both considerably below those of the preceding week, and the temperature a little below the average. Generally a cool and dull week with a good deal of rain.—G. J. SYMONS.

LILIUM AURATUM IN THE OPEN BORDER.

THE cultivation of *Lilium auratum* in pots and under glass is now well understood and moderately easy; but though many hundreds of pages have been written on its cultivation in England in the open air, the conditions under which it will thrive and become permanently established are as yet imperfectly understood. For those who wish to try it in their gardens the first step is to obtain bulbs. Those grown in England from seed are to be preferred for many reasons. The chief of these is that they need be only a very short time out of the soil; besides, plants from seed generally possess especial vigour and vitality until they have attained their full growth; but the price of English bulbs from seed is generally so much higher than that of imported bulbs, and the number offered for sale in the market so much less, that most gardeners have recourse to the latter. For the last year or two the importations from Japan of *L. auratum* have been so large, and the price at which they have been sold by auction in London so low, that it has been worth while to buy, even to flower once, which, with proper treatment, most of them will do. Still, there will always be a larger per-centage of failures amongst those planted in the open ground than amongst those planted in pots and grown under glass. The plant is as hardy as a common *Crocus*, but is liable to decay if soaked with wet whilst dormant in winter. Another common cause of failure is thought to arise from imported bulbs being often dug up when in full flower and before they are ripe, and it is therefore better to obtain bulbs in January or February than to buy the earlier importations.

Having obtained bulbs, the best way to find whether they will do well in your garden is to try them in the ordinary soil, planting them with the crown about 6 inches beneath the surface, and placing some very coarse sand or fine gravel round them. My habit has been to plant at once in the open ground regardless of any consideration of weather. In January, 1880, I planted fifty bulbs when the ground was frozen to a depth of several inches, only taking care to remove all the frozen ground, and to fill up with made soil which was free from frost. These Lilies all lived and did as well as those planted at any other time. I do not approve of the plan of potting the bulbs as a temporary arrangement and planting them out in spring, because it is hardly possible to adopt it without causing some check to the growth—a matter which I am inclined to think more injurious to Liliiums than any other plants. Liliiums started into growth under cover ought not to be expected to do well unless grown under cover until they flower. If as many as 70 per cent. of those planted flower well you

may consider that the soil suits them, and hope that they may become permanently established; but if less than half of them flower, and most of those badly, you should try to find out the reason why they fail. If the subsoil is cold clay without any artificial drainage, or if the soil is shallow with red gravel underneath, or if the subsoil is saturated with water at any time of the year within 2 or 3 feet of the surface, it may be presumed that any of these causes prevent the Lilies from doing well.

A foot of drainage and 3 feet of good soil is sufficient to insure success as far as soil and drainage can do it; but for the exact composition of the soil it is difficult to give any rule. If the soil is heavy it should be lightened with coarse sand and leaf soil, until a spade may be driven into it without difficulty at any time during the driest summer. It is a commoner fault in the cultivation of *L. auratum* to have the soil too heavy and retentive than too light. If the soil is light on the surface and deep the bulbs will be encouraged to make long roots, and nothing seems more important to the welfare of these Lilies than this habit.

If the bulbs are examined at the end of the first season's growth it will be found that many of them have made no roots at all from the bottom of the bulb, but only stem roots round the base of the flower stalk and above the crown of the bulb. These roots nourish the leaves and stalk, but play no part at all in forming a new bulb for next year's flowering; the consequence is that the whole plant perishes as soon as the flowering is over. To establish the plants permanently everything should be done to encourage roots below the bulb, and not above it; rich soil should be put beneath it, and sand and poor soil above it. It is true that by rich top-dressing and surface soil you will do much to develop the flowers of the year, but if you look forward to next year you must consider how to cause a bulb for next year's flowering to be formed. Some gardeners have a theory that the imported bulbs contain the germs of two years' flowering, and that after the second year they will die; but I find that if the stem comes strong and healthy the second year the plant is likely to be permanently established. If it comes weaker than it did the first year it is likely not to appear at all afterwards.

As regards the position in the garden in which to plant *L. auratum*, we are often told that they like shade; but the more I see of them the more inclined I am to think that in the English climate it is not easy for them to have too much sun. Shelter no doubt is good, and vacant places in *Rhododendron* beds, where the young growth is sheltered from parching winds and spring frosts, are good situations to plant them; but overhanging trees, which encourage damp and cause the air to stagnate, are favourable to a disease called "spot," which destroys the flowering of these Lilies. After trying every part of my garden I find that they do best in some exposed beds with 3 feet of moderately strong soil mixed with blocks of stone, and below that a foot of drainage. There they grow not more than from 4 to 5 feet high, making from six to ten flowers on a stalk; but up to this time—namely, the end of August, at which the flowering of many is past, they are quite healthy. Still, it must be confessed that the English climate, with its summer storms of wind and rain, is not quite suited for a flower so liable to be damaged by weather as that of *L. auratum*. The petals become blotched, and broken, and stained with the brown pollen, and they seldom pass through a

season without looking as if they would like better to be under glass. Still, when circumstances favour them, they look so grand in a garden that it is worth while everywhere to give them a fair trial, especially when they may be bought at the ordinary price of a Dutch Hyacinth.—C. WOLLEY DOD.

MUSHROOMS FOR THE MILLION.

(Continued from page 170.)

SECURING THE CROPS.

WHEN Mushrooms are gathered for market it is important, especially in cold weather, that only a small portion of a bed be uncovered at once—not more than a space over which a man can conveniently reach. From this the produce should be quickly pulled and the covering material promptly replaced. If the entire side of a long bed or ridge were uncovered before commencing gathering it would be exposed so long as to cause such a loss of heat as would seriously check the succeeding crop and impair the value of the bed; while even if the weather were not cold, yet dry, there would be a loss of moisture that it is most desirable to conserve. Mushroom beds in bearing must always be moist, many being kept too dry; and it is decidedly faulty practice to expedite the escape of moisture from them, and then have to make good the loss with the aid of the watering pot, as this, to say the least, involves needless labour, while the beds are not in such a satisfactory state as they would have been had they not been permitted to become dry.

It is not unusual for 9 or 10 lbs. of Mushrooms to be secured at one gathering from the small space above indicated; and as these represent as many shillings, the work, if sometimes of a cooling nature, as it is during a period of frost and snow, is yet not disagreeable to the workman who is gathering his own crops. During mild weather in autumn and late spring it is customary, in the case of young beds, to clear off the crops twice a week. During colder weather or with older beds the produce is only collected once a week. As a rule a productive bed will yield ten gatherings, seven of them full, the first and two last lighter by comparison.

In securing the crops it is convenient, as has been previously suggested, for the workman to have two baskets, one for the cups and buttons, the other for the broilers. This separation, when the Mushrooms are first handled, results in a saving of time at the weighing table, a matter of some moment when several bushels have to be divided into pounds, arranged in punnets, and tied down separately in the shortest possible time. This is the form in which all Mushrooms are sent to market. They are packed with their stems entire just as gathered from the beds minus the soil that is drawn out with the roots, and which is shaken off as the pulling proceeds. They are snatched rapidly, and, as an inexperienced on-looker would think, roughly, from the ridges; the collector always having a knife in his hand with which, for the reason previously stated, he quickly scoops out the stumps of any of the clusters that snap off close to the surface.

RETAINING THE STEMS OF MUSHROOMS.

The retention of the whole of the stems obviously benefits the grower, as they materially increase the weight of the crop, and the practice is also advantageous to greengrocers and others who make large purchases in the market with the object of retailing the

Mushrooms to their customers. Consumers are in one sense, and that not an unimportant one, benefited, too, by the custom in question. No doubt there are readers who will be glad to know in what manner the two last-named classes can derive any advantage by purchasing what cannot be eaten, as before the Mushrooms are cooked the stalks must be cut off and thrown away—unless, indeed, they are utilised for making catsup, which is only practicable when they are collected in large quantities. The benefit arising from retaining the stems is this: Mushrooms keep sound and wholesome much longer than if the stalks were cut off. This is a distinct advantage to the retail vendor, as his goods are thereby rendered less perishable, and his liability to loss by a slow sale is materially reduced. If the vendor derives benefit by the freshness and good quality of his wares so also must the consumers, and by purchasing Mushrooms in their entirety he has them as far as is possible in possession of their full flavour; whereas if divested of their stalks a few days previous to use they are insipid if not worse, as their virtues have escaped through their wounds, incipient decay has been accelerated, their constituents have been changed, and their wholesomeness impaired. Fresh Mushrooms—true samples of the Fungus, *Agaricus campestris*—are quite safe; it is only false Mushrooms or stale Mushrooms that are questionable or dangerous.

DIFFERENT GRADES OF MUSHROOMS.

There are three distinct grades of Mushrooms in demand in the markets. These are known as Buttons,

Fig. 35.—Buttons.

Cups, and Broilers, and each is in request for different culinary purposes. "Buttons" are Mushrooms in embryo—that is to say, the cap of the pileus is united to the stalk, and the laminæ or gills are not visible. It does not matter what the size of these young Mushrooms may be, whether of the dimensions of a small Cobnut or a large Walnut, if the gills are veiled they are still buttons. "Cups" are a step advanced in development. Immediately the membranous covering that unites the hood with the stem breaks, the term "buttons" is no longer applicable, and the young Mushrooms are recognised as "cups," but only retain that designation so long as they are unopened and do not show more than a ring of the laminæ half an inch in diameter. When they expand fully and assume the form of an inverted tea-saucer, showing the gills clearly, they are matured for culinary purposes and become broilers; but they are not perfect for the purpose of reproduction, as spores are not distributed until the laminæ have changed from a lively pink colour to a brownish black, and they should be gathered, sold, and eaten before that change occurs.

RELATIVE VALUE OF MUSHROOMS.

As there are different grades of Mushrooms so also these grades have different values. As a rule, when large Mushrooms or broilers realise 1s. per lb. the cups will sell for 1s. 3d. and the buttons for 1s. 6d. It does not follow, however, that the latter are the more profitable to the cultivator. Probably the reverse is the

case, as the enormously greater weight of the broilers more than compensates for the reduction in their value as determined by their price per pound; but even here there is a set-off, as if no buttons were gathered, but all were allowed to expand, the beds would be more quickly exhausted, and instead of yielding nine or ten crops they would probably only produce six or seven. The practice, then, of gathering all the grades is a safe one, and, as has been shown in preceding pages, is sufficiently profitable, while the market demand is met in a manner that is satisfactory all round. It is well, therefore, when securing the produce to clear all off that is readily marketable either as buttons, cups, or broilers.

The different grades of Mushrooms are represented in the annexed engravings, which also show the manner in which the produce is arranged in punnets. Fig. 35 indicates buttons; fig. 36 cups, and fig. 37 broilers.

Fig. 36.—Cups.

Details of the methods of packing and preparing for sale will be given in the next and concluding paper on this subject.—J. WRIGHT.

(To be continued.)

BETTER EATING STRAWBERRIES.

I SEND you specimens of the beetles which eat our Strawberries. The largest one of the three is, we consider, the principal offender, and up to the present year has been most numerous, but this spring No. 2 has been more often met with; in fact, we could not move a tile, heap of rubbish, or a mat without finding specimens in concealment there. No. 3 is a bright-looking active little fellow, by no means easy to catch; in fact, they are all very nimble, and they are, moreover, scarcely ever to be seen in the open by daylight. No. 1 is probably identical with "E. D's." "black bob," but it would be interesting to know if any of those I send are the same as the species which has eaten your correspondent's fruit.

A striking illustration of the love of these beetles for Strawberries was afforded us this year. The fruit from some young plants which we did not wish to bear was cut off when about three parts formed, and was left lying on the ground in a heap, becoming accidentally covered with weeds. A week or so afterwards the rubbish was cleared away, and on less than 2 feet square of ground were upwards of a hundred beetles, attracted there by the Strawberries, every one of which was more or less eaten.

I see that a correspondent speaks of weevils having been found in Strawberry beds; we have them also, but with us they do not attack the fully formed berries, but come on the plants when in flower, eating away the embryo berry. Last spring this pest threatened to become very troublesome, as, although its ravages were plainly discernible, it was scarcely ever to be seen during the daytime, but we eventually got rid of it in a rather curious manner. The frames being pulled off on mild mornings for several hours, we noticed that the sparrows made a point of visiting the plants on those occasions; and as we were well acquainted with the fact that the sparrow is as fond of insects as of grain, we did not disturb them, with the result that in a few days they cleared off the weevils. For the future we shall know what to do. We shall leave our friends the sparrows to deal with this pest. How I wish they could come at the beetles.—J. CORNHILL.

[The specimens were submitted to our entomologist, whose remarks on the subject are as follow:—

The beetles kindly forwarded by Mr. Cornhill and numbered

1 and 2 belong to the genus *Pterostichus*. No. 3 is an *Amara*—the identification of the exact species must be left for the present, as in this difficult group it could not be made without a larger number of specimens. All the three are ground beetles or *Carabidæ*, and are similar in habit. The small one belongs to a small group called "sunshiners," from their frequently showing themselves when the sun shining upon their wing-cases exhibits them to advantage, and there is an old superstition which I may mention that it is very "unlucky" to kill an *Amara*. Concerning the attack made by these species upon the Strawberry, I would remark firstly that it was a likely circumstance to arise from the greatly increased culture of this plant that we should discover it had enemies previously overlooked, or had attracted to itself new depredators. The *Carabidæ*, as a family, prey upon other insects and upon molluscous animals (snails, slugs, &c.). These latter are, as we know, constant pests in our Strawberry beds. In search of their wonted food these beetles would naturally resort to the places where this might probably be obtained; nor is there anything exceedingly unusual in a carnivorous insect devouring fruit. The instance of the wasp occurs to us at once. Partial to our fruit as the insect is, it is also a wholesale slaughterer of other insects that it can conquer. Few creatures, again, are more indefatigable in hunting their prey down than are the centipedes, yet one of these revels in a ripe Peach or Plum.

Now in dealing with such a case as this it is important to distinguish between what may be accidental or temporary and what is fixed habit. These beetles and their near relatives have been for many years reputed to be useful in gardens rather than injurious, because they kill a variety of species both in their larval and mature states. Are we as yet entitled to reverse our general opinion of them? If it were, however, considered needful to extirpate them from the garden, no method would be satisfactory, I suppose, which only dealt with the beetles. The burrowing larvæ or grubs would have to be destroyed on some one of the plans adopted in the case of the wireworm and other hard-skinned subterranean feeders.

As the subject of beetles attacking Strawberries is now under notice I may mention that *Phyllopertha horticola*, also called the June bug, Bracken clock, or by anglers "Cockerbundy" (a corruption of a Welsh name) is an old offender. In the "Magazine of Natural History" Mr. Bree writes: "Being on a visit to Staffordshire in the month of June I observed whole beds of Strawberries likely to prove nearly barren, though they had flowered copiously and the season was favourable. I was informed that the failure was owing to the 'Bracken clock,' which is accused of eating the anthers and interior parts of the blossom. In the same garden my attention was called to the ravages committed by this depredator on the Apples by gnawing holes in the young fruit, which consequently dies or falls off. I had been previously aware of the insect's partiality for the buds and blossoms of the Rose, which it greedily devours."

Mr. Cornhill gives a very graphic description of his beetle foes.

Fig. 37.—Broilers.

Miss Ormerod and some other friends of mine are much interested in this matter, and we hope to throw more light upon it soon. Upon the remark concerning the "weevils" I do not comment, feeling slightly in doubt whether we both attach the same meaning to that word, though *Otiorhynchus sulcatus* at least does infest Strawberries during some seasons.—J. R. S. C.]

ROSE MADAME GABRIEL LUIZET.—In my paper in last week's Journal I stated that I feared this fine Rose was not a Perpetual. I have just received a note from Mr. G. Mount of Harbledon near Canterbury, whose name I mentioned in it, in which he says, "I have a plant growing in my garden which has now five buds on it, grow-

ing from shoots which have already given a bloom this year." This is satisfactory, and I hope others may be able to confirm it.—D., Deal.

FRUIT-PACKING IN MOSS.

THOROUGHLY dried and well-beaten moss is no doubt a good material for packing fruit with, but we have discontinued its use on account of the fruit tasting of it when packed in it any length of time. Last year we commenced using it for packing fruit for sending to Scotland, but soon had complaints that it tasted of the moss. Being unwilling to give it up we baked the moss in a slack oven and wrapped the fruit in double tissue paper, but this did not remove the objection, which was most perceptible in Peaches and Nectarines. No doubt the length of time the fruit remains in the packing material going from Worcester to the north of Scotland has something to do with it, as when sent only short distances the flavour of the moss is not noticed.—A. BARKER, Hindlip.

I THINK the flavour complained of in the Nectarines which I sent to the Fruit Committee at South Kensington may be attributed to the fact of their being eaten immediately after being unpacked. I have known Nectarines delicious and sprightly in the morning before packing being perfectly flavourless in the evening when taken from the box in which they had remained all day. I have used moss for packing for some time; when properly dried and prepared there is no better packing material.—T. FRANCIS RIVERS.

THIS year we sent a quantity of Peaches and Nectarines to London. Each fruit was wrapped in thin paper, and then packed in moss in shallow boxes. Once we heard that the fruits had a slight mossy flavour, and on inquiry found that those who were responsible for them at the other end only took a few fruits from the box as they were wanted, some of them being allowed to remain in the moss for several days; thus it was that the moss flavour was imparted. Were the fruits unpacked immediately on their arrival and placed in a dry position the flavour would be equal to any newly gathered from the trees.—J. MUIR.

HANDSWORTH SHOW.

THE nineteenth annual Exhibition of the Handsworth Horticultural Society was held on the 30th ult. Four capacious tents were erected for the exhibits and the shelter of visitors, and lucky it was the Committee were so prodigal in canvas, for from four o'clock in the afternoon till half-past six there was an almost continuous downpour of rain, though from the thousands of visitors who arrived early in the afternoon it is hoped the receipts will at least equal the expenditure.

The Exhibition was scarcely equal to some held in previous years. There was a falling-off in the gentlemen's gardeners' class, and the produce in the open class was not nearly so good as the Committee had a right to expect considering the liberal prizes offered.

Plants.—The premier prize of £10 for eight stove or greenhouse plants (open), four foliage and four flowering, was easily won by Mr. Shelley, gardener to Mrs. Hobson, Buntstones, Sheffield, with a capital group of well-grown evenly balanced plants, the most noteworthy being a grandly flowered example of *Miltonia spectabilis*. *Dipladenia Brearleyana* and the old but ever beautiful *Croton angustifolius* were also extremely fine. Groups of plants arranged for effect had a tent set apart for them. Four competitors entered the lists, none of whom displayed any originality of design, the form of the group in each case being a dwarf pyramid. The first prize of £8 was won by Mr. Keeling, gardener to David Ward, Esq., Sheffield, with a massive group. The second prize fell to Mr. Dore of Clay Cross, the chief features of his group being half-specimen *Crotons* and *Eucharis*; the edging of this group was faulty. The remaining two groups, which were scarcely less meritorious than the winning collections, were arranged respectively by Messrs. Benjamin Crossland, nurseryman; and J. Walker, gardener to B. P. Broomhead, Esq., Broomhall Park, Sheffield.

Mr. Walker took first honours in the gentlemen's gardeners' class for six stove or greenhouse plants, also for six exotic Ferns in the same class, specially noticeable being a splendid specimen *Adiantum farleyense* and *A. tenerum*. Mr. Shelley's exhibit of exotic Ferns are worthy of special mention, every plant being in the greatest luxuriance and without spot or blemish, and all nearly equal in size. The kinds were *Adiantum cuneatum*, *A. farleyense*, *A. gracillimum*, *Davallia Mooreana*, *D. bullata*, and *Pteris scaberula*. Mr. Foggin, gardener to Mrs. Wilson, Tapton, exhibited the best specimen *Fuchsias*, *Zonal Pelargoniums*, and British Ferns. Window plants, flowering and foliage, were fairly well represented in the cottagers' class; but their forte here as elsewhere is amongst the vegetables, the improvement in this department being very marked—a proof that flower shows have done a valuable work during the past twenty years.

Fruit.—This was fairly well exhibited in the open class. Mr. J. Ward, gardener to T. H. Oakes, Esq., Riddings House, Alfreton, carried off the first prize, £5, with a good all-round collection, consisting of splendidly coloured Bowood Muscats and good Madresfield Court Grapes, with fine Queen Pines, Peaches, and Nectarines. Mr. J. Keeling was placed second with a good collection, and he was closely followed by Mr. Webb, gardener, Kelham Hall, Newark, who had a dish of very fine Peaches in his stand.

For two bunches of black Grapes Mr. J. Simpson, Wortley Hall Gardens, was first with large compact bunches of Black Hamburgs, and well coloured medium-sized berries. Mr. Keeling was a very close second with Madresfield Court Muscat. In the class for two bunches of white Grapes Mr. Simpson was again first with not large but well-ripened examples of Muscat of Alexandria; Mr. Webb being placed second with much better bunches of the same variety, but several points behind in finish. Mr. Jefferson, Carlton House, Worksop, took first honours for two Pines with very fine specimens of Providence; Mr. Clements, Whittington Hall, Chesterfield, being second. For a dish of Peaches the prizes went in the order named to Mr. Webb and Mr. Ward; Nectarines, Messrs. Clements and Keeling; and Apricots, to Messrs. Webb and Ward. There was much room for improvement in the exhibits of fruit in the gentlemen's gardeners' class, the principal prizetakers being Messrs. Foggin, Verelst, and Pring. Vegetables were well shown by Messrs. Walker, Foggin, Penistan, and Crossland.

Cut Flowers.—These were well represented in the open class, the Hollyhocks being exceptionally good, the first prize for twenty-four being won by Mr. Boston of Bedale with a splendid stand. The same exhibitor was also first with twenty-four Dahlias and also in the class for twelve blooms. Mr. T. J. Wright of Doncaster was a good second with twenty-four Hollyhocks; whilst Mr. Henry Clarke was equally as good second with twenty-four Dahlias and twelve blooms. For twenty-four Roses, dissimilar, Mr. Proctor of Chesterfield secured the first position with a good stand; Mr. Holland, gardener to Mr. Duncan Gilmour, being second.

The extensive nurseries of Messrs. Fisher, Son, & Sibray were very generously thrown open to the public, who were not slow to avail themselves of so great a privilege, and it is said that there were quite as many visitors to the nursery as to the flower show. The plants in all the houses are in clean condition and robust health, particularly the magnificent stock of hybrid greenhouse *Rhododendrons*. In one house of cool temperature is a truly floriferous specimen of *Stephanotis*, which at the present time is a perfect sheet of bloom, as it has been during the months of August and September for several years. In another span-roofed house is an excellent lot of Vines in pots carrying six to eight good bunches of fruit. The kinds are Black Hamburg, Muscat of Alexandria, Mrs. Pince, Madresfield Court, Buckland Sweetwater, Gros Colman, Bowood Muscat, and White Frontignan. The pots, 12-inch, are not plunged, but have sheets of brown paper tied round them, which protect the roots from the too drying influence of the sun's rays. In another house is a good display of Orchids, amongst which are conspicuous *Mormodes pardinum*, *Miltonia Regnellii* pur., *Zygopetalum maxillare*, *Oncidium lanceanum*, *Dendrobium heterocarpum philippense*, *Lælia Dayana*, &c. Other houses contain sturdy batches of *Ericas*, *Epacris*, *Azaleas*, *Camellias*, Ferns, cool Orchids, and *Lapagerias rubra* and *alba*. *Hyacinthus candicans* with spikes 5 to 6 feet high was very effective. The arrangement and condition of the whole stock in the glass department reflects great credit on Mr. Williams, Messrs. Fisher, Son, and Sibray's propagator and foreman.

EARTH-CLOSET MANURE.

THERE is no discrepancy, such as "INQUIRER" suggests, between sound science represented by Dr. Voelcker, and sound practice as represented by Mr. Taylor. "INQUIRER" has simply not adverted to the quantities employed in each case. Dr. Voelcker was writing of applications of from a half ton to one ton per acre, and of a price of £1 charged per ton, and he showed that the real value of the manurial addition to a ton of soil was about 2s. But Mr. Taylor applies half a bushel, which may be taken as about half a cwt. per square yard, which is at the rate of more than 100 tons per acre, and would, at Dr. Voelcker's estimate, be worth above £10. Furthermore, in so large a quantity of good soil, containing also, as Mr. Taylor tells us, a quantity of burnt clay, there would be, apart from the manure, a very considerable proportion of fertilising matter which the copious waterings would wash into the border. But Dr. Voelcker in the same paper also anticipated the remark of Mr. Taylor, that the earth-closet manure from private houses is probably richer than that from prisons, and he gives an analysis by Dr. Gilbert of earth once used in a private establishment, which proved to be nearly two and a half times as valuable as that obtained from a prison. This value would make Mr. Taylor's application equal to £25 worth per acre. Or comparing the constituents of the earth-closet manure with those of farm manure, it would be equivalent to an application of 33 tons per acre of the best rotten farm manure, made under cover and by beasts fed on cake. This,

applied year after year, far from being an inadequate manuring, is an exceedingly heavy one. It would probably be even injurious were it not for the very copious waterings which Mr. Taylor gives in the course of the season, and which, being much more than the soil can retain, will wash the surplus of nitrogenous products into the drainage.

It is not everyone, however, who can obtain either carth-closet manure or farmyard dung in sufficient quantities, and even Mr. Taylor has been driven to supplement his supplies with Standen's manure; but between the natural and the artificial manures there is a distinction which it is important to keep in view. The former operate by degrees, as their organic matter decays, and by decay furnishes the soluble compounds of nitrogen which the roots take up. Thus there is no immediate risk from an overdose, and there is a continued supply afforded. But in the artificial manures the most active ingredients are usually extremely soluble; they are at once offered to the roots, and they are entirely washed out by one or two thorough soakings which descend to the drainage. Those who use them ought, therefore, to divide them into as many doses as there are waterings administered, omitting them of course when it is desired only to moisten but not to wash the border.

The principal manurial ingredients in Mr. Taylor's application would be furnished by the following quantities per acre—sulphate of ammonia 14 cwt. (or nitrate of soda 18 cwt.), bone meal $4\frac{1}{2}$ cwt., muriate of potash (80 per cent.) 10 cwt. These would be certainly hurtful quantities to apply in one dressing, but divided by 10 they would form a safe and beneficial application to be given five or six times in the season. Each would then be not very different from what a farmer would give once for all to a single crop, except that he would probably add, what might here usefully be done, a larger proportion of the slow-acting bones. Anyone can easily calculate the proportion necessary for his own border, but it may be taken as a little over 1 oz. of the mixture per square yard for each application; but to those who cannot make such a mixture for themselves I can strongly recommend the artificial manures compounded for Vines (as well as special manures for other garden crops) by Messrs. Arnold & Co., chemists, Guernsey. They are prepared by a good agricultural chemist with much care, so as to contain all the elements which each description of plant requires at its different stages of growth, and they are not charged at the prices of fancy manures, but at the actual cost of the ingredients, with a moderate per-centage to cover the expense of mixing and give only a fair profit. Such combinations of artificial manures have long been called for by gardeners, and I am glad of an opportunity to bear testimony in favour of some that are trustworthy.—J. B. K.

SELECTIONS OF SEEDS.

ALTHOUGH Mr. Bartrum (page 114) may not have made his case quite plain, nor stated his precise requirements, yet it is questionable if his grievance is purely a sentimental one, notwithstanding the critical remarks of "A PARSON'S GARDENER" last week. I think it will not be denied that purchasers do pay more than they used to do for "exercising their right of private judgment" in selecting seeds; nor can the increase in price be attributable altogether to bad harvest seasons, as if this were so the collections ought also to be dearer than formerly, which does not appear to be the case. Even the Peas which your correspondents recommends, presumably on economical grounds, were last year one of them 1s. 6d., the other 2s., and the third 3s. per quart; and I have a few years ago certainly purchased Champion of England for 1s., and Ne Plus Ultra for 1s. 6d. per quart. Other seeds, too, appear to have "crept up" in the same proportion; still the collections, at least according to the vendors of them, are better and cheaper than ever. There must be a reason for this disparity, and possibly a good one, but it is not familiar to cultivators.

It is, however, little use complaining. The articles are priced, and we do as we like about purchasing. Do we? In my case, and I am not alone, I must not exceed a given sum for seeds, and I do not do quite as I like, or I should spend more of my employer's money. According to some of the high-morality fraternity I should do wrong in that. But I am of opinion I do wrong as it is, for many a packet of seed have I bought and many a shilling have I spent for seeds out of my own pocket for sowing in my employer's garden. This is, I think wrong, and it certainly would not be done except as an act of necessity, and to keep things going as smoothly as possible. It is a wrong done to avert greater unpleasantness arising than paying a shilling or two, much as they might be wanted for other purposes. This is what I call "paying too dear for private judgment."

Collections were no improvement in my case, for I got so much

of what I did not want, and not enough of some things that were absolutely necessary. I eventually found a remedy, and that was to save seed of some crops instead of purchasing it. This I must continue to do so long as seeds cannot be grown and sold for lower prices than at present. Thinner sowing, too, will have to be practised, and half an ounce of seed bought instead of an ounce by those who either cannot or will not spend more than when money was more plentiful and seeds less dear. Perhaps as the present season has been fairly fine, the seed harvest may be better than usual to the advantage next year of both sowers and sellers. This, however, will scarcely explain the difference in price of seeds when selected by the purchaser and chosen by the vendor. Can anyone explain it for the information of—A POOR GARDENER?

THE ETHICS OF EXHIBITING.

WHEN I wrote some time ago on the ethics of exhibiting I stated that, as far as my experience went, there was less of dishonesty in flower shows than in most other competitive exhibitions; but this opinion has been rudely shaken by some things which I have seen and heard this year. I have seen, for example, in the month of August excellent Black Hamburgh Grapes and Nectarines exhibited by a cottager, in which case we must either suppose that a very wide latitude was given to the interpretation of the term "cottager," or else that the exhibitor's ideas of fairness were of a very shadowy character; but that is nothing to what I now subjoin. The following letter which I send you, having erased the names, was handed to me by a leading nurseryman, with permission to make what use of it I liked.

"Dear Sir,—I take the liberty of asking if you are in a position to supply me, on the 14th September, all set up on stands ready for show, the flowers named below; and if so your price, carriage paid here. If you cannot supply all please quote price for those you can. Terms cash before delivery. If you have one of your catalogues in print I shall be glad to receive one.—Faithfully yours, —"

"Twelve Dahlias, nine varieties; three ditto, fancy; three ditto, fancy; six ditto, three varieties; six cut Roses, six varieties; twenty-four ditto, twelve varieties; six Pansies, four varieties; six ditto, Belgian; six Carnations; six Picotees."

It will be readily imagined that a very straight answer to this was given, and in reply the exhibitor stated that it was entirely uncalled for, for that in the Society at which he exhibited there were two classes—one in which the exhibits were to be grown by the exhibitor, and in the other they might be obtained wherever he might be able to get them. I can hardly conceive this to be true; but if it is, and this should meet the eye of any of its managers, I hope they will see that nothing can possibly tend to injure a society so much as such a regulation, while it must demoralise the exhibitor and certainly do no good to horticulture.—D., Deal.

PROPAGATING BEDDING PLANTS.

THE time has now arrived when propagating for next year's supply of bedding plants must commence in earnest, for be it remembered one week at the present time is worth two or three later on. Where the work has not already commenced not a day should be lost. Perhaps it would be as well to say at once that these remarks are not intended for the professional man, but only for those who keep no regular gardener of their own, who have to do most of their own propagating in their leisure time.

For summer bedding first stand the Pelargoniums; and with these August is the best month for propagating. Not that they are difficult to strike at any time of the year for the practical man who has the necessary conveniences at hand; but because in this month the wood or shoots is in the best possible condition—i.e., half ripened, and the temperature of both soil and atmosphere is such as to induce the formation of roots in a very short space of time. Begin with the variegated section—bicolors and tricolors. Many persons insert these singly in thumb pots. With choice kinds and where a little extra labour is no object this is perhaps the best plan; but with older sorts and where the greatest amount of work in the shortest possible time has to be considered, the best plan undoubtedly is to insert a number of cuttings in 4 or 5-inch pots. In these they may be wintered and transferred singly into 60-pots in the spring. Other sorts—such, for instance, as Vesuvius—may be inserted in boxes about 18 inches long, 14 inches wide, and 4 inches deep: these when filled should contain from fifty to sixty cuttings each. Both pots and boxes should be placed on coal ashes outside till the end of September or the first week in October, when they should be moved into their winter quarters, which may be either a greenhouse or vinery, where they will be safe from frost. The best compost is two parts of finely sifted soil, one-fourth leaf soil, and one part silver sand. One good potsherd at the bottom of each pot will be quite sufficient. Cover with moss or fibry loam, and fill up with the above-mentioned

compost to within about an inch of the top; press it down quite firm, and insert the cuttings, standing the pots outside in the full sunshine. No watering will be necessary for a week or ten days unless the weather is very bright and warm, when, late in the afternoon, a slight watering with a rose pot occasionally would be suitable to keep the foliage fresh.

For the propagation of most other kinds of bedding plants which have to be kept in a greenhouse through the winter a frame and hotbed will be necessary. Such admirable directions have recently appeared in your columns respecting the proper way of making up hotbeds that I need not dilate on the matter here further than to say, Let the rank steam subside before inserting the cuttings, or disastrous consequences may be the result. An immediate beginning may be made with the undermentioned, all of which will need the aid of frames—viz., *Alternantheras*, *Verbenas*, *Ageratums*, *Coleus*, *Gazantias*, *Lobelias*, *Konigas*, *Mesembryanthemums*, &c. In addition to cuttings of these it is advisable—in fact some people adopt the plan in preference to autumn propagating—to lift and pot a few plants of each of the above: these will furnish abundance of cuttings in the spring. More drainage in the pots will be required for these than for *Pelargoniums*; indeed it might almost be said that half the success in striking the cuttings depends on good drainage. The pots ought, therefore, to be nearly half filled with potsherds, on which should be placed a layer of common moss. I may also add that 6-inch pots are generally employed for these cuttings, to be filled to within an inch of the rim with the same compost as that used for *Pelargoniums*, but with this difference—the pots must have a good layer of sharp silver sand on the top.

We now come to another class of plants—viz., those which will stand a few degrees of frost, and which may be propagated somewhat late in the season. Amongst these *Calceolarias* and *Violas* are perhaps the most important. The month of October will be quite early enough to begin with these. A cold frame, either turf or wood, is the best place to propagate them in. This should be filled to within 9 inches of the glass with half-decayed manure, being at the same time well trodden down. On the top of this place about 6 inches of the compost recommended previously, finished off with a good layer of sand, and smooth it with the back of a spade. Insert the cuttings in rows about 2 inches apart each way; give a slight watering through a rose pot, put on the lights, and keep the frame close. Shade from bright sun until the cuttings are rooted, after which air should be given on all favourable occasions.—H. J. H.

SOUND POTATOES AND THEIR CULTIVATION.

My Potatoes have again turned out a very fine sound crop. The early sort, Improved Ashleaf, was lifted at the end of July. Suttons' Reading Abbey, also a fine crop, lifted on August 14th. For main crop I have adhered to Suttons' Magnum Bonum, lifted August 22nd, which, as usual, has proved an immense crop—about six sacks from a bushel of seed. No sign of disease was detected in either variety. They were all planted during the first week in March, on ground which was cropped with green vegetables the previous year. I never use any manure in planting Potatoes; simply a good dressing of leaf soil, the ground having been well manured for green crops the previous year. I incline to the opinion, after many years' experience, that the great secret of success is early planting without manure. The soil here is a very dry sandy loam, on which the rain never rests, but percolates through it at once. I have been reminded by gardeners that early planting can only be carried out on dry soils. I am not in a position to dispute or corroborate such statements. If, however, my dry soil grows large crops of sound Potatoes without manure, why do they use large quantities of the latter on wet soils? The ground was so dry when my Potatoes were lifted that the tubers came out bright-skinned and clean. How seldom is this the case when they have been exposed to the heavy autumn rains.—W. G. Surrey.

HARPENDEN HORTICULTURAL SOCIETY.

THREE years of well-directed energy in the management of this Society have demonstrated that where all the promoters of an undertaking are zealous and work together with a good will, the ratio of success which can be achieved in a short time is not in proportion to the population of the district nor to the size of the town which may be the seat of their labours, but rather attends upon the organising powers of a few who are frequently in close association in public or private business; and to this must probably be attributed the prevalence and prosperity of so many of our good horticultural exhibitions in the smaller towns and even villages, when the larger cities and centres are often only able at best to make intermittent spurts. The Harpenden Society is fortunately in close alliance with

Rothamstead, the park of which adjoins Harpenden, and is under the fostering influence of Sir J. B. Lawes, Bart., and the able staff of the renowned farm and laboratory, the good results attending their labours and experiments having in many respects impregnated with science the whole locality; and at Harpenden almost every child, if not half a botanist at birth, soon receives his botanical baptism at school, where botany and horticulture are radically but perhaps insensibly engrafted with admirable results into the ordinary educational routine of the district; and it is not uncommon at Harpenden to meet with children who are not only able to identify plants but also the grasses, their habitats and uses, an advantage not possessed by all advanced botanists or by few experienced agriculturists.

The fourth Exhibition of the Society was held in Rothamstead Park on the 31st ult. The morning opening most auspiciously; but the afternoon belied the barometer, and unfortunately an almost continuous downpour of rain greatly marred the success of the Show as a holiday. Horticulturally, however, little was left to be desired, so complete were the arrangements. The show of plants although good was not one of the strong features at Harpenden, but some well-grown specimens were shown by Mr. G. Underwood, gardener to C. R. Fenwick, Esq., High Firs, Harpenden, who was first for the collection of twelve miscellaneous plants, and for the group of plants arranged for effect. In the former exhibit *Vinca ocellata*, *Dipladenia boliviensis*, and *Bougainvillea glabra* were very fine and well flowered. For twelve plants in 6-inch pots Mr. C. Pollard, gardener to J. B. Maple, Esq., Childwick Bury, St. Albans, was first, having lovely little plants of *Cyanophyllum magnificum* and *Pandanus Veitchii*. Ferns, especially the hardy varieties, were well shown; Mr. J. Freeman, gardener to W. B. Greenfield, Esq., Beechwood Park, Dunstable, being first for a collection of eight, containing a good plant of *Scolopendrium vulgare crispum*, and all being very clean and healthy. Zonal *Pelargoniums* and *Fuchsias* were both well grown and well flowered, although not large; the first prize for the former going to J. S. Hill, Esq., Hawkswick, St. Albans, in whose collection was a fine scarlet with distinct white eye, named Mrs. Whitley. For the latter Mr. J. Elmer, gardener to Mrs. Warde, Harpenden, was first; *Giantess*, *Enchantress*, *Rose of Castile*, and *Duchess of Lancaster* being very good specimens.

Cut flowers were largely and well shown, and were a striking attraction here. Roses came from Messrs. Paul & Son, The Old Nurseries, Cheshunt, and for the season were clean and in good colour. For forty-eight distinct blooms in the open class they were awarded the first prize. Amongst their best blooms were noticeable William Köelle, Charles Darwin, R. N. G. Baker, and Edouard Andre, all good new varieties; *Marquise de Castellane*, *Marie Baumann*, *Madame Margottin*, and *The Shah* were also conspicuous. Messrs. E. P. Francis and Co. of the Hertford Nurseries were very creditably second. For twenty-four varieties in the open class the Rev. W. H. Jackson, Stagsden Vicarage, Bedford, was first, having *Paul Neyron*, *Capitaine Christy*, *A. K. Williams*, *Marie Baumann*, and *Madame Lambard* very fine, and it is no discredit to the great firm who took honours in the larger class to note that Mr. Jackson's twenty-four were quite equal in merit to the best box of Messrs. Paul's forty-eight which adjoined it; size, substance, colour, and form, all being good points present in Mr. Jackson's stand. The same gentleman was also first for twelve and six varieties in the amateurs' classes with equally meritorious flowers. The best bloom, however, in the Show was one of *Senateur Vaise* in the stand of Messrs. W. Paul & Son of the Waltham Cross Nurseries, who had some very fine flowers, including six of *Marie Baumann*, which would not have shamed a July prize stand. They also staged some good herbaceous and hardy flowers, but not for competition, and in which a fine strain of French *Marigold* was noticeable.

The great contest of the day was in *Dahlias* between Messrs. G. Paul & Son, who appear to be new exhibitors in this department, and the veteran Mr. H. Glasscock of Bishop's Stortford, who had each magnificent stands of forty-eight varieties, and ultimately Messrs. Paul were placed first, and Mr. Glasscock second. In the first stand was a unique flower of Northern Spy, rich purple, tipped reddish pink, and fine blooms of *Christopher Ridley*, *Lord Chelmsford*, *Henry Bond*, and *J. Wyatt*. Amongst Mr. Glasscock's best flowers were *Mrs. Saunders*, *Prince of Denmark*, and *Lady Wimborne* (mauve). Mr. C. Turner of the Royal Nurseries, Slough, also exhibited a very fine stand of twenty-four, but not for competition. For twenty-four *Gladioluses* Messrs. Kelway & Sons of Langport, Somerset, were the only exhibitors; striking flowers in their collection being *Pitys*, bright vermilion with large clear white throat; *James Kelway*, *Egyptian King*, and *President*.

Herbaceous plants were well represented, Mr. J. Henshaw, an enthusiastic amateur of Harpenden, staging in an effective manner very showy collections, and for which he was awarded first honours in the open and amateurs' classes. In the former his flowers were *Dahlias Juarezii* (splendid) and *coccinea*, *Campanula pyramidalis alba*, *Lilium tigrinum splendens*, *Galtonia* (*Hyacinthus*) *candicans*, *Oenothera macrocarpa*, *Achillea Ptarmica fl.-pl.*, *Rudbeckia Neumanni*, *Coreopsis lanceolata*, *Tigridia pavonia*, *Gladiolus brenchleyensis*, and *Lobelia cardinalis*. Messrs. G. Paul & Son were second with a fine stand containing *Harpalium rigidum*, *Lathyrus latifolius splendens* of the deepest crimson, and *Stenactis speciosa*. Miss Debenham, Ivy House, St. Albans, was awarded an extra prize in this class, *Achillea rosea* being very showy in her collection. We have rarely seen herbaceous plants better or more effectively shown.

Fruit was not largely represented, but the collection of six varieties from Mr. Pollard, who obtained first place, contained fine Black Hamburg Grapes, Peaches, and Nectarines. For black Grapes Mr. G. Chuter, gardener to Captain Ames-Lyde, Ayot St. Lawrence, was first with well-finished Black Hamburgs. Very good Souvenir du Congrès and Jargonelle Pears, and Kirke's and Diamond Plums were staged, but the other fruits do not call for special notice.

Vegetables were largely contributed, and for the district, with the exception of Potatoes, were in fair condition. The latter were, however, rough and not clean. White Elephant as shown here and elsewhere was not white, but seems to be a coarse edition of Beauty of Hebron. Reading Russet, a good medium-sized, pinkish, flat Potato, one of Mr. Fenn's seedlings, was well shown, its skin russet, and apparently a useful Potato for general purposes. Mr. C. Pollard was first for the collection of twelve varieties, and Mr. Wilson of St. Albans for the six. For Peas the first prize was awarded to Mrs. Robinson, Harpenden, for Omega, a good sample of Telegraph being also shown. Cucumbers were generally coarse, the best brace in both classes coming from the Rev. W. H. Jackson. In the cottagers' department the vegetables were good. A very neat tray from Mr. J. H. Crawford, Cravell's Road, Harpenden, contained fine Telephone Peas, a few Tomatoes, Cucumbers, and other vegetables, all excellent and not too coarse. It is not often so good and regular a collection is seen in the cottagers' class.

In the miscellaneous exhibits single Dahlias were strongly shown, but not for competition, by Messrs. Paul & Son, Cheshunt; C. Turner, W. Paul & Son, and Mr. T. S. Ware, Tottenham; amongst the most striking flowers were White Queen, Cervantesii, Mauve Queen, Paragon, Dash, and Flower of the Garden (G. Paul). Good Zinnias were also shown by Miss Debenham and others.

For table decorations the first prize was awarded to Miss H. Field, Harpenden, for a light but replete table. For a vase of flowers and for a memorial wreath Miss Henshaw, Harpenden, was first in both classes. The best three buttonholes came from Miss M. Brown, Digswell, and ladies' dress decorations from Miss H. Sibley, Harpenden, all showing real taste, the dress decorations being effectively composed of *Lilium tigrinum* and *Rose Niphetos*, combined with *Adiantum*.

Wild flowers were largely and better set up than usual at exhibitions, the nomenclature and classification being generally correct. The prizes for wild fruits were well contested, but the exhibits did not indicate a correct appreciation of the meagre indigenous pomology of the district, many introduced species being represented, and a very wide interpretation of the term "fruits" being admitted. As will be seen, the Committee were rewarded for their spirited endeavours with a good competition, and Harpenden may be congratulated on the position it is taking in horticulture.

EXACUM MACRANTHUM.

A FEW weeks ago the plant, a spray of which is represented in fig. 38, was alluded to in a contemporary as a "beautiful new stove plant." The flowers are certainly most beautiful, but the plant is decidedly not new. On the contrary, it flowered in the Glasnevin Botanic Garden in 1853, and is figured in the "Botanical Magazine," tab. 4771, March 1st, 1854. Our engraving has been prepared from a flowering specimen, and, as will be seen, the flowers have a great resemblance to *Solanum*s, though the plant belongs to the *Gentian* family. They are about 2 inches in diameter, the corolla being divided into five broad ovate segments, slightly recurved, terminating in a rather sharp point. Their colour is almost of indescribable richness, being a rich indigo purple with a satiny sheen; the flowers, which are borne on a terminal corymb, being the more striking by the deep yellow prominent anthers. The leaves are opposite; those on the upper part of the stem being sometimes 3 inches long and an inch wide, tapering to both ends; the lower leaves are smaller and less pointed. They are bright green and slightly ribbed. The plant grows about 18 inches high, and succeeds in an intermediate house. It was found in Ceylon at an altitude of 6000 feet, and, though still rare, it is worthy of being largely increased and widely distributed.

FRUIT NOTES.

FRUIT of all kinds except Apples is abundant and fine this year, but there is a deficiency of flavour in most of it, arising from the low temperature of the dull wet summer. The contrast between the Apple crop of last year and this is remarkable; then we had trees crushed beneath the load of fruit, now we have hardly a fruit upon hundreds of trees. Exceptions to the general scarcity are few and far between, and they invariably occur in orchards thoroughly sheltered from high winds. I have only met with two such as yet, one in Sussex and the other in Berkshire. How thorough such shelter must be to be really effective was shown clearly and forcibly in the great storm of April 29th, a regular "Black Saturday," for many trees, but more scathing in its effects upon Apples and Oaks than anything else, lacerating

the foliage and destroying the entire crop of the Apples, and blasting the spring growth of the Oaks so thoroughly that they remained without a shoot or leaf till midsummer, gaunt and bare as though they were dead. Balmy genial midsummer! how its kindly vivifying touch brings life and fulness to much that was apparently dead and bare. The scars of spring disappear as though by magic; foliage perfect and abundant crowds the deciduous growth with a beauty and freshness not often seen in spring time.

That other fruits suffered in a proportionate degree to the exposure of the trees to the storm there can be no doubt, and many striking examples might be quoted. One of the most remarkable is that of two Plum trees, one a Golden Drop and the other a

Fig. 38.—*Exacum macranthum*.

Diamond, growing upon a gable of a lofty building here. The lower branches are screened from south-western winds by another building, and have plenty of fruit, but all those above the building have none. A row of pyramidal trees of various sorts of Gage Plums were very full of bloom, but exposure to the storm caused the whole of it to be swept away. In contrast to this some Rivers' Early Prolific much exposed had a heavy crop of fruit, so also have some Victoria Plums growing near them. Damsons are abundant, so also are Prince Englebert Plums.

Many sorts of Pears are very plentiful, Comte de Lamy and Jargonelle among pyramids. Upon a west wall there are full crops of Beurré Clairgeau, Fondante d'Automne, Doyenné du Comice, and moderate crops of Glou Morceau, Josephine de Malines, Beurré de Rance, Williams' Bon Chrétien, and Maréchal de Cour. Upon an east wall out of many I may select as having very full crops Citron des Carmes, Monarch, Louise Bonne of Jersey,

Beurré d'Anjou, Beurré d'Aremberg, Dana's Hovey, and Nouvelle Fulvie. Beurré de l'Assomption has some fine fruit of excellent flavour, much superior to any I have previously tasted. Such freaks of flavour-development are peculiar in a season remarkable for poverty of flavour; and, strange to say, I have never had such excellent fruit of Early Albert Peach from an open west wall before. The fruit is remarkably handsome, and is equally fine in size, colour, and flavour. Early Beatrice Peach was very good from an open wall, so also are Royal George and Belle Baucé. Early Rivers was ripe a fortnight sooner than usual; its fruit was large, poor in flavour, and had the stones split almost without an exception.

Nectarines are very plentiful on open walls, Lord Napier having rather the smallest crop, but the large size of the fruit well atoned for this. Rivers' White Nectarine, Stanwick Elruge, Violette Hâtive, Balgowan Pine Apple, Pitmaston Orange, and Downton are all good, and the trees have fully recovered from a severe spring attack of blister; I ought to have said the usual attack, for they rarely escape it.

Both Red and Black Currants had heavier crops than I had ever seen here before; Gooseberries, too, were very plentiful, and Prince of Wales Raspberries were remarkable for size and abundance. American Blackberries are just ripening, and are much valued as a preserve, a row some 70 feet long affording several bushels of fruit. They are planted in very rich soil, and are well worthy of it, for there is no wasted vigour among Blackberries—the stronger the growth the finer and more plentiful the fruit.

Strawberries in compact rows 2 feet apart had plenty of fruit, but much of it decayed before it could be picked. Single plants kept well apart certainly proved most useful this year. Both systems of culture possess peculiar advantages, the rows giving most fruit, but that of solitary plants ripen earlier and is not so liable to suffer from decay. In striving to accelerate and prolong the season of this favourite fruit plant early sorts upon steep sunny sheltered slopes, as well as out upon the flat open quarter of the garden, and late sorts upon north borders and under the shade of trees.—EDWARD LUCKHURST, *Sussex*.

A WEEK IN BELGIUM.

[THE SIXTH DAY—Completed.]

LAST days are often busy days—days of rush and bustle; much has to be seen and done in a little time. In this instance it was so. A rush round three nurseries, attending a funeral in one city, a show in another, and catching a steamer in a third, in the meantime traversing a distance of sixty miles, rendered it necessary to keep moving. A year has elapsed since then, and the holiday season has come round again. My notes, therefore, however long retarded, of the last day of a holiday trip will scarcely be unseasonable. After having referred briefly to the different establishments visited, it were ungenerous indeed to omit the last; and on the principle of better (or worse) late than never, I will record something of what I saw during

HALF AN HOUR AT Pynaert's.

Pynaert-Van Geert is the complete patronymic of this gentleman—under certain circumstances the wife's name being added to the husband's in Belgium—and under that compound his business is known throughout the civilised world. Still his establishment is not large; on the contrary, in comparison with our large English nurseries it is small; but mere extent of territory is not always an index of position, of which our own country, which is represented by a mere speck on a map of the world, forms a sufficient illustration.

Mr. Pynaert is not a nurseryman exclusively, but is a "garden architect" of great repute, or what we should call a landscape gardener. He is also, with M. Rodigas, an editor of an important monthly horticultural publication, the "Revue de l'Horticulture Belge." Thus Mr. Pynaert is a busy man—one of the working bees in the great horticultural hive of Belgium. He is frank and most pleasant withal, and gives an English brother of the craft and pen a warm welcome, greets him in his own tongue, makes him at home in a moment and feel as if he would like to stop longer and then go again. This is one of the penalties that all Belgian horticulturists incur, and is also why their recent visit to this country was so much enjoyed by all who had the pleasure of their company.

The nursery under notice is situated near the Porte de Bruxelles, Ghent, within gunshot of Van Houtte's, De Smet's, Dallièrè's, D'Haene's, and some others, for there appears to be a nest of them in this horticultural suburb of a horticultural city. And what is the nursery like? It is just like a fish. Imagine a huge fish laid on its side, about a quarter of a mile long, and of fish-like proportions, the flattened tail resting on the public road, a canal running round every other part, and you have the structural character of Mr. Pynaert's nursery, the north side being sheltered by a very high hedge. It would be like a fish out of water but for the life and activity prevailing. But what is there in it? Just where the tail narrows the commodious residence stands, and in the space in front a number of splendid match pairs of standard and pyramid Bays of various heights

and sizes are arranged, admirable in symmetry and excellent in health. These Bays are fine ornaments for terraces in towns where refreshing green trees are wanted and space is limited. They tone down the harshness of masonry where it cannot be clothed with vegetation, and impart repose to the surroundings of private homes and public squares. In the grand open space round St. George's Hall, Liverpool, a number of specimen Bays in tubs are arranged, and they add greatly to the appearance of the noble building, and render the square highly ornamental. But the position is too cold for them. The rough winds driving up the Mersey whistle through the comparatively narrow streets, and the beautiful Bays cannot endure without injury blasts so keen. This is a misfortune. Specimen Hollies would be better at Liverpool, and the Bays safer further inland. They require shelter in winter, and at Mr. Pynaert's the largest house is devoted to them, this building being of course empty in summer. But other houses are not empty.

Several structures are devoted to Palms, splendid decorative plants in exuberant health and rich colour. One house is filled with *Areca Baueri*, a second with *Phoenix reclinata*, a third with *Geonoma gracilis*, a fourth with *Kentias* in the different forms and so on—all the kinds in demand being represented. One span-roofed house was filled with *Gloxinias* planted out on ridges, as if they had been earthed up like Potatoes. Another large structure was devoted to *Clivias* (*Imantophyllums*), the finest and most complete collection of these plants I ever had the pleasure of inspecting. Their leaves were of the deepest green, and a few solitary trusses were 18 inches in diameter, the petals being 3 inches across. The varieties are numerous, Mr. Pynaert having devoted special attention to them, and during the flowering season the house must be grand. Other houses are filled with *Dracænas* and decorative plants of all kinds usually found in nurseries, and we must pass them to pause at the *Begonias*.

Ornamental-foliage *Begonias* are steadily increasing in public favour. They are amongst the finest of town and room plants, and the new varieties are beautifully marked. Mr. Pynaert has 150 varieties, several being planted out in side beds in the houses, and thousands in the course of propagation. A few striking varieties in this great collection were *Madame Bichol*, much mottled reddish veins; *Pluie*, marbled red veins; *Margaritacea*, dark leaves blotched with silver; *Madame Banchothe*, dark, wavy, silvered, free; *Argentea picta*, silvery green, mottled margin, distinct; *Teneque*, dark centre, wide silvery band, clearly defined, velvety margin, effective; *Robert Schumann*, dark centre, broad silver band, edge composed of two distinct shades of green, good; *Juliette Raulin*, silvery centre splashed with black, band red with white spots, edge maroon; *Lustre*, dark ground, colour densely spotted with white, silvery band; *Ed. Pynaert*, fine leaf, dark centre with clear silver marbling, edge still darker spotted with white; and *Madame Dehée*, compact, velvety leaves marbled with white, distinct. These are quite dissimilar from the familiar *rex* varieties, and the rich velvety and metallic lustre of their leaves command attention.

In frames were large numbers of *Tuberous Begonias*, *Cannas*, *Aspidistras*, and other plants in great demand; in beds, *Azaleas* of the *indica*, *pontica*, and *mollis* types (fine plants in good varieties), also healthy *Camellias*, *Choisias*, and *Rhododendrons*. In the open ground every inch was occupied with evergreens and ornamental trees (variegated and weeping), *Thuias*, *Retinosporas*, *Cupressuses*, *Weigelas*, the walks being margined with *Dentzias*, variegated *Spiræa japonica*, and hardy herbaceous and alpine plants. In fact, every part of the fish-shaped island was turned to the best account, indicating a brisk trade, and the order gave evidence of skilled supervision.

CONCLUSION.

And now having told something, but not all, of what I saw during my week's holiday, I will tell what I did not see. I did not see the wonderful examples of fruit culture on the railway embankments which we read about in books, for the best of all reasons—that there were no "embankments" worthy of the name, for the country is flat, while there is scarcely any margin of ground between the rails and the fence on the lines I traversed. Perhaps the culture in question is further south, and perhaps also it has been made the most of—on paper.

But while I saw little of fruit, forest tree culture was apparent enough. There are long lines of Poplar trees almost everywhere. By the sides of roads and ditches these trees abound. They are planted 6 or 8 feet apart, and grow rapidly. The Canadian Poplar is the variety selected. It is the most productive of trees in Belgium, and its value increases at the least one franc per year. In about thirty years the tree is fit for sale, and fetches generally from thirty to fifty francs. The wood is chiefly used as boards for packing cases, and in some instances for the manufacture of wooden shoes. The administration of many villages in the country plant Canadian Poplars on the public roadsides, and derive a good part of their income from them. In the Waes district between Antwerp and Ghent the proprietors abuse their privilege of tree-planting by surrounding every piece of land with Canadian Poplars, and the tenants are willing to pay a franc per year and per tree to get them away—so much amongst other things of the "paradise of small holdings."

I have found more than once that a week can be spent pleasantly, profitably, beneficially, and inexpensively along the eastern shore of the German Ocean. I wish more gardeners could enjoy such a holiday and experience such a change as they would find there, with strangers

all around them but friends on every hand. True they must cross the, at times, tempestuous sea, and take their chance of having a taste of the dreaded *mal de mer*. Once they have this they will have a "change" indeed, as on a never-to-be-forgotten occasion I bitterly experienced. What is it like? It is just like what Captain Marryatt has described of a terrible passage across the same sea, as follows:—"Paddle, paddle—splash, splash—bump, thump, bump. What a leveller is sea sickness—almost as great a radical as death! All grades, all respect, all consideration are lost. The master may summon John to his assistance, but John will see his master hanged before he'll go to him. He has taken possession of the master's great coat, and intends to keep it; he don't care for warning. Then the poor children. 'O lauk, Mary, do just hold this child,' says the upper nurse to her assistant, 'I do feel such a *sinking*.' 'Carn't indeed, nurse, I've such a *rising*.' A young lady will recline unwittingly in the arms of a perfect stranger, and the bride of three months, deserted by her husband, will offer no resistance to the uncouth seaman who, in his kindness, would loosen the laces that confine her heaving bosom. One would imagine that the passengers were so many pumps all worked at once by the hundred-horse engines of the vessel, for a hundred people were about me each as sick as a horse."

There is no exaggeration there, and the facetious captain wrote the "sober" truth for once. But let no one be deterred. The passage is not always so, but only occasionally, during the raging equinoxials of autumn. In the summer the sea is smooth and beautiful, and the boats better than they used to be. I was fortunate in securing the same favourite steamer home (the *Princess of Wales*) that took me out from Harwich, and steadily, smoothly, pleasantly, almost luxuriously, we glided into the familiar port once more.—J. WRIGHT.

We are informed that the entries of DAHLIAS for the National Show that opens on Friday at the Crystal Palace are more numerous than was expected; there is, however, plenty of room for all competitors, and the Exhibition will be a very large one. The display of single Dahlias will be by far the finest that has ever been seen. A good show of fruit is also expected.

— "A. B." will be glad to know "the name of some CHEAP WHITE GLADIOLUS, to flower along with *G. brenchleyensis*. He has seen one with a light crimson throat in gardens, which would do if he could ascertain the name. The flowers are just the same size as those of *brenchleyensis*." Perhaps some of our readers can supply the information requested.

— A CORRESPONDENT informs us that Mr. Bardney of Donington, near Spalding, Lincolnshire, planted on April 16th 3 lbs. of the WHITE ELEPHANT POTATO in two different parts of his garden—viz., 2 lbs. in one, and 1 lb. in another. These Potatoes were lifted on August 16th, and the produce from the 2 lbs. was 9 stones 2 lbs., and from the remaining 1 lb., 4 stones 5 lbs., the total yield from the 3 lbs. being 189 lbs., or 13½ stones, many of the tubers weighing 1 lb. and over, all being good and sound.

— THE WIMBLEDON AND DISTRICT ROYAL HORTICULTURAL SOCIETY will hold an exhibition of Chrysanthemums at the Lecture Hall, Wimbledon, on Wednesday, November 22nd, when prizes will be offered in fourteen classes, the most important being that for a group of Chrysanthemums in pots.

— THE WESTERN CHRYSANTHEMUM SOCIETY will also hold an exhibition in the Guildhall, Plymouth, on November 14th and 15th, when numerous prizes will be offered for Chrysanthemums, miscellaneous plants, and fruit. Several valuable special prizes are offered by gentlemen in the neighbourhood.

— MR. CANNELL has sent us blooms of new CONTINENTAL TUBEROUS BEGONIAS of extraordinary size and substance of petal, and of great richness in colour. The petals exceed 2 inches in diameter, and the flowers, which are described as "small examples," produced after the plants had travelled four hundred

miles, are nearly 6 inches across. We should like to see what Mr. Cannell regards as large flowers when they are produced by his latest introductions.

— THE INTERNATIONAL SHOW, which will be held in the Waverley Market, Edinburgh, on Wednesday and Thursday, the 13th and 14th inst., is expected to be of great magnitude and excellence, preparations having been made for submitting the best examples of cultural skill in the kingdom. The schedule includes 160 classes, or about ninety for fruit, fifty for plants, and twenty for vegetables. Without being of startling magnitude the prizes are liberal throughout, and sufficient to induce a brisk competition. If the Exhibition is even nearly equal to the grand display of 1875, the year of the last Edinburgh International, it will be worthy of a journey from the most remote parts of the kingdom by all who are interested in horticultural pursuits. A visit to the beautiful northern city is a treat in itself, and all the more enjoyable since Scottish horticulturists are proverbial for their courtesy and hospitality. We advise all who can do so to arrange for an inspection of the coming Show. Gardeners especially will admit the excellence of the rule under which they and their assistants are admitted from nine till eleven on the first day on payment of 1s. each, the Exhibition opening to the members of the Society at twelve and to the public at one o'clock.

— A CORRESPONDENT sends us the following note on CAM-PANULA PYRAMIDALIS:—"This species, both white and blue, is highly effective in the greenhouse and out of doors in the Cambridge Botanic Garden. Out of doors it is perfectly hardy, and has lately proved a valuable border plant, for which purpose it is not too often used. At the Trinity College Botanic Garden we saw it much finer, the moisture of the climate seems to suit it so much better. There it was simply magnificent, and at both places no more ornamental plant could be desired." Several plants of this Campanula are now highly effective in the new large herba-ceous bed at Hampton Court.

— LAST week completed the three months during which the INNER TEMPLE GARDENS, LONDON, have, by permission of the Benchers, been open to the public every evening from six until nine, a kindness of which many thousands of poor children from the surrounding close and crowded districts have gladly availed themselves; and it is satisfactory at the same time to be able to state that, notwithstanding the number of children who have nightly visited the gardens, there has not been a single instance of damage or injury occasioned by their presence. The next occasion on which the gardens will be opened to the public will be for the annual show of Chrysanthemums in November next, preparations for which are already being made. The flower beds in the gardens have been very beautiful this summer, and have fully equalled those in the parks. Their condition has shown what can be done with good plants and good management of rendering gardens attractive even in the centre of London.

— THE effects of the NEW PARCELS POST have already become apparent in the lowering of parcel rates by the railway companies, which date from the 1st inst. Their tariff is for parcels of 1 lb. weight and under, 4d. for fifty miles, and 6d. for all longer distances. For 7 lbs. the charge will be 6d. for thirty miles, 8d. for fifty, 10d. for a hundred, and any distance for 1s. 6d. The post office proposes to charge 3d. for any distance for parcels not exceeding 1 lb.; over 1 lb., and not exceeding 3 lbs., 6d.; not exceeding 5 lbs., 9d.; and from 5 up to a limit of 7 lbs., 1s. Thus for short distances the large parcels can be the most cheaply transmitted by rail, but for sending small parcels, regardless of distance, the post office scheme offers clear advantages. The plan of the railway companies of charging by distance as well as by weight is probably tentative, and it is not unlikely that ex-

perience will suggest to them the advisability of charging uniform rates for given weights irrespective of distance.

— MR. FERGUSON writes as follows on RHUBARB AND ELDER BERRIES—"Amongst other things that are allowed annually to go to waste nothing strikes me more forcibly than the quantity of Rhubarb that is unused every year. Tons of it all over the country lie and rot in the gardens of both the plebeian and the patrician. This ought not to be so. First-class jams and good British champagne can be easily and cheaply made of it. Nothing that I know of is much better drinking than good, wholesome, home-made Rhubarb wine; and in the homes of the poorer classes it would be much better and cheaper than much of the bad beer that finds its way there. I wonder very much that the wholesale jam manufacturers of our great towns do not use Rhubarb for making either Rhubarb jam, or for mixing it with other fruits, in preference to some of the unstateable ingredients that go to make up that curious compound sold in the shops as jam. It would be much more wholesome than some things we know of. Elder berries are another plentiful product in many places that are not made the most of. Like Rhubarb [they make equally good wine and jelly. In fact, for coughs and colds, and for all the purposes that Black Currant jelly is used for, that of the Elder berry is to be preferred."

— AMONG recent GARDENING APPOINTMENTS we learn that Mr. W. K. Woodcock, late gardener to F. Mappin, Esq., has been appointed gardener to Mrs. Mark Firth, Oakbrook, Sheffield; and that Mr. Robert Abbey has succeeded Mr. Young as gardener to Sir Henry Scudamore Stanhope, Bart., Holme Lacy, Hereford.

— A CORRESPONDENT writes:—"Those who desire to see a GRAND DISPLAY OF TUBEROUS BEGONIAS should visit the nurseries of Messrs. John Laing & Co. at Stanstead Park, Forest Hill. For sturdiness and vigour the plants are remarkable; while their floriferousness and the great size and varied colour of the flowers produce an effect that is at once brilliant and imposing." Relative to the plants in question, the proprietors of the nursery have issued a general invitation to all persons interested in these flowers to inspect the collection, whether they are purchasers of plants or not.

— UNDER the heading of "A WARNING TO EMIGRANTS," a Liverpool paper publishes the following:—"At the Birkenhead police court fourteen men were charged with being stowaways on board the steamer *Kansas* of the Warren Line, which arrived at Birkenhead from Boston on the previous day. One of them, a gardener named Cain, said he had been in America only since June, having gone out thinking he could get plenty of work. He could only earn 4½ dols. a week, however, out of which he had 4 dols. to pay for board. Other of the men made similar statements. The officer from the steamer said, on behalf of the Company, he must press for a penalty, as it was desired to make an example of the prisoners, there being so large a number. The Magistrate said the case of the men was undoubtedly very hard, and in some cases painful, but as the owners pressed for penalties he must send them all to gaol for ten days, with the exception of one man, who had stated that he was employed on the steamer to tend the cattle. The Magistrate hoped the case would prevent people from rashly going to America."

— SOME time ago a correspondent sent us the following extract from a Durham newspaper:—"A REMARKABLE ROSE TREE.—There is growing at the New Gardens, Whitby, a Maréchal Niel Rose tree which is exciting considerable interest from florists and horticulturists as well as from the general public. It was planted about eighteen years ago, and the present extremity of its growth horizontally is no less than 102 feet, being 48 feet to the left and 54 feet to the right of the parent stem respectively. The average

depth of the tree is between 6 feet and 7 feet. Last year 2500 Roses were plucked from it, but this season no less than 3500 were counted by the proprietor of the gardens, Mr. H. K. Williamson. It is said to be the largest and most prolific tree of the kind in the United Kingdom." Our correspondent adds:—"It would be interesting if we could give any further information as to the tree and its treatment. Although an old subscriber to the Journal, I do not remember having seen any record of a similar thing."

— THE value of FRUIT-GROWING, says a daily paper, seems to be understood in the eastern counties. In one district the production of Gooseberries has been of late years greatly developed. The present has been a prolific and a profitable season, and the prices obtained for crops on the ground have ranged from £70 to £100 per acre. The raising of Gooseberries has been evidently stimulated by the demand from the north of England for the raw material for the manufacture of champagne.

VIOLETS IN FRAMES.

"A GOOD Violet frame is always a centre of interest in gardens," wrote the prompter of the remarks that will be given upon this subject, which are written in hope of meeting the request for information regarding the treatment of Violets for winter blooming from a correspondent ("C. R. W."), who has a two-light frame with a good selection of Violet plants thriving in their summer quarters, including Victoria Regina, Lee's Argenteaeflora, London, Single Red, De Parme, New York, Marie Louise, Old Neapolitan, Double Red, Queen of Violets, and Belle de Chatenay. I have about forty varieties. It is satisfactory, however, to observe that "C. R. W." has given the names of the best for the purpose required. As there are doubtless other readers who have two-light frames and would like to have Violets in them, notes on the subject suggested by your correspondent may be generally useful at this period of the year.

I ought to state at the commencing that I have some of every sort grown here under glass from September to May, and have them outside as well for blooming in autumn, winter, and spring as the weather may favour, for, except in warm localities, such as the southern counties and near the coast, Violets are very uncertainly produced outdoors from November to March, and it ought to be stated from frames during that period should the weather be severe. Some have an idea that Violets may be gathered without hindrance through the winter from frames, but such has not been my experience. Much, nay everything, depends upon the weather. It is necessary to state this to prevent disappointment. The case is different when heated frames or pits are at command, then a supply of blooms may be had despite wind or weather if a temperature of 50° be secured by day with free ventilation, and frost excluded at night. It is further necessary to observe that Violets delight in moisture, never damping except in a close atmosphere, which last points to the need of liberal ventilation; and they like rich soil—such as is afforded by decayed leaves and manure, while the footstalks and substance of the flowers are improved by the presence of calcareous matter. The disposition to flower and their continuity are also dependant upon the texture of the soil. If it be loose the plants will make a great amount of foliage with long petioles, the flowers being small, few, and unsatisfactory. But the soil being rich and firm the plants will make sturdy short growth and develop crowns, from which in due season will spring a profusion of large flowers with stout stems, long-lasting, and of great beauty and fragrance.

With these preliminary remarks I will endeavour to answer "C. R. W." in the order of his queries.

1st, "The best aspect and inclination for the frame?" The best aspect is south, and the inclination one at which the water will pass off readily from the lights; our lights have an angle of 30° to 35°. The site should be sheltered; if it have a hedge or wall to the north so much the better, for the warmer the situation the greater prospect of having Violets in winter or during unfavourable weather. It should also be dry; at least means should be adopted to prevent the bed becoming saturated by heavy rains or the melting of snow.

"The drainage, depth of manure, proper soil, and distance between the plants and from the glass?" If the site be dry, so that water percolates through it freely, no drainage is necessary; but if wet, about 6 inches of rubble or the coarse siftings of ashes will meet every want as to drainage. The depth of manure should be about 3 feet; stable manure and leaves in equal proportions answer satisfactorily by affording a very gentle heat. Loam with

the turf reduced and of medium texture is the most suitable soil, adding a third of well-reduced leaf soil or manure thoroughly incorporated, and of a depth of 6 or 8 inches, according to the size of the plants. The distance between the plants will depend upon their size and the variety. Such strong growers as Victoria Regina require a distance of at least 9 inches every way, and strong crowns more, whilst the Neapolitans, New York, De Parme, and Marie Louise will not require more than 8 inches, and smaller plants about 6 inches. All that is necessary is to keep them from being very much crowded, placing them so that there will not be much bare soil or waste space. The distance from the glass—*i.e.*, the soil, should for the smaller-growing sorts be 9 to 12 inches, and for the stronger 12 to 15 inches. Violets may also be grown in frames without a bed of fermenting materials by placing a layer 4 inches thick of decayed manure and leaf soil on the ground, covering this with the compost at the depth recommended above.

“The time and mode of planting?” Early in September is the best time for lifting the plants, as they will then have completed their growth and ripened the crowns so as to have commenced flowering—in fact, we have picked flowers of New York, Venice, De Parme, Princess Louise, Duchess of Edinburgh, and Marguerite de Savoie since the beginning of August; and Argentæflora (Lee), Devoniensis, and Russian forms since July. The plants should be lifted carefully, preserving as many roots with the soil adhering to them as possible. Place the soil firmly round them and about the crowns, giving at once a thorough soaking of water, shading for a few days if the sun be powerful, and sprinkle the plants every morning when shading is likely to be necessary. This will keep them from flagging and prevent the leaves turning yellow prematurely. The lights must not be placed on for the present, but the plants exposed as much as possible to air in dull weather and to night dews.

“Ventilation, watering, and general after-treatment?” The lights are not to be placed over the plants until frost, or say in October, then they are to be drawn down or off whenever the weather is mild or when the temperature in the frame from sun heat is over 50°; indeed too much ventilation cannot be given when external conditions are favourable. We open our frames when the temperature is about 40° outside, and always ventilate a little in dull mild weather constantly. During frost protecting material should be placed over the lights at night, and removed in the morning if the day is likely to be sunny; but should the day be frosty or the sky overcast keep the frames covered as long as the frost prevails. No harm will result from the plants being in the dark, and if frost affect them do not uncover until a general thaw commences. If the sides of the frames be banked up with leaves they will assist in protecting the plants. In spring also free ventilation by day and protection from frost at night will be needed. The plants should be examined occasionally for the removal of yellow or decayed leaves, and in the case of single-flowered varieties the seed pods must be removed directly the flowers fade. Water will not be required much in winter, if indeed at all, but the soil must not be allowed to become dry, giving when needed thorough supplies. As spring approaches more water will be necessary, and weak liquid manure will help them greatly, keeping it as much as possible from the foliage. Slugs are very fond of the flowers, and should be guarded against by dusting with soot or searching for them after dark with a lantern. Green aphides sometimes attack Violets, and are best destroyed by fumigation, as they fix on the young growths and curl up the leaves, being difficult to reach with an insecticide. I have used nicotine soap 4 ozs. to the gallon, applied through a rose watering pot advantageously.

“The best kinds of Violets?” This is a poser! I give my experience first as to the kinds named by “C. R. W.” Of single varieties Victoria Regina is unrivalled as a purple for autumn, winter, and spring blooming, and a good light sort is Argentæflora, which, with its runners, gives more flowers over a longer period than any Violet. London is a good pale purple or bluish-coloured variety, and only objectionable from its short footstalk and small flowers. With but one frame I should not grow any of those by that means, but place them in a position where protection could be given them in severe weather and on frosty nights. Double Red and Single Red are pretty, that is all, and spring bloomers. De Parme, New York, Marie Louise, and Neapolitan will give “C. R. W.” the greatest satisfaction from his frame, and those I should plant in it, having a few plants of Queen of Violets and Belle de Chatenay, both of which are spring-flowering varieties, and when in good condition lovely, being only eclipsed by Swanley Queen—a gem—fine in form and pure in colour, white, perfect double rosettes, and delightfully fragrant.

Other single varieties of great merit may be mentioned—the

beautiful and very free Devoniensis, an autumn flowerer; Princess of Prussia, with finely formed large flowers, and an autumn bloomer; Prince Consort, the prince of single purple Violets, blooming with Victoria Regina; and Odoratissima, that flowers grandly in spring, to which must be added White Czar, very pure and good for pots. The Russian family, though free enough in autumn and winter, are deficient in quality, though the number may compensate for that. New York, Marguerite de Savoie, Venice, Duchess of Edinburgh, and Princess Louise are all good, differing but little, but still so much so as to have distinct features, yet they clearly came from one type, and all are first-rate, having large, sweet, double flowers freely produced from August to May in favourable weather. De Parme and Marie Louise are of a lighter colour, more white in the eye, without the splash of red, and bloom from autumn to spring. Belle de Chatenay cærulea is a fine double blue, larger than King or Double Russian, with a long footstalk, and it blooms in spring.—G. ABBEY.

THE EALING NURSERIES.

HAVING visited the above-named branch nursery of Messrs. Charles Lee & Son of Hammersmith, a few brief notes may interest those who are unacquainted with the establishment.

In an orchard house there were about eight hundred pyramid Peach trees in pots in robust health and models as to training. Condor was considered a variety of great excellence. In the herbaceous ground fifty varieties of Phloxes were represented, the trusses being grand, two which attracted my attention being Hercules, bright cerise, and Madame Rivers, very rich magenta. Pyrethrums are also grown in great variety, and for supplying cut flowers are indispensable; the stock consists of forty varieties. Aquilegias also receive much attention, but the best of them are A. cærulea and A. chrysantha. Amongst Delphiniums conspicua is considered the best, but several beds of seedlings coming into flower promised spikes of great merit. Helianthus major is a most effective plant for borders, and also valuable for cutting from. Helianthus orgyalis has strange foliage, but was not in bloom. Bocconia cordata, of which there were good clumps, is a grand-foliaged plant, and very ornamental as specimens on lawns. Geum coccineum flore-pleno is a good hardy plant, rich in colour, and remains in bloom a long time. Iris Kæmpferi in variety is also largely grown; an old friend I had not lately seen being Chelone barbata coccinea, a compact plant with long spikes of bright scarlet flowers. The Chrysanthemums in pots, of which there are over one hundred varieties, promise to be exceptionally good. Single and Pompon Dahlias are largely grown; White Queen and alba among the single varieties are grand, but much alike.

Amongst the Pinks, Mrs. Sinkins, which is not yet much known, is a good variety, with large white flowers and highly fragrant, the habit also being good. The principal walk in the nursery is 700 yards long; fine specimens of Yews, Cupressus, Wellingtonias, and Deodars are planted on each side.

Roses and fruit trees in open quarters are largely grown, forty thousand of the former being worked this season, twenty thousand being on the seedling Briar, the ground devoted to the above being 25 acres. Ten thousand pyramidal Pears on the Quince stock are very promising; being regularly transplanted have made short-jointed wood, which will not fail to ripen well. Such varieties as Louise Bonne of Jersey, Beurré Hardy, Beurré Diel, Beurré Superfin, Doyenné du Comice, Fondante d'Automne, and Marie Louise d'Uccle are bearing fruit of good size. In Apples Chiswick Codlin, Cellini, Hawthornden, Lord Suffield, Ecklinville Seedling, Stirling Castle, Gloria Mundi, King of the Pippins, Northern Greening, and Norfolk Beefing were fine, small trees bearing good fruits.

The trained Peach, Cherry, and Plum trees were models of culture, and there was scarcely a trace of black fly. Where space exists between the rows of fruit trees choice varieties of annuals and vegetables are grown for seed. Cleanliness and order prevail here under the able supervision of Mr. Cannon.—J. S., *Knole*.

SHOULD A MONEY VALUE BE ASSIGNED TO MAGNESIA IN A MANURE?

IN your able review, at page 135 of the *Journal of Horticulture*, on the Potato experiments carried on during 1881 at the Munster Farm, you recommend to your readers that they should study Mr. Carroll's report for themselves. I have done this, and I am much obliged to you for the recommendation. The report is of the greatest interest to anyone seeking any information on the action of potash. In your review of it reference is made to a falling-off in the crops obtained in the Sussex experiments when magnesia was withheld. I am not surprised at this result. (See my letter, page 416, No. 102, of the *Journal*.) I hope you will allow me to offer a few further remarks on this subject; and the more so as I shall by so doing advance a step, I hope, towards convincing your esteemed correspondent, Mr. Taylor, that I cannot be said, with all my respect for them, to believe chemists are “infallible.” My real opinion, indeed, is that they have much

more to answer for than arises from their low estimate of earth-closet manure. By constantly neglecting to assign any value to potash in manures (it is usually lumped in with soda, as "alkaline salts, magnesia, &c."), and by disallowing all money worth for magnesia, they are delaying the progress of scientific agriculture as much, perhaps, as they have done by their eccentric valuations of different forms of phosphoric acid. A friend remarked to me a few days since when discussing this subject, "Chemists have been far too much accustomed as a body to exalt the merits of nitrogen and to depreciate the effects of potash, magnesia, and other fertilisers. They have apparently been caught by the rapid show which nitrogen produces, but which is after all a mere flash in the pan, accompanied, unfortunately for the future prospects of the country, by a most impoverishing effect upon the soil. The fact is, the whole question of the valuation of manures requires revision." But on this occasion I wish to confine my remarks to magnesia only, to which I now return.

Ville, in his admirable treatise on "Artificial Manures," does not, I venture to think, write on this subject with his usual judgment. He found, as your review above mentioned indicates to have been, to some extent at least, the experience in Sussex, that the omission of magnesia from the soil and manures used produced disastrous effects. Ville quotes from Davy the analysis of six soils, in one only of which magnesia does appear to have been present; and he also quotes an analysis by M. Rivot in which only traces of magnesia occur; and yet he tells us that he excludes magnesia from his manures, as also some other ingredients, "because the soil is provided with them naturally." But this is true likewise of ingredients which he thinks it most essential to add. The real question is, Do these ingredients occur in the soil in sufficient abundance? "Every field," says Liebig (page 213, "Laws of Husbandry"), "contains a maximum of one or several, and a minimum of one or several, nutritive substances. It is by the minimum that the crops are governed, be it lime, potash, nitrogen, phosphoric acid, magnesia, or any other mineral constituent: it regulates and determines the amount or continuance of the crop." And again (page 72) he says, "To be productive in the fullest sense of the term, a soil must be able to afford food at all points in contact with the roots of plants; and however small this quantity of food may be, it must necessarily be distributed through every part of the soil." Now it is a noteworthy fact that very generally (with the exception apparently of the soils analysed by Sir H. Davy at a time when analytical methods were comparatively imperfect and the magnesia may have been overlooked) "barren" soils are deficient in magnesia, whilst "exceptionally fertile" soils contain it in abundance. (See analyses given at pages 519-527, Johnson's "Lectures on Agricultural Chemistry and Geology." The evidence is the stronger, perhaps, since Johnson's attention does not appear to have been attracted by this point.)

Liebig, again, in his "Natural Laws of Husbandry," (pp. 257, 258), shows that the seed ashes of plants such as Wheat, Peas, Beans, and Rape contain larger proportions of magnesia as well as of potash than is found in guano—that most valuable of all manures. And he urges upon his readers the importance of the part which magnesia appears to take, not only in the formation of seeds, but also (in common with lime) by influencing perhaps "the presence of the soluble nitrogenous compounds (albumen and casein), or of the insoluble (gluten or vegetable fibrine)."

It appears from the experiments which were made in different localities in 1842 on cereals, Turnips, Potatoes, and Clover at the instance of Professor Johnson, that these views of Liebig were supported at least by practical results, as the use of sulphate of magnesia proved to be very advantageous in all cases. And we know that Messrs. Lawes and Gilbert, in their Rothamstead experiments, always made this salt a constituent of their "mineral manures," a practice followed also by Voelcker in the trials at Woburn. Why, then, I may fairly inquire (in the name of all the fertilisers) does not magnesia carry some value with chemists in estimating for buyers the worth of a manure? I leave it to the agricultural chemists to explain this; but I am glad to see that M. de Joulié in a paper on "Permanent and Temporary Meadows and Pastures," which was awarded a gold medal by the Société des Agriculteurs de France, and of which a translation appears in No. xxxv., part 1, vol. xviii., the last number published, assigns to magnesia a value of 3.048*d.* per lb. (or about 5*s.* 8*d.* a unit) which is nearly half as much as he assigns to potash, and almost three-fourths of the price he quotes for phosphoric acid. Have any of your contributors any definite information tending to confirm or contradict the correctness of Monsieur de Joulié's estimation?

Since writing the above I have observed in the last issue of the *Gardeners' Magazine* (August 26th, p. 453), a notice of a paper

by Mr. H. Scott of Aluwick on the "Valuation of Manures." This was read before the Coquetdale and Vale of Aln Agricultural Association, and it puts the value of magnesia at something like the same value as Monsieur de Joulié. May these indications of a growing appreciation of this too much neglected fertiliser produce some change in the valuations of our agricultural chemists, and render these valuations more worthy of the farmer's confidence as correct indications for his guidance.—INQUIRER.

HARDY PLANTS IN FLOWER IN AUGUST.

THESE are very numerous, but the following are very striking and showy:—*Scabiosa graminifolia*, a very pretty dwarf species of close growth with narrow glaucous leaves. The flower stalk rises to about 9 inches or a foot high, with capitula about 1½ inch across of a lavender-blue colour, and they last some time in beauty, and being very floriferous it is really a good plant, the foliage at all times being pretty. It delights in a dry position and sunny, the rockery being a good place for it, and in such a position it is perfectly hardy. I have found it very slow to strike; or it can be easily secured at most dealers, but it is easily raised from seed, which ripens outside. There is also another *Scabiosa* named *S. suaveolens*, and it is quite distinct from the last. It has pinnatifid leaves, and it grows from a foot to 18 inches high, probably more in rich damp soil; but I plant it on the rockery or in a dry position with poor soil, and it makes a pretty dwarf plant crowded with flowers. The flower heads are about the same size as those of the last, of a pinkish-purple colour and sweetly scented. It is easily obtained by divisions, cuttings, or from seed; but it is certainly a plant not frequently met with, although far superior to many more generally cultivated. *S. caucasica* is a much better known plant, and even more showy than either of those mentioned above. It has a tufted habit, while the flower heads are of a rich lavender or sky-blue colour, on peduncles about 18 to 24 inches high, or even more in strong soil, and when the plant is in good condition it is extremely showy—in fact, one of the best border plants now in flower, most serviceable for cutting purposes, the colour being extremely delicate.

What a very variable genus is *Phyteuma*, usually with curious heads of horned flowers! but what a strange species is *P. stylosa-stricta*! Many enthusiasts have expressed astonishment at the plant. Mr. Leo Grindon wondered at first what *Campanula* it was! No, it is not a *Campanula*, for there are not five stigmatic divisions. It is a *Phyteuma* with erect spikes, sometimes branched, about 18 inches high, of blue flowers about half an inch across, and quite open. Is it very common? I have only met with it at Messrs. James Dickson & Sons' of Chester, where there are many curious hardy plants in flower on the rockery. *Phyteuma Scheuchzeri* is one of the apparently endless kinds with spherical heads of bluish-purple flowers; but it is a very pretty one, with slender stems from 9 to 12 inches high very freely produced. There are a number of species and varieties, many of which are not found in our gardens at all, although natives of southern Europe. Some of them certainly are difficult plants to cultivate, but if care is bestowed upon them they can be established.

A plant known in many collections as *Chrysanthemum maximum* is very showy, with a bushy habit, 3 or 4 feet high, thickly covered with flower heads like very large Ox-eye Daisies, but a much stouter flower for cutting purposes and border decoration. It is really a fine plant, most easily grown and readily increased by cuttings, which root freely in a young state.

Amongst yellow-flowered Composites the two most showy are *Harpalum rigidum* and *Coreopsis lanceolata*, or *grandiflora* as it is frequently called. The former (see fig. 39) is a very showy plant, exceedingly floriferous, and of a freely branching habit. The leaves are more or less bluntly lance-shaped and rough; the capitula are from 3 to 5 inches across, with broad deep yellow rays and yellow disk florets. It grows from 2 to 4 feet high, the lesser height being obtained when planted in a dry position. It rapidly increases itself by underground stolons, which can be separated in the autumn and planted where required, as it is perfectly hardy. In the north it is now in fine character, but in the south it is much earlier in bloom—at least a month. The *Coreopsis* grows about the same height, forming a large bush crowded with flowers, which measure from 2 to 3 inches across, with fewer and broader rays than the *Harpalum* and thinner in texture, and the disk is smaller. The leaves are more fleshy. As a plant for supplying an abundance of yellow flowers for cutting it cannot be surpassed at this season; the flowers have a very light appearance, and are most useful for vases, and the plant is equally useful for the border.

Erodium carnifolium is a very pretty species of Heron's-bill. It

does not grow more than 6 inches high, with finely pinnate leaves of a deep green colour. Flowers in umbels from four to six in number, about half an inch across, of a deep magenta colour and very striking. *E. olympicum* is also very pretty. The leaves are more or less ovate in outline and finely divided, on long petioles covered with fine white hairs. Umbels few-flowered, not more than 6 inches high, with flowers of a pale lilac colour. They are both quite hardy, and flourish in a well-drained and sunny position on the rockery, and, like all the other Heron's-bills, they are charming rock plants. They are readily increased by cuttings,

which can be rooted in a cold frame if a portion of the old wood is left upon the cutting, or they can be raised from seed. Neither of these species were noticed in the article on *Erodiums* which appeared recently in the Journal, although quite as pretty as some there described.

Not many of the *Primulas* are in flower just now. *P. involu-crata* is, however, very pretty, with smooth foliage and slender peduncles from 6 to 9 inches high, terminated with an umbel of pure white sub-pendulous flowers about half an inch across, freely produced. It is a very attractive species, very similar to *P. Munroi*,

Fig. 39.—*HARPALIUM RIGIDUM*.

which I am not certain is not a variety of it. They are both from the Indian Mountains, and the difference between them scarcely warrants specific distinction. Among other *Primulas* in flower for the second time are *P. Cashmeriana*—(Is not this *P. purpurea* of Royle? Judging from specimens I have examined in the British Museum I should think the plants are identical)—*P. capitata*, *P. decora*, *P. ciliata* in various forms, and the charming double yellow-flowered *P. auricula*. The latter is always welcome, as it is certainly a most beautiful plant of easy culture and sweetly scented.

Amongst bulbous plants noticeable are *Colchicum speciosum*, which is a very lovely species. The flowers produced by the bulbs under notice are about 6 inches high, of a clear magenta

colour, not so deep as some of the varieties I have seen, as it is an extremely variable plant in point of colour, but always very charming. The varieties of *C. autumnale* are also cropping up, and will soon be in full bloom. These are all very showy, as well as all the other *Colchicums*. *Allium pulchellum* is pretty; the flower heads are not so crowded as in many of the species, with pendulous flowers of a pinkish-purple colour. It is very dwarf in habit, growing not more than 9 inches high either in pots or planted out. *Crocus aurea* is very bright with its racemes of orange-red flowers freely produced, and as the plants are well established they are particularly attractive in clumps or in large pots. By the side of it is the curious-coloured *Alstromeria pelegrina*, with its umbels of cardinal red and green tubular flowers.

This is an old-fashioned and very interesting plant, thriving well in a warm border.

There are several *Liliums* in flower. *L. Batemannia* is an especial favourite. My plants are about 18 inches high, with four to five flowers in an umbel; each flower about 4 inches across, open, with the perianth divisions but slightly reflexed, of a deep orange-red colour without spot or markings. It is certainly one of the most lovely Lilies grown. *L. Leichtlini* is also good. Some cultivators prefer it to the last, and it is quite distinct from it. The flowers are rather wider across and solitary, pendulous, with more sharply reflexed divisions of a clear lemon colour freely spotted with chocolate brown. *L. longiflorum eximium* is certainly superior to the typical form, the flowers being much larger and stouter in texture, and pure white. For outside culture this is a very excellent Lily, and deserves much attention. The various forms of the Tiger Lily (*L. tigrinum*) are now out in full bloom. The variety *Fortunei* is particularly stately and free-flowering, and deeply coloured. The double-flowered form is very handsome, and lasts much longer than the single varieties.—T.

THE LONDON PARKS.

HAVING referred last week to the floral decorations in the great park in the west end, we have to notice now what is provided of the same nature in the extensive enclosure in the northern district of the metropolis. Here trees and shrubs abound, and form a fine feature; but their contiguity to flower beds and borders does not conduce to the floriferousness of plants nor heighten the colours of flowers and foliage. Still, even in regard to these there is much that is excellent in the first of the parks now to be noticed, while the other great floral rendezvous at the east end has long established its fame for the beauty of the designs and the bright masses of flowers in the beds. Hardy plants are extensively grown, and in their season are highly attractive in the great extent of borders that margin the shrubberies.

REGENT'S PARK.

Since the early part of the season the appearance of this park has greatly improved; and although it is never possible to make a very brilliant display, as plants do not thrive there as they do in more open and less smoky districts, yet several beds and borders are noteworthy and effective in no ordinary degree. It is observable, however, that the *Alternantheras* have not coloured well, for though they have made good growth they are very deficient in the quality which usually renders them so useful in carpet beds. Even the golden form of *A. paronychioides*, which is in excellent condition in most places this season, at Regent's Park is scarcely distinguishable from the ordinary green kind. Probably this want of colour is due to the beds being so much shaded by trees, for without full exposure to the sun these plants rarely assume their distinctive tints in a satisfactory manner. With this exception most of the plants employed in the beds have succeeded well, and *Lobelias* are especially good, both Blue King and Emperor William being densely flowered. The latter is uncommonly fine, two lines in a ribbon border being a mass of bright blue flowers, the clearly defined white centres of which seem to show up the intense blue to better advantage. The plants of this variety, too, are of compact close habit, admirably fitting them for margins to beds. Except in the case of a few varieties the *Pelargoniums* are slightly deficient in the number of flowers. Mrs. Turner, a good pink-flowered variety, is the most notable exception, this being in first-rate condition; but the usually profuse *Vesuvius* is comparatively dull—such are the depressing effects of an unfavourable locality for bedding, and which the utmost skill cannot contend with successfully.

Near the centre of the flower garden the parallel quadrangular beds by the large vases are very attractive. The centres of these are Flower of Spring or Gold Leaf *Pelargoniums* alternately in adjoining beds, surrounded by bands of *Coleus Verschaffeltii* or *Iresine Lindenii*, these being margined with a broad band of *Lobelia Blue King* and edged with *Antennaria tomentosa*. Opposite to these is a series of circular beds containing crescent-shaped or circular panels of Flower of Spring and Gold Leaf *Pelargoniums* on a ground of *Iresine Lindenii* or *Coleuses*. Around the vases are beds of *Alternantheras*, in which triangular beds of *Mesembryanthemum cordifolium variegatum* appear to excellent advantage. Several carpet beds of excellent designs are rather ineffective from the cause named above—viz., the want of colour in the *Alternantheras*. A ribbon border already referred to, in which the Emperor William *Lobelia* is so fine, has also lines of *Coleus Verschaffeltii* and a background of *Pelargonium Mrs. Turner*. This is one of the most striking and pleasing borders of the kind in any of the parks this season, and proves the value of simple combinations when judiciously arranged. On the opposite side of the broad central walk is another pretty ribbon border of *Ageratum* and *Pelargonium Vesuvius*, and near this is a peculiar bed of mixed scarlet, crimson, and pink *Pelargoniums* margined with *Gazania splendens*, which may claim attention for its novelty.

Subtropical bedding is not largely attempted here, but several fine clumps of *Ricinus* are noteworthy. *Cannas* have not made sufficient growth, but the specimens of *Musa superba* which are freely em-

ployed are in fine condition and very effective. One bed of *Ferdinandia eminens*, a most distinct plant when in good condition, though perhaps less so than the *Wigandias*, is striking, the central plants of the above being surrounded with *Lobelia fulgens*, scarlet Zonal *Pelargoniums*, *Tropæolums*, and *Santolina incana*. An effective bed of succulents, chiefly *Agaves* and *Sempervivums*, on a ground of the Gibraltar Pennyroyal edged with *Pyrethrums* and *Echeverias*, is also noteworthy.

The condition of the park generally is very satisfactory, the turf being in excellent condition and the shrubs thriving, the Bladder *Senna* apparently succeeding better than any, and it is now bearing abundance of its peculiar pods.

VICTORIA PARK.

Probably none of the metropolitan parks is more appreciated by the surrounding residents than this; and anyone who has visited it on a Saturday afternoon, Sunday, or any general holiday would fully understand the benefits conferred upon the mechanics and others who are so numerous in that neighbourhood by so convenient and pleasant a resort. Everything is done to render the park as bright and cheerful as possible, and with no mean degree of success, as is well testified by its popularity and the admiring crowds which gather round the brilliant beds of *Pelargoniums* and other flowers in various portions of the park. What are known as the "Prince of Wales' Feather" beds are a particular source of attraction, and this year they are especially gay, scarlet and pink *Pelargoniums* largely predominating in the design—perhaps too largely for those who prefer quiet harmony and diversity of tints. As regards abundance of blossom, however, they leave nothing to be desired, and as they appear to delight the most numerous portion of the frequenters of the park the chief object of the management is attained.

Victoria Park is famed for its carpet beds, and as usual this year we note several tasteful and effective designs. The large scroll bed near the subtropical garden has a ground of *Mentha Pulegium gibraltarium*, in which are numerous small heart-shaped panels of *Alternanthera aurea* very well coloured, margined with *A. amœna* and *Echeverias*. Raised circular panels of *A. versicolor grandis* edged with *Mesembryanthemum cordifolium variegatum* and two rows of *Echeverias* are also pretty. Panels of *Coleuses* and *Alternantheras* with single plants of *Echeveria metallica* and *Sempervivum tabulæforme* are freely employed, the centre design being an ellipse of *Alternanthera amœna* and *A. versicolor grandis* margined with Golden Feather and *Echeverias*, the whole bed being edged in a similar manner. On each side of this is a four-lobed bed that is even more effective than the preceding. The ground consists of the dark green *Herniaria glabra*, with centre circles of the Gibraltar Pennyroyal and a raised cross-like panel of *Alternanthera grandis*, Golden Feather, and *A. amœna* edged with *A. paronychioides major* and *Echeverias*. In other parts of the bed are panels of *A. aurea* and *A. amœna* and the *Echeverias*. Both the beds are planted alike, and the contrast of bright colours with the dark ground is very pleasing, and far more striking than where the lighter *Mentha* is employed. Circular beds of *Alternantheras* tastefully combined, and circles of *Pelargoniums* and *Lobelias*, render this series of beds extremely attractive. They are thoroughly well kept, all the designs being as clearly defined and as well filled as possible.

The subtropical garden is in excellent condition, large beds of *Ricinus*, *Cannas*, *Nicotianas*, *Ficus elastica*, and *Wigandias* being very effectively employed. The *Wigandias* are especially vigorous, with broad handsome leaves, and more telling plants for this department can scarcely be found when they are in good condition. Very healthy young *Ficuses* are also abundant, and though they have a somewhat formal appearance they are valuable plants for such beds. All the others are similarly healthy and strong, the general surroundings being in admirable keeping with the style of the bedding.

NOTES FROM NORTH DURHAM—PERPLEXITIES OF SHOWING.

WE are now in the midst of the flower-show season, and we have the usual grumbling and disqualifying. I have often pointed out the desirability of having some recognised standard or authority for the regulation of flower shows. Every society seems to go on like the famous Scot who "fought for his ain hand," and every society manages to word and construct its schedule and its rules so that it gives any amount of scope for the touchy and the litigious exhibitor to carp and criticise over. One local society offers prizes for the best "tray" of vegetables, and because one exhibitor displayed his produce without a tray at all—showed them, in fact, on the benches provided by the society—and was disqualified he grumbled, but not more than did another one who made use of the orthodox "tea-tray" to show his products upon, because the winner exhibited a collection staged upon a wooden tray made especially for the occasion.

Another prolific cause of dispute is the meaning of the term "amateur." Is a working or a professional man, who has a small garden which he uses for his own pleasure and in his spare moments, to be deemed a professional gardener because he sometimes sells his spare stock of various things, or it may be disposes of the whole

of his stock of exhibition plants of certain sorts to take some "new departure?" or ought a man who grows exclusively for sale and for exhibition to be deemed an eligible competitor in a class set apart for gentlemen's gardeners or amateurs?

What is meant by "artificial means" in the "setting up" of flowers? I noticed at many of our local shows that the bouquets were more like anything rather than natural or artistic combinations of flowers, wire and wool being so obtrusive as to deprive them of all the charms that bouquets ought to possess, and "button-hole" arrangements bristling with wire are getting as common as they are objectionable. Ought such artificial monstrosities to be encouraged? Equally obtrusive are the paper collars used by many florists for staging their flowers in, and surely the practice is reprehensible of "wiring" blooms to such plants as *Lapagerias*, *Allamandas*, and *Dipladenias*. Do not all these practices come under the category of "artificial means?"

Selections of words can be taken from nearly all schedules to which exception might be taken. For instances, "dish," "plate," "basket," &c. All these leave room for raising a quibble. All analogous words or terms should be carefully eschewed and eliminated.

All the flower shows that I have been at this year where Roses were shown proved the superiority of Alfred Colomb, if that can be judged by the decided advantage that it showed over all others both in point of numbers and in the form in which it appeared upon almost every stand.

A feature at one show was cut blooms of *Tuberous Begonias*. At another cut blooms of single *Dahlias* shown on moss with their own foliage and buds as Roses usually are. These were shown by Mr. Sibbald of Bishop Auckland and Messrs. Fell of Hexham respectively.

A respected clergyman in our neighbourhood, who used to hold a flower show for his parishioners, has just told me that he does not intend to hold it this year, because, he says, the whole thing was a huge cheat and a sham from beginning to end. Next year he intends to distribute amongst such as care to have them seeds and plants that can be cultivated by the persons who receive them, and then at a reasonable time he will offer prizes for the best grown examples of the various things he distributed amongst them. This he expects will give a much more healthy tone to window and town gardening than the mere getting by any means a good plant or a good flower for the "show day."—PETER FERGUSON.

ACHILLEA PTARMICA FLORE-PLENO.

MUCH is written on hardy border flowers, and many plants are recommended from time to time for their effectiveness in the garden and their usefulness for cutting from for vase decoration. I have several hardy herbaceous plants, but I do not think that any one of them has given more satisfaction this summer than the plant under notice. For ten months the clumps have been dense masses of purity, composed of thousands of miniature, perfectly double, and pleasingly symmetrical flowers. Though the flowers do not exceed a quarter of an inch in diameter they are so numerous as to produce almost an imposing effect, while the sprays, large or small as may be desired, can be used for bouquets and room ornaments, from the smallest finger vase to a large trumpet vase. Then the plant is so accommodating that it will almost grow anywhere, while it spreads and increases with rapidity. When the growth first appears in the spring there is not much to look at, and it is almost marvellous to see what a number of flowers are eventually produced by such slender shoots. I consider it a border plant of the first order of merit, requiring no protection and no care except to prevent it spreading too far and encroaching on space that it is undesirable it should occupy. I find it a good plan to dig up the outside portions in the spring when the growths are an inch high and plant them where required, as if left alone the soil becomes exhausted and the central growths weak and unsatisfactory.—A SUBURBANIST.

TOMATOES FOR WINTER AND SPRING.

AS Tomatoes have rapidly gained favour with nearly all classes of society my subject must be a popular one, and no apology is needed for broaching it. The wealthier classes have long been familiarised with them, and this may have something to do with their comparative indifference to Tomatoes, more especially as a salad, this indifference probably arising from the fact of the first attempt being made with imperfectly ripened fruit. Now Tomatoes have only recently been extensively grown under glass, and are seldom ripened to perfection in the open air; indeed, it is doubtful if for quality they ever equal house-grown fruit. It is generally admitted the taste for this esculent must be acquired,

consequently the start should be made with perfectly ripened fruit; and later on, if this cannot be had, fruit of inferior quality, such, for instance, as that imported, will be relished. The recent advance in house culture has been principally made in medium-sized or small gardens, the owners of which, perhaps, have become very fond of Tomatoes, and are, besides, justly proud of their productions. Many of these have grown profitable crops during the summer and autumn, and, provided they can command sufficient heat, there is no reason why they should not grow them during the winter also. Ornamental and useful they will undoubtedly prove, and this cannot be said of the majority of the ordinary occupants of our houses during the winter months.

Cuttings may be struck or seed may be sown at the present time for the winter and early spring crops. The former should be well-ripened top shoots, taken off about 6 inches in length, trimmed at the lowest joint, dibbled in thinly round the sides of well-drained 6-inch or 8-inch pots, and placed either in a warm frame or a handlight in a heated house. They should be watered in and be kept moist, but not saturated, and should not be damped overhead; and if much moisture condenses on the glass air should be admitted for a short time every morning in order to properly dry the glass and foliage. They require to be shaded from bright sunshine till struck, after which the plants must be gradually exposed to sun and air. The cuttings to be preferred are the strong yet well-matured tops of plants grown under glass; and those to be avoided, as being liable to damp off, are the gross shoots often formed on plants grown in the open. Light loamy soil is suitable for cuttings or seeds. The latter may be sown thinly either in pots or pans, and placed in heat till germinated, after which the plants require to be disposed near the glass to make them sturdy. Thin out where at all crowded, and when the rough leaves are fairly visible pot off singly in 4-inch pots, or in pairs in 6-inch pots, sinking the stems up to the seed leaves. This will tend to keep them dwarf, and the buried stems rooting freely materially strengthen the plants.

Various methods of fruiting Tomatoes are adopted, these being, or ought to be, in accordance with the intended sites. We have fruited them singly in 11 and 12-inch pots, or in pairs in larger pots, in any rather flat common boxes available, and planted out in ridges of soil as we treat Cucumbers. They are grown on the front, side, and central stages, and staked, or in the two former positions tied to wires disposed across the roof or ends as the case may be. We have also utilised the back walls of forcing houses for the purpose. In each case the result has been most satisfactory, and what we can achieve is equally possible to others if they choose to make the attempt. As compost we prefer roughly broken turfy loam with a liberal addition of decayed manure, but it is possible to grow excellent crops of fruit or plants rooting in ordinary well-enriched garden soil. It should always be remembered the Tomato loves good living, and, no matter how planted, is benefited both by frequent supplies of liquid manure and occasional top-dressings of rich compost, the latter being quickly taken possession of by the roots. Those who are unable to procure farmyard liquid manure are advised to give the "Crown Manure" or some other artificial manure or guano a trial, using these at the strength recommended by the vendors.

Although our plan is to grow and fruit the young plants with single stems, rubbing out all side shoots as they form, and stopping beyond the second or third bunch of bloom, and allowing the leading shoot following to extend and fruit, this is not necessarily the only or best method; but as a rule heavy crops can be had in this way without unduly shading the other occupants of the house. Unless the house is devoted principally to them they should be disposed at least 2 feet apart; but if they are of primary importance and plenty of root room is provided they may be planted closer. If preferred fewer plants may be thus grown, these being disposed 2 feet apart, and second growths from the base may be laid in and fruited. It is also easy to fill a house with one or two plants, much after the manner of trained Cucumbers. For this method plants that have been previously fruited in pots or boxes are available. These should have their balls slightly reduced, and be shifted either into larger boxes or small pits about 2 feet square and as much in depth, which may be formed with loose bricks, allowing room in both instances for top-dressings. When this reserved space is filled further top-dressings may be given if a rim is formed with slates or boards in the first instance, or more bricks in the other. Such plants, if kept thinned out and stopped occasionally beyond the bunches so as to gradually occupy the allotted space, prove very remunerative.

From the commencement in every case the plants should never be allowed to become dry at the roots, and should receive light airy positions as near the glass as possible. Syringing must be avoided, and at times when many flowers are expanding the fruit

may fail to set unless the atmosphere of the house be kept rather dry. We grow a variety of fine-foliaged plants and Ferns under our Tomatoes, the temperatures of the house ranging on most occasions from 55° to 60° by night to 60° to 65° by day, the ventilators being slightly opened for a short time towards the middle of every mild day. In this manner, and by attending closely to the watering with tepid water varied with liquid manure, and top-dressing whenever exhaustion is apparent, that healthy growth can be maintained which may be relied upon for perfecting moderate crops throughout the winter and spring, or till such times as the house may be wanted for other purposes. We make three annual sowings; the first in January for plants to be fruited in pots during April, May, and June; the next in April for plants to be fruited in boxes in Peach and other somewhat cool houses during July, August, and September; and the last in August or early in September for the winter supply. Any fruits of the late autumn crop there may be unripe in October are cut and hung up in bunches in a warm house to ripen, and these and any we may cut green at the end of September from the few we have on the open walls and ripened similarly prove of service in maintaining the supply till the house-grown produce is fit to use. Tomatoes may also be ripened in boxes placed before the kitchen fire whenever convenient, or on a rack at a safe distance above the fire.

Not a little depends upon the choice of varieties. After having tried all the catalogued varieties we have arrived at the conclusion there are none to equal the old corrugated sorts for house culture. The newer varieties, principally of American origin, are nearly all very smooth, large, and handsome in appearance, but for quality and fruitfulness are inferior to such as the old Large Red, of which there are some excellent selections offered, the best probably being Earley's Defiance. The Dwarf Orangefield, if obtained true, will be found very productive and good in quality, and the same may be said of Keye's Prolific. The Conquerer, a ribbed American variety, is very prolific, grows to a good size; while, if a smooth sort is preferred, Hathaway's Excelsior is recommended. Selected kinds of Trophy or its synonym are the worst that can be grown, as but few succeed in setting good crops, and connoisseurs do not admire the quality of the fruit.

A difficulty is frequently experienced in setting good crops during the dull autumn and winter months even with notorious free setters. Every care should be taken that the plants receive no check in any way, and by closely rubbing out all superfluous growth the bunches of bloom will be encouraged to develop strongly. A drier atmosphere maintained and frequent smart taps given towards midday or about an hour after air has been given will distribute the pollen and ensure a good set. If this fails the blooms may be lightly touched over with a camel's-hair brush. We invariably secure good sets; in fact find it necessary to thin out the bunches, as a constant if comparatively light supply is preferable to occasional gluts, which result if extra heavy crops are allowed to mature at one time.—W. E. G.

MANURE FOR VINES—CRITICISM.

No one rejoices more than myself to be informed that the quality of Standen's manure is not lowered, for I do not like losing an old and trusted friend.

That a parcel I had last spring was faulty I am certain, but it is satisfactory to know that, as far as the proprietors can guarantee it, "the ingredients and manipulation are precisely the same as when introduced twenty years ago."

"INQUIRER," I think, is hardly fair when he makes it appear that I "once thought I could grow Vines as well without lime as with it." Of course I knew before I commenced that lime was a necessity for Grape culture; my error was in thinking there was already sufficient lime in the natural soil, and which I owned that I ought to have found out before, as there was plenty of evidence to the contrary. But having voluntarily exposed my weakness in this and other points for the purpose of preventing learners falling into similar errors, I did not expect men of the calibre of "INQUIRER" to take advantage of it by rather enlarging on the facts and holding me up to ridicule.

Again, as to the quality of Standen's manure. Although there was only two months between the two statements appearing in the Journal, there was a much longer time between the writing of them, and there was a difference in a whole season as to the results spoken of.

Of course I do not expect to convince your correspondent as to the value of earth-closet manure in the face of the evidence of the great authorities he mentions; but I may tell him there are many practical men who could say much in its favour, and my faith in it will tempt me to use it and wood ashes alone to a portion of my Vines till such time as they show signs of failure, and when

that happens I will be candid, as I have endeavoured to be all the way through, and will freely acknowledge it.

I have still another critic ("J. S. W.") to notice; but as he only accuses me of dishonesty and falsehood I will merely refer your readers back to the answer given him in this Journal three weeks ago, feeling "I can safely leave the verdict with those of the public who understand such matters."—WM. TAYLOR.

[As both "J. S. W." and Mr. Taylor agree in leaving the "verdict with the public," the controversy referred to in the last paragraph of this article naturally ceases.]

TREE FERNS.

THIRTY years ago Tree Ferns were comparatively scarce in this country, and were only to be found in very large establishments and botanic gardens; but within this last twenty years I may venture to say that hundreds of tons of these Ferns have been imported, and at present a brisk trade is going on amongst our leading nurserymen in providing them to meet the ever-increasing demand.

What conservatory of any size would be complete without a pair or two of Tree Ferns and a few good-sized Palms? Anyone that has visited the Crystal Palace could not fail to appreciate the remarkably fine Dicksonias that are to be seen there, and are so well adapted for the positions they occupy, giving a cool and refreshing appearance to their surroundings. At Kew also, in what is called the temperate house, there are some grand specimens of Cyathcas and Dicksonias, and when seen from the gallery they are objects not likely to be soon forgotten. At Gunnersbury Park there was a few years ago a pair of Dicksonia antarctica, supposed to be the finest in the country, and no doubt they were. I will not pretend to give the dimensions of them here in case I may under-estimate them, for they are giants compared with what I had seen before. At Sir G. Macleay's, Pendell Court, there are also some very fine specimens.

The most useful species of all Tree Ferns is undoubtedly Dicksonia antarctica. This is by far the most common in collections, and well adapted for conservatories and cool houses. It requires little or no shade provided the temperature is not too high and will stand a little frost with impunity. The size of the stems would suggest that enormous pots or tubs would be required for their well-being, but such is by no means the case. If large or medium-sized stems are imported they may at once be placed in pots or round tubs well drained and only a trifle larger than the stem itself, so that sufficient room is given to work a little soil between the stem and inside the pot or tub. They should be potted moderately firm, using good fibry peat and loam in equal parts, with a little silver sand. After they have started freely into growth copious supplies of water will be necessary, and particularly up the stems, for good-sized Fern stems are all alive with active fibres. Care must be avoided that they never suffer from being kept too dry. In the tubs or pots that they are first placed in I have seen them remain till the tub has become thoroughly decayed, thus proving that very little pot room is necessary. The best plan, however, to grow this very valuable Fern is to plant it out, after being well established in pots, in a thoroughly drained border.

D. fibrosa, a New Zealand species, is a very useful Fern, and should find a place in all collections. It is much dwarfer than *D. antarctica*, the stem not attaining nearly the size of the latter. The stipes are very short. The fronds are 3 to 4 feet long, rhomboid, tripinnate; the central pinnae lanceolate, 6 to 9 inches long, the stem being covered with dense bright brown scales.

D. squarrosa, another New Zealand Fern, is a desirable species. The stipes are about a foot long, clothed with soft, spreading, fibrillose scales; fronds oblong-deltoid, tripinnate, the texture of which is rigidly coriaceous.

There are many species of *Alsophila* that are worth growing, but in this note I only intend to name a few of the best. *A. australis* is perhaps one of the most popular species in cultivation. In its native habitat it attains the height of 50 feet or more, but slender. *A. excelsa*, a native of the Norfolk Islands, is said to attain the height of from 60 to 80 feet, surmounted with a handsome crown of fronds. It appears to be a much larger and stouter-growing plant than the latter, both being well suited for high houses.

Cibotium, or, as now classed, *Dicksonia*, includes two or three species that are extremely useful and ornamental. *C. Schiedei* is amongst the most useful of Tree Ferns for exhibition purposes. The peculiar arching habit of the fronds give it a very graceful appearance. The fronds are tripinnate, light green above, and very glaucous beneath. It is a native of Mexico, where the stem attains the height of from 10 to 15 feet.

C. regalis somewhat resembles the above, but grows larger in every way. It is of spreading habit. The fronds often attain the length of 12 or 15 feet. The plant requires to be elevated, so as to show the fronds off to the best advantage. It is a native of Mexico, and makes a handsome conservatory plant.

Cyatheas are numerous, and some species in this genus are favourites with all. They are amongst the most noble plants that assist in furnishing our large conservatories. *C. medullaris* is the largest and strongest-growing of the genus: a very fine specimen may be seen in the temperate house at Kew, which for some years has been one of the greatest ornaments of that noble structure. The stipes are glaucous black; the fronds are bi-tripinnate and coriaceous. This is another New Zealand species, and thrives admirably planted out in a well-drained border, requiring abundance of water when growing.

C. arborca is a native of the West Indian Islands and is very abundant in Jamaica, therefore requiring a stove temperature. This is a well-marked plant, and attains the height of from 30 to 40 feet. I lately saw a plant at Kew that must be quite 30 feet high. The stem is rather slender, carrying a fine whorl of fronds at the head, and is covered the whole length with prominent scars formed by the old fronds.

C. insignis is one of the most useful and ornamental, and well adapted for an intermediate temperature. The fronds are dark green above and glaucous beneath. The lower part of the stipes are furnished with long glossy scales.

C. Gardneri is a Fern that should become more popular. It is supposed to be a very scarce plant, and is certainly ornamental. Large specimens can be grown in pots of moderate size provided water is freely supplied after the plants become root-bound. The stipes and around the crown of the plant is densely furnished with light brown scales. Being a native of Brazil it requires a moderately high temperature.

The above are a few of the most useful and showy of Tree Ferns. There are many others that could be mentioned, for they are all more or less ornamental and deserve more attention from horticulturists.—W. K.

HARDY FRUIT GARDEN.

CONSEQUENT upon the light crops fruit trees have required more than usual attention in stopping their shoots, this more particularly applying to bush, pyramid, and espalier trees, which have not yet ceased growing. These should now be attended to, and have the lateral stopped back to one bud so as to strengthen the buds for next season, and by admitting more light and air insure the thorough ripening of the wood. Trees that have the spurs much elongated, and are little less than clusters of sappy growths, may have such cut back to suitable buds nearer their base, as it is rare that such growths can by any amount of summer pinching be converted into spurs—i.e., fruit buds. Any trees that produce fruit sparingly and are unduly prolific of wood should be marked for root-pruning at the proper time, as the part above ground is indicative of the condition prevailing at the roots. Rooting in too rich and loose a soil can only be remedied by allowing more extension to the growths or by restricting the root-action.

Pear and Plum trees against walls are, from their light crops and the moist weather, producing much spray, which should be removed where the trees are already well furnished with spurs, as the growth stopped so late in the season and so closely cannot possibly be converted into blossom buds, and their retention is certain to be followed in the coming season by growth difficult to restrain. Trees that grow too luxuriantly for fruiting should be judiciously root-pruned, as no amount of pruning will cause the formation of fruit buds, but tends to crowd the trees with growths, which appropriate most of the alimentary matter afforded in excess by the roots.

Peaches and Nectarines.—The trees will require attention in securing the growths and stopping the laterals on vigorous shoots to one leaf of growth as made. Late kinds will need to have the foliage turned aside or shortened, so as to expose the fruit as much as possible to

light and air—the great imparters of colour and flavour. Any long sappy growths may be shortened, but this must be done carefully, or the diversion of the sap will cause the buds that would otherwise be developed as fruit buds being started into growth. Trees that have been cleared of fruit should have the older bearing wood cut out, and the wood where too crowded should be well thinned.

Where it is intended to plant new walls or renew old worn-out trees the borders should be prepared as soon as possible, so as to get the soil ameliorated before the time for planting arrives. All fruit trees thrive best in a medium-textured loam, inclining to be heavy rather than light. Where the soil is of a heavy clayey nature it would be much improved by burning part of the clay and mixing it with the surface soil to a depth of 24 to 30 inches, or by mixing with it a goodly proportion, say one part in six, of old lime rubbish and ashes. Light soils should have a good marling, mixing clay in as small pieces as possible with the soil, one part in six not being too much for very light soils, a lesser proportion being added as the soil inclines to medium texture. Soils not calcareous should have an addition of lime rubbish or chalk, one part in ten being ample for most soils. Heavy soil will be improved by a good liming, a bushel per rod not being too much. Drainage must be attended to, as no fruit tree will long remain healthy with water lodging in the subsoil. It is also necessary to make choice of such varieties as seem most likely to succeed in the locality, much disappointment resulting from indiscriminate planting, which careful note-taking and an exchange of views with careful observers in different localities would do much to prevent.

Strawberries should now, if not already done, have all runners or weeds cleared off between the old stools, and a good manuring given as opportunity offers and material is available. Where it is necessary to defer planting until spring runners should be thickly inserted in nursery beds, from which they can eventually be transferred with balls to their permanent quarters.

FRUIT HOUSES.

Vines.—The earliest-forced Vines must now be pruned, it not being necessary to wait until all the foliage falls before doing this, provided the wood be hard and brown and the majority of the leaves are turning yellow, as early pruning induces early resting. Both the house and Vines should have a good cleansing; and if insects have been troublesome the wood should be washed with soap and water, and the Vines, after removing the loose bark, be washed also, and afterwards dressed with an approved insecticide. Perhaps the readiest and most effectual means of cleansing a vinery is syringing the Vines and the house thoroughly with petroleum and water, as practised by Mr. Wm. Taylor. This is especially to be recommended where the Vines are infested with scale or mealy bug. Remove the loose inert soil from the border and replace with fresh strong loam, to which has been added some fertiliser such as bone meal or earth-closet manure, which, though so long neglected, seems destined to become an important factor in horticultural practice. Any Vines in an unsatisfactory state may be improved by partially lifting the roots, removing the old soil, and adding new, lifting and laying in the roots in fresh soil, which, however, should be done before the leaves have fallen. Keep the house as cool as possible, so as to induce complete rest.

Vines in pots intended to be placed in warmth in November ought now to be fully ripe and at rest. They should be kept rather dry, but the roots suffer great injury when the soil is allowed to become dust dry. Later Vines in pots should now be turned outside, and be secured to walls or other situations to mature the growth and insure rest.

Young Vines that have made strong growth will require a considerable time to ripen, and fire heat will be requisite with a free circulation of air to enable them to mature the wood, keeping moderately dry at the roots, but not entirely depriving them of moisture, as the buds will need plumping as well as the wood ripening. Discourage any further growth by keeping the laterals closely pinched.

Late Vines, with the object of checking further growth, should have the laterals cut back after the Grapes are perfected, and what is

needed to insure their thorough ripening should be applied forthwith—i.e., fire heat to allow of a circulation of dry warm air. Ripe Grapes should be frequently examined and decayed berries removed, a dry airy atmosphere being the only preventive of mould. If the roots of late Grapes are in outside borders it will be necessary to protect them from heavy rains by covering with glass lights, wooden shutters, or tarpaulin.

Cucumbers.—The necessity for fire heat will be determined by the weather. A minimum of 70° to 75° should be maintained in the daytime, and 65° at night. Shorter days and cooler nights will suggest earlier syringing and the earlier closing of the ventilators. Encourage the autumn fruiters, removing the first fruits together with male blossoms and tendrils, giving them the benefit of the full sunshine, and avoid morning syringing as much as possible. A sowing should be made at once to ensure a supply of fruit at Christmas onwards, Telegraph being one of the most reliable sorts.

MUSHROOM HOUSE.

To insure a supply of Mushrooms in winter the beds must be formed at once. The best materials are horse droppings direct from the stables mixed with short particles of straw, these not only increasing the bulk, but aiding in drying and maintaining the material longer in a fresh and undecomposed state, upon which depends the continuance of the beds in bearing. These materials, neither too wet as to decompose quickly, nor so dry as not to decompose at all, should be formed into a bed of 15 to 18 inches thickness, and beaten as firmly as possible. When the heat has risen and is on the decline press in the spawn when the temperature of the bed at the depth of 2 inches does not exceed 90°. When the temperature has declined to 75° put on 2 inches thickness of fibrous loam, beating it down hard, and smooth the surface with the back of a spade. In six weeks Mushrooms will appear, and the surface must be kept moist by sprinklings of tepid water, and a moist atmosphere secured by the damping of available surfaces. In order to a supply of Mushrooms in winter we find a temperature of 55° to 60° essential.

PLANT HOUSES.

Epiphyllums.—These useful winter-flowering plants which have been started into growth early in the season will now be coming into flower, and are very effective either as standard or pyramid-grafted plants, also as dwarf plants on their own roots. They do best in an intermediate house, or one in which a temperature of 55° to 65° is maintained artificially. We grow them in quantity, and find the plants very useful for decorative purposes, and for vase decoration the flowers when cut are always acceptable.

Tree Carnations.—Every attention should be given to these, it being hardly possible to have the plants too strong. They should be housed without much further delay, assigning them a light airy position in a house where they will have a temperature of 50° to 55° by artificial means, in which they will flower freely during the winter months, and be highly appreciated for buttonholes, &c., by their delicious fragrance.

Mignonette.—This should be encouraged to make vigorous growth by keeping the plants near the glass and shifting them into larger pots as they require it. If aphides attack them fumigate moderately on two or three consecutive evenings. Remove all flower spikes for the present, and tie out the growths as they advance, keeping them well furnished to the base of the plants or the top of the pots.

Pelargoniums.—Plants that were cut back some weeks ago and have now produced fresh growth should be shaken out and repotted. If they have been in 8-inch pots they should be placed in 6-inch pots, trimming the roots a little and removing most of the old soil. Good fibrous yellow loam, with a fifth of well-decayed manure and a sprinkling of sand, is the most suitable compost. Pot firmly and place in a frame or pit, where they should be kept rather close and sprinkled occasionally for a few days, after which they can hardly be kept too cool and dry provided frost be excluded. The latest-flowered plants should at once be pruned, placing them in a frame or pit where they will be kept rather dry until they have broken.

Hardwooded plants that are being grown for specimens should have their growths regulated and the plants trained in proper shape.

If there should be a trace of mildew promptly dust with flowers of sulphur, but be careful to keep it from the roots of the plants, where it is certain to cause their death. It is necessary to house all hardwooded plants upon the first appearance of frost. Any plants needing larger pots should be shifted without delay, so that they may become well established before winter.

Azaleas that were started early and have completed the growth, also set the buds, should be placed in a cool house to enjoy a season of rest preparatory to their being put in heat for early flowering. Plants that have been stood outdoors to harden the growth should be moved inside before danger is to be apprehended from heavy rains or frost, similar remarks applying to other description of hardwooded plants, including Camellias, which are questionably exposed to outdoor influences. They certainly should be housed before the roots are saturated by heavy rains—a prolific source of the roots perishing and the buds dropping.

Medinilla magnifica grows strongly enough in a moist stove, but does not flower freely, and should now be given drier treatment, ceasing to syringe the foliage. When the wood is well ripened it flowers freely, not only from the current year's growth but from the old wood down to the base. *Achimenes* that have nearly ceased flowering should not be thrust anywhere out of sight, but be kept in a temperature as warm as it was requisite to grow them in, giving water moderately until the roots are fully ripened and the tops die gradually. *Gloxinias* require similar treatment—i.e., sufficient light and warmth, with water to keep the soil moist until the tubers are matured and the tops have gradually died. Any choice varieties may be increased by inserting the leaves, which now they are matured are less liable to damp off. They may be inserted four or more round the side of a 6-inch pot in sandy loam and peat, the pot being surfaced with half an inch of sand.

Winter-flowering *Begonias* should be given every attention. Any needing potting must be attended to at once; but unless the pots are small and very full of roots this is not desirable, as the plants are most useful in 7 or 8-inch pots. *Dipladenias* required to flower early in spring should be kept drier at the roots for a few weeks and then be cut back, giving at the same time a thorough cleansing with an insecticide. When they have made fresh growth remove about half the old soil, returning them to the same pots in good fibrous peat, and secure to the trellis. As the young shoots extend they can be trained to strings near the glass through the winter. Plants of *Clerodendron Balfourianum* that flowered early, and have since been pushed on to make growth, should be encouraged with liquid manure to make growth up to October, when the supply of water should be gradually diminished.

Most *Amaryllises* will be completing their growth; and although enduring a low temperature it must not be given until the growth is completed and thoroughly ripened, or they will not flower freely: indeed to grow these fine plants well they should have a light and well-ventilated position, so that the growth through the whole course of its formation will be thoroughly solidified.

THE BEE-KEEPER.

BEE-KEEPING RETROSPECTIVE.

WE do not intend in this paper to go back over the honey seasons of the last eight years, telling of all the causes which have separately and collectively caused a revolution in the bee-keeping world. These shall be treated of in later papers when our work for the year is done, and when by the cheerful fireside, our bees all snugly wintered, we can pass a few quiet hours and learn from the doings of the past what to do, how to do it, and when to do it, in the future. Yet our glance is retrospective, looking back over the last few months of the fast waning season. Although we all have learned much about bees which we did not know before—for who can keep bees for a single season without learning many a lasting lesson?—yet to one and all, to the practised bee-keeper and to the novice, the season has been one of disappointment.

Like many days in the past month of August, opening with a sunny sky, but ere many hours changing to cloud and rain, this season gave promise by the first glorious burst of spring in April and early May to be one of light and heat, and perforce of abundance of honey. An early and continuous income from the sweet May flowers brought joy and happy expectation to bees and bee-keepers. Queens hurried from cell to cell, from comb to comb, to deposit eggs, and the army of joyous labourers was soon having daily additions to its strength in the shape of newly hatched bees, which teemed out into the brilliant sunshine. All was joy and work and sweet reward for labour. Supers were placed on hives, and many a convert to the modern system of bee-keeping saw his first sections being rapidly filled, and he already built up a goodly pile on the show tables of future exhibitions. Alas! they were veritable *chateaux en Espagne*. A change came—a sudden, unexpected, disastrous change. The latter part of May and leafy June brought clouds and rain, frosts at night, and truly blasting winds. The bees, obliged to go out for pollen and water to satisfy the cravings of thousands of larvæ, were overtaken by cold showers, and battered to death by chilly winds, were mocked by the sight of myriads of beautifully painted flowers in which no nectar was secreted. Queens walked slowly and disconsolately over the combs; the desire for depositing eggs ceased, or the foreseeing workers prevented their deposition. The newly hatched bees, instead of rushing out to the glorious sunshine, welcomed by their fellow labourers and ready to assist the veterans in their attack on the flowers, now proved so many thousands of hungry ones to feed from the rapidly emptying store cells. Driven to despair by the changeless leaden skies, by the dearth of food, that curious instinct came uppermost which transforms the careful nursing bee into a remorseless assassin. A general massacre of the innocents took place. Strwn on the alighting board were seen the dead bodies or emptied skins of the white unhatched brood. But matters had only come to this pass in the hives of those who through ignorance or carelessness allowed the poor insects to approach the threshold of starvation; not so with the stocks of the bee-master. He had taken care, as the cold change in the weather gave him warning, to contract the size of the brood chamber, which he had gradually enlarged during the few weeks of prosperity. He anticipated the daily wants of his colonies by the constant application of wholesome food. Given in the shape of thin syrup, both food and water were regularly supplied, and although breeding did not continue at so rapid a pace as during the continuance of beautiful weather, yet the colonies did not lose strength. But what have we to say of the newly hived swarms kept on the let-alone system? We know of a cottager who, from the want of knowing what to do, lost four strong swarms out of seven, and the remaining three will not fully recover from the effects of the starving until too late in the year to give any surplus honey, should a few weeks of fine weather yet allow the Heather honey to be gathered. And now we are rapidly approaching the end of the ingathering season, which may, as far as we are concerned, be put down as one of the worst we have known.

Those who are not in the neighbourhood of Heather knew that their hopes of a harvest were over as the month of August drew towards its end, but ourselves among others still hoped for some recompense when we saw acres of purple Heather expanded to the sight, and giving us whiffs of its sweet perfume when a gleam of sunshine lit up the hills. These hopes, we fear, will be blighted. Drenching rain and cold winds prevail as we write, and although our hives are teeming with bees, they cannot work; and although the heathery expanse is purple on the near hillside, there is no genial heat to cause honey to flow in the blossoms. Then what reward has the bee-master had beyond the careless and the ignorant? During the season of gloom his bees have been made to pay for the attention bestowed on them by having work apportioned to each hive according to its strength, such work consisting of the building of combs, the drawing-out of foundation, the contribution of frames of brood and eggs by the stronger to the weaker colonies, and in a very few well-favoured districts both super and extracted honey were obtained in some abundance during the early summer, when the fine weather prevailed.

Lincolnshire stands first among the well-favoured counties of the current season. Nine-tenths of the honey exhibited at South Kensington came from Lincolnshire, collected in the nick of time from the fields of Mustard and similar flowers.

One other drawback has to be added this season to the many others caused by a long period of showery weather. It has been a season especially favourable to the propagation of the aphid tribes. Trees and shrubs have been literally eaten up by vermin, the Hops more especially. The secretions of these vast armies of insects form what is called honeydew. Bees have collected it

during the intermittent gleams of sunshine, and mixed it with the little honey they could obtain. Thus much honey which has been on exhibition tables and for sale has been the colour and consistency of thin treacle, having a slightly bitter taste, and causing a slight irritation of the throat. It was, as far as we can remember, in the year 1877 or 1878 when during a similarly rainy season honeydew was collected in great quantities, and much honey spoiled. An avenue of Limes was near our hives, and the bees managed to secure a certain amount of beautiful honey, but so much of the dark-coloured honeydew was scattered through the combs that we could not employ the extractor without spoiling all.

We have now taken a retrospective glance at the season; we have confined our remarks to the doings of the bees and the bee-keeper. Altogether the season has, as we have shown, been a most discouraging one. Yet the science, for it is a science, of bee-keeping is rapidly gaining ground, and bee-keepers' associations have during the past year multiplied exceedingly. Shows have been held in all parts of the kingdom, and to judge by the enthusiasm awakened by the sight of the various manipulations with living bees, by the numerous questions asked by intelligent visitors, and by the success of tradesmen in all parts of the country who have established a business for the manufacture and sale of bee-keeping appliances, it is very certain that the day is not far distant when foreign honey will be driven out of the market, and the culture of bees become a national industry. To those who have only during the present season begun bee-keeping we would say, Do not be put out of heart by one bad summer. One really good year will make up for the disappointment of previous bad ones; and taking the average return in five or seven seasons for our labour and capital, bee-keeping will decidedly give a better per-centage on expenditure than that given by many other investments. This is only considering the subject in a pounds, shillings, and pence light, without taking into account the pleasure the possession of a few stocks of bees gives to a man fond of natural history, to whom apiculture becomes a delightful hobby—a perpetual source of enjoyment.—P. H. P.

THE SOUTH KENSINGTON BEE AND HONEY SHOW.

[Conclusion of Report.]

AMONGST modern bee-appliances the article termed a "rack" has come into very general use wherever the 1 lb. and 2 lb. sections are used. It is merely a frame for holding together the sections on the top of the stock hive, allowing sufficient space beneath for the free passage to and fro of the bees. To these most necessary adjuncts to the apiary Classes 10 and 11 were devoted, the former to those suitable for bar-frame hives, the latter to those adapted to straw skeps. The two classes contained thirty-one entries; and although of necessity a great similarity prevailed, yet in several cases we noticed improvements over former years, especially in the manner of binding together or tightening the sections. The preferable plan appears to be by means of the wedge rather than the elastic band, which is liable to split and crack and requires constant renewal, while the wedge is simple and lasting, being also most easily manipulated. In several exhibits we noticed a bad principle which should always be avoided—viz., placing the rows of sections too near to allow of the insertion of the fingers in order to withdraw any single section when filled, and to replace it with another, with little or no disturbance of the bees.

In the honey classes, 12 to 20, the display was by no means equal to that of last year either as regards quantity or quality; taking into consideration, however, the cold and wet season, we were agreeably surprised by the exhibits in several of the classes, and particularly by the large quantity of comb honey from Lincolnshire, without which the Show would have proved all but a failure in this department. The bee-keepers of that county were fortunate in the large breadth of land devoted to the cultivation of Mustard, during the blooming of which the fine weather enabled the bees to revel in its golden flowers. The quality of the honey derived from this plant is not of the finest quality, and it lacks the aroma and the pale golden colour of the white Clover honey. It is also said to granulate or become candied immediately after collection by the bees. Mr. Woodley's first-prize glass super weighing 30 lbs. was one of the finest we ever remember to have seen. Some few of the prize sections were also well filled, evenly wrought, and of fine quality.

The extracted honey was displayed in glass jars of improved shape, and well secured by metal caps. In quality it was equal to that of former years, and very far superior to the generality of adulterated trash sold in the chemists' shops as pure honey. That great desideratum of bee-culture—a ready sale at remunerative prices for the honey produced at home—if not already attained is, there can be no doubt, in a fair way of accomplishment.

The classes for comb foundation were fairly well filled, and the Judges evidently preferred the natural-based to the flat-bottomed by awarding the prizes to the former, Messrs. Abbott making a clean sweep of all the prizes.

The prizes offered in the four foreign and colonial classes, we were sorry to find, produced one entry only, that of an "Italo-American hive," by P. Bernizzi, which, however, did not appear. This is much to be regretted, as the advantage of comparing ourselves with other nations in apiculture, as well as in other matters, would tend towards clearing away our insular prejudices.

The class for mead or metheglin attracted four competitors and seven entries, Mr. Cowan sending four out of the seven, and most justly obtaining the prizes offered with twelve bottles each of what he termed Orange, Pine Apple, Raspberry, and Strawberry, "Melidone"—a technical word suggested, we suspect, by the now well-known "Zoedone," and which may be translated into English by the term "Honey-pleasure."

Through the courtesy of this gentleman, who is the able Chairman of the British Bee-keepers' Association, we, with many others, had the pleasure of tasting these beverages, of which we cannot speak too highly.

Six bottles of each exhibit were labelled "sweet," and six "dry." We preferred the latter, and consider that both will greatly improve by age.

The whole was effervescing, and hermetically sealed in small champagne bottles. It was stated to be non-alcoholic, and to be made of the juice of the fruits and pure honey. Mr. Scott also obtained a high commendation. If any further notice of the exhibits in this class were necessary, we would sum up our remarks in the old distich:—

They were like to Jeremiah's Figs:
The good were very good indeed,
The bad too sour for pigs.

Mr. Cowan again, as is his wont, made a clean sweep of all the prizes in the honey-extractor class with his Automatic, Commercial, and Rapid Extractors. In the Commercial a new and most excellent feature appeared, that of a reservoir with strainer attached capable of receiving a large quantity of extracted honey, which may be afterwards drawn off in its purest form—a great saving of labour indeed.

In the miscellaneous classes the specimens of beeswax were as fine as we ever saw. The glass honey jars were beautifully clear and their prices moderate, and most especially to be recommended were those with patent fastenings which obtained the first prize in Class 37.

In crates for the safe conveyance of comb-honey sections by rail or otherwise Mr. Cowan again had no mercy on his *confrères*, carrying off all the prizes in Class 38; and, with the exception of Mr. Blow's first in Class 39 also (for crates for glass jars) with admirable specimens for safety in transit.

The foundation fixer which obtained the silver medal for the same gentleman in the Any other invention class appeared to us somewhat similar to the American machine so generally used in that country. Messrs. Hart of Stockbridge, Hants, exhibited in Class 44 some very superior, strong, English-made 1-lb. sections, cut by machinery from the whitest poplar, and which we were informed could be supplied on more advantageous terms than the American sections. This being the case, we predict for Messrs. Hart an enormous sale of this now necessary article to all advanced bee-keepers.

In the driving competition Mr. J. K. Filbee was placed first, Mr. Walton second, and Mr. Martin third, the shortest time occupied being 3 min. 50 sec.

In concluding our remarks on this the greatest annual event in our bee-keepers' calendar, we must beg to offer our sincere congratulations to the British Bee-keepers' Association, and to all lovers and promoters of English apiculture, on the results achieved since the establishment of the Association in the year 1874, and most heartily do we bid them God speed.

DRIVING BEES.

I SHALL be glad to know through the pages of the Journal what drug is used for stupefying bees for the purpose of driving. I witnessed an operation of driving about three weeks ago, when the operator had in addition to the smoky torch, a small bottle containing a watery-looking fluid; a little sprinkling of this was put on the alighting board some few seconds before commencing his task. This torch was used only in getting the few remaining bees from their combs. The bees were rendered stupid and harmless. I should say the operation was very complete and well performed, doing no harm whatever to the bees. The operator refused to say what his drug was.—J. P. C.

HERTFORDSHIRE BEE-KEEPERS' ASSOCIATION.

THE annual Show of this Association was held in the Castle grounds, Hertford, on Wednesday and Thursday, August 30th and 31st, by the kind permission of A. P. McMullen, Esq. The grounds are admirably situated and well adapted for a show of this kind. Considering the Hertfordshire Association has only been established about four years the Exhibition was an extensive one, and the Committee are to be congratulated upon having disseminated so much useful knowledge upon a pleasing, important, and profitable industry in so short a time. Nearly every important town within the county sent exhibits, and many of the villages were ably represented.

The number of entries of honey were not so numerous as could be wished, but this is accounted for by the adverse weather which prevailed during the month of July. Notwithstanding, some excellent exhibits both of comb and extracted honey were shown by the Rev. F. G. Jenyns and F. Noules of Stevenage; Miss Gayton of Much Hadham; Mr. E. Mathews, Royston; Mr. Gulston, King's Langley; Mr. H. E. Roberts, Hitchin; Mr. Sambels, and others. The prizes for honey offered by the British Bee-keepers' Association were awarded to Mr. E. Gulston, first, silver medal; Miss Gayton, second, bronze medal; Mr. E. Mathews, third, certificate. The special prize of £2 2s., offered by the Hertford Local Committee, was awarded to Miss Gayton.

The exhibits of hives made by members of the Association not being carpenters or hive-dealers, showed a considerable advance in the knowledge of hive-construction. The first prize was awarded to Mr. G. H. Baines, a pupil teacher residing at Tring; the second prize to the Rev. J. L. Seager of Stevenage; and the third to Mr. E. Jackson of Welwyn. There were nine entries in this class, and two extra prizes were awarded. An excellent display of hives and other appliances were shown in the classes open to all England. For the best and most complete hive the first prize was awarded to Messrs. Dines and Son of Maldon, Essex, for a well-made and cheap hive ("The Raynor Eclectic," price £1 15s.). Messrs. Neighbour & Son took second, and Mr. Blow third prizes. Messrs. Dines & Son were also first "for the best hive for cottagers' use," Mr. Blow being second. "For the best collection of hives and bee furniture," first, Mr. T. B. Blow; second, Neighbour & Son; third, Abbott Bros. Mr. Blow also took first and second prizes for the best observatory hives, the third prize being awarded to Abbott Bros.

Mr. J. M. Hooker (from the British Bee-keepers' Association), assisted by the Rev. J. S. Seager, Col. E. Smyth, Rev. F. G. Jenyns, and Capt. Croft, acted as Judges, their awards giving general satisfaction.

Capt. Croft, as Chairman of the Local Committee, was most assiduous in his labours to promote the success of the Show. The honey on sale found ready purchasers at good prices.

TRADE CATALOGUES RECEIVED.

- Harrison & Sons, Leicester.—*List of Flowering Bulbs.*
Hooper & Co., Covent Garden, London.—*Autumn Catalogue of Bulbs.*
Louis de Smet, Ledeborg, Ghent, Belgium.—*Supplementary Catalogue of Plants.*
Charles Turner, Royal Nurseries, Slough.—*Catalogue of Hyacinths and other Bulbs.*
De Smet Frères, Ledeborg, Ghent.—*Autumn Catalogue of Plants.*
Dobbie & Mason, 66, Deansgate, Manchester.—*Catalogue of Bulbs, Roses, Fruit Trees, &c.*
Joseph Schwartz, Lyons.—*List of New Roses.*
James Carter & Co., 237 and 238, High Holborn, London.—*Illustrated Autumn Catalogue of Winter and Spring Flowers, &c.*
Edward Philip Dixon, Yorkshire Seed Establishment, Hull.—*Autumn Catalogue of Bulbous Plants.*

* * All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Antirrhinums (S. & M.).—Many of the flowers sent are beautifully marked, but small; possibly the plants may belong to the dwarf section of this family, and if the spikes are good masses of them would be very attractive. The insertion of this reply was inadvertently omitted last week.

Duchess of Oldenburg Apple (G. Marsden).—This is both an early Apple and an early bearer—that is to say, the trees bear in a small state, and hence are suitable for small gardens. The fruit is attractive in appearance, being streaked with dark red, deepening to crimson in the sun. It is a very good Apple for dessert purposes, and excellent for cooking. It is of Russian origin, and will succeed in your Yorkshire garden.

Wintering Alternantheras (J. M. O.).—If you carry out the plan you propose of enclosing a space with boards and glass over the "bend" of the hot-water pipes in the corner of your greenhouse, you will no doubt be able to maintain a temperature of 50° to 55°, and in this you may, with care, preserve sufficient plants for supplying the requisite number of cuttings for striking in

the spring. *Alterantheras* cannot be safely wintered in a greenhouse from which frost is with difficulty excluded in severe weather.

Turf Litter (C. D.).—We do not understand your question, but print your letter of request in case any of our readers can comprehend the nature of the material to which you allude, and can give any information such as you are seeking:—"I have some of the above offered to me for manure. Do you think it will do as well as the old kind—of course, I mean after it has been in the stable, and if it can be used in the same proportion as the old?" If you had stated as precisely as possible the nature of the "turf litter," and explained what you mean by the "old," your letter would probably have been answered. We doubt if anyone can answer it satisfactorily as it stands.

Hexagon Netting (A. F. M.).—This is a thinly woven material, made, we believe, at Nottingham, but can be had from most of the principal nurserymen both in London and provinces. It is useful for protecting fruit trees from frost in spring, and the fruit from wasps and flies in the autumn, also for placing on the glass and affording a light shade to the occupants of frames in summer. The price varies with the size of the "mesh," the substance and quality of the material, and the width of the pieces. You can no doubt obtain samples and prices on application from the nurserymen and seedsmen with whom you deal.

Extirpating Worms (C. A. J.).—No doubt if you mix half a pint of carbolic acid with a gallon of water and apply it to the walk it will extirpate both worms and weeds; it will kill the grass and Box edgings too if allowed to touch them. Half an ounce of corrosive sublimate (bichloride of mercury) dissolved in 15 gallons of water will cause worms to come to the surface, but care must be taken that fowls do not eat them, otherwise they will be poisoned. A peck of freshly made quicklime mixed with 40 gallons of water, and allowed to stand till it clears, if applied through the rose of a watering pot will have the same effect.

Trees for Avenue (G. S.).—In all probability Beech trees would succeed as well as any in a medium that consists largely of chalk, and either the green or purple-leaved kinds make a good avenue and endure exposure. As evergreen shrubs the different kinds of Hollies would be suitable and effective, while such flowering shrubs as Lilacs, Syringas, Guelder Roses, Weigelas, and Hibiscuses would in all probability grow and flower freely. Whatever you plant you will find it of great advantage to procure some fresh good soil for surrounding the roots, especially of the more important trees, with the object of giving them a good start. Be careful, also, to secure healthy trees to begin with, as if stunted or checked when young they make slow progress afterwards.

Shelter for Currants (Beginner).—We know of no shelter more effective for a plantation of bush fruits in an exposed position than a row or two of Austrian Pines on the windward sides; but then you ask for something "profitable" as well as protective, and the Pines would only be profitable by the shelter they would afford, thus rendering the Currant crops of greater value. If you want a fruit-bearing screen you might plant Filberts and Damsons. The quickest screen is formed by planting Lombardy Poplars close together, so as to form a hedge, which can be kept of any required height by annual trimmings. A number of these narrow hedges intersecting exposed fields devoted to bush fruits would not occupy much space, while they afford valuable protection against cutting winds.

Hoya carnosa (W. H. B.).—This is the name of the plant of which you have sent a small truss of flowers. It is also called the Wax Plant as expressive of the character of the flowers, and the Honey Plant because a drop of clear very sweet fluid exudes from each flower when in perfection. It is a stove evergreen twining plant, and grows freely in a compost of rough peat and loam in equal parts and a liberal addition of lime rubbish and pounded bricks. The plants flourish best in a light position in a stove, but succeed well in a greenhouse where the temperature in winter does not remain for long below 45°; but an occasional fall to 40° is by no means fatal if the soil is, as it should be then, kept rather dry. Cuttings strike freely in sand in a close heated frame or propagating house; even the leaves will emit roots, and soon produce small healthy plants. It is a good old plant, worthy of culture. *Hoya bella* is much dwarfier, very floriferous, and highly attractive.

Planting Ivy (J. R. W.).—We doubt if there is a better and quicker growing form better suited for your purpose than the common Irish Ivy—*Hedera Helix hibernica*, sometimes also called *canariensis* and *graudifolia*. It clings to walls well, covers them rapidly when the soil is good, and forms a close green surface. The ground should be rich yet well drained, and trenched 2 feet deep. Ordinary fertile garden soil enriched with decayed manure, vegetable matter, and wood ashes, adding also a little lime rubbish, will be suitable for promoting quick growth, the plants being watered copiously in dry weather. The distance of planting depends entirely on the size of the plants, and the time of planting on the manner in which they have been prepared. If they have simply to be removed from one part of the garden to another October will be a good time; they succeed also when planted in spring. If we required to cover a wall as quickly as possible we should purchase extra strong plants established in pots, and plant them so that the growths would be trained a foot apart. As the number of growths on the plants vary the distance of planting is necessarily governed by these. If you furnish the requisite particulars to a nurseryman who possesses Ivies in pots he will supply you with the proper number of plants. The time in which your wall may be covered depends entirely on the soil, treatment, and character of the plants. Under very favourable circumstances it might be covered in five years, but under other conditions twice that time might elapse before you attained your object.

Thrips on Vines (S. H. C.).—As the thrips are only attacking three or four Vines near the hot-water pipes the surest, safest, and most effectual method of destroying them would be to sponge the leaves with a solution of soft soap and tobacco water, which your gardener will know how to prepare if he has read the Journal attentively, or nicotine soap at the strength of 3 ozs. to the gallon of water, Gishurst compound of the same strength, or half a glass of petroleum mixed in a gallon of water. We name all these remedies so that you can adopt the one most convenient. A man would be able to sponge all the infested leaves in an hour, and his time would be well employed. We should not fumigate the house now, because of the risk of affecting the flavour of the fruit, as we presume it is ripe, or nearly so. Probably, as you say, the thrips not being numerous would not do much harm. Still, it is very advisable to destroy them, as, if let alone this year, they will probably appear sooner and in greater numbers next season.

Woodlice Eating Peaches (Adam).—It is no trouble whatever to us to endeavour to aid you, or any of our correspondents to whom we can be of service. It is too late now for you to syringe the trees with any strong insecticide, but you might syringe them forcibly with pure water with a view of dislodging any insects that lurk about the wall or branches. Once on the ground you may

prevent them ascending the wall or trees by a barrier of tar, the stems being wrapped in cotton wool and smeared with tar, not applying it to the bark. It will do no harm placed along the wall close to the ground, and as long as it is moist no woodlice will cross it. You had better also trap or poison the insects. Boiled parsnip dressed with arsenic, or, what is better, cooked in an arsenical solution, and then placed in flower pots laid on their sides, these being placed where the insects abound, will entice many of them to take their last meal; or boiled potatoes put in flower pots and covered with moss will form favourite haunts of the pests, which can be shaken daily into boiling water and meet with painless extermination. Perhaps better than the tar for forming a barrier against the woodlice is a mixture of resin and sweet oil—two-thirds of the former melted and one-third of the latter. This if smeared along the base of the wall will keep moist, and none of the insects can cross it. If you had adopted the measures recommended sooner you would have saved many of your Peaches. The fruit may be gathered when it commences to soften near the stalk, and be placed in a warm place to ripen. The flavour may possibly not be quite so good, but fruit of moderate quality is better than such as you describe as not fit to be placed on the table.

Plant Stove Exposed (Rosa).—No doubt the end facing the north-west and much exposed is objectionable, and you might find a difficulty in maintaining the requisite temperature during severe weather. This, however, is easily obviated by having the end of brickwork instead of glass, and facing the wall with Lycopods, small Ferns, fine-leaved Begonias, Tradescantias, and other plants of a snitable nature, or it might be covered with *Marcgraavias* or *Ficus repens minimus*, both of which cling to masonry with great tenacity and have an ornamental effect. For establishing the plants previously named it would be requisite to affix stout galvanised wire netting 2 inches from the wall, filling the space behind with turfy peat faced with moss, and in this inserting the plants. With plenty of moisture and the requisite heat they would grow luxuriantly and be highly attractive. Or, again, the wall might be built so as to resemble rockwork, with pockets for plants. If either of these methods were well and tastefully carried out the beauty of the house would be much enhanced and the necessity for hard firing greatly reduced, while at the same time there would be quite sufficient light for any other plants you required to grow in the body of the house. We cannot advise you as to piping without knowing the height, width, and length of the house, and the kind of plants you desire to have in it, or, at least, the temperature you wish to maintain in the winter. The sprays did not arrive in good condition. The one with dark fruits appears to be a *Phytolacca*, perhaps *P. dcaudra*, and the other *Lycesteria formosa*.

The Electric Light on Vegetation (E. Best).—Our experience on this subject is limited. We can only testify to what we have seen at exhibitions, and examples of plants that had been grown under the influence of the light in question were certainly more advanced than others of the same age, and, we presume, grown in the same temperature, that had not been exposed to its rays. We have observed also that such colours as blue and yellow are seen to the same advantage under the electric light as in the daytime; under gaslight, on the contrary, blue is changed to a greenish hue, and yellow to a tinted white. On the subject of your letter Dr. Siemens, in his presidential address at the British Association's meeting at Southampton, observed:—"In experimenting upon Wheat, Barley, Oats, and other cereals sown in the open air, there was a marked difference between the growth of the plants influenced and those uninfluenced by the electric light. This was not very apparent till towards the end of February, when, with the first appearance of mild weather, the plants under the influence of an electric lamp of four thousand candle power placed about 5 metres above the surface, developed with extreme rapidity, so that by the end of May they stood above 4 feet high, with the ears in full bloom, when those not under its influence were under 2 feet in height, and showed no sign of the ear."

Zonal Pelargoniums (J. H.).—Provided you have good varieties and proper conveniences for growing the plants your failure to produce large trusses is entirely your own, and is not in any degree attributable to the method of culture to which you refer. The best evidence of the instructions being sound was the condition of the plants which we saw, many of the trusses exceeding 18 inches in circumference. The term "loam" is a very indefinite one, and we are not at all prepared to dispute the statement which you quote, as some kinds of loam are quite rich enough to produce such results as you indicate. Perhaps the loam you employ is light and poor; perhaps you attempt to grow more plants than you have space for or time to attend to properly; or possibly you did not commence with stout healthy cuttings. If we knew the nature of your soil and the character of the house in which you have been trying to succeed we might be able to point out the cause of failure; without this information general notes on culture, we fear, would not be more serviceable to you than those which you have endeavoured to follow with such disappointing results. If you will supply us with information of the nature suggested, and submit the names of some of your best varieties, we will endeavour to give information that will be of service to you in your endeavours to produce large trusses of flowers.

House for Roses (J. S.).—We do not think you can grow Roses satisfactorily in the manner you propose, but with ventilators in the sides, also two at each end close to the roof, one over the door and the other to correspond, you would succeed in your object. If you further stretch some such material as open canvas of closely woven hexagon netting over the apertures permanently few sooty particles would find access when the ventilators were open. Instead of having 2 feet 6 inches of glass at the sides we should only have 1 foot 9 inches, the remaining 9 inches above the footboard being a ventilating board on hinges, and made to open the entire length, or if you prefer you might reduce the footboard by 3 inches; you would then have 2 feet of glass at the sides. Without ventilation your Roses would get too forward, and if they were not injured by frost in the spring they would be by insects. With the screens we have suggested and the free use of the syringe you will be able to keep the foliage clean during the season, but in our opinion ventilation is essential for success. The size of the panes will do provided you use thick glass. Such glass as is usually employed would be too weak for such a wide space between the sashbars. You would have light enough if the panes were a foot wide, using 21 oz. glass. The woodwork throughout is abundantly strong.

Names of Plants (E. M.).—*Hypericum umbinum*. (F. F.).—1 and 2 *Agrostis alba* (White Bent Grass), easily distinguished from *A. vulgaris*, the ligule at the base of the leaf being oblong in *A. alba*, while in *A. vulgaris* it is very short and truncate; 3 and 4, *Agrostis canina* (Dog's Bent Grass); 5, *Panicum miliaceum* (Millet). (Pen and Ink).—No. 1 is not the Spurge Laurel; it appears to be a *Veronica*, but a spray showing the character of the plant is necessary for the purpose of identification. 2 is *Cerastium tomentosum*. (W. Thornton).—*Acanthus mollis*; the other specimen did not reach us. (A. E. A., Woodbury Hall).—Two of the fronds are *Asplenium fontanum*; the other appears to be a form of *Lastrea spinulosa*, but from such a poor specimen as the one received it is almost impossible to name correctly. (W. McK.).—1, *Lychnis Salicaria*;

2, a Coronilla, species not determinable; 3, Helianthus, insufficient for specific identification; 4, Coronilla Emerus; 6, Abutilon striatum. The specimens of the hardy plants are too fragmentary.

COVENT GARDEN MARKET.—SEPTEMBER 6TH.

A FAIR supply of Cobs reaching us, but clearing at moderate prices. Trade quieter.

POULTRY AND PIGEON CHRONICLE.

THE HEREFORD BREED OF CATTLE.

THIS breed of cattle was formerly known as the Middle-horn, which appellation was also applied to the Devon and Somerset cattle. Since we can recollect, these cattle, now called Herefords, consisted to some extent of four different colours, but the style and type of each animal were much the same except in colour. The first to be mentioned was the tribe with mottled faces, with red marks intermixed as red spots upon the parts of the body usually white—as the face, feet, &c.; the horn of a moderate length, of a waxy colour, with a slight turn upwards, and tipped with black, the skin being especially mellow, of moderate thickness, and well covered with plenty of soft glossy hair. They were usually good upon the chine; and although they were not considered so docile as some other classes of Herefords, yet they displayed great aptitude to fatten. Another variety, the dark greys, were so called from the broad white stripe which extended the whole length of the back, and the parts usually white being thickly interspersed with small red spots. The horns being rather shorter, with a more upward tendency, the animals were also smaller in size and smoother in hair than the other classes, being better on the chine than the mottled-faces, and possessing flesh of excellent quality. The light grey or white Hereford with red ears were closely resembling the now general red-with-white-face Hereford, the general characteristic of which breed as regards colour is a rich dark red, with a white face, throat, and chest, and white on the neck and along the back, and also inside the legs and the under parts of the body.

Allusions have been found in old chronicles to a breed of white cattle with red ears as being possessed by the Welsh princes on the north side of the river Wye. It is also recorded that Lord Scudamore, who died in 1671, introduced red cows with white faces from Flanders, which may have cropped up in the bull calf

spoken of by a Mr. Fully, by whom it is related that the introduction of the white-faced cattle was accidental, and occurred in the stock of one of that gentleman's ancestors, who lived at Huntingdon in Holmer, and in the following manner:—"That about the middle of the last century the cowman came to the house announcing as a remarkable fact that the favourite cow had produced a white-faced bull calf. This had never been known to have occurred before, and as a curiosity it was agreed that the animal should be kept and reared as a future sire. Such in a few words is the origin of a fact which has prevailed through the county, for the progeny of this very bull became celebrated for white faces." This simple matter in itself was the origin of the peculiar distinction as regards colour now existing in the Hereford breed of cattle, and which is universal wherever the Hereford cattle are met with. We get further information from the above source, which states:—"That it ought never to be forgotten that our county breed might have remained for years located if it had not been for Mr. Westcar, who from 1779 to 1819 never omitted visiting the Hereford October fair and making purchases, and who induced the Duke of Bedford, the Duke of Manchester, Lord Talbot, and other noblemen to adopt the same plan."

Whatever Mr. Westcar might have done towards the advancement of the Hereford cattle, yet it must be admitted that the establishment of the "Hereford Herd Book" by Mr. Eyton, which commenced its records in 1845, had a greater and more far-reaching influence in bringing out the merits and advantages to graziers of the Hereford cattle. Mr. Eyton, however, at first did not receive any very hearty support, and after compiling the second volume resigned his task to Mr. W. Styles Powell, who died before he had completed the third, and Mr. T. Duckham, the late editor, entered upon his labours in 1857. Certainly a more able registrar of the Hereford cattle could not have been found, owing to his practical acquaintance with their breeding and management in his own farming business, and on whose opinions we set so much value that we shall take the opportunity as we proceed of quoting from them. At the commencement of the "Herd Book" there was no little strife amongst the county breeders, for not only were adherents of the white and mottled faces clamorous to be represented, but the light and dark grey breeds possessed some very influential and loyal adherents. All four claims and their breeders were allowed in the drawings on stone, and the mottled-faced Wellington, which was sold for £233 in 1816; the dark grey Victory; the white-faced Cotmore (376), a first-prize Royal Agricultural Society's bull at Oxford; and the light grey Brockswood were the chosen portraits for the first volume.

When the century was young we are informed that the Hereford breeder's pride was wont to develop itself in giving show-yard challenges. The eminent breeder, Mr. Price of Ryall, did not shrink from giving the Short-horned breeders a challenge in 1839 with twenty cows and a bull, when Mr. Bates was flushed with his victories at the Oxford meeting of the Royal Agricultural Society; but the Kirklevington philosopher, as Mr. Bates was frequently called, did not come to terms, and the stipulated month was allowed to pass over without any results. Mr. Ben Tomkins, another celebrated Hereford breeder, although he did not care to send cows from home on such a mission, yet he offered to place twenty cows for a hundred pounds against all comers at Hereford. The Rev. Mr. Smythies of the Lynch, a "singular grand divine" (as shepherds phrase it) among Herefords, as the Rev. Henry Berry was among Short-horns, felt anxious to show five times as many of all ages for the same sum, and Mr. Weyman was ready to bring out his white-faced bull Stockton (237) against all England for five times as much. Such spirited action met with no response, and the breeders contented themselves with a more solid proof of excellence in the prices obtained for the herd of Mr. Ben Tomkins after his death in 1819. Twenty-eight breeding animals averaged £152; and Lord Talbot, who always stood very stoutly by the sort, gave £262 15s. for a cow, and considerably more for a bull.

Before proceeding further with our subject we will give the description and points of the Hereford breed of cattle as stated by Mr. T. Duckham, the ex-editor of the "Hereford Herd Book," as follows—"The face, throat, chest, and lower part of the body and legs, together with the crest or mane and the tip of the tail a beautifully clear white; a small red spot on the eye, and a round red spot on the throat in the middle of the white, are distinctive marks which have many admirers. The horns are of a yellow or white waxy appearance, frequently darker at the ends. Those of the bull should spring out straightly from a broad flat forehead; whilst those of the cows have a wave and a slight upward tendency. The countenance is at once pleasant, cheerful, and open, presenting a placid appearance, denoting good temper and the quietude of disposition which is so highly essential to the successful grazing of all ruminating animals. Yet the eye is full and

lively. The head is small in comparison with the substance of the body. The muzzle is white and moderately fine; cheek, thin. The chest is deep and full, the bosom sufficiently prominent. The shoulder bone is thin, flat, and sloping towards the chine, well covered on the outside with mellow flesh; the kernel is full up from the shoulder point to throat, and so beautifully do the shoulder blades bend into the body that it is difficult to tell in a well-fed animal where they are set on. The chine and loin are broad, hips long and moderately broad, legs straight and small. The rump forms a straight line with the back, and is at a right angle with the thigh, which should be full of flesh down to the hocks without exuberances; the twist should be good, well filled up with flesh, distinguishable by its yielding with a pleasing elasticity to the touch. The hide is thick, yet mellow, and well covered with soft glossy hair, having a tendency to curl. Such are the characteristic marks of a first-class Hereford."

The "Hereford Herd Book," which, in 1878, had recently been disposed of by Mr. Duckham to a company, recorded in its ninth volume the herds of 219 breeders, and had a list of 347 subscribers. The number of bulls entered in the entire work had then reached 5176; of cows, with their produce, 4723; and of heifers, 4905. Within the last few years the most prominent exhibitors at the Royal Agricultural Society amongst others we may mention, are Mr. Wm. Taylor of Showle Court, Ledbury; Mr. Wm. Tudge of Adforton, Leintwardine; Mrs. Sarah Edwards of Wintercote, Leominster; and Her Majesty the Queen. In wishing to obtain the best blood in the kingdom, the home farmer cannot do better than select stock from the prizewinners' herd, although he may not wish to play the part of an exhibitor at the agricultural shows. If he has for breeding purposes the best and purest blood he will be enabled to obtain the most profit, whether of grazing in the summer months, or box-feeding during the winter time, or to make the best price for those animals he may choose to sell for stock. Further, he can obtain the most meat for the food consumed, and in the shortest time, upon the principle of early maturity. If the stock is sold as veal at four or five months old, the Hereford calf will pay better for suckling than any other breed at weight for age, although the only difference we have ever found in our own practice was that the Devon calf was of the best quality and sold at the highest price per pound to the butcher, yet the Hereford calf, under the like circumstances of suckling, would yield the greatest weight for age and fetch the most money. The same rule applies in the rearing and feeding as "baby beef."

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—This is a particularly busy time now for the horses, so that unless some means are adopted for supplementing their work, such as the use of oxen for a time, as we remarked last week, or the aid of steam power for cultivating, all the work required or necessary to be done before the 1st of December next cannot be accomplished in a satisfactory manner. Since reaping commenced the tillage of the land has crowded upon us, all requiring immediate attention in addition to the actual horse labour required for drawing the reaping and binding machine, the carting of corn to the rick or barn, as well as cutting the latter growth of Clover and other grasses, and the carting of the hay to rick. It must be considered that it is not good commercial farming to allow this work to have stood in the way of proceeding with tillage work; for unless we have the power available by steam or otherwise of tilling the stubbles directly they are cleared our tillage power is insufficient; in fact, much should be done in the way of drilling stubble Turnip seed between the stooks of corn. It is in this way in the early districts that capital stubble Turnips are obtained after Wheat, Rye, white Oats, winter Oats, and early Peas, otherwise our establishment for autumn tillage, &c., is by no means equal to a profitable mode of conducting the labour of the farm in the autumn period. The sooner Trifolium sowing is done the better; 25 lbs. of seed should be sown per acre on the bare stubbles (which, however, should be free from couch), and then by using the iron harrows crossways and lengthways, followed by the chain harrows, and then rolled down. The collected stubble should be removed for use in bedding pigsties. The next work is sowing Rye, 3 bushels of seed per acre. The land should be ploughed and pressed, and the seed sown after the presser, or, which is better, by the press drill; it will then be buried deep enough to obtain firm hold of the subsoil, a matter of great importance in the event of a severe winter ensuing.

Winter Barley must next be sown, 3 bushels of seed per acre in the same manner as for Rye. In the event, however, of the black variety being sown 4 bushels will be required, for it does not tiller so much as the ordinary sort, but leaves the ground quicker in the spring, and is the most forward cereal plant known as a green-fodder crop. Vetches of the winter variety should now be sown, and if required for early feeding the early sort a very small grain should be sown with Rye or winter Barley in admixture, as the leaves of the cereals protect the Vetches in their first growth, and hold them up off the ground at full growth; 2 bushels of Vetches and 1 bushel of cereals will be sufficient

seed per acre. Italian Rye grass, too, may now be sown on a clean stubble, as it will give two good foldings for stock, or cuttings of green fodder before the preparation of the land is required for the root crop following; 3 bushels of the best foreign seed well cleaned and prepared by the seedsman is required for an acre, but we would not sow seed grown at home upon any account, as it does not produce either such a full crop or come so early or so quickly in the successional growth. Cart manure from the farmyard, the cattle boxes, pig-pens, &c., to the field where required, and the sooner it is spread and ploughed under the better, whether it is on lea or fallow ground; and the land when ploughed should be pressed at the same time; the land may then remain until seed time, as it will become stale and mellow to receive the seed. On the fallowed land, especially where the soil is cold and lies flat, the sooner the dung can be laid out the more likely it will be to finish the carting work before the heavy autumn rains and without injury to the seed bed by treading; the dung, however, should be ploughed in a good depth in order that it may be properly buried, because if done in that way the land may remain undisturbed until drilling-time, the first or second week in October being the best time. Upon such soils the Wheat should be drilled 12 inches apart between the lines; 2 bushels of seed at the early season will be sufficient, but should the seed time be delayed 2½ or 3 bushels should be drilled. This wide drilling applies more particularly to strong soils, which are usually subject to Goldweed, black bent grass, &c., for either of them in some seasons will ruin the Wheat crop unless horse and hand-hoeing can be carried out. In fact the home farmer is never master of his position unless he can destroy the weeds, which he cannot do under broadcast sowing, except upon land after Clover lea, which is seldom troubled with weeds in spring; this should always be seeded after the presser. We do not like drilling on lea ground, as the young plants are more likely to be lifted by frost and injured by wireworms, and again if required, horse and hand-hoeing may be done equally well after the presser or press-drill as after that seeded by the ordinary drill.

Hand Labour.—Hedge-trimming, especially Whitethorn hedges, should now be done, the last time before the young shoots get hard and wiry. Drawing straw and piling away ready for use in thatching should be done at those intervals of showery weather which interfere with harvest work; and we must again advise the home farmer to teach every capable labourer in his employ to build ricks and thatch them; the weather has been so stormy that stacks have been damaged on nearly every farm in consequence of not having been thatched as soon as built.

Live Stock.—All those bullocks which are fat and having been grazed upon the pastures may be sold, but those not quite fit should now be allowed about 4 lbs. of linseed cake and 2 lbs. of crushed beans or peas, as the grass lands are getting stale and the aftermath not so healthy and forcing as that of summer growth. Where the pasture have been grazed by dairy cows during the summer there will be tufts of grass left, and these should be cut off and cleared away, as these bunches of seedy grass often contain ergot, which produces abortion. If, however, these pastures are fed by steers or young stock they may be allowed to eat it down during winter without receiving injury. The hill flocks of down breeding ewes, as well of the long-wools, in the vale pastures of the midlands will now have the rams running with them; and if it is desired to force the ewes by extra feeding for the purpose of obtaining earlier lambs and more twins, the food and feeding ground should be changed twice a day, and they may also receive with advantage crushed beans, maize, or cotton cake about half-a-pound per day each. In purchasing sheep stock for winter feeding great caution will be required, for they are selling at high prices, which means an investment of more capital without any extra profits in view to compensate for the outlay.

HOP PROSPECTS.—The *Kentish Observer* finds that its special reports from the Hop districts are more unfavourable this week than ever. The ungenial weather has caused great damage throughout the county, but greater mischief still has been done by the spread of mould. It is impossible now for the grounds as a whole to yield what they promised to do about a fortnight ago; they will, it is estimated, produce from 1 cwt. to 2 cwt. per acre less, as a consequence of the combination of deterrent influences recorded above. In most of the grounds about Canterbury the Hops look shrivelled up and the leaves brown and black. Inside they are better, and here and there were some nice-looking Hops—fairly well developed and of a bright green hue. Mould and mildew are spreading. Although the Faversham district is favoured as compared with other parts of the county, there will not be so many Hops grown in this district as it was thought there would be a fortnight since. The weather is not warm enough to make them grow out, and some few gardens are going off with mould. In the neighbourhood of Maidstone artificial aids have done much to improve the condition of the crops which have been preserved, and though the yield will be small some compensation is looked for in higher prices.

THE FRENCH HARVEST.—The annual report upon the French harvest supplied by the firm of Estienne & Co. of Marseilles, states that the Wheat crop has been very good in twenty departments, good in forty-six, pretty good in eleven, inferior in nine, and bad in

one (Corsica). The Oat crop is described as being very good in twenty-two departments, good in fifty-five, pretty good in three, and inferior in seven. The Maize crop is very good in two departments, good in twenty-four, pretty good in three, and inferior in six. Rye is described as being very good in six departments, good in fifty-one, fairly good in eleven, and inferior in eight; while the Barley crop is very good in fifteen departments, good in forty-five, pretty good in nine, inferior in four, and very bad in two. The report is, therefore, upon the whole a very favourable one.

PRIZES FOR CROPS IN NORTH DURHAM.—The Judges appointed by the East Chester Ward Agricultural Association to adjudicate between the competitors for the prizes for the best crops offered by the Association for its members have given their decisions as follows:—Wheat—first, Mr. William Ebdon of Fulwell; second, Major Briggs, Hylton Castle. Potatoes—first, Mr. Wm. Snowdon, Harton Down Hill; second, Mr. John Douglass, Whitburn Bent. Even upon this strip of fertile land along the coast the Judges say the crops are not above the average; but they are glad to place on record the fact that up to the time of judging no disease is to be seen among Potatoes.

HAY MITES—SALT IN STACKS.—Many years ago after stacking Italian Rye Grass hay, grown from seed imported direct, and from which I had two cuttings, both bearing seed, available for the following year, salt was scattered upon the hay when stacking, and around the base of the stack a few weeks after was found a heavy line, particularly on the southern side, of buff-coloured insects dead. I at once came to the conclusion that seemed to be the only reasonable one—that the animalculæ escaping from the salt in the interior had come to the outside, and then, dropping to the ground from the eave, had perished in a body. When the cattle were supplied with the hay in winter there was a marked improvement in their condition and yield of milk, partly, I suppose, due to the superior quality of the hay, and partly to its having been sprinkled with salt in stacking.—N. (*Irish Farmers' Gazette.*)

POULTRY AND PIGEONS

LATE POULTRY SHOWING.

It is not long since we gave our opinion generally upon the early showing of young poultry—*i.e.*, the exhibition during the summer months of forward young birds of the year. We freely expressed ourselves against it as the general rule, though it has its use in particular cases and for particular breeds. We much prefer late showing—*i.e.*, the exhibition of young birds in autumn which have nearly or quite reached their growth for the first year, and they have or ought to have strong and matured constitutions. For the former chickens must necessarily be forced if they are to make a good appearance, in the latter case those reared under the most natural circumstances are frequently the most successful.

Autumn is near at hand, and it is high time for the poultry fancier to have his eye upon those birds likely to be the representatives of his or her yard at the great autumn shows. Now, therefore, is the time to give some instruction for their management henceforth. Those who only attend to their poultry just before the time of shows can hardly expect to be successful. All chickens with glaring faults have of course long ago been weeded out. From time to time unfortunately something will go wrong with some of those which have seemed the most promising. Over-quick growth brings wry backs, and abnormally heavy frames cause weak legs; but even after the further deduction of the stock that follows such misfortunes there will be differences in the residue. A quick eye will observe a chicken here and there which seems to grow faster than its fellows of the same age; often it may for a time appear an ungainly creature, but experience becomes prophetic and teaches to descry in it the signs of future excellence; or in a bird of colour here and there a back or hackle feather of surpassing richness or purity will peep through the chicken garb, hitherto mixy and unpromising. We need hardly say that such birds should have the best runs, and that all inferior birds should be made to give way to them. This holds good for all kinds, from the largest Brahma to the smallest Bantam. The fewer fowls that are kept together the better they thrive. Beyond this, however, there is considerable difference in the treatment proper for birds of mere feather, and for those which must be large as well as of typical beauty. We will take the two classes of varieties separately.

1. In the case of those kinds in which size is of no advantage, as Hamburgs and Polands, or is a positive disadvantage as Bantams, we should generally leave the chickens of both sexes together, un-

less the cockerels become very troublesome and spoil the pullets' plumage. Full development of the male plumage, especially of flowing tails and well-grown hackles, is in nearly all these a great point, and this is promoted by the presence of hens. It is, too, absolutely necessary that a show cockerel should not be bullied. In the case of Hamburgs and Bantams we have specially observed that the cockerel of the walk advances in sickles far beyond his subordinate brothers. It must therefore be managed that any very promising bird may have command of his run, either by moving him to a vacant one or by the removal of all others likely to clash with him. Stimulating foods always stimulate pugnacity, and should therefore never be given so long, as it is desired to keep a large party as a happy family.

It must not be forgotten that a bad fray even between half-grown cockerels is a serious matter. The crest feathers torn from a Poland chicken will often not be replaced for months, and a tear in the lobe of a Spanish, a Hamburg, or a rose-combed Bantam may spoil him for life as an exhibition bird. If any tendency to bickering shows itself such cockerels must at once be separated. It is impossible to keep any number of cocks whose beauty is so easily damageable without many small enclosed runs in which they can be isolated or mated with a hen or two. As long, however, as all goes on quietly, and the favourite cockerels are not kept under by others in such a way as to retard their due development of plumage, we should leave them together quite into the autumn. On large premises, especially where the birds form themselves into parties which range in different directions and do not interfere with each other, this arrangement may long continue with a little management. We have in this way kept many show Hamburgs together, even after the cocks had frequently been shown; it is not, however, an experiment to be tried by a beginner.

As the day of exhibition approaches, say ten days beforehand, the chosen young chanticleer, unless he be veritably the cock of the walk, should be put with a couple of hens in a run by himself and well fed. A very few days of such treatment will make the greatest difference in his looks and courage. Pullets of such breeds, if tolerably early hatched, seldom need any special preparation beyond confinement for two or three days, not necessarily the last days, before exhibition in a show pen to accustom them to it. This makes a great difference in their chance of success, if they are at all wildly inclined.—C.

(To be continued.)

OUR LETTER BOX.

Italian Rye Grass (Farmer).—This will last the second year, but will not be so profitable as during the first year, as it is apt to die and become hollow at the bottom in the winter months; but still it will give large crops in succession, especially if nitrate of soda is applied immediately after each cutting, at the rate of 1½ cwt. per acre, and the best foreign seed has been sown in the first instance. We recommend that the back number of this Journal should be obtained dated the 24th of July, 1879, wherein the cultivation, &c., of Italian Rye Grass is set forth in every detail. It can be had from our office in return from 3½d. in postage stamps sent to the publisher, with the date of the paper required.

REMARKS.

27th.—Overcast with scarcely any sunshine.

28th.—A little sunshine in the afternoon, but generally dull and overcast; heavy shower at 8.30 P.M.

29th.—Morning showery; afternoon and evening fine and bright.

30th.—Heavy clouds in morning; bright afternoon and evening.

31st.—Dull overcast morning; very wet afternoon and evening.

1st.—Morning bright at intervals; showery afternoon and evening.

2nd.—Cloudy with high wind, but on the whole fair.

A dull and cloudy week with a good many showers. Mean pressure slightly below that of the preceding week; mean temperature about the average, and almost identical with that of the preceding week, but there was less sunshine.—G. J. SYMONS.

GATHERING AND STORING FRUIT.

I AM afraid the above heading will appear like a grim joke to many of the readers of this Journal, and some, perhaps, will uncharitably remark: "What is the good of advising upon the subject when we have little or no fruit to gather and store?" Luckily all of us are not so badly situated, and those who own or are in charge of gardens well sheltered from the furious gale experienced on April 29th have good cause to congratulate themselves. Up to that date the prospect generally was bright enough, but the storm completely changed it; and instead of heavy crops of Apples and Pears in particular, the question was not whether this season's crops would be worth anything, that being easily determined, but whether next season's prospects would not be blighted, so seriously cut were all exposed trees. All, however, have not lost their crops of Apples and Pears, and as these are likely to prove of considerable value I propose to offer a few remarks upon securing and storing the fruit.

More judgment is required in this matter than is generally exercised, as not a little depends upon gathering at the right stages and properly storing. Pears especially in one man's hands may prove of little value, while the same examples might easily have been transformed into delicious dessert fruit. Apples may also be easily mismanaged. There is a certain stage when both kinds should be gathered, and if this is anticipated or passed the quality is risked. According to my experience neither kind should be gathered and eaten at once, neither should they remain on the tree till presumably ripe—that is to say, in a dropping state, as by storing only for a short or long time, according to the variety, can richness and lusciousness be obtained. The proper time to gather is when the seeds are found to be nearly brown or black, and the stalks part freely from the trees when the fruit is lightly lifted. If gathered before they arrive at this stage the fruit is almost certain to shrivel, while if allowed to remain till ready to drop they are liable to become flat in flavour, both results being objectionable.

At times it may be advisable to gather part of the crop before being really fit, in order to artificially ripen the fruit, and thereby both obtaining dishes when perhaps much needed, and also lengthening the supply. This practice is particularly necessary in the case of notorious bad keepers, such, for instance, as the delicious Pear Williams' Bon Chrétien. It is useless to pick these before the pips have commenced changing colour, but when found to be changing a quantity of fruit may be gathered, packed in hay in a hamper or box, and placed in

a warm forcing house or a kitchen at a safe distance from the fire, which will induce early ripening without much impairing the quality. To succeed these more may be gathered at the same time or in the course of a day or two and placed in the fruit-room, this again hastening ripening, and in this manner the whole of the crop may be ripened and eaten with the loss of few if any fruit. We ripened a good dish of Williams' Bon Chrétien by August 24th, and from the trees growing in three different aspects we shall continue to gather small quantities, and ripen the fruit in all probability throughout September. Another very delicious Pear, Louise Bonne of Jersey, is also very amenable to this practice. The same method of inducing early ripening may be adopted in the case of heavy crops of Apples or Pears, or where it is necessary to maintain the supply without the assistance of certain varieties generally relied upon.

Last season it was not a question of hastening but of retarding ripening, as nearly every variety was fit for use at unusually early dates, great offenders in the respect being Winter Nelis, Knight's Monarch, and Easter Beurré Pears. This season the reverse will probably be the case, as, unless a great change in the weather occurs soon, the absence of sunshine may result disastrously to the fruit. In all probability early frosts will be experienced before much of the crop can be considered fit to gather. Even slight frosts may not prove serious evils, but I prefer the fruit to part freely from the tree without their intervention. Neither Apples nor Pears are frost-proof to any appreciable extent, though in the case of some long-hanging sorts a slight frost is often of service in preparing them for gathering. Apples and Pears should, as a rule, be gathered as they become ready, neither before nor after if required to keep unimpaired in quality, and this plainly indicates the danger of gathering all sorts at a certain date. It may be more convenient to have a wholesale clearance, but it is far from being the most profitable practice. They should always be gathered in a dry state, every care being taken not to bruise them.

Storing, the second part of my subject, is by no means the least important. We sometimes see gardens where fruit trees have been planted well and extensively, and yet no adequate provision made for properly storing the produce; while others provide an elaborate fruit-room far beyond the requirements of the garden. The former, at any rate, err greatly in not providing a good fruit-room, neither are we in favour of a large half-empty room. Apples and Pears are too often stowed away in various unsuitable places, those responsible evidently forgetting that a great chemical change has to take place before the so-called ripe fruit is really fit for eating, and that the circumstances under which this change occurs materially affect the quality.

When first gathered the fruit is composed largely of starch and acid, and in course of time this, by a natural process which I shall not attempt to explain, is converted into sugar, much of the water of the juice being evaporated. Now the most favourable position to assist this conversion is a dry, airy, but not draughty room, and the worst a close, damp, badly ventilated structure. Fruit gathered from the same tree and placed in two such widely differing places will, when in season, be found as widely different in quality as two distinct varieties, those in the drier warmer room being invariably richer, sweeter, and brighter in colour. Evaporation form-

ing part of the process of conversion, it is very evident this is not much encouraged in a damp cold structure; but at the same time rapid evaporation caused by either excessive heat, light, or strong currents of air is harmful, and may result in shrivelling and loss of quality.

If we wish to improve the appearance of either Apples or Pears, as well as to hasten the ripening process, these are packed in hay in boxes and placed in heat as previously mentioned. If near their proper time of ripening, Apples and Pears will bear a good heat and ripen in two or three days; but if we endeavour to ripen them out of season the process must be gradual, or the fruit will inevitably shrivel. Artificial ripening will sometimes convert examples thought to be worthless, and which but for the experiment would have remained worthless, into delicious fruit.

The commoner sorts, more especially of Apples, may be stored in heaps or thinly on the floors of the fruit-room, while the choicer varieties ought to be disposed thinly in single layers if possible on the shelves, the Apples stalk downwards, and Pears the reverse. Each sort should be divided with strips of wood and be properly labelled. If there is no provision for keeping out the frost the latticed staging or shelves and the floor should be covered with hay or straw previous to bringing in the fruit, and more of the same material be at all times kept near in readiness for covering the fruit when frost is imminent. Frigi domo, canvas, and mats may also be utilised for the same purpose. For our room we have a portable stove heated with paraffin, but should not depend entirely upon this, as I have seen much fruit spoilt by severe frosts, and now am always anxious to be "on the safe side." The less fire heat employed the better, however, for the simple reason it is certain to hasten ripening generally, whereas it is our aim to maintain the supply as long as possible.

Apples and Pears must be handled carefully when picked, and at all times if they are expected to keep, and when tested as to ripeness should be pressed with the thumb only near the footstalk. If not soft there they are not at their best, and, besides, the slight bruises do not disfigure the fruit or greatly impair its keeping qualities, as would otherwise be the case. All should be frequently examined, as a few decaying fruits will spoil others that are in contact with them. Heaps especially will be greatly benefited by being turned and sorted, and great care should be taken in the first instance not to mix any bruised or otherwise damaged fruit with the sound ones, or all may be spoilt. Fruit with small holes picked in them by birds will not keep. Blackbirds and tomtits are great scourges this season, and as the former only visit us when fruit is to be had we have no mercy on them.

Filberts and Walnuts when gathered, the former before they shell out too freely, should be dried on the floor of the fruit-room, and then packed away in boxes or jars and placed in the darkest and coolest corner. They keep fresher in a cellar or in jars buried in the earth, but this deprives them of much of their sweetness, and in my estimation renders them worthless.—W. IGGULDEN.

PROPAGATING EUONYMUSES.

IN January last I pointed out the value of these variegated shrubs for decorative purposes, and notes on their propagation will now be seasonable and probably acceptable to some of your readers.

All the varieties can be propagated by cuttings. The treatment of *E. radicans variegatus* differs slightly, as it is perfectly hardy, grows rapidly, and is often increased by division, yet thousands are annually produced by cuttings. This variety is too well known to need any comments from me. The cuttings should be taken if convenient during the month of September, the earlier the better, providing the wood is sufficiently ripened. Although the time mentioned is preferable, they can be inserted any time during the winter, and success will follow, as they root readily when judiciously treated. The points of the shoots should be selected, and the cuttings then trimmed 2 to 3 inches in length. The wood must be cut clean below a joint, and the leaves removed for about half the length of the shoots. Care must be taken not to let them wither before inserting them. Eight-inch pots are the best for the cuttings. These should be well drained and filled with sandy soil, with a good layer of sand over the surface. The soil should be pressed rather firmly into the pots. The longest

should be placed in the centre, with the next size near them, the smallest being placed at the sides of the pots. In nurseries great care is exercised in this respect, not that the cuttings root any better, but they look neater and more workmanlike, and little if any longer time is required than by an irregular system. After insertion a good soaking of water should be given, and the pots placed in cold frames or boxes similar to those recommended for Conifers, only sufficiently large to hold at least a dozen pots. These frames or boxes must be placed between two span-roofed houses, or on the shady side of a hedge or wall where the temperature will be uniform. The frames should be kept close, and but little other attention is needed, only to see that the soil in the pots does not become dry. After one good soaking the plants will not need water again for a long time, as evaporation is limited with the frame kept close. If the weather is sunny shading must be resorted to and the pots lightly damped occasionally with the syringe. The cuttings can remain in this position as long as the weather continues open—in fact if the winter is not severe, no better place could be given them. In severe weather the less hardy varieties should be removed to the close frame in the Conifer house. The green-leaved varieties, such as *E. latifolius* and the hardy *E. radicans variegatus*, can remain in the boxes, but must be protected with mats or other material to prevent, if possible, the cuttings and soil becoming frozen. I have known many deaths result from this cause, especially if removed when frozen to a warmer place.

When they are conveyed from the cool boxes to the Conifer house some care is necessary for a time to prevent the cuttings damping. If taken late it is preferable to place them in the close frame in the house where a gentle heat can be given, or if they have been taken early they will be callusing, and will be somewhat benefited by the change. In this stage the warmth of the Conifer house assists them to produce roots, after which they should be transferred to 3-inch pots, and if the close frame can again be spared them for about a fortnight so much the better. In nurseries generally there is abundance of pits or frames with one or more small hot-water pipes running through, where such plants can be kept close and properly treated for a time when first potted; then the heat is gradually reduced and the plants finally grown on under cold-frame treatment without a check.

Sandy loam and a little manure mixed with it suits these plants well. If the loam is good and rich the manure need not be employed. When all fear of frost is past the young plants can be plunged outside in long narrow beds, the pots being entirely covered with the plunging material. The points of the shoots should be taken out to induce the young plants to become bushy, supplying water whenever they require it, which is all the attention needed until autumn. The green forms and *E. radicans variegatus* are treated exactly alike, only heat is not required by them. They are kept in pots for a time, and eventually planted out and lifted for transplanting during the same season as Conifers and other evergreens.

I may add for the good of those who wish to grow them for window plants and increase their stock, if the cuttings are made as I have described, inserted in a pot, and a tumbler placed over them, a fair percentage may be rooted even in rooms.

In growing standards it is best to keep them growing in pots without stopping them, removing all side shoots as they appear until they attain the desired height, when they should be pinched to form a head. Standards are induced to grow most quickly by keeping them indoors.—W. BARDNEY.

RENOVATING OLD PEACH TREES.

To keep Peach trees in good health the roots must be well attended to, as if these are out of order the crop will be lost. Having had some experience with old Peach trees I will now state it, as it may be of use to those who may be placed in the same predicament as myself a few years ago. The trees were covered with red spider, the shoots very succulent, some of the branches dying, no roots within 2 feet of the surface, and those devoid of fruit-feeding fibres. My employer told me that he had not had a crop of fruit for seven or eight years.

I commenced the work of improvement by cutting out most of the succulent shoots and well syringing the trees early every morning to keep the red spider in check, and employed a little fire heat, affording free ventilation to ripen the wood. When the leaves commenced changing I dug a trench 6 feet from the base of the tree and worked the old soil out with steel forks. It was very light, having been in the border for several years. When the roots were clean the drainage was rectified and the border filled with good yellow loam, lime rubbish, and charcoal dust, and

the roots laid near the surface, a good watering being then given to settle the soil about them. The house was kept as cool as possible consistently with the health of the plants that had to be grown in it. The trees were started during the last week in February. This would have been deferred, but fruit was wanted early. The pipes were only just kept warm until the stoning was completed, and after then the growth was not hurried.

The result of the above practice was that the fruit was very much finer than formerly, but the trees were only allowed to carry a moderate crop. The two subsequent seasons the trees were pronounced grand, and carried a heavy crop.—A. YOUNG.

PRESTON FLORAL AND HORTICULTURAL SOCIETY.

THE Exhibition of the above Society was held in Moor Park, Preston, on Wednesday the 6th inst., lasting three days, in connection with the Royal Manchester, Liverpool, and North Lancashire Agricultural Society's Show. Although on Monday and early on Tuesday it was very wet, and the grounds were in a very bad condition, the prospects were greatly remedied on the appearance of summer-like weather. The decision of the above Society to hold their Show during the Guild week was evidently a wise one, as the Show was well attended, and we trust the financial condition of the Society will be materially improved.

There were three large tents well filled with a good collection of plants, fruits, and vegetables, and a liberal schedule was arranged for cottagers and amateurs. There were also two other smaller tents filled with miscellaneous exhibits. Specimen plants, both stove and greenhouse, were good and clean, including *Lapagerias*, Palms, Cycads, Ferns both exotic and hardy, and a very varied assortment of other plants. The specimen of *Lapageria alba* exhibited by Mr. Forshaw was particularly fine, and richly merited the prize for the best plant in the Show. It had abundance of its charming white wax-like flowers. Softwooded plants were numerous, such as *Coleuses*, *Pelargoniums*, Tuberos-rooted *Begonias*, *Salvias*, &c. Some of the two former groups were finely grown and of good colour. Lilies and other hardy flowers were not quite satisfactory. Cut flowers were largely staged, and the wreath of *Camellias* shown by Mr. Wm. Troughton, the Secretary of the Society, was well arranged, and well merited the award. Fruit was but scantily shown, and certainly not up to the average; but for this deficit the vegetables made satisfactory amends, as many of them were very good.

Messrs. Dickson, Brown, & Tait of Manchester exhibited a fine collection of Potatoes, Roses, and Dahlias, and received a special prize. The Roses were fine for so late in the season, while the Dahlias were examples of good culture. Messrs. W. Caldwell and Son of Knutsford, Cheshire, exhibited a collection of Coniferous plants, including but few rare specimens but those most useful for general decorative purposes, and these were effectively arranged. A special prize (silver medal) was also given to that firm for the exhibit. The hot-water appliances, &c., exhibited by Messrs. Medcalf & Dilworth, hot-water engineers of Preston, was unique, and merited a special prize. Other miscellaneous groups which received special prizes were those of Mr. L. Black, nurseryman, Fulwood, for a variable group of plants; Mr. Tyson of Ulverston, for hot-water apparatus; to Mr. W. Clapham for an artistic rockery; and to Mr. William Troughton of Church Street, Preston, for his magnificent stand of plants, which upon the whole was one of the finest features in the Exhibition, the plants being well grown and most effectively arranged. Much of the success achieved is due to the energy of the Chairman and Secretary of the Society, Mr. Alderman Forshaw and Mr. Wm. Troughton.

In the plant classes the principal prizetakers were the following:—Mr. W. Troughton, Preston; E. Forshaw, Esq., Fulwood; Col. Wilson, Cooper Hill, Preston; W. Denny, Esq., and C. W. Hawkins, Esq., Ashton. For twenty herbaceous and alpine plants a silver medal was given to Mr. T. Miller of Woodplumpton, who exhibited a very creditable collection.

In the cut flower classes the most important prizewinners were Mr. Wm. Troughton, W. Birley, Esq., Mr. A. Barker of Fulwood, Mr. J. B. Dickson, Preston; Mr. R. Teebay of Fulwood, and Mr. J. Counce.

In the fruit classes the following exhibitors were the most successful:—Mr. W. Loose of Winmarleigh, Col. Wilson, R. J. Flowerdew, Mr. E. Pirley, S. C. de Trafford, Esq., of Croston, and Mr. R. Smith.

Vegetables were largely exhibited and in very fine condition. For the best collection of twelve varieties of vegetables the first prize was given to J. Wilding, Esq., of Walton; second Mr. J. Parker; third Mr. J. Titterington of Fishwick.

THE ROYAL MANCHESTER, LIVERPOOL, AND NORTH LANCASHIRE AGRICULTURAL SOCIETY'S SHOW—HORTICULTURE.

There were several important exhibitors in the grounds upon which the Agricultural Society's Show was held. Messrs. Sutton and Sons of Reading had their grand display of seeds and roots, which were a great centre of attraction. Messrs. Webb & Sons of Stourbridge also had a remarkably fine exhibition, comprising chiefly seeds, vegetables, and farm produce. Messrs. Dickson & Robinson of Manchester exhibited a fine collection of Potatoes, which were well arranged. The same firm also exhibited a collection of Dahlias—

Show, Fancy, and Pompon varieties, the flowers of most being large and of good form. Mr. J. Matthews of Weston-super-Mare had a stand of pottery, including pots of various patterns, vases, &c. Messrs. James Dickson & Sons of Chester exhibited a fine collection of stove and greenhouse plants, including Tree Ferns, Palms, Crotons, *Dracaenas*, exotic Ferns, &c., which were tastefully staged in a large tent with double Tiger Lilies and trays of superb Roses for so late in the season, as well as trays of about fifty varieties of hardy herbaceous plants and a tray of a dozen flowers of their new white *Carnation Duchess of Westminster*, which was greatly admired. Outside the tent was a large well-arranged group of Coniferous and other hardy shrubs, interspersed by brilliant *Gladioli* and Tiger Lilies; and not the least striking feature for this season were the numerous

Fig. 40.—*Scabiosa caucasica*.

small Apple trees well laden with fruits of excellent form and good size. There were also boxes of blooms of Roses, single and double-flowered Dahlias, *Gladioli*, and a good collection of Apples outside. Excellent examples of Grape Vines were also shown. Messrs. F. and A. Dickson from the same locality had also an excellent collection of stove, greenhouse, and decorative plants, as well as a choice assortment of hardy shrubs, &c., all of which were creditable to the firm represented.—VISITOR.

SCABIOSA CAUCASICA.

THE common Scabious, *S. atropurpurea*, is well known and much valued in gardens, not only as a border plant but in pots

for decoration or to furnish a supply of fragrant blooms, and in many establishments it is now largely grown for the latter purpose. A beautiful but quite distinct companion for it in the flower border is *Scabiosa caucasica*, of which a woodcut is given in fig. 40. This species undoubtedly deserves a place in every collection of hardy plants; and though it has no claim to novelty its beauty is amply sufficient recommendation to cultivators. The flowerheads are 3 or 4 inches in diameter, bright pale blue, and they are very freely produced, rising above the long slender pinnatifid leaves. It is of compact habit when growing freely, as it will in any moderately good garden soil, but rarely exceeds 3 feet in height even when most vigorous. The flowers are well adapted for cutting, as they last a considerable time in water.

LATE GRAPES.

FOR some weeks past the weather has been unfavourable for the ripening of late Grapes, and more fire heat than usual has been needed. Those who started their Vines gently early in the season will now have their fruit well coloured and ripe and in good condition for keeping. I have always found Grapes keep better when ripened moderately early and without having to force them too hard in their last stages, and none has ever kept better with me than those ripened towards the end of August last year. Both Alicantes and Lady Downc's were fresh and plump, with their footstalks as green as when cut from the Vines; in fact, in such condition that they were used until the new ones were ripe and placed on the table with them the following May. It is difficult, especially in seasons like the present, to thoroughly ripen Grapes on Vines that were allowed to start naturally and develop during the best part of the season without fire heat. To attempt to keep back Vines, as is frequently practised, for the purpose of having them late or for fear of their ripening too early, is a great mistake and a waste of time, not to mention the extra fuel required in autumn to ripen them and the wood. Grapes ripened six weeks or two months later than the time I have mentioned will not keep in good condition for that length of time longer the following season than those ripened earlier. Early in the season only little fire heat is needed to start late Vines into growth when the power of the sun is daily increasing, which gives the cultivator every chance to allow the Vines to take their time as soon as they show signs of colouring. Many late Grapes fail to finish and keep well through the efforts made to ripen them when the days are short and the sun's power decreased. I have long since failed to see any advantage in retarding Vines during the best part of the season, and then resort in autumn to an unnatural system to bring them to perfection; but prefer starting them moderately early, and allow them to develop with abundance of ventilation both night and day, which ensures thick leathery foliage and firm wood, which will be thoroughly ripened by this time and certain to produce good fruit again the next season.

I am acquainted with more than one grower who will not have their Grapes ripe for some time yet, and who wish now they had started the Vines earlier. It is always wise to be on the safe side, and this season may teach valuable lessons.—CULTIVATOR.

THE LONDON PARKS.

HAMPTON COURT.

ALTHOUGH this magnificent old pile is not usually reached in much less than an hour from the Waterloo station (while the journey by river, however pleasant in fine weather, is nearer three hours), yet it must still rank in the above category, at least in its gardening aspects, for the pleasure grounds are under the same governmental supervision as the other parks, while it is essentially a great rendezvous of Londoners. And not Londoners only; all parts of Europe, America, and the Antipodes send visitors to see the great building and its beautiful surroundings.

Passing through the Palace the visitor enters the grounds about the centre of a noble terrace walk nearly 40 feet wide and approaching a mile in length. Before him, looking across the extensive lawn, are three grand avenues reaching far across the park. In a line with these are walks intersecting the lawn and flanked with ancient Yews; thus the avenues appear to converge on the main eastern entrance of the building. On each side of these walks the flower beds are arranged also along one side of the terrace walk and round the lawn. Altogether there are ninety beds, many of them 12 feet wide and some 36 feet long, but the majority are 24 feet in length. Then on the opposite side of the long walk is a ribbon border, and behind towards the back part of the lawn herbaceous borders recently planted 200 or 300 yards long and perhaps 15 feet wide. No small space, then, is devoted to flowers, and every foot is occupied well.

Where all the beds are so good it is difficult to select, but a few of striking appearance are the following:—*Veronica Andersoni variegata* thinly planted in a groundwork of Hampton Court Crimson

Verbena, edged with three rows of Golden Harry Hieover *Pelargonium*. There are, indeed, more than one bed so planted, and they have a splendid effect. The surface is a sheet of fiery crimson relieved with the silvery *Veronica*, for the *Verbena* grows as freely as it flowers profusely. It may be described as an enlarged form of *Crimson King*, from which, however, it is quite distinct, and is unsurpassed if equalled as a bedding variety. It is a splendid acquisition, and Mr. Graham must be congratulated on his good fortune in raising such a useful plant.

The *Pelargonium* that excels all others in richness of effect—huge trusses closely packed of deep crimson—is *Henry Jacoby*, the beds of it being broadly margined with *Centaureas*; they are indeed most striking. The scarlet variety that shows to the greatest advantage in large beds is *Warrior*; these are edged with *Alyssum saxatile variegatum*, and are very bright. The most effective pink masses are of *Pelargonium Amaranth*, and of rose *P. Rose of Allendale*. A new salmon or oculated variety named *Surprise*, from Mr. Cannell, makes a fine bed, the plants being dwarf and floriferous.

Several beds are planted with variegated sorts—gold and silver bicolors—mixed with *Violas*, and the effect is most pleasing. Flower of Spring and *Viola Favourite*, rich blue, edged with *Iresine Lindeni* and margined with the *Golden Stellaria*, is an attractive arrangement; equally so is *Mrs. Pollock* and *Viola The Tory*, edged with *Coleus Black Douglas* mixed with the same *Viola*; and *Bijou* mixed with *Blue Bell*, and banded with *Iresine*, cannot be passed without admiration. The *Iresines*, both *Lindeni* and *Herbstii*, are deep and rich, but the darkest of all is *I. Wallsi*; it appears intermediate between the two, having the leaf of *Herbstii* but smaller, and the colour of *Lindeni*, but richer.

Some mixed beds cannot be overlooked. They are what Mr. Graham calls "September beds," and at the present time no beds on the lawn are more beautiful. They are planted with *Iresine Lindeni* and *Abutilon naviium maculatum* 18 inches apart in a groundwork of *Verbena venosa*, and broadly banded with three rows of the *Iresine*. The effect is most striking, the grand foliage of the *Abutilon* contrasting effectively with the dark foliage and flowers. This, it may be remarked, is the best of all the fine-foliaged *Abutilons* for garden decoration, the variety *Thompsoni* being poor in comparison.

Beds of mixed seedling *Verbenas* are both attractive and fragrant, and masses of the fine old *Rose Souvenir de la Malmaison* command general approval. The plants flower three times during the season, the beds containing thousands of blooms. A late autumn bed of the early white *Chrysanthemum Madame Desgrange*, of the Japanese type, above which rise brilliant masses of *Verbena fulgens*, is a most effective combination. These *Lobelias* will be employed more largely next year, so grand are they now; but edging *Verbenas* of the *Erinus* type are not to be seen at Hampton Court, not succeeding well there, and there is sufficient of purple and blue in the *Violas*.

The carpet beds remain to be mentioned, for it were futile attempting to describe them. Both as regards design and planting they must decidedly rank as superior examples of this mode of decoration. Difficult as it must be to provide fresh patterns, there is not the slightest sign of any abatement of public interest in these beds. The striking feature of the beds is the liberal employment of *Echeveria Peacocki*—by far the finest and best of all the succulents for such work. An oval of some three hundred plants of it, with end panels of *Leucophyton*, a dividing scroll of *Echeveria secunda glauca*, and masses of brilliant *Alternantheras*, forms an arrangement worthy of a long journey to see by those who wish to see a finished example of this mode of decoration. There are other beds also worthy of inspection, each totally dissimilar from the rest; but we cannot make their appearance intelligible, and those who cannot see them and desire to know more about them cannot do better than purchase Mr. Graham's descriptive pamphlet of the bedding arrangements. It contains many useful hints, and can be had for 1s. We have been told he would sell more copies if the plants in the beds were named, as this would incite interest in them and a desire for further information. Single *Dahlias* are well represented, and a selection of the best herbaceous plants is being established.

There has not only never been so many species and varieties of plants at Hampton Court as at the present time, but it may be safely asserted that the grounds have never during their history—over some three centuries and a half—been more attractive than during the present year. Mr. Graham is perhaps the only good judge who is not quite satisfied with his work. That it is not perfect in his estimation is to be gathered from his intentions of having some better arrangements another season. We hope he may succeed in accomplishing his self-imposed task, for assuredly it is no light one.

GARDEN FAVOURITES.

Ampelopsis Veitchii.—The extraordinary annual growth of this popular plant strengthens the conviction that it is the most useful as well as the most beautiful climber of modern introduction. It is emphatically a climber, requiring no support from shreds, nails, or tying; laying hold of everything with which its young growth comes in contact, and clinging with a tenacity that renders the removal of any part of it a difficult matter. No building is too lofty for it, its young growth at a height of 60 feet being as vigorous as it was at 6. Onward it goes, spreading outwards and

upwards over every inch of surface : masonry, woodwork, or iron, all is covered, and it is curious to see how every projecting beam and gable is clothed by the neat growth. The large foliage upon the old branches is already changing from its summer green to the purple and crimson of autumn. As growth ceases the smaller leaves of this year's shoots will gradually assume many varied tints of crimson, scarlet, purple, and carmine till they are all glowing with a brilliancy that is quite unique. Would that it were more durable! But while it lasts we will enjoy it to the utmost, and turn the lovely slender branches to account for all sorts of decorative purposes, for they are so abundant that plenty may be taken off without disfigurement or harm.

Ampelopsis sempervirens.—This is an evergreen climber with abundant pretty lobed deep green leaves, admirably suitable for clothing bare walls or the sides of buildings with perennial greenery, and for mingling with the growth of deciduous climbers. I have planted it at the side of a lofty building over which *A. Veitchii* is fast spreading, and its growth this season is long and strong enough; but it has not the Ivy-like habit of clinging to walls which renders *A. Veitchii* so valuable, its tendrils having only the property of twining like *A. hederacea*.

Linaria Cymbalaria.—Better known, perhaps, as the Ivy-leaved Linaria. This is frequently met with growing wild, trailing over old ruins, among the stones of which it establishes itself, and also among our choicest rockery plants, but always as a trailer; and certainly its long slender growth is very ornamental thus. But this summer it has taken a useful place among what may be termed dwarf climbers, for a plant of it growing at the bottom of a wall and near the stem of a Grape Vine has pushed its growth upwards among the Vine branches fully 6 feet high, clothing every part of the wall left uncovered by the Vine, and imparting an aspect to it as novel as it is pleasing. I have frequently advised the planting of evergreen climbers for clothing the lower part of buildings that are so often left bare by tall-growing climbers, and gladly add this old favourite to the list.

Chenopodium atriplicis.—An old favourite of the flower garden, which I last recommended to notice some fourteen or fifteen years ago. I am glad still to see its name in the catalogues of some of the principal seedsmen, for it is a plant of much beauty suitable either for subtropical groups or for a mixed border. It is an annual of most easy culture. Sow the seed in March under a handglass upon a warm border, harden the plants by gradual exposure to the open air, then plant them in their summer quarters just as you would a Cabbage plant; and once established there, all they require is sufficient space to develop fully their attractive pyramidal growth some 3 feet high, with dark red stems, purplish green and red leaves, and every branch crowned with a curious red inflorescence.

Commelina caelestis.—One may go into a dozen gardens without seeing this lovely hardy perennial; and yet we have few plants more attractive than are its deep blue flowers so charmingly disposed upon its light loose branching growth about 2 feet high. It produces seed so freely that a packet of it only cost 3d. The tuberous roots used to be taken up and stored in sand during winter, but they have now been left undisturbed in the soil, and are always in full beauty at this season of the year.

Blue Hydrangeas.—These are just now so attractive that I am constrained to draw attention to them once more. All of them were nearly killed to the ground by the late two severe winters; but they have wonderfully recovered, most of them being now 7 or 8 feet in diameter, with a handsome globular outline, and with huge trusses of blue flowers clustering by the hundred among the fresh green foliage. It is the Chinese variety, *H. hortensis*; and the presence of oxide of iron in the soil in such abundance as to impart a dark red hue to it is the well-known cause why the flowers come blue instead of pink. The soil I have used contains a natural ochreous deposit from a powerful chalybeate spring; but anyone may produce the change of colour in the flowers by mixing red ochre plentifully with the soil.—EDWARD LUCKHURST.

TOMATOES AND CUCUMBERS.

Tomatoes are becoming more generally grown. Those who did not even know the name of a Tomato a few years ago now know how to cultivate them, and use them too. Last year we had some thirty-six varieties on trial, but three-fourths of them were very inferior. This year we have not more than half a dozen, and these will be reduced further, as we shall not grow President Garfield again, it being too rough and unproductive. Crossling's Glamorgan is coming well to the fore. Here, and every place I have seen it, it is giving satisfaction. It has a splendid constitution, doing well in the open air as well as under glass, and no other is so prolific, while the fruits are large, well formed, slightly ribbed,

and highly flavoured. If I were limited to one sort this would be relied on.

Cucumbers in house, frame, and on ridges have done well with us. Amongst market salesmen the complaint is that the supply has been greater than the demand. Tender and True is a large showy Cucumber, better suited to grow for exhibition than for the table. For the latter purpose Telegraph is a good one, but with many Pettigrew's Cardiff Castle is taking its place. In doing this nothing will be lost, as this variety is really a first-rate one. It is a sure and robust grower, and the fruit are produced most freely. They are from 12 to 15 inches in length, and even from end to end. One plant of it will produce twelve fruit for every one on Tender and True, or any other of the show varieties. Lately we have planted a dozen winter Cucumber plants, and they are all of Cardiff Castle. We would give the same advice about this as the Glamorgan Tomato—namely, where only one variety is wanted this should be selected.—M.

NATIONAL DAHLIA SHOW.

WHEN it was announced that a committee was formed with the object of having what was described as a National Exhibition of Dahlias at the Crystal Palace, and when the support of the leading cultivators was assured, it was a foregone conclusion that the Exhibition would be a success. And so the event has proved. The Show was held on Friday and Saturday last, and the display of double and single Dahlias was brilliant and imposing. In magnitude it excelled all other shows of the kind of recent years, but it is impossible to say the same as regards the general quality of the blooms. While not a few were magnificent, and the prizewinning stands generally excellent, yet there were hundreds of rough examples—some overgrown, some undergrown, others worn, and some undeveloped. This, however, was only to be expected, and the result has shown that many cultivators have much to learn in bringing this noble autumn flower to perfection. It has shown also that many blooms of the present day are no better, if as good, as those of twenty years ago; and this fact, for such we believe it to be, affords the best evidence for the necessity of increased efforts being made for extending the culture of a flower that has proved itself so singularly tractable and capable of improvement in the hands of skilled cultivators. But while the double varieties have not made any appreciable advance of late, the single forms have increased as it were by magic, and come on the world like a shower of floral meteors. Hundreds of varieties were represented in the Show, and almost every conceivable colour which double Dahlias possess was embodied in these new comers. There is just a fear that they may come too fast and bewilder, but they will not be "common" for a year or two; and the Judges acted wisely in their decision not to grant certificates except to varieties of commanding excellence. But we must refer to the classes. Upwards of £100 was offered in prizes, and in most of the classes there was good competition, a few only being sparsely filled. The plants in pots were not so good as we expected to see them, and the best of them fell far short of a collection so grown at Chiswick last year.

In Class A, open to nurserymen, for forty-eight distinct Show varieties, there were nine competitors, the premier award falling to Messrs. Keynes & Co., Salisbury, for the following collection:—James Cocker, Lady Gladys Herbert, Prince Arthur, sport from Gaiety; Mrs. P. Wyndham, Flora Wyatt, George Rawlings, George Edwards, Arbitrator, Joseph B. Service, Henry Bond, Frederick Smith, Herbert Turner (champion bloom), James Stevens, Duke of Connaught, Joseph Ashby, Mrs. Harris, William P. Laird, William Rawlings, Goldfinder, George Dickson, Henry Walton, Rosy Morn, Enchantress, Mr. Spoforth, Admiration, Annie Gibbon, Champion Rollo, Mrs. Stancombe, W. N. Williams, Thos. Goodwin, Rifleman, Prince Bismarck, Canary, Clara, John Bennett, Michael Saunders, Prince of Denmark, Flag of Truce, James Vick, Miss Cannell, Lord Chelmsford, Triumphant, and four seedlings, all of them fine flowers. The second prize was awarded to Mr. Charles Turner, the Royal Nurseries, Slough, for a collection almost of equal beauty, these being only three or four points behind the Salisbury collection; Henry Walton, Lady Gladys Herbert, James Vick, Herbert Turner, Fred Smith, John Wyatt, Chris. Ridley, Modesty, John Green, and Flag of Truce being especially fine. Mr. William Boston, Manor Farm Nursery, Carthorpe, Bedale, Yorkshire, was adjudged third honours. Annie Neville, Criterion, Vice-President, Henry Walton, and Acme of Perfection were amongst his best flowers; Messrs. H. Cannell & Sons being placed fourth for a good collection. W. H. Williams, Sunbeam, Charles Wyatt, E. Edwards, Aurora, and Lady G. Herbert were conspicuous for colour, purity, and form. The real contest in this class rested between the Salisbury and Slough collections, and Mr. Turner's blooms were undoubtedly the finest, several of Messrs. Keynes' being undeveloped, and possibly on this account their freshness and brightness placed them in the premier position. It appeared to be a question of colour *versus* form, and the greatest importance was attached to the former by the Judges, who spent much time and took great pains in arriving at a decision.

In the class for twenty-four distinct Show varieties there were twelve competitors. Mr. Charles Turner was awarded first honours

for a matchless stand of the following varieties:—Henry Walton, George Rawlings, Lady G. Herbert, Burgundy, Perfection of Primroses, H. W. Ward, Alex. Cramond, Royal Purple, Lady Wimborne, Constancy, John Standish, Julia Wyatt, Prince Bismarck, Goldfinder, Jos. Green, Hon. Mrs. P. Wyndham, James Vick, Chas. Leicester, J. N. Keynes, a seedling, Ethel Brittain, John Rawlings, Herbert Turner, and John Wyatt. Messrs. Keynes & Co. were a very good second. Mr. W. Boston, and Messrs. Harkness & Sons, Bedale, Yorkshire, third; both showing good collections. This and the three following classes were for nurserymen only.

Class C was for twelve distinct varieties. Messrs. Paul & Son, The Old Nurseries, Cheshunt, were awarded the first prize, their collection consisting of Walter H. Williams, George Barnes, Lord Palmerston, Constancy, John W. Lord, Criterion, Ben Crossland, Emily Edwards, James Service, George Chricht, Christopher Ridley, and Flora Wyatt; the second, third, and fourth prizes falling respectively to Mr. John Walker, Thame, Oxon; Messrs. Saltmarsh & Sons, Chelmsford, Essex; and Messrs. R. Veitch & Sons, New North Road, Exeter, in the order of their names.

Class D, twenty-four distinct Fancy varieties, there were five competitors, Messrs. Keynes & Co. being placed first with a splendid collection. The flowers were of large size, and included Miss Lily Large, Hercules, Jessie McIntosh, Professor Fawcett, Hugh Austin, John Forbes, Parrot, Chorister, Polly Sandell, Henry Glasscock, Monsieur Chauvire, James O'Brien, Maid of Athens, Mrs. Saunders, George Barnes, Singularity, sport from Gaiety; John Saunders, Robert Burns, Rev. J. B. M. Camm, Fanny Sturt, and two or three seedlings. Mr. Charles Turner was a good second, Jessie McIntosh, Grand Sultan, James O'Brien, Beauty, and a sport from Gaiety being amongst the best. Mr. William Seale, Vinc Nursery, Sevenoaks, Kent, had the third prize, and Messrs. Cannell & Sons the fourth. Mr. William Boston was recommended for an extra prize.

Nine collections were staged in Class E for twelve Fancies, Messrs. Rawlings Bros. securing the first award with the Rev. J. B. M. Camm, Peacock, Hugh Austin, Egyptian Prince, Gaiety, Chorister, George Barnes, Hercules, Miss Browning, Barnaby Rudge, Jessie McIntosh, and Mrs. Saunders; Messrs. Paul & Sons the second; Mr. John Walker the third; and Messrs. James Gilbert & Sons, St. Margaret's Nursery, Ipswich, fourth.

We now come to the amateurs' classes. For twenty-four distinct Show varieties first honours were awarded to Mr. Henry Glasscock, Rye Street, Bishops Stortford, for a remarkably even stand of William Rawlings, Mrs. Harris, Prince Bismarck, The Countess, Ethel Brittain, Joseph Green, James Vick, J. N. Keynes, Alexander Cramond, Lady Golightly, W. H. Williams, Prince Arthur, W. G. Harris, Miss Cannell, Miss M. Batchelor, Miss Hodson, Thomas Goodson, Herbert Turner, Prince of Denmark, Rev. J. Gooday, Sunbeam, Miss Edwards, and Modesty. The blooms in this stand were not large, but their symmetry and freshness were remarkable, and they were greatly admired. Mr. E. Fletcher Charleston, Baildon, near Leeds, received the second prize, Chas. Leicester, Acme of Perfection, Clara, Vice-President, Countess of Lonsdale and James Vick being the most noticeable. Mr. Thos. Hobbs, Lower Eaton, Bristol, secured the third prize; and Mr. Godden, gardener, Manor House, Tovil, Maidstone, the fourth. There were eleven competitors in this class.

In the class for twelve Show varieties sixteen collections were staged, first honours falling to Mr. W. B. Butterworth, Green Hill, Kidderminster, with an even and fresh collection, comprising Julia Wyatt, Duke of Connaught, Mr. Harris, Prince Bismarck, Vice-President, Frank Rawlings, Perfection of Primroses, James Cocker, Sunbeam, Royal Queen, Harry Walton, and Criterion. Mr. J. T. West, gardener to W. Keith, Esq., Brentwood, Essex, was placed second; Mr. H. Glasscock third; and Mr. J. Trawter, Upper Assenden, Henley-on-Thames, fourth, all running each other very closely. In the class for six hlooms there were only four competitors, Mr. F. Masters, Sheperd's Cottage, Peneden Heath, Kent; Mr. J. Monk, Brickford Cottage, White Horse Hill, Chislehurst; Mr. John Palmer, The Larches, Handsworth; and E. Mawley, Esq., Lucknow House, Addiscombe, Croydon, each taking the prize in the order of their names.

Fancy Varieties.—For twelve distinct hlooms Mr. Henry Glasscock was well ahead with Flora Wyatt, Henry Glasscock, Mrs. Browning, Parrot, Mrs. Saunders, Professor Fawcett, Viceroy, John Lamont, Wizard, Letty Coles, Fanny Sturt, and Gaiety. Mr. W. Butterworth received the second prize, Mr. E. Fletcher the third, and Mr. C. Hockney, Greenfield House, Stokesly, York, the fourth. Seven collections were staged in this class. For six hlooms Mr. J. F. West; Mr. J. Ridout, gardener to J. B. Haywood, Esq., Woodhatch Lodge, Reigate; Mr. G. Boothroyde, gardener to Miss Ellice, Woodville Hall near York; and James Wigan, Esq., Bishops Stortford, shared the honours in the order of their names.

Class L (open) twenty-four distinct blooms, Pompon varieties, set up in bunches of not more than ten trusses, with huds and foliage, on boxes covered with moss after the manner of staging Roses, Mr. Chas. Turner was worthily awarded first honours, his style of arrangement being both pleasing and attractive. His collection consisted of E. F. Jungker, Louis Rodani, Isahel, Prince of Liliputians, Fair Helen, Wilhelm Nitsche, Little Eva, Garnet, Rosetta, Adonis, White Aster, German Favourite, Mabel, Gem, Titania, Professor Bergeat, Amelia Barbier, North Light, Nemesis, Princess Sophie, Comtesse Von Sternberg, and Favourite. Messrs. H. Cannell & Sons were

worthily awarded second honours, though the boxes were too crowded, and Messrs. Rawlings Bros. third. For twelve blooms, Pompons, Mr. Turner was again in the foremost place; and in addition to those named in the larger collection he exhibited The Khedive, Little Arthur, Torstmeister, Gschwina, Lady Blanche, Little Duchess, and Coquette. Messrs. Keynes & Co. were placed second, Messrs. Paul and Son third, and Mr. John Henshaw fourth.

For twelve single hlooms Mr. C. Turner was once more first. The same attractive mode of setting up is adopted as with the Pompon collections exhibited by him; the flowers are both fresh and bright, and consisted of Yellow Gem, Foxhall, Mauve Queen, Huntsman, Canary Bird, Cocceina, Paragon, Lutea, Firefly, Bronze Queen, Alba, and The Baron. The flowers were kept in position with wire passed round their stems. Second, Messrs. Keynes & Co. with Paragon and several good unnamed seedlings. Mr. T. S. Ware, Halc Farm Nurseries, Tottenham, third, and Messrs. H. Cannell & Son fourth. For six singles Messrs. Turner, Keynes & Co., Ware, and Gilbert and Son were awarded first, second, third, and fourth respectively.

Mr. Turner secured the leading prizes with plants in pots, followed by Mr. Cannell in all the classes, except in that of varieties of *Dahlia gracilis*, in which Mr. Cannell secured the prize offered by Mr. Moore.

The following new varieties were awarded first-class certificates:—*Condor* (Keynes).—A Show variety of a distinct and pleasing colour, light cinnamon; bloom compact, neat and symmetrical.

Senator (Keynes).—A dark self Show flower, purplish maroon suffused with violet; hloom solid, compact, and of good form.

Hope (Keynes).—An attractive Show variety; colour pinkish lilac, very soft; petals cupped, and bloom of good outline.

Earl of Ravensworth (Harkness).—A large Show flower, but petals thin and bloom not compact; colour light fawn, and more singular than beautiful.

Gem (Turner).—A deep scarlet Pompon variety, shown in a pot; plant free; blooms compact, and apparently of faultless form. Rich and good.

Evening Star (Keynes).—Single; velvety maroon, with smooth overlapping slightly recurved petals. Very rich and glowing.

Acquisition (Keynes).—Single; body of petals crimson scarlet margined with bright scarlet; bloom small, neat, and petals of good substance.

White Star (Ware).—Single; flower small, neat, well formed, almost pure white, with a stout stalk which shows the hlooms to advantage. A variety of much promise, and sure to become popular.

It should be added that the champion Show bloom in the Exhibition was Herbert Turner, a beautiful white flower, in Mr. Turner's stand, and the champion Fancy hloom Flora Wyatt, exhibited by Mr. Walker.

Several miscellaneous exhibits contributed to the effect of the Show. Mr. Ware staged some hundreds of hlooms of single Dahlias in great variety. Some dotted in moss, which did not look well; others on boards that looked better; still others in finger-glass looking better still; and last and best of all, arranged in vases and glasses, representing them as eminently suitable for dinner-table decoration. The curious and almost black Zimapani and the small neat *gracilis* "went well" together, and Juaresi, or the Cactus Dahlia, had a rich effect in large vases. Of this Mr. Turner had a fine stand, and Mr. Cannell several bright groups of it with a companion, the white Cactus Dahlia, named Constance, and the floriferous Fire King, or Glare of the Garden; he had also fine Cockscombs, Petunias, Marigolds, Tuberos Begonias, and Zonal Pelargoniums. Messrs. Saltmarsh & Son of Chelmsford staged splendid Asters of the French Pæony and German Quilled type, and Mr. Walker had also excellent hlooms of these beautiful autumn flowers.

Mr. Thomas Moore efficiently discharged the duties of Secretary, and the Committee have good reason to be satisfied with their first grand National Dahlia Show.

EARTH-CLOSET MANURE.

ON reading the letter of "J. B. K." on earth-closet manure, at page 218 of your last issue, my first impression was that I must have committed some error in the way I had put the matter. My next reflection was, What a capital letter "J. B. K." has written! and I concluded, finally, that whilst there was some reason to be impressed with the letter, he had really proved that the mistake, if there was one (which I began to doubt), was none of my making, and that so far from differing from me his letters really supplied strong confirmation of all that I had suggested—viz., that Dr. Voelcker was undoubtedly right in the low standard which he assigned to earth-closet manure, and that unless used on the spot where it is produced, or close to it, the cost of carriage of such a weak manure more than eats up its real value. It seems to follow, if this be the case, that Mr. Taylor's preference for it for Vines, even if the manure be an advantageous one to use in his own case, could not generally be followed with advantage. There was no discrepancy, in fact, between "sound science as represented by Dr. Voelcker and sound practice (advice?) as represented by Mr. Taylor," because Mr. Taylor's advice, at least, was not sound, even if his practice in his own peculiar circumstances (earth-closet manure being more readily available than a manure better adapted intrin-

sically for his purpose) was judicious. Dr. Voelcker's opinion is that the high value put upon earth-closet manure by market gardeners and others, a value varying from £1 to £3 per ton, did "not rest on any solid foundation," and it is clear that this opinion is expressed irrespective of the quantity that may be used in this or that case. Now, as "J. B. K." states that the value of the manurial addition to a ton of soil is only 2s., there would appear to me to be no difference between Dr. Voelcker's opinion and his own on this point, nor any question between "J. B. K.'s" opinion and mine. At all events, so long as market gardeners, and especially growers of Grapes, are made aware that whether they want to employ half a ton per acre or 100 tons, they are purchasing a manure worth only from one-tenth to one-thirtieth of the sum which it has generally been esteemed by the practical man to be worth, the object of my inquiry will be fully answered and the necessity for it be justified.

I must, however, be allowed to ask "J. B. K." two questions before leaving the subject. Dr. Voelcker's statement, be it remembered, is that "the earth of an earth-closet manure, after it has been once used" (the condition in which Mr. Taylor has employed it), "is not more valuable for manuring purposes than in its original dry and sifted condition."

1st, Is it the intention of "J. B. K." to affirm that a good garden soil can be enriched in nitrogen, or potash, or phosphoric acid, or in any other constituent of plant life, by admixture with a manure which is more deficient in these elements than itself? I can scarcely imagine so.

2nd, Does "J. B. K." consider that earth-closet manure is really superior to that prepared by Messrs. Arnold & Co., for instance, for manuring Vines? We will suppose, of course, that the manure is, if necessary, to be mixed with a sufficiency of earth to prevent any possible ill-consequences of using artificial manures of fair strength.

In reply to Mr. Taylor's last letter on this subject (p. 200), I can assure him that nothing was further from my intention than to take an unfair advantage of anything that he had written; still less should I think of attempting to hold such a man up to ridicule, and I am grieved that he should think it possible. I did not suppose that any such deduction could have been drawn from what I had written; and I must, in self-defence, remind Mr. Taylor that "SINGLE-HANDED" having written, "Perhaps the most valuable part of Mr. Taylor's experiments was his attempt to do without lime," he (Mr. Taylor), in replying to my first letter on earth-closet manure, adds to his answer, "I wish to tender my thanks to 'SINGLE-HANDED' for his papers on manuring. I hope your readers will turn his advice to good account." I can assure Mr. Taylor that it had never entered my head that he could have overlooked such a fact as that the Vine, or any other plant, could prosper if lime were excluded absolutely from the soil as well as from the manure employed; nor did I quote the mistake which he had made with any other object than to prove to him, that as on his own showing he at least could not be considered infallible, I might be pardoned if I ventured to doubt the value of his recommendation as to the best mode of manuring Vines.

I have only further to add, May I always be as ready to confess my mistakes, and they are not a few, as Mr. Taylor's treatise proves him to be, and may they carry with them as useful lessons to others as "his attempt to do without lime" as a manure! May I also show myself less sensitive about those I commit to friendly criticism!—INQUIRER.

EDGE HALL.

My visit lasted nearly four hours, and yet it was nothing more than a peep, for so great is the multitude of plants under the fostering care of Mr. Wolley Dod and his gardeners that each can only have a mere glance in time so short.

Edge Hall is the quiet and happy home of a host of plant gems, both curious and handsome—some in a marvellous state of development, and in nearly all cases they are doing well. The great variety and arrangement is particularly appreciable. There is what Mr. Dod calls "his long border," and a wonderful border it is, mainly filled with quite hardy flowers, a few half-hardy plants being intermingled with them, such as single Dahlias, Pelargoniums, &c., and the effect was such as could scarcely be equalled. The great variety and blendings of the flowers are simply charming, and is likely to continue until the frost puts an end to all flowers; and with the aid of early-flowering bulbous plants, which are now in a dormant condition, there has been a rich display of flowers in this border ever since March. There are masses of Carnations, Phloxes, Sunflowers, Fuchsias, Japanese Anemones, Coreopsises, Polemoniums, Rudbeckias, &c., flowering most profusely, and can only be fully appreciated when seen. Remarking upon Sunflowers reminds me of a beautiful variety of the common

large annual species, which was very plentiful. The colour was clear yellow and very striking.

There are other borders and beds of various forms and sizes; very numerous, too, they are, and all filled. One circular bed on the lawn filled with *Salvia patens* in full bloom was well worth seeing, and rarely have we seen it in such state; and what a grand plant it is when well done, and how sad it is that it is employed so sparingly in our gardens! Close by this bed is one of *Lobelia cardinalis* and *fulgens*, the former with its green leaves and the latter with its deep crimson foliage surrounding it. What a picture is this bed, with its long spikes of deep crimson flowers, rarely equalled in floriculture! The same plant was happily employed in pots, with Marguerites, to decorate the entrance to the front door of the Hall.

The rockeries, of which there are several, are all well stocked with plants, alpine and others, a large number of which are in beauty; they will be showy for a long time to come, and possessing enough of interest to please most people. The last rockery Mr. Dod constructed is noteworthy on account of the method of arranging the stones, so that they interlock and support each other. This rockery is planted with many very choice and rare species, and it has a new appearance about it, as the plants have not nearly covered the rock; in fact, I really think Mr. Dod has too much stone exposed, as many of the plants will be a great number of years covering them, which, in my opinion, is undesirable, and the primary object of the rockery is lost sight of.

Amongst the great variety of plants in flower notes were made of the following, as being very pretty and useful for the hardy flower garden. *Veronica longifolia subsessilis*, with its long spikes of deep blue flowers, was very plentiful. It is easily increased from cuttings, and is extremely showy. *Asteriscus maritimus*, a Spanish plant which Mr. Harper Crewe informed me grows very near the sea, is very dwarf and spreading, with golden-yellow leaves about 2 inches across, similar in form to a *Gazania*. It is not quite hardy, but cuttings are easily rooted at this season of the year, and they should be kept in store pots in a cool house through the winter, then planted out in a warm position in gritty soil. It is a most effective rock plant, flowering very freely. *Helenium pumilum* is also showy, with bright yellow flowers. *Geranium argenteum* grows more freely than ever I saw it; on the new rockery it was very fine with its silvery foliage and light pink flowers. A well-drained position suits it well. *Physostegia speciosa*, though tall-growing, is a good plant with light rosy-purple flowers. *Bupthalmium salicifolium* is also a showy Composite, with narrow leaves and yellow capitula about 1½ or 2 inches across. *Veronica tenuifolia*, or sometimes called *parviflorum*, is particularly handsome. It has a bushy habit, about 18 inches high, freely branching, with very numerous racemes of light pink flowers. For the rockery, border, or even table decoration this is a most charming plant, and when seen must be appreciated. *Salvia Pitcheri* has sky-blue flowers very freely produced. Among the Sunflowers were *Helianthus cucumarifolia*, *decapetalus*, *maliflorus* (single and double-flowered forms), *rigidus* (*Harpalium rigidum*), *doronoeoides*, &c., all of which are very ornamental and effective. The latter is particularly useful for cutting. Among the *Coreopsises* were *C. lanceolata*, or *grandiflora* as it is frequently called, *auriculata*, and *tenuifolia*, the former two of the best border plants possible to have, and the latter a much more slender-growing and dwarfer plant with linear leaves and small flower heads, is very suitable for the rockery. *Achillea Filipendula* is one of the best Millfoils, with elegant foliage and broad heads of canary-yellow flowers, about 2 feet high.

Mr. Dod has succeeded in establishing the capricious *Tropæolum speciosum* against a north wall; it is flowering freely, and a lovely plant it is! *Campanula haylodgensis*, a hybrid raised by Mr. Anderson Henry, is very handsome and free-flowering; but at Edge Hall the foliage turns brown, which is not the case in other places where I have seen the plant growing. A very old plant is *Tournefortia heliotropoides*, but not quite hardy, with, as its name implies, cymes of Heliotrope-like flowers. The single-flowered variety of *Spiræa Filipendula* is much more elegant than the double form so frequently seen, and certainly more serviceable for floral work. The true *Veronica corymbosa* is very charming. What a number of *V. corymbosa* there are! As at Malpas, it is of dwarf and spreading habit, with branched spikes of sky-blue flowers, most profusely borne, with wiry stems. It is a very pretty rock plant, and if Mr. Dod will strike the young shoots in spring it may be more frequently seen in future. *Cyananthus lobatus* seems to thrive remarkably, as there are several strong plants in flower, and I understood it had ripened seeds this season. It is a charming plant, with sky-blue funnel-shaped flowers on trailing stems. *Montbretia Pottsii*, with its orange-scarlet spikes of flowers, is very showy. *Epilobium Fleischeri* is very like *E. Dodonia*, and I think they are identical. Dwarf in habit and very floriferous, it is just the plant for the rockery or front portion of the border, with pinkish-purple flowers. *Senecio pulcher* and *S. niveus* are both fine plants, the former well known, the latter with silvery foliage and cymes of yellow flowers. It is rather rambling in growth, but if planted in a hot and dry position it is very pretty. The old *Phygelius capensis* is very pleasing with its scarlet tubular flowers, and it was in full bloom. *Arnebia echioides* was well in flower for the second time this season. It is a very handsome and interesting plant, and may be increased by seeds or cuttings taken off with a heel and rooted in a cold frame. *Prunella Webbiana* is very striking with reddish-purple flowers. *Hypericum empetrifolium* is a charming

little species about 9 inches high. Is not this plant synonymous with *H. Coris*? It is most attractive on the rockery. Close by it was the rather tender *H. egyptiacum*, which is also an elegant dwarf bush with yellow flowers. *Androsace lanuginosa* Mr. Dod regards as one of the best alpines, and it was in excellent condition, enjoying a thoroughly well-drained position. There were also good patches of *A. sarmentosa* and *A. helvetica*. The little Arctic Bramble (*Rubus arcticus*) was flowering freely, and has done so for some months. The rare *Phlox amœna* was doing well and in flower—quite a treat in itself to see such a rarity so happy. *Neja gracilis*, with a multitude of yellow capitula, is showy; it needs, however, some protection during winter. Cuttings should be struck in the autumn and just protected from frost. *Erigeron philadelphicus* is one of the best in the genus; the flowers are small but very freely produced, extending over some months. *Linaria anticaria* exhibited a great variation, but the best variety has purple bars on the white corollas, and in that state it is very desirable. *L. pallida* is also very pretty, but quite a weed at Malpas. The lovely *Coronilla iberica* was still in flower, and it is certainly the best of the hardy species, the bright yellow flowers blending with the foliage so happily. *Campanula soldanellæflora* or *C. rotundifolia* fl.-pl., the latter being more precise, is, when the flowers are double, a very handsome plant; but it degrades very readily, and seedlings from it exhibited very curious-formed petals, quite narrow and lengthened out, and very dissimilar to the plant which produced the seed. *Anemone vitifolia* is a distinct species much in the way of *A. japonica alba*, and in connection with *A. japonica* is undoubtedly the progenitor of the latter.

I might go on much further, but space forbids, and I have only to add that the hospitality met with rendered my visit to Edge Hall gardens a most enjoyable one.—X. Z.

SCARCITY OF CATERPILLARS IN 1882.

ALTHOUGH there have been published this year in your Journal and elsewhere complaints about injury done by caterpillars to fruit trees and to some plants in the kitchen garden, such as the Brassicaceous species, these have only come from a few districts. We have no general returns that can be tabulated yet; but so far as we can judge by communications received from various gardeners and entomologists, caterpillars of the order Lepidoptera—*i.e.*, those which, if they thrive, develop into butterflies or moths, have in our gardens, as also in the open country, been less abundant than usual. To the stroller in any direction away from the crowded streets hardly an object is more familiar than the Hawthorn hedge. We see the well-trimmed compact hedge surrounding a garden, orchard, or shrubbery, and, perhaps more pleasing to the eye, the somewhat ragged mixed hedge, with its memories of many scrambles belonging to youthful days. Almost, as a matter of course, we expect to see the Hawthorn more or less disfigured by the webs of those small pests, the caterpillars of the Winter Moth (*Cheimatobia brumata*), and of the little Ermine (*Ypmomeuta podella*), besides exhibiting traces of the jaw work of the Lackey (*Bombyx neustria*), the Goldtail (*Liparis auriflua*), and of other allied species. In 1881 some of these insects were very scarce in some districts, nowhere, I think, in average numbers; and as several of them also attack fruit trees our fruit crops escaped one mischief, though they had to suffer from "blight" in another form and from unfavourable weather. The effects of the latter, in fact, prevented the Hawthorn showing fully the advantage it had gained through the scarceness of caterpillars, since it, in common with many shrubs, felt the hurtful influence of cold and rough winds in early summer. We frequently notice that if plants escape damage in one direction they fare rather badly in another; the Currant offers an instance this season. It is not uncommon for it to be partly stripped of its leaves, when gardeners have been unobservant or careless, by the caterpillars of the Gooseberry Moth (*Abraxas grossulariata*). This spring they were comparatively few in number upon those bushes I was able to examine; but then, unfortunately, I found that the Black Currant especially had been severely injured by more than one species of aphid in various gardens. The leaves were curled and blackened by these pests, which, if allowed, as they sometimes are, to proceed undisturbed, not merely disfigure but also weaken the vitality of the bushes.

It has been shown by incontrovertible evidence that a scarcity of caterpillars may be expected to follow such a season as was that of 1881-2—an autumn, that is, of heavy and frequent rains, followed by a winter mild nearly throughout, and with very little snow. A large proportion of our Lepidoptera are unfavourably affected by this weather, whatever may be the stage of life in which they pass the winter. Should this be the egg stage, the result of unseasonable mildness is the bringing-out of the young caterpillars too soon, perhaps before their food is sufficiently advanced, or at least before the rough weather of early spring has passed away. If a species is in hibernation as a caterpillar much moisture during autumn or winter will often kill a great part of

the brood, and they, too, are tempted from their retreats too early. In the pupal or chrysalis stage a mild season also acts as an accelerator, not salutarily, and many decay through excessive damp, or are devoured by insect enemies, which are rendered unusually active by the absence of cold. Those that hibernate, as butterflies or moths, have been found to appear in less than the average numbers after such winters as the last. They are tempted from their retreats by mild or sunny days, and fail to get back to them from various causes; often, indeed, they are devoured by birds or spiders on the alert for prey.

But, on the other hand, it should be stated that certain species are hardly at all affected, or seldom, by the variations in our English winter. This is the case with some of the subterranean caterpillars living deep down, and also with the bulk of those feeding within plants or under bark. Amongst the smaller tribes of moths, such as the Tineæ, the seasonal influences are less notable than amongst the larger species.—J. R. S. C.

BATH FLORAL FÊTE.

SEPTEMBER 6TH AND 7TH.

A MORE picturesque or favourable site for a horticultural exhibition than the Sydney Gardens, Bath, could scarcely be desired, and a great part of the success of the shows held there is doubtless due to the beauty of the surroundings furnishing so strong an additional attraction. Though of moderate extent, the surface of the grounds is greatly varied, rising considerably towards the north, whence charming glimpses of the town may be obtained. The gardens, moreover, are very convenient of access, being within a short walking distance of the principal station and the busiest portion of the town. Some care, too, is exercised to avoid as much as possible the prevalent formality of arrangement at exhibitions generally, for at Bath the tents are placed singly in different parts of the grounds, though this would prove a disadvantage in unfavourable weather. The arrangement of the exhibits, too, is well carried out; but the system of affixing the prize cards is antiquated and cumbrous in the extreme, and the Committee might with considerable profit give some attention to the South Kensington method, which is incomparably superior to the one they adopt.

The Exhibition held last week is the third of the season, but was well attended both by exhibitors and visitors, the latter being especially numerous, as the weather proved extremely fine—a most agreeable surprise after the heavy rains of the preceding day. All the chief classes were well represented, one large marquee being devoted to Fuchsias, stove and greenhouse and miscellaneous plants; another of similar size to Ferns, smaller classes, and cut flowers; a third to fruit; and the fourth to stands of flowers, bouquets, &c. In all sections the exhibits were distinguished by their freshness and good quality, the Fuchsias and cut flowers being unusually fine; but some of the fruit classes were not quite so satisfactory as might be desired, especially the white Grapes, which, though large, were very unripe.

Fuchsias.—Very rarely are Fuchsias shown so extensively and well as they are at Bath, and in that neighbourhood where their culture is quite a speciality with many gardeners, who are also perhaps favoured to some extent by the climate. Some dozens of handsome pyramidal specimens 6 to 9 feet high, vigorous in the extreme, evenly but not formally trained, and most profusely flowered, produced an effect that might be termed unique; indeed, these plants constituted the leading feature of the Show. Five classes were devoted to them, the principal being that for nine specimens of distinct varieties, in which the first prize of ten guineas was awarded to Mr. J. Lye, gardener to the Hon. Mrs. Hay, who has long had a great reputation for his skill in Fuchsia culture. His plants were 8 or 9 feet high, and about 3 feet in diameter at the base, conical in form, and abundantly clothed with foliage and flowers; in fact, they were as even and beautiful a collection as could be desired, and well deserved the honours accorded them. The varieties were Mrs. Bright, Thomas King, Mr. Brooke, Arabella, Doel's Favourite, Lye's Favourite, Annie, Lustre, Mr. Hooper Taylor, and Charming. Mr. G. Snell, gardener to Mrs. Counsell, was a close second with well-grown plants, but his collection as a whole was not quite so even as the preceding, though they were very profusely flowered, especially the varieties Arabella, Load Me Well, Conspicua, Elegance, and Doel's Favourite. Mr. H. Jones, gardener to General Doherty, followed with healthy plants, and bearing abundance of flowers, but the specimens were less symmetrical than the others; Load Me Well, Gazelle, and Conspicua were the most noteworthy.

For six plants Mr. G. Tucker, gardener to Capt. W. P. Clarke, took the lead, staging abundantly flowered specimens, Load Me Well being especially handsome, large, and healthy, but several of the others, such as Miss Emily Doel, Doel's Favourite, Arabella, and Queen Victoria were rather uneven. Mr. W. J. Mould, gardener to E. C. Bryant, Esq., was placed second with plants that were not formerly trained but vigorous, flowering freely; Elegance, Arabella, and Conqueror were very fine. Mr. W. C. Drummond was third, staging good examples of Arabella and Doel's Favourite. The best collections of four were from Mr. G. Garraway; Mr. J. Riddick, gardener to Mrs. Pinder; and Mr. G. Hallet, gardener to Mrs. West, all

of whom staged praiseworthy plants, those from the first-named being especially well-flowered and vigorous. For a single specimen of a light-flowered variety Mr. Snell gained the chief prize with a beautiful example of *Marginata* about 6 feet high, not too rigidly trained, and well clothed with foliage and flowers. The finest single specimen was, however, that in the class for dark varieties, Mr. G. Garraway securing the chief award with a plant of *Elegance* 8 feet in height and about 4 feet wide at the base, well covering the pot, and thus having a much better appearance than most of the others, which were rather too narrow and formally cylindrical. The plant was as healthy and vigorous as could be desired, gradually tapering to the apex, and was grandly flowered.

Stove and Greenhouse Plants.—Though not so extensively shown as at some earlier exhibitions this year, the majority of the plants staged in these classes were distinguished by a most pleasing freshness and health, several being specimens of considerable merit in every respect. The leading class was that for nine plants, in which Mr. J. Cypher, Cheltenham, easily won the premier award with one of the most beautiful collections he has staged this year, all the plants being even, vigorous, and exceedingly well flowered. *Ixora Williamsi*, very neat, about 3 feet in diameter, had over three dozen fine trusses; *Ixora Duffi* had twelve full trusses; *Erica Marnockiana* and *E. Irbyana* were in beautiful condition; *Allamanda nobilis*, *A. Hendersoni*, *Clerodendron Balfourianum*, and *Stephanotis floribunda* were similarly good, the last named being about 4 feet in diameter, admirably trained in globular form, and finely flowered. Mr. Tudgey, gardener to J. F. G. Williams, Esq., Worcester, was a close second, but his plants were not equal to the preceding, except, perhaps, his admirable examples of *Dipladenia hybrida* and *Erica Uhria superba*, both of which were in first-rate form; *Dipladenia amabilis* and *Anthurium Andreanum*, the latter with seven fine spathes, were also notable. Mr. J. Mould was third, *Dipladenias Brearleyana* and *profusa* being the best. The best collection of three plants was contributed by Mr. T. Jolly, who was deservedly awarded the first prize for very neat specimens of *Bougainvillea glabra*, *Stephanotis*, and *Cassia corymbosa*, the last-named of globular form, about 3 feet in diameter, and bearing a great number of its bright yellow flowers. Mr. Long, gardener to C. Gardiner, Esq., had the best single specimen stove plant, a very fine example of *Ixora Williamsi*, 4 feet high, healthy and well-flowered. In the corresponding class for a greenhouse plant Mr. J. Cypher won the principal award with a globularly trained plant of *Rhododendron Princess Royal*, which was finely flowered and in superb health, being greatly admired by all the visitors.

Fine-foliage Plants.—The entries in the two classes devoted to these were not numerous, but all the collections were of great merit, especially in the class for sixteen specimens, which formed an important part of the display in the large *Fuchsia marquee*. In this, as with the stove and greenhouse plants, Mr. Cypher took the lead with a grand lot of specimens mostly of good size, as vigorous as possible, and the *Crotons* magnificently coloured. Amongst them those most notable for their size and fine condition were the *Palms*—*Latania borbonica*, *Kentia Canterburyana*, and *Latania rubra*, the last-named being in superb condition, as healthy a specimen as has ever been shown. *Croton Queen Victoria* 4 feet in diameter was richly coloured, as were also *C. fasciatus* and *C. majesticus*, which was about 5 feet high and proportionate diameter. *Cycas Normanbyana*, *Cycas revoluta*, and *Yucca variegata* were all similarly notable. Mr. Tudgey again secured the second place with plants of great size, but in some cases slightly different in colour, apparently from excessive vigour; *Crotons Queen Victoria* and the broad-leaved *Morti* were, however, unusually fine. *Thrinax elegantissima*, *Areca Verschaffeltii*, *Scaevola elegans*, *Cordyline indivisa*, and *Cycas Normanbyana* were well grown and effective. A large potful of *Sarracenia purpurea* was another remarkable specimen, the plants being very highly coloured. Mr. W. C. Drummond followed with neat healthy specimens, amongst which *Pandanus javanicus variegatus* and *Theophrasta imperialis* were the most remarkable.

Ferns were not represented by any very large specimens, but a number of particularly healthy small plants were staged in some of the collections, though the effect was in a great measure spoiled by their crowded appearance. The chief class was for twenty plants, and in this Captain Clark was placed first with fresh and healthy samples; *Adiantum gracillimum*, *formosum*, *farleyense*, and *peruvianum*; *Gymnogramma Laucheana*, *G. peruviana cristata*, and *Selaginella Martensi variegata* being the principal species represented. Mr. G. Smith, gardener to J. Kemp, Esq., followed with similar plants, *Asplenium Belangeri* and *Gymnogramma calomelanos* being well shown. Mr. W. C. Drummond took the third prize with small but healthy specimens. In the class for twelve exotic Ferns Messrs. W. J. Mould, H. Brooke, Esq., and F. P. Cox were the prizewinners, all contributing vigorous plants of moderate size. British Ferns were exhibited by Messrs. A. T. Hall and F. P. Cox, who gained the first and second prizes in that order, both staging large collections, including several rare forms.

Achimenes were well shown by Mr. W. Marchant, gardener to J. Murch, Esq., who won the leading award in the class for six specimens with neat examples about 18 inches in diameter and surprisingly well flowered. *Mauve Queen*, *hirsuta*, *longiflora alba*, *Carl Woolforth*, *Edmund Boissier*, and *Dazzle* were the varieties, forming a very good collection. Mr. H. Jones was second, his best specimen being

Ambroise Verschaffelt. Mr. A. Hawkins, gardener to Thos. Jolly, Esq., followed with fair specimens; but this exhibitor staged his best productions in the class for *Cockscombs*, gaining the premier award with well-grown plants, the "combs" being very large, arched, and richly coloured. *Pelargoniums*, *Gloxinias*, *Tuberous Begonias*, and *Petunias* were numerous, but the last-named were the most remarkable, the plants being trained on flat circular trellises and very freely flowered.

Cut Flowers.—An important feature in the Exhibition was formed by the numerous collections in the classes for cut flowers, all being well represented. For twenty-four bunches of stove and greenhouse flowers Mr. Long was the most successful exhibitor, winning the first prize with some handsome blooms of *Ixoras*, *Francisceas*, *Poincianas*, and *Rondeletias* amongst others, Mr. G. Howe, gardener to Lewis Fry, Esq., M.P., Mr. F. Mould, and Mr. Webb followed in that order. *Dahlias* were contributed by Messrs. H. Bush, W. Shaw, G. Horsel, and J. Hobbs in very fine form; the *Gladioli* from Messrs. Stephen Brown, A. A. Walters, J. Wheeler, and Bird, gardener to S. Dobree, Esq., being also of considerable merit. *Roses* were very bright, fresh, and of good substance, especially the stands from Messrs. Perkins and Son, Coventry, Mr. W. Smith, Kingswood, Bristol, Mr. John Mattock, Oxford, and Messrs. Cross & Steer, Salisbury. Both German and French *Asters*, too, were superbly shown, particularly by Messrs. W. S. Harding, J. Nation, H. Hooper, A. A. Walters, and G. Garraway. Table decorations, bouquets, and stands of flowers all added greatly to the extent and interest of the Show.

Fruit.—This is invariably shown extensively and well at this meeting, and with few exceptions there was no diminution in either quality or quantity. Much interest was centred in the class for a collection of twelve varieties of fruits exclusive of *Pine Apples*. Here the competition was remarkably close, only a point or two separating the first three collections. Mr. W. H. Bannister staged fair examples of *Bowood Muscats* and *Black Hamburg Grapes*, good fruits of *William Tillery* and another *Melon*, and *Chancellor* and *Noblesse Peaches*, *Pitmaston Orange* and *White Newington Nectarines*, *Victoria Plums*, *Morellos*, *Figs*, and *Doyenné Boussoch Pears*, all in good condition, and was awarded the first prize. Mr. G. Howe, gardener to L. Fry, Esq., M.P., though awarded the second prize might well have been placed equal first, his admirable collection comprising good *Bowood Muscats* and *Lady Downes' Grapes* (the latter not being in season militated against him), good *Melons*, *Peaches*, *Nectarines*, *Plums*, fine *White Turkey Figs*, and poor *Apricots*. Mr. A. Miller, gardener to W. Long, Esq., M.P., followed with a fine collection but lacking variety. His *Black Alicantes* were fine, but *Black Hamburgs* were weak. He also staged a fine dish of *Sir C. Napier Strawberries* and good *Peaches*. Mr. W. Fisher was awarded the fourth prize.

For eight bunches of *Grapes* in four varieties the premier award went to Mr. W. Nash, gardener to His Grace the Duke of Beaufort; but in point of quality this exhibit was surpassed by the collection staged by Mr. W. Hazard, gardener to J. Chaffin, Esq. Mr. Nash had fine examples of *Black Alicante*, *Black Hamburg*, *Muscats of Alexandria*, and *Lady Downes*, while the second-prize lot staged by Mr. Hazard consisted of perfect examples of *Meredith's Alicante*, and good *West's St. Peter's*, *Madresfield Court*, and *Lady Downes*. The third prize in this class went to Mrs. S. Broadley, and the fourth to Mr. H. Jones, gardener to General Doherty. With three bunches of *Black Hamburg* Mr. J. Gibson, gardener to Mrs. Miller, was first, being closely followed by Mr. Miller, both staging creditably. Mr. H. Atherston, gardener to the Misses Brackenridge, was a good third. For two bunches of *Black Hamburg* Mr. T. King, gardener to R. V. Leach, Esq., was first, his bunches being small but even and good. The second prize was awarded to Mr. Lintern, gardener to W. Butler, Esq., and the third to Mrs. W. Willis. Mr. J. Gibson had the best *Muscats of Alexandria Grapes*, the bunches being of good size and the berries even and fairly well coloured. Mr. G. W. Shelton, gardener to W. R. Waite, Esq., followed with very fine bunches but scarcely ripe; while Mr. Nash's very fine third-prize bunches were quite green. In the Any other white class Mr. J. Loosemore, gardener to W. Cooper, Esq., took the lead with *Foster's Seedling* in good condition; Mr. W. Willis following with small bunches of *Buckland Sweetwater*, and Mrs. S. Broadley took the third prize. In the corresponding class for black varieties Mr. Nash easily secured the first prize with handsome perfectly coloured *Black Alicante*. Mr. W. Hazard followed with good *Madresfield Court*, the third prize going to Mr. Miller. *Melons* were shown in great numbers, but the majority were very indifferent. Mr. Bannister staged the best green-flesh—a good example of *William Tillery*, the remaining prizes going to Mr. T. Tilley, gardener to Col. Colgrave, Mr. J. Weston, gardener to the Rev. C. C. Layard, and Mr. W. Burridge in the order given. Mr. Nash, Mrs. Broadley, Mr. E. T. Pocock, and Mr. H. Jones were the winners in the class for Any other variety of *Melons*. *Peaches* and *Nectarines* were well shown. The best dish of nine fruits of the former was staged by Mr. S. Cottel, variety *Royal George*; Mr. G. Pymm, gardener to J. Goldsmith, Esq., following with *Walburton Admirable*. Mr. Nash staged *Barrington* in good condition, and was placed first in the class for six fruits. Messrs. T. King, H. Lewis, and J. Riddick were the other successful exhibitors in this class. Mr. G. Pymm with highly coloured *Lord Napier* was first for nine *Nectarines*, Messrs. W. Carpenter, W. Nash, and W. Winters securing the remaining prizes. In the class for six fruits Mr. T. King took the

lead with good Prince of Wales; Mr. H. Lewis, gardener to B. Castle, Esq., following with Pitmaston Orange; the third prize going to Mr. A. McKay, gardener to R. Warmesley, Esq. Plums were well shown in the classes devoted to them. Messrs. J. Lye, A. Beavis, A. T. Hall, and H. Jones received the awards as named for Green Gages; while for any other dessert variety Mr. J. Beryer took the lead with well-ripened Coe's Golden Drop, the remaining prizes going to Mr. W. Long, gardener to C. Gardiner, Esq., and Mr. T. King. With a culinary variety Mr. J. Carpenter was first, Messrs. A. T. Hall and J. Ricketts taking the remaining prizes, the large fruited variety known as Fonthill or Pond's Seedling being the favourite.

Pears were shown in great numbers and good in quality. Mr. W. Winters took the lead with three dishes, the varieties being Williams' Bon Chrétien, Beurré d'Amanlis, and Albertine. The remaining prizes were awarded to Messrs. A. Beavis, R. Martin, and W. J. Smith, all staging creditably. Single dishes were staged by twenty-seven exhibitors. The first prize went to Mr. R. Martin for Williams' Bon Chrétien, the second to Mr. E. Hall for Beurré d'Amanlis, the other prizewinners being Messrs. E. Thomas and H. Beavis. Apples were scarcely so plentiful as usual, the only variety extensively shown being Lord Suffield. The best six dishes were staged by Mr. Beavis, these consisting of Tankard Codlin, Blenheim Pippin, Hollandbury, Lord Suffield, American New Town, and Ribston Pippin. The other prizes were taken by Messrs. W. J. Smith, A. T. Hall, and J. Goddard. There were thirty-six dishes in the class for a culinary Apple, Lord Suffield being the prevailing variety. The prizes were awarded to Messrs. G. Pymm, W. Shellard, H. S. Dutton, and E. Salter in the order named. Mr. Pymm was also first with a single dessert variety with Golden Pippin, Mr. J. House following with Kerry Pippin. The other prizes were taken by Mrs. Beard and Mr. H. Beavis. Morello Cherries were well shown by Messrs. F. Cox, H. Jones, and E. T. Pocock; Filberts by Messrs. W. Burrige, E. Salter, and R. Martin; and Nuts by Messrs. W. Fisher, J. Goddard, and W. Burrige, the prizes being awarded in the order named in each instance.

Vegetables.—These were well shown by both gardeners and cottagers, the exhibits in both instances being most creditable. The gardeners' class for twelve varieties was particularly good. Mr. H. Scott was a good first with a collection consisting of Autumn Giant Cauliflowers, Improved White Celery, Trophy Tomatoes, Telephone Peas, Champion Scarlet Runners, International Kidney Potatoes, Queen of the West Marrows, Improved Reading Onions, Early Six-weeks Turnips, and Ward's Improved Green-leaved Beet. Mr. W. G. Tylee was a close second, his collection including very similar varieties. The third prize was awarded to Mr. G. Smith, and an extra prize to Mr. F. March. Messrs. M. Barnfield, J. Pollard, gardener to C. J. Pictor, Esq., and W. Willis were the successful exhibitors of nine varieties of vegetables; and Messrs. G. Ricketts, G. Horsell, and J. Lye of six varieties, the exhibits generally being very meritorious.

Miscellaneous exhibits, though not very numerous, were of noteworthy merit, the most important being the following. The Roses, Tuberos Begonias, Dahlias, and Clematises from Messrs. G. Cooling and Son, Bath, formed a fine group at one end of the plant tent, and were greatly admired. Mr. G. Garraway, Lower Swanswick, Bath, had some fine single Dahlias; Messrs. Cross & Steer, Salisbury, blooms of the white Clove Carnation The Governor. Mr. H. Hooper of Bath had large stands of single Dahlias and Pansies.

ORCHIDS IN SEPTEMBER.

WATERING and damping-down will require to be very carefully done now. It should be attended to before noon, and the houses allowed to become dry, ventilating freely on every available occasion, closing the East Indian, Mexican, or Cattleya and Dendrobium houses about 3 P.M., and in the cool house the ventilation may be reduced an hour later.

The Dendrobiums which have finished their growths, such as *D. crassinode*, *D. chrysotoxum*, *D. Pierardii*, and *D. Wardianum*, should now be removed into a cooler and drier atmosphere. *Calanthe vestita rubra*, *C. vestita lutea*, and *C. Veitchii* are producing their spikes. They should be kept near the glass, and will be greatly assisted by a liberal supply of liquid manure, which will ensure a good display of blooms next month. *Cattleya bicolor* is bearing its spikes of from eight to ten pale green, rich purple-lipped flowers. *Cypripedium Ashburtonæ*, *C. Crossianum*, *C. barbatum purpuratum*, *C. Harrisianum*, *C. Roezlii*, *C. Sedenii*, *C. vexillarium*, are now finely in bloom.

Dendrobium bigibbum now bears its rich rosy purple blossoms. This requires considerable warmth and moisture, and thrives well exposed to the sun. *D. chrysanthum* is rich with its drooping spikes of lovely golden flowers, whose beauty is best seen when the plant is suspended in a hanging basket. *D. formosum* is exhaling a delicious perfume from its pure white flowers with yellow-centred lip. The scarce *D. triadenium* is bearing its pretty trusses of small white flowers, which continue in perfection for about a fortnight, and are extremely useful for cutting. *Lælia Perrinii* and *P. major* with their beautiful rosy lilac flowers are blooming finely, and last about three weeks.

The Miltonias are making a good display, the following being

very conspicuous—*M. bicolor*, with its white flowers with violet-spotted lip; *M. Clowesii*, with chocolate-barred yellow blooms with violet-spotted lip; *M. candida*, yellow, white-lipped flowers; *M. Moreliana*, deep violet Jonquil-scented blossoms; *M. Regnelii*, white and rose-coloured flowers; *M. Regnelii purpurea*, delicate rose-coloured blooms with purple crimson lip; *M. spectabilis*, creamy white with violet and white lip. These Miltonias are best grown in shallow pans with good rough fibrous peat, from which the earth should be shaken, charcoal and sphagnum moss, with a good supply of water. They grow well and flower freely on blocks, but require more attention as regards dipping when grown in this way.

Odontoglossum rubescens is a pretty small-flowering Odontoglossum, and is flowering well now, and when grown in a mass is very effective. It proves very useful for cutting, and is of easy culture. A rich display is at present obtained from the white purple-spotted flowers of *Odontoglossum Andersonii*; the brown-spotted light green blooms of *O. bictoniense*, with white or rose-coloured lip according to variety; the large, rich yellow, whitish-lipped flowers of *O. grande*; the pure white crimson-sprinkled blooms of *O. navium*; the straw-coloured flowers of *O. Schlieperianum*; and the numerous delicate blossoms of *O. Pescatorei* with their charming mixture of rose and white.

Oncidium Papilio, with its butterfly-like bright yellow and brown coloured blooms, is in good condition, as is also *O. ornithorhynchum* with its masses of pretty rosy white flowers exhaling a delicious odour. *O. varicosum* is pushing up its spikes, promising a fine display shortly.

Phalaenopsis amabilis has its bluish white flowers. *P. cornucervi* with its greenish yellow white-lipped blooms, and *P. rosea* with its dozen or more of rose-coloured blossoms, are also beautiful at this season.

Vanda Batemanii, *V. cærulea*, *V. lamellata*, *V. suavis*, *V. tricolor*, and *V. tricolor insignis* are all in bloom, the last three flowering regularly twice a year, the colours of the flowers being richer in hue in autumn than in the spring.

Zygopetalum Gautierii with its bright green and brown violet-lipped flowers, and *Z. gramineum* with white and purple blooms, are both in condition.—ORCHIDIST.

INSTEAD of giving a mere list of prizewinners at the INTERNATIONAL SHOW that opened at Edinburgh yesterday (Wednesday) by telegraphic report, we have decided to give a complete critical report of the Exhibition next week, as this will, we presume, be most agreeable to our readers, and certainly of greater service to them than a skeletonised account of the awards.

— THE CATALOGUE OF EXHIBITION ROSES of the National Rose Society is a very useful compilation. The Sub-Committee appointed to prepare the work have been guided by the following principles:—1, To admit but very few Roses which are known to be of extremely delicate growth. 2, As regards the newer varieties, to insert only those which have been grown extensively enough for an accurate estimate to be formed of their value. 3, In bracketing Roses as synonymous, to be guided neither by foliage nor habit of growth, but simply by the similarity of flowers. Upwards of a hundred Hybrid Perpetuals are named alphabetically, and accurately and soberly described; upwards of forty Teas and Noisettes and one Bourbon Rose—the extremely useful Souvenir de la Malmaison. The catalogue can be had post free for six penny stamps from the Hon. Secretaries, Rev. H. H. D'Ombraïn, Westwell Vicarage, Ashford, Kent; and Edward Mawley, Esq., Lucknow House, Addiscombe, Croydon.

— MESSRS. J. VEITCH & SONS, King's Road, Chelsea, have sent us a copy of an Italian edition of their "MANUAL OF CO-NIFERÆ," which has been translated by Signor Giovanni Sada of the horticultural firm of Sada, Milan. It appears to have been

faithfully rendered, is well printed, and will form a valuable addition to Italian horticultural literature.

— WE have received the schedule of prizes of the *HARBORNE AND DISTRICT POTATO EXHIBITION*, which is to be held on the 15th and 16th in the Masonic Hall, Harborne, near Birmingham. A silver cup value £10 is provided for twelve varieties of Potatoes, and three prizes in money are offered in each of the twenty classes. Messrs. Sutton, Messrs. Webb, and Mr. Merris also give special prizes for competition. Mr. G. Stacy, York Street, Harborne, is the Hon. Secretary of the Society.

— IN a note on *LETTUCES* an experienced gardener says Webbs' Summerhill and Suttons' Marvel are his two favourite kinds. They are both large, well-flavoured, and crispy. Cabbage Lettuce for summer and Cos Lettuces for winter are what he endeavours to provide. He further remarks:—"Clean open surfaces and plenty of space between the plants or crops are rules which should be well attended to in the kitchen garden this autumn, as most of the plants are inclined to be soft in growth, and if a severe winter comes on crowded tender crops it may leave us without vegetables."

— *MESSRS. JAMES CARTER & Co.* have sent us specimen blooms of their select strain of *EMPRESS PETUNIAS*. These flowers are representative of a collection of nearly ten thousand plants grown in pots for seed in their nurseries at Perry Hill. The variety is very great, and we know not which to admire most—the pencilled, lace-edged, green-edged, or double rosette forms. All of them are undoubtedly very fine, the diversity of colour being extraordinary, the markings of the rayed flowers well defined, while the selfs and edged varieties, both double and single, are well formed and of good substance. We never saw a more beautiful collection.

— A *CORRESPONDENT*, writing in reference to the *APPLE CROP*, observes:—"The American Apple crop will be even less than the abnormally poor one of the past year. The excessive rainfall at what is known to growers as the setting-time destroyed the extraordinary promise of the spring. The English crop is the worst seen during the last ten years, and prices will rule high accordingly. The news from Canada, however, is of a more cheerful character, and producers and exporters have the prospect of high prices and corresponding profits."

— *MESSRS. JAMES DICKSON & SONS* of Chester write:—"We send for your inspection a small sprig of our new *CUPRESSUS LAWSONIANA* 'SILVER QUEEN.' It is perfectly hardy, and of neat, compact, pyramidal growth. Of course you will take into consideration that in Chester we have much smoke from railway works, &c., which affect the appearance of all variegated plants in our nurseries. We have been awarded a first-class certificate for it by the Royal Horticultural Society." The spray has an attractive silvery appearance, and is certainly not defective in vigour. Good specimens on lawns will be highly ornamental, and there is reason to believe that the variety will prove worthy of the honour it has received.

— *MR. F. A. FAWKES*, Mansion House Buildings, 4, Queen Victoria Street, writes:—"In travelling about the country I have met with numerous gardeners who have expressed a desire to purchase my book on '*HORTICULTURAL BUILDINGS*,' but could not afford to do so (the published price being 10s. 6d.). Actuated by a desire to assist the fraternity as much as I can, I beg to intimate that I shall be very pleased to place at your disposal a hundred copies of the above work for distribution to any *bonâ fide* gardeners who may choose to apply to you for them at 3s. each copy (which is under actual cost price). Any applications by post must be accompanied by 1d. extra to pay the postage of the book."

— *RELATIVE* to a good *WHITE GLADIOLUS* for planting with *G. brenchleyensis*, required by "A. B.," a correspondent recommends Mrs. Neville, which is ivory white faintly flaked with violet, and is described as a free grower, cheap, and effective. Mr. Kelway also recommends the same variety as suitable for the purpose in question.

— "W. B. H." desires to know the name and address of the firm or gardener who laid out the flower beds in front of Westminster Abbey.

— *ALLUDING* to *VEGETABLES*, a correspondent observes:—"The season of 1882 will long be remembered as being very unfavourable for some crops, such as Apples and Potatoes, but vegetables generally are by no means scarce or of inferior quality. We are inclined to regard the season as most favourable for vegetables, as the crops are abundant and better than they usually are in drier seasons."

— *MR. H. G. SMYTH*, horticultural sundriesmen, 17A, The Coal Yard, Drury Lane, W.C., has sent us a sample of *ORCHID PEAT*. It is a clean, sweet, compressed, yet yielding mass of fibre, just what Orchid growers delight in when potting their plants. It is of a texture for receiving any quantity of fibre, while the chance of its being rendered sour is extremely remote. Wherever Orchids are grown a supply of such material as this is indispensable, as with it and good attention the plants will flourish.

— "NORTH YORK" writes:—"We are experiencing some of the effects of our unsettled climate. *Helleborus olympicus* and *H. atro-rubens* are now in full bloom, and others are throwing up their flower stems, giving us the idea of autumn rather than Christmas Roses."

— *THE* same correspondent observes—"We have on a south wall a very fine tree of the *WINTER NELIS PEAR*. In early summer it was much affected with aphides; then followed mildew, next the falling of the leaves, and now, the beginning of September, it is breaking into young growth and is in full bloom, being left without fruit this season. In all probability we shall be left without next year also."

— *THE* correspondent who sent us a spray of *KENNEDYA MARRYATLÆ*, which was figured in this Journal on page 341 of the last volume, informs us that he has saved some seed, which he will be happy to forward to anyone interested in the plant. Applications to be forwarded to this office, addressed to the Editor.

— *THE INTERNATIONAL POTATO EXHIBITION* will be opened on Wednesday next at 1 P.M. by the Lord Mayor, who will be accompanied by the Sheriffs and the promoters of the Exhibition. Luncheon will be served at 2 P.M. The Judges are desired to be ready for work at 11 A.M. precisely.

— "J. H." writing on *WASPS* says—"Bad as the season has been in fruit, wasps have come to devour what little there is. Trap as we may—turpentine, paraffin, sit up and dig out in the night, the cry is, They come. Up to the second week in August we scarcely saw a wasp, but to our surprise they came, and they stay night and day; and the only consolation I have is that they will leave us when they have devoured what we have—the thieves."

— *THE Annual Cryptogamic Meeting of the EPPING FOREST NATURALISTS' FIELD CLUB* will be held on Saturday, the 23rd inst., in the northern section of Epping Forest (High Beach, Monk Woods, Theydon Woods, &c.) The following well-known botanists have promised their valuable aid as referees and directors at the meeting:—For Fungi—Dr. M. C. Cooke, M.A., F.L.S., Mr. James English, C. B. Plowright, Esq., M.R.C.S. (of King's Lynn), Dr. Spurrell, Worthington G. Smith, Esq., F.L.S., F.R.H.S.,

M.A.I., Dr. H. T. Wharton, M.A., F.L.S. For Mosses, Lichens, and Phanerogams—Professor Boulger, F.L.S., F.G.S., Dr. Braithwaite, F.L.S., F.R.M.S., &c., E. M. Holmes, Esq., F.L.S., W. W. Reeves, Esq., F.R.M.S. The Club will assemble in the Woods about one o'clock, the rendezvous being the large sedgy glade in Monk Wood. Tea will be provided for members and visitors, after which a discussion of the gatherings and discoveries of the day will take place, and the following papers and notes will be read: "Some Observations upon the Reproduction of the Uredines," by C. B. Plowright, M.R.C.S. "On the Rhizocarpeæ," by Prof. Boulger, F.L.S., F.G.S. "On Fairy Rings," by Worthington G. Smith, F.L.S., F.R.H.S. "On Marine Algæ," by E. M. Holmes, F.L.S. "Fungi as Food," by Dr. Wharton, M.A., F.L.S. Persons desirous of joining the party can obtain all particulars and instructions by communicating as soon as possible with Mr. W. Cole, Buckhurst Hill.

— "SALOPIAN" writes:—"Would some of your correspondents state if they consider YELLOW A GOOD COLOUR TO USE IN TABLE DECORATIONS under gas or any artificial light? I have seen it stated, I believe by Mr. E. Luekhurst in the Journal, that it is not a good colour to use, while several of my friends who have been prizewinners assert that it is. Perhaps this question may elicit information from one or two sources that would be conclusive."

— IN reference to the variability of the ROSE MADAME GABRIEL LUIZET, "DUCKWING" writes:—"Possibly the character of this Rose varies under different circumstances. On my two original plants purchased on Manetti stocks in 1879 I have about a dozen buds and blooms; on nine standards budded in 1880 and 1881 I have a single bloom among them. On Magna Charta, which its raiser considers doubtful as a Perpetual, I have eight blooms on one stand, one on another, and none on the remaining eighteen." "A NORTHERN AMATEUR" also writes:—"A plant of Rose Madame Gabriel Luizet, from which I formerly had one or two beautiful blooms, is at present set with five buds, two of which should expand within a week." And the Rev. J. A. Williams, Alderminster Vicarage, sends us two flowering shoots of this Rose, stating, "You will see where I have cut flowers earlier in the season. I have but four plants of this Rose, and but one of them is really a Perpetual. I have budded from this one only. This one tree is a thorough Perpetual." Mr. J. Brown, Great Doods, Reigate, also writes:—"In a recent issue 'D., Deal,' expressed some doubt as to the above Rose being perpetual. I beg to say that I have cut two blooms of it during the last few days, and have other buds showing. It has also flowered recently in a neighbouring rosarian's garden; therefore it has a tendency to be perpetual, but not so free as many varieties. No doubt by budding from those shoots which flower in autumn would tend to make it more perpetual."

— THE July number of the *Agricultural Students' Gazette* (Royal Agricultural College, Cirencester) contains an article by Professor E. Kitch on the SOY BEAN (*SOJA HISPIDA*). This Bean, of which there are a dozen or more varieties known in the East, is very largely used as an article of food in Japan and China, where it is manufactured not only into soy, now exported in considerable quantities to Europe, but also into bean cheese and other forms of food. The Soy Bean in its proximate composition approaches more nearly to animal food than any other known vegetable production, being singularly rich in fat and in albuminoids, and it is therefore a valuable adjunct to the food of the almost vegetarian Japanese. Of late years, especially since the Vienna International Exhibition, many efforts have been made to acclimatise this Bean in various parts of the European continent, chiefly in Hungary and Germany. France and Italy have also attempted it, and some of the experiments have been fairly

successful. We notice that Professor Kitch is trying to grow some of the varieties in the botanic garden at Cirencester; and though our climate is probably too uncertain and the temperature often too low for most of the varieties to attain perfection, still if any of them could be acclimatized a valuable leguminous cross would be added to our present list. The paper contains detailed analyses of the Bean as grown in different countries, of several of the foods made from it, of its straw, which is a useful fodder, and of the ash of the bean and straw.—(*Nature*).

CANKER IN MELONS.

THIS is often very troublesome among late crops of Melons, and is most prevalent among the, apparently, most healthy and vigorous plants, and especially so in dull weather. The plants look the picture of health until a bright day comes, when they suddenly flag, and no attention will revive them. But the experienced cultivator will detect the disease on its first appearance, when the bark takes the form of a brown spongy substance, generally at the base of the stem first, and rapidly spreading upwards and inwards. Immediately this is seen scrape the diseased parts clean with a knife and apply hot lime, rubbing it in with the finger and thumb until a good coating of it adheres to the stem. If taken in time this will generally stop the disease, but sometimes a second or third application is necessary. At the same time stop all luxuriant shoots, keep the house dry, give only enough water to prevent flagging, and plenty of fire heat in dull weather, with ventilation in proportion.

I lately saw one of the most successful instances of Melon culture that has ever come under my notice at Messrs. T. Frost and Sons, the Bower Nurseries, Maidstone. The plants were growing in a span-roofed house running north and south on the west side, and were planted in a very small portion of soil about 4 inches deep by 15 inches wide, placed on the surface of a pit filled with coal ashes, &c., which answered the purpose at other times of a cool bench to stand plants on, and was almost as firm as concrete; but I have no doubt the roots had penetrated it, and derived a certain amount of sustenance from it. The plants were carrying a good crop of fruit of a useful size.—W. H. DIVERS, *Burghley*.

SOME INQUIRIES.

I AM desirous of knowing how to proceed with seed of *Tropæolum speciosum*. This plant has been remarkably fine this season, having grown through the last winter, began flowering in early summer, and still continues. It is the admiration of all who see it, and is now ripening seeds. Will some of the readers of the Journal be kind enough to say when and how is the best time to sow the seed and the mode of treatment, as I am anxious to raise some plants? As I have had many inquiries relative to establishing my plant, I hope this beautiful climber will soon be found in all gardens, as it ought to be.

Tuberous Begonias.—These have proved the most effective of our bedding plants this season, and now, though the weather is anything but favourable, they are the gayest of the gay. I am anxious to increase them in their separate colours; can I do this by cuttings and divisions, or will there be a possibility of their coming true from seed? I expect to see them in the foremost ranks of bedders, numerous as plants are for bedding purposes.

Antirrhinum versicolor.—Years ago we used to have this as an annual, and it was thought much of by many, but I have lost sight of it for some time. I have been trying for some years to renew my acquaintance with it, but I cannot find it in any seed list, or hear of it by inquiring. Can any reader tell me anything of it?

Corydalis glauca.—This plant seems to have disappeared. We used to have it sow itself and flower in the spring. It was distributed by the Horticultural Society many years ago. It is one of the very best of our hardy annuals. I should be glad to hear of its whereabouts.—J. H.

ONIONS.—These have had many stops and starts this year, but on the whole the crops are well developed, the bulbs being large as a rule but very soft. Too much rain and sudden sunshine has caused many of the finest to split and decay in some cases. Trebons has done this to a great extent. The best way is to pull all such up that are observed swelling a little too much to one side: indeed all which have attained a fair size now may be pulled up at once and dried. This may not be easily done in the open, but an airy shed will do as

well. Those with much soft green top should have part of it twisted off in taking them up. They will dry quicker after this has been done.—M. M.

CHRYSANTHEMUM MAXIMUM.

IN many gardens for some weeks past there has not been a more striking plant than this fine Chrysanthemum, which during August and September produces its large white flowers in such numbers that the foliage is almost hidden. Particularly handsome is this plant in one of the borders at Hampton Court, where

several clumps at intervals amongst the numerous other occupants have an excellent effect. The flowerheads are of considerable size—3 inches or more in diameter; the outer florets broad, pure white, and of great substance, the centre florets being bright yellow. It is of easy cultivation, and in rich soil grows very strongly, forming a large bush-like clump of imposing appearance.

CRYSTAL PALACE FRUIT SHOW.

WHETHER exhibitors are reserving their produce for the International Show at Edinburgh, whether the prizes were not sufficiently

Fig. 41.—CHRYSANTHEMUM MAXIMUM.

tempting, or whether fruit is not so good as usual this year, we know not; but this we know, it was far from being on the whole in high-class condition at the Show under notice. That there were good examples we readily admit, but many Grapes were not ripe, and much of the fruit had been seriously rubbed in transit; consequently there was an absence of cleanness and smartness that contribute so much to the attractiveness of an exhibition of fruit. There were, too, many blanks in the tables, which Mr. Head did his best to furnish with the materials at his command; but it was beyond his power to make the Show either a great or a good one.

Collections.—In the class for twelve dishes of fruit there were three competitors, Mr. Coleman being distinctly first with two good Pines,

fine 4-lb. Black Hamburg and neat Muscat Grapes, with good dishes of Bellegarde Peaches, Victoria Nectarines, Jefferson Plums, Moorpark Apricots, Brown Turkey Figs, fine Pitmaston Duchess Pears and Morello Cherries, and a large Melon. Mr. Roberts, gardener to the Baroness Rothschild, Gunnersbury Park, was an excellent second, his Black Hamburg Grapes being very good, and Madresfield Court fine in the berry; Pines and Pears weak; other dishes good. Mr. Goodacre, The Gardens, Elvaston Castle, was an extremely close third, the loss of points in Melons losing him a higher position. Five collections of eight dishes were staged, Mr. Ocle, gardener to the Marchioness of Lothian, Blickling Hall, Aylsham, securing the premier position with rather small but ripe Muscats and excellent Madresfield

Court Grapes, large Lord Palmerston Peaches, and fair Pitmaston Orange Nectarines, good Williams' Bon Chrétien Pears and Brown Turkey Figs, with small Green Gage Plums. Mr. Goldsmith, Sandhills, Bletchingley, was second with large but green Muscats, good Alicantes, a large Melon, and fair dishes of smaller fruits. Mr. Miles, Wycombe Abbey, was placed third with the ripest fruit of all, but generally wanting in size. Judged by the palate alone this collection would have had a higher position.

Grapes.—Collection of ten kinds, six black and four white. Mr. Roberts of Gunnersbury was distinctly first with a creditable collection. Alicantes excellently finished, Buckland Sweetwater well ripened, Muscats good, Muscat Hamburgh, fine bunches but irregular berries; Madresfield Court, excellent berries; Tokey, large; Alnwick Seedling, very fine indeed; Foster's Seedling, small berries; and good Black Hamburgs comprised the collection. Mr. Goodacre was a close second, Venn's Muscat being good, as also were Madresfield Court, Cannon Hall Muscat, Gros Colman, and Alicantes; but many of the berries were rubbed. In the class for five bunches there were that number of competitors, Mr. Allan, gardener to Lord Suffield, Gunton Park, being first with Alnwick Seedling, good; fine bunches of Chatsworth Seedling, the berries resembling Madresfield Court but smaller; Gros Colman, and Muscat of Alexandria. Mr. Coleman was second, all the varieties being black. The notable bunches were Black Morocco full and fine, with Alicante, Lady Downes, Madresfield Court, and Black Hamburgs all good. Mr. Elphinstone, gardener to E. Miller Mundy, Esq., Shipley Hall, Derby, had the third position, his Grapes not being ripe.

Mr. Coleman was first in the class for three bunches of Black Hamburgh, large (4 lbs.), with splendid and well-coloured berries. Mr. Holmes, gardener to T. Wallis, Esq., Sister House, Clapham Common, followed with medium-sized good-shaped bunches and fine berries. Mr. Herrin, gardener to J. W. Hibbert, Esq., Chalfont Park, Bucks, was a close third. Mr. E. Hill, gardener to Sir N. M. Rothschild, Tring Park, was clearly first in the Muscat class with large, full, ripe, well-shaped bunches; Mr. Johnson, Lamberhurst, Sussex, being second with large unripe examples; followed by Mr. Smith, gardener to W. H. Sewell, Esq., Warren Hill, Longton, Essex, with "lumpy" bunches but good berries. Mr. Goodacre staged small bunches, but with good well-coloured berries of Gros Colman, and secured the first prize; Mr. Holmes following with very small examples. In the Madresfield Court class Mr. Wallis was placed first of the six competitors with 2-lb. well-filled bunches and good ripe berries; Mr. Herrin being second with much larger bunches, and Mr. Goodacre an extremely close third. Only the first-prize Grapes were ripe in this class. Seven collections of Alicantes were staged; Mr. Howe, gardener to H. Tate, Esq., Streatham Common, being placed first with undoubtedly the best examples, said to have been cut from a Vine bearing a hundred bunches. Mr. Herrin and Mr. Elphinstone had the remaining prizes in this class, their productions being of nearly equal merit, but not ripe. It is noticeable that several of the white Grapes in the classes were shown on pink paper, which appeared to display them to the best advantage.

Pines.—For one Queen Mr. Coleman was first with a good well-ripened fruit; Mr. Ford, gardener to Earl Cowper, West Park, second; and Mr. Bailey, gardener to J. T. Drake, Esq., Shardeloes, third. The display of Pines was limited, several in the Show being of inferior quality.

Peaches.—For three dishes Mr. Roberts was placed first with Bellegarde, Barrington, and Belle Bance, all of good average size and well coloured. Mr. Oclew was second with Princess of Wales, Barrington (small), and Newington; and Mr. Miles third with Early Crawford, Bellegarde, and Late Admirable. Mr. Coleman would have been first in this class had he not inadvertently staged two dishes of the same variety. Seven collections were staged, but many fruits were small. For one dish Mr. Coleman was first with Bellegarde, splendid; Mr. Roberts second with Barrington; and Mr. Holliday, gardener to James Norris, Esq., Bletchingley, third. Eleven dishes were staged.

Nectarines.—For three dishes Mr. Coleman was an easy winner with Lord Napier, Stanwick Elruge, and Elruge, all very fine; Mr. Elphinstone and Mr. Goldsmith, Hollenden, Tonbridge, following as named with creditable examples. For one dish Mr. Coleman was again first with beautiful examples of Elruge, Mr. Oclew being second, and Mr. Richards, gardener to the Earl of Normanton, Somerby Ringwood, third, both with Pitmaston Orange.

Melons.—In the green-fleshed class Mr. Herrin was first with Hero of Lockinge. Mr. Knellar, Malshanger Park, second with an unnamed fruit resembling Golden Perfection; and Mr. George, Putney Heath, third with Hero of Surrey, all staging good examples. Fifteen fruits were placed in competition in this class. Ten were submitted in the scarlet-fleshed class; Mr. Herrin, and Mr. Barker, Hindlip Hall, being first and second with good fruits of Blenheim Orange, and Mr. Bailey third with Victory of Bristol.

Plums.—Twelve collections were staged in the class for three dishes; Mr. Fay, gardener to L. J. Baker, Esq., Haydon Hall, Pinner, being first with Emperor, Transparent Gage, and Belgian Purple—all good. Mr. Goodacre second with Washington, Jefferson, and Transparent Gage, the last-named very fine; and Mr. Coleman third with Kirke's, Emperor, and Jefferson—all good dishes. For a dish of Green Gage Mr. Fry was first; Mr. Lemmon, gardener to J. Omer Roper, Esq., Calcot Gardens, Reading, second with Calcot Green Gage; and Mr. Wells, gardener to R. Ravenhill, Esq., Windsor Forest, third with

Webster's Green Gage, ten dishes being staged in the class. For a dish of red or purple Plums Mr. Goodacre was first with Pond's Seedling, very large. Mr. Coombes, gardener to Sir Henry Meux, Bart., Sheen House, Surrey, second with the same variety; and Mr. Wells third with Victoria—a good class of eight dishes. The first prize, offered by Messrs. Cheal & Son for their new Melons, was awarded to Mr. Goldsmith, gardener to Sir W. Farquhar, Bart., Polesden Lacy, Dorking, who appeared to be the only exhibitor; and an extra prize of £2 was worthily granted to Mr. Neighbour, gardener to G. Wythes, Esq., Bickley Park, Bromley, for a collection of twenty dishes of fruit. This completes the classes of a Show which was decidedly inferior to many previous exhibitions we have seen in the Palace.

Several miscellaneous exhibits covered much space effectively, notably a great collection of Apples and Pears from the Waltham Cross Nurseries of Messrs. Paul & Son, comprising apparently about one hundred varieties of the former and half that number of the latter. Messrs. Cheal & Son, Crawley, Sussex, sent forty good dishes of Apples and Pears. From Calcot Gardens came twenty-four dishes of Apples and eighteen of Nuts. Messrs. Saltmarsh exhibited their fine new Apple The Queen; and Messrs. Atherton of Chatteris sent a new seedling Apple of the type of Fearn's Pippin, but darker in colour.

Flowers were also represented on the side stages, Messrs. Kelway staging ninety-six spikes of Gladioli—a fine display; Messrs. Wm. Paul & Son ten grand boxes of Roses in about a hundred varieties—one of the finest collections of September Roses we have ever seen. Excellent boxes of Roses also came from Messrs. Pauls of Cheshunt; and Messrs. John Laing & Co. staged a tasteful group of plants, composed largely of splendid varieties of Tuberous Begonias. Thus with this Exhibition in one nave and the Dahlia Show in the other the company had plenty to admire. The condition of the plants in the Palace, too, and their arrangement are very satisfactory, and the flower and carpet beds in the grounds highly attractive.

THE KINVER SEED FARMS.

ABOUT five miles from the Stourbridge station of the Great Western Railway is situated an establishment which possesses considerable interest for both agriculturists and horticulturists, as in a comparatively few years its productions have rendered the name of Messrs. E. Webb & Sons familiar to British farmers and gardeners throughout the empire. The district around Kinver is much elevated, diversified, and picturesque, some parts being finely wooded, and from Kinver Edge, as the highest point is termed, an extensive view of some very charming scenery can be obtained upon a clear day. The approach, too, from Stourbridge is a most agreeable drive in fine weather, which, unfortunately, I was not favoured with; but even under the depressing influence of a heavy sky and continuous rain it was impossible not to be sensible of what might be termed the latent beauty. With surroundings so attractive we find the Kinver seed farms occupying a space exceeding 1000 acres, open, high, and in every way admirably fitted for the purpose to which they are applied, the healthy vigour and sturdiness of all the crops well indicating not only the attention that is paid to them, but also the suitability of the soil and district for ensuring satisfactory produce. It is evident, indeed, in all departments that the great object of the firm is to secure the confidence of their customers by providing them with the best quality obtainable, and no efforts are spared that tend to this result. Messrs. Webb claim, and apparently with good reason, that they are the largest seed-growers in the kingdom, for together with the 1000 acres at Kinver, the greater portion of which is their own freehold, we are informed they have over 10,000 acres under crops in different parts of the country and on the continent; and the immense amount of seed raised on so great an extent of land can scarcely be realised, though some idea of the magnitude of a business which requires such enormous supplies may be gathered from the statement. Everything is on a large scale. Specially approved kinds of vegetables or cereals are grown by the hundred acres, and on one farm in an adjoining county to the head-quarters 400 acres are devoted to Potatoes and cereals. Turnips, Mangolds, Peas, and many others are similarly provided for, while the flowers for seed form an important department that is being rapidly extended.

To enumerate in detail all that is worthy of note upon the Kinver farms alone would require a volume, and will only be possible here to briefly glance at the chief features and the most important crops. As already indicated, Messrs. Webb pay great attention to the culture of cereals, Barley, Wheat, and Oats being largely grown, and some of the firm's selections in each have attained a high position in the agricultural world as reliable, prolific, and good quality varieties. Of the 153 acres devoted to Barley the principal portion is occupied with Kinver Chevalier and New Beardless, both bearing the name of this firm as a testimonial of their merit; 137 acres are appropriated to Wheat, the most notable varieties of which are "Webb's Challenge White," which was awarded the gold medal of France this year, and other prizes. Selected Golden Drop, Selected Square Head, and of Harcastle—all very promising, together with an Australian Wheat of fine quality now being acclimatised. Fifty-two acres of Webb's Challenge White Oats and 70 acres of Webb's Prolific Black Oats are also grown, and other good varieties in addition.

Turnips, Mangolds, and Swedes form another important feature; Webb's Imperial Swede, also known as "the Great Swede," the

Mammoth Long Red Mangold, and New Champion Yellow Globe Mangold, all three remarkable varieties that are much prized by cultivators having considerable space devoted to them, common Turnips also being grown in enormous quantities. Potatoes, it may be readily imagined, are similarly largely represented. In one portion of the farm forty selected varieties are grown chiefly for garden use, over 30 acres being devoted to these. Among them are four seedlings, the result of several years' careful crossing and selection, that will be distributed next year; they have been found to be of good quality, prolific, and disease-resisting. The Improved Schoolmaster, sent out by this firm, occupies 25 acres, and it is said to have yielded crops of 21 tons per acre under good cultivation. This is highly valued by many growers both for exhibition and the table, its even form fitting it for the first-named purpose, and its quality for the latter. In addition to those at Kinver Potatoes are grown in large quantities in other parts of the kingdom, the most favoured districts being selected.

Peas are strongly represented, but the bulk of these is grown elsewhere, over 800 acres being engaged for the purpose. The most interesting in connection with this crop on the home farm is the trial ground, where more than 120 varieties have been grown together for comparison, both for the satisfaction of the firm and their customers. All the best varieties in cultivation were represented, including Messrs. Webb's latest additions to these useful and much-prized vegetables. Such varieties as Kinver Gem, Triumph, Perfection, Electric Light, and Kinver Marrow, have given most satisfactory evidence of their merit even under so severe an ordeal as this. Other crops are similarly largely grown, such as Cabbage, Kale, Kohl Rabi, Carrots, Parsnips, Lupins, Comfrey, Giant Cow Grass, Colossal Italian Rye Grass, Seakale, Asparagus, Rhubarb, Strawberries, and Artichokes, some for seed and other for the roots. But it is unnecessary to refer at length to all these, as what have been already mentioned will indicate the general scope and extent of the business.

The trial ground—one of the most interesting and instructive portions of the farm to visitors—occupies considerable space, some thousands of varieties of vegetables and flowers being grown for comparison and selection. In this way not only have the firm abundant evidence to direct them in recommending particular sorts, but intending customers have also the opportunity of judging the relative merits and characters of all the most approved varieties. For example, taking the vegetables first, there are over fifty Lettuces, thirty Turnips, forty Onions, fifty Cabbages, and 120 Peas, besides Carrots, Parsnips, Mangolds, Beet, and innumerable other kinds. In each of these trials were new varieties or selections, several being very promising. New Summerhill, Immense Hardy Green, and American Gathering of the Cabbage Lettuces, and Superb Monstrous White amongst the Cos varieties, were very prominent and evidently useful forms. A new Cabbage of similar promise with a large firm heart was also noteworthy, but Webb's Emperor was exceedingly fine, and it is reputedly of quick growth, hardy, and early. Of Savoys, Webb's Little Wonder, a very dwarf compact form, Drumhead, and Marcellin, were particularly good. Of the Onions, Webb's Improved Banbury at once attracted attention by its size and handsome form, Red Globe, Italian Tripoli, Red Wethersfield, Trebons, and Naseby Mammoth being also noteworthy. Amongst several sorts of Parsley by far the best was a row of Webb's Giant Curled, which well merits its title, and as grown at Kinver a better sample of a good Parsley could not be desired. Early Six Weeks and New Early Purple Top were two of the leading varieties of Turnips, Chirk Castle also deserving mention; but the second named was particularly fine, and is much esteemed by gardeners who have grown it. So of all the other vegetables tried, something good was noteworthy in each; and it is only fair to state that in every case which came under my notice the varieties specially recommended by the firm well deserve the prominence accorded them.

Notwithstanding the heavy rains, that portion of the trial ground devoted to flowers was extremely bright, presenting masses of colour, which had a surprisingly fine effect. Large beds of white and crimson Candytuft, dwarf bright blue Lupins, *Linum grandiflorum*, *Clarkia pulchella*, *Godetias*, *Rhodanthes*, *Saponaria calabrica*, *Virginian Stocks*, *Tropæolums*, *Asters*, *Zinnias*, *Phlox Drummondii*, *Stocks*, and numerous other well-known annuals and popular garden flowers afford a diversity of tints that impart to the trial ground the appearance of a most extensive and brilliant flower garden. Of special excellence were the dwarf *Asters*, the flower-heads being large, full, and variously coloured, of the richest shades of purple and crimson to fine white. Sweet Williams, too, have a great space devoted to them, and the strain is one of considerable merit, the individual flowers of good size and form, richly coloured, and borne in dense heads. Marigolds, both African and French, are also a feature of much interest, the lemon and orange-coloured varieties of the former producing flowers of enormous size, and the beautiful striped blooms of the other type are neat in form and deeply coloured. *Tropæolums* are similarly well represented, the scarlet, spotted, Golden King, Crystal Palace Gem, and King Theodore varieties of the Tom Thumb section being the leading forms, the first very bright and the last extremely dark; all are compact growers and very floriferous. The Larkspurs, both double and single, and the dwarf Rocket type are grandly represented, very large quantities being grown to meet the demand existing for these popular and effective plants. The *Rhodanthes* are fine, other so-called Everlastings being grown in considerable numbers, the *Helichrysums* especially. Orna-

mental Grasses, such as the *Brizas*, *Agrostises*, *Lagurus ovatus*, and other favourites constitute another important feature. In fact, all the most useful garden flowers are grown in quantity, and by careful selection the various strains have been rendered highly meritorious. Indeed, the great attention paid by Messrs. Webb in recent years to this department of their business has resulted in a surprising development, which is annually increasing rapidly. Good evidence of this is afforded not only by the great quantities of plants grown for seed at Kinver, which only represent a portion of the stock disposed of, but also by the seed offices at Wordsley, the department appropriated to garden, flower, and vegetable seeds being on an extensive scale.

It should be added that, in addition to the flower and vegetable trials, considerable space is appropriated to testing the different mixtures of grasses for lawns and permanent pastures—a matter of great importance to both farmers and gardeners. Of other features possessing special interest for agriculturists may be noted the large herd of cattle and the flock of Shropshire sheep, which have obtained more than local fame.

The seed offices at Wordsley near Stourbridge are like the farms surprisingly extensive, several buildings of great size being devoted to the storing, cleaning, packing, and general business. The most important is a warehouse with five floors each 180 feet long, 60 feet wide, and 13 feet high, through which enormous quantities of seeds pass every year, and that £15,000 should be expended annually in postage and carriage is a striking indication of the extent of the demands which have to be met. The basement of this building is devoted to Potatoes in addition to another storehouse of great size. The first floor is for Clover seeds, and it is said that sufficient seeds for 150,000 acres of land have been sent out in one season. The second floor is devoted to grass seeds, the third to Turnip and Mangold seeds, and the fourth to cereals. Of the grasses seed for 75,000 acres, and of the Turnips and Mangolds for 140,000 acres are sent out annually, the cereal trade being similarly extensive. A portion of one of these floors is specially fitted up for the garden, vegetable seed, and bulb department, all the arrangements for the speedy execution of orders being most admirable. The export trade has assumed considerable dimensions in recent years, and consequently much space is devoted to the preparation and packing of seeds for the colonies and distant countries, while the elaborate machinery for cleaning seeds is another feature of interest. The manager's and clerks' offices occupy another spacious building, of which blacksmiths and carpenters' shops, stables, &c., complete one of the most perfect establishments of the kind in the country.

In concluding these brief notes it may be mentioned that Messrs. Webb also have an extensive flour and Hop trade, and with some relatives they are engaged in glass manufacture; but alike in all sections of their diversified and enormous business, their energy, attention, and earnest desire to provide articles of first-rate quality have gained them both wealth and fame.—VISITOR.

SILKWORMS AND SILKWORM REARING.—15.

(Continued from page 183.)

FIVE silkworms, out of the numerous insects of the Bombyx tribe that have been made the subjects of special experiment in the hope of finding out a rival to *B. Mori*, stand in a position of importance, either from the facilities afforded for rearing the worms, or from the texture and quality of the cocoons. Amongst others of less note we have described three of these—namely, *Attaeus Mylitta*, the Tussock species of India; the handsome Chinese *A. Cynthia*; and the portly American *A. Polyphemus*. Although as yet only mentioned in passing, we must devote to the Japanese species, *A. Yama Mai*, a place in our series more ample than has been bestowed upon some of its kindred, because the insect is one that has received much attention from silkworm breeders and naturalists also. In fact, there are those who would have us consider it as only second in value to the Mulberry species; its silk, which is of a light green, being rather less fine and strong than is that of the insect which has supplied the civilised world with silk for many centuries. I fear, however, that the result of a variety of experiments in rearing the *Yama Mai*, which have been made in Britain by persons not lacking patience and skill, will not put this insect second to the other in the important particular of suitability to a life of confinement. *B. Mori* has always taken kindly to domestication wherever the Mulberry will grow. *A. Yama Mai* proves to be rather peculiar in habit through all its stages, and, if accounts are correct, variable as to its likes and dislikes while a caterpillar, therefore more likely to succeed when leading a life of freedom. The facts we shall have to adduce presently will show that the worms, while having this in their favour that they subsist upon our common Oaks, can scarcely be left exposed to the changes of our climate, though they might then be, to appearance, in a more favourable position than when under cover. On the other hand, it might certainly be argued that by perseverance within suitable districts the insect might be so far acclimatised as to breed from year to year where protection was afforded only under special circum-

stances. But could it be reared thus in sufficient numbers to afford a supply of silk? Concerning this we can at present say little, but we may hope that A. Yama Mai, amongst the newer silkworms that attract notice, will not have its claims overlooked, since there are countries where the silkworms have been reared in quantities, and what little English silk has been got is of good quality. Moreover, in this era of education it ought to be easy to "educate" a silkworm, and so modify its habits.

The Japanese name of the species has been adopted as its specific designation. Until about thirty years ago it was both unnamed and unknown in Europe. Travellers in its native region had reported that the Japanese obtained silk from two insects, although the silk yielded by A. Yama Mai does not seem to have been distinguished from that of B. Mori. Some stated that the profits arising from the silkworm which fed upon the Oak were all added to the imperial revenue, and others declared that the silk, on account of its excellence, was reserved for the Royal Family or the Court. At all events this fact was ascertained, that for some cause a death penalty was attached to the offence of conveying the Yama Mai out of the country. With questionable ingenuity, however, a few Japanese traders had obtained what were represented to foreigners as the eggs of this silkworm, but which were really small objects made from wood. At the beginning of the year 1861, a French fleet being off Japan, the attention of several persons was drawn to the beautiful texture of the silk produced by A. Yama Mai, although the Japanese put forth as one objection to the material that it would not take a dye, which assertion was afterwards proved contrary to fact. That year true eggs in small quantity were got by the French Consul-General at Japan, and sent to Paris. These were taken charge of in the Jardin des Plantes, and a part of the batch of eggs hatched during March, but died speedily, refusing all the leaves that were offered them. Seemingly, the worms had been forced out too soon by the temperature at which the eggs had been kept. More caterpillars emerged early in April. The food plant was still unknown: the Oak chanced to be one of the species now offered them, and it was found they would not eat its leaves. Out of the forty counted only an eighth—that is, five, spun very poor cocoons, and no moths emerged. A few eggs had, however, been given to an entomologist at Passy, and he obtained one caterpillar, which, under his care, produced a cocoon, and afterwards a fine moth, which was handed to M. Guerin Melville. This enabled him to give the species a name; some acquaintance had been made with its habits, but the breed could not be continued.

The prohibition of any export of eggs, and the penalty on detection remaining unaltered, put difficulties in the way of further experiments; yet two years later a fresh supply was transmitted to Europe by a Dutch gentleman, director of the Imperial School of Medicine at Nagasaki. M. Pompe van Meedervoort, and a friend of his, tried repeatedly to procure eggs of A. Yama Mai from merchants, naturalists, and silk-growers. All ended in disappointment. Then he bethought himself of trying to induce a pupil to obtain some, who happened to come from the district of Hirgo, where many of the silkworms were reared. The youth undertook to collect eggs at the risk of his life, and gave his teacher as many as he could get, this second supply thus coming by way of Holland to France. Some were kept in Holland; and in that country, as also in France and Germany, there have been both successes and failures, open to various explanations. An Austrian nobleman, Baron le Bretton, has been remarkably successful with the species, rearing many thousands of moths, the eggs from which have been much in demand, being more certain than those imported from Japan, for it should be mentioned that the old restriction has now been taken off. From several dealers in foreign insects, Japanese, German, and also English eggs of A. Yama Mai may be purchased. In 1865 the first English specimens were seen, and for some years subsequent to that date Dr. Wallace spared neither time nor expense in his endeavours to acclimatise the species. He reared the worms under a variety of conditions, and having distributed eggs to many correspondents chronicled the results, which he had to own were less satisfactory than he had hoped. But our friends on the continent tell us that we ought to do well with the insect in Britain.

Reserving further remarks upon its habits, we only add here that the moth bears a resemblance to its brethren of the genus *Attacus*. Our illustration (fig. 42) exhibits a rather small specimen. Some of them measure 6 inches or more across the wings, the males being the larger; their forewings are more hooked, and the antennæ very feathery. The ground colour of the wings is generally

yellow or orange, in some specimens shading into yellowish brown, or occasionally darker than that.—J. R. S. C.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 12TH.

SINGLE Dahlias and the collection of Apples and Pears from Waltham Cross constituted the chief features of this meeting, but other exhibits were not very numerous. The collection of Rose blooms contributed by Messrs. W. Paul were, however, especially worthy of notice, for rarely are Roses shown so fresh and bright at this time of year, particularly after so much rain.

FRUIT COMMITTEE.—John Lee, Esq., in the chair. A letter of thanks was accorded to Messrs. Lane & Son of Great Berkhamstead for a collection of nine varieties of Cobnuts and Filberts, the finest being the Close Filbert, Kentish Cob, and Frizzled Filbert. Mr. Laxton, Bedford, sent examples of a white selection from Beauty of Hebron Potato even and good. He also sent fine samples of Girtford Giant Scarlet Runner Beans; fruits of two fine American Crabs named Dartmouth and Whitney, for which a vote of thanks was awarded; and a large fruit of the Red Betigheimer Apple of handsome appearance. Mr. C. Ross, Welford Park, Newbury, was awarded a vote of thanks for a new green-fleshed Melon named Emerald, of very good quality and well netted. Mr. Bonsall, Campsount, Doncaster, sent a Melon named Campsount Hybrid, a red-fleshed variety which was too far past its best to enable the Committee to form an

Fig. 42.—Moth of *Attacus Yama Mai*.

opinion respecting its merits. A cultural commendation was awarded to Mr. George, Putney Heath, for fine examples of Beurré d'Amanlis Pears and Duke of Albany Apples. A vote of thanks was awarded to Messrs. W. Paul & Son, Waltham Cross, for a collection of 250 varieties of Apples and Pears, the former being of fair size, but most of the Pears were much below the average.

FLORAL COMMITTEE.—G. F. Wilson, Esq., in the chair. Mr. T. S. Ware, Hale Farm, Tottenham, sent a large and beautiful collection of single Dahlias, comprising a great number of varieties, mostly of great promise. The small deep maroon Zimapani, the deep yellow Orangeman, the rich scarlet Fusilier, the maroon and rose-striped Pantaloon, Mauve Queen, White Queen, Violet, Yellow Queen, Christine, White Star, and Beauty of Cambridge were some of the best amongst many of great beauty. A collection of summer-flowering Chrysanthemums was also sent, the varieties represented including Souvenir d'un Ami, white and dwarf; Curiosity, mauve and neat; Andromeda, yellow; Scarlet Gem, deep red; and Chromatella, orange. Fruits of the peculiar *Pæonia decora* were also shown, the valves of the capsules being strongly recurved, displaying the black seeds on the scarlet interior. Sprays of the red-fruited *Actæa spicata* were also shown. Votes of thanks were accorded for both collections. Mr. Smythe, Basing Park, Hants, sent blooms of white and red Japanese Anemones. Messrs. Rawlings Bros., Romford, exhibited several seedling Dahlias, the best of which were Shylock, a bright scarlet Show variety; Sir B. Seymour, deep maroon; Golden Drop, yellow; President, yellow; Beauty of the Grove, rosy mauve; James Gilbert, deep scarlet; and John Henshaw, which was certificated. Messrs. J. Carter & Co., High Holborn, sent some fine examples of *Lilium lancifolium album, monstrosum, superbissimum*, and roseum, with *Hyacinthus (Galtonia) candicans*. The Lilliums were very well flowered, and the *Hyacinthus* vigorous. A vote of thanks was accorded to Messrs. Hooper & Co., Covent Garden, for a large and beautiful collection of Pentstemons and single Dahlias, comprising some richly coloured varieties; plants of *Begonia diadema*, with its deeply cut white-spotted leaves; the rich-coloured *Tydaea Robert*

le Diable; and the pink-flowered *Nægelia Cassiopée*. A basket of plants of *Gynura aurantiaca* was also shown in very good condition.

Messrs. W. Paul & Son, Waltham Cross, exhibited eight boxes of Rose blooms in remarkably fine condition for the season, such well-known varieties as La France, Niphotos, Marie Baumann, Fisher Holmes, A. K. Williams, Madame C. Crapelet, Alfred Colomb, Senateur Vaisse, Duchess of Bedford, and Queen of Queens. Messrs. C. Lee & Son, Hammersmith, sent plants of *Cupressus Lawsoniana erecta viridis variegata*, very neat and with the variegation well marked. Examples of *Laurustinus marginatus aureus* were also shown. Mr. Morse of Epsom sent a plant of *Vanda cœrulea* bearing a spike of eight flowers. In addition to the plant of *Vanda Hookeri* shown by Mr. C. Hill of Tring Park, Herts, a specimen of *Dendrobium bigibbum superbum* with very large flowers was also shown, two spikes bearing each six flowers. Messrs. H. Cannell & Sons, Swanley, sent a fine stand of Show and Fancy Dahlias and blooms of a white *Juarezii* named Constance. A vote of thanks was accorded to Mr. J. Duffield, Winchmore Hill, N., for a collection of blooms of seedling Perpetual Carnations of extremely fine colour. Mr. Goldsmith, Hollanden, Tonbridge, sent plants of *Iresine formosa*, a variegated form of the *I. Lindeni* type which has been before noticed. A large collection of *Nægelias* was sent from the Society's garden at Chiswick, all the plants being in excellent condition and freely flowered. Some of the best were Bouquet, rose; Jocrisse, yellow; Eremeus, orange, red, and white; Greuze, and Franklin, scarlet.

First-class certificates were awarded for the following:—

Dahlia John Henshaw (Rawlings).—A beautiful Show variety. The blooms of moderate size but excellent in form, deep, full, symmetrical, of clear crimson purple hue.

Dahlia Ruby King (Hooper & Co.).—A single variety. Flowers of good size and moderately good form. Florets broad, but the colour, a distinct rich rosy tint, is its most striking characteristic.

Dahlia Christine (Ware).—A handsome single variety with finely formed flowers. Florets broad and rounded, of a soft rosy mauve colour. Quite a distinct shade, and very pleasing.

Vanda Hookeri.—This was shown by Mr. E. Hill, gardener to Sir N. M. de Rothschild, Tring Park, Herts. It is a species resembling *V. teres* in habit, with slender cylindrical stems and leaves. The flowers are borne in pairs on a peduncle 5 to 6 inches long, the sepals and petals being white suffused with rose, and the lip large, marbled and streaked with rich crimson on a white ground.

BEANS.—Of Kidney Beans Canadian Wonder is the favourite for open-air culture; Osborn's Forcing for pots. Of Runners Sutton's Giant White and Carter's Champion are the only kinds we have this season, and they both bear such quantities of fine large pods that there is no occasion to grow any others. Of Broad kinds the Seville Longpod is fine for the first crop; and a new variety we have from Messrs. Dicksons, Edinburgh, surpass all others for the main crop. It is most prolific. Some of its pods have lately been 16 inches in length, and the leaves are both numerous and well flavoured.—M. M.

KITCHEN GARDEN.

TAKE every opportunity in favourable weather to use the hoe amongst all growing crops, so as to prevent the necessity for hand-weeding, always a tedious and unremunerative process. At this season a few days suffice to mature the seeds of quick-growing weeds, such as Groundsel and Chickweed; and these, if allowed to ripen, are speedily scattered and become an endless source of trouble next season. Late Turnips should be moderately thinned, also Winter Spinach, so as to allow of the free development of the plants.

Take advantage of suitable weather to earth up Celery, and tie up Lettuce and Endive so as to secure well-blanching heads for salads. If Radishes are required late a sowing should be made in a frame, but not employing the lights until frost occurs. For forcing, Red and White Turnip, French Breakfast, and Wood's Frame are the most suitable varieties.

Onions which have been taken up and exposed a few days should be stored thinly on shelves in a dry room, the best ripened examples being tied in bunches or strung, so that they can be removed to a cooler situation in early spring to prolong the season of use.

Tomatoes on walls will be advancing fast, and should be well exposed to the sun to assist the ripening process, and all growth beyond and which shade the fruit must be removed. The more

forward clusters of fruit may be cut and laid on shelves or hung in a dry airy house to ripen, and this will assist the swelling of the later-set fruit. Tomatoes in houses should have the lateral growths pinched one joint beyond the trusses of bloom, and exhausted growths thinned out so as to encourage fresh growth in their place, and continue the plants in bearing if necessary through the winter, keeping the growths fully exposed to the light. Surface-dress the soil with rich compost as the roots protrude, and afford weak liquid manure in a tepid state occasionally. Artificial heat will be necessary to maintain a temperature of 55° to 65° artificially, advancing 10° to 15° from sun heat, affording on all favourable occasions a free circulation of air. Those needing a supply of Tomatoes in winter, and not having a house with plants already established, may utilise any spare house, such as a Melon house, either growing the plants in pots or bed as may be most expedient. Instead of raising the plants from seed, cuttings should be inserted, they striking readily in a moist genial atmosphere, close and shaded. Planted about 18 inches apart and trained with single stems to the roof wires, they will come into bearing quickly and afford satisfactory returns. Trentham Early Fillbasket has afforded very satisfactory results this season, and being very free would no doubt answer for winter work. Orangefield Dwarf and Vick's Criterion are excellent.

A first sowing of French Beans should now be made in pots, three parts filling the pots with good rich loam made moderately firm, inserting half a dozen beans around the sides of the pot, and about an inch deep. The pots (9-inch) should be well but not excessively drained. Place them in a house with a temperature of 55° to 65° artificially, and as near the glass as the growth of the plants ultimately admit without touching. Osborn's Forcing is very free, and Ne Plus Ultra excellent.

FRUIT HOUSES.

Pines.—As the natural influences under which young growing plants luxuriate are now rapidly declining, care will be necessary to prevent the growth becoming soft and attenuated, to avoid which a dried condition of the atmosphere should be maintained, even if fire heat has to be used when unfavourable weather prevails. Syringe only occasionally, and then early on fine afternoons. Attend carefully to the ventilation, opening and closing the house at 80°, above which ventilate freely, especially on warm sunny days, the minimum temperature at night being maintained at 65°. The bottom heat should be kept steady at 80° to 90°. Collect all the fruiting plants into a house suitable for finishing the fruit perfectly, encouraging those with the fruit swelling off with a liberal supply of heat and moisture, keeping the night temperature at 70° to 75°, and the day from 80° to 90°, closing the house at 85°. At the close of this month the most likely of the plants started in March last as suckers for fruiting early in next year, should be brought together where they can be given a comparative rest of about six weeks, which will insure their throwing up fruit at the required time.

Peaches and Nectarines.—The earliest forced trees will now be at rest, and should, if the lights have not been removed, be kept as cool as possible. If the house needs painting or repair the trees should be loosed from the trellis, and work of the description named proceeded with, otherwise the house should be thoroughly cleaned, and the trees, being dressed with an improved insecticide, secured in their positions to the trellis. Pruning, if former instructions have been carried out during the growing season, will be a mere trifle, simply removing any shoots interfering with the symmetry of the trees or where they are too much crowded; as shoots, no matter how long they may be, will, if well ripened, be studded with bloom buds to their points. The surface soil should be scraped off without interfering much with the roots, and fresh material added, making it firm. If there be the least appearance of the borders being dry afford a thorough supply of water, as any deficiency of moisture at the roots is a great incentive of the buds falling. Presuming the lights have been taken off, they may remain off some weeks longer, but as soon as the cold autumn rains set in they should be put on, as cold drenching rains are scarcely less inimical than a too dry condition of the soil. Those about to plant houses for early forcing should include Alexander, the earliest Peach with size to recommend it.

After the crop has been gathered from the late succession houses, the shoots that have borne fruit this season, and not being extensions, should be cut out, as well as any weakly growths calculated to crowd the trees too much, also other growths where too crowded should be well thinned out, so as to admit light and air freely to those retained and secure their thorough ripening. If the trees be vigorous and the autumn prove cold and wet, a little fire heat with a free circulation of air will materially aid in ripening the wood, but there must not be any attempt at ripening the growth by keeping the roots parchingly dry, although a drier condition of the border is permissible. Sufficient moisture must be afforded for keeping the foliage healthy until the wood is thoroughly ripe and the buds plumped. Red spider must be kept under by occasionally washing the trees from the syringe or engine.

FLOWER GARDEN.

Cuttings of bedding Pelargoniums must not longer be delayed insertion, and as the season is so advanced it will be best to insert them in cutting boxes or pans under the shelter of lights, giving all the air possible till cold wet weather sets in. Verbenas, Heliotropes, and similar plants will require the aid of a little bottom heat, keeping them close, moist, and shaded until rooted, then ventilate freely to harden them before winter. A sufficient stock of Alternantheras, Coleuscs, Iresines, Mesembryanthemums, and similar plants should be secured to afford the requisite cuttings in spring, these plants being best from spring-struck cuttings. The routine work will now be great, as, in addition to picking off bad flowers and foliage, the beds will require constant clearing of tree leaves. Run the machine over the grass frequently, and keep the walks as clean and firm as possible.

Herbaceous plants should be examined to remove all dead stems or stalks, tying up those that require it. Annuals may yet be sown of such kinds as Alyssum (Sweet), Candytuft, Collinsias, Eschscholtzias, Gilias, Nemophilas, Saponarias, Silenes, Virginian Stocks, &c., which come into flower in April or May of next year, and make a pleasing display.

Yew, Privet, and other hedges may yet be trimmed. Irish Yews, Cupressuses, Junipers, Retinosporas, &c., should be tied-in to prevent breakages and preserve the symmetry of the plants. During any showery weather after this time transplanting evergreen trees and shrubs that have completed their growth may be proceeded with, the late summer and early autumn months being favourable for the performance of such operations.

PLANT HOUSES.

Orchids.—The temperature may still range from 75° to 80° by day in the East India house and 65° at night, which should be continued until the end of the month. Maintain a genial atmosphere, and give every encouragement to *Aerides*, *Phalænopsis*, *Saccolabiums*, and *Vandas*, damping the blocks, baskets, and pots in the morning, and in the afternoon of fine days a syringing will be of great benefit, care being taken not to have the sphagnum or peat in a soddened state. Shade as little as possible, only employing it to prevent the sun scorching the foliage. Dispense with shading on the *Cattleya* house; clean the glass so as to admit all the light possible, affording all pseudo-bulbous plants that have completed their growth an increased amount of air. *Laelia purpurata* and *Cattleya Mossiæ* may now be repotted and placed in the warmest part of the house to enable them to complete their growth as soon as possible. Encourage *Calanthe vestita* var., *C. Veitchi*, and *C. Turneri* by the application of weak liquid manure to make large pseudo-bulbs, as the stronger those are the finer will be the flower spikes. Any *Odontoglossums* that started late into growth and require larger pots may be given them safely, but the roots must be disturbed as little as possible. Endeavour by exposing the plants to as much sun as they will bear to have the pseudo-bulbs and leaves well matured before the dull days set in.

Stove.—*Ixoras* that have been employed through the summer for conservatory decoration must now be placed in the warmest part of the stove, as they have had sufficient rest in the cooler quarters. Cut away all the old flowers, and if infested with scale or mealy bug wash with an insecticide, as the plants, from the firm state of the wood and leaves, will bear it stronger than at any other season.

Bougainvilleas and *Clerodendrons* and other plants that have for a time been in cooler houses should also be removed to a warmer position, but should not have so much as to start them into growth, not withholding water to the extent of causing the premature shedding of the foliage, but by a drier atmosphere and lessened supplies of water gradually hardening the growth.

THE LANCASHIRE AND CHESHIRE BEE-KEEPERS' EXHIBITION.

THE members of this Association have cause to congratulate themselves on the success of their first Exhibition, which took place on Wednesday, Thursday, and Friday last, at Moor Park, Preston, in connection with the Show of the Preston Floral and Horticultural Society. No doubt much of the success as regards the numbers attending was due to the fact of it being the week of the "Preston Guild Merchant," a time-honoured institution many centuries old, and which is celebrated only once in twenty years.

It is well the festival recurs so seldom, as it would be impossible for the inhabitants of any town in England to endure the strain of excitement consequent on the holding of a week's high carnival such as this, when all business is entirely suspended, and everyone is on pleasure bent. As a result of the above large numbers attended the bee Show. The manipulating tent was well patronised, and the whole affair was deservedly successful. It will surprise us if the Lancashire and Cheshire Association does not receive a large accession of members, which already number over one hundred, though it has only been in existence some three months.

It was thought that Lancashire and Cheshire were counties in which success in bee culture could not be hoped for; but the result proved the contrary, for the classes for members only, though small, contained exhibits which bore favourable comparison with those open to the United Kingdom. The unfavourable season militated greatly against the chance of a large entry, and at one time it seemed as if the Exhibition would turn out a comparative failure; but a circular was sent out urgently asking the bee-keepers of the various county associations to come to the rescue, and an excellent display, almost the finest yet held this year, was the result.

The Committee cannot but thank those who spared neither time, trouble, nor expense in aiding them to give an impetus to bee-keeping in this part of the country. The block in the traffic arrangements on the various railways, consequent on the enormous number of people who flocked to Preston from all parts, affected the exhibits in a most unfortunate way, many of the supers having their combs fractured, and the jars broken and emptied of their contents. An examination of the injured packages showed plainly that the art of packing honey is still unknown to many; and if committees would obtain a supply of the best material known for breaking the effect of a sudden jar—*i.e.*, paper shavings, and supply exhibitors with them at cost price, with a printed slip containing a few instructions, we believe that fewer complaints of breakages will be heard.

Much has been said as to sending out sections in crates glazed at the sides showing the fragile nature of its contents, so as to cause railway people to use care in handling. Several crates were so sent, and if the owners could have seen them and compared them with exactly similar ones which had been properly packed in boxes, and which were turned out clean, bright, and uninjured, while the first-named were soiled, the glass broken, combs down, the crates covered with various labels and directions, and altogether presenting a most uninviting appearance, no further argument would be needed to convince exhibitors of the folly of putting their trust in railway porters.

Much credit is due to those who had the management of the staging department in promptly tying-up and protecting leaking exhibits, though we fear the weight will have considerably decreased when returned to the owner from the number of bees which, attracted by the odour of the honey, visited the tent and helped themselves to an unexpected feast. No one was stung, the bees being too intent on their own business to mind anything else, while the presence of the busy little creatures amused the visitors and alarmed no one. A very novel feature was introduced on the second day of the Show—an employé of Messrs. Neighbour and another of Mr. Blow's each performed the Wildman feat of going about the grounds with a swarm of bees on his hat, to the astonishment of all who saw it. On Friday the presentation of prizes by the Countess of Lathom took place, when a large and distinguished company were present, including the Guild Mayor (E. Birley, Esq.), the Earl and Countess of Lathom, the Earl and Countess of Sefton, Colonel and Lady Augusta Stanley, the Lady Mayoress (Mrs. Birley), the Right Hon. C. Raikes, M.P., &c. After the presentation of prizes the whole party proceeded to the tent of the Association, where they witnessed with great interest various manipulations with bees, and afterwards went through the large marquee where the exhibits were displayed, expressing the pleasure they felt at seeing so fine a collection. Mr. Jackson, the Hon. Sec., conducted

the visitors through the Show, explaining the various hives, &c.; and Mr. W. Broughton Carr had the honour of presenting, on behalf of the Association, samples of prize honey to the Countess of Lathom, Lady Augusta Stanley, and the Mayoress (Mrs. Birley).

The exhibits in the honey classes for members only were small in number, but the quality was so good that it compensated for quantity. The first-prize extracted honey was very fine, and in the opinion of several apiarians who have visited most of the shows the best which has been exhibited this year. The first prize for a collection from one apiary had some fair supers; but the best one, a square Lee's super, was damaged in transit, and much deteriorated in consequence. The whole exhibit weighed a little over 1 cwt.

The first-prize sections were neatly put up in a reticule sort of glazed case, with leather handles to carry by. No doubt many will admire this style of section case, particularly if it induces the purchaser to keep the case and send it each year to be refilled. The similar collection in the open class was a very fine display, and consisted of honey in sections entirely, while the neat way in which the wood was concealed by a paper covering, and the usually imperfect cells round the edge of the comb hidden by a border of lace paper, was a lesson which will not be lost by those who came to see and learn. Class 11 was very poorly represented, the one which took first being a square Lee's super containing straight combs, but rather dark Heather honey. Class 12, for the best glass super, is one we should like to see done away with. It looks very nice, no doubt, to see a huge bellglass filled with good white comb, but those who have had much to do with such things look with a certain amount of horror on the task of cutting up such a super, especially as was the case with one of the three exhibits. There was a counterpart of the abominable "stick through the centre of a skep" in the shape of a lath, or something carefully worked by the bees into a solid mass, right through. If exhibitors will have circular glass supers, why not adopt the plan of a circle or rim of glass—which can be had for a few pence—and have a top and bottom board of wood? This sort of super when full can be turned bottom upwards, the board and glass removed, and the combs cut away neatly as required. Messrs. Abbott Brothers' collection was not quite so large as either of the others, but every article displayed was of a good and useful kind. The Irish hive exhibited by this firm is wonderfully cheap, and will no doubt be largely used; and their cheap extractor at 25s., which won second prize in its class, while simple in principle, is one that will do its work well, and we think will become popular.

Class 5, for the best hive for observation purposes. There were four exhibits. Mr. T. B. Blow took first with a hive which combined the good qualities of the second and third-prize hives. H. Gibbons took second, Messrs. Neighbour & Sons third. The mechanism of the last hive was ingenious, but not so safe in working as Mr. Gibbons', while it had the advantage of a revolving platform similar to Mr. Blow's hive. In Class 7, for the best and cheapest hive, the price not to exceed 12s. 6d., some excellent hives were shown, and the wonder was how several of them could possibly be made for the money; but in the case of two exhibits much feeling was displayed, and the Judges unanimously excluded them from competition, as being both unfairly described in the catalogue and calculated to mislead. We quite agree with the Judges in their effort to put a stop to this sort of thing. Here was a hive which upon being looked at and examined would be set down by most people as worth £1 to £1 5s. It had a strong outside case, well painted, with hinged roof, and a large let-down shutter at back, set on legs, with floor-board, porch, &c., and on opening it contained two large stock boxes made of mahogany or teak, with windows at back, ten frames in each, had crown boards, comb foundation, supers, quilts, &c., and the whole of this was priced in the catalogue 8s. On inspecting the roof a written statement was found giving some particulars, by which it was seen that the outer case and roof were made from a bacon box, value 1s.; the two stock boxes from a tea chest, value 6d.; the twenty frames, 1s. 8d.; legs, hinges, &c., 10d.; and labour and profit, 4s. Underneath this was a statement to the effect that paint, crown boards, comb foundation, supers, &c., were extra, but how much was not stated. This, we maintain, is not legitimate hive-making, and certainly not fair to regular manufacturers, whose business is not to buy up bacon boxes and tea chests for working up into bee hives; and we heard the opinion expressed by many that exhibits of that kind retard rather than promote bee culture, unless a special class was devoted to home-made hives and such like. In this case much merit would be awarded to the makers.

Class 14, for the best extracted honey, was a very singular collection, consisting of over twenty entries, and the honey varying in colour from a white crystallised lot somewhat resembling furniture paste to almost black honey gathered occasionally, we think, from Oak trees when honeydew is plentiful.

The three collections of hives and apiarian appliances sent by Messrs. Neighbour, Mr. Blow, and Messrs. Abbott Bros., reflected great credit on those gentlemen. An examination of the various articles displayed made it clear that each manufacturer had specialities of his own; Messrs. Neighbours' containing workmanship of a very high order, almost too good for the purpose of bee-keeping. Mr. Blow, on the other hand, while not forgetting to stage some very costly articles, had a great number of a cheap and useful description. His extractor, which won first prize, was a very good one, and worked admirably. He also showed a most useful little feeder, though the

principle was not quite original, being an improvement on the well-known one invented by Mr. Abbott. He had an excellent case of apiarian cutlery, and also a sample of the new Dunham Comb Foundation, said to be better than any other, but having had no experience of it we cannot give an opinion.—WM. BROUGHTON CARR.

The following is the prize list:—

Class 1.—For the best exhibition of honey (super honey in preference) from one apiary. First, W. B. Carr; second, not awarded.

Class 2.—For the best super of honey (not being a sectional super). The super to be of wood, glass, straw, or of wood in combination with glass or straw. First W. B. Carr; second and third not awarded.

Class 3.—For the best exhibition of 1-lb. or 2-lb. sections of comb honey, the total weight not to be less than 12 lbs., nor more than 30 lbs. First, J. H. Buekley; second, W. Watkin; third, W. B. Carr.

Class 4.—For the best exhibition of 12 lbs. to 30 lbs. of run or extracted honey in 1-lb. or 2-lb. glass jars. First, W. B. Carr; second, G. Stocks; third, P. Wood.

Class 5.—For the best hive for observation purposes, all combs to be visible on both sides, to be exhibited stocked with bees and their queen. First, T. B. Blow; second, H. Gibbons; third, G. Neighbour & Sons.

Class 6.—For the best moveable-comb hive, complete, for summer use, with facilities for harvesting honey and with arrangements for wintering. First, T. B. Blow; second, Abbott Bros.; third, G. Neighbour & Sons.

Class 7.—For the best and cheapest hive on the moveable-comb principle, for cottagers' use, with arrangements for summer and winter. Price not to exceed 12s. 6d. First, T. B. Blow; second, C. Foxon; third, Abbott Bros.

Class 8.—For the best stock of Ligurian Bees. 1, G. Neighbour & Sons; second, T. B. Blow.

Class 9.—For the best stock of English bees. First, T. B. Blow; second, G. Neighbour & Sons.

Class 10.—For the best exhibition of super honey from one apiary. First, W. Raitt; second, J. W. Measnes; third, J. Walton.

Class 11.—For the best super of honey, not being sectional supers. The super to be of wood, straw, or of wood in combination with glass or straw. First, T. Christie.

Class 12.—For the best glass super of honey. First, T. Sells; second, Mrs. J. Howard; third, J. Lighton.

Class 13.—For the best raeck or erate of 1-lb. or 2-lb. sections of comb honey, the total weight not to be less than 20 lbs., nor more than 30 lbs. First, W. Raitt; second, J. Rogerson; third, J. Walton.

Class 14.—For the best exhibition of 12 lbs. to 30 lbs. of run or extracted honey in 1-lb. or 2-lb. glass jars. First, P. Wood; second and third, W. Martin.

Class 15.—For the best and largest collection of hives and bee furniture, most applicable to modern bee-keeping. First, G. Neighbour & Sons; second, T. B. Blow; third, Abbott Bros.

Class 16.—For the best honey extractor. First, T. B. Blow; second, Abbott Bros.; third, S. Walton.

Class 17.—For the best sample of comb foundation (a) for worker-cells, (b) for supers, not less than 2 lbs. of each. First, T. B. Blow; equal first, W. Raitt; second, Abbott Bros.

Class 19.—For the competitor who shall in the neatest, quickest, and most complete manner, drive out the bees from a straw skep, capture and exhibit the queen. First, J. Walton; second, G. Stocks; third, E. Devenport.

Special Class.—Highly commended, Rev. W. E. Burkitt (erate of sections with cover for use on straw skeps); T. B. Blow (method of snpering a straw skep); commended, F. Lyon (self-adjusting and removeable frame ends).

Special local prize given by the Guild Mayor.—First, J. Forshaw.

The following gentlemen officiated as Judges:—*Honey Classes:* C. N. Abbott, G. Neighbour, and T. B. Blow. *Hives, Bees, and Apiarian Appliances:* W. Broughton Carr, W. Raitt, and C. Woodhead.

BEE-KEEPING FOR BEGINNERS.—No. 5.

SWARMING VERSUS NON-SWARMING.

IN bee-keeping as in other things first principles should be well understood. Though the subject of swarming has been often discussed in the pages of this Journal we have resolved to notice it once more for the benefit of beginners. That it is natural for honey bees to swarm all intelligent and experienced apiarians freely admit, and the bees prepare for swarming months before it takes place. The diligent care and labour which bees undertake in preparing for the important event are interesting, and which, like other secrets of Nature, appear more surprising as they are better understood.

My aim in these notes is simply to express my opinions on the advantages of managing bees on the swarming principle, and when and where it should be interfered with, and the non-swarming system resorted to or followed. In investigations of this subject many points have to be noticed—viz., large and small hives, good and bad seasons, early and late localities, spring and autumn flowers. On the swarming system of management large strong hives have great advantages in good seasons and good localities. In such seasons and localities bees, under fair management, swarm early, and the swarms do better and rise to greater weights than hives managed on the non-swarming principle. It may be difficult to explain how it comes to pass that early swarms in good seasons fill their hives with combs and often surpass hives of bees that never swarm at all. Very few bee-keepers will question the fact here stated, even if the reasons given in explanation are unsatisfactory.

Swarms are beginning life on their own account, and this seems to stimulate the bees to make greater exertions. How fast they work, secrete wax, and build combs! A single swarm has been known to fill its hive with combs and weigh 45 lbs. in seven days. In such cases both season and locality were favourable; but all

through life we have been struck with the rapid progress of swarm hives in good seasons. For two or three days after being hived swarms are placed at a disadvantage by having to lay the foundations or beginnings of their combs at mere points, so small that few workers or builders can get at them to help. Hence the desirability of using guide combs—say a few pieces of artificial comb foundation to commence with and build on. In the absence of a few guide combs a pound or two of sugar syrup given to swarms for one or two nights after being hived helps them very much. It is never wasted, and for which there is an ample return and great progress made. Notice how fast they work after the first few days; trip up some of the field workers as they hasten to enter their hives, and flakes of wax will be seen coming out of the rings of their abdomens. Combs are now rapidly built, and as rapidly filled with brood; and there can be no question that the cells of young combs give more space for the full development of brood, and the combs themselves, being less cloyed and cumbered with pollen than older ones, yield greater hatches of brood. By the records of experienced men who manage bees on the swarming principle which have appeared in the *Journal of Horticulture* during the last few years it has been seen that some swarms in good seasons have risen in weight to 140 lbs. and 160 lbs., and if I remember correctly Mr. George Campbell in Aberdeenshire had one that rose to 173 lbs. It is seldom that unswarmed hives, however, managed to reach such weights. On the swarming principle the old stocks and second swarms are not idle in good seasons, and they claim a fair share of notice in the account. In good seasons and good localities for honey the swarming system of management is, in my opinion the best, being, as it is, the most natural, safe, healthy, and profitable.

All this cannot be said in bad seasons and bad localities. But my experience leads me to think that taking a run of years—say five or ten years, good and bad together, the swarming system of management is most desirable and profitable. On the non-swarming principle there is the fear of losing swarms, and the fact that many are lost. Then there is the danger of foul brood and other diseases; accumulations of pollen choking the cells and causing slow progress. In bad seasons for honey the non-swarming system has advantages in this respect, that the fewer hives the bee-keeper has in such seasons the less feeding is necessary, and no honey is expended in comb-building. There are no empty hives to be filled, and therefore all the honey gathered is used in feeding the brood and bees, and in storing for winter food. In ordinary seasons such as we often have in Great Britain one cannot speak with any degree of certainty as to which system is the better of the two. Much depends on the objects of the bee-master and how he manages his apiary. If he has well learnt the art of supering, and aims at a return from honeycomb, the non-swarming system will serve his purpose best in such ordinary seasons. This opinion is held by a great number of intelligent and advanced bee-keepers. Much has been said in support of it, and very little can be said against it. The danger of losing swarms is great, for in such seasons hives are generally full of bees whose inclination for swarming is difficult to remove or control. The loss of a swarm in such a case and season is ruinous to the hive and disappointing to the bee-master. Though we have not a word to offer in opposition to the arguments of those who practise the non-swarming system in ordinary seasons, we prefer and follow the swarming system of management for several reasons. 1st, By swarming we have no anxiety about losing swarms. 2nd, By feeding swarms for a few days after they are hived they soon become equal to hives that do not swarm at all for work of various kind. We thus increase our number of hives, and derive more profit from the sale of some of them than can be done otherwise. But this cannot be done everywhere.

In ordinary seasons in Great Britain it is understood that we have days and weeks of wet weather. Well, in such weather we do not hesitate to swarm bees that are ready, for by so doing the swarms are taken from the old hives where they waste their time and consume honey, and made to work and build combs in new hives. Both honey and time are thus saved, and combs are built of syrup—a very cheap material—and prepared for the reception of honey when the weather becomes favourable. It is a nice art and a stroke of good policy to get bees to build combs in unfavourable weather from a cheap material and filled with rich honey afterwards. The time is coming when bee-keepers will know better than to allow their bees to remain idle during the summer months whatever be the state of the weather. Idleness in a bee hive should not be tolerated.—A. PETTIGREW.

(To be continued.)

LINCOLNSHIRE BEE-KEEPERS' ASSOCIATION.—The seventh annual Exhibition of this Society will be held in the Arboretum, Lincoln, on

Thursday and Friday, September 21st and 22nd, when numerous prizes will be offered for bees, honey, hives, wax, extractors, and various apiarian appliances. A silver cup will also be offered for the best and largest exhibit of honey taken without destroying the bees, the cup to become the property of the member who wins it three times. The Exhibition is under the patronage of the Mayor of Lincoln, and the Honorary Secretary is Mr. R. R. Godfrey of Grantham, who has rendered great services to bee culture by his energetic and well-directed labours.

SUSSEX BEE-KEEPERS' ASSOCIATION.

THE first annual Show of this Association was held at Horsham on Thursday, September 7th, in connection with the Horsham Horticultural Show. Although the Sussex Bee-keepers' Association has only been established a few months it has already created a considerable interest in bee-keeping in the county, as the bee tent which it was resolved to purchase at the first meeting in April last has been sent to the principal flower shows in the county. At Brighton the Association held a show in connection with the Royal Counties' Agricultural Show, but unfortunately, the weather being bad, the attendance of visitors was small. The Show held on Thursday last must be reckoned as a decided success. The liberal prize list brought together such a competition in hives and appliances as astonished everyone, although there was very little honey shown, and most of that was Heather honey. It was evident that the honey season in Sussex had been a bad one, and the usual display of beautiful sections from the well-known Sussex apiaries were absent. What was exhibited, however, was good, and that for sale found ready purchasers at good prices.

The tent in which the Exhibition took place was 70 feet long and 30 feet wide, and as all the tables round the tent and up the centre were well filled the Show was an imposing one.

The principal prizetakers in the hive classes were Messrs. Abbott, Baldwin, Taylor, and Worldridge, the latter also taking first prize for the largest and best collection of hives and appliances most applicable to bee-keeping. The principal winners in the honey classes were Messrs. T. W. Cowan, M. Freeman, T. Marsh, R. Edwards, and G. Green. The competition in the honey classes was confined to residents in the county of Sussex only.

The manipulating tent was as usual a great centre of attraction, and great many persons witnessed the ease with which Mr. J. Baldwin handled the bees. The Judges were Captain Campbell, Messrs. J. Garratt, and F. Lemare, and their awards were generally approved.

Amongst the articles not for competition were some beautiful sections and bottles of extracted honey exhibited by Mr. J. Garratt from St. Mary Cray, Kent.

TRADE CATALOGUES RECEIVED.

[Geo. Cooling & Son, Bath.—*Catalogue of Bulbs (Illustrated).*

Wilhelm Büchner, Erfurt, Germany.—*Trade Catalogue of Garden and Farm Seeds.*

Bruant, Boulevard Saint Cyprien, Poitiers (Vienne, France).—*List of Plants and Fruit Trees.*

E. G. Henderson & Son, Maida Vale, London, W.—*Catalogue of Dutch and Cape Bulbs, &c.*

James Yates, Underbank, Stockport.—*Catalogue of Continental Bulbous Plants.*

Barr & Son, King Street, Covent Garden.—*Catalogue of Bulbs and Plants.*

* * All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Catalogue of Roses (H. K.).—The National Rose Society's catalogue can be obtained post free for six stamps from either of the Hon. Secretaries—Rev. H. Honeywood D'Ombraim, Ashford, Kent, or Edward Mawley, Esq., Lucknow House, Addiscombe, Croydon.

Urine for Vine Border (J. M. B.).—Both kinds are good (that of which you have abundance at your command perhaps the better) when the Vines need it, not otherwise. The quantity to be given and the strength depends wholly

on their condition. One part to six of water will be quite strong enough for summer use, but in the resting period it may be given as strong again, but only, we repeat, if the Vines need it; if otherwise, the application would do harm instead of good. It is not possible for anyone to give precise instructions on this matter without a knowledge of the condition of the Vines and the border, and this is not easily conveyed except by one who has practised in Vine culture and is a skilled cultivator. You will find useful information on the application of sewage in our "Manures for the Many." If you do not possess this manual you can have it in return for 4½d. in stamps sent to the publisher.

Fertilising Moss (Anxious).—Some surprising results have been reported concerning the effects of the substance you mention, but we have not had an opportunity of testing its efficacy as a substitute for soil.

Polyanthus Narcissuses (J. E. O.).—The plants in the borders will require no further care, but will grow and flower annually. The bulbs in pots in all probability had better be planted out, as unless the plants had good attention after flowering, the foliage having been kept fresh and healthy as long as possible, they will not give a satisfactory return if forced another season. For this purpose you had better obtain fresh bulbs and pot them at once in a mixture of loam, leaf soil, decayed manure, and sand, burying the pots 6 inches deep in cocoa-nut fibre, asbes, or other light material until the plants have grown an inch long; then afford them a light position in a cool house. Hollies may be pruned now—at once.

Window Fern Case (M. E. W.).—As the case is to be outside all the year you will not be able to employ any Palms, but any of the following hardy Ferns would be suitable, as they are of moderate growth:—*Adiantum Capillus-Veneris*, *Asplenium Adiantum nigrum*, *Asplenium marinum*, *Asplenium Rutamuraria*, and *Ceterach officinarum*. For climbers the small green and variegated Ivies might be employed with *Ficus repens*. Some of the deciduous Ferns, such as the *Cystopterises*, might be grown in pots and placed in the case in summer, and they would improve its appearance considerably.

Lifting Dahlia Tubers (H. I. J.).—When the leaves and growths are blackened by frost the stems should be cut off and the tubers lifted, exposing them for a day or two to partially dry, and then store them in a dry position quite secure from frost, either in soil, sand, or any similar material. Keep them dry until it is necessary to start them early in spring, when if cuttings are required the tubers should be placed in a warm frame and supplied with water. You do not state definitely what kind of book you desire to obtain. Is it a work on British plants, or one devoted to botany generally that you purpose studying?

Cigarettes for Fumigating (H. Watson).—Perhaps the "paragraph" which you have read and forgotten was written by Mr. Keane. "Provide a strong solution of nitre in water, in which soak some sheets of strong brown paper, and afterwards dry it slowly and cut it into lengths of convenient size, the largest 18 inches by 12 inches; then get some strong tobacco and strew it thinly over the paper, and with a coarse pepper box dredge in a good coat of common Cayenne pepper, wrap the whole up loosely like a cigarette, paste the end over, and when dry it is fit for use. Two or three of these suspended by a wire under a greenhouse stage, and lighted at each end, will quickly settle the accounts of the green fly and thrips, and that with comparatively little trouble; indeed, if a quantity of these cigarettes be kept ready made a few plants may be put into a pit or small room and be cleaned, at least have their insect pests destroyed, in a very short time. By using Cayenne much less tobacco is required, and the effect of the two combined is most deadly; for, as the cigarettes will burn for a considerable time, say an hour or more, it is impossible for insects to live in an atmosphere so thoroughly suffocating."

Wintering Potatoes (W. W. X.).—We prefer the Potatoes placed in thin heaps on the level of the ground rather than in excavations or pits below it, but by the former plan greater care is requisite in protecting the tubers from frost. The site should be dry and firm, from 3 to 4 feet wide, the tubers being neatly piled so as to form a sharp ridge or apex. They should be perfectly dry when placed in the heap, not one diseased tuber being admitted. A covering at least 6 inches in thickness of very dry and straight straw should next be given, then with the spade commence digging a foot from the straw all round, and continue that thickness of soil over the entire heap. For ventilation 3-inch drain pipes may be placed on end at intervals of 3 or 4 feet, their ends being just, and only just, above the soil at the apex of the ridge. These ventilators must be securely closed during wet and frosty weather. With thin heaps of perfectly dry sound tubers carefully covered as directed we do not find ventilators necessary in wintering Potatoes. When several tons of Potatoes are stored in very large heaps drain pipes are often conducted quite through the centres of the heaps and out of the tops, and if the tubers are damp when stored the practice is a good one. Such ventilators, however, must have attention, or they do as much harm as good.

Charred Garden Refuse (E. Elmdon).—It is valuable for gardens, and may be prepared as described in our manual on manures, from which we cite the following:—"To char turfy soil the best method is to cut it into sods of about a spade's width and 2 or 3 inches thick when the soil is not over-saturated with moisture. Burning any kind of material, and allowing it to be consumed, producing nothing but smoke and ashes, is a real waste of valuable substance which could be turned to beneficial account for the culture of the soil. Commence by placing a small quantity of combustible material, such as dry weeds, hedge-trimmings, furze, heath, shavings, brushwood or bushes, or any kind of dry vegetable refuse the place produces near at hand; then commence packing the sods, no matter how or what thickness, as any thickness may be charred by placing amongst them as the heap or kiln is proceeded with, some one of the before-mentioned materials, or old tan or sawdust, just to keep the materials ignited. It is no matter how large or small the kiln may be formed, for this may be regulated by the convenience of the material at hand and the quantity of charred materials required; only, when the kiln is formed it should be slightly covered or cased with flue earth to prevent the fire from flaring and to maintain a steady smouldering, charring, or roasting. Much smoke will escape for a time, and when the smoke begins to subside it is a sign that the materials are charred enough. The fire should then be smothered by casing up the outside of the kiln quite close with earth. Although turf sods only are mentioned, the same process of charring may be carried out with weeds and other garden refuse if the outside of the heap is covered over closely with sods of earth, so as to exclude the air sufficiently to ensure the burning to be very slow and smouldering."

Planting Anemones (N. A. L.).—We cannot do better than repeat what we have published before on this matter. "The Anemone requires a pure loamy soil, well mixed with sand, such as sometimes is found on the sides of rivers naturally mixed with the sand. Choose a situation that is open, but sheltered from violent winds or strong twisting currents of air; then dig out the soil a foot or more, according as the situation is high or low. If high it may be dug

out 3 or 4 inches deeper, but if low and wet a foot will be sufficient. Mix the soil with sand if it requires it, and fill in the bed again to within 6 inches of the level of the surface; then level it, and lay on it a thin covering of thoroughly decomposed hotbed manure or cow dung; the latter is to be preferred. Mix this well with the soil below. Upon this mixed enriched soil place as much of the pure sandy loam as will raise the bed an inch or two above the walk. No dung must be among this top stratum of soil, because dung causes the peculiar disease called 'mould' to attack the bulbs that come in contact with it. The best season for planting is from about the middle of October to the first week in November; the bulbs then form roots before severe frosts set in. Should the planting be unavoidably delayed the bed must then be covered with fern or straw. Choose a time when the soil is moderately dry and the day fine. Draw drills across the bed 2 inches deep and 5 or 6 inches apart, and plant the tubers 5 inches apart in the rows. For choice varieties a thin layer of sand scattered under and around each tuber will be useful. As soon as the bed is planted cover the tubers with sandy loam from a basket or wheelbarrow. Take care that the tubers are placed the right side up by observing the side that has the old small fibres on it; that side place next to the bottom of the drill. When all are planted and covered up the right depth (2 inches) then level the surface with a garden rake."

The Royal George Peach (Lorrimore).—The following account of the history of this Peach is given in the "Fruit Manual":—"The first mention we have of the Royal George is by Switzer, who says it was raised by his 'ingenious and laborious friend, Mr. Oram of Brompton Lane.' He describes it as 'fattish and pretty large, with a dark red coat on the sunny side, the flower is one of the large whitish kind.' 'Earlier than the Anne, of great esteem, and inferior to none that comes after it.' At the time Switzer wrote this account of it (1724), George I. was on the throne, and no doubt the Peach was named in honour of him. This must therefore have been the original Royal George. But that which is now cultivated under this name is a very different variety with small flowers, which seems to have superseded the original one. This is not surprising, when we find from his account that 'such is its aversion to mite with stoeks in general, and so sad a destruction does it make in the nursery stocks, that I find all nurserymen are weary of it.' There is every probability that the high reputation the Royal George of Oram attained, and the difficulty of its propagation, induced other cultivators to substitute a variety which could be more easily multiplied, and this they found in Millet's Mignonne, which was also new at the same time, and was introduced by Millet, a market gardener at North End, Fulham, and it has continued to represent the Royal George ever since. So late as the beginning of the present century Forsyth describes the flowers of Royal George as large. I quite believe that the original Royal George of Oram was a seedling from Grosse Mignonne, and little different from that variety; and not improbably it may have been what Grimwood afterwards grew as Grimwood's Royal George, which is a form of Grosse Mignonne. This being so, the difficulty of propagation is easily explained, for the Grosse Mignonne requires to be budded on the Pear Plum."

Plants in Rooms (Perplexed).—No doubt, as you say, doctors differ on the subject as to whether plants are beneficial or injurious in rooms. The question is one of constitution and circumstances. Some remarks by the late Mr. Fish on this subject are worthy of perusal:—"Are plants in rooms promotive of health and cheerfulness? In the case of all living-rooms I answer in the affirmative. Delicate people complain of headaches and sickness from their presence, and will, therefore, have them excluded, and rightly too. Plants with powerful odours will sometimes produce that effect. I have known ladies that could not go near a Jasmine; others that hated Musk; some that would faint at the propinquity of a Heliotrope, and others that only approved of Mignonette when not nearer than a furlong. All of us have something peculiar in our likes and dislikes. It is rather ill-natured to consider such peculiarities as mere fid-fad imaginaries. Common prudence would say, 'Keep at a distance from whatever harms you.' In bedrooms that are shut close at night I would advise dispensing with flowers having powerful odours, even though agreeable to the olfactory nerves of the owner. If he prefers retaining them it would be advisable to place them nearer the floor than the couch on which he reposes. But why not have air in the sleeping-room at night, instead of shutting it up close, when the weather is at all favourable, and thus serve the interests of the occupant and those of the plants at one and the same time? The idea of the unhealthiness of plants in living and sleeping-rooms has been suggested by our chemical friends demonstrating the influence of vegetation on the atmosphere, and the reciprocal action ever going on between the vegetable and the animal world. They tell us truly that animals are continually taken oxygen gas from the atmosphere, and throwing, by exhaling, carbonic acid gas into it, and that from this and other causes, but for living vegetation, the air would become impure and unfit for breathing. The solid part of plants being chiefly carbon—of which charcoal may stand as a familiar type—and every green part of a plant having the power to absorb this carbonic acid gas in the atmosphere during light, its quantity is thus lessened, while the action of the sunbeam enables the plant to decompose the carbonic acid thus received, to retain, add, or assimilate the solid matter, the carbon to itself, and to set the other constituent (oxygen) free for the benefit of the animal world. Thus it would seem that the nearer we get to healthy vegetation the more likely we shall be to get the benefit of this fresh-forming oxygen; but, as if to damp our enthusiasm, we are presented with a lesser and a greater drawback to our satisfaction. This lesser is, that all unhealthy parts of a plant, yellow leaves, &c., and, what is more painful still, all *flowers* in proportion as their colour recedes from the green, vitiate the atmosphere rather than improve it even during the day. The second drawback is, that at night, or in darkness or much shade, even healthy plants exhale carbonic acid gas and inhale oxygen, and just in proportion to their size and powers deteriorate the atmosphere like ourselves, and therefore become, especially after twilight, very undesirable neighbours in our dwelling and sleeping-rooms. To this heavy accusation I reply that, in general, the size of flowers, in proportion to green leaves in plants grown in rooms, is so small that during the day the advantage greatly outweighs the disadvantage; and though undoubtedly plants do give off carbonic acid gas at night, yet at that time the rooms are generally at their coolest, and as this gas is something like three to two heavier than common air, it will, in such circumstances, fall to the floor, and only be mingled with the general atmosphere by the heat and the sunbeam of the following day. Unless the plants were extra numerous the absorption of oxygen would not much influence the air of the apartment. All or almost all injury might be avoided by seeing that the plants were lower than the seat or couch of the owner. I believe this the more because *dew*, the condensed moisture in the air near the ground, holds much more of this gas in solution in general than common water does. On the whole, then, unless in the case of delicate invalids, or of plants with very large flowers or having a powerful odour, I believe that healthy plants in rooms are decidedly beneficial, and promotive alike of cheerfulness and health, and that this is especially the case in large cities and towns."

Names of Plants (A. B.).—The large flower is *Godetia rubicunda*, or one

of its varieties, which are numerous; an effective hardy annual. The spray is *Linaria Cymbalaria*. (*M. D.*).—1, *Sophranitis grandiflora*; 2, *Linaria vulgaris*; 3, *Tradescantia discolor*; 4, *Passiflora caerulea*; 5, *Jasminum gracile*; 6, *Chrysanthemum segetum*. (*Celt.*).—1, *Ophiopogon spicatum* var.; 2, *Dietyogramma japonica*; 3, *Doodia caudata*. (*Fisher*).—*Nigella damascena*, popularly called Love in a Mist, sometimes even Devil in a Bush, a pretty annual for beds and borders. (*Rosa*).—We cannot undertake to name a plant from a single leaf. (*J. G.*).—The fungus is a small specimen of *Lycopodon*, but was too immature to enable us to identify it. The Grapes were quite unrecognisable, having been much crushed in transit.

Driving Bees (*Old Subscriber*).—With a view to obtain the honey from your two old stocks drive the bees into empty hives. The work of driving is simple and easily done. First blow some smoke from fustian or calico rags amongst the bees; turn up the hives and place them on their crowns upside down; put empty hives over them; roll a table cover or piece of cloth of any kind round the junction of the hives; and drive the bees up by drumming on the bottom ones for fifteen or twenty minutes. This drumming shakes and disturbs the bees below, and causes them to run up for safety. If the work is well done almost all the bees will be found in the empty hives. If a few stragglers remain in the old hives shake them out by a thump or two on the ground. If your servants cannot do this then destroy the stragglers with sulphur. Remove the hives to some house, and there take the honey before it has time to cool. At once unite the two swarms in an empty hive, and give the bees 2 lbs. of sugar made into syrup every night for twelve days, and thus you will have a stock excellent in every respect. If you follow this advice you will be able to convince the bee-keepers around you that the brimstone pit is a cruel and wasteful expedient, and that bees saved from it can be fed into stocks of great value.

COVENT GARDEN MARKET.—SEPTEMBER 13TH.

A QUIET business doing, prices generally easier. Kent Cobs in good supply, but cleared at lower rates.

POULTRY AND PIGEON CHRONICLE.

THE HEREFORD BREED OF CATTLE.

(Continued from page 237.)

THE farmers of Herefordshire delight in good cattle, and more particularly take pleasure in breeding and rearing the kind of animals which have derived their name from the county in which they originated. Their beef-raising system is their especial boast, and the estimation in which their fat bullocks are held by the butchers and consumers of first-class beef justifies the great interest taken by the graziers in selecting and feeding the choicest of animals. Farm after farm has played its part well, not only on the "home fields" of Hereford and Leominster and under the Norman fortress of Ludlow, but also in a wider sphere each December; formerly on the Smithfield stands and Baker Street Exhibition, but latterly at Islington Metropolitan Christmas Market and also at the Agricultural Hall, where the best of the best of every breed of horned and poled cattle meet each other in

rivalry and contend for the coveted gold medal of the Smithfield Club. Formerly Herefords were not considered as well adapted for dairy purposes, but this arose chiefly from the grazier in the Hereford districts having neglected the female, and bestowed the whole of his attention to the male. This defect, however, may be remedied now gradually, owing to the premiums given at various societies, especially at the Dairy Stock Shows, which will probably induce breeders to emulate each other in rearing superior female stock.

We again quote from Mr. T. Duckham in reply to Mr. J. C. Morton, who made inquiries as to the value of this breed for dairy purposes, and his own statement, together with others from his correspondents, will be found not only interesting, but calculated to show that they can be made profitable for the dairy as well as fit for beef only, and especially in districts distant from Herefordshire. Mr. Duckham states:—"The Hereford is peculiarly a flesh-producing animal, displaying great aptitude to fatten, and unsurpassed for early maturity. The soil of the county, the home of the breed, is not adapted for dairy purposes; thus the general system of calf-rearing is to allow it to run with its dam during the summer months, weaning it when the cow is brought to the straw yard for the winter. In all well-cared-for herds the calf is never allowed to lose the flesh it has thus acquired, but during the winter months it is fed upon hay, roots, and a small allowance of linsced cake, after which, whether steer or heifer, it pays for fairly liberal treatment that it may go out to grass in the spring in fine condition. The steers so managed will at eighteen months old realise £1 per month on their age." Now this very fairly represents the system adopted in their native county; but it must not, as is frequently the case, be supposed that they are not suitable animals for dairy purposes, as will be seen from the letter Mr. Duckham received from a correspondent, Mr. J. W. James, of Mappowder, Dorsetshire, and whose stock we have often seen. He says:—"I do not know I can add much more than I wrote to you a few years ago respecting the Herefords; only I still like them for dairy cows, and find them answer better than any other breed. They are more hardy than Shorthorns or Devons on this land, and give richer milk than Shorthorns. I let two dairies of eighty cows, forty in each dairy, find them in land and hay. The cows calve in January, February, and March. I like the calving to finish by the first week in March, as they are small when turned out on May 20th if taken up later. The calves are taken from their mothers at ten days old and given skim milk, and we always keep some good hay in the rack. When weaned I give them bruised oats, cracked beans, and a little oil cake. I give it them through May and June, and if we have plenty of grass the calves do not care about corn after that time. The first white frost they have hay, say about the latter part of October; but I never give them any straw for bedding. We used to have them die from quarter-evil, now they eat their hay under cover, and when finished out they go under sheltered hedges and lie down. Under this treatment I have not lost one for some years. I generally rear about thirty a year, principally heifer calves. The Herefords fatten with me much better than any other breed. I generally turn out thirty in May, and sell them about Christmas. I find those I breed are better than what I can buy, even at Hereford. The steers are sold at three years and ten months old, but I keep the cows as long as I can; they retain their age wonderfully. I have sold cows nearly twenty year old, and you would think them about ten. With regard to butter and cheese made, it all depends on the season; but I have made inquiries and should say a good season 6 lbs. of butter a week per cow and 1½ cwt. of cheese a year. I let the cows at so much per cow a year, but my agreement is they are not to be milked for ten weeks before they calve; then the cow is strong, and so is the calf when born. When the calf is young the dairyman milks the cow, and leaves what he

thinks enough for the calf, so the udder comes to a good shape. They do not run together; the calf is put in a box and the cow turned out for a few hours. If the Hereford people were to adopt our plan I think they would find the Herefords as good for milk as any other breed. I think the cow is more healthy for being turned out; the stalls are so much sweeter than when they are in all the winter. One thing speaks well for the Herefords—if there is one at any sale she is sure to make a good price."

The system of letting the cows go dry for ten weeks may answer with the Hereford breed if they are not too highly fed during the period; but our experience is that, with other breeds, they would lay on fat internally and endanger the cow at calving time, as they frequently suffer from the downfall in the udder or puerperal fever, besides which it reduces the value of the cow by loss of milk for a period. When the animals are allowed to go dry too soon the lacteal ducts become clogged with coagulated milk, and is often the cause of can-bagged udders, and the frequent loss of one or more teats. If Mr. James's plan is correct it is certainly because the Herefords are known to accumulate less fat internally even when fat than most other breeds.

Other breeders in Dorset keep the Hereford cattle and speak very highly of them. Mr. Chapman Saunders of Watereombe, Dorset, has often stated in our hearing, that having a herd of upwards of a hundred Herefords they answered extremely well as dairy cattle, and we also know that he makes up some noble steers as Christmas beef. We have also information relating to this breed from Australia. A Mr. Charles Price, in communication with Mr. Duckham, writes:—"I am glad to tell you that my herd of 130 are all doing well, and about fifty just commencing to calve. It is considered that 150 or 200 guineas is considered a high price for Hereford cattle. But how if they were to make their calves into steers? I can and do make more of mine than any breeder of Shorthorns in any of the colonies does."

It is recorded that Herefords have been bred at Woburn Abbey by the Duke of Bedford as far back as 1790. Three first Smithfield Club prizes fell to their lot, and it was three of these that John Duke of Bedford, in 1825, beat three of the Hon. Charles Arbuthnot's Shorthorns in a sweepstakes. The chief difficulty with them at Woburn has been to make them milk, and latterly they have merely suckled their calves. As regards milk, "the Herefords generally dry themselves fast enough;" still, if in point of quantity they fall below many other pure breeds the quality of their milk is undeniable. The Prince Consort's Flemish farm (where the Herefords were first specially located in 1855) held its own well under Lieut.-General Lord Bridport's management, both with fat and store beasts, at the Royal Agricultural and the two great Christmas Shows. The Royal Farm winnings with this breed in these three arenas up to the end of 1867 amounted to £400 for twenty-nine prizes, a large proportion of which were firsts, exclusive of gold and silver medals. And as a rule all animals shown were bred on the Royal Farm. The Herefords as fat bullocks took a long lead from the foundation of the Smithfield Club, and up to 1857 inclusive (after which period the different breeds were shown in separate classes) they had won 185 bullock prizes, or only five less than all the other breeds put together including the Shorthorns. At Bingley Hall Show during 1851 to 1867 the gold medal for best bullock in the yard has nine times fallen to their lot. The Berwick grey of Mr. Heath, who showed the best Hereford bullock in the yard three years in succession in Birmingham, will long be remembered for its 9 feet 7 inches girth.

The Hereford are seldom crossed with the Shorthorn, but the blood mixes well when it is pure on both sides. Other crosses are well spoken of, such as the Hereford and Ayrshire, Hereford and Channel Island, especially the Guernsey. In conclusion, for labour in the yoke the Herefords combine the activity of the Devon and the strength of the Durham or Shorthorn. They are very little used in their own county, but the Wiltshire farmers and others buy them at Hereford Fair on the third Tuesday and Wednesday in October, and after ploughing with them for a couple of years they put them into the stalls or boxes for fattening, or pass them on to the Buckinghamshire graziers to be fattened on their rich pastures. The late Mr. Forbes of Echt, in the north of Scotland, used them in teams of six to trench-ploughs, which turned up whin, heather, and stones to the depth of 14 inches. Despite the immense strain upon them they never broke step, whereas horses, if such a task had been set them, would most probably have snapped every trace.

WORK ON THE HOME FARM.

Horse Labour.—On the hill farms and later districts as to climate the horse power may now be employed fully in carting manure on to the lea ground, and also on fallows in preparation for Wheat.

The sooner the land is ploughed the better either of Clover leas or fallows on the stronger soils. We frequently find very strong land upon the chalk hills. Such land would be in fallow after Vetches or Turnips, Rape, &c., fed off by sheep. Where that has been done no yard dung need be applied, especially as the hill fields are usually outlying and distant from the farm premises, artificial manure being added. On such farms, however, the steam cultivator ought to be employed daily until all the land intended for Barley in the spring or root crops next year has been cultivated, and it will then lie rough to take the rains and frosts of winter. If, however, such land has any couch, &c., upon it, it must either be worked out by Howard's self-lifting drag, or if the couch is in a few bunches only it may be forked out by women or old men at low wages. This practice will save the costly horse labour and prove more effectual.

The stormy weather and heavy rains of the last week in August and first few days in this month have made it very difficult to proceed with the carting of Barley where Clover prevailed with it. This matter requires further consideration on the part of the home farmer, because he is not tied to the four-course rotation, which would oblige him to sow the Clover seeds in the Barley if he grew Barley at all. He is, however, fortunately in most cases at liberty to arrange his course of cropping so that the seeds may be grown in Oats, drege, spring Wheat, or Rye, according to circumstances of soil, situation, and climate. In all these crops Clover may not only be grown without injury to the cereal crop, but when the straw is cut a little above the Clover it will not interfere with the harvesting, and will afford a capital autumn growth or cutting as green fodder in those seasons where the harvest is fairly early. When it has been decided to grow winter Beans, winter Oats, or Barley, the work should be done immediately after the seeding of Trifolium, Rye, and Vetches has been completed, and just before the Wheat sowing. Ploughing, pressing, and seeding by the press drill is the surest and most expeditious method; the harrows following the drill presser complete the work simultaneously—a matter of much importance in the short days and uncertain weather of our climate. Those who have not a press drill for use can easily have one attached to an ordinary two-ringed presser for about £4 10s. by almost any implement maker.

We must caution the home farmer not to attempt following any Clover lea intended for Wheat, although there may be some couch in the land, for it proves fatal to a full crop of Wheat nine times out of ten in making what is called a bastard fallow, as the straw generally grows weak and falls before harvest, and seriously injures the yield.

Hand Labour.—When hoeing the late Turnips is finished, the men and women too must soon be employed in raising the Potatoes, and this should first be done by the plough frame made for the purpose, capable of being attached, as it should be, to all horse hoes, the men and women following to pick up the crop and have the tubers stored for the winter in a continuous conical heap about 4 feet wide at the base, and then covered with some coarse dry straw or border grass trimmings, delaying the covering with earth until November. When seaweed can be obtained no earth covering will be required, for if properly laid on it will resist any amount of frost. We, however, have always preferred to sell Potatoes in the ground, the crop to be raised and removed at the purchaser's expense, as this does not then interfere with the ordinary labour of the farm, and we have found no difficulty in obtaining substantial men as purchasers in the vicinity of towns or railway stations. Hedge-trimming must now be completed as soon as possible. The irrigated meadows now should be attended to, so that the drowners or labourers appointed for the purpose of making the watering and drawing trenches may complete the work before the flooding rains of autumn commence, whether they are flood meadows or catch meadows, the latter being so arranged that the water shall be caught by one trench and led to another, and spreading each time over the land by its own gravitation. It is also a fact that much pasture land not so treated may in many instances be irrigated without any expenses except that of properly laying out and making the trenches, which are of two kinds, for the spreading and catching of the water.

Live Stock.—The breeding ewes will now be either in lamb or running with the rams. In either case the abundance of food on all kinds of stubbles or grass land is this year so abundant that they require but little else than a change twice a day from old leas, Sainfoin, or Clover at night to maintain them in good condition. We decidedly object to allowing the ewes to run on the young seeds, as the autumn growth will be great this year and the seeds will afford a cutting of green fodder on good land in the vales; but in other districts where the growth is not strong, it is not only injurious to the Clover in the succeeding winter to feed down bare with sheep, but the food is not well adapted for breeding ewes in lamb. The Dorset horned ewes are now forward in lamb, and must be treated accordingly. The best flocks will commence lambing the first week in October, and in case of the ewes and lambs being required to be fattened and sold together at the earliest period the ewes may be allowed a little cotton cake before they lamb, as many of this breed of ewes bring twin lambs, in which case the higher the condition of the ewes the better they will suckle a numerous fall of lambs.

The cattle fattening in the stalls or boxes may now have Cabbage or hybrid Turnips, as the Swedes are not yet fit for feeding; therefore, as soon as the Clover as green fodder to cut up is finished the vegetable crops should be passed through Gardner's cutter, and the cake or corn both given in the meal state and mixed with the cut

roots, as this plan prevents waste. The quantity of roots given per day should not exceed 56 lbs. and the cake 4 lbs., with 2 lbs. of bean or barley meal, otherwise maize meal. They will then eat a good quantity of sweet Oat straw, which we prefer to hay for two reasons. Hay is too expensive, and we sometimes find the animals refuse their other food when eating hay, but never when allowed straw in the racks without cutting. We never feed with roots and cake more than twice a day, and a little straw at thrice; they will then have plenty of time to ruminate and take their rest undisturbed, quietude being essential to the fattening of cattle under cover. The dairy cows for butter-making should have all the grass possible reserved for them, but the cows for milking for sale of milk may now receive full allowances of roots of any kind, such as Cabbage, Turnips, and Carrots, and hay at the racks, with 3 lbs. of cotton cake per day each in addition.

SCIENTIFIC CHEESE-MAKING.—A French chemist, M. E. Duclaux, has made some interesting experiments in cheese-making, with a view mainly to discover the causes which determine the flavour of cheeses. It has often been asked why cheese made in different districts in a precisely similar manner vary greatly in flavour, while those of one particular spot, although manufactured in very different ways, are almost precisely alike to the taste. The researches of M. Duclaux tend to prove that neither climate, soil, food, manipulation, nor variety in the breed of cows largely affects the quality of the cheese. It would appear rather that a fungus mould allied in some cases to yeast, in others to mould, is communicated by germs in the atmosphere to the cheese, and this it is which gives it its distinguishing flavour. Sanguine people already look forward to the time when the farmer will be enabled to inoculate his cheeses with a variety of ferments, so as to produce Cheddar, Stilton, Parmesan, or Gruyère at will.

INTERNATIONAL DAIRY SHOW, DUBLIN.—This Exhibition is to be held on the premises of the Royal Dublin Society, Ball's Bridge, on the 11th, 12th, and 13th of October of the present year, when prizes will be offered for competition in 117 classes, devoted to dairy cattle, butter, dairy utensils, vehicles, fittings, models or drawings of dairy homesteads, farm produce, poultry, &c.

POULTRY AND PIGEONS

LATE POULTRY SHOWING.

CONTINUING our remarks on this subject from page 238 last week, we may observe that the treatment proper for young birds of those breeds in which size is a great point differs materially from that we have previously described. In this case the great object is to keep them growing steadily as long as possible, and then just to bring them into blooming condition when they are required for exhibition. Of course, we presuppose, as a rule, the separation of the sexes at an early age of all these varieties. This is one of the chief means of keeping them chicken-like. Then they must be fed with nourishing, not exciting, food. Oatmeal gives strength of constitution and stamina for future development. Cockerels require much more support than pullets, and from three to nine months old must have as much as they can eat three times a day. Pullets should be fed as often, but should not at each meal have all that they are willing to eat. House scraps and such dainties should be kept for the cockerels till it is desired to bring the pullets into show condition. A little bone meal is a valuable addition to whatever meals are used for both sexes. Care must be taken that it is genuine bone meal, and not the dust sold by ivory turners. It keeps chickens growing in frame, and does not at all stimulate them.

One of the satisfactory points in late showing is that it gives time to the whole young stock to show their good points, and to younger and more promising ones to pass their elders. Too often at the very early shows forced and precocious birds win simply because they are precocious. They may have serious faults, but a judge dare not pass their flowing tails and rosy combs for mere chickens, though in the end the latter may be ten times as valuable as the former. By October and November the younger birds will have had time to pass their elders in the race. In the case of Dorkings it is wonderful how April and May-hatched birds often grow. We have known chickens hatched in the middle of April carry off the cup at Oxford late in October, and even June birds in the Birmingham prize list at the end of November. Asiatics do not develop nearly so fast; still, with good management chickens hatched early in April may be had of great size by the late autumn.

Pullets which lay very early are seldom of any use for exhibition in autumn. If they become broody a heavy moult follows. They sometimes come out in fresh plumage by Christmas, but then look hen-like, and are liable to be disqualified as old birds. A pullet is

at her perfection of beauty when on the point of laying for the first time. The longer, then, that this stage can be deferred the better. A move to a fresh run will often check laying and consequent development of comb, but we should prefer to retard it merely by keeping our pullets growing and on simple fare if backward in comb. A fortnight before they are absolutely required for show they should be separated from the general flock, put in a good run, and liberally fed. No cock should come near them, or their plumage will be spoilt. The sexes are now shown separately at almost all the great shows. It is a bad plan to exhibit cockerel and pullet together. Here and there lack of space in an exhibition hall makes it a necessity. When this is the case we somewhat against the grain put the cockerel and pullet together a few days beforehand. A first introduction in the exhibition basket is often fatal to the plumage of both.—C.

CARRIER PIGEONS.—An interesting trial of the speed of Carrier Pigeons was made last week by the Paris "Colombophile" Society. Three hundred of these birds were taken from Paris to Oron, in the Canton de Vaud, where they were released. The fleetest arrived at its home in Paris, a distance of 250 kilometres, within six hours and a half, and the slowest arrived only half an hour afterwards, notwithstanding a violent south-western wind which was blowing.

OUR LETTER BOX.

Rye Grass as Manure on Land (*J. W. Dal*).—Your best course would be to sow the land with Mustard or Rape, as that could be ploughed in early in next season, whereas you would have to wait until autumn for the Rye Grass.

Chickens with Gapes (*W. R.*).—The only method of curing gapes which we have found thoroughly effectual is the removal of the small worms, the presence of which in the windpipe of the chick constitutes the disease. This can be done by means of a small quill feather from which the greater part of the feather has been removed, only about half an inch at the end being left on. This must be inserted in the windpipe of the chick, the opening of which will be seen just behind the tongue, gently pushed down as far as it will easily go, twisted round, and drawn out again. It will generally be found that there are a number of small worms adhering to the feather. Care must be taken that the chick is not choked during the operation. A difficulty is sometimes experienced by beginners in getting the feather down the windpipe, but by holding the chick's beak open with the finger and thumb of the left hand applied from behind, and pressing the throat of the chick slightly with one of the other fingers of the same hand, the opening of the windpipe can be clearly seen. If the feather be moistened with spirits of turpentine before use it will be an advantage. The turpentine kills the worms, but the feather must only be moistened, not soaked, with it, as a drop going into the lungs would be fatal to the chick. Another mode of cure recommended is holding the chick until nearly, but not quite, suffocated in the fumes of sulphur or carbolic acid. We have not found this cure at all reliable. Scrupulous cleanliness with a liberal use of disinfectants (such as carbolic powder), and the separation of the infected chicks from the others, are the only means of prevention. The ground is said to become tainted with the germs of this disease, so it is as well where possible to avoid putting other chicks where those with gapes have been.

Mustard and Cress on Farms (*N. S.*).—The quantity of seed required per acre is for the former about 16 lbs., and the latter about 12 lbs.; both should be drilled at about 14 inches apart in order that the land may be hoed if requisite. The produce of these in seed is so various and so much depending upon soil, situation, &c., and the crop being so uncertain and speculative, as well as in some cases seriously injured by small birds before it can be harvested, that we may only mislead some people if we were to name the quantity of seed which is sometimes obtained.

REMARKS.

3rd.—Fair morning, bright afternoon, fine calm evening and night.
 4th.—Cloudy morning, fine and moderately bright afternoon.
 5th.—Dull showery morning, soaking wet afternoon and evening.
 6th.—Fine, bright, pleasant day.
 7th.—Fine bright day, clear cold night.
 8th.—Fine, bright, pleasant day.
 9th.—Fine day, though a little cloudy.
 With the exception of Tuesday a fine and bright week, but showing decided signs of autumn. Temperature above that of the preceding week, and considerably above the average.—G. J. SYMONS.

27th	W	Sale of Bulbs at Stevens's Rooms, Covent Garden.

CHANGE OF SITUATIONS.

MUCH caution should be exercised by gardeners in changing places, for it is easier to leave one than find another. In nine cases out of ten it is, in my opinion, a mistake, loss, and disadvantage to change situations. In practical gardening it is important to lay a good foundation, and in every branch of the profession it is important to look well ahead, as preparations have to be made for future success. This is true in the management of both flower and kitchen gardens, as well as in making Vine borders and cultivating hothouse plants. Generally speaking it is those who begin well that succeed and rise to distinction. Leaving a garden before the results of good practice are manifest is a great loss to clever young men, and it is equally a loss to their employers, for hardly two gardeners follow the same practice or work on the same lines. Viewed from any standpoint, changing situations is disadvantageous to both employers and employed. This is well known, for in the gardens of gentlemen who change their servants often there is seldom much to admire—nothing first-rate attracts attention. And if the careers of clever young gardeners who unwisely leave situations be followed and examined it will be found that their mistakes have not been unattended by misfortune, mistakes sometimes so great as to excite the sympathy of friends, though accompanied with some disapproval. These things are well known. If there is no remedy—no way of preventing such mistakes—the matter should not be mooted at all; but if such failures can be prevented, why not discuss the matter fully in a common-sense way, with a view to guide young men to begin well, and help them in a career of happiness and success?

Some twelve or fifteen years ago a fine young gardener requested me to find a situation for him. He was asked what he was leaving his present one for. "Because I don't get wages enough." "Is that all?" "Yes." "Have you asked for higher wages?" "No; because I know my employer wo'n't advance my wages." "I know your employer better than you do, and I am certain he will raise your wages if you are a good servant and keep his gardens in good order—that is, if you respectfully ask him for a rise of salary. But pray do not give the slightest hint of leaving his employment, and assure him that you like his place and have no fault at all to find with the treatment you receive, but owing to the high price of meat, bread, and house rent you would feel indebted to him for a rise of salary." When the young man carried out these instructions his master said, "Gardener, I have to buy dear meat and bread as well as you, but I will give you

£10 a year more salary." So far as I know the gardener is still with the same gentleman.

Why are there so many changes of places? Many reasons doubtless could be given, and many men will differ in opinion as to the fundamental cause. It is well known that many ladies and gentlemen do not like changes of servants; and gardeners, for their own sakes and that of their families, should dislike it more, for changes to them often are greater losses and inconvenience than to the employers. Why, then, change situations and look forward to an uncertain future for greater advantages? Why not let well alone and make the most of our present possessions? In my opinion very many men are their own greatest enemies—fight most against their own interests, and are influenced by discontent and undue ambition. I believe in the competency of wise and instructed gardeners to give satisfaction to ninety-nine employers out of every hundred. A great American once said, "I can't do it' never did anything, 'I'll try' has done wonders, but 'I will do it' has performed prodigies." I like this statement much, for I believe that men who do their duty willingly and cheerfully, and serve their masters to the best of their abilities, are everywhere held in high esteem. In all situations dutiful and upright conduct is highly appreciated. Well, then, let duty to employers be the pole star of service. Gardeners are expected to grow good crops of fruit, vegetables, keep their gardens well, and treat their employers with respect. All this is in the contract, which, if well done, will give satisfaction to all parties, and, moreover, go a long way to prevent separations between masters and servants.

Active thoughtful gardeners consider no effort too great to meet the wishes of their employers. They anticipate their wants and prepare for them beforehand. Unfortunately some men look on service as a kind of slavery, and never enjoy happiness of freedom. Such men are slaves indeed. Others, again, fancy they should be gentlemen without going along the dusty road of duty. Very often they get their reward, which is one of disappointment and discomfort. Let the watchwords of all servants be, "duty" and "willing cheerful service." Let the gardens entrusted to their care be in as perfect a state of keeping as possible. Measure not time or service by the hour, nor decline extra labour.

Failures to please employers arise oftener from inattention and carelessness than from inability. To those who are conscious of having failed to meet their employer's wishes and expectations what can be said? If they are quite certain the fault is not on their side, and that it is impossible for them to keep the gardens well or give satisfaction, we fancy their better way is to leave, first explaining their difficulties to their masters; but if they are conscious of not having fulfilled the duties of their position they ought at once to redouble their efforts by devoting more energy and attention to their work.

One word to young men commencing gardening. If they begin well they will probably continue to do well. During their pupilage or apprenticeship they should give their best attention to the study of gardening in all its branches, for if they acquire a thorough knowledge of it they will become increasingly fond of it. Enthusiasm in any profession is no mean virtue, for such men inspire those around them with a similar feeling. All this tends in the direction of success and distinction. When a head situation falls to the lot of men of this stamp they do not forget to serve, for they love gardening

for its own worth and sake, and do things well. If they succeed in growing fruit and plants well they have an immediate reward. Their virtues and value are highly appreciated. The services of such men and servants are far beyond a money value. Young men, then, have much to encourage them to endeavour to excel in their profession.—A. PETTIGREW, *Bowdon*.

WATERING VINES.

THIS subject has frequently been adverted to in these pages, but it is one of so much importance, and I might say so imperfectly understood, that many readers would do well to give the matter more attention. In nine cases out of ten, especially with amateur growers, I am of opinion that Vines do not receive sufficient water at the roots. Outside borders are frequently well watered naturally, but those wholly or partially under glass are neglected in this respect. The finest-coloured Grapes I have seen this season were on Vines which were almost swamped with water from the time the buds were breaking until the fruit was completely ripe and coloured, and after that they were not dried off in any way. On the other hand, the worst-coloured Grapes I have seen this or any other season were on Vines growing in a border which stood high above the surrounding ground. The gardener had his own ideas about watering, and would never think of giving more to a high border than to a low drainless one, considered that "two waterings were enough," one being given when the Vines were breaking into leaf, and the other when the berries had finished stoning. The result of this was that the Grapes assumed a motley foxy colour, and like this they remained. All other conditions were favourable to proper Grape-growing, but the watering at the roots was greatly deficient, with the result I have stated.

In a contrary case, some young Vines planted last year are now maturing a fine crop. In the hands of a painstaking grower they were most carefully attended to in supplying them with water. The wood and leaves they developed were extraordinary, the fruit has coloured magnificently, and the gardener in charge attributes much of this success to copious watering.

Another bad case may be given. In the spring of this year a gentleman of our acquaintance put up a fine range of vineries. The borders were most carefully made, and the best systems were followed in everything. The greatest success was anticipated. Good young Vines were secured and planted, and at first they gave every indication of making unusual progress; but now they are disappointing, as the long shoots they have made are little thicker than one's finger, and the leaves about the size of our hand. On visiting this vinery the other day we found the atmosphere quite arid, the surface of the border dust-dry, and a tank was pointed out as having been twice emptied on the border during the season. Then we had no hesitation in informing the anxious proprietor that his man had given his Vines about fifty times less water than they ought to have had. "But," says the gardener, "the Vines are ripening their wood, and do not want water at the roots now;" and this also was a mistake, as in their state the wood might ripen quickly but it would not be plump. Had those Vines been under our care they would have received copious waterings every other week, and now they are ripening and throughout the winter we would apply it at the same rate, and all inside borders would be treated in the same way. Of all Vine requirements there are none of so much importance as abundance of water, and without this badly developed wood and inferiorly coloured and flavoured fruit can only be expected. With ordinary good drainage and waterings of the kind we refer to there is little danger of any Vines or Grapes failing.—J. MUIR.

DOUBLE PYRETHRUMS.

THESE plants are of great value for all purposes where good flowers are in demand, whether it be for the decoration of the border or for planting in permanent beds, where they make a splendid show if a good selection of varieties is procured and the colours effectively arranged. They require, too, only a small amount of labour and expense, for even the first outlay in the purchase of stock is nominal; and there is no need of further expenditure unless fresh varieties are required, for they are most easily increased by dividing the roots after the season, or any time, in fact, so that the divisions can establish themselves again previous to sharp weather. During the last fortnight I have divided many plants; and as it was desirable to increase my stock very largely, they were cut into very small pieces and potted separately, and placed in a cold frame, where they will be kept close and shaded until root-action is again resumed, when they may be gradually exposed and finally planted out.

The present is perhaps the best time to plant, as after this they make very rapid growth until the frost entirely checks it; and it is well in the case of young plants to cut away all stems which attempt to flower, so as to give the stool the full advantage of all the roots; thus much stronger plants will be the result, and a much finer show of flowers will be had next year. To obtain good results the ground should be well enriched with decayed manure, spent hotbed material being very suitable for them. The ground should be deeply dug, or even trenched, and the manure deeply buried, as they are deep-rooting plants, which is a great advantage during very dry weather, and if the manure is well buried the plants are benefited twofold. Pig manure I consider very prejudicial, as I have known the plants to suddenly die on more than one occasion where such was used without any other apparent cause.

The nature of the soil need not be an obstacle in the way of their much more extended cultivation, for I have known them to thrive in all kinds of soil. Very heavy damp soils are least suitable to them; they will make rapid coarse growth in such, but flower very poorly, and usually die suddenly. Light well-enriched soils are the best, and a sunny position, when they make much more roots and are more floriferous, and can consequently be much more largely increased. Good strong plants well established in pots are the best to begin with, and when once planted they will require no further attention until the flower heads appear next season, when stakes will be necessary for their support, or their weight will cause the stalks to bend to the soil.

The number of varieties is very large, but many of them are very similar. Those named below are selected from a collection of nearly a hundred, and they are certainly distinct and very showy, and others might be added without exhausting the good varieties. *Niveum plenum*, a very fine white-flowered kind, very free, and the flowers are full of good petals, pure white, with slightly yellow centre. *Mont Blanc*, more robust than the last; flowers not quite so double, pure white, less yellow in the centre; a splendid kind. *Virginale* is another white, very free, and the flowers are very large, with rather long outside florets. The above are the three best white-flowered varieties in my opinion. *Dr. Livingstone* is an extremely free variety, with large spreading and very double flowers of a delicate flesh colour. *La Vestale* has richly blush-tinted flowers, large and numerous. *Madame Muniac* is in the same way, but deep in colour and very free, the flower stems being rather more freely branched than most kinds. *Panorama* is a delicate blush, with the tip of the outermost florets yellow; a very double and large flower. *Aurora* has sulphur-coloured flowers, very double, with deep yellow centre. *Madame Benary* is also a yellowish-coloured variety with a good flower and free disposition.

Among the very numerous rose-flowered kinds there are five extremely good—viz., *floribundum plenum*, rich rosy pink, very double and free; *Herman Stenger*, rich lilac rose, a very finely formed flower and very robust, one of the best varieties; *Modèle*, bright rose, very free; *Mons. Barral*, rich rosy red, very conspicuous, and certainly a leading kind; *Nemesis*, deep rose, with the outer flowers distinctly tipped with crimson, very showy indeed; *Spectabile*, light rosy lilac, very floriferous, and certainly distinct in colour. Among the deeper shades of colour are *Captain Nares*, rich purplish crimson flowers of excellent form and profuse; a leading kind. *Emile Lemoine*, flowers large, deep crimson edge with yellow; very distinct and handsome. *Fulgens plenissimum*, rich carmine; excellent form, and very free both in growth and flowering. *Gloire d'Italie*, a grand variety; flowers intense crimson, and very freely produced. This is very largely grown. *Michael Buchner*, almost equally good flowers, deep magenta crimson and very large; in fact I have known it larger than any. *Haage et Schmidt*, a very floriferous kind, similar in colour to the last; very dwarf and robust. *Purple Prince*, a splendid variety with purple-carmine flowers. These deep-coloured kinds are extremely showy when well arranged. In clumps they are particularly effective either when wholly composed of one variety, or so arranged with the white and light-flowered sorts that the flowers are intermingled. If the different colours are arranged in lines, as we frequently see them in nurseries where they are largely grown, the effect is unique, and the abundance of flower is astonishing.—N.

POTATOES AND PEAS.

Potatoes.—We have not had many kinds this year, and never had fewer diseased tubers. This is not owing to cultivation, but to selection. Two or three years ago, when we had scores of sorts on trial, it was difficult to save the seed of some of them; but those we soon discarded, and by degrees we reduced our stock to the

best bearing and disease-resisting kinds. Now we have only some half a dozen varieties. These are Schoolmaster, Magnum Bonum, Scotch Champion, Improved Peach Blow, Gloucester Kidney, and Mona's Pride. Probably we may yet discard Peach Blow and the Champion, but the others are excellent. Not one in a hundredweight of Schoolmaster nor Magnum Bonum are diseased, and we advise all who grow Potatoes in garden or field to give those two a good trial.

Peas.—These have been very satisfactory this season. Mildew has hardly existed. Had it become bad, good quantities of soot water have been given to check it. Of new kinds Webb's Electric Light has done well. It grows about 5 feet high. The pods are rather narrow and dark green in colour; on an average they contain nine and ten well-flavoured peas. It is very prolific, the pods being crowded with peas, and appears well worth growing in all gardens. Walker's Perpetual Bearing is another good variety. It does not become ready for use so soon as the preceding, but it continues bearing much later. The pods come in long succession, and the produce is well flavoured. Day's Sunrise will be grown again. It has a splendid constitution, is an enormous bearer, and good for coming in very early or late in the season. It may be termed a good all-round Pea. Of larger kinds Culverwell's Giant Marrow has everything to recommend it. It grows most freely and robustly. The pods form and fill well from the first, there being frequently as many as twelve peas in them. The flavour is second to none, and it might well be termed the Pea of Peas. There is another of Mr. Culverwell's seedlings, but it is now in the hands of Mr. May of Leeds, and is not yet in commerce. It is as robust as the Giant Marrow, also as prolific and good, the chief differences being that it is a little narrower in the pods and paler in colour. As a brace of Peas these two would be difficult to match. Laxton's Omega is always a favourite late sort. Woodford's Marrow, and some more of the "good old Marrows," are far inferior to the newer kinds. It will be long before Telegraph is pressed out of the market. It is grown in almost every garden throughout the country, being much valued for its deep green colour and other good qualities.—A KITCHEN GARDENER.

COSMOS BIPINNATUS.

THE plant shown in the woodcut (fig. 43) is a beautiful Mexican annual that is far too seldom seen in gardens, as it well merits a place in the border or on the rockery. Its rich rose-coloured flowers and divided leaves give it a unique appearance, readily distinguishing it from its numerous allies in the great family Compositæ to which it belongs. It is an old plant, having been described by Cavanilles in 1791 from specimens which flowered at Madrid in the autumn of 1789, and it is said to have been introduced to England about twelve years subsequently, although it is still comparatively rare. Willdenow changed the name to *Cosmea*, but the older title is now generally adopted. The plant well deserves its name, which signifies "beautiful."

NOTES ON ROSES AND TOMATOES.

I AM very glad "ROSARIAN" has written so decidedly about standards. I daresay your readers may think I am prejudiced, but he has very concisely and practically stated what I have always considered the objections to them. In 1860 I lost every standard I had but two out of about 150. Old Baronne Prevost and Général Jacqueminot were the only two that lived. I made up my mind I would never plant another, but a friend of mine made me a present of a dozen a few years after, from some which he had imported from a French nursery; but another severe winter (I forget exactly which winter it was) again killed every one. I maintain it is contrary to the nature of a Rose to grow it in the way standards have to be pruned and treated. A Rose naturally recuperates itself from the base by throwing up young and vigorous shoots, especially if care is taken to cut away all old wood that is more than two years old.

I am quite sure that Mr. Bardney is right in recommending amateurs to try their success in growing Roses on their own roots from cuttings. I am also quite sure in my own mind that the reason why Roses on the Manetti succeed so well, as a rule, on ordinary good garden soil is that after two or three years, if the junction of the scion and the stock is sufficiently covered with soil when planted, the Roses soon get established on their own roots, especially those which are more vigorous in growth. Very likely the dwarf and tender sorts, especially if the soil is at all clayey or damp, or if the aspect is unfavourable, may succeed in that case better either on seedling Briar or on cultivated Briar cuttings.

Where the failure of standards and half-standards often arises

is from the way in which they are in the first instance rooted-up ruthlessly from the hedgerows by men who in late autumn or during the winter, when other work is slack, go round with a bill-hook and a small-pointed long draining spade and cut them out of the hedgerows, regardless of their roots. They are then tied up in bundles, perhaps laid in a shed, or earthed-up for a time in some outlying place, till there is a sufficient number collected to take to a Rose nursery for sale. These stocks are then planted, and all that shoot sufficiently strongly are budded when the time comes; but the question is, How many of these have really recovered their rough treatment? and how many will bear transplanting at the end of another year or two years, as the case may be? I believe any person who has a cold frame facing north, as

Fig. 43.—*Cosmos bipinnatus*.

some have, at the back of a vinery or stove may strike Roses very well by putting from 5 to 6 inches of good light soil—half leaf soil and sandy loam being the best—and dibble in good strong cuttings from 6 to 8 inches long, covering all afterwards with riddled ashes, and after a good watering with a rose keep the lights close, only ventilating occasionally on dull days. There is hardly any necessity for watering again unless the frames get very dry, or till there are signs of fresh growth in the earlier spring months.

"W. E. G." sends some very useful remarks on Tomatoes. I can strongly recommend growing Tomatoes from cuttings and not from seed. I grew several from a mixed packet of seed last year, and selected out from some which I had in pots in a vinery one which bore more freely and had better-flavoured fruit than any other. I do not know its name, but I will send two or three fruits next week to see if it can be recognised. I grew some seedlings I saved from it, but I also struck it pretty freely, and am

growing it in pots from 8 to 10 inches in size on shelves in theinery, and also on the stage of a small lean-to 18 by 10, facing south against the back wall; but in every case the cuttings have fruited better than the seedlings, and I have gathered two or three dishes every week since 1st of June. I have both seedlings and cuttings out of doors against a south wall, but in every case the cuttings are dwarfer and surer bearers, and some seedlings from Trophy are of no use whatever. When in Cardiganshire two years ago I tasted a great many varieties, such as Greengage, Golden Drop, &c., but do not think any of them are better than the older varieties of Orangefield and Tomato de Laye. I cannot see the advantage of growing them too large or coarse, and I think the rounder and smoother varieties, when well ripened in a house, are much the best for table purposes.—C. P. P.

[The fruit sent was the true Orangefield, a most useful variety, and one which is grown in many large establishments in preference to all others.]

ROYAL CALEDONIAN HORTICULTURAL SOCIETY'S (INTERNATIONAL) SHOW.

EDINBURGH, SEPTEMBER 13TH AND 14TH.

SEVEN years ago the Society which has done so much for the promotion of horticulture in the north—indeed in the kingdom, achieved a triumph in the character of an exhibition which has been deeply graven on the page of history, by having been the scene of a contest unrivalled in the annals of Grape culture. Those who had the privilege of inspecting the grand display of fruit on that occasion, even exclusive of the nearly quarter-hundredweight bunches of Grapes, will not soon forget it. Undoubtedly the prestige of that great Show—indefinitely too large for the building in which it was held—has continued to the present time, and has in no small degree stimulated the wide public interest that was manifested in the Exhibition we have now to describe. By the earnestness of individuals and the enterprise of societies some great undertaking is organised from time to time, to which the attention of horticulturists is directed from every district in Great Britain. Since the last Edinburgh tournament we have had the Carlisle "International," and its attendant deluge in 1877; the Preston fiasco, and the same concomitant—rain—in 1878; and last year the great Manchester gathering, and the deluge again; and now the turn of Edinburgh has come round once more.

Great provision was made for the Show under notice. The schedule was characteristically northern, sober but sound. It was divided into eight classes—what in the south would be termed sections—and embraced 175 sections—what are generally known as classes. Thus to the majority of readers there was a topsy-turverdom of terms. It will be convenient to us, as well as more intelligible to readers generally, to adopt the ordinary form—namely, to regard the exhibits as arranged in classes under eight sections or divisions. The first division contained six classes for Pines, the prizes ranging from £3 to 10s.; three collections of Grapes, two of six and one of four varieties, the prizes ranging from £8 to £1; classes for two bunches each of all the leading varieties of Grapes, with corresponding classes for single bunches and for seedlings, the prizes ruling from £3 to £1, only two prizes, however, being provided in several of the classes. Division 2 was devoted entirely to Grapes, in fifteen classes, in none of which the exhibitors in the thirty-seven classes in Division 1 could compete—a wise provision—as thus a field was provided in which the greatest possible number could win a place in the prize list. Altogether upwards of a hundred prizes were provided for Grapes alone, of the aggregate value of nearly £170. Division 3 was, except in three collections, for fruits other than Pines and Grapes. Division 4 was for fruits of foreign growth, £160 being offered in six prizes. It was in virtue of this offer that the term "International" was justified, although in all probability competition was scarcely expected, and perhaps not urgently required. Division 5 was for plants from gardeners and amateurs in thirty-seven classes, the chief for ten stove and greenhouse specimens, for which the prizes were £20, £15, and £10. The last-named sum was also provided for the first prize for six plants, and for a table of plants 20 by 5 feet for quality and effect. In this section also were fifteen classes for cut flowers. Division 6 was for dinner-table decorations; Division 7 for nurserymen's plants and cut flowers, the prizes not exceeding those offered in the preceding sections; and Division 8 contained fifteen classes for vegetables. Altogether provision was made for awarding 450 prizes, of the collective amount of nearly £1000; and now let us see the result.

The response of exhibitors was at once great and gratifying—great because they produced an Exhibition that must rank as one of the finest that has been seen; and gratifying because the products as a whole were a honour to the cultivators, even to many of those who failed to obtain a place in the prize list. The entries exceeded two thousand, and we were told, what is a remarkable circumstance, and evidence at once of the earnestness of the competitors, and at the same time highly creditable to them—namely, that only one failed to meet his engagement and appropriate the space allotted to him.

The Show was held in the Waverley Market—a glass-roofed building upwards of 300 feet long and 150 feet wide, a side gallery

surrounding it—the finest and most convenient place for an exhibition we have seen, as the vans containing the plants, &c., could be brought to the side of the tables. These, 18 inches high and 6 feet wide, were arranged in seven rows, but not unbroken rows, for spaces were left between at intervals for facilities of promenade, and thus everything could be conveniently inspected. A table was also formed along one side and both ends of the building for vegetables and hardy fruit. The whole of this space was filled—crowded—and, what is especially worthy of mention, there were fewer exhibits of an inferior character than we ever noticed at an exhibition approaching this in magnitude; indeed, there was scarcely anything but what was creditable to the respective cultivators. In referring to the classes we shall follow the order of the schedule in giving priority to the fruit; but the classes will not be followed exactly according to their arrangement, as we shall commence with what formed unquestionably the greatest feature of the Show—namely,

GRAPES.

Prominence was appropriately given to these, the prince of exotic fruits, no less than forty classes being devoted to them. The display was a splendid one, by far the best that has been seen this year in this or, it may be said with much confidence, in any other country, some fourteen hundred bunches being placed in competition. A few were small and unripe, but only a few; the majority were undoubtedly of excellent quality—indeed to secure a third place in some of the classes was a greater honour than would be achieved by a first position at the majority of exhibitions. In the special class for two bunches each of six varieties eleven very fine collections were staged, Mr. McIndoe, gardener to Sir Jos. Pease, Bart., Hutton Hall, securing the coveted position. Gros Guillaume, grand bunches, about 9 lbs. full, and with fine berries; Trebbiano, equally large and good; Black Hamburg, about 3 lbs., good hammered berries; Golden Champion, nearly the same size, good berries, and very clear; Gros Colman, of full average quality; and Mrs. Pince's Muscat, full and regular but not quite ripe. Mr. Hunter, gardener to the Earl of Durham, Lambton Castle, followed with Golden Champion and Gros Colman, both fine; Trebbiano, Alicante, and Gros Guillaume, large, 6 lbs.; and Muscat of Alexandria, good. The third prize falling to Mr. Kirk, gardener to Thomson Paton, Esq., Norwood, for even 2-lb. bunches, with splendid berries of Gros Colman, Muscat Hamburg, Alnwick Seedling, Duke of Buccleuch, Black Hamburg, and Muscat of Alexandria. This exhibitor has only, we are told, a smallinery. Mr. McKelvie, gardener to Dowager Duchess of Roxburgh, Broommouth; Mr. Hammond, Brayton, and Mr. Johnston, Glammis, had wonderfully fine collections.

For the best six sorts of Grapes, one bunch of each, ten collections were staged, which contained many splendid examples of culture. Mr. Hunter was awarded the chief honours with Muscat of Alexandria, 4 lbs., full and fine; Gros Guillaume, heavier, also fine; Mrs. Pearson, 1 lb., neat, well finished; Gros Colman, a small, but model in shape and finish; Calabrian Raisin, 3 lbs., full and ripe; Black Alicante, 5 lbs., full and well finished, and Trebbiano weighing 7 or 8 lbs. Mr. Kirk was placed second with superb examples similar to those referred to in the previous class, and Mr. McKelvie third with heavier bunches; Muscat of Alexandria 5 to 6 lbs., splendid; Gros Colman and Buckland Sweetwater 2 lbs., superior; neat Black Prince and Black Hamburg, with a large bunch of Calabrian Raisin. Messrs. Roberts, Goodacre (Elvaston Castle Gardens), and Lees staged very good collections. In the class for four varieties, one bunch of each, the competitors in the two preceding classes excluded, seven collections were staged. First, Mr. Elphinstone, gardener to E. W. Mundy, Esq., Shipley, Derby, with Gros Colman, splendid berries; Golden Queen, fine; Muscat of Alexandria, small but ripe; and Madresfield Court, very good. Second, Mr. Dickson, gardener to J. W. Melville, Esq., St. Andrew's, with Golden Queen, Muscat of Alexandria, Black Hamburg, and Gros Colman, all superb quality, bunches averaging 1½ lb. Third, Mr. Roberts, gardener to Lady Emily Howard, Tullamore, with large loose bunches, but berries ripe and well finished.

We now come to the two-bunch classes. For two bunches of Black Hamburgs ten lots were staged, a few being brown. Mr. McIndoe was first; 2-lb. bunches and very fine berries, not all, however, jet black. Mr. McIntyre, gardener to C. Tennent, Esq., M.P., The Glen, Innerleithen, second with smaller bunches but better berries. Mr. Roberts, Gunnersbury, third; had his berries been a trifle larger he would have been first, for they were the blackest of all.

Remarks were freely exchanged relative to what may be termed the comparative weakness of the Black Hamburgs, but the fact is this: The "Hamburg season" is practically over so far as regards the finish of this fine old Grape, for although the fruit will hang long and retain its good quality, it will not retain its density of bloom, and bunches that were splendid a fortnight or three weeks ago are by no means so attractive in appearance now.

Two bunches of Muscat Hamburg.—The first prize was awarded to Mr. G. Reid, gardener to A. Moncur, Esq., Rockfield, Dundee, with 1-lb. bunches, full, regular, well-finished berries; the second to Mr. Roberts, Gunnersbury, with bunches as large again and full, but not perfectly ripe. We did not see a third award, but Mr. Elphinstone deserved that position.

Two bunches of Madresfield Court.—This was an excellent class of seven competitors. First, Mr. Goodacre with almost faultless produce, but berries a trifle small; second, Mr. Roberts, Gunners-

bury, with medium bunches and grand berries; third, Mr. McKelvie, Broxmouth, large but not quite ripe. Fully equal to these appeared two bunches from Mr. Fennell, gardener to E. Cazalet, Esq., Fairlawn, Tonbridge, which, however, failed to obtain a place.

Two bunches of Black Alicante. A splendid class of sixteen competitors.—First, Mr. Wallis, Keele Hall; bunches about 2 lbs. and berries highly finished. Second, Mr. Hunter, also finely finished; bunches good. Third, Mr. Roberts, gardener to Hussey Packe, Esq., Prestwold Hall; very fine. None of the very large bunches in this class had highly finished berries, and the Judges wisely attached the first importance to quality. This, however, was not quite the case throughout the Show.

Two bunches of Gros Colman.—A grand class of twelve competitors, Mr. Wallis being well placed first with singularly fine and well-coloured berries; bunches about 2 lbs. Mr. Elphinstone a close second with fine examples; and Mr. Upjohn, gardener to the Earl of Ellesmere, Worsley Hall, Manchester, an excellent third. Mr. Hammond staged the largest bunches, but with one or two decayed berries, which lost them a position in the prize list.

Two bunches of Lady Downe's. Fourteen collections.—First, Mr. McKelvie, Broxmouth; 2-lb. bunches of neat form, full, regular, and well finished. Second, Mr. McIndoe with equally good berries. Third, Mr. Wallis, also good, but the berries rubbed in transit.

Two bunches of any other black variety.—Fourteen lots were staged in this class, the chief prize falling to the successful Mr. McIndoe with splendid examples of Gros Guillaume; 6 or 7 lbs. Second, Mr. Wallis with smaller bunches, but wonderfully fine berries of the same variety; and third Mr. Hudson, The Gardens, Gunnersbury House, Acton. Bunches of Cooper's Late in this class, staged by Mr. Lees, were very good.

Two bunches of Muscat of Alexandria.—Thirteen collections of remarkable excellence were staged in this class; Mr. Day, gardener to H. T. Brodhurst, Esq., Garliestown, being first with large, full, and decidedly superior examples. Second, Mr. D. Murray, Culzean Castle, Maybole; and third, Mr. G. Mackinnon, gardener to Lord Melville, both staging bunches 2 to 3 lbs. of great excellence. Mr. Hill, Tring Park, and Mr. McKelvie staged very fine examples. It should be added that a Veitch Memorial medal and £5 were deservedly awarded to Mr. Day for his splendid Muscats as the finest white Grapes in the Show.

Two bunches of the Duke of Buccleuch.—Mr. McIndoe was the only exhibitor, the bunches weighing not more than a pound each, but berries of good size and high finish.

Two bunches of any other white Grape.—Of the sixteen lots staged the best came from Mr. John Gray, gardener to Rev. J. H. Turnbull, Lismahagow, who secured the first place with splendid bunches of Buckland Sweetwater weighing 6 to 7 lbs. Second, Mr. Wallis with Golden Queen, good, full, clear, and ripe. Third, Mr. Dickson, St. Andrews, with the same variety.

The single-bunch classes now follow. One bunch of Black Hamburg brought out only four entries, Mr. McIndoe being decidedly first with a small bunch with berries of good size and quality. Mr. Boyd, gardener to W. Forbes, Esq., Callender Park, Falkirk, an excellent second, but neither bunch superior. One of Black Alicante (ten competitors), Mr. D. Roberts, gardener to Hussey Packe, Esq., being first with a bunch about 1½ lb., fine in berry and superbly finished; Mr. Jas. Maconochie, gardener to P. B. Smollett, Esq., Cameron House, Alexandria, closely following with a little larger bunch, but not such well-finished berries. Twelve bunches were exhibited in the class for one bunch of Lady Downe's, Mr. W. Elphinstone winning the premier place with a 1-lb. bunch and splendid berries, followed by Mr. W. Lees, gardener to the Marquis of Downshire, with a larger bunch and good—a creditable class. One of Alnwick Seedling.—Five excellent bunches were staged, Mr. Bell, Clive House, Alnwick, securing the first prize with a bunch of about 1½ lb. and splendid berries; Mr. Roberts, Gunnersbury, closely following with a larger bunch and excellent—a fine class. One bunch of Gros Maroc.—Mr. Wallis staged a small bunch with beautifully finished and large berries, securing the first place, Mr. McIndoe closely following. Three lots.

One bunch of Muscat of Alexandria.—Fifteen bunches were placed in competition in this excellent class, every one of them being creditable to the cultivators; Mr. Day, Garliestown, being first with a good-shaped bunch of 2 lbs. and superbly finished large berries, followed by Mr. McKelvie, Broxmouth, with a larger bunch of excellent quality. Mr. Gordon, Greenock, Mr. Gellatly, gardener to the Earl of Wemyss, Gosford, and Mr. Austin, Ashton Court, deserve honourable mention in this fine class. One bunch of Golden Champion.—Only three bunches were staged, but all good. First, Mr. James Brown, gardener to C. H. S. D. Moray, Esq., Abercainey; bunch of nearly 3 lbs., berries good and clear. Mr. Roberts, Gunnersbury, a very close second with larger berries and nearly clear. One bunch of Mrs. Pearson.—Mr. Hill, Keele, and Mr. Austin, Ashton Court, were placed in the order named, both exhibiting neat three-quarter-pound bunches and clear berries, and we thought the remaining bunch from Mr. Hunter as good as either of them.

One heaviest bunch of black Grapes.—First Mr. Roberts, Tullamore, with Gros Guillaume, 18 lbs., not ripe; second Mr. McIndoe with the same variety, 10 lbs. 8 ozs., and of fine quality. Five competitors. One heaviest bunch of white Grapes.—First Mr. McIndoe with Trebbiano, 10 lbs. 4 ozs., full and fine berries; second Mr.

Hannah, Monreith Gardens. Several decidedly not large, but certainly inferior Grapes were staged in these classes.

One bunch of finest-flavoured black Grapes.—First Mr. McIndoe with Madresfield Court; second Mr. Brunton, Gilmerton Gardens, Drem. Finest-flavoured white.—First Mr. Roberts, Gunnersbury, with Duchess of Buccleuch, small, rich; second Mr. Souza, gardener to Sir H. J. S. Stewart, Bart., Touch House, with the same variety; third Mr. Way with Muscat of Alexandria. One bunch having the finest bloom.—Twelve very attractive bunches were staged. First Mr. Wallis with Gros Colman, superb; second Mr. Johnston, Glamis, with Gosford Black, a little smaller than Gros Colman. No awards were made for seedling Grapes, although several bunches were exhibited.

Exhibitors in the above classes were not allowed to compete in the following. Six bunches, in not less than three varieties.—Five competitors entered, Mr. Witherspoon, Red Rose Vineries, Chester-le-Street, being placed first with Gros Maroc very fine but not quite ripe, excellent Buckland Sweetwater, and very good Foster's Seedling, Madresfield Court, Alnwick Seedling, and well-coloured Mrs. Pince. Second Mr. McLure, gardener to John Milne, Esq., Trinity, with Duke of Buccleuch small but good, Alicante good, Muscat of Alexandria and Black Hamburg small but ripe. Third Mr. McLeod, gardener to G. Younger, Esq., Westbourne House, Tillicoultry, his noteworthy bunches being of Abercainey Seedling, resembling well-finished Alicantes but rather small. Two bunches of Black Hamburgs.—Mr. G. Finlay, gardener to Mrs. Maynard, East Layton Hall, Darlington, was first with excellent produce. Mr. Young, Edinburgh, a good second. Seven lots. Two bunches of Black Alicante.—Seven also competed in this class, the first prize going to Mr. W. Collins, gardener to J. Ballantyne, Esq., Walkerburn, with highly creditable bunches and fine and well-finished berries. Second Mr. McLeod, smaller but very good. Two bunches of Lady Downe's.—First Mr. Shaw, gardener to Lord Muncaster, Ravensglass, Carnforth; second Mr. Hugh Watson, Stirling—a neat but not ripe class. Two bunches of Muscat of Alexandria.—First Mr. McLure with well-shaped bunches and berries of excellent finish; second Mr. James Harper, gardener to J. Russell, Esq., Dundas Castle, fine but not quite ripe.

One bunch of Black Hamburg.—Eleven bunches were staged. First Mr. Jeffrey, gardener to A. Pringle, Esq., Langholm, splendid berries, bunch less than a pound weight. Second Mr. Watson, Stirling, also small but good. One bunch of Madresfield Court.—First Mr. McDonald, gardener to J. Younger, Esq., Ashfield, small but neat. Second Mr. Harper, large berries but not quite ripe. One bunch of Black Alicante.—Ten bunches competed. First Mr. Collins with very well-finished berries; second Mr. Harper with excellent produce. One bunch of Lady Downe's.—First Mr. Grey, gardener to W. Christie, Esq., Craighend Park, very good; second Mr. Jeffrey, both having very fine berries. One bunch of any other black variety.—First Mr. McLeod with Abercainey Seedling; second Mr. Witherspoon with Gros Maroc, very fine but not quite ripe, cut from a graft attached in the spring. One bunch of Muscat of Alexandria.—First Mr. Jeffrey, fine quality; second Mr. McLure, larger but not quite ripe. The last-named exhibitor was also first for one of Duke of Buccleuch; it weighed about a pound, and the berries were good and clear. One bunch of Golden Champion.—First Mr. Grey, small bunch, fine clear berries; second Mr. Kay, gardener to Sir J. L. Foulis, Bart., large but rather loose, yet of good quality. One white of any other sort.—First Mr. Young with good Muscats; second Mr. Witherspoon with Buckland Sweetwater, good berries.

A basket of Alnwick Seedling Grapes from the original Vine planted in 1870, bearing fifty-six bunches of an aggregate weight of 100 lbs., exhibited by Mr. Bell, Clive House, Alnwick, commanded general admiration by their size and splendid quality.

COLLECTIONS OF FRUIT.

The splendid competition in the three classes formed in the aggregate a grand display, 124 dishes being staged, most of them of great excellence, some of superlative merit, and scarcely any that was not worthy of being included in a good dessert. In the class for twelve sorts of fruit, including two Pines, two sorts of Grapes, two Melons, and six other kinds of fruit, there were five competitors. The redoubtable Mr. McIndoe won the chief position with grand Gros Guillaume and Trebbiano Grapes, the four bunches averaging 9 to 10 lbs. each; Charlotte Rothschild Pine, 9 lbs., but not quite ripe; a fair Queen Pine, with good Melons, Peaches, Plums, and Pears, and rather small Nectarines, Apricots, and Figs. Mr. Goodacre was an excellent second with beautiful Pines, very fine Madresfield Court and Muscat of Alexandria Grapes, good Melons and Apples, Figs and Plums being rather small. Mr. Austin, gardener to Sir Greville Smythe, Ashton Court, Bristol, was an extremely close third. His Grapes were of superb quality, Pines rather small but in prime condition; Peaches, Pears, and Figs very fine; Melons, Apples, Nectarines, and Plums good. It was thought by many that the superior quality of the fruit of the two last-named exhibitors would have placed them higher, but they were overweighted by Mr. McIndoe's grand Grapes. The last-named gardener—the premier exhibitor in one of the best fruit shows that has ever been seen—was also awarded two Veitch Memorial medals and £10 for the best collection of fruit and the best black Grapes in the Exhibition.

There were five competitors also in the class for twelve sorts exclusive of Pines, and not more than two sorts of Grapes. Mr. Hunter

of Lambton Castle won the chief position here with highly superior Muscat of Alexandria and Black Alicante Grapes, bunches from 3 to 4 lbs., and berries large and excellently finished; also capital dishes of Peaches, Nectarines, Melons, Plums, and Figs, and good Apples and Pears. Mr. Dickson, Mount Melville, St. Andrews, was placed second with Muscat Grapes of high quality and very good Black Hamburgs, Peaches, Nectarines, Melons, and Figs of good dessert quality, but not of striking excellence. Mr. McKelvie was third with heavy and fine Black Hamburg and Muscat Grapes, good Melons, three fair dishes of Peaches, one of Nectarines, two of Plums, and one each of Figs and Apricots of average merit.

Twelve dishes, exclusive of Pines and Grapes.—Seven excellent collections were staged, Mr. McIndoe being placed in the first position with McIndoe's Premier and Best of All Melons, both good; excellent Negro Largo and Brunswick Figs, Kirke's and Jefferson Plums, Louise Bonne of Jersey and Beurré d'Amanlis Pears, Royal George Peaches, Belle Magnifique Cherries, and Hemskerk Apricots. Second Mr. Williamson, gardener to J. H. Rigg, Esq., Tarvit; Peaches, Nectarines, and Plums being very fine. Third Mr. P. W. Fairgrieve, Dundeld, an excellent third, Ickworth Impératrice Plums being splendid, and Kirke's, with Peaches and Melons good. Mr. G. Barrie, gardener to J. Fletcher, Esq., of Saltown exhibited a very fine collection. Mr. Brunton, Gilmerton, Drem; Mr. Kerr, gardener to W. Scott Kerr, Esq., Sunlaws, also staged excellent fruit in this excellent class.

PINES.

The display of these was by no means extensive nor strikingly meritorious. In the class for two plants in pots bearing ripe fruit, Mr. Calderhead, The Gardens, Wemyss Castle, Fife, secured the first position with average examples; Mr. McIntyre, The Glen, Innerleithen, being second; and Mr. Westcott of Raby Castle third, who exhibited what was represented as a twin plant, two fruits having issued from a crown of Smooth Cayenne that had been damaged, the second, a sport—Charlotte Rothschild? This is certainly remarkable, if there has been no mistake. In the class for two Smooth-leaved Cayennes Mr. McIntyre, so far as we could learn, was the chief prizewinner; for two Queens, Messrs. Calderhead, Johnstone, and McIndoe; for Charlotte Rothschild Mr. Goodacre; and for any other sort Mr. McIndoe with Prince Albert. Owing to displacement or non-attachment of cards we were unable to ascertain satisfactorily the results in some of the Pine classes.

MELONS AND FIGS.

Melons.—About seventy fruits were staged, many of them very good, and few inferior; by far the finest exhibition of Melons seen this year. In this green-flesh class, Mr. McIndoe was first with a beautiful example of Best of All, 3 to 4 lbs.; Mr. Maule, gardener to J. C. Hope Vere, Esq., Lasmalayan, second with Colston Bassett, 2 to 3 lbs.; and Mr. Elphinstone third with Hero of Lockinge, 2 lbs. Best scarlet-fleshed—first, Mr. McKelvie with Bloxholm Hall, well netted, and weighing about 3 lbs.; second, Mr. McIntosh, gardener to Col. David Milne Home, Esq., M.P., Paxton House, Berwickshire, with a smaller fruit of the same variety; third, Mr. Watson, Stirling, with Christian's Favourite. Mr. Pratt exhibited his seedling Melon Hawkstone Seedling, which was highly commended by the Judges, the variety that was certificated at Manchester last year.

Figs.—Eight very fine dishes were staged. First, Mr. Boyd, Calender Park, Falkirk, with Brown Turkey; second, Mr. Wallis, Keele, with White Ischia; third, Mr. Heggie, gardener to the Dowager Duchess of Northumberland, with Osborne's Prolific.

PEACHES AND NECTARINES.

Peaches.—Twelve dishes of twelve remarkably fine fruits were placed in competition, but as a rule they were rather deficient in colour owing to the dull and wet season in the north. Mr. A. McMillan, gardener to W. McBraire, Esq., was first with large fruits unnamed, but resembling Princess of Wales; Mr. Young, Edinburgh, second with Walburton Admirable; and Mr. McLeod third with Noblesse. For dishes of six Peaches, first, Mr. McLeod, Stirling, with Lord Palmerston of immense size; second, Mr. Patterson, Torrie Gardens; and third, Mr. Calderhead, both with Royal George, thirteen dishes being staged.

Nectarines.—Mr. E. George, gardener to J. W. Boord, Esq., Sussex, secured the first position with twelve fruits with Victoria; Mr. Gilbert, Burghley, closely following with the same variety, and Mr. Murray third. Seven dishes were staged. For dishes of six Nectarines.—These were poorly shown, a second prize going to Mr. Patterson.

Apricots were small, the best being Moorpark from Gilmerton Gardens. Plums also small, the prizes for three dishes going to Messrs. Short, Brunton, and Williamson, following in the order named.

PEARS AND APPLES.

Pears.—Six Jargonelles.—First, Mr. Short, Hummersknott, with very fine fruit; second, Mr. L. Dow, gardener to Sir David Baird, Bart., Newbyth—ten dishes. In the class for six Pears, in two sorts exclusive of Jargonelle, the first prize went to Mr. Fraser, Upper Hall, Ledbury, with Beurré d'Amanlis and Bon Chrétien. Collection of Pears, twelve sorts, two of each, ripe or unripe.—Mr. Austin, Ashton Court, was the premier exhibitor of excellent fruit, followed by Messrs. Williamson and McIndoe in the order named—six compe-

titors. As scarcely any of the Pears were ripe it is not necessary to give their names. In the class for six heaviest Pears Mr. Brotherton, Tynninghame Gardens, won the chief prize with Calebasse Grosse, the six fruits weighing 5 lbs. 13½ ozs.

Apples.—Collection of dessert Apples, two each of twelve varieties, ripe or unripe.—Mr. McIntosh, Paxton House, had the chief prize with generally green and late fruit—thirteen competitors. Mr. McIndoe staged an excellent collection of twelve baking Apples, and secured the position with which he is well acquainted—first. Lord Suffield was admirably shown by thirty exhibitors, the prizes going to Mr. John Blackie, Viewforth House, Leith; Mr. Brunton, Gilmerton, and Mr. Hunter, Lambton. Thirteen dishes of Stirling Castle were staged, the prizewinners being Mr. Edgar, gardener to James Cleland, Esq., Crossgar; Mr. Matheson, gardener to Wm. Tod, Esq., Glenesk, and Mr. Kay, gardener to Sir J. L. Foulis, Bart., all with moderate-sized fruit. Ecklinville Seedling was represented by a fine class of twenty dishes; the successful competitors being Mr. Gellatly, Mr. Sharp, Priorswood Gardens, Melrose, and Mr. Bowman, gardener to Lord Deas, Pittendreich, all staging excellent examples of this good Applc. Ribston Pippin Apples were green, and most of them small. Mr. Edgar staging the best, also the best Blenheim; Mr. Brunton having the best King of the Pippins. For a dish of the heaviest Apples Mr. Williamson was first with Warner's King; Mr. McIndoe second with Gloria Mundi; and Mr. Galloway, gardener to the Earl of Minto, third with Warner's King. A fine class.

Gooseberries were fresh and fine. Mr. Lornie, gardener to B. F. Hall, Esq., Dunglass, having the best. Red and White Currants were also good.

Beauty of Moray Apple exhibited by Mr. Webster was certificated as a free-bearing variety; the branches submitted being quite wreathed with fruit. It is below medium size, flattish, with rather prominent ribs, colour yellowish green. Messrs. J. Cheal & Sons, Crawley, Sussex, staged a very fine collection of fifty Apples and forty Pears, Brockworth Park being very fine; also excellent examples of their new Melons Paragon and Crawley Perfection. Messrs. James Veitch & Sons, Chelsea, staged 200 dishes—140 of Apples and 60 of Pears, all grown in their nursery at Southill. It was a magnificent display, and fully merited the extra prize that was awarded. An extra prize was also worthily granted to Messrs. Cheal. A handsome collection of about seventy varieties of Apples and Pears was also exhibited by Mr. Barron from the Royal Horticultural Society's Gardens at Chiswick. Some of the Apples were especially fine.

Exotic Fruits.—Mr. Muir, gardener to R. C. M. Talbot, Esq., Margam Park, South Wales, secured the chief prize with twenty dishes of the Citron family beautifully arranged with foliage of the trees and flowers—Orange blossom. Mr. McIndoe was second with Oranges, Lemons, Bananas, fruits of the Egg Plant, Capsicums, and Tomatoes. Why not Grapes? It was a very attractive collection, and merited its position.

Table of Fruit.—For the best table of fruit, 10 feet by 5 feet, there were only one exhibitor—Messrs. J. Boyd, Bayne, & Co., Prince's Street, who were awarded the first prize. The table contained a very good collection of fine samples, especially hardy fruits, such as Apples and Pears. Stirling Castle Apple was large and fine. The whole of the Pears being of French growth were large, and in every respect all that could be desired.

Vines in Pots.—Messrs. Lane easily won the prizes in both the Black and White classes with Foster's Seedling, bearing twenty bunches, some of them nearly a pound in weight, and fine berries; and Black Hamburg of the same number of bunches and quality—splendid examples of culture. In the Black class Mr. Gellatly was second with Mrs. Pince, bearing good bunches of fine well-coloured berries, and in the White class with Muscat of Alexandria bearing nine bunches.

Fruit Trees in Pots.—Mr. Murray, gardener to T. L. Learmouth, Esq., Polmont, was placed first with fruitful Pears and Plums, followed by Mr. McIntosh, Paxton House; the first especially being satisfactory examples of culture.

Much discussion has ensued on the question of comparing the fruit at this Show with the great displays of the past. Has the Show been equal to that of 1875? With the exception of the two marvellous bunches of that year the present show of Grapes is generally regarded as superior, as it is probably the most extensive that has ever been seen; but when we take the fruit as a whole and note the few yet fine Peaches, the small (in size and numbers) Nectarines, and not fine Plums, with the less fine Apricots and by no means extensive display of hardy fruits—when we consider all these facts, then it becomes difficult to say that the present Show, grand as it was, was the finest exhibition of fruit that has been seen in this country. We think we could name three that have excelled it, but not one as limited to the classes for the fruit of the Show—Grapes. An exhibition of this magnitude could not have been arranged in the limited time at disposal and the crowded building without some little inconveniences occurring. Until ten o'clock in the morning of the day of preparation the market was devoted to its ordinary purpose, the sale of vegetables; and it was only by active labour that the clearing and staging could be accomplished in readiness for the exhibits. On account of this pressure there was much shifting and moving of fruit especially, and waiting for positions by exhibitors. This was not, in the very nature of things, over-pleasant at the time; but during the night

all was reduced to order, and these—or at least those who obtained prizes—forgot the little difficulties of the night in the success of the morning.

PLANTS.

These generally were in good condition, both flowering and foliage, and on the whole the classes devoted to plants were well filled, and in some instances the competition was very keen. There can be no doubt that the Exhibition contained the finest display of plants ever seen in Scotland.

Stove and Greenhouse Plants.—In the class for ten stove and greenhouse plants, distinct, not more than five fine-foliage, there were eight entries. Mr. E. H. Letts, gardener to the Earl of Zetland, took the lead with grand well-flowered examples of *Allamanda Hendersonii*, *Ixora coccinea* fresh and well flowered, *Stephanotis floribunda* well bloomed, and a fresh healthy plant of *Erica Marnockiana*. The foliage plants in this collection were large and well-grown examples, including *Cycas revoluta* 7 or 8 feet in diameter, *Croton Weismannii* about the same size and well coloured, *Cycas circinalis* very fine, and a good *Croton Queen Victoria*. Mr. J. Patterson, gardener to J. Syme, Esq., Millbank, was a good second, having *Eucharis amazonica* 5 feet in diameter and well flowered, *Stative profusa*, *Erica Austriana*, *E. retorta major*, *E. McNabiana*, and *E. Irbyana*, his best foliage plant being *Stevensonia grandiflora*. Mr. A. Henderson, gardener to S. Clark, Esq., Paisley, was awarded the remaining prize, having a good *Cycas circinalis* and *Erica Marnockiana*. For six plants in flower Mr. J. Patterson took the lead, and staged really good plants of *Erica tricolor Wilsonii*, *E. Irbyana*, *Stative profusa*, and *Clerodendron Balfourianum*. Mr. A. Paul, 111, Gilmore Place, Edinburgh, was second with large well-flowered plants of *Clerodendron Balfourianum* and *Stative profusa*. Mr. J. Souza, gardener to Sir H. J. S. Stewart, Bart., first for a single specimen in flower with a wonderful plant of *Pancreatium fragrans* having over a dozen flower spikes; Mr. J. Robertson, gardener to J. Still, Esq., Spring Bank, Stirling, second with a well-flowered *Lapageria rosea* on a trellis fully 7 feet high; Mr. J. Shearer, gardener to D. McGregor, Esq., third with a fair plant of the same variety. There were eleven entries.

In the nurserymen's class for twelve stove and greenhouse plants introduced since 1879 Messrs. Ireland & Thomson, Edinburgh, were the only exhibitors, and staged a very choice collection, including *Croton Archibaldii*, a well-coloured and effective variety; *C. Weismannii superba*, much denser in habit than the ordinary *C. Weismannii*. *Croton Holdsworthii* was also good, *Adiantum Victoria*, *Dracæna Wilsonii*, *Nepenthes Masteriana*, *N. Williamsii*, *Anthurium Waroquanum*, *A. Veitchii*, and *Asparagus plumosus*.

Groups.—In the nurserymen's class for the best table of plants 30 feet by 6 feet for quality and effect there were four entries, which caused the Judges considerable difficulty. Their decision placed Messrs. Ireland & Thomson, and Messrs. Clark & Co., Carlisle, equal first, and the Horticultural Company (John Cowan), Garston Vineyard, Liverpool, third. This, however, gave much cause for complaint, the first-named being well to the fore, and staged a remarkable group of very fine plants. Those placed equal were certainly arranged lighter than those from the Vineyard, but were not of equal quality. These plants were arranged on tables about 2 feet 6 inches from the ground, and sloped gradually from the centre to the sides. The collection staged by Messrs. Ireland & Thomson contained *Nepenthes Henryana*, *N. superba*, *N. Outramiana*, *Sarracenia flava*, *Darlingtonia californica*, *Anthurium Veitchii* with grand foliage, *A. Andreanum* with fifteen flowers, *Croton Princess of Wales*, *C. Lord Chelmsford*, *Croton Thomsonii*, a grand new variety; *Cypripedium niveum*, *Saccolabium Blumei majus*, a good variety with two spikes; *Cypripedium Sedeni*, *Odontoglossum Alexandræ*, *Alocasia Thibautiana*, intermixed with Ferns, Palms, *Amaranthus tricolor*, *Nertera depressa*, small *Ixoras*, and Ferns for edging the group. Those from Messrs. Clark & Co. contained three rows of Palms down the centre, and small plants of *Crotons*, *Abutilons*, and *Cyperus alternifolius* grouped round them, with small *Crotons* rising out of a groundwork of small Ferns. The third-prize collection was similar, the style of the first-mentioned, and contained many well-grown comparatively new *Crotons*, *Dracænas*, Palms, and a number of small Orchids.

In the corresponding gardeners' and amateurs' class for a group 20 feet by 5 feet there were five entries. These were arranged on the opposite side of the Exhibition to the previous class. Mr. A. Paul, and Mr. J. Hammond, gardener to Sir Wilfrid Lawson, Bart., Brayton, Carlisle, were awarded equal first, the former for quality and the latter for effect. The first-mentioned contained a good number of Orchids, the best being *Odontoglossum Skinnerii*, *Cypripedium selligerum*, *C. Stonei*, *Oncidium incurvum*, *Saccolabium guttatum*, and a number of *Masdevallias*, intermixed with *Crotons*, Ferns, Palms, *Ixoras*, and others. Mr. Hammond's group was very light and effective, its only fault being rather too many *Crotons*. Mr. J. McIntyre, gardener to Mrs. Pease, Woodside, Darlington, was the remaining successful exhibitor, and staged a very creditable collection of small decorative plants.

Orchids.—The display of these plants was not large, but those exhibited were in good health, and very well flowered. Especially noteworthy was a plant of *Renanthera coccinea*, with large branching spikes of bloom, each spike having between sixty and seventy flowers fully expanded. The plant was growing in a remarkably small pot, and was not more than 4 feet high, having three stems. This plant was green and in luxuriant health, and did not present the appear-

ance of having been ripened in full sun to bloom it, as is practised by many. In the nurserymen's class for eight plants Messrs. Ireland and Thomson were the only competitors, and were awarded the first prize for healthy well-flowered plants of *Cypripedium longifolium*, with three spikes of bloom; *Phalænopsis amabilis*, one large spike; *Vanda tricolor*, and *Cattleya guttata*. In the corresponding gardeners' and amateurs' class for six plants Mr. A. Paul took the premier award with neat healthy well-flowered plants of *Odontoglossum grande* with fifteen flowers; *Saccolabium Blumei majus*, one large spike, good variety; *Cattleya Harrisoniæ*, *Miltonia spectabilis*, *Lælia elegans*, and a good *Vanda suavis*. Mr. A. Gov, gardener to Mr. McDonald, Woodlands, being a close second, having good *Lælia crispa*, *Odontoglossum Pescatoria*, *O. Alexandræ*, both good varieties; and *Masdevallia ignea* (Meadowbank variety). Mr. A. McGregor third, having a fair plant of *Oncidium macranthum*, *Cypripedium Lawrencianum*, and *Odontoglossum grande*. There were four entries. For three plants there were six competitors. Mr. J. Curror, gardener to G. Douglas, Esq., Eskbank, was well first with a grand form of *Miltonia spectabilis*, *Cattleya gigas*, one fine spike, and a grand plant of *Oncidium incurvum*. Mr. McGregor was placed second, his best plant being *Odontoglossum grande*; Mr. A. Paul third, with a very fair lot. For one plant, Mr. D. Paton, gardener to Mrs. Tait, Melrig, Galston, was well first with the grand plant of *Renanthera coccinea* before alluded to. Dr. Patterson, Bridge of Allan, second with a fine form of *Cattleya Dowiana*; the plant was not large, and bore one spike with two flowers. Mr. J. Curror was the remaining successful competitor.

Ferns.—In the nurserymen's class for six distinct sorts, excluding Tree Ferns, Messrs. Ireland & Thomson were the only exhibitors, and were awarded the first prize for good plants of *Adiantum cuneatum*, *A. formosum*, *A. Flemingii*, a grand plant; *Pteris serrulata cristata*, *Gleichenia rupestris*, and *Neottopteris australis*. In the corresponding gardeners' and amateurs' class for six Mr. W. Anderson, gardener to P. Niel Fraser, Esq., was well ahead with the finest pan of *Goniophlebium subauriculatum* I have ever seen exhibited with fronds fully 8 to 12 feet long, with about two hundred fronds, and shown to advantage by being suspended from the gallery. *Lygodium scandens* was also very fine, as well as *Pteris serrulata cristata*. Mr. Souza was second, having a large plant of *Davallia Mooreana*; and Mr. S. Graham third with a grand plant nearly 4 feet through of *Davallia Tyermannii*. There were six entries. In the nurserymen's class for two Tree Ferns, stems not less than 4 feet high, Messrs. Dickson & Co. Waterloo Place, Edinburgh, took the lead with *Dicksonia antarctica*, the remaining four classes being devoted to gardeners and amateurs. For three *Gleichenias* Mr. A. Henderson, gardener to S. Clark, Esq., was first with very fine plants, and Mr. A. Paul second. For four *Adiantums* there were five entries, and the exhibits throughout were good. Mr. J. Curror took the lead, having a beautiful specimen of *A. gracillimum* and *A. farleyense*. Mr. C. Cumming was a very close second with equally good plants but slightly smaller. For one *Todea superba* there were four entries, all being good. The prizetakers were Messrs. A. W. Anderson, R. Greene, gardener to Miss Falconer, Falcon Hall, in the order as named.

Mr. Lyall, gardener to Sir A. Hope Pinkie, was first with six British Ferns, large specimens. Mr. A. Kerr, gardener to W. Scott Kerr, Esq., second with small but fresh plants. For twelve plants in 6-inch pots Mr. A. W. Anderson first with conspicuous plants of *Blechnum cristatum*, *Asplenium septentrionale*, and *A. lanceolatum microdon*; Mr. J. Cumming, gardener to Miss Ivory, second with small but equally neat little plants. In the class for three Filmy Ferns Mr. A. W. Anderson, 19, Pilrig Model Buildings, took the lead with *Trichomanes reniforme*, *T. radicans*, and *Hymenophyllum demissum*. There were eight entries for two pots or pans of *Lycopodiums*, and Mr. J. Cossar, gardener to G. F. Melville, Esq., took the lead with grand plants, and was followed closely by Mr. S. Graham.

Dracænas.—These were not numerously shown, but the plants staged were of good quality in the three classes devoted to them. Messrs. Ireland & Thomson were the only exhibitors in the nurserymen's class for six plants. The best were Rossi, very good; Barroni, *Salmonea*, *gigantea*, *amabilis*, and *Illustration*. In the corresponding gardeners' and amateurs' class for six plants in pots not less than 9 inches in diameter Mr. W. Pratt, gardener to Lord Hill, Hawkstone, Salop, was well ahead with neat, sturdy, well-coloured plants of *Robinsoniana*, *Berkleyi*, very fine; *Regina*, *Mooreanus*, and a good specimen of *Anerleyensis*. Mr. A. Henderson second, having a good *Chelsoni* and *Denisonii*. There were seven entries in this class. The prizetakers for three plants in 6-inch pots were Messrs. G. Atkinson, gardener to T. Ford, Esq.; S. Graham, gardener to H. Rose, Esq.; and J. Robertson. Five entries.

Crotons.—These were generally good, especially those shown by Messrs. Ireland & Thomson in the nurserymen's class for six plants. The varieties were *fasciatus*, a conspicuous variety and well coloured; *Princess of Wales*, fair; *majesticus*, good; *Princ of Wales*, very fine; *Queen Victoria*, and a grand plant of *Etna*. In the corresponding gardeners' and amateurs' class for four plants Mr. McIntyre won chief honours with a large specimen of *Andreanus*, *Weismannii* well coloured, *majesticus*, and *Queen Victoria*. Mr. J. Hammond followed, having a good *Weismannii* and *majesticus*. Mr. R. H. Reid third with much smaller but clean healthy young plants. For two plants Mr. G. Atkinson, gardener to F. Ford, Esq., first with *Weismannii* and *Disraeli*; Mr. Hammond second, and Mr. R. M. Reid third. There were four entries for one plant, Mr. A. Scott, gardener to Lord Elphin-

stone, first with a well-grown plant of *Weismannii*; Mr. Hammond second with *Queen Victoria*, and Mr. McGregor the remaining prize with *Disraeli*.

Fine-foliage Plants.—The prizes given for four plants were well contested, seven or eight competitors staging plants. Mr. J. Hammond, Brayton, took the lead with *Bonapartea juncea filamentosa*, *Croton majesticus*, and *Dasylyrion glaucum*. Mr. A. Henderson and Mr. R. M. Reid, gardener to D. Wright, Esq., Ravenswood, followed in the order as named.

Palms.—In the class for four Palms of sorts Mr. S. Graham took the lead with grand examples of *Latania borbonica* large and healthy, *Kentia Fosteriana*, and *Seaforthia elegans*; Mr. J. Hammond second with *Cocos Weddelliana* and a good plant of *Phoenix rupicola*.

Table Plants.—The competition in the two classes devoted to these plants were keen, some twenty exhibitors staging plants, and the whole were highly creditable to the exhibitors. The plants were arranged down the centre of the fruit table. In the nurserymen's class for twelve plants Mr. J. Samson, nurseryman, Kilmarnock, took the lead with grand even plants of *Dracæna superba*, *D. elegans*, *C. otton interruptus*, *C. angustifolius*, *Geonoma gracilis*, *Pandanus Veitchei*, and *Aralia gracillima*; Messrs. Sutherland & Co., Victoria Nursery, Lenzie, a close second with similar plants. In the gardeners' and amateurs' class for six plants Mr. J. Gordon was first with a grand assortment of neat well-coloured plants of a very suitable size for the purpose for which they were shown, and were similar in variety to those mentioned above; Mr. W. Lowe, gardener to John Paton, Esq., being a good second; and Mr. McIndoe third with very even plants.

Ericas.—The plants shown in the classes devoted to these plants were very satisfactory, being in the best of health—fresh and profusely flowered considering the lateness of the season; they, however, were as good as could have been expected two months earlier. Mr. J. Patterson, gardener to J. Lyme, Esq., was well first with *E. obbata*, *tricolor Eppsii*, and *retorta major*; Mr. E. Boyes second, having a good *Marnockiana*; and Mr. A. Henderson third, having a very neat plant of the same variety. For one plant Mr. E. Boyes took the lead with *Marnockiana*; Mr. J. Smith, gardener to Miss Anderson, second with the same variety; and Mr. A. McGregor third with an equally large but not so well-flowered plant.

Liliums.—These were only of fair quality, but a number of competitors entered for the prizes given. Mr. S. Graham was well first with very fair plants, and Mr. A. Paul second. For one plant of *Lilium auratum* Messrs. G. M. Clure and W. Duncan, gardener to Mr. A. O. Riddell, Craig Lee, were the prizetakers in the order as named.

Zonal Pelargoniums.—The competition in the classes devoted to these were keen, and the plants exhibited were in fair condition and moderately well bloomed with trusses of a large size. Mr. J. Matheson, gardener to W. Tod, Esq., Glenesk, took the lead and staged a good plant of John Gibbons with very large trusses of flower. Mr. J. Cumming was a good second, having larger but not such well-bloomed examples. Mr. J. Wood, gardener to Dr. Hutchinson, obtained the remaining prize. There were five entries in the class for four variegated varieties. Mr. S. Graham was placed first with well-grown plants which were well coloured; Mr. R. Johnston second with very neat plants, and Mr. J. Souza third.

Fuchsias.—Some of the plants shown in the classes devoted to these plants were large and profusely flowered. Mr. J. Ball, gardener to W. J. Menzies, Esq., Canada House, was first, followed closely by Mr. A. Clark and Mr. A. Henderson. For one plant the last-named exhibitor was again first.

Chrysanthemums were very well represented, and the competition was good and keen. For four summer-flowering varieties Mr. G. M. Turc, gardener to J. Milne, Esq., took the lead with well-flowered plants fully 4 feet in diameter; Mr. Smith, gardener J. T. Wilson, Esq., second; and Mr. Pearson, gardener to Lady Dundas, Beechwood, third.

Begonias.—These were not numerously shown, as the schedule only provided one class, which brought a collection from Messrs. Ireland and Thomson. The six plants staged by them were very creditable, of fair size, and really well flowered, the best being *Sedeni*, *Exquisite*, *Kallista*, *Oriflamme*, and *Vesuvius*.

Cockscombs were well shown, the combs being of large size and of superior shape. Messrs. T. Brown, gardener to C. McKirdy, Esq., Birkewood, and R. M. Reid, were the principal prizetakers in the order as named.

Vallota purpurea.—The schedule provided one class for this fine autumn-flowering plant, which brought six competitors, who staged remarkably fine specimens. The first plant was a remarkable specimen, having over thirty spikes of bloom. The premier award was obtained by Mr. R. Grossart, gardener to J. Buchanan, Esq., Eswald Road; the second-prize plant being very little behind, and was staged by Mr. J. McDonald, gardener to J. Younger, Esq.; and the third by Mr. R. Johnstone, gardener to F. Gibson, Esq., Woolmet.

Conifers were remarkably fine in the class provided for six plants in pots or tubs. The Lawson Seed Company took the lead with very large specimens in luxuriant health, and the golden varieties of *Yews* and *Retinosporas* of good colour. Messrs. Ireland & Thomson followed with rather smaller, but equally good plants in other respects.

CUT FLOWERS.

The classes devoted to these exhibits were well filled, and on the whole of superior quality. The Roses were remarkably fine considering the lateness of the season, those from Ireland being very far ahead, and many of the blooms were as good as could be expected much earlier in the season. For twenty-four distinct sorts Mr. H. Dickson, Belmont Nursery, Belfast, won with blooms of a large size, fresh, and of good colour; Mr. J. Smith, Stranraer, being placed second. In the gardeners' and amateurs' class for twelve blooms Mr. A. Hill Gray, East Ferry, was placed first with a very fair box, and Mr. J. Kidd, Huntley Place, second.

Gladioli on the whole were very fine, especially those shown in the nurserymen's class for thirty spikes, which was won by Mr. A. E. Campbell. A few of the very best were Horace Vernet, Ondine, Sylvia, Orpheus, Camille, and A. Brongniart. Mr. J. Service, Dumfries, was second with a fair lot, but not so neat as the former; and Messrs. Harkness & Sons third. In the corresponding amateurs' and gardeners' class for eighteen Messrs. J. Grey, Taylor, and A. Kemp were the prizetakers. Messrs. W. Kilgour, H. Sime, and J. Bald were the successful competitors for twelve spikes. Mr. Kilgour's collection of Gladioli was especially fine, and such handsome spikes are never seen in the south except from Messrs. Kelway and Son's nursery. Hollyhocks were only fair, and the prizes were withheld in the nurserymen's class for eleven spikes, while in the gardeners' and amateurs' class for seven spikes Messrs. D. Macfarlane, gardener to Sir R. Ray, Bart., J. Souza, and R. Johnstone were the successful exhibitors. For five spikes Messrs. P. Robertson, W. Henderson, and J. H. Campbell, Millfield, obtained the awards in the order as named.

Dahlias were well shown, and of the finest quality. In the nurserymen's class for twenty-four blooms Messrs. Harkness & Sons, Bedale, were first with grand blooms of James Cocker, Criterion, J. C. Reid, John Wyatt, Rev. Dr. Moffatt, and Rev. G. Goodday. Messrs. Downie & Laird followed closely with a very fine even assortment. In the gardeners' and amateurs' class for eighteen the prizetakers were Messrs. T. Hogg, gardener to T. Gordon, Esq., first, with a very good lot; Mr. W. Veitch, The Cemetery, Carlisle, second; and Mr. N. Glass, gardener to J. C. Bollon, Esq., third. Messrs. Simpson, Wyton, J. Pearson, and G. Wybar were successful for twelve blooms, all staging well. For twelve fancy Dahlias Messrs. W. Veitch, J. Stewart, and N. Glass obtained the awards. Messrs. Downie & Laird, Edinburgh, and J. Cocker & Sons, Sunnybank, Aberdeen, were successful in the nurserymen's class for twelve fancies. For twelve Phloxes Messrs. Downie & Laird took the lead, followed by Messrs. Dickson & Co., Edinburgh. The first-named exhibitor was also first for Pentstemons. For twelve hardy annuals Messrs. W. Henderson and H. Campbell were the principal prizetakers. Messrs. J. Menzies and J. Stewart were the leading prizetakers for Aster blooms, which need no further comment. Messrs. Grosset, J. Bald, and J. Sutherland were the leading exhibitors for bouquets.

TABLE DECORATIONS.

The prizes offered for a table 10 feet by 4½ feet, completely laid out for twelve persons and arranged so as to show the best means of utilising fruit and flowers in its adornment, brought only two competitors. Messrs. Todd & Co., Edinburgh, were adjudged the premier award, and Mr. James Horne, Polmont House, the second, but neither of the tables were elegantly or tastefully furnished. The first-prize table was too heavy in the centre for the size of the table, a small *Cocos* in the centre being plunged in a raised rather square bank of *Lycopodium*, from which rose nine small Palms about 6 to 8 inches above the moss. Quantities of *Adiantum cuneatum* fronds were dotted amongst the moss, as well as *Eucharis*, *Lapageria alba*, and other suitable flowers. From the top of the bank arched tastefully a number of spikes of *Odontoglossum Alexandræ*, and at each end of the table a vase of cut flowers and Ferns. Button-hole bouquets were inserted in each napkin. The fruit consisted of black and white Grapes, Plums, Figs, Melon, and a Pine. The arrangement would have looked well on a table double the size. The second-prize table was much the neater to our taste, and numbers capable of judging shared with us this opinion. A very different system was followed, in the centre being a small *Croton*, which was elevated in a suitable vase, and the base edged with moss laid on the cloth, and a number of scarlet berries. A similar arrangement with Ferns, flowers, and foliage *Begonias* was placed round the fruit, and other vases and dishes on the table. The material used was not so choice as on the first-prize table, but the arrangement was lighter and on the whole neater. Mr. Jenkinson, 10, Prince's Street, Edinburgh, also contributed a table laid out for eighteen persons, not for competition, which was good but rather formal.

VEGETABLES.

These were arranged on a side table placed along one end and up the side of the market place. They were admirably represented, an inferior dish being the exception, and high quality the rule. Taking the classes in the order of the prize list, the first is the basket of salads, of which six lots were shown, Mr. J. Muir, Margam, South Wales, being placed first with a well-arranged basket of all kinds of salads of very fine quality; Mr. Smith was second, and Mr. Bowman, Pittendriech, third, but in style of arranging and quality these were far behind the first-prize basket. Collections of vege-

tables numbered fifteen. Here again Mr. Muir was first with twelve splendid dishes of the following:—Defiance Celery, Pettigrew's Cardiff Castle Cucumber, Crossling's Glamorgan Tomato, Telephone Pea, Webb's Banbury Onion, Suttons' King of the Cauliflowers, Hollow Crown Parsnip, Snowball Turnip, Manhattan Potato, Carters' Champion Runner Bean, Muir's New Hybrid Marrow, and Intermediate Carrot—altogether a grand lot, not an inferior dish being visible in this tastefully displayed collection, each dish having its separate round basket. The second prize was awarded to Mr. McBean, Craigends, Renfrew; and the third to Mr. Brown, Abercorn, Perth, with highly creditable collections, their Leeks being remarkably good, as they also were in many of the other stands.

For twelve Onions there were twenty-seven competitors, Mr. Porter, North Berwick, being first; and Mr. J. Pringle, Edinburgh, second, with well-developed round bulbs. Fourteen lots of six Leeks were staged. First, Mr. A. Thomson, butcher, Kirkintilloch, with fine specimens as thick as one's arm for the length of 18 inches; second, Mr. Glass, Colbrook, with specimens only slightly inferior to the others.

Of twelve Tomatoes there were fourteen lots. First Mr. J. Ramsey, Fife, with fine specimens of the Drumlanrig variety, which weighed about 1 lb. each; second Mr. Mackinnon, Scone Palace, Perth, with the same variety, which is both good and beautiful.

For the class for four Savoys there were twenty-two entries. First Mr. R. Blair, Craigie House, with very large heads; second Mr. Thomson, Edinburgh, with samples of the same gigantic description; quality was left in the background here. In the four Cauliflowers' class seventeen exhibitors staged. First Mr. Gourling, Loanhead; second Mr. Bowman, both lots being good samples of Veitch's Autumn Giant. There were ten entries of four stalks of Brussels Sprouts. First Mr. C. Smith; second Mr. Curror, Eskbank, but those and all others were far from maturity. Four stalks of Celery—first Mr. Thomas Hogg, Cathcart; second Mr. Souza, both having fine samples of a red variety.

Ten braces of Cucumbers were staged, first Mr. D. Ross, St. Martin's; second Mr. Brown, Abercorn, the first with Telegraph and the second with Pettigrew's Cardiff Castle. Fifty pods of Peas, eighteen lots, first Mr. Williamson with Veitch's Perfection; second Mr. Forester, Ralemont, with good Telephones. Fifty French Beans, twenty-eight lots, first Mr. Hall, Kelso; second Mr. McLean, Maidstone. Potatoes were very numerous shown, and the quality as a rule was high.

Twenty-two collections of twelve varieties were shown. Mr. J. Culton, Castle Douglas, was first with fine clean even samples of the following varieties:—Schoolmaster, Climax, Snowflake, Beauty of Kent, Salmon Kidney, Scotch Queen, Porter's Excelsior, Mrs. Langtry, Queen of Whites, Challenger, and Beauty of Hebron. Mr. Blair was second, and Mr. Robertson, Jedburgh, third. In the class for six varieties Mr. Potter was first, Mr. Mackinnon, Melville Castle, Dalkeith, second, and Mr. Brewer, Ormiston, third with fine clean samples.

MISCELLANEOUS EXHIBITS.

These were very numerous and varied, and added materially to the effective appearance of the Exhibition. Mr. B. S. Williams, Victoria and Paradise Nursery, Upper Holloway, London, contributed a very fine group of choice stove and greenhouse flowering and foliage plants, including many Orchids, Ferns, and Palms all tastefully arranged together, a few of the most conspicuous being Begonia Williamsii, a fine white variety; Nepenthes superba, N. coccinea, Cattleya crispa superba, fine; Delabachia rupestris, grand table plant; Lælia elegans var. prasiata, Vanda tricolor, insignis, and many others. Messrs. J. Dickson & Co., Inverleith Nursery, Edinburgh, a similar group of plants, including many Zonal and Fancy Pelargoniums very tastefully arranged on a long narrow table. The Horticultural Company (John Cowan), Garston, Liverpool, had a similar group, but not quite such a large number of plants, also some good pot Vines. Messrs. W. Gordon & Sons, Coltbridge Nursery, had a fine group, including Tea Roses, Gardenias in small pots, Ferns, which largely predominated, intermixed with Rhodanthe Manglesii, which gave to the whole a very pretty effect. Messrs. T. Methven & Sons, Edinburgh, contributed a tastefully arranged table of plants, including many French and Fancy Pelargoniums; Messrs. Cunningham & Fraser Conifers, amongst which were associated Statice profusa and a number of an early white-flowering Chrysanthemum; Messrs. Dickson & Co., Waterloo Place, had a large collection of plants, with cut flowers and fruit trees in pots bearing fruit, out of which rose a number of large Palms and Tree Ferns, the effect being very striking. Messrs. Ireland and Thomson contributed cut Roses, Reses in pots, Conifers, intermixed with Hydrangea paniculata grandiflora and baskets of Heaths. This firm also had several other small exhibits. The Lawson Company, Edinburgh, exhibited a large number of choice Conifers in pots, which filled two large corners in the Exhibition, and were very effective. Messrs. Little & Ballantyne, Carlisle, had a remarkably fine group of choice Conifers in large pots and tubs, amongst them being a fine specimen of Pinus Balfouriana, said to be the largest specimen of this variety in the country. Messrs. Drummond Bros. contributed plants, wreaths, and bouquets. Messrs. Brotherstone and Munroe, Abercorn Nursery, Chrysanthemums in flower in small pots, and herbaceous cut flowers. Mr. King, gardener to G. H. Potts, Esq., staged a table of herbaceous and alpine plants in pots. Messrs. J. and A. P. Currie a large collection of London and Russell's vases suitable for Ferns. Messrs. Laing & Co., Forest Hill, London, sent a

large collection of single and double Begonia blooms, which were much admired. Mr. J. Forbes exhibited boxes of Pansies, Verbenas, and single Dahlias. Mr. T. Ware, Hale Farm, Tottenham, London, had a very large collection of single Dahlias, which included a pretty variety named Union Jack. Messrs. Downie & Laird sent a similar collection, also a number of bouquet kinds. Messrs. Roger McClelland & Co., Newry, Ireland, a table of curious plants, including a remarkable specimen of Trichinium Manglesii, with about thirty of its curious heads of bloom. From the Botanic Gardens also numbers of large Palms, Nepenthes, and many other interesting plants were sent.

Populus alba Bolleana, a strong-growing sort with large leaves, was exhibited by Messrs. Dickson & Co., Waterloo Place, Edinburgh, also Coleuses with wonderful foliage, one Laurence Goldring, 6 by 5 inches, yellow, broadly banded with red. Mr. Ware, Tottenham, exhibited a collection of single Dahlias, and Messrs. Ireland and Thomson several boxes of fresh Roses.

Croton Thomsoni.—Messrs. Ireland & Thomson showed a number of young plants of this fine distinct Croton, for which a first-class certificate was awarded. This variety has leaves about 1 foot in length and about 2 inches wide, and are of a true golden colour slightly dotted with green. From the appearance of the plants exhibited this grand Croton will colour well in a very small state, and in consequence prove a useful variety for decoration as well as exhibition. They also exhibited a seedling named Sir Garnet Wolseley, which resembles C. Disraeli, but appears to colour much better.

Everything was ready for the Judges at 6 A.M.; and previous to opening the Show to the public the excellent and appropriate custom of allowing gardeners to have a private view for a shilling each proved by the numbers who entered the Show how this privilege is appreciated. The Exhibition was opened to the public by the Lord Provost.

On the evening of the Show a grand banquet was held at the Waterloo Hotel under the presidency of Bailie Hall, supported by Canon Hole and Messrs. W. Thomson and Methven. The Rev. Canon was, as usual, most entertaining, and received the customary ovation. Mr. Thomson was equally cheered at the close of his excellent speech—historical, practical, and suggestive; and Mr. D. T. Fish concluded an extraordinary address by making a Bishop—the Bishop of Horticulture. The genial Canon rose to acknowledge his translation, and with befitting modesty covered his face with his napkin, but when he unveiled he did not appear to have been weeping. Other eloquent speeches brought to a close a most enjoyable evening. The unfailing courtesy and open-handed hospitality of our Scottish friends have been just what might have been expected, hearty and genuine; and many hundreds of visitors have greatly enjoyed their brief sojourn in the Queen of the North, beautiful Edinburgh.

ASPARAGUS AND GLOBE ARTICHOKE.

Asparagus.—This has been much blown about this season. The growths from each root were tied to a stake early in the season, but in many cases this was not strong enough to resist the gale, and the stems were broken. This check to the main stems has caused many of the young buds to start into growth, and good bundles of grass might be cut now; but the stems have been fixed again, and will remain so until they have ripened, when it is hoped the roots and crowns may be no worse for their rough treatment. Many do not stake their Asparagus stems, but allow them to be blown any way or lie down, so as to completely hide the surface of the soil, consequently the roots have no chance of maturing. Plenty of space between the roots and branches is a certain way of insuring a good supply of strong Asparagus.

Globe Artichokes have been unusually good this season; last winter being mild was much in their favour. We cut the first heads in April, and we have scores coming on yet. The secret of inducing them to produce so long is to cut all the heads off before they become too old. When they are allowed to flower the stems wither and cease to emit side growths. This removing of the old produce is necessary to prolong the bearing of all vegetables, and ought to be generally practised.—M. M.

FOSTER'S SEEDLING GRAPE.

THE variety is well known to most cultivators as a useful white Grape, but I think that it is not so generally cultivated as it ought to be, and that no collection is complete without it. Few Vines have a stronger constitution or greater powers of bearing heavy crops, and when well grown the bunches are large, well set, and of excellent shape. The berries are large, too, and when fully ripe are a most beautiful amber colour.

I have heard complaints made by some that it was deficient in flavour, and at best only a third-rate Grape. My experience of it is quite the reverse. With me it is sweet, richly flavoured, and of first-rate quality. The bunches, if properly thinned, are compact, the berries are firm and not easily bruised or broken, and can be

sent long distances without the slightest injury if properly packed. To add to its other good qualities, the bunches hang for a long time before shrivelling.

As to its fruitfulness, perhaps it would interest some of your readers to know the results obtained from Vines that were struck from buds here in the spring of 1880, and planted out permanently 4 feet apart in May of the same year. The house in which they are planted in a large span-roofed vinery, some 60 feet long, 24 feet wide, and about 20 feet high, divided in the centre by a glass partition.

The first year the Vines grew to the top of the house, made strong canes, and ripened them thoroughly to the core. In the autumn they were pruned to within 5 feet of the ground; the wood was as hard as a bone, and scarcely any pith discernible. In the following spring, 1881, the Vines were a long time in starting, and broke weakly at first, but after a little they advanced vigorously, and three canes were allowed to grow from each to the top of the house. My idea for allowing the three canes to grow was that they would not be so strong if I only left two—the number required to fill the house—and that they would break better the following year on that account. By the autumn they made very strong canes again, and ripened the wood well. At pruning time one of the canes on each Vine was cut off close to the main stem, except the end Vine, which required the three to fill the space. The remaining canes were allowed to retain from 5 to 6 feet each of young wood. In the spring of the present year the Vines broke well, showing from two to three large bunches on each shoot. These were reduced to eight or nine bunches to each Vine, which they ripened and finished off thoroughly, many of the bunches weighing 3 and 4 lbs. each, and none of them less than 2 lbs. The Vines have made strong canes this season, which are thoroughly ripened and as brown as a nut, and none of them seems the least weakened or exhausted by finishing their heavy crop.

In conclusion I might say, a dry border, and a cool and dry atmosphere is recommended by some noted Grape-growers when the fruit is ripe. For my own part I prefer to water the borders when they need it, and I never allow them to get dry at any time. The house is regularly damped down in good weather whether the fruit is ripe or not. It is seldom that ever I have a decayed berry in the house, and they do not shrivel up so fast under this treatment. The leaves keep much longer green and healthy than they do when treated otherwise.—A. PETTIGREW, *Castle Gardens, Cardiff.*

[A fine well-shaped 4 lb. bunch of Foster's Seedling accompanied this communication. The berries are full-sized, admirably finished, and the best flavoured examples of this variety we have yet tasted.]

ON the opening day of the INTERNATIONAL EXHIBITION that was held at Edinburgh last week (which is fully reported in our present issue) the weather was very fine, and we learn that upwards of 15,000 visitors attended the Show. On the second day, which was very wet, especially in the afternoon, when the rain fell heavily and continuously, about the same number visited the Exhibition. The charge for admission during the whole of the first day was 1s., the second day 6d., and the amount received during the two days was about £1060, which is in excess of the amount derived from the great show of 1875, when the prices for admission were higher.

— ON the second day of the above Show Messrs. Smith and Dewar sold by auction at their rooms in George Street, Edinburgh, collections of specimen ORCHIDS, the property of Dr. Alexander Paterson, Bridge of Allan, and of Mr. F. Sander, St. Albans. There was a large attendance of buyers, including some from the Continent, and good prices were realised. In Dr. Paterson's collection was a magnificent specimen of *Cattleya labiata* Warneri, measuring 27 inches across, with seventy-nine bulbs, sixty of which had leaves, sold for 45 guineas. This plant was in the first collection of Orchids belonging to the late Provost Russel of May-

field. The following are among the highest prices obtained for plants in this lot:—*Cattleya labiata*, 39 guineas; *C. Trianae* Symei, ten bulbs, all with leaves, 39 guineas; *Dendrobium thyrsoiflorum* Walkerianum, 37 guineas; *Aerides Fieldingii*, 25 guineas; *C. Mendeli*, 27 guineas; *Lælia anceps* Barkeri, 26 guineas; *Vanda tricolor* Patersonii, 21, 16, 14, 13, and 10 guineas; *Vanda suavis*, 21, 19, and 16 guineas; *Lælia superbiens*, 20 guineas; *Anthurium Schertzerianum*, 20 guineas; *Angræcum sesquipedale*, 18 guineas; *Aerides suavissimum*, 17 and 11 guineas; *Odontoglossum vexillarium*, 15 guineas; *Epidendrum prismatocarpum*, 11 guineas; and *Chysis bractescens*, 10 guineas. The proceeds of the sale amounted, we believe, to about £800—a wonderful result when it is considered that the plants were grown in three small houses not averaging more than 20 feet long and 12 feet wide, and were merely duplicate plants, removed to afford space to the smaller and remarkably healthy specimens with which the houses are quite sufficiently filled now. Thus Orchid-growing, besides being a delightful and fascinating pursuit, is also profitable when carried out intelligently and well. Dr. Paterson employs no gardener, but pots and attends to the plants himself as agreeable recreation, a woman being engaged to keep them clean. Clean they certainly are and healthy, and, as the owner avers, are more easily grown than greenhouse plants. We shall probably be able to publish more relative to Dr. Paterson's collection and garden generally on a future occasion.

— MR. E. S. DODWELL, Stanley Road, Oxford, being unable from ill health to remain in active business, announces that he intends devoting himself entirely to the cultivation of the CARNATION AND PICOTEE. He deeply feels the kindness and consideration shown to him in former years, and in offering the present selection of fine seedlings to his friends and fellow-lovers of floriculture he refers with proud satisfaction to the high position the varieties raised by him have already taken—a position he confidently believes which will be sustained and enhanced by those now offered. The complete set will be sent for £4 4s., or twelve pairs, Mr. Dodwell's selection, for 50s. All transactions cash. Post orders are requested to be made payable at the General Post Office, Oxford. Cheques crossed "London and County Bank, Oxford." Purchasers of quantities will be very liberally dealt with. Plants ready from the first week in October. A priced list of the varieties is issued.

— MESSRS. OSBORN & SONS, The Sunbury Nurseries, S.W., forward us sample of labels made of a patent material called LINCRUSTA, resembling indiaruber which they state is "impervious to wet, frost, or any kind of weather. A piece of the material has been exposed now for about two years, and is still intact. They can be produced at 4s. per hundred, showing the names in relief, and in the various forms of hanging labels." They appear to be adapted for the purpose; the names being shown in relief are easily read; and if they prove really durable their utility cannot be too highly estimated.

— "B. E." writes respecting SCHIZANTHUSES:—"It is not yet too late to sow a few seeds of *Schizanthus pinnatus*, *S. retusus*, *S. retusus alba*, &c., for spring decoration. The seed should be sown in pots or pans, placed in a cold frame, and kept close for a few days until the seedlings appear; afterwards free ventilation is needed. The plants will be ready to prick off in about a week or ten days after they appear. Prick them singly into thumb pots and pot on as they require it, the final shift being into 5 or 6-inch pots. Winter the plants in a dry pit or house free from frost. Treated in this way *Schizanthus* are extremely useful for spring work. Sweet Scabious, Cornflower (*Centaurea Cyanus*) treated the same way are also very useful."

— WE are desired to state that at the recent PRESTON SHOW the only first-prize silver medal given for seeds was awarded to

Messrs. Sutton & Sons, Reading. Messrs. Primrose & Co., Sheffield, also state that the greenhouses glazed on the Eclipse system exhibited by them were highly commended by the Judges.

— MR. KIRK, of The Gardens, Norwood, Alloa, N.B., complains to us that in the report of the Edinburgh Show in a contemporary he is spoken of "as a new competitor," and requests us to correct this in our "first number." For the last six or seven years Mr. Kirk has been a constant exhibitor, and in our pages his name has frequently appeared as such; notably, on September 26th, 1878, we find the following—"Mr. Kirk has taken good prizes in Scotland this year, and it redounds much to his credit as a cultivator that all the Grapes he has exhibited have been grown in a house 30 feet long." Mr. Kirk was then gardener to Mrs. McKie, Castle Douglas.

— WRITING respecting the VAGARIES OF FLOWERING PLANTS, "G. O. S." observes:—"I have a Cyclamen in my open garden unprotected. Three years ago it flowered freely in March, the year after it was planted out. For two years it has not bloomed at all; but this year the last week of August it has thrown up a very pretty head of flowers. Some Primulas which would have bloomed in spring, but were injured by snails, are now flowering, and in a neighbour's garden the Gentianella is in bloom."

— MESSRS. JAMES CARTER & Co., High Holborn, announce that they will shortly send out the scarlet-flowered CLEMATIS COCCINEA, a very distinct and rare species of the *C. tubulosa* type. They have issued a coloured plate, which fairly represents the characters of the species, a single flower of the full size being very truthfully depicted. The species is not, however, as they state, unknown in this country, as it has been in cultivation at least ten years.

— A CHIPPENHAM correspondent writes in reference to the FRUIT CROP:—"The Apples, save in very sheltered gardens, are few, almost *nil*, also those few are blighted, spotted, and misshapen. I have no crop except on the Ecklinville Seedling trees; these are many and fine, and altogether good. Peaches are absolutely flavourless."

— MR. GEORGE RUDD, Undercliffe, Bradford, Yorkshire, sends us some blooms of the WHITE CLOVE CARNATION VIRGO, which has been in cultivation several years, and is justly esteemed for the excellent form and purity of the white rounded petals; in fact it is equally as good as the white Clove Carnation we recently noticed in these columns.

— MESSRS. STUART & MEIN, Kelso, send us some fine blooms of their STRIPED FRENCH MARIGOLDS, the excellence of which indicate a thoroughly good strain. The blooms are of moderate size but very full, and most richly coloured with orange and maroon.

THE SUNFLOWER.

FANCY verily has strange freaks and plays odd tricks. We can understand how she (for Fancy must be a lady) may alter dresses, blowing out or collapsing skirts as she chooses; now putting out something really graceful, and bringing in something by all the laws of art utterly hideous. But can she, does she, dare she bring in and bring out a flower, making a flower the rage? To a Peter Bell "a Primrose by a river's brim" may be only a "yellow Primrose" and nothing more, but surely educated and refined minds ought not to be influenced by fashion in regard to that "thing of beauty" a flower, "that thing of beauty and joy for ever."

However, so it is, and so it has been, and will be no doubt to the end of time. Let the flower at the head of this article bear witness. Until a year or two since in the garden of some very out-of-the-way farmhouse you might have seen uprising by a wall a Sunflower or two; and my lady or miss driving past, if they could see such vulgar things, would have said in scorn, "What horrid

staring things those are!" They would not have called them flowers. But now Sunflowers are in bonnets; Sunflowers are in the hand, or pinned on the dress, or are laid on the book board at church by hands wearing No. 6, or even dainty No. 5½ gloves. Enter houses, there amid some pretty white fluffy stuff in the drawing-room hearth are Sunflowers, larger higher up; while on the hearthstone itself lie a perfect flooring of little Sunflowers like shells on the seashore; while on brackets around in some queer, dingy, ill-shaped, but æsthetic-coloured bit of crockery stands up a Sunflower.

In modern books on gardening, published, say, between the years 1856 and 1876, the very name Sunflower does not occur. The flower had died out, and its name ceased to be printed—nay, if it had become spoken of at all it was as an agricultural plant. I have searched through twenty volumes of this periodical, and find it mentioned once or twice as affording by its dried seeds good food for fowls, and that it gave a gloss to their plumage. In so recent a number as that for September 2nd, 1875, there is an answer to a query in these words to one "H. W."—"We presume you wish to cultivate the Sunflower for its seeds." Hark ye to this, O ye æsthetic people, wild disciples of Mr. Oscar Wilde! "These are to be sown early, the beginning of April being most desirable, and the crop will be fit to harvest" (only the seeds thought of) "at the close of August or early in September. Drills 30 inches apart should be drawn, and the seeds disposed evenly or drilled in about an inch deep. The plants should be kept clean and thinned to 18 inches distance apart." All this from a purely agricultural or poultry view. Then there is a quotation in the number for September 19th, 1872, to the effect that, according to the "Argentine Republic," Sunflowers are strongly recommended because the flowers afford the best material for wax and the best honey; the petals yield a valuable dye; the seeds give 50 per cent. of oil, excellent for cooking and illuminating purposes, while they are also a superior food for poultry and for cows, increasing the flow of milk. The bottom of the calyx may be used for food in the same way as the Artichoke, which it closely resembles. The leaves may be used as food for animals, or made into good smoking tobacco; while the bark affords material for the manufacture of paper. All these very practical uses, but decidedly not æsthetic.

Then there is another answer to a query to "A CONSTANT READER" in vol. xxv., some nine years ago, in which the Sunflower is described as having the power to purify the air—that its leaves make excellent fodder, and the stem, being rich in saltpetre and potash, makes good fuel, and the seeds are good for fowls. Some wise man, if I remember aright, advocated Sunflowers being grown solely for fuel. Methinks I hear some æsthetic damsel exclaim to her beloved flower, "Oh! to what base uses thou mayest come." Still the fact remains, that until quite recently the floral beauty of this high-growing plant was absolutely ignored.

It was always a beautiful flower, though its charms have been unnoticed so long, and now it is regarded favourably in a laughably exaggerated sense.

Let me next trace a little the history of the Sunflower as connected with English floriculture. John Parkinson, an apothecary of the sixteenth century, sufficiently distinguished to be employed in that capacity, mentions the Sunflower among his list in a chapter entitled, "Of the Nature and Names of Divers Outlandish Flowers," and his directions in regard to raising the Sunflower are as follows:—"It requires to be raised early in a hotbed, or they never perfect their seed, but in very hot summers;" upon which Mr. Johnson makes this remark—"Either these plants have changed their habit or our climate is much ameliorated." But among writers I have come across, Gerard, A.D. 1597, writes in his "Herbal" most fully of the Sunflower. In a pretty, taking, old-fashioned way he speaks of "the Flower of the Sun or the Marigold of Peru," dividing it into two sorts: No. 1, Flos Solis major, and No. 2, Flos Solis minor. Of the former he says, "The Indian Sun or the Golden Flower of Peru is of such stature and tallness that in summer, being sown of a seed in April, it hath risen up to the height of 14 feet in my garden." This giant sort appears to have produced but one flower of "the size of 16 inches across." The stalk was the bigness of a man's arm. Gerard prettily and accurately says, "The middle part of the flower is made as it were of unshorn velvet, or some curious cloth wrought with the needle, which brave work, if you mark it well, it seemeth to be an innumerable sort of small flowers resembling the nozzle of a candlestick broken from the foot thereof."

Of the Flos Solis minor Gerard says that it was altogether lower and the leaves more jagged and very few in number; that the flower is smaller, and I infer there were more than one. "The thrummed middle part is blacker than the last described."

To come now to the present time. In cottage gardens, unin-

fluenced by importations of improved seed, the sort most common is the tall one with one large flower. In other gardens there are to be found tall ones somewhat improved, and lesser ones. The general division after a reference to height is dark-centred and light or brown-centred, the darker as a rule being the smaller. People differ as to their liking for dark-centred and light-centred. I own I prefer the latter; I think the colours, though less contrasted, are purer, clearer, and brighter. But there are improved varieties; these are from seeds procured from the larger nurseries. They are not more than 4 feet in height, stout-stemmed and strong. The first centre flower is decidedly large, but unlike the old tall variety is not the only flower, but from side branches come other flowers; perhaps six, eight, or even ten may be seen in bloom at once. These improved sorts are both dark-centred and light or yellow-centred, and these are flowers worthy to be grown at the back of a border in any garden however large or aristocratic, and are in every way superior to the old varieties. There is yet another sort to be had—the double, which comes direct to us from Texas; the seed not ripening in this country, or, if it does, producing a very inferior small flower. The plants are tall, and have only one flower each, quite double, and of course without the usual centre. At the best they are a sort of coarse-handsome, at the worst they are poor in the extreme.

The revival of these flowers in their improved condition is a gain to gardening and gardens. Giving them a very high place as flowers is absurd. They deserve a better use than their ancestors of forty years back, which were planted to hide an ugly old wall or a pigstye. The Sunflower mania is owing quite as much to the farce called "Patience," intended to ridicule the æsthetic movement, as to the æsthetic movement itself.

Let me transcribe one little passage more from old Gerard. "The buds before they be flowered may be boiled and eaten with butter, vinegar, and pepper." "Oh, fie!" an æsthetic would say. "Boiled! I scream, I faint! Boil and eat what I desire to live up to!" In conclusion I would say, Only cultivate the improved varieties, and plant them in suitable situations. They are handsome flowers and deserve to be grown, but not in hundreds, anywhere.—WILTSHIRE RECTOR.

POTATO WHITE BEAUTY OF HEBRON.

BEAUTY OF HEBRON has now proved itself to be a most valuable early market Potato, as in produce it is quite equal to the Early Rose, whilst in colour, shape, and precocity it is decidedly an advance on that variety. A crop of Beauty of Hebron grown this season between Scarlet Runner Beans produced more than double the weight, and making in the market only one-fourth less in price than Myatt's Prolific Ashleaf grown under similar circumstances. The value of Beauty of Hebron may now be enhanced, as this excellent variety has given off here a white or rather colourless (if the want of red or purple on the skin may be so termed) sport, the sport in all other respects possessing the good qualities of its parent; and as the difference in value in the market between a white and coloured Potato is considerably in favour of the white variety, it follows that the white Beauty of Hebron is likely to be an acquisition. Anent coloured Potatoes, it has often been a matter of wonder to me why our principal raisers aim so much at the production of pretty-looking coloured varieties, and why the authorities and judges at exhibitions give so much encouragement to colour; for as yet, so far as quality, production, and power of resisting disease go, no coloured Potatoes are equal in these respects to our best colourless sorts. Why, too, are new sports from Potatoes practically excluded from the International Potato Society's Show, seedlings alone being recognised as worthy of being certificated? I have a suspicion that some of the best new American sorts are but sports from Early Rose, and yet are equally as good and more distinct than some seedlings.—T. LAXTON, *Bedford*.

AUTUMN NOTES ON RASPBERRY CULTIVATION.

AMONGST small hardy fruits few if any are more useful than Raspberries, and none can be relied on for a crop of fruit with more certainty. In the majority of seasons, when Gooseberries, Currants, and Strawberries are injured by early spring frosts, Raspberries invariably escape through coming into flower later in the season. When in luxuriant health a long succession of fruit can be obtained; in fact, I have been gathering for nine weeks, and could still gather a quantity of small fruits suitable for cooking purposes, but prefer sacrificing these for the sake of next season's crop. Where Raspberries are judiciously managed the young canes not required for producing next season's crop of fruit have been thinned, so as to admit light to those remaining.

The early thinning of the growths is as important in the cultivation of the Raspberry as with the Vine or Peach, and if unnecessary growths are allowed to grow until the end of the season they rob those left of both strength and light. The thorough maturation of their canes is an important object if a large crop of really fine fruits is anticipated. The freedom with which the Raspberry fruits annually under the most unfavourable circumstances is often the main cause for not treating them liberally and well.

If the old fruiting canes are not already removed it should be done without delay, and the young canes retained made secure to the stakes or wires employed for supporting them. A wire trellis such as that used for espalier trees of Apples and Pears, is more suitable for supporting Raspberries, and decidedly preferable to the use of stakes. A suitable trellis will not need so many wires as is necessary for the above-named fruits, three moderately strong wires being ample. The first should be about 18 inches from the soil, the second in the middle, and the third near the top. The height of the trellis will depend upon the length of cane to be left; here they are left from 6 to 7 feet. The canes to fruit next season should now be permanently secured to the wires, so that no more tying will be needed until the following autumn. With a trellis of this description, and the canes early thinned, they have every chance of ripening well before winter; but when stakes only are employed it is not wise to permanently tie them now, for if tied closely together they have no chance of ripening.

Where pruning the top of the canes is practised it is a good plan to carry out the operation some time before the foliage falls, say towards the end of the present month. By so doing the buds plump wonderfully, and with free exposure to light fruit much nearer the ground than would otherwise be the case. Where early autumn tying and pruning can be done it will be found a decided advantage towards aiding the winter work, especially if very severe weather follows.

The soil here is very light, resting on a sandstone formation, and the variety I have found to succeed the best is Cutbush's Prince of Wales. It is a strong robust grower, and produces abundance of large well-flavoured fruits. In a season canes are produced 12 and 13 feet long, and would undoubtedly in more suitable soil attain even a greater length. This excellent variety does not appear to be generally known or grown, but from my experience of it here it is admirably adapted for a light soil. It is easily recognised, having almost a smooth stem with a few black spines, the stem being very silvery in autumn.—LANCASTRIAN.

NEPENTHES MASTERSIANA.

PITCHER PLANTS appear to be gaining increased popular favour, and they are now regarded as something more than mere vegetable curiosities, for better cultivation, the introduction of handsome species, and the raising of numerous distinct hybrids having attracted much attention to the genus, proved also the beauty of such plants in a decorative point of view. In consequence we find hundreds of gardens where Pitcher Plants are grown now for every one that could have been named fifteen or twenty years ago, and further interest is added to collections by the diversity of forms, colours, and markings which distinguish the various species, varieties, or hybrids now in cultivation. The gradations in form and size are very striking. From pitchers 2 or 3 inches long to the gigantic *N. Rajah* there is every intermediate stage; and in form there is a similar range, some being long, thin and tubular, others cylindrical, and still others nearly globular. The colouring varies from green to the deepest red, nearly black, either what may be termed self-coloured or spotted, mottled, or streaked. An excellent idea of all these characters, their diversity and attractiveness, may be gained by inspecting Messrs. J. Veitch & Sons' extensive collection of *Nepenthes* at Chelsea, and a better time than the present could not be chosen for the purpose. The houses devoted to these plants now present quite a unique spectacle, the vigorous growth and thousands of pitchers hanging in all directions being suggestive of a tropical thicket. The pitchers, too, are finely coloured, and it is doubtful if there has ever been a finer display of these plants at Chelsea or elsewhere.

Prominent amongst the newer forms is that represented in the woodcut (fig. 44)—*Nepenthes Mastersiana*, which is one of the most distinct, richest-coloured, and freest-pitchering hybrids yet raised. A row of some twenty or thirty plants in small baskets, each about 5 or 6 inches square, indicate the above characters admirably, most of these comparatively small specimens having six to nine pitchers each, of an exceedingly deep red hue, very neatly formed, and clustering closely round the sides of the baskets, the leaves being shorter than in many other forms. *N. Mastersiana* is a hybrid, having been raised by crossing

N. sanguinea with *N. Khasyana*, or *N. distillatoria* as it is known in most establishments. It is curious that from the seed thus obtained two distinctly coloured forms should be raised, both exactly similar in shape and habit, but one much darker than the other, the lighter form possessing more of the true *N. sanguinea* colour. Both, however, bear the name given above, and it is not easy to distinguish them except in the tint of the pitchers.

GROS MAROC GRAPE.

No one can see the splendid crop of this handsome black Grape in Mr. Rivers' Nursery at Sawbridgeworth without being impressed with a desire to add the variety to their collections. The Vines

there are thoroughly established, being four or five years old, and thus the character of Gros Maroc has been well proved, and fairly too, for they are about the centre of a mixed house, and cannot thus be subjected to any special treatment as to soil and temperature. Almost every lateral produced a bunch, and some more than one. The bunches are hanging quite close enough together, and are of good size, while the berries have a noble appearance by their pleasing form and magnificent colour; the quality also is very refreshing.

In habit of growth Gros Maroc must be described as robust, in this respect bearing a close resemblance to Gros Colman. The Vine, therefore, needs more space for development than kinds of the Black Hamburg character, and the rods should be quite 5 feet

Fig. 44.—*NEPENTHES MASTERSIANA*.

apart. If worked on the spur system a firm yet good border would seem to be advisable, netted with fibres close to the surface. Firm short-jointed wood would then be produced, essentially fruitful in its nature; but a light rich border deeply penetrated by long thong-like roots would induce luxuriant growth, long-jointed, and probably fruitless, especially if closely pruned.

It is not unlikely that the oldest system of all of training and pruning Vines would be particularly adapted to this variety—the extension system, not in its modified forms, which have passed for extension of late, but the system in its integrity. This consists in

preparing a young cane and fruiting it its entire length, training another growth beside it at a proper distance for the next year's crop, cutting out the "old," yet only two-year-old, fruiting cane entirely after the crop has been secured. This is extension whether the main stem of a Vine is trained horizontally along the front of a house or not, so as to produce canes for covering the entire roof. The so-called extension of the present day is a combination of the ancient or modern, or a number of rods trained from the same stem, and each spurred as in the case of Vines restricted to one rod. With the old extension or "long rod" system there are no

spurs. It was just the Raspberry plan—cutting out a cane when it has done its duty, and having another of equal length and strength ready for taking its place.

In all probability the Gros Maroc would produce more and finer fruit by this plan well carried out than any other; at least, so young canes that have not been shortened much at Sawbridge-worth indicate. It is, according to the same rule, proving excellent for fruiting in pots, every eye showing a bunch, and the berries set freely. This is not the experience of Mr. Rivers alone, but Vines have been fruited satisfactorily in many places this year, for the variety has become widely distributed, and its further increase will only be limited by the supply of plants.—J. W.

EARTH-CLOSET MANURE.

WHEN I see such implicit reliance placed on Dr. Voelcker's analysis and estimate of the above where the earth has been passed only once through the closet, as has been done by your correspondent "INQUIRER," I think it well to state the following experience of my own. I had such a closet constructed for my use, and it was kept exclusively for that. Fully as much earth was used each time as is said by Mr. Moule in his pamphlet to be sufficient; if anything else, rather more. The vault being on a slope was perfectly dry, and, being of a good size, the contents were allowed to accumulate for a year, and then used immediately after being taken out as manure for the Cabbage tribe, the quantity being rather less than that of mixed farmyard manure used for other plants of the same kind in the same quarter of the garden. The difference in growth and colour was markedly in favour of those grown with the contents of the closet, so much so as to strike the eye at once on entering the garden. I should say that, bulk for bulk, the latter was worth double the amount of dung, and this, too, although it was necessarily of the poorest kind, as I am a vegetarian.

Some unknown circumstance must have vitiated and rendered valueless Dr. Voelcker's experiments to elicit such an opinion on earth passed once through the closets as that quoted by "INQUIRER"—viz., "The earth of an earth-closet manure after it has been once used is not more valuable for manuring purposes than in its original dry and sifted condition." This is obviously wrong upon the face of it, and suggests either that there was something wrong with the analysis, or that a trick had been played on the doctor.—A. BOYLE.

A USEFUL PLANT FOR THE MANSION.

To have a continual supply of flowering plants for the rooms and corridors of a large mansion requires a careful selection as well as a considerable amount of forethought, for there are many plants which are very beautiful, and would last a long time in a conservatory where the conditions are favourable, but would begin to lose some of their beauty immediately were they placed where there is comparatively little light. In this class are Fuchsias and Pelargoniums, especially the former, four days at most being as long as they can be expected to look really well. For this reason, although Fuchsias are extremely well fitted in appearance for the lofty corridors I have to furnish, my culture of these plants is confined to the outdoor garden, and the varieties consist mainly of the old Riccartoni and what is now known as *F. gracilis*.

The plant above all other flowering plants for retaining its beauty in the mansion is *Campanula pyramidalis*. Mention was made in last week's Journal of this plant for outdoor ornament, but no one who has ever seen it done well indoors will be quite content with its appearance as it grows outside. True, it will flower when grown in the mixed border as a biennial, and is prettier than many other things often found there; but we do not see a tenth part of its beauty under such conditions, and when I add that I have repeatedly had it in full beauty in the corridors for six weeks at a time, and sometimes it has remained good enough for the purpose for fully two months, it will be readily conceded that it is well worth the little trouble required to grow it. Some twenty or thirty years ago this *Campanula* used to be grown well in many places, and I have seen noble specimens of it 9 or 10 feet high with several stems clothed in beauty to within a foot or two of the ground; but such plants, although they look very grand in a lofty conservatory, are scarcely suited for my purpose, and those I grow are from 5 to 7 feet high, and have but one stem. Grown in this fashion they are not pyramidal, but are a simple cordon of flower nearly from base to summit. They are in 7 and 8-inch pots, and the flowers stand out to a little more than that width, completely hiding the stem and leaves. The prevailing colour I should say is lavender blue (I am writing from memory, and am not quite sure of the particular shade); but a few plants

of the white variety are grown, and they form a pleasing contrast. They look best in groups of ten or a dozen together. I have two large oval-shaped vases which hold that number, and nothing that we can ever put in them has a nobler appearance.

Their culture is very simple. A few seeds are sown in a pot in spring at the time of sowing half-hardy annuals. They are potted off into 4-inch pots after the bedding plants are turned out, and kept in a frame till they become established, when they need no further protection till winter arrives. About the beginning of August they are shifted into pots a size larger, and they remain in them till the flower stems commence to show in the following spring, when they sometimes have another slight shift; but they do not always get it, and it is surprising what a stem a plant will throw up, even when confined to a 6 or 7-inch pot, if a little stimulant is given occasionally.

The only difference required in the treatment to grow the larger-sized plants I have spoken of is to give them more root room during the first summer; but when treated in this way they do not often flower before the third year, and I have seen many plants die during winter when they have been treated rather too liberally. They appear to be safest with a small root space and very plain fare till the flower stem appears, and then they require to be treated liberally. A little frost will not hurt them, a cold frame with a little litter thrown over it during the severest weather being ample protection. The time of flowering is August and September, just immediately preceding the *Lilium speciosum* when grown outdoors, and which I have to succeed them. Common garden soil, or such as ordinary bedding Pelargoniums are potted in, suits them very well.

The common Canterbury Bell also well repays for indoor culture. I saw some which Mr. Iggulden had lifted during autumn and potted, which were flowering rather early in spring, and the white variety especially was extremely pretty. The hose-in-hose varieties—*C. calycanthema*—would doubtless do the same should any of your readers prefer them to the simple-flowered varieties.—WM. TAYLOR.

LIFTING PEACH TREES.

THE notes that have recently appeared on this subject are sound and seasonable. The summer is certainly the best time for moving Peach trees, after the crops have been gathered and a good length of growth made. It is a good plan also to replant Peach trees frequently, as a great mass of fibres then form, and whatever food is given to the trees is quickly appropriated and turned to profitable account.

Mr. Bardney grows Peaches rather extensively and certainly well at Norris Green, a long range being devoted to the trees. He thinks no more about digging up and replanting a Peach tree in July than of potting a Pelargonium. Trees are lifted every year—that is, if in his judgment they need it, and that his judgment is sound the trees testify. The fruit he obtains is of the first size, quality, and colour; in fact, trees having such clean dark green foliage, medium-sized short-jointed wood, with bold buds, bushy roots, and a good border, could not fail to produce high-class fruit; but that the colour should be so good during a season that has been remarkable for its dull and wet days in the Liverpool district was scarcely to be expected, and it would seem to follow that, given really healthy trees, fruit will colour better without sun than it will with abundance of sunlight and an absence of health. If this were not so Grapes would scarcely finish so well as they admittedly do in some of the dullest and wettest districts in the north-west of England and in Scotland.

A very able gardener, describing Mr. Bardney's practice in a contemporary, refers to the Norris Green Peach trees as the largest he has ever seen moved. This shows that he has only inspected the small battalions; but while the trees are not remarkable for their size they are not pigmies, and if they were as large again they could be moved with equal safety, as, to use a very familiar expression, they are "used to it." The roots are masses of fibres, and the surface of the borders a network of feeding roots. This is the secret of the hard short-jointed wood and fine fruit; this the secret, too, of the fine fruit that Mr. Coleman grows at Eastnor, and of that also grown by everybody else who produces heavy crops of heavy, well-coloured, and highly flavoured Peaches and Nectarines.—S. N.

BRIGHTON AUTUMN SHOW.

SEPTEMBER 13TH AND 14TH.

AN excellent Show was this, favoured by fine weather and thronged with visitors, who found many features of especial excellence. The Pavilion, with its suite of large lofty rooms with glass doors opening

on to the lawn, is admirably suitable for the purpose, and to the plant groups a large tent was devoted on the lawn.

Plants.—For culture and arrangement these were alike excellent. Many were used in the rooms to impart relief and variety to the stands of cut flowers and fruit; but the tent was wisely devoted solely to plants, huge stove and greenhouse plants occupying the centre, with mixed groups and Ferns along the sides—not in formal angular outlines, but in softly rounded or semicircular groups. For the silver cup given by the London and Brighton Railway Company for twelve stove and greenhouse plants Mr. W. Balchin gained an easy victory. All of them were good, but the most noteworthy was a grand *Gleichenia rupestris glaucescens*, a *Croton majesticus* perfect in colour and form, *Allamanda Wardleana*, *Latania borbonica*, a pair of *Cycas revoluta*, and a fine *Stephanotis* very full of bloom. Mr. Balchin also contributed many fine large plants not for competition, which were most useful in imparting the requisite finish to the long central group. For four plants of the same class Mr. Balchin was again first, his *Dipladenia amabilis* being especially remarkable for the large size and abundance of its lovely flowers. Mr. E. Meachen, gardener to C. Armstrong, Esq., was second, and for a grand pair of *Erica Eweriana* and *E. retorta* major merits special mention. Mr. Meachen was first in groups of four confined to Sussex gardeners; Mr. W. Huggett, gardener to Dr. Jeffery, Eastbourne, being second; and Mr. H. Townshend, gardener to Captain Thompson, Withdean, third.

Miscellaneous groups arranged for effect, and each occupying a space of 150 square feet, were highly meritorious. Here Mr. Balchin took first honours with a magnificent group, the colouring charmingly varied—an undergrowth of *Coleus* and *Maidenhair* Ferns, out of which sprang dwarf Palms, a few *Crotons* very highly coloured, and in the background a pair of *Lilium auratum* with the flower spikes half concealed by the gracefully pendent leaves of loftier Palms. Mr. W. Miles, West Brighton Nurseries, was second. Smaller groups of 75 square feet were also good. Mr. E. Meachen was first with a nice bright group in which some *Crotons* and *Amaryllis* were noteworthy; and Mr. J. Turner, gardener to Major Way, Wick Hill, was second with a tasteful arrangement.

To those general favourites, Ferns, an unusually prominent position was given, three prizes being offered for groups of 200 square feet, and a like number for groups of 75 square feet. In the first class Mr. J. McBean, florist, Cooksbridge, won the silver cup presented by James Ashbury, Esq., with an arrangement of great beauty and remarkable originality, for, instead of the stereotyped mound or undulating slope, the surface of his group was boldly broken into a series of miniature hills and valleys, the loftiest hill being in the background, two somewhat lower standing out near the front, one crowned by a noble *Adiantum farleyense*, and the other by an equally fine example of *A. cuneatum*; still lower was a mound of *A. gracilis*, and between these giants were charming undulations of *Maidenhair* Fern. It was really amusing to hear the exclamations of delight from the crowd, and Mr. McBean's triumph was enhanced by the fact that he had three formidable opponents in Messrs. W. Miles, W. Balchin, and the veteran E. Spary, to whom second, third, and extra prizes were awarded in the order in which they are named. An extra prize was also awarded to Mr. H. Vincent, gardener to Mr. J. Hart, Keymer. For the smaller groups Mr. Turner, gardener to Major Wick, was first; Mr. E. Meachen second, and Mr. H. Townshend third.

Of other groups *Fuchsias* were very good, Mr. W. Trangmer, gardener to H. Davey, Esq., Grand Parade, Brighton, being first for well-arranged plants of various useful sizes, all fresh and well bloomed. Mr. Meachen was second. Mr. T. Martin, gardener to J. G. Langham, Esq., Eastbourne, and Mr. W. Hills, florist, Steyning, were respectively first and second for pretty groups of *Coleuses*. Zonal *Pelargoniums* were fine and in excellent condition. For scarlet varieties Mr. H. Townshend was first, Mr. Meachen second, and Mr. J. Spottiswood third. The same three exhibitors divided the prizes for other colours of Zonals, and for Gold and Silver Tricolor *Pelargoniums*. For six double Zonals Mr. Balchin was first, and Mr. Huggett second.

Of other plants Tuberous-rooted *Begonias* were present in considerable numbers, and in great beauty. Mr. R. Pannett, florist, Crawley, had a first-prize group containing upwards of sixty plants—small but very full of large finely formed flowers with colours of many shades of pink, crimson, scarlet, yellow, and white. Mr. W. Margetts was second. Mr. Margetts was first for four plants, and Mr. W. Huggett second, his Mrs. G. B. Howes, a fine scarlet variety, being especially noteworthy. For variegated plants John Warren, Esq., was first with some highly coloured *Crotons*, a magnificent *Anthurium crystallinum*, and a good *Pandanus Veitchii*. Mr. Meachen was second.

Cut Flowers.—Six prizes were offered in two classes for twenty-four varieties of cut flowers in bunches. These were very much admired, nine stands in all being shown, all the flowers being choice kinds cut from stove or greenhouse plants. Mr. Balchin's stand was best, but excellent stands were also shown by Mr. T. Gilbert, nurseryman, Hastings; Mr. W. Archer, gardener to G. S. Gibson, Esq., Saffron Walden; and Mr. E. Morse, nurseryman, Epsom. Some good *Roses* for this time of year were shown. Messrs. Paul & Son, Old Nurseries, Cheshunt, for three trusses each of forty-eight varieties, the flowers of Duke of Teck, Comtesse de Choiseuil, Duchess of Bedford, and Perle de Lyon being really excellent. Messrs. Mitchell of Piltown were second, and Mr. W. Virgo, nurseryman, Guildford, third. For

twenty-four varieties, three trusses of each, Mr. Balchin was first, and Mr. W. Seale, Vine Nursery, Sevenoaks, second. Mr. Balchin had excellent trios of Marie Baumann and A. K. Williams. Messrs. Paul were again first for twelve Teas with Alba Rosca, a lovely white; Perle de Lyon, yellow, full, and finely formed flowers; Catherine Mermet, Etoile de Lyon, lovely pale yellow; Madame Lambard, Niphotos, Madame Camille, Souvenir de Paul Neyron, Souvenir d'un Ami, Marie Guillot, Bouquet d'Or, and Comtesse de Nadailac. Mr. A. Slaughter, Jarvis Villa, Steyning, was second, and Messrs. Mitchell third. For twelve Perpetuals Mr. A. Slaughter was first, and Mr. R. Spinks, gardener to Lady H. Somerset, was second. Dahlias, Asters, Phloxes, and *Gladiolus* were all well represented. Single Dahlias, especially those by Messrs. Keynes, were deservedly admired, for they were very lovely, comprising shades of white, yellow, rosy purple, striped pink, and scarlet.

Of table decorations Mrs. Seale, Vine Nursery, Sevenoaks, had the best three stands, of which the leading characteristics were lightness with fulness, no crowding, and the colours well blended. Mr. W. Miles was second, and Mr. J. R. Chard, florist, Clapham Common, third. Twenty-three bridal and ballroom bouquets were shown, most of them meritorious, though some were sadly crowded. They were shown in pairs, and Mrs. H. H. Moore, florist, Chichester, was first with excellent bouquets—light, full, and elegant; the leading flowers in the bridal bouquet being *Eucharis*, *Stephanotis*, and *Tuberose*, and in that for the ballroom *Eucharis*, Blush *Roses*, white *Lapageria*, and scarlet *Bouvardia*. Mr. W. Balchin was second, and Mr. W. Miles third. Eight funeral wreaths were shown on black velvet, Mr. W. Brown, florist, Richmond, being first with a magnificent wreath some 2 feet in diameter; Mr. Balchin being second, and Mr. H. H. Moore third. *Eucharis amazonica* was much used in every wreath. Wild flowers were shown in a neat and creditable manner, Mrs. M. Dixon, Searles, Fletching, being first with upwards of a hundred varieties. Mr. W. Hills was second, and Mr. J. Budd, Worth, Crawley, third.

Fruit.—Grapes were generally well coloured among black varieties, but the bunches were of medium size. Muscat of Alexandria was shown in considerable quantities, most of the bunches being large; but almost all were deficient in colour, a striking exception being the two first-prize exhibits of Mr. T. Chatfield, gardener to T. Holman, Esq., East Hothly, whose bunches were small but of a rich uniform golden amber that was highly creditable. Other prizewinners for Muscats were Messrs. C. Goldsmith, S. Ford; and for black Grapes first prizes to Mr. S. Ford and Mr. J. Austin; seconds to Mr. G. J. Warren, gardener to Mrs. Hankey, Balcombe Place, and Mr. J. Spottiswood; and third to Mr. W. Huggett. Melons.—Mr. W. Martin, Blackstone, Woodmacote, was first with a small Hero of Lockinge. Other fruits were inferior, excepting some fine examples of Shepherd's Perfection exhibited by Messrs. Cheal & Sons, nurserymen, Crawley, who also had a creditable exhibition of forty dishes of Apples. Good examples of Warner's King, Nelson's Glory, Dumelow's Seedling, Reinette du Canada, and Lord Suffield were also shown by other exhibitors. Among Pears were several good dishes of Bcurré d'Amanlis, Mr. H. Townshend gaining a first prize with it. Very few Peaches were shown. The best were some fine Barringtons by Mr. R. Biggs, High Beeches, Crawley; and Mr. McLeod, gardener to The Speaker, Glynde Place, had some Lord Palmerstons, to which a third prize was awarded. The best Plums were Golden Drop and Green Gage, first prize being awarded to both in different classes, the one to Mr. J. Staples, Chipstead, Sevenoaks, and the other to Mr. J. Burtenshaw, gardener to Mr. Cartwright, Albourne Place. A first-prize dish of fine Brunswick Figs came from the Speaker's garden, Mr. T. Butler, North Lancing, being second, and Mrs. M. Wood, Shoreham, third, both for the same kind. Only one collection of twelve dishes of fruit was exhibited by Mr. C. Goldsmith, gardener to Mrs. Lambert, Bletchingley, who had excellent examples of Black Alicante and Muscat of Alexandria Grapes, and a handsome Melon well netted.

THE APPLE CROP.

THE Apple crop generally appears very small this year, and nearly all well-known varieties have failed; yet there are solitary instances where trees are heavily laden, while the majority of their neighbours are fruitless. Some of the late-flowering kinds, of which Court Pendu Plat is an example, are conspicuous for their absence of fruit, while comparatively small bushes of the same size and age of Lord Suffield, Cellini, Cox's Pomona, and Sturmer Pippin are heavily laden with large fine fruit. The first two have never failed with me during the past five years, and could not be in a much worse locality in any part of the country. The first-named is too well known as a free, useful, early kitchen Apple to need any recommending; but this variety with all its good properties is useless for planting where the soil is wet and cold. I am well acquainted with localities in Lincolnshire where fruit generally does well, but Lord Suffield fails to give satisfaction, and the trees after they have been planted a season or two canker badly. During the winter of 1880 and 1881 hundreds of trees of this variety were most severely injured, and it is questionable if ever they recover. Here the soil is well drained from the rock being very near the surface, and consequently of too

light a nature for fruit trees generally, yet it is in every way suitable for the first two varieties. They could not flourish and fruit with greater freedom in any good soil or locality. It is strikingly evident that these two varieties of Apples are at home when planted in a light dry soil, for the majority of other fruit trees in a dry season become infested with red spider, while these retain a healthy vigorous appearance, and are not subject to the attacks of this troublesome enemy.—L. D. W.

THE SPRUCE-GALL APHIS (CHERMES ABIETIS).

We have received during the present summer examples of the above insect from counties as widely separated as Yorkshire and Sussex, and it would appear that this pest is now decidedly on the increase throughout England. With regard to Scotland, we are not at this moment possessed of observations that would enable us to form an opinion. The species, also known as the Spruce Adelges, has been noticed during many years in Germany, though its life history has not yet been satisfactorily made out. As the name indicates, it is particularly attached to the Spruce, but doubtless several other Conifers are liable to its visits. Mr. Carter of Keighley, who has seen the Spruce-gall aphis in a variety of places, attributes the spread of the insect, at least partly, to the wholesale destruction of wasps. He has often, so

Fig. 45.—Chermes abietis. The Spruce-Gall Aphis.

he informs us, watched the wasps busily engaged amongst the Spruce Firs, and believes they clear off Chermes Abietis very effectually. Hence he argues that foresters ought certainly to protect wasps, although gardeners may wish to reduce their numbers on seemingly good grounds.

The insects that are placed in science under the genus Chermes occupy a place somewhat intermediate between the aphis or fly, and the coccus or scale. Unlike the aphides, they do not winter in the egg state, but larvæ are hatched out in autumn. Whether these form or live in galls is uncertain; these are, it is supposed, full-fed before the winter, and after pupation they show themselves during the spring upon the buds of the Spruce as wingless females. These are oval, flattened, and woolly, of various tints, mostly green or purple, and certainly very mischievous, since each one deposits about a couple of hundred eggs, besides which they cause the irritation that produces a gall by driving their suckers into the young twigs. While these are gradually increasing in size, the Chermes larvæ are growing and feeding on or around the galls, within which at last they are hidden. This is a singular fact in the history of these larvæ, considered by some naturalists to arise from the enlargement of the morbid growth of leaves, which, as they become puffy, overlap the tiny insects. Miss Ormerod, however, explains it differently, her observations, which are generally accurate, leading her to the opinion that at a certain stage a crack opens along the gall, towards which the Chermes larvæ direct their course, and so shelter in the chambers within the gall.

About six weeks are required to bring the Spruce galls to their full size, when they begin to harden, the larvæ enclosed having by this time entered the pupal state. The pupæ are of a dull white colour and powdery. It is just as they are ready to produce the

mature Chermes that the galls crack, and the flies soon appear. These seldom fly far from the tree on which they have been reared, the females ere they die depositing small parcels of eggs. These are small in number, probably not more than a tenth of those laid by the females of the spring brood. The economy of the second brood of larvæ has not been fully investigated. Evidently these autumn feeders develop into the flies that are troublesome in spring. Afterwards the empty galls, as is commonly the case, if unremoved afford a home to sundry mites or Acari.

It is agreed that no remedial process can be of any good when mature trees in a plantation are found to be badly infested. Not unfrequently it happens that the pest makes its appearance upon a few scattered trees in a plantation. It is worth while to sacrifice these, because they are likely to prove centres of infection. If the gall-covered shoots are not removed and burnt they may, should they be laid by for a few weeks amongst underwood, after all produce a swarm of the Chermes. Trees that are but partially attacked in the early part of the season may be washed with one of the liquids which are proved to be effective in the destruction of aphides and cocci. In the event of an arrival of Chermes Abietis upon saplings of the Spruce, it has been recommended to carefully examine them and cut off the shoots that are beginning to show galls. Plantations that are too thickly set are specially liable to this pest, which is seldom seen in open and elevated positions.

The woodcut (fig. 45) represents the insect of its natural size, and greatly magnified.—J. R. S. C.

ROOT-PRUNING.

As the time will soon arrive to commence this useful operation, it will be well to carefully note all those trees that are making too much wood and bearing no fruit, also those that make hardly any wood, and those that are in bad health. Lifting and root-pruning will be the best practice to adopt for improving all trees that are in an unsatisfactory state. Apples on the Paradise and Pears on the Quince are naturally free fruiters and shy growers, but they require lifting occasionally to keep them in good health; and if any trees are given to canker it will help to remedy that evil. The best time to root-prune is when the leaves commence changing colour.

In the case of trees that are producing too much wood it will be best to open a trench about 6 feet from the stem, work the soil carefully from the roots to within 2 feet of the tree, cutting the tap-roots well back, removing those that have a tendency to descend, but retaining the fibrous roots, which are the fruit-feeding roots. When working the soil back mix plenty of lime rubbish and burnt earth with it, so as to encourage fibrous roots.

Trees that are not making sufficient growth should have the soil removed from the roots, adding fresh rich soil, and top-dress with manure in summer. Dig a trench round those that are unhealthy and work the soil from the roots, supplying good dry fibrous loam, with little lime rubbish mixed with it. Top-dress in the summer, and keep the fruit off for a year or two, when the tree will regain its former health.—A. YOUNG.

GOOD NECTARINES.

ALL who have these fruits to produce as early in the season as possible should secure a tree of Lord Napier for the early house. It is not wise to throw out any tree that annually produces a good crop of fruit, and plant a young tree, thus losing a crop for a season or two. Much the better plan is to grow the tree in some light position, under glass if possible, until it is in a fruit-bearing condition, when it can be removed to the early house, and the other tree removed and planted somewhere else or destroyed. In the latter case the tree of Lord Napier can after the first season be planted in the early house, and the other cut away as the young tree develops, by which means the house will rapidly be furnished and no crop of fruit lost. From my experience of Lord Napier I am inclined to believe it will become a very popular early variety. It is a vigorous grower and produces fruits of a very large size, which colour well when fully exposed to the sun. I was under the impression that it did not colour really well from several examples I had seen exhibited before my tree commenced fruiting; but with me its fruits coloured much more highly than I had anticipated, but to accomplish this they must be fully exposed to light. I have heard this variety is rather shy, but it has not displayed this faulty disposition here or in a neighbouring garden, as it commenced fruiting freely in a very small state and has continued prolific ever since.

The tree I have is very vigorous in spite of being lifted every

season since I first obtained it; in fact this is the treatment the whole of my Peaches and Nectarines receive, and some of the trees have a spread of branches of 25 feet or more. It is surprising what fine healthy roots trees have that are lifted every year: they never lose a bud in spring, and seldom drop a fruit in stoning. These two faults were serious here when I took charge, the fruit also developing very unevenly during their first swelling; but with annual lifting and working into the borders a quantity of clay, fresh turfy loam, and a good sprinkling of lime for the roots to work amongst, the whole of the above annoyances have disappeared. When trees are left undisturbed for a number of years their roots disappear from the surface, and soon present any but a healthy appearance. The soil, too, is liable to become dry, and if once allowed to get into this condition it is difficult to thoroughly soak it with water afterwards, and failure is sure to result. When lifted carefully and replanted the water passes freely through the soil and the roots are readily kept moist through the whole season, which is the secret of success.

The Pine Apple is a very good Nectarine, which should be accorded a place in every garden. Few, if any, surpass it for richness of flavour, high colouring, or freedom of fruit-bearing. Its parent, Pitmaston Orange, is a grand variety of first-rate flavour, but for colour cannot be compared to the Pine Apple. It is said that Byron is an improvement on Pine Apple, and if it really is it must be superb. I have a young tree, but it has not yet fruited, and I shall be glad to see in the Journal the opinions of those that have tried it. Although Elruge is a valuable well-coloured free-fruited kind, it cannot favourably compete with the Pine Apple, which is much better than any variety I am acquainted with. It appears to have one fault in some gardens, and that is cracking; but whether this is really a fault of the variety or the system of cultivation I do not know. Here it has never produced a cracked fruit, but it is kept a little drier at the roots when the fruits are ripening than is necessary with any other variety I grow. This appears to suit the Pine Apple, and the fruits swell to a large size. It is a very accommodating Nectarine, and will do well at the coolest end of a second-early house as well as in later succession houses, and is valuable for the latest house of all.—W. BARDNEY.

STRIKING EUONYMUSES.

To succeed in striking the variegated forms of *Euonymus*, the care advised by Mr. W. Bardney at page 240 may be necessary; but *E. japonicus*, the commonest of the evergreen kinds, can be increased much more readily, as the following will show.

Some years ago short pieces were taken off with a heel in October sufficient to fill two large handlights. They were inserted in sand, well watered once, kept shaded, and efficiently protected from frost. By the following May, with no other care, they were all rooted and growing, and, being hardened off, were planted in a nursery bed the commencement of June. They were shaded there too for a fortnight, and by the end of September were good plants.

It is well to state that plants of that age require protection from frost during their first winter, so far as to prevent the soil being frozen. Careful mulching is sufficient protection against ordinary frost.—A. B.

HERBACEOUS PLANTS.

THE great glory of my herbaceous border I think culminates in the end of June and on into July, when the grand masses of Delphiniums are in full flower, some Lilies are in their prime, and certain other plants have not yet passed away; and it is for this reason that I do not at all agree with the prudery that banishes everything from the border but hardy perennials. The gaps that are made by bulbs which have died down and herbaceous plants which have died off I do not hesitate to fill up with Geraniums, annuals, &c. I can thus secure a certain gay appearance to the border, which I think is impossible when only herbaceous plants are issued. Dead stools of Delphiniums and flowerless stems of Lilies do not tend to make a border pleasant to look on, and therefore I think that it is perfectly allowable to supplement them with other plants. Single Dahlias come in usefully if sparingly used, and the slugs have this year taken very good care that I should not have too many of them; and although I am not at all likely to be run away with by the fashion which now prevails regarding them, I yet think that they are very useful. If, however, it is attempted to increase their size, their usefulness will be greatly destroyed. Their chief value is for cutting, and if you get them too large they are of no use. The white one, of which so much has been said, I do not care a rush about. It is not nearly

so good as the white Japanese Anemone, and that is good enough for me.

My chief herbaceous border is about 100 feet long, and this I have for the first time edged this year with the pretty little *Campanula pumila alba*. I planted it amongst the Crocus early this year, and it has now made my border very pretty, as it is full of bloom with its pure little white bells, and will form a pretty carpet through which the Crocus will push their way. At the back I have had some grand masses of Lilies—*testaceum* with stems 6 feet high; the lovely old white *L. candidum*; the common Tiger Lily, bold and good; while in the front there have been some other kinds recently planted, which I fear the wet winter did not suit, such as *Humboldtii*, *superbum*, *Michauxii*, *Leichtlinii*, and *Batemaniae*. I had a fine mass of the old Orange Lily last year, but this season it has not flowered, and looks altogether in a very dilapidated condition, I imagine owing to the wet. Some of these have flowered, but so small as hardly to be deserving of being noticed. I am hopeful that another year they may do better. But I think the chief glory of this border has been a magnificent plant of *Campanula pyramidalis*, white. I had it in a pot and planted it out early this year. It has thrown up about a dozen flowering stems varying in height from 3 to 5 feet, and one mass of flower from the very bottom. Nothing can be more beautiful than the mass of snow-white blossoms standing so grandly up above the foliage and the surrounding plants. It is truly what some have described it—a noble plant. I have had also here a very common bulb which I have never flowered before—*Ornithogalum arabicum*, but which is certainly deserving of more extended culture. It is much prettier than the common Star of Bethlehem, taller in growth, pure white, with a black spot in the centre of the flower. Another white flower very useful for cutting is the old *Achillea Ptarmica fl.-pl.*, which indeed is almost a weed, as it runs so far under ground and the clump requires taking up every year. I see a correspondent mentions this as being in flower ten months in the year. Surely this is a mistake. It does not come above ground until March, nor commence to flower until May. Nor must I forget the delightful *Gypsophila paniculata*, of which I have now a large bush with its light cloudy-looking blooms which make it so valuable for the upper part of a stand for the table, giving that lightness which is so desirable and so seldom achieved. *Anemone Honorine Joubert* has flowered early this year, and will doubtless continue for weeks to come, and contrasts well with *Lychnis chalcedonica flore-pleno* close by.

Of yellow flowers I have had several of the *Hypericums*, some of which are very pretty. *H. olympicum* is a dwarf-growing kind, while the old garden flower *H. calycinum* is always showy and interesting. I had also two *Senecios* which ought certainly to go into the Index Expurgatorius of herbaceous plants. I received them under the names of *empetrifolium* and *asterifolium*; but whatever their names may be they are unworthy of a place, as the common Ragworts of our lanes and fields are much brighter and prettier. *Bupthalmium salicifolium* is a very hardy and bright-flowered plant, and its blooms are very valuable for cutting. There is also a pretty little *Coreopsis tenuifolia*, interesting from the fact that it is a perennial.

Blue flowers were not so plentiful with me as during June, when the Delphiniums were so fine. A few, however, of these were in flower; while large masses of *Echinops*, though hardly elegant in form, were yet by their pleasing colour very attractive. *Aster alpinus* can hardly be called a blue flower; still there is a grey shade in it which makes it desirable as a contrast.

The rockery at this season does not present many objects of interest. There is, however, in flower the charming little *Androsace lanuginosa*, one of the hardiest and most easily grown of this pretty tribe. I see, moreover, that *A. carnea* and *A. carnea eximea* have well established themselves, so I hope to see good blooms of them by-and-by. *Dianthus Segucii* is pretty and interesting for its flowers after all the other Dianths have ceased. *Campanula pulla*, too, lasted on well into July, and I doubt if there be amongst this very numerous class any prettier representative of it than this.

There is one plant which has been a puzzle to me. I received the seed from a young friend in Canada, and on flowering it proved to me the white variety of *Verbascum Blatta*; but I was assured by an eminent botanist that I must have been mistaken, as it was not indigenous to Canada, although my friend assured me that it came up on every piece of waste ground. Is it, then, one of those cases in which an introduced plant has taken the place of the indigenous plants? It seeds, indeed, in sufficient quantities to fill up a whole country side, and it may possibly have thus established itself. It grows to a height of 6 feet and more, and is pretty enough in moderation; but it must be carefully watched, or, like Borage, it will seed itself all over the garden.

The little Paquerette Roses keep continually in flower in the border and cannot be too highly recommended, as they flower from the beginning to the end of summer. I have said nothing about Phloxes and Pentstemons, but they of course occupy a prominent place just now; and as I look out on my borders gay with the flowers I have mentioned (save the Lilies, which have many of them ceased flowering), and with plants of Geraniums of various colours, and the fine foliage of Maréchal McMahon, with annuals such as Sweet Sultan, and fragrant with rows of Sweet Peas and Lavender, and with Stocks and Mignonette, I can feel perfectly satisfied with my little plot; and am not in the least envious of some of my richer neighbours, whose parterres are glowing with crimson and gold, or with carpet beds laid out in such artistic devices as coats of arms and butterflies, while not a breath of sweet odours comes from acres of these brilliant polychromes. Everyone to their taste, but my experience of this spring and summer has only confirmed me in my preference for the mixed borders.—D., Deal.

INTERNATIONAL POTATO SHOW.

SEPTEMBER 20TH AND 21ST.

YESTERDAY the annual Exhibition of Potatoes was opened as usual at the Crystal Palace, Sydenham, an extensive and excellent display of these useful vegetables being provided. Both in numbers and quality the exhibits compared very favourably with those at some shows in preceding years, the competition being very keen in all the leading classes, as is shown by the numbers given under each of the classes in the following brief report. Two hundred and seventeen collections were staged in competition, comprising over 1300 dishes, or a total of 12,000 tubers, these numbers being exclusive of the numerous large collections staged by nurserymen not in competition. After the judging was completed a luncheon was held in the Marble Hall, Mr. Alderman de Keyser presiding in the unavoidable absence of the Lord Mayor.

The following is a list of the prizewinners and the names of the principal varieties shown in the respective classes:—Twenty-four varieties of Potatoes, distinct, nine tubers of each (open). All the prizes in this class are given by the Crystal Palace Company, who contribute thirty guineas towards the Exhibition. Twelve collections were staged. First, Mr. W. Ellington, West Row Gardens, Soham, with large, even, and handsome samples of Queen of the Valley, Bresee's Prolific, Carters' Eight Weeks, International Kidney, Vicar of Laleham, Blanchard, Adirondack, Porter's Excelsior, Covent Garden Perfection, Schoolmaster, Matchless, White Emperor, 'Triumph, Early King, Reading Russet, Wiltshire Snowflake, Grampian, Rector of Woodstock, Mr. Bresee, Woodstock Kidney, Prizetaker, Pride of America, Tifties Annie, and Early Border. Second, Mr. Thos. Pickworth, Loughborough, also with a fine collection; the tubers rather smaller but very even and clean. Third, Mr. H. E. Gribble, Canon Hill Gardens, Maidenhead. Fourth, Mr. William Finlay, Wroxton Abbey Gardens, Banbury. Fifth, Mr. W. Kerr, Dargavil, Dumfries; and sixth, Mr. James Cannc, Winmarleigh, Garstang.

Eighteen varieties of Potatoes, distinct, nine tubers of each, open to noblemen's and gentlemen's gardeners only, and the awards to be made by three gentlemen's gardeners, not competitors. All the prizes in this class are given (in medals, plate, or money) by Messrs. Sutton and Sons, seedsmen, Reading. Eighteen collections—First, Mr. James Matthews, Woodstock Park Gardens, Sittingbourne, who had a most creditable collection, comprising Beauty of Kent, Pride of America, Holborn Favourite, Reading Abbey, Superior, Magnum Bonum, Triumph, Woodstock Kidney, Adirondack, Suttons' First and Best, Beauty of Hebron, Bedford Prolific, Pride of Ontario, Early Goodrich, Trophy, Wiltshire Snowflake, Reading Russet, and Myatt's Ashleaf. Second, Mr. J. Hughes, Eydon Hall Gardens, Byfield, his best being Triumph, Reading Russet, International Kidney, Mr. Bresee, and Jackson's Improved. Third, Mr. R. West, Northlands, Salisbury, very close in quality; fourth, Mr. H. E. Gribble; fifth, Mr. W. Finlay; sixth, Mr. W. Skarratt, Woolley Firs, Maidenhead Thicket.

Twelve dishes of Potatoes, to consist of six English and six American varieties, distinct, nine tubers of each, open. The first prize in this class is given by Messrs. Bliss & Sons, seedsmen, New York; the second by Vice-President Mr. Alderman Hadley; and the third by Messrs. George Ure & Co., Bonnybridge, Scotland. Twelve collections.—First, Mr. T. Pickworth with fine samples of Woodstock Kidney, Matchless, Ashtop Fluke, Queen of Valley, International, Rose, King of Flukes, Trophy, Beauty of Hebron, Amazon Queen, Triumph, and an unnamed variety. Second, Mr. R. Dean, Ranelagh Road, Ealing, with a very beautiful collection of clean even tubers. Third, Mr. W. Ellington with large samples. Fourth, Mr. H. A. Gribble; fifth, Mr. W. Finlay; sixth, Mr. Joseph Butt, Little Church Street, Wisbech.

Six dishes of Potatoes, distinct varieties, nine tubers of each, open. The first prize in this class is given by Vice-President James Abbiss, Esq., J.P.; the second by Vice-President L. Fawell, Esq., 4, St. Paul's Churchyard, London; the third by William Holloway, Esq., 5, St. Paul's Churchyard, London. Twenty-one collections.—First, Mr. J. Pickworth with a neat collection, comprising Reading Russet, Ashtop Fluke, Woodstock Kidney, Blanchard, Grampian, and International. Second, Mr. W. Finlay with a collection very close in merit to the preceding. Third, Mr. J. Tooley, Newland, Banbury; fourth, Mr. F. J. Hart, Ospringe Road, Faversham; fifth, Mr. G. Akhurst, gardener to the Rev. J. Brama, Faversham.

Four dishes of Potatoes, the largest and handsomest, six tubers on each dish, of any variety. All the prizes in this class are offered by Messrs. Harrison & Son, seedsmen, Leicester. Ten collections.—First, Mr. J. Pickworth with four dishes of International even and large. Second, Mr. W. Ellington with extremely large samples of Queen of the Valley, White Elephant, Silverskin, and International. Third, Mr. H. E. Gribble; fourth, Mr. C. Osman, Sutton, Surrey.

Three dishes of white round Potatoes, distinct varieties, nine tubers of each, open. The first prize in this class is given by James Wright, Esq., Falkirk, N.B.; the remainder are given by the Amies' Chemical Manure Company, 75, Mark Lane, London. Thirteen collections.—First, Mr. R. Dean with Bedford Prolific, Porter's Excelsior, and Model—very even and good. Second, Mr. W. Ellington with Bedford Prolific, Schoolmaster, and Porter's Excelsior. Third, Mr. W. Kerr. Fourth, Mr. Oliver Goldsmith, Polesden Lacey, Dorking; all showing very neat samples.

Three dishes of coloured round Potatoes, distinct varieties, nine tubers of each, open. The first prize in this class is given by Mr. Richard Dean, seed-grower, Ealing and Bedford, London. Nineteen collections.—First, Mr. J. Pickworth, with large samples of Reading Russet, Blanchard, and Queen of the Valley. Second, Mr. F. Miller, Northdown, Margate, with Vicar of Laleham, Blanchard, and Reading Russet, very good. Third, Mr. R. Dean; fourth, Mr. H. E. Gribble.

Three dishes white kidney Potatoes, distinct varieties, nine tubers of each, open. The first prize in this class is given by Messrs. Thos. Gibbs & Co., seedsmen, Piccadilly. Seventeen collections.—First, Mr. R. Dean with Woodstock Kidney, Edgecote Seedling, and International. Second, Mr. F. Miller with Jackson's Improved, Yorkshire Hero, and Woodstock Kidney. Third, Mr. H. E. Gribble; fourth, Mr. W. Ellington.

Three dishes of coloured kidney Potatoes, distinct varieties, nine tubers of each, open. The first prize in this class is given by Vice-President Shirley Hibberd, Esq. Thirteen collections.—First, Mr. R. Dean with American Purple, Mr. Bresee, and Beauty of Hebron. Second, Mr. W. Ellington; third, Mr. F. Miller; fourth, Mr. G. Akhurst.

Best two dishes of Potatoes, to consist of one dish of Suttons' First and Best, and one dish of Suttons' Magnum Bonum, nine tubers of each. All the prizes in this and the next class are given by Messrs. Sutton & Sons, seedsmen, Reading. Eight collections.—First, Mr. W. Finlay with Suttons' First and Best and Magnum Bonum. Second, Mr. R. Stowe, Kimbolton, St. Neot's; third, Mr. J. Matthew, Woodstock Park Gardens, Sittingbourne; fourth, Mr. Ross, gardener to C. Eyre, Esq., Newbury, all staging very even clean tubers.

Best two dishes of Potatoes, to consist of one dish of Suttons' Reading Abbey, and one dish of Suttons' Red-skinned Flourball, nine tubers of each. Six dishes.—First, Mr. G. Akhurst with large tubers; second, Mr. W. Finlay; third, Mr. T. Pickworth; and fourth, Mr. P. Cornish, The Shrubbery, Enfield. Best dish of Schoolmaster Potato, nine tubers, open. All the prizes in this class are given by Mr. Charles Turner, Royal Nurseries, Slough. Thirteen dishes.—First, Mr. W. Kerr with beautiful even tubers of moderate size; second, Mr. C. Osman; third, Mr. W. Ellington; fourth, Mr. P. Cornish.

Best dish of Potatoes, new varieties in commerce, not offered to the public before season 1882, nine tubers, open. All the prizes in this class are given by Messrs. Hooper & Co., seedsmen, Covent Garden, London. Thirty-five collections.—First, Mr. F. Miller with handsome specimens of Reading Russet. Second, Mr. P. McKinlay, Heady Lodge, Penge, with the same variety, and he was also third with Suttons' Prizetaker; Mr. W. Ellington being fourth with Reading Russet; fifth, Mr. W. Kerr with Queen of the South; and sixth, Mr. T. Pickworth with Reading Russet.

Nine dishes of Potatoes, distinct varieties, nine tubers of each, open. All the prizes in this class are given by Mr. C. Fidler, Reading. Twenty collections.—First, Mr. J. Hughes, gardener to Col. Cartwright, Byfield, who had even samples of Beauty of Hebron, Purple Ashleaf, Adirondack, Manhattan, Porter's Excelsior, Reading Russet, Blanchard, Queen of the Valley, and International. Second, Mr. C. Hott, Wakefield Park Gardens, Mortimer, with Purple Kidney, Surprise, Wonderful Red, Vicar of Laleham, Tifties Annie, Reading Russet, International, Standard, and Garibaldi; third, Mr. J. Butler, Sittingbourne; fourth, Mr. J. Butt; fifth, Mr. F. J. Hart, Ospringe Road, Faversham.

In the classes for seedling varieties not in commerce the entries were numerous, but when our reporter left the Exhibition only the following had been certificated:—

Recorder (Dean).—A seedling white kidney from American Success crossed with Woodstock Kidney. Of neat even shape, few eyes, and very regular; white, and of moderate size.

Alderman De Keyser (Fenn).—A second early coloured kidney; a cross between American Snowflake and a discarded seedling. Skin rough, dull red, inclining to white; form roundish, even, and few eyes.

James Abbiss (Fenn).—A white round very early dwarf variety, a cross between Turner's Union Round and Shutford Seedling. Of moderate size, but even and of good form.

Sir Walter Raleigh (Ross).—A seedling from Excelsior, white, round, and of good form.

Miscellaneous exhibits were numerous. Messrs. Sutton & Sons, Reading, had a very extensive and handsome collection of English and American Potatoes, representing a great number of varieties, large heaps of Reading Russet, Suttons' First and Best, and Magnum Bonum being staged. Messrs. Harrison & Sons, Leicester, had a large collection of Potatoes, comprising numerous varieties. Mr. R. Dean, Ealing, had an extensive collection of Potatoes, some fine samples of Trebons Onions, and a number of Fenn's seedling Potatoes. Messrs. Webb & Sons, Stourbridge, exhibited a large collection of handsome tubers, representing over seventy-five varieties. Messrs. C. Lec and Sons, Hammersmith, contributed a large collection of varieties, the tubers being mostly of good size and even. Mr. T. Laxton, Girtford, Bedfordshire, sent samples of his new Runner Bean Girtford Giant, Selected White Spanish Onions, and White Beauty of Hebron Potato. Mr. G. Fidler, Reading, had a large collection of Potatoes representing a number of the best varieties, and Messrs. Daniels Bros. had a large heap of White Elephant Potato.

HARDY FRUIT GARDEN.

ROOT-PRUNING is absolutely necessary to insure fertility in fruit trees confined to limited space and formal training as wall trees, cordons, espaliers, pyramids, and bushes, which are not forced into fruitfulness by summer-pruning or pinching. From the absence of fruit in this and previous seasons trees have made much foreright or breastwood, the early pruning or stopping of which has caused a multiplicity of subsequent growths, which are more likely to be followed by a late growth than be formed into spurs or fruit buds, especially if the autumn prove wet and sunless. It seems that in planting fruit trees to be trained formally and limited to space, that the root space is not taken into consideration so as to insure a reciprocal action between the head and roots; consequently when the season is moist the roots extend in the unrestricted area, often of loose and rich soil. The nutriment absorbed is more than is needed for the swelling of the fruit and the formation and perfecting of growth for future crops. Pruning in cases of this description, instead of being an aid to fertility, induces late growth, and is thus practically useless, as is evidenced by a number of trees in gardens which, though faultless as to training and to outward appearance healthy, are conspicuous year after year for sterility. If trees can be induced to bear full or fair crops of fruit there is little difficulty with them either as regards the pruning to keep them in shape or insure their continued fertility.

Root-pruning is generally postponed until the fall of leaf, when no change can occur in the character of the buds. This should be borne in mind by those contemplating root-pruning, as, if done after the leaves fall, a year must elapse before any transformation of the buds can be anticipated. It has been proved that root-pruning practised sufficiently early in the autumn or late summer to check any tendency to late growth may cause the wood buds to be developed into fruit buds, and its benefit be felt in the ensuing year. To effect any good for next season it must be done during the present month carefully and judiciously. The very vigorous must not be operated upon so severely as those that are moderately vigorous, as they will have larger sap vessels and be likely to suffer most from the larger extent of their evaporation surface when the supply is cut off; hence in their case a root or two should be cut at a time, and its effect seen before proceeding further. If the severing of a few roots does not cause any drooping of the young sappy growth, or only slightly under powerful sun, then a few more roots may be cut, and at the same time any useless spray removed. If the root-pruning be so carried out as to prevent any further growth in the trees, but not to the extent of causing the shrivelling of the young shoots or the severe flagging of the foliage,

the object of the operation will be attained—i.e., the prevention of late growths, the conversion of wood into fruit buds, and the thorough maturation of the growth; but with the sudden collapse of the foliage none of those can be effected.

Trees only moderately vigorous will need but little root-pruning to check the tendency to late growth and secure the thorough ripening of the wood. In any case it must be done with judgment and suited to individual requirements, remembering that it is not the roots near the stem of the tree that should be detached, but those at a distance of not less than one-third the distance the tree is in height or extension of head, calculating from the stem, so as to save as many as possible of the fibres proceeding from the root-stem and encourage them there.

It will also be necessary to discriminate between trees that are of full size and those that are extending. The former, having shorter and firmer growth, will bear more severe root-pruning than young trees with fewer and more sappy growths. If the growth be not completed any severe check given the growth of young trees will probably cause them to lose their points or die, if indeed it does not cause the wood generally to shrivel. This must be carefully guarded against. Another example of the need for cautious proceeding will be present in the Peach and Nectarine, they being prone to make late growth and have the shoots more sappy in late summer than most other fruit trees. These should be operated on very moderately at first, by degrees curtailing the supply of nutriment to check fresh growth and yet retain the foliage for the benefit of the wood and buds.

FRUIT HOUSES.

Melons.—Plants just swelling their fruits require attention to guard against canker at the collar and in the old growths, freshly slaked lime being applied on the first appearance of canker, rubbing and pressing it well into the affected parts. Repeating the application if it becomes necessary will arrest the further progress of the malady. As regards cracked fruits, the best preventive is a lessened supply of water at the roots and a drier condition of the atmosphere, cutting the shoot carrying the fruit about half way through a few inches lower than the fruit towards the collar of the plant. Maintain a night temperature of 65° to 70° and 75° in the day, advancing to 80° from sun heat, increasing to 85° or 90° with ventilation. Syringing must only be practised on bright afternoons, and then early and moderately. Earth up the last batch directly the fruit commences swelling, and keep the laterals closely pinched, so as to admit all the sun possible to the principal growths. The foliage of plants in pits or frames should seldom be damped, and water at the roots must be given carefully. Apply good linings to the bed to finish off the crop as soon as the heat is found to be declining, and close early, employing a covering over the light on cold nights.

Vines.—Vines intended to ripen their fruit next April or early in May must be pruned at once, so as to afford a season of rest before commencing to force. Clean the glass and woodwork thoroughly, painting if necessary, so as to have it hard and dry before closing the house. Remove the old mulching and inert surface soil, and supply good loam and a little bone manure. This annual surface-dressing encourages the formation of surface roots, which should be fed in summer or during the growth of the Vines by manurial mulchings. Intermediate houses will now, or soon, be cleared of the crops; and if the wood of the Vines is not thoroughly ripe fire heat should be applied in the daytime, ventilating freely, turning the heat off at night, and check all lateral growth.

Young or recently planted Vines that have been allowed to ramble may now have some of the surplus growths removed, being careful to retain the leaves on the principal rods, maintaining a warm dry airy atmosphere till the wood is brown and hard. Late Grapes ought now to be fully ripe, or if not afford a circulation of warm rather dry air until all uncertainty about their being thoroughly ripe is past. Black Hamburgs in their stages of ripening should also have a little fire heat in the daytime. Thin-skinned kinds of Grapes will require frequent examination for decayed berries, damp being their greatest enemy, which should be expelled as much as possible by fire heat in the daytime when ventilation is given, turning off the heat at night.

PLANT HOUSES.

Pelargoniums of the Show, Spotted, and Fancy varieties that have been shaken out and repotted and placed in pits or frames, should at once be transferred to their winter quarters. They should be raised to within a foot or two of the glass, allowing plenty of space between them, and when the shoots are 3 or 4 inches long they should be tied out. Water carefully, only giving sufficient to keep the foliage in good condition; if kept wet the plants root badly, and too much growth in the leaves is induced. Zonal Pelargoniums that have been some time flowering should be encouraged with weak liquid manure, and be given a light position. Zonals grown in 6-inch pots for winter flowering, and fully hardened by exposure to the sun and air, should now be placed under cover. Place them in a light airy house or pit, and when wanted in bloom a temperature of 50° at night should be provided them. Solanums that have been planted out must now be lifted and potted, 6 or 7-inch pots being the most serviceable, using ordinary loam, and pot firmly, soaking well, and place on the north side of a wall, preferably in frames, as the lights can then be placed over them when there is danger of frost.

Salvias, Heliotropes, and other greenhouse plants of similar character standing outdoors must be conveyed under cover before frost, assigning them a light airy position and a temperature of 45° to 50°.

Encourage Cyclamens to make free growth in an intermediate temperature. Chrysanthemums should be finally staked and trained, the ordinary upright bush fashion being best for general purposes, only using sufficient sticks to keep the plants in form. To insure good blooms the small lateral shoots should be removed from the principal, and the blooms must be thinned to a single bud to each shoot, which should be done as soon as they are large enough. Give plenty of liquid manure, and if green aphides attack them promptly apply an insecticide.

Hyacinths, Narcissuses, and Tulips should be potted, plunging them in a bed of ashes under a wall where protection can be given from frost, and allow them to remain there until well rooted.

THE BEE-KEEPER.

HONEY EXHIBITION AT DUNDEE.

THE East of Scotland Bee-keepers' Society held its annual Exhibition at Dundee on August 31st and two following days. Notwithstanding the unfavourable nature of the season the display was unusually full and of splendid quality. Many of the leading bee-keepers in the lowland districts were unable to stage a single exhibit, but those from the interior and highland districts came forward in force with large and well-finished lots. Altogether about 2000 lbs. of honey were staged, and every class was well competed in. The most striking exhibits were those in the classes for the most artistic displays over and under 100 lbs. Our contributor, Mr. Raitt of Blairgowrie, was first in both classes, and his exhibits were justly admired for their excellent finish and tasteful arrangement. Part of the same lots took two first prizes at the great Preston Show in the following week, and there elicited many comments highly flattering to Scottish bee-keepers. Altogether there were seven entries in the display classes, and in all the quality of the honey was very fair. The poor taste shown in the arrangement of some entries where shelves and stages were relied on, received a check in the awards of the Judges in favour of those exhibiting less carpentry work, but more variety in the size, form, and decoration of the sections and glasses of extracted honey.

The exhibit of D. W. Soutar of Tannadice was given the second place, and was of splendid quality, as were also his other exhibits in the classes for single supers, sets of sections, and glasses of extracted honey. His 30-lb. single super was entirely of Heather honey, and has never been excelled at any previous Show at Dundee. It had evidently been got in a very short time, as its well-finished parallel combs were of the most delicate quality. Altogether it was perfect as a single super with one exception—it had been removed so suddenly from the hive that the cut cells had not been dried up by the bees.

The splendid supers exhibited by Richard MacGregor, Inchmarlo, were all of Heather, and, as usual, of fine colour and finish. One of his supers contained a very beautiful comb of Heather honey in the form of a heart with a Latin cross in the centre, the interstices being neatly filled in with Heather blooms. Mr. MacGregor was first as usual with his extracted Heather honey, as C. Carnegie of Marykirk was with a fine sample of Clover honey. Some of the exhibits in the

extracted classes were very dark, and gave evidence of an origin rather animal than floral. Considering, however, the uncommon prevalence of aphides this season, and consequent abundance of so-called honeydew, it is gratifying to find that so little of this spurious honey was brought forward. Its sale can only damage the interests of honey-producers, and its exhibition should be strictly discouraged by judges.

In the classes for living bees the Exhibition was unusually full, no less than ten observatory hives being staged, containing bees of four different races—blacks, Italians, Cyprians, and Syrians. Besides these there were five neat nests of humble bees and one enormous "byke" of wasps. Several of the observatory hives presented novel features in the direction of an attempt to keep the combs in their natural position side by side, while rendering them capable of individual inspection. The one exhibited by the Secretary, Mr. Warden, accomplishes this by having the hive double the usual height, and so arranged that the padded quilt could be raised to the top, and any separate frame thereafter lifted to a position open to inspection. That of Mr. James Lorimer, which was entirely of glass and exhibited in an unfinished state, is similar in principle to that of Neighbour.

Mr. Valesian Novitzky, Pitlochry, exhibited a beautiful model of a Russian log hive tenanted by Ligurian bees, and having a card attached explaining the method of taking honey without destroying the bees.

In the hive and appliances department there was a large display and keen competition. The prize for the best hive went to Mr. Morrison, Bridgend, Perth, for a rather expensive hive, presenting no very novel features, but indicating great thoughtfulness and precaution on the part of the maker. In extractors there was keen competition, those of Messrs. Coghill and Kinnear being almost exactly alike, taking first and second places. Both admit of taking the frames as they hang in the hive, and are fitted with a novel set of gearing. They are marvels of cheapness at a guinea. Notwithstanding the large quantity of honey staged, and the difficulty of transacting business in such crowds as always visit this Exhibition, it is satisfactory to know that Mr. Warden, the indefatigable Secretary, was able to sell nearly everything entered for sale, and that at fair prices.

The Society has also held Exhibitions this season at Forfar and Arbroath, and honey shows are now so popular in the district that nearly all the local horticultural societies have added prizes for honey to their schedules.

THE BLACK BEE AND RED CLOVER.

IN reply to a query by "EAST RIDING," it is generally conceded that the black bee is unable to work upon the bloom of red Clover, although when other flowers are scarce it may be seen encircling the bases of its petals, no doubt attracted by the scent of the nectar within. The ligula, or tongue, of the Ligurian is slightly longer than that of the black bee and more hairy. This fact has been brought to light by numerous experiments, notably by those of Professor Cook. A simple machine has been patented in America for measuring the length of the bee's tongue. It consists of a vessel covered with wire cloth, and containing honey or syrup placed at certain distances beneath the gauge; and a small index finger revolving upon a circular disc, finely graduated, denotes the length of the tongue when sipping the food.

The Ligurian bee can work to a certain extent upon the red Clover bloom, but greatly prefers the white. Indeed, in our experience the second crops of the red are those which are chiefly visited, and we remember some years ago, during an extremely cold and wet summer, that the red Clover crops failed to produce seed in all the country around the neighbourhood in which we had some dozen stocks of the Ligurian bee located, with one exception only, and that was within a mile of our own apiary, where the crop produced abundance of seed. Upon any fine day, say in August or early September, if the Ligurian bee exists within a distance of three or four miles, it may be seen busily at work upon the red Clover, chiefly, however, on the smaller blooms and petals, and the same remark applies to the first cross of hybrids.

We would, therefore, advise "EAST RIDING" by all means to carry out the proposed plan of introducing the Ligurian variety of the honey bee into the neighbourhood, since it is far more prolific and a better honey-gatherer than the black.

THE DERBYSHIRE BEE-KEEPERS' ASSOCIATION SHOW.

AN interesting and useful Exhibition of the apian industry and its produce, promoted by the Derbyshire Bee-keepers' Association, was held at Derby on the 6th and 7th inst., in the grounds of the Derbyshire Agricultural Society. The President of the Association is the Duke of Devonshire, and its Vice-Presidents include a number of the leading county gentlemen, who take a practical interest in bee

culture. The Treasurer is Mr. Walter G. Copestake of Derby, and the Hon. Secretary Mr. H. V. Edwards, Ockbrook, Derby. The present Exhibition is the first one of any importance held by the Association. This being so, it cannot but be regarded as an unqualified success. The hives were a first-rate collection, constructed chiefly of the plainest and most economical materials, but evidently excellently adapted for rearing purposes. A cheap hive made from old materials, costing altogether 2s. 3½d., and the labour of which was stated to be only four hours, was shown by Mr. W. G. Copestake, surgeon of Derby, and sold during the Show. The show of honey was considerably larger than had been anticipated from the badness of the year, and the quality seemed splendid. There was a display of appliances for extracting the honey, which attracted considerable attention. Mr. H. V. Edwards showed a new extractor known as "Edwards' Improved Extractor," which holds four combs, and takes any size, from a "Woodbury" to a "Langstroth," and is fitted with a strainer. The price is 30s. Mr. J. Best, of the Witham Apiary, Boston, had a quantity of section supers, honey extractors, comb foundations, and other appliances on view, and he also had for sale most of the standard books on bee-keeping. As regards the bees, which were chiefly contributed from the county, they were very fair indeed if every adverse circumstance is taken into consideration, and doubtless next year's Show will be a considerable advance on the present one. The Judges were Mr. R. R. Godfrey of Grantham, and Mr. Yates of Grantham, both of whom are well known for their intelligent acquaintance with bee culture. At intervals during the day Mr. P. Cotton of Olney, Buckinghamshire, an "expert" of the British Bee-Keepers' Association, gave, outside the tent, practical illustrations of manipulating with live bees, showing the best methods of driving, making artificial swarms, transferring combs from straw skeps to bar-frame hives, finding queens, &c. The manipulations afforded a great amount of information to visitors.

LIST OF AWARDS.

The following were the successful competitors:—

HONEY.

Class 1.—For the best stock of bees, of any race, to be exhibited with their queen in observatory hives. First, Rev. W. Humphries, Long Lane Vicarage; second, H. V. Edwards, Ockbrook, Derby.

Class 2.—For the largest and best exhibit of super honey, the produce of one apiary during 1882. First, H. V. Edwards; second, A. E. Rawlins, Coalville.

Class 3.—For the best twelve sections. First, H. V. Edwards; second, Dr. Ogle.

Class 4.—For the best honey in the comb. First, Isaac Potter, Spondon.

Class 5.—Best run honey in glass jars. First, J. Birtles, Norton, Sheffield; second, W. Handby, Hasland, near Chesterfield.

HIVES, ETC.

Class 6.—Best frame hive with arrangements for summer and winter use, price not to exceed 10s. 6d. First, C. Foxon, Croft, near Leicester; second, Abbot Brothers, Fairlawn, Middlesex; third, W. Handby; fourth, J. and G. Haywood, Derby.

Class 7.—Best hive made by a cottager, on the moveable-comb system. First, W. Handby; and special prize given to J. Birtles.

Class 8.—For the cheapest, neatest, and best super for harvesting honey in the comb. First, Abbot Brothers; second, W. Handby; third, Abbot Brothers.

Class 9.—Best collection of hives and bee furniture. First, J. Best, Witham Apiary, Boston; second, J. and G. Haywood; and special prize given to W. Handby.

THE HONEY CROP IN AMERICA.

THE outlook for the American honey crop of 1882 is only little better than that of 1881. New York State, a leading honey-producing centre, will run short of its general good average, but this deficiency will be compensated by gains in Illinois, Michigan, and other western States which produced less than usual in 1881. California promises a quarter of an average crop this year, against a total failure in 1881. This will constitute the surplus over the quantity of honey marketed in 1881. The heavy honey year was 1878. The crop has not equalled the output of the bees since that date. Mr. Joseph M. M'Cauley, who has just returned from a visit to the leading bee-keepers of the Golden State, states that, placing California's crop of honey in 1878 at 720,000 lbs., about a quarter crop, as above stated, may be looked for there this season, some 180,000 lbs. The taking-up of alternate sections of land in California for grazing and allowing sheep to range across the intermediate plots tends to destroy the blossoms on which the industrious bee has depended. A fire swept across a county or two in Southern California two years ago, and all verdure was destroyed. This discouraged the bee-keepers as well as the bees, although by next season it is reported that blossoms will be fairly plentiful once more. This explains the failure of the honey crop in that State this year. But the probability of recurrence of fires, together with the grazing trouble, points to the steady reduction of the honey product in California, unless measures are taken to cultivate bee food in the canons and elsewhere, which plan is meeting with serious consideration with California bee-keepers. The falling-off in the honey crop in New York State in 1881, where the product had heretofore been uniformly large, was due to cold weather in June delaying the blossoming of plants. Later a dry season continued the damage already done, so that the western States alone this year are ex-

pected to present average crops. New York and California being responsible for a large proportion of the honey produced in the United States, the importance of knowing the situation in those regions is at once perceived.—(*Irish Farmers' Gazette.*)

TRADE CATALOGUES RECEIVED.

M. Mulié, Neuville-en-Ferrain, Toureong (Nord), France.—*List of Strawberries, Potatoes, &c.*

Boulton & Paul, Norwich.—*Illustrated Catalogue of Garden Appliances.*

Robert Parker, Tooting.—*Catalogue of Herbaceous Plants, Fruit Trees, &c.*

Messenger & Co., Loughborough.—*Illustrated Catalogue of Horticultural Buildings.*

H. Cannell & Sons, Swanley, Kent.—*Autumn Catalogue of Soft-wooded Florist Flowers.*

* * * All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (C. L. & Son).—A new edition of the "Fruit Manual" is in course of preparation, and will be published before the next fruit season. Mr. W. Thomson's "Practical Treatise on the Cultivation of the Vine," price 5s., published by Messrs. W. Blackwood & Sons, Edinburgh and London, will probably meet your requirements. The "Vine Manual" published at this office, price 3s., post free 3s. 2d., also contains full cultural particulars. (*H. J. G.*)—The "Gardener's Dictionary," which can be obtained from this office, post free 8s. 3d., appears to be the work you require; it gives a list of all the most important plants in cultivation, with a brief review of their culture and other useful information. The word "noisette" should be pronounced noaset. (*G. C. S.*)—"The Greenhouse," published at this office, will suit you. It can be had free by post for ten penny stamps.

Guide to Hampton Court (M. F.).—The guide to which you refer can be procured from Mr. Graham, Superintendent, Hampton Court Gardens.

Alexandra Peach Failing (W. A.).—This variety is of hardy constitution, and the failure in the ease of your trees is doubtless due to the stock being unsuitable. The remedy you propose, however, cannot be recommended, as it would lead to results even more injurious to the tree. The best plan would be to endeavour to procure another tree on a different stock.

Shrubs for Shaded Border (Willesden).—Common Laurels will no doubt succeed the best in such a position as that you describe, and the greatest portion of the border should be planted with them. In addition, to diversify the appearance, a few plants of the following might be employed:—*Euonymus europæus*, *Leycesteria formosa*, *Berberis aquifolium*, *Berberis Darwinii*, *Ruscus aculeatus*, *Symphoricarpos racemosus*, and for the fore part of the border *Hypericum calycinum* will succeed well.

Spruce Firs Dying (Gertrude H.).—We, too, have been puzzled as to the cause of death of many, and the disfigurement of most of our common Spruce. The affection being so general in the one season will scarcely admit any theory of parasitical injury being entertained, and we have little doubt now that the injury is from the effects of the two very severe winters we lately experienced. We advise intending planters to make more use of the Douglas Fir, as, although it has not entirely escaped the affection alluded to, it is, as far as our experience goes, hardier than the common Spruce, and of much quicker growth.

Treatment of Pelargoniums (Sol).—You do not say whether the Pelargoniums are of the Show, Fancy, or Zonal types, but probably they are the first-named. If that is the case the most likely cause of the leaves turning yellow and falling is that the house has been kept too close, and perhaps also water has been too freely supplied. The remedies for either of these evils are obvious. Should the plants be infested by aphides, as is also probably the case, fumigate repeatedly until the pests are destroyed. When the growth is thoroughly ripened is the best time to cut them in if the plants are too large.

Climbing Roses (M. C. B.).—If the variety that has been already employed succeeds well you cannot do better than replant some more of the same. To these you may add any or all of the following according as a large or small collection is required—*Gloire de Dijon*, *Climbing Devonensis*, *Brennus*, *Charles Lawson*, *Chénédole*, *Général Jacqueminot*, *Madame Plantier*, *Paul Ricaut*, *Paul Verdier*, *Amadis*, *Thoresbyana*, *Félicité Perpétuelle*, and the White and Yellow Banksian Roses. The best position for *Tropæolum speciosum* would be a cool moist wall with a north aspect. Frequent forking the ground and burning the roots removed is the only way to exterminate the Bindweed.

Watering Vines (J. T. S.).—In the present issue of this Journal are several communications from practical gardeners fully corroborating your experience in regard in supplying water to Vines when the Grapes are colouring. It is

often advised to discontinue watering the border when the fruit is ripening, but this is carried to the extreme, and there can be no doubt that moderate supplies are beneficial until the wood is thoroughly matured. Of course this especially applies to borders inside the house, as those outside usually have sufficient naturally at this time of year, indeed frequently too much in districts where the rainfall is heavy, and consequently they need protection by shutters or some similar contrivance.

Roses for Buttonholes (W. W. R.).—No Roses are equal to the Teas for this purpose, but Moss Roses are often acceptable. Hybrid Perpetual Roses are too large, Général Jacqueminot being perhaps the most useful, and we think fifty plants of it would be more profitable than one plant each of any fifty varieties that could be selected. Teas, however, are the most suitable, and it will be better for you to have a number of plants of a few varieties than a large number of varieties represented by one or two plants each. For roofs and walls grow Maréchal Niel, Gloire de Dijon, Madame Trifle, and Cheshunt Hybrid. Near walls and in other positions grow Niphctos and Isabella Sprunt in large numbers. Madame Falcot, Lamarque, Madame de St. Joseph, Marie Van Houtte, Safrano, Mons. Furiado, and Catherine Mermet are also suitable. Some others may be equally good, but we have already named too many, as those who grow buttonhole Roses for sale find it to their advantage to grow few varieties. A number of the Tea Roses should be grown under glass, the others in the open air, to be protected if needful during the winter months. Some of the most hardy of the Teas are Madame Berard, Bouquet d'Or, and Madame Bravy. Mrs. Bosanquet is also suitable for outdoor culture, and the white Boule de Neige and Baronne de Maynard afford a profusion of white flowers, but not tea-scented. They will succeed well in your soil on the Manetti stock.

The Cucumber Disease (R. Potter).—The form of disease that has ruined your crops is, we regret to say, incurable, at least it has baffled the efforts of the most skilled gardeners and best Cucumber growers who have attempted its extermination. You appear to have done all in your power to save your plants and crops, and we can only suggest that you cease attempting to grow Cucumbers in the house for two years, and endeavour to produce a supply in frames or hotbeds. We have known cases where it was impossible to grow Cucumbers in a disease-stricken house while the plants in frames flourished, but this is not always the case. The only practical mode of maintaining a supply of fruit where the disease exists is to keep on constantly raising young plants, and let each, if they will, bear two or three fruits before the disease develops into a virulent form. If you would like to read much that has been published on this form of disease you will find it in vol. xx. of the Journal; if you do not possess this volume the following numbers, which can be had from the publisher in return for 3½d. each, will answer your requirements—524, 526, 529, 530, 532, 534, and 536. No. 720 contains illustrations of the Cucumber-root disease, which will afford you instruction.

Covering Vine Borders (J. A.).—The outside border of the house, started on the 1st of December, should at once have shutters placed on, especially as they are of glass, which will prevent the soil being soaked and cooled by the autumn rains, and retain the heat of the soil much longer. We presume the Vines, now that the wood is ripe and the leaves down, have been pruned; if not it should be attended to at once, so as to allow the Vines to have a season of rest before starting. The other Vines that are not ripening the wood well would be benefited by a little fire heat by day with free ventilation, turning the heat off at night, and maintaining a dry condition of the atmosphere. Keep the laterals closely stopped. The shutters may now be placed on the borders, which will aid the ripening of the wood by preventing the border being saturated by heavy rains. Too much bone dust would affect the Vines injuriously by inducing too vigorous a growth, but it is more likely the border is too wet and cold. If by "muffled" you mean that you employed some substance on the glass that would shade or break the force of the sun's rays, that would certainly affect the Vines injuriously, as too much light cannot be afforded them, except when the sun is very powerful.

Skeletonising Leaves (M.).—Nearly all leaves may be skeletonised, but some require a longer time than others to become macerated. For instance, the seed vessels of the Winter Cherry, Henbane, and Poppy require a fortnight or three weeks if the weather be hot. Leaves of Ficus elastica (Indiarubber Plant) and Magnolia grandiflora require several months; leaves of the Tulip Tree, Poplar, and Maple a fortnight; leaves of the Holly and Ivy two or three weeks. Ferns require a long time, and so do the leaves of Beggars' Broom, Butchers' Broom, the Orange, Lemon, and Camellia. Great care must be taken in choosing the leaves, as the smallest speck spoils one. Many more should be placed in the water than are needed, as not more than one in twenty will be perfect. The time required depends on the weather. Beginners examine them too soon. The leaves should be put into soft water in a sunny situation, taking care that they are covered with water. Evergreen leaves may be skeletonised at any time, but deciduous leaves not before the end of June or beginning of July. Seed vessels must be operated upon when nearly ripe. When quite ready for skeletonising put the leaves into boiling water to remove the offensive smell. Remove the scum from the water. Brush off the pulp with a rather hard brush. If the leaves are tender bump them gently, which removes the pulp without disturbing the nerves of the leaves. Pour clean water over them until quite clean; put them on blotting paper to dry—a piece of glass is useful to brush them on. Tender leaves should be floated in water and caught on a card, as are fine Seaweeds. Bleach with chloride of lime and then wash them thoroughly with clean water, otherwise they become yellow. It is better not to bleach them until required for setting up. Thistles and Teazels look well when bleached and aid much in arranging a group.

Flower Beds, Westminster (W. B. H.).—We have applied to the Superintendent who has charge of the flower gardens in Palace Yard, Westminster, and are informed that they were laid out fifteen or sixteen years ago, and that he does not know by whom the beds were designed.

Names of Fruits.—Several parcels of fruits have been received, but all of them being still unripe an examination of them is postponed for the present.

Names of Plants (G. O. S.).—The specimens sent are quite insufficient for identification. (H. M.).—The fungi sent are true Mushrooms—*Agaricus campestris*. (W. R.).—1, *Asplenium viviparum*; 2, *Adiantum assimile*; 3, *Blechnum brasiliense*; 4, *Cheilanthes elegans*. (N. S.).—1, *Rudbeckia Neumannii*; 2, *Dahlia Paragon*; 3, *Dahlia glabrata*.

COVENT GARDEN MARKET.—SEPTEMBER 20TH.

PRICES without alteration generally, Kent Cobs only excepted, which have been selling freely at a good advance. All other goods firm.

POULTRY AND PIGEON CHRONICLE.

THE INFLUENCE OF CLIMATE ON CULTIVATION.

In considering this subject it is our object to state as concisely as possible the effect of climate on the successful production of the plants and cereals which are chiefly cultivated; to consider the agricultural practices prevailing in various districts; also to point out the variations prevailing in the rotations of cropping, the system of cultivation and manuring of crops, which are more or less influenced by climate. We shall endeavour also to keep steadily in view those other elements often predominating over those of climate, and are principally concerned in arranging our farming rotations.

It will be found in all parts of the kingdom that the demand for certain crops, together with ample supplies of manure, render farming systems very much alike in the immediate neighbourhood of large towns and railway stations. But it is principally in the inland districts where the features of distinct systems are the most noticeable and more generally adhered to. We usually find that those crops which are most cultivated are the most suitable to the soil and climate. Still there are many exceptions to this practice, owing to what may be termed the economy and frequently the necessities of cropping. For instance, Turnips are well known to thrive best in the cooler climates of the kingdom and where the rainfall is more persistent. As it is found the climate of Scotland and the western counties of England are more suitable for the growth of Turnips than Norfolk and other eastern districts. We have often thought it a curious circumstance that Turnip culture should have commenced originally in the eastern counties, and then become a more important produce in the north and west. Still it is a singular fact that in no part of Scotland is a fourth part of the arable land devoted to the culture and growth of Turnips as is the case in Norfolk. It is an expensive crop to cultivate, and when raised to such an extent as one-fourth of the arable land it necessitates a correspondingly greater breadth of the higher-priced cereals. But this is a resource which neither the Scotch nor the west of England farmer can resort to. Strictly speaking they cannot, except in the Lothians, afford to grow so large a breadth of Turnips as the Norfolk farmer on account of not

being able advantageously to grow so large a breadth of Wheat or Barley, which have for a long period been the most valuable of the cereal crops. Other beneficial products, however, such as Potatoes, intervene and enable the Scotch farmer to pay as high rent for land of equal fertility as the Norfolk farmer.

We must now refer to what chemistry will teach the home farmer, for thereby he can learn the changes which are enforced by the laws of climate and the conditions under which the various sorts of plants flourish and yield their different products in the greatest abundance and perfection. It must be understood that, other things being equal, the force and vigour of vegetable growth is largely in proportion to the temperature of the atmosphere and soil. It is well known that plants grow with much greater rapidity in summer than in spring in tropical countries than in temperate climates. It is ascertained that the higher temperature enables plants to assimilate a larger portion of food in a given time. Plants may, therefore, be said to be more grateful for a supply of manure when applied in summer than for spring growth. For instance, the vegetables grown by the market gardener are said to be forced by manure, because the ordinary kinds are grown during the colder period of the year. Again, not only are plants enabled to assimilate a larger quantity of manure during the summer season, but they also appear to have much greater powers of absorbing food from the atmosphere. This, however, may arise from two causes, as it is assumed that ammonia, a most fertilising agent in producing vegetable growth, exists in much greater abundance during the warmer season, its quantity in the atmosphere being in a great measure regulated by that of its water or vapour, which is always greatest in the summer season. Another cause of the greatest power possessed by plants of absorbing ammonia during warm weather is attributed to the greater vigour of the plants and their enlarged leaf surface. When manure is abundant and cultivation correct the farmer should endeavour to select those plants which have the capacity of yielding a growth or crop in proportion to the quantity and quality of the manure applied; but this can only be fully obtained when their period of growth continues during the summer season. For instance, we may state that these conditions are fulfilled in flood meadows and those under irrigation, also in a field of Cabbages or similar vegetation, for both grow well as long as the temperature is suitable for vegetable growth, and both possess great capacities for growth under liberal treatment. It may also be noted that in case of irrigated meadows, even in the early spring and winter months when ice prevails, the grass will grow under it to a certain extent whilst the meadows are in flood, for the simple reason that the temperature is higher under the ice and water than in the atmosphere above.

The quantity of plant food to be obtained from the atmosphere appears to depend in a great measure upon the capacity of plants and the extent of surface they expose in the form of healthy and luxuriant leaves which they can maintain during the period of growth. Under favourable conditions we may notice that grass and the Clovers produce a continual succession of leaves, which renders them much less dependant on a supply of food to their roots when derived either from manure or natural fertility of the soil. Again, take the case of the natural vegetation of woodlands, including our various plantations of the Fir tribes, which yearly obtain a large amount of sustenance through the large leaf surface exposed during the summer months, and it is consequently seen the profitable production of timber trees, although planted upon the most worthless and otherwise useless soil, even in the highest altitudes and most exposed situations. With regard to our forage plants, within certain limits the strength of vegetation relies upon the temperature if a due supply of moisture is present, but when moisture is deficient the most abundant supplies of food in the shape of manure are of little avail in promoting growth.

It is, therefore, to be noticed that much of the skill of the home farmer as well as farmers in general consists in selecting those plants and cereals which are most suitable to the climate, as well as in adopting those special modes of cultivation which tend to compensate for deficiencies of climate; and with due observation the farmer may generally rely in a great measure upon the products of nature, and the best examples of cultivated productions upon any particular district in which it is his fortune to be placed. For instance, the blowing sands and rocky seacoasts are occupied by those species of grasses which can resist the extreme aridity of the strata in which their roots are working. Again, it is only on deep loamy and naturally fertile soils that the finer and more luxuriant grasses flourish in dry climates. Deep-rooting plants like Lucerne, Clover, and Sainfoin are less under the influence of drought, and are necessarily objects of culture in all our driest climates. On the other hand, the more rainy districts of the west of England render them specially genial to the

growth of the shallow and surface-rooted varieties of grass, which are consequently an economical means of restoring and maintaining fertility to land previously exhausted by cropping. Italian Rye Grass furnishes an excellent and practical illustration of the influence of climate, and it may also be said to be the cause of one of the peculiar contrasts between the rotation of Norfolk and that of the west of England and in Scotland, for in these latter districts the climate promotes its continuous growth throughout the season, whereas in the drier climates of the eastern and southern counties frequent and liberal dressings of liquid manure or nitrate of soda only enable it to produce a rapid successional crop.

Pasturing seeds successfully for two years is another system which is very generally adopted with success as a means of restoring fertility in Scotland and districts of the west of England; in fact such a practice is often covenanted for in leases, and is well calculated to maintain the productiveness of the soil and husband its resources. It must, however, be considered best adapted as a system or rotation upon good useful loams which can maintain the herbage in a growing state. There is a point to be considered by the home farmer in this matter, which is to him of some consequence. Very shallow and weak soils do not generally support certain grasses, such as ordinary Rye Grass, the second year, and it is only when indigenous varieties appear, or when the few of the best kinds of permanent grasses are sown, that the produce in the second year becomes advantageous. As pasturing seeds for two years ought to be regarded, although in a lesser degree, as a substitute for improving the land like consuming a crop of Turnips for two years in succession, the advantage at any rate is found in its requiring no expense in manure and cultivation.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—All the horse power and also that of steam should still be continued on the autumn tillage of land which may have couch, black bent, or onion grass upon it wherever the land is not under crop, such as young Clover seeds and Clover leas. All the rest of the land should be very carefully examined to ascertain what weeds exist which autumn tillage will destroy, whether it is intended for Mangolds, early Barley, Potatoes, Carrots, Peas, and Beans. We wish especially to call the attention of the home farmer to the advantage of forking out grass by hand labour. If there is but little of it so much the better, and it should not be allowed to remain. It is no use to say that the grass is but little, that it will not injure any crop. That may be true for the time being, but it will be sure to increase if allowed to remain while the land is under crop, especially where it has been liberally manured. There is no plan which saves so much horse labour as forking out grass at every opportunity; for instance, in preparing the land for Potatoes. During many years we never thought of giving the land much costly tillage, our plan being after harvest as soon as the stubble Turnips were seeded was to plough the land a fair depth without working down, and after about two months any bunches of couch which may have started were forked out. The land was allowed to remain without working during the winter, and again in February, carefully forking out any lumps of couch which may be seen, and then only working the land with iron harrows twice, crossways and transversely, just before ploughing and planting, which was done simultaneously, the manure being strewed by hand in the furrows with the sets at planting time. We always avoided yard or town manure, because the laying-out takes time and frequently treads the land and traeks it in adverse weather, seriously injuring the condition of the land for planting. Thus it will be seen that the actual work of preparing the land is reduced to a minimum, the horse labour being only two ploughings and five harrowings, and the hand labour only two forkings of couch, planting the sets, and hand-strewing the artificial manure, guano being found the most successful. In carrying out such a course of management and cultivation our farm was always clean; for the same system of forking was continued under all circumstances. We never employed more than four horses except an odd horse or mule to each hundred acres of arable land, and yet no steam cultivator was ever required or employed on the farm, no regular fallow being made for a period of twenty years except for Mangolds, and these generally were grown after stubble Turnips fed-off by sheep in the early spring or winter months.

Hand Labour.—The labour question in most districts is fast becoming a very serious and costly affair. Education appears to have taught the rising generation of the labouring classes that anything is better than working on the farm, therefore large numbers of the most enterprising youths are employed in the towns, any employment being considered better than agricultural labour. We therefore ask the home farmer to consider how the habits of the farm labourers can be improved, by exciting amongst them a spirit of emulation in their various departments of labour, such as ploughing, rick-building, and thatching. Within our recollection there used to be labourers' encouragement societies existing in nearly every district, by which prizes were offered for the best ploughing, for the best ricks built

and for the best thatching, and awarded to men who formed part of the staff of labourers on the particular farms where they worked. Many of these excellent associations have, however, fallen into disuse, and very unfortunately, for they are at present more needed than at any former period. It is now not only more difficult to get labour properly performed on the land of various kinds, but it is equally difficult to get a fair day's work done, although the wage is higher than it has ever been before, and which wage will purchase more of the workmen's family necessities than at any former period. In our district the workmen on the farm are encouraged by prizes for various kinds of farm work, and rewards given for long and faithful servitude, and we believe the idea is extending, as it has an excellent effect; for unfortunately at the present time there is not only a strong desire on the part of the workmen in various localities to do as little as possible for their wages, but a hankering after change possesses them, so that labour now has become more casual than ever. This, however, the home farmer may meet to a certain extent by a sufficient number of cottages on the estate being made available to accommodate men and their families, to do the work on the farms of every kind, and by a system of living which shall fix them in their position as long as possible, but at any rate it should be for not less than twelve months.

Live Stock.—Cattle and sheep are extremely high in price, the latter especially, and we cannot help thinking that the home farmer should reconsider his position as regards the maintenance of a large stock of sheep, and that it should not extend beyond the actual requirements of the estate and the ornamentation of the parks and pastures of noblemen and gentlemen, especially as nearly all of these have a taste or liking for the sake of appearance to some particular class or breed of animals. This is well; but when we come to take into serious consideration the advantage and benefit to be derived from the keeping of sheep on the arable land, it is time to think about a new departure, and inquiry at any rate into the cost and returns obtained by the feeding or fattening of sheep on arable land, other than the value of their manure. One thing at any rate we feel assured of, that manure can be purchased cheaper than it can be obtained by sheep feeding on the farm; but as we shall return to this subject, and hope on a future occasion to afford reliable calculations upon the cost and expenses as compared with returns obtained by the fattening of sheep. We hope the home farmer will at once discard all former notions and prejudices upon this matter, it being too commonly supposed that it is stock instead of corn which pays the farmer for producing.

POULTRY AND PIGEONS

POULTRY NOTES.

THE entries at the Newnham-on-Severn Poultry, &c., Show, to be held to-day (September 21st), closed as follows:—Poultry, 130; Pigeons, 340; Rabbits, 50. Considering that the first prizes are only 15s. in the poultry classes and 12s. 6d. in the Pigeon and Rabbit classes this entry is extremely high, and shows that there must be confidence in the management of the Show. We believe that a second Judge will be obtained, as Mr. Cresswell is always unwilling to undertake more classes than can be carefully judged.

OUR readers may be interested to hear the sequel of the Warwick frauds. Some of the would-be exhibitors who paid entry fees have lately received the following circular:—

Warwick, 25th August, 1882.

WARWICK DOG AND POULTRY SHOW FRAUD.

SIR,—The promoters of the above Show having been tried, convicted, and sentenced respectively to fifteen and four months imprisonment, it is intended to divide a portion of the moneys found upon the prisoners amongst those persons who paid entry fees.

After payment of the costs incident to the prosecution of the prisoners (which have been considerable), and at the suggestion and with the concurrence of numerous exhibitors of a gratuity to Inspector Hall of the county constabulary, through whose active exertions the prisoners were apprehended, and but for whom they would undoubtedly have evaded justice, and also setting aside a small reserve fund to meet demands at present unknown, the balance in hand will extend to make a return of 6s. 8d. in the pound, being one-third of the entrance moneys paid by each exhibitor, and this can only be paid to them on their giving me a written indemnity.

Be good enough to inform me the amount of entrance money paid by you, and that you concur in the above scheme for the distribution.

I am, Sir,

Yours obediently,
W. B. SANDERSON,
Solicitor to the Prosecution.

We understand that certain exhibitors refuse to "concur in the above scheme" till further particulars on various points are published.

MANY exhibitors will miss the well-managed Oxford shows, where most of the promising chickens of the year used to appear.

An energetic committee are striving hard to continue the annual shows abandoned at Oxford in the neighbouring town of Banbury. It is hoped that a schedule will shortly be issued drawn up on the lines of former Oxford shows for an exhibition to be held about the usual Oxford date.

MEANWHILE we have received the schedule of the Dorchester Show on October 18th and 19th. It also is not unlike that of former Oxford shows, and offers very extended classification—viz., fifty-six classes for poultry and over eighty for Pigeons, besides local classes confined to residents in the county of Dorset. The last Dorchester Show took place during the memorable snow-storm of January, 1881, and was consequently a failure. With such a prize list this Show should make up for the financial loss consequent upon the last. The Secretary is Mr. Charles Parsons.

THE schedule of the Nottingham Show, to be held on October 5th, 6th, and 7th, contains a somewhat unusual regulation—viz., the price of Pigeons and Rabbits must not exceed £10 each. The object of it is of course to exclude a few "well-known and certain winners," and to give a chance to would-be purchasers of procuring good birds at not extravagant prices. We are pleased to see it, and shall watch the result with interest. The Judge of Pigeons is Mr. Fulton, a pretty good guarantee to exhibitors that the birds will be well placed.—C.

OUR LETTER BOX.

Crossing with Game Fowls (J. N.).—Dorkings are decidedly the best breed to cross with Game for table purposes. We have frequently recommended the cross in our pages.

Peacock Moulting (X. F.).—Keep it warm and give generous food. Do not let it out early in the morning if the weather is chilly, but feed under cover with soft food such as bread and ale. Milk porridge made very thick with oatmeal, a little boiled meat cut small, and potatoes.

Stocking a Rabbit Warren (W. S.).—Wild rabbits are better than tame for a warren, and the best time for stocking is early spring. One male to thirty females will soon stock an acre. The number that can be grown depends entirely on the pasturage and the food that is otherwise supplied. If they eat the trunks of established trees it is evidence that the warren is overstocked, and the animals must either be reduced in numbers or the food supply increased. Rabbits will bark young Larches and destroy them—that is, trees that have been newly planted, but they will not attack established trees unless driven by famine to do so. Galvanised wire netting 3 feet above ground will suffice if it is properly fixed below ground also. It is little use sinking it straight down, as the animals are very persevering, and will burrow under it sooner or later. The best mode of fixing is to bend the bottom of the wire inwards, or facing the warren, covering a foot of it 3 or 4 inches deep. They invariably commence scratching within a foot of the fence, and of course, if they come in contact with a layer of wire, their further progress is obstructed; but if there is no such obstacle they will descend for 3 or 4 feet if the soil is light.

Roup (X.).—We can only suggest the application of the usual roup remedies. Begin with a dose of castor oil, afterwards wash the face and nostrils frequently with Labarraque's solution of chlorinated soda diluted with twice its quantity of water. Give also Walton's roup pills as directed on the box. The house where the birds have been should be thoroughly disinfected. If there are any other symptoms than those you have described write again, and we will advise you as to further treatment. We cannot understand the blindness of the recovered birds. Do you mean that one eye remains closed, or that the sight of one eye is destroyed?

REMARKS.

10th.—Hazy and dull all day.

11th.—Foggy in morning; dull cloudy day; rain at night.

12th.—Rain and drizzle early; fine and bright about midday; cloudy afternoon.

13th.—Fine, bright, and pleasant.

14th.—Fine and bright early; thunderstorm in afternoon with heavy rain; foggy evening and night.

15th.—Fog early; fine bright day.

16th.—Fine pleasant day, brightest in the morning.

On the whole a fine and pleasant week, but with a good deal of mist and fog in the early morning and at night. Mean temperature about 3° below the average, and nearly 6° below that of the preceding week.—G. J. SYMONS.

TREE AND SHRUB PLANTING.

IS the subject exhausted? No; but it is so familiar that I have repeatedly decided everybody must know all about it. Sooner or later, however, this conclusion invariably proves erroneous, and we feel constrained to put forth a helping hand to those who are willing to be helped and are sensible of their need. It is for such that I once more offer a timely word of warning and advice about planting, for the season for this important operation is fast approaching, and success or failure as regards the subsequent health and growth of the trees depends very much upon early planting and close attention to every detail of the work.

In the first place decide forthwith what to plant. Why are you going to plant at all? If for shelter for house or garden, then consider how this may best be done. Sturdy fast-growing trees are undoubtedly best for house shelter, and of such, if the soil be somewhat shallow, dry, and poor, take common Beech, Spanish Chestnut, two of the Willows—*Salix alba* and *S. caprea*, white Birch, the London Plane (*Platanus occidentalis*), the Tulip Tree, wild Cherry, Larch Fir, and Locust Tree (*Robinia Pseud-acacia*) among deciduous trees; and of evergreens common Silver Fir, Austrian Pine, *Pinus insignis* if the position is moderately elevated or on steep slopes or hillsides, Scotch Fir, and Corsican Pine. But if the soil be deep and heavy, then to the Beech, Plane, Tulip Tree, and Chestnut add the common Oak, Turkey Oak, Scarlet Oak, the handsome evergreen Lucombe Oak, and common Ash, which is not half so much planted as it ought to be, for it soon becomes a fine tree, and its foliage is very beautiful. Never plant for shelter solely with evergreen Firs; the effect is invariably heavy and monotonous. Let evergreens predominate if you will, but blend with them enough deciduous growth to impart variety and summer fullness and brightness. Avoid straight lines and formal belts as much as possible. If a belt is unavoidable, then let its front be made picturesque with boldly projecting clumps, not in mere serpentine outlines, but sufficiently far out to arrest the eye and take it along glades of greenery before the background is reached, and then it will never have the harsh repellent air of an ordinary belt.

Garden shelter may, of course, be imparted by any of these trees, but much may be done in exposed situations by throwing up banks and planting them with shrubs. I have made a perfect screen in this way by using common Holly. At Rosemundy, on the north coast of Cornwall, the garden is admirably sheltered from the heavy gales that so frequently blow there from the Atlantic by banks clothed with Japanese Privet, and

at Battersea Park excellent examples of this easy mode of shelter exist in several parts of the gardens. Such banks also give privacy to roadside gardens, and are less expensive and more ornamental than walls, the inner slope being available for both shrubs and flowers.

If it is intended to plant tree and shrub groups for ornamental purposes, again strive for cheerful combinations and soft flowing outlines. Circular groups are my especial favourites, whether standing alone or in clusters. They should never be less than 30 feet in diameter, unless you are much crippled and confined for space, and when in clusters 10 or 12 feet of turf between them affords ample space for inspection, and nothing can be more delightful than a stroll among them when their occupants are in the full beauty and freshness of spring and early summer. If there is but little lime in the soil Rhododendrons will, of course, predominate. Plant thinly, and put in plenty of Lilies, such as *L. aurantiacum*, *L. speciosum*, and *L. auratum* among them, so as to have a succession of bloom after the Rhododendrons have flowered. Break up the soil deeply and drain it well, for Rhododendrons do not answer in close retentive soil.

Mixed groups are lovely, and we have a rich store to choose from. Here are a few favourites of proved merit:—*Forsythia viridissima*, with golden yellow flowers clustering thickly along its long flexible growth in spring, more beautiful this year than I have ever known it. *Hibiscus syriacus* of varied colours, blooming in autumn. *Ribes*, yellow, white, and crimson, with a double-flowering kind which comes later than the others, but all flower early in the year, as do the *Berberises*, of which *Darwinii* with its rich yellow flowers is best either for clumps or alone. Then there are the *Spiræas*, to which attention has recently been given, and *Weigelas* of various shades of pink; *Hydrangeas*, so beautiful just now; the lovely *Rhus Cotinus*, with soft, downy, rosy-purple inflorescence; *Escallonia maerantha*, a mound of glossy green foliage and abundant bright pink flowers both in spring and autumn; Japanese Privet with bold white flower spikes in summer; the best of the *Andromedas*, which are *A. formosa*, *A. Catesbæi*, and *A. floribunda*; *Kalmias glauca*, *rubra*, and *latifolia*; the tall-growing *Heaths*, *Erica codonoides*, *E. herbaacea*, and *E. mediterranea*. A mixed group of hardy *Heaths* is very ornamental; most of them are fading, but *Allportii*, *vagans alba*, *earnea*, and *rubra*, the Cornish *Heaths*, and the Irish *Heaths* are still good.

Of trees much, except in a general way, cannot be written in this brief paper; but I would strongly advise the more general planting of *Pinus insignis*. It does not succeed in low-lying, cold, damp situations, but it is so beautiful as to be worthy of a trial in all others. At Lamorran, where it has become a timber tree, it has the advantage of being planted upon the slopes of the valley; but its elevation above the sea level is by no means considerable. *Thuja Lobbii*, of which I planted some hundreds about eleven years ago, proves very ornamental near the sides of carriage drives and among deciduous growth. Some of them are upwards of 20 feet high, probably nearly 30. *Cupressus Lawsoniana* was also planted in considerable numbers at the same time. It has thriven and is ornamental, but is inferior to the *Thuja*. Of the *Piceas Nordmanniana* has taken the lead. The growth is free, stout, handsome, and symmetrical, with every appearance of making fine trees; *P. nobilis*, though far behind it, is doing well.

Abies Douglasii evidently requires a deep rich soil. Several have been planted, and all have made tolerably free growth, but the shallow soil does not suit them.

Particular attention should be given to select trees and shrubs suitable for the positions they are to occupy. To plant Conifers near to or beneath other trees is ridiculous, yet I have seen it done by persons professing to have competent knowledge of the work. Hollies and Rhododendrons answer beneath trees so far as to continue healthy and grow freely, but blossom must not be expected. Conifers may in many instances require some shelter, but they also want an airy open position and a pure atmosphere.

The best time for planting is near the end of October or early in November; no favourable weather should then be lost. Plant well then, and there will be very little risk of subsequent failure. "Plant well" is a comprehensive term, pointing to well-drained soil, carefully prepared stations, quick transplantation, little exposure to the air or injury of any kind to the roots, soil well and firmly packed among the roots, a mulching of litter at the time of planting, and due support to the stem at the same time, so that there is no risk of wind rocking and a consequent loosening of the roots in the soil. These are matters worthy of our best attention, for I am sure that they make success almost a certainty and failure an exception, arising from causes altogether remote from the planting.—EDWARD LUCKHURST.

AMONG THE CANTERBURY ROSES.

THERE are some good people who affect to doubt the good influence that exhibitions have in encouraging the growth of flowers. Now I know no place that can better refute such an idea than the good old city of Canterbury. Like most cathedral cities where manufactures have not reached, rejoicing in that *dolce far niente* which seems so consonant with the old walls and the glorious cathedral, it seemed as if no power could wake it out of its sleepiness. No flower shows seemed able to make anything like a firm foundation there; but some few years ago there went to the old city a parson who had for many years been a rosarian, and who has taught both by his practice and writing had shown that his was no 'prentice hand. He found there one or two who were equally ardent in their love for the Rose; and to these three gentlemen—the Rev. H. B. Biron, Captain Lambert, and Mr. Wm. Mount—Canterbury is indebted for having established a most vigorous and flourishing Rose Society. It has brought out other exhibitors, encouraged those who already grow the Rose, has brought some of our largest growers for sale to exhibit there, and altogether has added considerably to the interest with which the Rose is regarded in East Kent.

Two causes led me to visit Canterbury. One was that I was anxious to see the garden of one of the most successful of our new exhibitors—Mr. George Mount of Harbledon; the other was that my valued friend Mr. Biron is about to leave to take the living for years held by his father at Lympne, and I wished before he went to take a last look at his Roses, for he has made Harbledon famous in the Rose world, not only by his own excellent growth, but also because Mr. Mount is his pupil.

Mr. Biron's Roses have had no exceptional advantages of either soil or situation. They are grown on the top of the hill near the church, and are very much exposed to high winds, while the soil is rather of a hungry nature and requires good feeding. Now from, I will not say carelessness, but from the pressure of other matters, they were not so liberally treated last autumn as usual, and as a consequence they have not been anything equal to his in former years, and the trees looked as if they resented the neglect. Orange fungus, too, had been, as in many places this year, very busy. A large quantity of the Hybrid Perpetuals had lost their foliage; and although I do not think that this materially affects the plants for the future, it does detract from their appearance at present; but it is a singular thing with regard to this pest, that neither here nor anywhere else that has come under my notice have I seen a trace of it on the Tea Roses. Here some Teas right in the middle of Hybrid Perpetuals that were badly affected had no trace of it. Probably the readers of the Journal will take note of this and see whether this coincides with their experience. If Mr. Biron has raised no new Rose, to him at least belongs the merit of rescuing a Rose from oblivion and making it famous. I allude to Eugène Fürst, one of the grandest of dark Roses, which had almost passed away unnoticed but for his excellent exhibits of it, taking more than once the National Rose Society's medal for the best Rose in the Show with it; and now the demand for

it is so great that nurserymen are unable to supply it. It is a fine Rose, somewhat like Reynolds Hole, but even richer in colour—that is, in texture, and more constant.

We had a talk over his flowers and his method of growing. In one thing I think he is unique—the manner in which he prepares his Briar stock for budding. Instead of being anxious to secure fibres on the wild stock he pares off everything, and when inserted in the ground it is as bare as a cricket ball; but the result justifies the practice, as his plants have always rooted well and grown vigorously. He had thought highly of Harrison Weir and budded it largely in various ways and on different stocks, but he is compelled to say that it is a poor doer although a pretty flower. We had Madame Gabriel Luizet under discussion, and he showed me what evidently seemed second blooms, while Mr. Mount and others have expressed the opinion that it is a Hybrid Perpetual—a fact which I am happy to corroborate from my own garden, for I have just looked at one of my plants with six blooms on it, and so all I can do is to take off my hat and humbly apologise to him for my rudeness.

From Mr. Biron's garden I walked on to Mr. Mount's a little further on, past the house and grounds of that grand artist Mr. Sidney Cooper, who has made the neighbourhood of the old city known to many, who would have been otherwise ignorant of it, by his grand cattle pieces, who so often in his pictures repose in the quiet meadows that border on the Stour. No external sign marks the home of the Rose at Harbledon, for Mr. Mount is the village blacksmith—not such a one as is described by Longfellow, for it cannot be said of him—

"The smith a mighty man is he,
With large and sinewy hands;
And the muscles of his brawny arms
Are strong as iron bands."

For our friend is a little man in stature, as unlike one's ideal of his craft as can possibly be—sparse, and by no means strong; but he is like Longfellow's, a man of good purpose and strong resolution; and so when he went in for Roses, and his preceptor Mr. Biron asked him, Did he wish to excel, and he replied "Yes," he set himself to it in right earnest. His garden is but a small one. It is sheltered and the soil is good: perseverance, skill, and determination have done the rest. What is that rest? Well, here it is. Sittingbourne Rose Show, June 22nd—First prize, twelve vars.; first ditto nine vars.; second ditto, six Teas; first ditto, three trebles; best box and best Rose in the Show. Maidstone—First, nine vars.; first ditto six vars., three trusses each; second prize, six Teas; second ditto, six of one variety. National Rose Society, Bath, June 29th—Second prize, twelve vars.; second ditto, six Teas. Farningham Rose Show, June 30th—First prize, nine vars.; first ditto, six Teas; second ditto, six, same var.; seven-guinea cup, twelve vars., which would also have had the prize for best box in the Show, but was precluded. National Rose Society, South Kensington, July 4th—First prize, nine vars.; first ditto, six Teas; third ditto, six same variety. Canterbury, July 6th—First prize, twelve vars.; first ditto, six Teas; second ditto, three trebles.

Now this I think an unprecedented record in Rose-showing; and when people say the victory must always be on the side of big battalions I can adduce this as a case *not* in point, for Mr. Mount has not all told more than four hundred Rose trees. When I was there, there were still some grand blooms, and I was therefore not surprised to hear that he had taken at Ramsgate on August 16th the following prizes—First prize, twelve Roses; first ditto, three Roses; first ditto, best box; and at St. Peter's, May 30th, first prize, twelve open; first prize, twelve amateurs. Thus out of twenty-eight boxes shown he has gained nineteen first prizes, seven second, and one third—in all twenty-seven. Surely we may say to him—

"Thanks, thanks to thee, my worthy friend,
For the lessons thou hast taught."

And I am sure the good wishes of all true rosarians will go with him in his future course.

From Mr. Mount's I went to his namesake, Mr. W. Mount, the active local Secretary of the National Rose Society, whose pretty Rose garden I have ere now described in the Journal; but its very prettiness has been its fatal gift. It has laid too close to the water, and consequently the plants have suffered; nor has the Tea shed which he put up been as successful as he had hoped, so that altogether he was somewhat downhearted. But this very want of success has led him to fresh determinations. He hopes to secure a place elsewhere, and is already arranging for the plants that are to occupy it. Thus must it be with true rosarians: success in one case encourages to future exertions, and failure to fresh efforts to gain successes.

Captain Lambert is another enthusiastic grower of the Rose,

and in his very pretty garden on the Dover road has a nice collection of excellent plants, more especially Teas, while the Sweetbriar hedge that surrounds his rosery is a delightful feature which might well be copied by others. I had not at the time leisure to visit it, but hope to do so at some other time. The object of my visit was accomplished, and hope it may in some little way prove of interest to the readers of the Journal.—D., *Deal*.

PATRIE VIOLET.

I AM agreeably surprised to find in this a valuable addition to our already numerous varieties of autumn and winter-flowering Violets with double flowers. It has flowers of a deep purple, with a considerable amount of white at the base of the petals or in the eye; perfect half balls, in good examples the size of a florin. The footstalks are of good length but slender, and, like most other double varieties, do not support the flowers, which are from their weight prostrate. The foliage is very neat, not unlike the double Russian, but more heart-shaped. The plant is very floriferous, and from its neat habit is fine for pots, which for such varieties as this and the Neapolitan types need not exceed 5 inches in diameter, in which well-flowered plants are always acceptable for rooms. De Parme, Venice, and New York are fine grown in pots, and a succession can be had by drafting the plants from cold frames to a house with a temperature of 50° artificially at intervals. *V. argenteaeflora* in pots, with its runners flowering from every joint as well as from the crowns right through the winter in a temperature of 40° to 45°, is useful for brackets. It is without an equal for elegance, sweetness, and abundance of blooms. The more I see of it the more I like it; yet its flowers are single with pointed petals, and the colour grey, whiter in late summer and autumn than in spring.—G. ABBEY.

FRUIT-JUDGING AT EDINBURGH.

THE chief aim of horticultural societies is to stimulate and foster a desire amongst gardeners to produce fruits, flowers, and vegetables of superior quality for supplying the wants of their employers, and as an encouragement to that end handsome prizes are offered for competition to gardeners who may be desirous of testing their skill by placing their productions side by side with those of their brethren on the exhibition table, where the merits of the respective collections are decided by judges appointed for the purpose. In some instances, however, quality receives little consideration, while quantity or size of individual objects in the competing collections receives an undue share of attention, and is the means of securing the coveted prize.

In the culture of flowers and ornamental plants the cultivator has but one thing to keep in view—namely, the production of an object to please the eye. On the other hand, in the culture of most fruits and many vegetables his efforts should be to please the eye and satisfy the palate; and he who is able to place on his employer's or the exhibition table Pines, Pears, and Peaches, Grapes, Melons, and Plums, Apricots, Apples, and Figs that are pleasing to the eye and satisfactory to the palate has reached a good position as a cultivator. The eye, however, is a great despot or monopolist, and, like all despots, so long as it is satisfied cares very little whether other members of the same body or community are so or not.

I am of opinion that in the case of some classes of fruit at the great Show at Edinburgh on the 13th and 14th inst. the eye asserted its despotic sway, and awarded the prizes without giving its coadjutor the palate a chance of expressing an opinion on the matter. This was strikingly evident in the class for six varieties of Grapes, two bunches of each. In the collection that secured the highest honours there were large well-formed bunches, some being certainly unripe and second-rate varieties. These large well-formed bunches caught the eye in "the grey of the morning" and satisfied it to repletion. If a few of the outer berries had been removed from these handsome-looking bunches, and one or two of the interior been submitted to the palate, I am of opinion that it would have recorded an opposite verdict to that rendered by the eye.

In the class for twelve varieties of fruit the eye was again charmed with the collection that contained large bunches of Grapes of similar build and quality to those referred to; and, as a consequence, the first prize was awarded to it. The third-prize collection in this class should unquestionably have occupied the first place. Every dish of fruit in it was ripe and fit to place on the table of a prince, whereas the large bunches of Grapes and one of the Pines in the first-prize lot were in an unfit state, as regards ripeness, to place on any table.

Another class, that for single dishes of Peaches, supplied a further illustration of how the eye is fascinated by large-sized

fruits. In this case the winning lot was composed of large unnamed fruit of a sickly yellow appearance, there not being a tinge of peach colour to be seen on one of them.

At the beginning I remarked that the chief aim of horticultural societies was to induce gardeners to produce fruit, &c., of superior quality for the supply of their employers' wants; and the question I would now ask is this—Can bunches of Gros Guillaume and Trebbiano Grapes weighing from 9 to 12 lbs. be ripened early in September in any part of the United Kingdom to that degree of excellence that bunches of Madresfield Court and Muscat of Alexandria can that weigh from 2 to 4 lbs.? Even supposing it could be done, are the larger bunches as profitable and useful for our employers' tables? and will they keep as well as those of the lesser weight? If these questions are answered in the negative, as I expect they will, then why should our great horticultural societies encourage the production of such unwieldy bunches and award the chief honours to imperfectly ripened Grapes? I trust this matter will be taken up by others competent to deal with it, as an important principle is at stake—namely, whether fruit that could not be properly included in a first-class dessert should be awarded high honours because of its size, while other examples abundantly large for any dish or table, and of much better quality, should be placed in the background?—H. B.

PLANTS FOR WINTER FLOWERING.

IT is now time for all plants which have been grown throughout summer in the kitchen garden to be lifted and placed in pots. The simplest way of managing these I have also found to be the quickest and the best. It is generally thought necessary, after potting any or all of these, that they should be placed under glass and kept in a close and moist atmosphere until root-action has commenced. But this is not so. In fact I have always managed so as to have root-action commenced before the plants have been housed. It may be useful to state the reasons why this system succeeds so well; and it may be premised that any plants which have previously been grown in pots do not need to be raised so as to break a portion of the roots a short time before lifting. With those which have not been in pots before, such as young Bouvardias, Chrysanthemums, &c., a slight raising a week previous to lifting is of advantage; but as a rule this is a part of the practice which has been considerably modified, as we find that very few plants suffer in the slightest degree lifted at this season. No safer time than the present can be found for removing and replanting strong border-flowering plants, young fruit trees, Roses, and shrubs. There is not enough heat to cause flagging, and when the days are warm the nights are cool and moist, so that root-action takes place quickly. All kinds of plants prepared by planting out in summer are under exactly the same conditions with these; and when placed in a shady position for a few days, with the little water that may be required, they become sufficiently established in a week to ten days to be removed into any house, whether cool or warm, without losing their foliage. Bedding plants which are occasionally lifted at this season are treated in exactly the same manner, and are found to do equally well.

A compost of three parts turfy loam to one of cow manure rubbed fine is suitable. Drainage must in every case be good, as a sufficient quantity of water is a necessity, and all chance of water-logging must be guarded against. Another point to be emphasised is that the smallest pots possible to contain the roots of the plants should be used, and the soil should be rammed very firmly down. These two latter points will ensure a floriferous condition in the plants. To maintain this condition manurial aid must be employed. This is done in our case by placing a small dressing of artificial manure once in every ten days on the surface of the soil, and is washed down when the plants are watered. A light position, ventilation when weather is favourable, and sufficient but moderate heat, are all that are required to give satisfaction to all concerned. Failure often follows through want of sufficient heat. A plant that will flower freely out of doors in August requires a stove temperature to flower in during winter.—B.

WASPS.—Much has been written from time to time about wasps since "DUCKWING'S" first communication last spring, which caused many to take more notice of these pests than they probably would have done; and I feel sure the more they are studied, even by "DUCKWING" himself, the sooner he will be convinced that he is in error. Last spring there were many queen wasps here, and we killed numbers with a garden syringe, which I find the most useful thing to bring them down with; but notwithstanding this and the continuous wet season there are many nests. We have already taken about a dozen, and I know of several more. This is not a large number in comparison with some places; but I think it is a lot for a

cold wet locality like this, and where a few bright sunny days in succession are of rare occurrence.—WILLIAM CONNELLY, *Leagram*.

WHAT IS THE MANURIAL VALUE OF PHOSPHATE OF MAGNESIA?

IN my letter, page 225 of the *Journal of Horticulture*, I endeavoured to show that agricultural chemists did injustice both to the buyers and sellers of manures in failing to appraise the magnesia they may contain. In my present communication I propose to carry forward my inquiry to the combination of this substance with phosphoric acid, which I believe to be the most useful form in which the latter can be applied to the soil for the nourishment of plants—an opinion which not only conforms with the teachings of Liebig, but is, so far as has yet been ascertained, supported by practical results.

In dealing with the question I shall, in the first place, recall to the minds of your readers how much uncertainty prevails concerning the efficacy of different forms of phosphoric acid, and that their true money worth to the farmer is by no means adequately measured by the valuations which the chemist puts upon them. I shall next inquire into the principles upon which, having a due regard to what is known of plant-nutrition and the mode in which it is brought about, these valuations should be made. Then I shall try to show that the teachings of science as explained by Liebig are fully borne out by practical experience; and, finally, I shall endeavour to persuade horticulturists as well as agriculturists that phosphate of magnesia meets all the requirements of a plant food in a most admirable manner, and ask your readers, if they are unable to show that it is futile, to assist me in my endeavours to spread a knowledge of the accuracy of what I advance. It may be assumed with confidence, I believe, that the generality of orthodox agricultural chemists fix, roughly speaking, the value of mineral phosphate of lime in a manure at a quarter the value which is given to it by dissolving it in oil of vitriol, and if, after having been brought into solution, the phosphoric acid is precipitated as phosphate of lime by an alkali or alkaline earth, the worth of this precipitated phosphate of lime is depreciated by one-half as compared with the same salt in the soluble condition.

This practice in valuation is (and as will appear on good grounds) departed from by some chemists, who put the value of precipitated phosphate of lime as almost, but not quite, equivalent to that of phosphate of lime in mineral superphosphates, say at seven-eighths of the value of soluble phosphate of lime in superphosphates, mineral phosphate untreated by acid being reckoned at one-quarter the value only of the soluble phosphate. The so-called insoluble phosphates (though not in fact absolutely insoluble) in bone or from guano are generally assumed to be of the same value as precipitated phosphate, or to differ little from it in value.

Let us now inquire upon what principle these valuations are confessedly based, or what chemists have to say in support of them. Broadly speaking we may assume that the point regarded is mainly if not wholly based on the solubility of the phosphates in water. Dr. Voelcker, in a very careful and conscientious paper on the "solubility of phosphatic materials," shows that one gallon of distilled water will dissolve the following amounts of phosphate of lime from different sources.

	In a gallon.
Estremadura phosphorite	0.10 grain.
Norwegian apatite	0.44 "
Coprolites (mean of Suffolk and Cambridgeshire)	0.62 "
Monk's Island phosphate.....	1.00 "
Pure bone ash (from very hard bone)	1.18 grains.
Pure tribasic phosphate of lime precipitated, burnt, } and finely ground	2.20 "
Guano	2.52 "
Pure tribasic phosphate precipitated and still moist..	5.56 "

The indications afforded by the foregoing results are summed up by Voelcker in the following conclusions. Extracts only are given from his table, and I have arranged the conclusions which I have selected in the order which seemed best to suit my line of argument:—

"7, The phosphates contained in coprolites, apatite, . . . Spanish phosphate, and other phosphatic minerals, especially when they are hard and crystalline, are very little acted upon by water."

"8, For agricultural purposes phosphatic minerals, as well as bone ash, should be treated with a quantity of sulphuric acid sufficient to convert the whole of the insoluble phosphates therein contained as completely as possible into soluble combinations. It is a waste of good raw materials to leave much of the insoluble phosphates unacted upon by acid."

"9, Insoluble phosphates present in superphosphate or other artificial manure have little or no practical value to the farmer."

"5, Bone ash is not sufficiently soluble in water to be used with advantage by itself or mixed with other fertilising matter as a manure."

"6, The earthy phosphates in Peruvian and phosphatic guanos still containing a good deal of organic matter or salts of ammonia are sufficiently soluble in water to be readily appropriated by plants."

And in an earlier part of his paper Voelcker shows that carefully prepared, precipitated, and dried phosphate of lime from bone phosphates constitutes "a very valuable fertilising material which is readily appropriated by plants."

These conclusions by Dr. Voelcker, which were arrived at about fifteen years since, would appear, in fact, to give some explanation of the results which Jamieson has shown by actual trial in Aberdeenshire and Sussex (see report of Review on the Experiments of the Sussex Association, page 110, *Journal of Horticulture*) to follow fine grinding of the coprolites used for manuring Turnips. With ground coprolites the results were as good as were obtained with superphosphate. If, then, phosphate of lime in finely ground coprolites, with a solubility in water of only 0.62 grains per gallon, can produce results but 10 per cent. below what follows from an application of soluble phosphate—and Dr. Voelcker considers (indeed no one disputes it) that phosphate of lime as found in guano, with a solubility of but 2.52 grains per gallon, is sufficiently soluble in water to be "readily appropriated by plants"—it ought not to astonish us, seeing that a small addition of sal ammoniac to the water increases the solubility of precipitated phosphate fourfold, that coprolite may become in a manure containing ammonia salts, or in a soil capable of yielding other equally or more powerful solvents, sufficiently soluble to produce the results which Jamieson obtained. But this question of the action of other solvents in conjunction with water must be left for my next communication. It is a question full of interest.—INQUIRER.

STRIKING EUONYMUSES.

ON page 270 of your last issue "A. B." has some remarks under this heading which I can fully endorse as being perfectly correct. Had he read carefully the whole of my article he would have found that I said these plants could be propagated in rooms by merely turning over them a tumbler, and by those who possess only a poor knowledge of window plants. When the choice variegated forms are required in quantity it is not wise to rely upon any makeshift system, but to follow judiciously one that is likely to lead to success.

There are many advantages to be gained by placing the cuttings in pots, as described on page 240. When the cuttings are callused they can be taken into the Conifer house where a little heat is always maintained, and thus they will form roots much more quickly than in cold frames. This saves valuable time (which means money to those who propagate them for sale), and the plants are established in pots and growing freely by the time "A. B." would have them rooted. The better variegated forms can be planted out from the cutting pots the same as "A. B." subjected his green kinds to; but it must be remembered the choice variegated forms do not grow so rapidly as the green varieties, and by establishing the former in pots they make greater progress than if planted directly outside. In extensive nurseries with which I am acquainted the better forms are kept in pots, which ensures their safe removal at any season.—W. BARDNEY.

ON PLANTING FRUIT TREES.

As the planting season will soon arrive preparing the ground should be commenced, as after-success depends much on this. If the ground is not properly prepared the trees will not do nearly so well, besides being a prey to canker and other evils. Some judgment must be used as to the stocks the trees are worked on. I should never think of planting Apples on the Crab stock in a small kitchen garden, as they soon grow out of bounds and shade the ground where good vegetables could be grown, and this remark may apply to gardens of a larger size. If the place is of good extent an orchard should be provided, where Apples on the Crab stock are the best to plant for large crops of fruit; but for a kitchen garden I should undoubtedly advise planting those trees that are worked on the Paradise stock. Have some method, not planting in the middle of the vegetable quarters, which spoils the appearance of the garden, besides vegetables, and wastes much valuable room. I recommend planting by the sides of walks, but not if there should be any danger of shading the trees on the walls.

Generally kitchen gardens are square, with a walk across the centre each way. That is the place to plant Apple and Pear trees,

and around the side walks opposite the walls espaliers are suitable, and these should not be planted unless they can be placed 20 feet from the wall.

In preparing the ground dig it 2 to 3 feet in depth and 12 feet wide. If the garden is old work some good turf and wood ashes with the soil. If, on the other hand, the garden is new, work in plenty of decayed vegetable refuse free from weeds, and burnt earth. When the time arrives for planting the trees, which is immediately after the leaves fall, no time should be lost if the weather is favourable. Never plant if the ground is frosty or wet. The trees on the Paradise stock should be 9 or 10 feet apart. Before planting cut off all bruised roots with a sharp knife, and dig the hole 18 inches larger than the roots when spread out. Be careful not to plant too deeply. After the tree is placed in the hole place some good prepared turf around the roots and shake it amongst them. Firm the soil, and spread a little litter about the surface. Do not prune them until the end of February, and if planted early they will start almost as well as established trees.

One thing must be borne in mind—that is, to procure trees that have been budded or grafted close to the ground, so that when planted the union may be covered with soil. If the trees are lifted once or twice annually after being planted and the soil well stirred it will help to make them handsome and fruitful trees. The following twelve varieties, culinary and dessert, will be found a good selection for succession.

Dessert Varieties.—Irish Peach, Kerry Pippin, Margil, King of the Pippins, Cox's Orange Pippin, Ribston Pippin, Ashmead's Kernel, Duke of Devonshire, Northern Spy, Mannington's Pearmain, Lodgemore Nonpareil, and Sturmer Pippin.

Culinary Varieties.—Ecklinville Seedling, Lord Suffield, Stirling Castle, Gravenstein, Blenheim Pippin, Warner's King, Betty Geeson, Wormsley Pippin, Loddington, Rymer, Dumelow's Seedling, and Northern Greening.—A. YOUNG.

AMONG THE ROSES AT CHESHUNT.

THE Cheshunt Roses! Who that has heard of them (and who has not?) or has admired them in their mossy stands at the Palace or elsewhere but has desired to see them in all their many thousands, and their surpassing beauty in their home in the fair Lea valley? Perhaps some to whom the fulfilment of this desire is among "the impossibles" may find some consolation in reading of what a more favoured fellow mortal saw on a fine Saturday afternoon.

Arriving at the nursery I was received (in the absence of Mr. Paul) by the intelligent Rose foreman, Mr. Gater, who conducted me first along the bank of the New River to the principal Rose quarters. Here our attention was devoted to a large piece of dwarfs on Briar cuttings; and here let me say that if it suits in other situations as it does at Cheshunt this bids fair to become the stock of the future. On one plant of Duke of Edinburgh I counted ten strong healthy shoots ranging from 2 to 3 feet in length, six of which were bearing blooms which would not have disgraced any first-prize stand. Another good quality of this stock is that Roses worked on it bloom intermediately between Manetti and seedling Briar, and thus what is often a gap in the blooming season is filled up and the beauty of the rosery maintained over a considerably longer period than could have been expected some few years ago. This piece is devoted principally to the older standard varieties, all of which appeared to be in splendid condition both of growth and of bloom, conspicuous among them being Marie Baumann, not (on this stock at least) the poor grower that our dear friend the late Mr. Radclyffe feared it was, but vigorous healthy bushes, with shoots 3 feet high and as thick as one's finger, bearing blooms that could only be described as magnificent in size and form. A. K. Williams, the greatest acquisition of late years; Louis Van Houtte, splendid; Alfred Colomb, in such style as I never remember having seen it before; Comte Raimbaud, an almost lost Rose till Mr. Baker astonished everybody with a bloom of it at Hereford about four years ago; Horace Vernet, Chas. Lefebvre, the "Old General," Sultan of Zanzibar, and Fisher Holmes among the dark Roses were also very fine. The lighter varieties had suffered much from wet cold weather, but the following among them were very fine—Capt. Christy, Comtesse de Serenye, Madame Gabriel Luizet, Baronne de Rothschild (shown in fine form everywhere this year), and the "everybody's Rose" La France. There seems to be some mystery about the parentage of the last-named Rose. Query, Is there any Noisette blood about it? It has been no uncommon thing this year to have a bunch of five or six blooms at the end of a single shoot.

From these we passed on to the Manetti quarters. Here the best of the bloom was over, but the following were proving themselves good late varieties:—Le Havre, very glowing; Beauty of Waltham, old but very good; Madame Victor Verdier, splendid colour and form; Baronne de Rothschild; Annie Wood, very bright; Marquise de Castellane, very fine this year; Royal Standard; Sir G. Wolseley, generally at its best late in the season; Ferdinand de Lesseps, Senateur Vaisse, and John Stuart Mill; Chas. Darwin also was exceptionally fine.

Our next advance was to the quarters devoted to the newer varieties. Here was a very fine display, and it was gratifying to note that

conspicuous among the best of them were those sent into commerce by English nurserymen. Harrison Weir is quite the Rose we should expect from such parents as Charles Lefebvre and Xavier Olibo. Mrs. Harry Turner, another Slough Rose, is splendid in colour, though perhaps a little inclined to open in the eye. Pride of Waltham will be a good addition to the light Roses, while Masterpiece is of the colour of Beauty of Waltham, but larger and fuller; and the bright crimson Rose honoured with the name of the lady who, until lately, reigned at the Old Weir, promises to afford blooms of fine size and substance long after her fellows have given up for the season. Of Mr. Paul's own new sorts it is sufficient to say that they will undoubtedly maintain the character their predecessors have gained—viz., good to begin with and improving upon acquaintance. White Baroness is being eagerly inquired for; George Baker is a large round bloom of the colour of Dupuy Jamain, and with foliage nearly as beautiful as its flower; Brightness of Cheshunt will add beauty to every garden in which it is found; and Duke of Teek is too well known and valued to need again describing. Among the newer introductions from the continent there also appear to be some decided acquisitions. Rosieriste Jacobs promises to be a gem of the first water. One bloom which I have in mind, I understand, was an exceptionally fine one; perhaps so, for it was as nearly as possible of the same size and form as Mr. Baker's medal-winning A. K. Williams at the Crystal Palace, with the colour of a good Xavier Olibo or Fisher Holmes. If of good constitution every exhibitor in the kingdom will want it. Another good dark one is Auguste Auchner, crimson, flushed with maroon. Guillaume Guillemot is a fine globular flower of a bright rose colour. Madame Montet is a delicate soft pink in colour, but rather loose in the petal; and Souvenir de Madame Alfred Vy is a useful distinct Rose, dark red, with a very decided purple shading. George Moreau and Comtesse de Camande are good additions to the bright reds; and Madame J. Periere is a very fine new Bourbon.

We next visited a fine piece of standard Teas, where we found Souvenirs d'Elise, d'un Ami, and de Paul Neyron; Devoniensis, Catherine Mermet, Madame Lambard, Jean Ducher, Niphetos, and many other well-known varieties of this beautiful class, most of them in very fine condition, though in many cases it would seem that as standards is not the best manner of cultivation for them. From hence we moved on to the unique Tea Rose garden, an enclosure surrounded by a thick hedge and laid out in beds, down the centre of each of which runs a wire trelliswork for the accommodation of Gloire de Dijon, Madame Berard, Cloth of Gold, and other free-growing sorts, the beds being completed by a row of standards and one of dwarfs (all Teas) each side the trellis. Among the many varieties of the Tea section which find a place in this snug spot Caroline Kuster and the little-known Princess Vera were uncommonly good.

This completed the outdoor programme, which was followed by an indoor one of almost equal extent. We visited houses devoted to plants in 10-inch pots for early forcing, houses of climbers in pots, houses of own-root Roses, to say nothing of almost acres of glass covering the usual stock of a first-class English nursery. By this time the genial proprietor had returned, and a pleasant chat about the Rose season in general, the French growers' establishments, the just-past exhibitions, and the many topics dear to the heart of rosarians, concluded one of the most pleasant outings ever enjoyed by—J. B.

LORD NAPIER NECTARINE FOR FORCING.

THIS subject is interesting to me from the fact that I have vacancies for a tree or two in the early houses, and Lord Napier being the best grower of all Peaches and Nectarines. I have several beautiful plants of this variety which I could select from if more evidence is forthcoming in its favour as a forcing variety. For my own part I have had no experience with it indoors worth taking into account, but out of doors it is a grand addition to our hardy fruits. Coming in as it does after Early Louise Peach and before Hale's Early, it fills what with me would otherwise be a blank. I have just pulled out a large plant of Early Beatrice which has never been satisfactory in the early house; and Hale's Early, which is the best of all the early Peaches I am acquainted with, has not always had a full crop indoors, but the trees are young, and they may become more reliable with age. I must confess, however, that as these two varieties are large-flowered, and Lord Napier Nectarine is the same, I have allowed myself to become a little prejudiced against large-flowering varieties for forcing. Still I cannot understand what there can be in the larger flowers to make the difference, and it may be only a coincidence with some other peculiarity of these varieties. I should be very glad if Mr. Bardney or anyone else can give us more particulars as to the time of ripening of Lord Napier when forced, say, to come in at the end of May, and whether it has borne a full crop under this treatment. I would also solicit the same kind of information respecting Hale's Early Peach compared with, say, Royal George.—WM. TAYLOR.

THIS Nectarine is highly spoken of on page 278 for an early house, where I have every reason to believe it will be very satis-

factory when grown under warm conditions to ripen the fruit and wood; but from what I can gather it is not a very reliable variety on walls outside, or even in cool late houses. I am acquainted with an able cultivator who formed a very good opinion of this variety last year, when the fruit swelled to a large size and coloured well. This season I tasted fruit from his tree, the crop only being thin, which was flavourless and not swelling satisfactorily. This he attributes to the heavy rainfall in the northern locality in which he lives and the cold sunless season. If this Nectarine, which promises so well for early forcing, proves unreliable outside or in late houses in this changeable climate, no time should be lost in discussing its merits or defects. The planting season is at hand, and if those who have grown it under cool conditions would record their experience in this Journal much valuable time and labour might be saved those intending to plant it in such positions. To grow a tree to a fruiting size and then have a failure is rather annoying, but this may be prevented by the records of experience.—LANCASTRIAN.

SEEDLING POTATO EXHIBITION.

THE first Exhibition of the kind was held at Northampton on Thursday and Friday last, within the enclosure for the Northamptonshire Agricultural Society and in connection therewith. The seedling Potato Exhibition originated through a suggestion of Lady Knightly of Fawsley Park, and the arrangements were undertaken by Mr. Farr of Fawsley Park Gardens, assisted by an energetic Committee; and although from the novelty of the attempt the working was somewhat crude and not altogether free from difficulty, yet from the material success which has attended their well-directed efforts on this occasion it is probable that the Show will become an annual one in connection with the agricultural meeting, when doubtless the experience gained this season will enable the Committee to remove or prevent a recurrence of any difficulties which may have occurred in the practical details of the Show. Sixteen prizes varying from £1 10s. to 5s. each in four classes for *bonâ fide* seedlings not in commerce were offered, and for these there were forty-six entries from various parts of Great Britain, a majority of the entries being in the popular class for white kidneys. The schedule required that, where practicable, the parentage should be stated; but this wholesome regulation was not, unfortunately, in several instances carried out, nor any explanation given as to the origin, or to enable identification of the variety. The specimens were judged after cooking, which would appear to have been defectively carried out, as none of the tubers tried were in really eatable condition, the excess of moisture not having been removed, and a test under such circumstances could hardly be thoroughly satisfactory.

The prizes were awarded as follows:—In Class A, for the best white kidney, Mr. J. Hughes, Eydon, Byfield, was first for a handsome longish white variety, described as a seedling from Paterson's Victoria, but it was not stated whether the variety was early, medium, or late, and the appearance indicated no connection with the parent variety. Messrs. F. & C. Myatt, Offenham, Evesham, were awarded second for King Offa, a seedling from Myatt's Prolific Ashleaf, but shorter and flatter than that variety. Mr. Cole, gardener to Earl Spencer, came third with Cole's Prolific, a good-looking kidney, but information as to its origin was altogether wanting. The fourth prize went to Mr. C. Ross, Welford Park, Newbury, for Welford Park Seedling, raised from Woodstock Kidney.

In Class B, for coloured kidneys, Mr. R. Fenn, Sulhamstead, Reading, was first for a long pink seedling from Snowflake; Mr. W. Kerr of Dargavil, N.B., being second for Sir Garnet, a longish-pointed red variety, broadly marked with white. The third prize went to Mr. Hughes for a handsome long flattish tuber, origin unknown. For the fourth prize no award was made.

In Class C, for white rounds, Mr. Fenn was again first with a variety of good quality, but hardly falling within the definition of a *bonâ fide* seedling nor a white round, as the tubers were marked with purple and said to be from a sport of Woodstock Kidney. Mr. W. Horley, Toddington, Dunstable, was second with a seedling from Giant King, but in appearance this variety was not much different from nor in advance of its parent. The third prize went to Mr. T. W. Hill, Durwards, Witham, Essex, for a deep-eyed seedling of the Champion type, but with whiter flesh, said to have been raised from a packet of mixed seed. Mr. Ross was fourth with his Sir Walter Raleigh, a seedling from American Excelsior.

In Class D, for coloured rounds, Mr. John Waugh, Castle Hill, Lochmaben, N.B., obtained the first prize with a pale red flattish round seedling, its cooking properties being above the average of the others exhibited. Mr. R. Roe of High Street, Northampton, was third, and Mr. Edward Simons of Harlestone, Northampton, third with a small round red. Fourth, no award.

Several good-looking tubers did not appear to find favour with the Judges, amongst them being two good-sized oval rough-skinned sorts from Mr. Hughes, stated to be crosses between Beauty of Hebron and Myatt's Prolific. A flat round seedling from Mr. Fenn, described as very early and possessing the dwarfest foliage of any known variety, appeared promising. Defective cooking is undoubtedly a serious drawback to a satisfactory test, and in future it would be well to have cooked some of the standard varieties and the parents of the seedlings,

where practicable, for comparison, due allowance being made for the size of the tubers and the period of ripening of the varieties, which should be given by the exhibitors.

ERYTHRONIUMS.

THE Dog's-tooth Violets form an extremely pretty genus belonging to the great Lily family, very distinct in appearance and easily grown. The majority of them are generally cultivated, as they are special favourites with most lovers of hardy bulbs. They are perfectly hardy, and, what is equally desirable, they appear to disregard the irregularities of our climate, which is not the case with a great many of our introduced bulbous plants, especially with those from North America. The common *E. Dens-canis* and some of its varieties are European, all the rest are American. There appears to be a considerable amount of confusion amongst amateurs as to the correct nomenclature of the species, many confounding the varieties of *E. Dens-canis* with the true species of similar names; for instance, the variety *albidum*, which is a European form, is frequently mistaken for *E. albidum* of Nuttall, and *vice versa*. I have frequently been asked, What is the distinction between the two plants? and the latter-named has even been regarded only as a synonym of the former. Such, however, is not the case, as the plants are distinct in bulb and foliage as well as floral arrangement. There are but few species, with some distinct varieties, and they are naturally divisible into two groups—viz., those with solitary flowers and those with from one to eight flowers. The former group include *E. Dens-canis*, and varieties *E. albidum* and *E. propullans*, while the latter is represented by *E. grandiflorum* and its varieties *E. Hartwegi* and *E. purpurascens*.

There is no difficulty attending the cultivation of these plants, neither are they very fastidious as to soil, as I have known them thrive in almost any soil and position with the exception of very stiff and clayey soil. A considerable number has just been raised, and the soil in which they have been grown during the last three years is very light and sandy, moderately rich and well-drained, while the position is quite open and exposed. I should not recommend a very exposed position, as owing to their early flowering they are very liable to be destroyed by strong cutting spring winds. To say the least, it is more than probable that the period of beauty may be materially shortened. But certainly they thrive admirably in light sandy rich soil, and if the position is sheltered they are extremely showy, and most interesting as a group of hardy flowers. It is not well to disturb them very often, as they will not be nearly so attractive if but half established. Allow them to remain undisturbed for some three or four years until the bulbs are overcrowded. There are a number of positions most suitable for them beside the ordinary border or bed, for it must be borne in mind that during the greater part of the summer they are dormant, and consequently there is only bare soil where they are planted. It is just as well to arrange them in such a position so that some half-hardy plants could be planted near them, and the barrenness would be reduced to a minimum. This could be very easily managed either on the rockery or in borders; but care should be taken to have the exact position of the Erythroniums marked, so they would not be disturbed when the summer-flowering plants are removed in the autumn.

Numerous chinks in the rockery could be filled with the bulbs which are frequently unoccupied, and they would be very charming when there are but few showy things in flower on the rockery. The various species of Croci are very pretty in such positions, and for naturalising in meadows, woodlands, by the margins of lakes they are admirably adapted. For this purpose the forms of *E. Dens-canis* are to be highly recommended, because they are very hardy and robust, and, what is equally important in such a matter, they are very cheap, costing but a nominal price per thousand, while the effect in association with Daffodils, Primroses, Oxlips, Croci, and a host of other plants would be very pleasing. They should be planted as early as possible after September in clumps to have the best effect. Most of the rarer species will probably be imported, but it is advisable to get home-grown bulbs if possible. In the event of having imported specimens it is desirable at first to pot them in light sandy soil (leaf soil, loam, and sand in equal parts) in small pots, and place them in a cold frame, just keeping them damp until root-action has thoroughly commenced, when they may without hesitation be planted out. This is merely advised as a prevention against possible loss and consequent disappointment.

E. albidum, Nutt.—A similar plant to the next species. Leaves oblong-lanceolate, not mottled or dotted. Flowers solitary, bluish-white, with the segments entire at the base. The flowers are rarely quite white. It is widely distributed, occurring from New

York and Pennsylvania to Minnesota and Texas. It flowers in April and May, and was introduced in 1824.

E. americanum, Smith.—Bulbs very small, brownish. Leaves oblong or oblong-lanceolate, mottled and dotted. Flowers solitary, light yellow, 1 to 1½ inch long, frequently spotted with purple at the base; segments slightly toothed at the base. Linnæus regards it as a variety of *E. Dens-canis*. It has also received the following names:—*E. carolinianum*, Walt., *E. lanceolatum*, Pursh (this was the accepted name for a long time), *E. angustatum*, Rab., *E. bracteatum*, Booth, and *E. Nuttallianum*, Schult. Thus it has a great variety of names, which are extremely misleading. It flowers with us in April and May, and has been known under cultivation ever since 1665. It enjoys peaty soil; in fact it does not thrive so well without as with peat. It is found from Canada to Florida and Arkansas.

E. Dens-canis, Linn.—Bulbs much larger than the last two species. Leaves ovate, ovate-lanceolate, or oblong, copiously mottled. Flowers solitary, 1 to 1½ inch long and nearly as wide, usually of a pinkish-purple colour, but there is a great variation of colour—white, yellow, and several shades of red. The white variety, which is named *albidum*, is very pretty, as also is the yellow-flowered kind. They are all of extremely easy culture, flowering outside early in April, being perfectly hardy. They are natives of Hungary, Italy, &c., and have been introduced ever since 1596, and it was well known to Parkinson, who describes it as "The Dog's-tooth with a pale purple flower." The typical form is well figured in "Curtis's Bot. Mag.," pl. 5.

E. grandiflorum, Pursh.—A very variable plant, with bulbs frequently 2 inches long but narrow. Leaves oblong-lanceolate, not mottled. Flowers solitary, or usually in racemes with from two to six flowers of a primrose yellow or cream colour, the base more or less tinged with orange, 1½ to 2 inches long. Mr. Sereno Watson has enumerated some varieties, all of which, however, he admits may be specific forms. Var. *albiflorum* (syn. *E. giganteum*, Lindl.; *E. grandiflorum*, Van Houtte) has large white flowers, orange at the base and mottled leaves. Var. *minor* has flowers about an inch long, bright yellow. Var. *Smithii*, Hook. (syn. *E. revolutum*, Smith) has large flowers tinged with purple or rose colour. Some if not all of these varieties are not found under cultivation in this country, or as far as my knowledge extends: I should be happy to learn that they were. The typical form is not very scarce, having been introduced since 1826. It flowers outside in April and May. It is found in Oregon, California, and Washington Territories.

E. Hartwegi, Watson.—Bulbs small. Leaves small, usually separated, ovate-lanceolate, mottled. Flowers usually two to three, very rarely solitary, in a sessile umbel 1 to 2 inches long, bright yellow, orange at the base, with spreading or slightly recurved segments to the perianth. It is Bentham's *E. grandiflorum* (*Pl. Hartw.*, 339). It is an extremely curious and rare species, occurring on the Sierra Nevada from Placer to Plumas counties, but not, I think, known in cultivation.

E. propullans, Gray.—Bulbs small. Leaves ovate, oblong acuminate, not mottled. Flowers solitary, about half an inch long, bright rose, yellowish at the base. A very scarce Minnesota plant, not existing in this country but cultivated in America, but of rare occurrence under cultivation, although a very pretty species.

E. purpurascens, Watson.—Bulb 1 to 2 inches long. Leaves large, more or less oblong, frequently undulated. Flowers usually from four to eight in a sub-umbellate raceme from 1 to 1½ inch long, light yellow tinged with purple, deep orange at the base. It has received several other names, and I enumerate all those that are reliable. *E. grandiflorum* var. *multiflorum*, Tour.; *E. g.* var. *multiscapidea*, Wood; *Fritillaria multiscapidea*, Kellog. Mr. Watson regards Baker's *E. revolutum* as only a slender one-flowered variety of this plant. It is of comparatively recent introduction, flowering outside in May. Native of the Sierra Nevada, found in the same localities as the last species. It is a very beautiful species, and by no means common.—N.

LILIUM CATESBÆI.—This charming little Lily is now in bloom in Messrs. James Dickson & Son's nurseries at Chester, although it has been with some difficulty induced to do so, as it is evidently not an easy species to establish. Its flowering is of very rare occurrence in this country. The flowers are about 3 inches across, solitary, on a slender stem about a foot high. The divisions of the perianth are sharply reflexed about two-thirds from the apex, bright scarlet, the lower part yellow with a few blotches. It is certainly very distinct and curious. A good figure of it occurs in the "Bot. Mag.," pl. 259, and Mr. Curtis says "he received bulbs of it at the close of the year 1787, sent by Mr. Robert Squibb from South Carolina, and many of

which flowered with various persons in this country." It seems to delight in good drainage and a compost of leaf soil, peat, loam, and sand.—CESTRIAN.

SILKWORMS AND SILKWORM REARING.—16.

(Continued from page 254.)

THE moth of the species *Attacus Yama Mai*, referred to and figured in our preceding article, is unlike some of its brethren in the silkworm group, which, as moths, are notably slow in their movements. Although neither the male nor the female of *Yama Mai* care for long flights on the wing, it is found that they in captivity perform, after emergence from the pupa, a succession of skips and jumps. The result of these "gymnastic feats" is by no means beneficial to their appearance. It is true, however, as Dr. Wallace observes, that their conduct when imprisoned may be, to some extent, different from their usual habits if at liberty, and

Fig. 46.—Cocoon of *Attacus Yama Mai*.

one of the experimenters has reported that his specimens thrive best in a cage which was both roomy and damp. Ere they force their way from the cocoon a liquid is discharged upon its fibres, which softens and loosens them. This by examination has been proved to be alkaline, not of an acid nature as in other species.

The cocoon of *Attacus Yama Mai* (fig. 46) is several times heavier than that of *B. Mori*, and the worm by preference encloses it in an Oak leaf; greenish in its exterior, the silk of the inner portion of the cocoon is paler or nearly white. In this the insect only remains a few weeks. The long period of quiescence during its life is passed in the egg state, which lasts from the autumn until the spring. This allows of the eggs being transmitted across the globe when necessary; it is only needful to keep them moderately cool, yet not too dry. The application of a magnifier has revealed the curious fact that the young worm or caterpillar hatches a few weeks after the egg is laid, but lies dormant in the shell until the end of April or May with us, emerging about the time the Oak is bursting into leaf. And although the species has been reared upon several plants beside the Oak, notably upon Apple and Beech, it seems to give preference to the Oak both in Europe and in its native land, Japan. Dr. Wallace rather thinks the Turkey Oak (*Q. Cerris*) is its special favourite, but the worms feed freely upon any species of *Quereus*. In repose

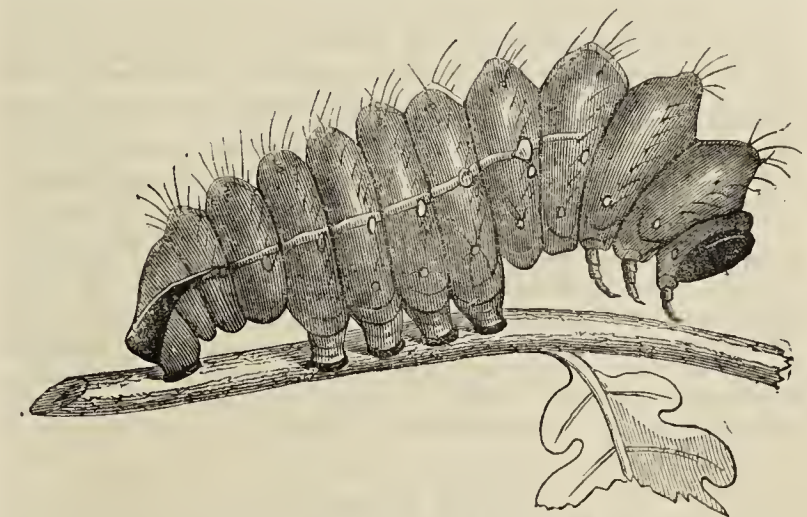

Fig. 47.—Caterpillar of *Attacus Yama Mai*.

this silkworm is fond of assuming the sphinx attitude (fig. 47), or with the head even more elevated than shown in the illustration. Before it begins to eat, the newly hatched worm shows a disposition to drink generally. The fact has been stated by a number of observers. Having sipped the morning dew and roved about a little, it may then be induced to begin upon the young leaves. Within an hour or two after quitting the egg it has so increased

its bulk that we wonder how it could have been enclosed in the shell so recently.

Of a yellow colour at first, with slight markings of black, the tubercles which are conspicuous later are hardly noticeable under an investiture of down. At each of the four changes of skin some alterations take place in its appearance, the grand increase of size, as is usual, occurring after the last moult. When adult the caterpillar of *A. Yama Mai* is of a beautiful green tint, having some curious silvery patches upon its sides; the tubercles are then blue. Occasionally these silkworms show a tendency to wander, which renders it impossible to keep them in trays as we do the common species, and, indeed, from the liability of Oak leaves to dry up, food distributed thus would want a too frequent renewal. There have been instances of these silkworms attacking each other (usually in hot weather), when they are immured in cages; but this should not be deemed a proof that they are naturally of a cannibal turn, like some caterpillars given to prey upon their brethren or upon other species. I might, however, remark that on showing one of these caterpillars to an entomologist who had never seen the species before, but who had been a careful student of caterpillar ways and doings, he observed on examination that he should have imagined from its appearance it could probably be vicious.

The experiments made with this silkworm both in England and upon the Continent during the years following the first arrival of eggs could not proceed very satisfactorily in consequence of our ignorance relative to its particular locality and its natural habits. To travel about Japan was difficult and dangerous, nor was information attainable by putting questions to traders and others who might be expected to know. Unaware to a great extent how *A. Yama Mai* might live in Japan, Dr. Wallace published in 1866 the following statement as the result of his practical investigations:—"It is necessary," said he, "to supply the very young larvæ with tender succulent leaves. They will bear a moderate amount of cold for brief periods with impunity. Though they avoid the direct sunshine, they like its warmth diffused through the natural leafy shade. Moisture is grateful to them at all times, and necessary to their existence, also a quick growth is most favourable. Dry hot weather is prejudicial to these larvæ, for which reason the climate of Ireland would probably prove highly favourable to the cultivation of this insect. Lastly, I am convinced that they would thrive better out of doors on the trees than in confinement."

Fifteen years have elapsed since, and a goodly number of experiments made under various circumstances uphold the Doctor's conclusions on the whole, but as yet, I fear, the Green Isle has not had her fair share of trial as a suitable home for the *Yama Mai*. The times now scarcely favour the introduction of a new industry to a land that furnishes statesmen and debaters with so many perplexing problems; but the day may come when the tourist, travelling in safety and comfort over Erin, may behold in many cottages the peasants busy over these or other silkworms, supplying them with food, collecting eggs from the moths, or winding off the cocoons.

Every silkworm has a liability to some malady or complaint, and the *A. Yama Mai* has been noticed to suffer from three at least, which are well defined as to their character and their period. Soon after the hatching, while they have only passed one or two of the changes of skin, the worms turn yellow and become soft. A similar complaint affects the common silkworm occasionally, French authors calling it the jaundice. The cause of this, Dr. Wallace suggests, is want of vitality or of power to assimilate nourishment from the food. Another complaint to which middle-aged worms are chiefly liable occurs in consequence of too high a temperature. The green hue of the surface fades to a dull brown, cracks appear at the segments, from which a white or greenish fluid issues when the worm attempts to move, and it speedily shrivels. Worms that are under the influence of the last complaint are familiarly said to be "peppered," from the tiny specks on the skin that precede the attack, under which they are sure to die if once seized. Unfortunately some of the largest in a brood are apt to be taken off.—J. R. S. C.

LATE GRAPES.

IN your opening remarks on the Crystal Palace Fruit Show you suggest two or three causes for the fruit not being first-rate, and you specially remark that many Grapes were not ripe. Speaking from experience Grapes do not ripen very freely this autumn, and the cause is obvious—namely, the very changeable weather, scarcity of sun, and, above all, the low night temperature throughout the summer. Certainly we look for cold nights in September, but to have a cold low temperature through July and August is

quite another matter. Noting your remarks on the Bath Floral Fête, I see again you say the Grapes were very unripe—this, too, in what I should consider a very favoured locality. The very pointed remarks of "CULTIVATOR" on late Grapes are opportune, and I fully endorse all he says as to early starting. He, however, mentions Lady Downe's and Alicante, which were ripe at the end of August, keeping until May. These varieties, however, unless the crop is very heavy, are two of the best for ripening early, and that, especially as regards the Alicante, means keeping well.

The Gros Colman, however, not being a quick Grape at colouring, will be far from ripe now—that is, where there is a fair crop. Of course Vines with only two or three bunches will be ready. Last year Gros Colman with me was not ripe until late in October, yet I failed to see the evil of late ripening. I cleared these out the last day of January, consequently did not start the Vines early, but let them gently start, then used the fire. My crop is heavy this year—too heavy perhaps; still I believe with a fair autumn, especially such bright days as we have had recently, they will be satisfactory. Having, however, determined to cut the Grapes out this year I shall start early to see the result. I always consider Gros Colman a grand Grape, though perhaps somewhat difficult to manage. It is greatly to be hoped that we may have a fine November, this being the most trying month for Grapes; and I scarcely wonder at growers cutting the fruit early in November and bottling it, the rest to Vines being also beneficial.

I have said nothing respecting the Muscat of Alexandria, but this must be forced early to have the Grapes well finished. I must, however, say that if not very highly coloured they will keep better than the blacks. This I always think is due to the extra heat given them. I do not advocate growing Grapes all the summer without fire; on the contrary, I believe in having fire from the day the Vines are started. I think fire heat employed late is almost useless as far as the Grapes are concerned, though the wood will receive some benefit.—STEPHEN CASTLE, *West Lynn, Norfolk.*

A VISIT TO CARTER'S SEED ESTABLISHMENT.

I HAVE just returned here from some holidays spent chiefly in Dublin, London, and Sussex. Like many of your correspondents and readers, gardening and all matters of collateral interest have for me on such occasions a special attraction. When visiting your metropolis I usually try and see as many of the public parks and remarkable nursery establishments as possible. I thought I should be breaking new ground and adding to my own horticultural knowledge if this time I tried to pass through and learn something of the nature of one of the monster seed warehouses, especially the wholesale department. Accident took me to Messrs. Carter's, High Holborn, and the requisite permission was freely granted.

While waiting a few moments in the wholesale office until the manager had disposed of the most urgent business, it was easy, even at the threshold, to see many things curious and new. Communication with the docks, other points of the metropolis, and the various departments of the establishment was by telephone, and almost instantaneous. Looking around the general office the staff seemed very numerous, though I afterwards understood this was only a portion of the clerical department. I noticed the manager running through a great mass of correspondence (some hundreds of letters) and dictating replies to several shorthand writers. I learned that the clerks included those who were not only masters of Her Majesty's English, but of almost all the modern languages—a matter easily understood to be indispensable when orders are received from almost every country in the world. I had an illustration while waiting of the international nature of the business, by the firm being called on to supply suitable seeds under specified conditions to the lately acquired island of Cyprus in the Levant, for laying down croquet and lawn tennis grounds on a new principle in Melbourne, and a request for the statement of prices "by the San Francisco mail of September 7th of Carter's machine-cleaned grass and farm seeds" from one of the largest consumers of California. London to Cyprus, Melbourne, and California! Here was food for reflection relative to the wide ramifications of the great seed industry of this country.

Even though hurrying rapidly along some hours were expended, and many things learnt by me that the exigencies of your space preclude a reference to. But one of the most striking features that few gardeners or amateurs have any idea of is the vast scale of supply and demand for a seed speciality with such a firm as this. Take an illustration that forcibly struck me here. Peas are a speciality, and it was very remarkable the labour and expense bestowed on maintaining their reputation, and to me instructive. The morning of my visit there were eighty-one women employed sorting peas in this department alone, and I learned on occasional exigencies the number runs up to 118. Every bruised, injured, or small pea was rigidly rejected, so that of the tons of their well-known varieties (Telegraph, Telephone, Stratagem, &c.) sent out how many gardeners think that every individual pea has passed through the fingers of the sorters! This no doubt is how great English firms maintain their reputation, and is well worth the notice of my countrymen as a typical case.

Another large department passed through was the grass seed houses. Here there were various machines at work, more or less different, but all devoted to sifting and cleaning, so as to secure a perfect sample. No wonder after such elaborate machinery, care, and expense the good article should be somewhat dearer. Subsequently I was introduced to the grass seed testing house, right up at the top, several storeys high. Here were several hundred specimen pots crowded with young lawn and farm grasses at several stages of development. This system gives firms enormous confidence as to what they send out. Convenient were the testing shelves for the more important farm and garden seeds, all of which were germinating strongly at a great elevation. Adjoining was a catering department where this firm entertain little short of a hundred of their employes on advantageous terms to them and with much thoughtful attention. At every turn the visitor is struck by the energy, rapidity, and despatch observed, without noise and without confusion, not less striking being the mechanical appliances for diminishing labour and curtailing expense. Very interesting just now were the bulb rooms. The first consignment from the Dutch farms had just arrived in splendid condition, and scores of hands were employed packing. We passed through the several flower and vegetable seed stores, on through the green crop and grain departments. I cannot now ask further space, except for a line thanking the employes of the firm, but especially the manager, for the courtesy extended to a stranger such as was—W. J. M., *Clonmel*.

IN accordance with the project described some time ago in these columns by Mr. J. Perkins, gardener to Lord Henniker, Thornham Hall, Eye, Suffolk, a GARDEN FETE WAS HELD IN THORNIAM PARK recently in aid of the Gardeners' Royal Benevolent Institution. Most unfortunately the weather proved extremely unfavourable, and in consequence the attendance of visitors was not nearly so large as it would otherwise have been, especially as a great variety of attractions was provided. The total receipts amounted to about £74, but it is not yet stated how large a balance will remain in favour of the Society when all expenses are paid. Despite this rather discouraging result Mr. Perkins deserves much credit for the energy he has displayed in the matter, and the generosity of Lord Henniker will no doubt be duly appreciated by friends of the Society.

— IN the Orchid house at Kew a very pretty little species is now flowering—namely, *LÆLIA MONOPHYLLUM*, which was received a short time since as a species of *Pleurothallis*, some of which it resembles to a certain extent in habit, but is totally distinct in its flowers. These are of moderate size, about 1½ inch in diameter, with elliptical slightly undulated sepals and petals of a rich orange scarlet hue, very similar to *Epidendrum vitellinum*. The leaves are narrow and only a few inches high, the peduncles slightly exceeding them in length. Its dwarf habit would apparently well adapt it for culture in small pans suspended from the roof, especially as the flowers have a partial drooping inclination. It is said to be from Jamaica, but is probably not confined to that island.

— MESSRS. H. CANNELL & SONS, Swanley, send us several distinct and handsome varieties of SUNFLOWERS, which, quite apart from their æsthetic interest just now, possess qualities well entitling them to notice. Some very popular names have been selected for them, foremost being "Oscar Wilde," and we should think the variety so designated would undoubtedly commend itself to the taste of the gentleman whose name it bears. The flowers are rather above the ordinary size, about 8 inches in diameter, with bold pointed florets of a fine clear orange hue, very showy, but symmetrical. Closely related to this is one named Mr. Charles Matthews, very similar in all respects, but perhaps slightly less refined. Lord Dundreary is a noble variety, with the broad florets closely placed, and of a rich yellow tint. Sarah Bernhardt is of good size, fully 8 inches in diameter, the

centre florets light colour, and the ray florets bright yellow and shady. *Æstheticus*, also a fine-flowered form, has the centre disproportionately large, and scarcely merits its name. Two fine samples of the large double quilled form, *H. globulosus fistulosus*, are also noteworthy, the size, substance, and rich colour being very striking.

— PROMINENT amongst the smaller-flowered varieties is Mrs. Langtry, which might be termed an Oscar Wilde on a smaller scale, of rather lighter colour, but graceful. Mr. Sothern also has neat flowers, the bright yellow ray florets being very regular and tapering. Specimens of the double *Helianthus multiflorus*, an exceedingly useful plant for borders, and *Helenium autumnale*, another fine Sunflower-like late-blooming Composite of moderate height and extremely profuse-flowering habit, were included, and equally deserve attention.

— ACCOMPANYING the above were several samples of two useful bedding DAHLIAS, GLARE OF THE GARDEN and the WHITE JUAREZI. The former we have previously noted as remarkable alike for its floriferousness and the intensely rich deep scarlet colour of the flowers; indeed, as grown at Swanley it is literally a mass of colour, most telling in association with lighter tints. The White Juarezi also appears to be very free and pure in colour.

— THE WOOLHOPE NATURALISTS' FIELD CLUB will hold the last field meeting of the year at Hereford on Thursday, October 5th, for a foray among the funguses, when the Club will be honoured by the company of many distinguished mycologists. There will be an exhibition of funguses in the museum room at the Free Library, and an evening meeting will be held there on Wednesday evening, October 7th, to name and study them. Any collections for exhibition should be sent to Mr. Chapman, at the Free Library, as early on Tuesday or Wednesday as may be convenient to the members sending them. The foray will be made on Credenhill Camp. A short paper will be read in the field by Dr. Bull on "Credenhill Camp—Magna Castra." A meeting of the members will be held in the Woolhope Club room, immediately after arrival in Hereford, to elect the officers for the ensuing year, and to transact the ordinary business of the Club. The dinner will take place at the Green Dragon Hotel at 4.30 P.M., when some edible funguses will be served, cooked from the Club receipts. An evening reception will be held at the house of Thos. Cam, Esq., St. Owen Street, at 8 P.M., to which he invites all who may be present at the meeting. After dinner, or at the evening meetings, papers will be read on the following subjects:—"Puff-Balls," by M. C. Cooke, M.A., LL.D., &c.; "The Meaning of British Birds' Names," by Henry T. Wharton, M.A., Oxon, F.Z.S., Member of the British Ornithologists' Union, &c.; "The Breconshire Raptures," by Mr. E. Cambridge Phillips; "A Revised List of British Discomycetes, with some Suggestions as to their Classification; and on the Polymorphism of *Rhytisma Radicale*, *Che*," by Mr. Wm. Phillips, F.L.S., &c.; "A New British *Venturia*, and Notes on *Glœoeapsa sanguinea*," by the Rev. J. E. Vize, M.A.; "Experiments on the Physiology of the Uredines, and on the Classification of Uredines," by Mr. C. B. Plowright; "The Structure and Appearance of Lichen *Jolithus*, *Linn.*," by Mr. Edwin Lees, F.L.S., &c. A series of enlarged microscopic drawings, by Miss Florence M. Reid; and a collection of other interesting microscopic objects will be exhibited by Mr. Blashill, the President. Gentlemen intending to be present are requested to send their names to the Secretary, Theophilus Lane, Broomy Hill, on or before Monday, October 2nd, that all proper arrangements may be made for their comfort.

— MR. T. WHITE, gardener to C. N. Newdegate, Esq., M.P., Arbury Hall, Nuneaton, sends us a box of very handsome CAMELLIA BLOOMS, white and pink, of good size, beautiful form,

and indeed unusually fine for this time of year. He states that he has had flowers of the same plants since the 20th of August. The blooms arrived in excellent condition, as they were most carefully packed—a rare circumstance; and though cotton wool was employed the blooms were separated from it by layers of paper both above and below.

— IN answer to inquiries respecting the WHITE CLOVE CARNATION "VIRGO," Mr. G. Rudd writes that "it was raised by the late Mr. John Fletcher of North Bierley, near Bradford, from a sowing of seed made by him in the spring of 1878, the plants from which flowered in August 1879. He partially distributed it in the autumn of that year to a few friends, and in the autumn of 1880 he sold the surplus plants of it along with other varieties to Messrs. James Dickson & Son of Chester, who have been exhibiting it this season under the name of Duchess of Westminster, at least I take it to be that sort from the description given. The original plant is still in existence, as I saw it in the same place a few weeks ago. The flowers are beautifully shaped, not too full, perfectly smooth, and of the purest white; a strong grower, very floriferous, and given to throw up autumn spindles, which frequently prolongs the blooming season of it until Christmas or past. In addition the pods never burst, and the fragrance excels in sweetness any variety of Carnation I know. Mr. Fletcher raised many varieties of Carnations and Picotees which have made themselves a name, some of which he has left behind, which I have no doubt will be heard of in coming years."

— "W. J. M., *Clonmel*," writes as follows respecting one of the BEST EARLY OR SECOND EARLY POTATOES:—"I wish to endorse all Mr. Laxton has said on page 274 concerning Beauty of Hebron Potato. I had twelve early varieties, three only introduced last year, all treated alike, and this comes first for use, and also both as to quantity and quality. Early maturity and size are very desirable, but to my mind quality stands first. Here I should like to ask if the cooking test was applied by the Judges at the National Potato Show, and if not, how was quality ascertained by them?"

— AS will be seen in our advertising columns, Messrs. Protheroe & Morris announce that they will sell by auction at the Mart, Tokenhouse Yard, E.C., on October 5th, at 2 P.M., the freehold estates known as MESSRS. OSBORN & SONS' NURSERIES, situated at Sunbury, Fulham, and Hampton. On October the 17th also a sale of plants will be held at the Sunbury Nursery.

— PARTS 22, 23, 24, and 25 of Messrs. Cassell & Co.'s re-issue of "PAXTON'S FLOWER GARDEN" are now to hand, and contain coloured plates of the following:—*Rhododendron Rollissoni*, a rich red-flowered species in the way of *R. arboreum*, from Ceylon. *Oncidium sessile*, a Peruvian Orchid with bright yellow flowers, related to *O. excavatum*. *Lælia autumnalis* var. *atrorubens*, one of the additional plates representing a handsome variety, but scarcely doing justice to the rich tint which distinguishes it. *Bryanthus erectus*, a pretty Ericaceous shrub with pink *Kalmia*-like flowers. *Dendrobium transparens*, a delicate pink-tinted species, with narrow petals and sepals. *Allium acuminatum*, a Californian bulbous plant with rather showy flowers, the upper portion of the perianth divisions being rich rose, the lower white. *Epidendrum longipetalum*, a distinct species; sepals and petals narrow, claret purple; the lip white, margined with yellow and streaked with red. *Poinciana Gilliesii*, a beautiful figure of a handsome plant that is rarely seen, the bright yellow flowers, long red stamens, and elegant bipinnate leaves being very attractive. The "Gleanings and Original Memoranda" are continued in each number, several notable plants of recent introduction being described.

— A KENTISH newspaper records the following:—"MIGRA-

TIONS OF LADYBIRDS.—On Sunday, September 10th, myriads of ladybirds visited Bexley and its vicinity shortly before noon. Their stay was a brief one, but for a few minutes they completely covered the fronts of houses, and entered rooms where the windows or doors happened to be open. Such a visitation has not been experienced for years." Concerning this "J. R. S. C." writes:—"The ladybirds (*Coccinellæ*) have certainly been unusually abundant in 1882, a natural consequence of the excessive swarms of their special food—the aphides or plant lice. The latter insects are well known to perform migrations every season, probably in May and September, but the spring migrations have been more particularly noticed. The exact time of these depends upon atmospheric and other causes not yet positively ascertained. Ladybirds do not, I think, so periodically migrate, although various instances of the kind have been noted both on the coast and inland. From personal observation I can state that there was a migration of ladybirds across North Kent on August 31st, the day being tolerably calm. The east side of Ifield Church, near Gravesend, was thickly studded with these insects about noon, indicating the direction from whence they came. In the vicinity they abounded on hedges and walls, many were also moving along. Just one week later, on September 7th, to the north and west of Gravesend ladybirds were so numerous upon the hedges, also in the gardens and fields, as to suggest that there had been an arrival during the night and early morning. This was another calm day. Upon the Hawthorn I examined a number of the insects, and they appeared to be all busily engaged in depositing eggs. Is it the case that those ladybirds which thus migrate are principally females?"

NORTHAMPTONSHIRE HORTICULTURAL SOCIETY.

ALTHOUGH many good horticultural exhibitions have been held at Northampton, and usually in connection with the annual Show of the County Agricultural Society, which is one of the most popular and flourishing of the county societies, and at intervals visits the county town, no regular horticultural society has hitherto been established. Advantage was, however, taken last spring of the intended visit of the Agricultural Society by several influential horticulturists, under the able direction of Mr. John Perkins, to call into existence the new Society, which held its first Exhibition on the racecourse at Northampton conjointly with the agricultural meeting on Thursday and Friday last, and the results of their efforts must undoubtedly be not only gratifying but encouraging to the promoters, as the Show was a large as well as a very successful one. Fortunately a favourable change in the weather on Thursday conduced to the comfort of the visitors, as the site of the Show, although a convenient one in other respects, would in case of much wet probably have been an unsatisfactory one. Preparations were being made for lighting up the tents in the evening by electricity, but this afterwards proved a failure, much to the disappointment of the visitors. Six large tents were filled with the various exhibits for competition, the local nurserymen, Messrs. John Perkins & Son and Messrs. Ball & Son, each also having tents for their own use.

In the competition for twelve stove and greenhouse plants, six in and six out of bloom, Mr. James Cypher, Cheltenham, was first with a very fine collection, consisting of *Cycas revoluta*, *Kentia Fosteriana*, *Thrinax elegans*, *Cordyline indivisa*, *Corypha australis*, *Crotons Johannis* and *majesticus*, large; *Ericas Irbyana*, *Marnockiana*, and *verticillata*, *Anthurium Schertzerianum*, and well-flowered specimens of *Stephanotis floribunda* and *Clerodendron Balfourianum*. Mr. J. Day, gardener to A. Seymour, Esq., Norton Hall, Daventry, was second with very fine and healthy plants, his collection containing a fine golden variegated seedling *Gymnogramma*. Mr. James Parker, Rugby, was third, his plants not being up to the usual exhibition form in which he has frequently appeared this season. For the group of miscellaneous plants Mr. Parker made a very handsome and effective display, and was placed first. For six exotic Ferns Mr. Parker was again first, his collection containing good specimens of *Adiantum trapeziforme*, *Neottopteris australasica*, and *Lomaria intermedia*. For six ornamental-foliage plants Mr. Cypher was first with a very fine *Cycas revoluta*, *Thrinax elegans*, *Cordyline indivisa*, *Dasylium acrotrichum*, and *Crotons Disraeli* and *majesticus*. Second honours deservedly fell to Mr. Farr, gardener to Sir R. Knightly, Bart., Fawsley Park, Daventry, who had very fine specimens, most promising amongst them being *Alocasia macrorrhiza variegata*.

In the gentlemen's gardeners' class for ten stove or greenhouse plants, five in and five out of bloom, Mr. Day was first; Mr. Holland, gardener to W. Jeffery, Esq., Northampton, second; and Mr. Farr third, all the collections being highly meritorious and the competition

close. In the same tent was a fine specimen of *Ananassa variegata* from Mr. Fairbrother, gardener to R. Turner, Esq., Northampton. Coleus were unusually fine and in excellent colour, those in the first-prize collection from Mr. J. Day remarkably so, the varieties being Ada Constance, Mrs. Langham, Mrs. Pawle, Edith Sentance, Miss Simpson, and Mrs. Steddall. Mr. Day was also first for a collection of Begonias, all his own seedlings, and for six Caladiums; for the latter Mr. Garfurth, gardener to P. Phipps, Esq., M.P., Collingtree, was second. For six exotic Ferns Mr. George Kilburn, gardener to C. J. K. Woolston, Esq., Wellingborough, was first with fine and healthy plants of *Adiantum farleyense* and *cuneatum*, *Davallia Mooreana*, and *Microlepia hirta cristata*; Mr. Holland was second, and Mr. Day third, all having fine plants, but crowded in a very limited space. In Mr. Day's collection was a handsome and promising seedling silver variegated *Gymnogramma* with frizzled fronds. Fuchsias were in better form than usual for the midland counties, and Mr. Gardener, gardener to Sir Hereward Wake, Bart., Courteen Hall, Northampton, had large, handsome, and well-flowered specimens of Conqueror, Beacon, Rose of Castile, Extraordinary, Alexandra, and Sir Colin Campbell. Mr. Kilburn, who was placed second, had also large and handsome plants. For double Zonal Pelargoniums Mr. Abrahams, gardener to Mrs. Hensman, Northampton, was first.

Table and miscellaneous plants were also attractively and largely shown by several exhibitors, and also a collection not for competition from Mr. R. Cole, gardener to the Right Hon. Earl Spencer. In Messrs. J. Perkins & Sons' tent were several very fine double Zonal Pelargoniums, including a remarkable specimen of *Guillaume Mangilli*, also two very attractive single Zonals—Mrs. Gordon, a large bright vermilion scarlet with white eye, and Bacchus, very fine deep crimson. In Messrs. Ball & Sons' tent was a stand of cut blooms of very promising single seedling Zonals, but the varieties were not named; they also exhibited good stands of single Dahlias and Carnations. Both these exhibitors made really interesting and worthy displays.

For dinner-table decorations Mr. Parker was awarded first, Mr. Cypher second, and Messrs. Ball & Son third; Mr. Cypher's table appearing to many to be in particular good taste, although it would be unjust to carp at the unenviable task of the Judges where taste is necessarily a matter of opinion.

For the collection of nine varieties of fruit, Pines excluded, Mr. J. Day was first, having good Black Hamburgh and Muscat Grapes, and very fine Peaches in variety. For three bunches of black Grapes Mr. Cole was first with very even and highly finished Black Alicantes, Mr. Thomas being second with Gros Colman, Alicante, and Madresfield Court, all handsome bunches. For three bunches of white Grapes Mr. Day was first and Mr. Turner second with good Muscats, Mr. Thomas deservedly carrying off the heaviest-bunch prize with a grand example of Gros Colman, Mr. Cole coming second with Gros Guillaume. Handsome Pines and Grapes not for competition came from Mr. J. Carr, gardener at Delapré Abbey. Outdoor fruit was not largely shown, Apples and Pears being especially below the usual standard in size and appearance; a good-looking Pear named Alexandrina, and Golden Skin Apple, a bright golden-coloured Codlin from Mr. Frank Coles, Wellingborough, being, however, worthy of note. In the amateurs' class for six varieties of fruits Mr. J. Richards, Tansor, Oundle, had a very good collection, and took first place.

Vegetables are perhaps nowhere grown better than in the neighbourhood of Northampton, and it would not be difficult for an unprincipled exhibitor at times to purchase a good winning collection of show vegetables from the ordinary green stuff which comes into Northampton market. On the present occasion the gardeners', amateurs', cottagers', and market growers' tents all furnished specimens of high quality. Potatoes were generally fine, regular, and clean of the usual show sorts. Messrs. Perkins' Snowdrop was frequently shown and in good form, and its appearance indicates it to be a desirable variety. Enormous Veitch's Autumn Giant Cauliflower measuring 45 inches in circumference came from Mr. G. Oram, gardener to Mrs. Whitworth, Dallington Hall, and white Spanish Onions $5\frac{1}{2}$ inches in diameter and quite sound from Mr. Day, who also took first prize for three handsome Telegraph Cucumbers. He was also placed first for the twelve varieties of vegetables, all his exhibits being good, Turnips and Telephone Peas especially so; but by far the finest Peas in the Show were in the cottagers' tent from Mr. Thomas Goode, Daventry, and appeared to be the almost extinct General Wyndham type of Ne Plus Ultra. Better Peas than these are rarely shown under any circumstances. The Rev. C. H. C. Hamilton, Chadstone Rectory, Castle Ashby, was a good second for the collection of twelve varieties of vegetables. For the collection of six varieties Mr. S. Allen, gardener to H. S. Pritchard, Esq., Alrugton Abbey, was placed first, and Mr. Oram second. In the market growers' department Mr. E. Rowe, Sheep Street, Northampton, was first both for the collections of vegetables and Potatoes; but upon the whole the legumes here were not equal to those in the other tents, the cottagers evidently leading in vegetables to the credit of the local leather industry, the toilers in which find agreeable and profitable relaxation in the good garden land of the locality. In the cottagers' tent very fine Trebons Onions were shown by Mr. Hickman, Kingsthorpe; White Spanish, almost equally fine, and excellent Intermediate Carrots from Mr. Philip Blencow, Long Buckby. Cut flowers were evidently suffering from the effects of the excess of wet, Roses especially so, the best twenty-four and

twelve coming from Mr. F. Perkins, Leamington; Mr. Parker, Rugby, having a first for twelve good *Gladiolus*.

There were many minor points in the Exhibition worthy of note, but want of space would preclude justice being done to all in so large and important a gathering.

RAVAGES OF CATERPILLARS.

MOST of us have cause to remember that during the last spring we had a storm which left its marks on our fruit and forest trees, the flowering of the Horse Chestnuts being completely spoiled, and the Pear trees in the open so much bruised about that they have never quite recovered. It was asserted by some writers that the salt spray was driven inland to a distance of forty miles or more, and thus assisted the wind to commit the terrible havoc on our trees which many of us have still to deplore.

Be this as it may, I found later on in the season that the storm was getting the credit for damage of which it was entirely innocent, that many people were put on the wrong scent as it were, and I therefore sent a letter to the *Times* on the subject, of which the following is an extract:—

"Living on one of the most beautifully wooded estates in this country, I have been greatly alarmed these last two seasons at the terrible havoc committed by myriads of caterpillars on the foliage of our stately Oaks and other trees which adorn the landscape, and when well managed bring a goodly return to the proprietor. Last summer I saw hundreds of Oaks in a batch as bare of foliage as they had been in midwinter; but they had made a little growth before the total destruction of foliage, and this little, however imperfectly matured, would assist the tree to drag out a lingering existence for a year or two. But this season the state of things is more alarming. The ravages having commenced unusually early, and the leaves of many trees being eaten as fast as they appear, little or no addition can be made to the growth of the tree. Now, any person who knows anything of the rudiments of vegetable physiology must be aware that the evil will not be stationary. If no growth is made for two or three years in succession the trees must die, and the blank they will leave is too dreadful to contemplate. The Oak so far has suffered the most, but hardly any timber tree or deciduous shrub appears to come amiss to the palate of these detestable little creatures. Much as we shall sigh over it, we can afford to have our Rose bushes disfigured and our Apple trees made barren—and I may say there is every prospect of both—but to lose stately Oaks which have beautified our landscapes for two or three centuries would be nothing short of a national calamity, and it behoves us to see if anything can be done in time to prevent or mitigate the evil."

I next pointed out that since the two very severe winters lately experienced insectivorous birds had become scarce, and starlings especially, which used to abound in this neighbourhood, had been reduced in numbers apparently to only a few hundreds, and recommended landowners and others able to make their wishes respected to look after the preservation of insect-feeders by preventing bird-nesting as much as possible and the insane practice of rook-shooting. The preservation of Owls is also recommended, and the destruction of rats and mice.

As I had anticipated, my account of the cause of the defoliation was challenged, and a gentleman who can write better than myself, but who evidently is not so close an observer, attributed all the mischief to the storm, and his beautiful poetical writing evidently carried many readers with him. I therefore sent some specimens of the caterpillars and their work to Miss Ormerod who kindly replied as follows, and gave me permission to use her letter as I thought best.

"Dunster Lodge, near Isleworth, June 19th.

"I have examined the injured Oak sprays and caterpillars that you have been good enough to forward me, and my opinion is that the trees are suffering from the attack of the exceedingly destructive caterpillar of the winter moth, the *Cheimatobia brumata*.

"This grub frequents almost all our common deciduous fruit and forest trees, and will clear the soft part of the leaves and then finish off as food gets scarcer with everything eatable, including the buds; consequently they are quite exceptionally injurious, and are a perfect scourge in some of the continental forests. Other caterpillars were present with them, but I did not find any traces nor more than one specimen of the caterpillar of the 'common leaf-roller moth,' the *Tortrix viridana*, which is the other great enemy of our Oaks.

"The leaf-roller moth has bright green fore wings, and its caterpillars are leaden or greenish colour; the winter moth has greyish-brown and ochrey fore wings, and the caterpillars are green or dingy with whitish lines along the sides and form a loop when they walk.

"Apparently nothing can be done, on the large scale of operation needed, to check forest attacks by the 'leaf-roller,' excepting to protect the birds; but as far as my own opinion goes, I would not include the sparrow. I believe investigation of the food in its crop proves it to be by no means a helper, and its habits in driving away other helpful birds make it a very doubtful good.

"The winter moth, now under discussion, lies more in our power, from the females having such abortive wings that they are obliged to creep up the tree trunks to lay upon the branches. They appear in early winter—November and December—and from sundown to about ten in the evening may be seen at their work. Therefore, if in good time a number of haybands or bands of any rubbish were twisted up, and when the season comes two men were sent round with directions to soak these in anything preferred of the nature of tar—tar and cart-grease, tar and oil—or anything the moths could not cross, and to lay one of these bands round the stem of each tree, the tree would be isolated.

"This remedy is one found to act practically, it is not expensive, and a couple of men would soon apply it to a very large number of trees. If preferred, fresh gaslime might be thrown in a ring round the trunk. This should not touch the bark, neither should the tar; but so long as something is laid round the tree which the moths cannot cross, so long is the tender leafage within as safe from

attack of these caterpillars as lambs in a foldyard from the fox outside the enclosure.

"The amount of attack of this moth depends very much on the weather. If the ground is frozen hard in November it is manifest it cannot come up through it; also much rain when the caterpillars are moulting is bad for them, and also such wet weather as will thoroughly soak the ground in which the chrysalids lie will destroy them.

"Yours truly, ELEANOR A. ORMEROD,
"Consulting Entomologist of the Royal Agricultural Society."

Let us hope, then, that the large amount of rain we had before the caterpillars came to maturity will have destroyed a great many of these troublesome creatures. It is marvellous to see the way in which the trees, which up to near the middle of July were "as bare as in midwinter," have recovered as to foliage; but the growth is still very soft, and I am afraid the frosts which we are already experiencing will prevent it ripening fully.—W. TAYLOR.

THE CHEMISTRY OF MANURES.

I WILLINGLY reply to the questions put to me by "INQUIRER"—though he will permit me to observe that the first of them, "Is it the intention of 'J. B. K.' to affirm that a good garden soil can be enriched in nitrogen or potash, or phosphoric acid, or any other constituent of plant life, by admixture with a manure which is more deficient in these elements than itself?"—hardly expresses any practical question arising out of the discussion. What actually occurred was, that Mr. Taylor spread on the surface of a border which had been exhausted by the production of probably 8 or 10 lbs of fruit, wood, and leaves per square yard, a dressing of about 1 inch thick, or some 50 or 60 lbs. per square yard, of soil which has been enriched with a quantity of solid excreta and a portion of liquid excreta equal to that which one individual would supply during a week; for this is about the quantity indicated by Mr. Taylor's statement, that he obtains the earth which has been used by fourteen persons during six months, and that this (as I understand) is sufficient for only half his border, or for an extent of 360 square yards. Now, what is the nature of the addition thus made? Assuming excreta of average quantity and composition, and that one-sixth of the daily urine voided is included, these 360 yards will receive annually (in addition to whatever value there may be in the earth itself, or the burnt clay employed in the closets), the following ingredients in pounds:—

	Supplied to border.	Rate per acre.
Nitrogen	18	250
Potash	4.2	60
Pho-phoric Acid	8.7	120
Lime	3	43
Magnesia	2.6	37
Oxide of Iron	0.7	10
Sulphuric Acid	0.6	9
Chlorine	6.5	95

This would be very nearly equivalent to a dressing at the rate of 30 cwt. of good guano per acre, or two-thirds of a pound per square yard, and such an application is obviously a very rich dressing. But while in the concentrated form of guano it can bear the cost of transport from Peru, if it were diluted with one hundred times its weight of common earth, which is its form when obtained from earth closets, it would not pay for its transport from the next parish. This is in fact the whole difference between guano and earth-closet manure. When circumstances permit the latter to be obtained without any charge for carriage it is as good as guano, provided enough of it be used; and Mr. Taylor is able to use, and does use, enough.

The second question—"Does 'J. B. K.' consider that earth-closet manure is really superior to that prepared by Messrs. Arnold & Co., for instance, for manuring Vines?" is virtually answered by what I have already said. The one is diluted and weak, the other is concentrated and strong; but if a pound of the earth is obtained at less cost on the spot than one-eighth of an ounce of the artificial manure, then it is the cheaper of the two. Whether it is the better depends entirely on how it is used. For a single application, to last through the season, earth-closet manure in adequate quantity is undoubtedly the better; but artificial manures have one advantage in the fact that they can be varied so as to supply the special demands of the plant at different seasons. Aware of this, Messrs. Arnold supply different preparations for use in spring, summer, and winter; the first containing, I believe, more nitrogen to support the earliest growth of leaves and wood, the second more potash to swell and firm the berries and ripen the wood, the third more phosphoric acid to encourage the growth of roots. In like manner the best farmers use both farmyard dung for the mainstay of their crops, and add during their growth special dressings of soluble forms of nitrogen, potash, phosphoric acid, or magnesia as may be required by the special crop; and when a gardener can do the

same he will probably find some benefit in it. In my own case, having no earth-closet manure, but having the advantage of a farm in which much cake is consumed by cattle under cover, I profit by the fact by giving the Vines in early summer a mulching of straw manure, both to keep the soil moist and to enrich the waterings; but I precede this with some waterings in which the urine of the cattle is administered, and these again are preceded by waterings in which artificial manures are dissolved, so as to supply the roots when they first start into growth with all that they require at the time of greatest pressure. No doubt if I had only one of these resources I could so arrange as to make it suffice. So Mr. Taylor, having an excellent manure of what may be called a universal character, makes it answer with the help of lime to quicken its decomposition and make it most soluble in early spring, while with copious waterings he washes out any superfluity. It was to gardeners who have not any of these resources that I recommended the artificial manures compounded for them at reasonable rates by a competent and respectable firm. I do not call them better than natural manures, but administered with due care they will act as well, and often they will be found a most serviceable addition.

The accidental delay of a week enables me now to advert to the letter of Mr. Boyle in the last number of the Journal. In the first place, the fact of his being a vegetarian does not of itself make the earth-closet manure less rich. The human body must have a certain supply of nitrogen and minerals whether derived from animal or vegetable food. Many vegetables contain as much (or, as Sir John Lawes has shown, often more) nitrogen than there is in meat with its usual proportion of fat; and a vegetarian, therefore, probably consumes and excretes as much as a flesh-eater, possibly even more in a solid form, for the solid excreta contain the undigested portion of the food, and a smaller proportion is digested of vegetable than of animal food. But, secondly, in all cases of the use of earth-closet manure there is a doubt, which only analysis can solve, how much virtue is in the earth itself before its use. Thus, for instance, Dr. Voelcker found that the earth employed in the Wakefield Prison had itself the composition of a "rich garden mould," and if we put the commercial value on the ingredients he found in it we shall find it would be valued as manure at 7s. 7d. per ton. Add to this 3s. or 4s. additional value after its use (supposing it employed in a private family instead of a prison) and we have say 11s. per ton as its true commercial value, which is double the ordinary price of farmyard manure. But even supposing the original earth used by Mr. Boyle, Mr. Taylor, or others is not so rich as this, we may observe that Mr. Boyle says it is "bulk for bulk worth double the amount of dung." But earth is greatly heavier than farmyard dung as it is loaded into a cart or harrow, probably quite twice as heavy, and therefore "bulk for bulk" would give twice the real quantity by weight of earth as of dung on an equal space of ground. But finally, and this is perhaps most important of all, the earth-closet manure contains all its ingredients in a state of complete disintegration, and thus ready for immediate decomposition and use by the plants, while farmyard dung is lumpy, wet, and consequently very slow in its action. The virtues of the former will be given out to one crop (as Mr. Taylor illustrates, for he gives his heavy dressing annually), while of dung the effect does not half appear in the first crop; it partly accumulates in the soil, and partly is lost in winter washings. This fact is probably a main reason why earth-closet manure shows on all crops to such immediate advantage, and if dressings are given of twice the weight of the dung with which it is compared there is no wonder it seems greatly superior, as in fact for one crop it is.—J. B. K.

COWS and horses are all strict vegetarians, and it is not suggested that farmyard dung is not so good as if the stock were fed on animal food. How, then, does Mr. Boyle make out that his vegetarian diet detracts from the fertilising qualities of his earth-closet manure? No doubt Dr. Voelcker's opinion is entitled to much respect; but everybody who has used earth-closet manure can testify to its value as a powerful fertiliser. The great pity is that so much valuable manure is allowed to pollute our rivers and poison our streams through the length and breadth of the land.—PETER FERGUSON, *Monk Wearmouth.*

IN a general sense, the manure most suitable for any given soil to increase its fertility is that which contains those constituents in which the soil is most deficient. The illustrious Liebig has enunciated what he calls a law of minimum, which he expresses as follows:—"Every field contains a maximum of one or several, and a minimum of one or several nutritive substances. It is by the minimum that the crops are governed, be it lime, potash, nitrogen, phosphoric acid, magnesia, or any other constituent."

Since the days of Liebig, however, the researches of Ville, Lawes, and Gilbert and others, have shown that the deficiencies in soils brought about by ordinary agricultural practice may be confined to three or four of its food constituents—viz., nitrogen, phosphoric acid, potash, and lime. The amount of these constituents present might therefore be said to govern the fertility of the soil, providing they exist in an available condition, and the physical characteristics of the soil are such as to allow of their favourable action. A liberal use of farmyard manure tends to keep a fertile soil in its normal condition, prevents its exhaustion, and in many cases even improves it; but unfortunately the supply of this

general manure is insufficient for the purpose, and recourse has to be made to more concentrated forms of the individual food constituents. Nitrogenous manures for gramineous crops, phosphatic manures for root crops, and potassic manures for leguminous crops, are those which produce the best results. These have been termed special manures, and their use is attended with considerable economy, since their application to the crops specially requiring them gives the best results with the least expenditure. It is necessary, however, that all other food constituents should be present in sufficient quantity, since, as Liebig states, the fertility is governed by the constituents present in minimum quantity.

Fig. 48.—*RUDBECKIA CALIFORNICA*. (See page 300.)

There is but little doubt that many discrepancies observed in the action of special manures are due to this cause. But little good, of course, will result from the application of special manures in cases where the soil already contains a sufficient quantity of the food constituents supplied in the manure. Great injustice has been done to artificial manures, and their efficacy has often been questioned, in consequence of their indiscriminate use on soils which do not actually require them.

Excepting the facts known regarding the special requirements of our ordinary cultivated crops, the cultivator has but little to guide him in the application of special manures. It is often a question whether this or that manure, which perhaps he could obtain at a moderate cost, would have a beneficial effect upon his

soil, and whether the result would be such as to compensate the expense involved. At present he knows but little of the latent resources of his soil beyond that he obtains from a knowledge of the crops which succeed best on it. This knowledge, although only of a comparative nature, is, however, of considerable value; for instance, suppose he finds that he can grow fair crops of corn but cannot succeed with root crops, from inference he may conclude that his soil was most probably deficient in phosphates.

The actual amount of food constituents in the soil, whether in the latent or available conditions, can only be ascertained by means of an analysis, which requires to be made by persons having the requisite skill and chemical knowledge. By means of an analysis the composition of the soil can be compared with

that of others of known fertility, and a deficiency, or otherwise, noted.

The method which is best adapted for ascertaining the effect of manures is that of field experiments. These are within the power of every cultivator, and are to be strongly recommended for more reasons than one. A small plot of land, or, in cases where the soil varies, representative portions of the several kinds, set apart and worked for purely experimental purposes, would tend to give an insight into the nature of the soil he has to work, and also confidence in the result of operations, far better than any other plan that could be adopted. The conditions existing in the soil tending to influence the action of manures would exert themselves on a small scale as well as on a large, and would influence the results, as shown by the increase of produce, quicker growth, and earlier maturity in the same degree.—GEORGE GRAY.—(*New Zealand Journal*.)

YELLOW COMPOSITE FLOWERS.

RUDBECKIA.

FROM the time when Leopard's-banes begin to flower in April to the sunny days of October when the borders are brightened by the later Sunflowers, few gardens where hardy herbaceous plants are grown at all are ever without some yellow Composites in flower. It is easier to have too many of them than to do without them, so it is as well to select the most ornamental kinds. A large proportion of them belong to North America, and some are in consequence rather difficult to cultivate in cold soils and sunless climates like those of West Cheshire, and therefore anything which will thrive in my garden has the merit of being quite hardy in nearly every part of the kingdom; though in the extreme north of it, or at high elevations above the sea level, many of the late-flowering species will hardly flower at all after cold summers.

I propose to begin by speaking of Rudbeckias, amongst which are some of the most ornamental of the class. They are distinguished by having the centre of the flower raised as soon as the flower opens, either in the form of a cone or of a hemisphere, the broadest part of the raised centre being where it touches the base of the rays or petals of the flower, whilst in some allied genera, like the *Helenium*, the receptacle of the florets expands like a ball from its base. The Rudbeckias are in sad need of a monograph, and I am quite unable to give anything like a synopsis of the genus, but can only mention some half-dozen kinds which I have in cultivation, and which are sold under various names, and I have done my best to reduce these names to something like order.

The first to flower is *R. laciniata*, which grows with me from 5 to 7 feet high. It comes out in June and continues in flower till September, the flowers being pale yellow, about 4 inches across, abundantly produced, elevating their centre into a conical form. The leaves are large, much divided into irregular curved straps, pointed at the ends. The stem is much branched. Though a coarse plant, from its large size it makes a great show for the back row of a long border. It requires frequent division to prevent the stalks being overcrowded and to encourage lateral stems. *R. digitata* resembles the last, though quite distinct from it, but is thought to be no more than a variety; with me, however, it grows 2 feet taller, being from 7 to 9 feet in height. It begins and continues to flower fully a month later. The flower centre, instead of being conical, is hemispherical, and the leaves are divided into three broad incised lobes. I have described these two plants by the names I have found generally adopted, but in Loudon's "Encyclopædia" the two names appear to be transposed.

R. californica (fig. 48, p. 299) is the handsomest of the tall-growing kinds. It grows with me from 5 to 6 feet high. The leaf is large and woolly, not much divided, oblong in form, and pointed at the ends. The flowers are borne upright on uprightly branched stalks, and are large, of great substance, dark rich yellow in colour, with a tall conical black centre rising like a cylindrical column to a height of 2 or 3 inches from it. It flowers in July and August, and though the flowers are not so abundant as those of the species above described, they are far more showy. It is sometimes grown as *R. columnaris*, a name which would seem to suit the form of the flower; but *R. columnaris* as figured in Curtis's "Botanical Magazine," No. 1601, is certainly quite a distinct plant, and one which I have never seen in cultivation.

R. maxima I raised two years ago from seed imported from America by Mr. W. Thompson of Ipswich. One or two plants have flowered this season, but not well, and I fear that it wants warmer summers than it finds in Cheshire. The leaf is large, smooth, and glaucous, oval in shape. The flower seems liable to be deformed by a mass of leafy bracts. It is large and light yellow, and the plant may do well in warmer and more sunny parts of the country. The plants are about 4 feet high.

R. speciosa is commonly called *R. Newmanni* in gardens, but

the latter name is repudiated by botanists. It is too well known to require description, and is generally thought an indispensable autumn plant. The time to divide it is when it is going out of flower in autumn. A top-dressing of leaf soil during summer will make it root at all the joints, and cause its increase to be unlimited, and another good dressing when transplanted will make every rooted shoot into a large plant by the next year's flowering time. The colour of the disk or flower centre varies from rich velvety green to black, and the leaf varies much in roughness. I have had a strong-growing rough-leaved form of the plant sent to me as *R. hirta*, but it seemed hardly distinct from *R. speciosa*, though I have never been able to meet with any other *R. hirta* in cultivation.

R. fulgida resembles a small form of *R. speciosa*, and I find the names confused, but it is a plant which I have never been able to keep, as it pines away and dies in cold wet summers. It is in every way inferior to *R. speciosa*, but flowers earlier.

The latest of the Rudbeckias to flower amongst those which I know is *R. subtomentosa*. It is an elegant and refined plant compared with the larger examples of the genus. It makes a rather slender growth of about 4 feet high. The flowers are deep yellow with a black centre, borne on lateral branches nearly all up the stem, and turned sideways. It increases slowly, but I find that, like nearly all the class, it may be grown from side shoots about 3 inches long if taken off when young. It is better suited to the south of England than to the colder counties, where it hardly completes its flowering before it is spoilt by the frost; but after a warm summer it is one of the neatest and prettiest Composites I have. Besides the purple-flowered species, commonly called *Echinacea*, the above are all the Rudbeckias I have ever seen in gardens, though I find several others described which I should be glad to have an opportunity of obtaining.—C. WOLLEY DOD.

APPLES AT THE EXPERIMENTAL GARDENS AT GIRTFORD IN 1882.

THE garden at Girtford, lying in a valley, is much subject to the baneful influence of spring frosts, the effects of which are intensified by the warm and exciting character of the soil, and the consequence usually is that the blossom of early Apples, as well as that of Pears and Plums, is greatly injured; in the past spring, however, a minimum of harm was experienced from that cause, and a fair crop of Apples has been secured.

The following varieties have during the last four years shown themselves constant and reliable bearers at Girtford—viz., Mr. Gladstone (Premier), Early Julien, Cellini, Schoolmaster, Missouri Pippin, Stamford Pippin, and Court Pendû Plat. Mr. Gladstone is a very handsome Apple, somewhat of the character of the Early Margaret, but larger, higher coloured, and otherwise distinct, and to my mind is the best of all the early market eating Apples, but it must be gathered and consumed as soon as ripe. Mr. G. Bunyard, the experienced Kentish grower, also informs me this is the opinion he has also formed of it. Early Julien is also a most valuable Apple either for cooking or dessert, as it may be gathered at the same time as Margaret, but will hang on the tree or keep sound for months if gathered. There are no two early Apples to equal these. The valuable properties of Cellini, especially in the dual capacity as a kitchen and table fruit and its remarkably handsome appearance, are too well known to need comment.

The large and handsome new Apple Schoolmaster, which comes in season in October and continues till January, is also a most prodigious bearer, and has not failed during the past four years, even when Keswick and Lord Suffield have fallen short; the young trees also appear to be productive. Stamford Pippin, my own first venture in horticulture, is of all the sorts I have ever seen the most prodigious bearer; and here in 1879 and 1880, when very few Apples bore a crop, Stamford Pippin was laden both on bush and standard, and this year it hangs in ropes on the boughs, which are almost borne to the ground with fruit. The good qualities of this Apple are not as yet, I think, generally appreciated, although I know a few pomologists who are well aware of its excellent flavour and great productiveness, and say that it will bear comparison for quality with the Ribston. I take exception, however, to its being classed, as it is sometimes treated, as a cooking fruit, for although it is adapted for that purpose also, there are many other Apples of the same period equally good for the kitchen. Missouri Pippin is a medium-sized fruit of handsome appearance and good keeping qualities, received here from the Continent, but I believe it to be of American origin; it is also wonderfully prolific on very young trees. Court Pendû Plat, which is the latest to blossom of all Apples, is consequently a

constant and reliable bearer, and one of our best late Apples for dessert.

There are many other well-known Apples which have this season carried good crops at Girtford, such as Cox's Orange Pippin, Lord Suffield, Keswick Codlin, Ecklinville Seedling, Golden Noble, Warner's King, Bedfordshire Foundling, Hawthornden, King of the Pippins, Early Strawberry, Franklin's Golden Pippin, and Cackle's and Sturmer Pippins. The chief failure is in Wellington or Dumelow's Seedling, which has only a quarter of a crop, and fewer still in the past three years, owing perhaps to the effects of the severe winters of 1879 and 1880, which played sad havoc amongst the trees of this variety. On the other hand, for the first time in thirty years I have a fair sprinkling of fruit of Blenheim Pippin both on young trees and standards.

Amongst the recent varieties tried here, Repa, a very early flattish round variety with pale skin, a medium-sized American Apple, appears well worth growing. Red Bertigheimer, a noble-looking fruit of a beautiful waxy pale crimson exterior, and with tender crisp flesh, appears to be a valuable introduction, also from America. Tetofsky, of the Lord Suffield type, but earlier; Primate and Williams' Favourite are fruits of much promise, probably of Russian or American origin. D. T. Fish (Warner's King), very large and good, but sometimes coming ugly; Lord Grosvenor, a very fine but later and firmer-fleshed; Lord Suffield, Grenadier, Lord Derby, and Prince Albert (Lane), Lord Burghley, and Peasgood's Nonsuch (the finest fruit in the garden), are all desirable acquisitions. Several promising seedlings, the productions of myself and others, are being tested, and I venture to prognosticate something good from a cross between Mr. Gladstone and Early Julien.—T. LAXTON, *Bedford*.

"THE NEW BOTANY."

UNDER the above title a lecture on the best method of teaching the science, by W. J. Beal, Professor of Botany in the Agricultural College, Lansing, Michigan, U.S., has been issued in pamphlet form by C. H. Marot, Chestnut Street, Philadelphia, and well merits the attention of all engaged in teaching botany in this country, and also of those who are about to study it. Some excellent directions are given as to what should be the objects in studying natural science, and the best modes of cultivating habits of correct observation. A few extracts will indicate the author's purpose, and doubtless prove advantageous to some readers. Discussing the advance in botanical science, the writer observes—

"Before fully considering the new botany let us glance at the old. Aristotle, Pliny, and other Greeks and Romans paid some attention to plants. So did the Arabs of the twelfth century. Still later Grew, Tournefort, Ray, and many others studied plants and wrote about them. A little progress, and but very little, was made in classification and description. Not until the last century, about 1735, less than 150 years ago, did botany begin to take rank as a science. This was largely due to Linnæus of Sweden, who well earned the title of 'Father of Botany.' His efforts were largely devoted to describing and classifying plants, and were ably continued by the four Jussieus, Robert Brown, A. P. De Candolle, Lindley, Endlicher, and their contemporaries. Except for medical students, botany hardly found a place until within the past forty years. Even in the higher educational institutions, and as late as 1850, botany was usually only considered a pleasant and proper pastime for young school girls. As generally pursued, the study consisted mainly in learning from a book the forms and names of roots, stems, leaves, inflorescence, and the several parts of flowers and fruits. The teacher was supposed to be a dried-up old fossil. He wore odd-looking clothes. He taught the class from the text-book, and preferred to pursue the study in winter, that the pupils might learn the names and peculiarities of plants before they appeared in the spring. There were many hard unfamiliar names. With no specimens to illustrate the lessons, and a dry teacher, most of the pupils acquired a thorough disgust for the study long before warm weather furnished materials for illustration.

"From 1770 to about 1800 Wolfe and Goethe of Germany and A. P. De Candolle of France developed new ideas of plant morphology. Schimper, Braun, Dunal, and Rœper aided in this work; but to no one are we more indebted for accurate information in regard to the difficult problems of plant structure and affinity than to Robert Brown of England. He was the most profound botanist of this or of any age. In this country Dr. Gray has long been foremost in developing and popularising the subject of plant morphology, which, for twelve years beginning with 1850, may be said to have been the leading idea in botany. The year 1862 will ever be memorable as the date in which appeared the classic work of Mr. Darwin on the fertilisation of Orchids. He caught the first glimpse of the subject from Sprengel; but to Darwin more than to anyone else are we indebted for the light thrown on the subject of fertilisation of flowers. Delpino, Ogle, Hildebrand, Bennet, Hooker, Lubbock, Kerner, Fritz

Müller, and Herman Müller, and a host of others in Europe and America, aided in rapidly making new discoveries in the same direction. In connection with this, many interesting discoveries have been made in reference to the motions of plants in climbing, catching insects, &c. Carnivorous plants have been examined and experimented upon. New modes have been discovered by which plants are distributed in various parts of the globe. From 1862 to 1875 in this country, what Gray calls 'How Plants Behave,' may be said to be the dominant feature in the science of botany."

Proceeding to the consideration of the modern and preferable methods of study, Mr. Beal states—

"What I have called 'The New Botany' began to appear in this country in 1862. It includes a study of the subjects as set forth by Darwin, Sachs, and others. It also includes a new or better way for students to learn the botany of our forefathers. In this we study objects before books; the pupil is directed and set to thinking, investigating, and experimenting for himself. To be constantly giving information in science makes intellectual tramps, and not trained investigators. Teaching the new botany properly 'is simply giving the thirsty a chance to drink.' It also creates a thirst which the study gratifies, but never entirely satisfies. This plan, in a general way, has been again and again brought to the attention of our best teachers, some of whom are carrying it into practice. I will now enter into details as briefly as possible, and try to mark out a plan which may assist some who are always looking for the best way. Specimens are essential; a greenhouse or a botanic garden are useful even if they are small, but almost every neighbourhood will furnish materials in abundance, which may be found in the fields, woods, and by-ways. Before the first lesson each pupil is furnished or told where to procure some specimen for study. If it is winter, and flowers or growing plants cannot be had, give each a branch of a tree or shrub; this branch may be 2 feet long. The examination of these is made during the usual time for preparing lessons, and not while the class is before the teacher. For the first recitation each is to tell what he has discovered. The specimens are not in sight during the recitation. In learning the lesson books are not used, for if they are used no books will contain a quarter of what the pupil may see for himself. If there is time each member of the class is allowed a chance to mention anything not named by any of the rest. The teacher may suggest a few other points for study. The pupils are not told what they can see for themselves. An effort is made to keep them working after something which they have not yet discovered. If two members disagree on any point, on the next day, after further study, they are requested to bring in all the proofs they can to sustain their different conclusions. For a second lesson the students review the first lesson—report on a branch of a tree of another species which they have studied as before. Now they notice any point of difference or of similarity. In like manner new branches are studied and new comparisons made. For this purpose naked branches of our species of Elms, Maples, Ashes, Oaks, Basswood, Beech, Poplars, Willows, Walnut, Butternut, Hawthorns, Cherries, and in fact any of our native or exotic trees and shrubs, are suitable. A comparison of the branches of any of the evergreens is interesting and profitable. Discoveries, very unexpected, are almost sure to reward a patient study of these objects. The teacher must not think time is wasted. No real progress can be made till the pupils begin to learn to see, and to learn to see they must keep trying to form the habit from the very first, and to form the habit they should make the study of specimens the main feature in the course of training. In nearly all important cases specimens are examined, and a need is felt for a name or definition before these are given. The use of technical names is not avoided, nor are these 'thrust upon a student.' They are learned as they are needed—a few at a time from the teacher or a text-book. Common terms for science are usually too indefinite in meaning to answer a good purpose. The difficulty of learning technical names is often much overestimated. The discipline required to learn them is itself worth all it costs to anyone."

In succeeding chapters directions are given for observing the phenomena connected with the fertilisation of flowers, the visits of insects, carnivorous plants, the motions of plants, seed-distribution, &c., similar principles being inculcated in all.

HARDY FRUIT GARDEN.

RIPENING fruit will need attending to carefully, examining Peaches, Nectarines, Figs, and Plums daily, removing any as soon as ripe, the Peach and Nectarine with the finer dessert Plums being improved in flavour by placing them for a few days in a well-ventilated fruit

room. Birds are usually troublesome, hence late Peaches and Plums should be securely netted. Gather Apples and Pears as fast as they become ripe, and place them carefully upon the shelves of the fruit room. Care should be exercised in gathering these fruits as well in doing it at the proper time, for if gathered too soon they will shrivel, and if allowed to become too ripe they will be deteriorated in flavour or become mealy. The fruit so far as practicable should be placed singly on the shelves, and be examined occasionally, removing decayed fruit. Autumnal Raspberries will soon begin to ripen their fruit, and will need to be protected with nets. The crop of these, if the autumn be favourable, will prove very useful. The plantation should be formed in an open situation, the soil being well enriched at the time of planting. When the fruiting season is over the canes should be cut down close to the surface of the soil, carefully selecting the young canes in spring, and cutting away all weak or superfluous ones. Strawberries placed out after being forced will be setting the fruit for an autumnal crop, and will need to be protected with nets.

KITCHEN GARDEN.

Cauliflower plants are now ready to be transferred from seed beds. Select the strongest for placing under handlights, employing good strong loam so as to secure a sturdy habit, this being further insured by attention to ventilation, it being necessary at this season to afford full exposure to all such vegetables in frames. Prick out into frames the requisite number of the remaining plants from the seed bed for transplanting in spring. Dust with wood ashes or quicklime as a preventive of the depredations of slugs and worms. A few of the larger leaves should be bent over the heads of Cauliflowers coming into use, both to keep them white and as a protection in case of sudden frosts.

Assuming that the crops of Onions and Potatoes were lifted and stored during suitable weather, the ground with but a forking-over will be available for Cabbages and Lettuces, breadths of which should now be placed out. The Onion ground will be a suitable change for Cabbages, which to insure fine heads should not be less than 18 inches apart every way, and 6 inches more for the large-heading sorts. If not already done a number of plants from the seed bed should be pricked out for transferring to their final quarters in spring and secure a succession of heads in summer to those afforded by the autumn-planted Cabbages.

For the spring and early summer supply of Lettuces a somewhat sheltered situation must be chosen, the plants succeeding admirably in the intervening spaces where early Peas will shortly be sown 4 feet apart, a row of the Cabbage variety being placed at a foot on either side of the row of Peas, and a row of the Cos between those, which will give two rows of Cabbage and one of Cos between each two rows of Peas. If this method does not afford a probability of supply equal to the requirements supplementary planting must be made in a sheltered position. Where the soil is light it should be made moderately firm by being trod over once and then raked level, and the plants placed out in drills. Stanstead Park Cabbage Lettuce and the black-seeded Brown Cos are reliable sorts. Careful attention should be given the plants, all vacancies being kept filled up regularly, and dustings of soot, wood ashes, or lime be applied as needful to keep down slugs and worms. After the planting of the main crop of Lettuces is completed a number of plants of Cos should be pricked out into a prepared bed in a sheltered place for transplanting in spring.

Lose no opportunity of earthing up Celery which may require it. The earliest crops should now have a final earthing-up, drawing the leaves close together, firming the soil well about the stalks, and well beat down the banks of soil so as to exclude the rain as much as possible. Parsley which is sown in pits should be well thinned, kept free of weeds and decayed leaves, exposing fully on all but frosty nights, when the lights should be put on and removed during the day. If no provision has been made for a supply in severe weather spring-sown plants may now be lifted and placed in pits or in deep boxes or pots, which, placed in a Peach house or vinery from which the Grapes have been cut, will furnish a moderate supply in severe weather. Chervil may be treated similarly.

In order to obtain a supply of the more tender vegetables as long

as possible every aid or protection to such in the open air should be attended to in due time, as by preventing the evil effects of a few cold nights the supply of such may be prolonged—possibly for some weeks longer.

Accommodation must now be provided for the Lettuces and Endive, which are to be lifted from the open ground to give a continuation to the supply when that which is outside is either exhausted or destroyed. The earlier the plants are placed into their quarters the better, moving with good balls, firming the soil well about them, watering well, and exposing fully on all but frosty nights, when the lights should be put on, and withdrawn in the daytime. Where large supplies of salading are in demand in winter shallow pits with moveable lights, and the command of sufficient heat to exclude frost, are essentially necessary to providing it in good condition and with certainty.

French Beans sown in August in pits as advised should now have the lights over them, but be ventilated freely in favourable weather; indeed a little should be given constantly, and artificial heat afforded to maintain a minimum of 55° and 65° in the daytime. Water when necessary with weak tepid liquid manure.

Tomatoes on walls should have the fruit cut as they give indication of ripening, placing in a vinery or other dry house to accelerate the process, and when there is danger of frost cut all the fruit of any size and lay them out in a similar place to finish.

FRUIT HOUSES.

Peaches and Nectarines.—The trees in the house started early in the year to afford ripe fruit in June will now be shedding their leaves, and the trees having had a tendency in previous seasons to cast the buds, not set well or stone indifferently, which is a sure indication of the imperfect ripening of the wood. The roof lights in such case have not been removed, as this will tend to ripen the growth. Yet something more than this is necessary to rectify the evils above alluded to, which chiefly arise from too rich, loose, deep, and unrestricted borders; indeed, most fruit trees under glass are given far too much root space. Trees in the condition above indicated should, as soon as there is the slightest indication of the maturity of the foliage, be at once root-pruned. In a majority of instances it will be sufficient to remove the soil between 3 and 6 feet from the stem, and, making an examination of the roots, cut through the thickest and deepest, removing the detached parts, and also the soil down to the roots towards the stem, and, without disturbing them, supply fresh loam rammed well down, giving a good watering. This will cause the speedy resting of the trees, whilst at the same time new roots will be emitted, continuing more or less active through the winter. In some instances it will be desirable to detach the whole of the roots at the distance above indicated, according to the size and vigour of the trees.

In the case of trees that have long-jointed wood and that do not fruit satisfactorily they should be entirely lifted. In this case the whole of the soil should be removed down to the roots, and then, commencing at the point most distant from the stem of the trees, the roots should be carefully lifted from that point towards the stem, laid aside and covered. The soil should be removed down to the drainage, which should be rectified and covered with a layer of turves. Putting in a foot of soil, a layer of the roots should be spread out carefully and covered with about 6 inches depth of soil, and then the remainder of the roots, which should likewise be covered with 6 inches of soil; the smaller roots from the collar being laid out should be covered but lightly with soil. A good watering must be given, and a mulching of partially decayed manure about 3 inches thick. If the weather be bright shade during the operation and for a few days afterwards, and syringe occasionally. The trees will soon produce fresh roots, when the usual routine should be resorted to. This operation must be performed before the leaves fall. Rather strong loam is the most suitable for Peach trees, adding about a tenth of old mortar rubbish. Trees in succession and late houses may be treated similarly, but it must not be performed until the growth is completed and the wood somewhat hardened, or it may cause the wood to shrivel or die. In the case of young and other trees growing too luxuriantly a trench may be taken out at a third of the distance from the stem that the branches cover in extent of trellis, and the roots detached from the trench may be

filled up again, ramming well down, removing the surface soil from the trench to the stem, supplying fresh material and making firm. When the fruit is all gathered in the late houses the next object is to get the wood thoroughly ripened, which is best effected by removing the shoots that have borne fruit, cutting them out to a successional shoot at the base, and thinning out the shoots where they are too crowded.

Figs.—Trees in pots for early forcing must at once be attended to. If needful a shift into larger pots may be given; but as it is usually desirable to confine the trees to the same size pots, a few inches should be removed from the base when the trees are turned, cutting back the roots and re-arranging the drainage, which should be efficient; replace the soil removed with fresh fibrous loam having a slight admixture of road scrapings or old mortar rubbish, ramming hard; remove the surface soil, and replace with fresh material. Water thoroughly, and place where they can be well exposed to air without being subjected to heavy rains or frost.

Fig trees planted out should be kept drier at the roots, and be freely ventilated. When the second crop is gathered keep the house cool and dry, ventilating fully except when frost prevails. Any trees not ripening the wood freely should have a circulation of dry warm air secured to them by day, keeping them dry at the roots, but not extremely so; and when the leaves give indications of falling root-pruning or partial lifting should be resorted to.

PLANT HOUSES.

Stove.—The earliest and strongest Poinsettias should now be placed in the stove at a temperature of 60° to 65°, attending well to with weak liquid manure. The remainder of the plants should be kept in a temperature of about 55°, being careful in watering, for if overdone in that respect they will lose the roots and the bracts will be poor. These plants will form a successional batch to the first lot.

Euphorbia jacquiniæflora must not be kept in a lower temperature than 50°, and not be overwatered, or the roots will perish and the flowering be indifferent. *Sericographis Ghiesbreghtiana* must be placed in a light position, and when in flower will stand in a conservatory for some time. A few plants of *Plumbago coccinea superba* and *P. rosea* should be placed at the coolest end of the stove to succeed the earliest-flowering plants; similar remarks applying to other winter-flowering plants, so as to maintain a succession of bloom.

Nepenthes.—These are fine for decorative purposes, and should be grown by those having a stove. To insure their forming plenty of fine pitchers they should be grown near to the glass, and only have shade to prevent scorching. Good fibrous peat, with a fourth of potsherds and a sixth of chopped sphagnum, adding a sprinkling of charcoal, the drainage being very liberal, will suit them well. Although the spring is the time to pot them, now is the time to procure plants, as the growth being matured they suffer nothing in transit. Keep them near the glass through the winter, and pot in spring, 6 or 7-inch pots being large enough. Plants that have become tall should be cut down to within a foot or so of the pot, and remove the eyes from the upper part of the stem down to three of the lowest, but leaving all the leaves entire; and when the eyes left have broken and grown somewhat the upper part can be removed. The ripe part of the tops cut off will make cuttings. Cut into lengths of two joints each, leaving a portion of leaf to the upper joint, inserting them in cocoa-nut fibre refuse and sand in a case or covering with a bellglass, and keeping close and moist, greater part will be rooted by spring. The tops or soft portion are of no use for cuttings.

Nymphæa cærulea, *N. cyanea*, *N. dentata*, *N. Devoniana*, and *N. rubra*, flowering over a lengthened period, are very interesting; the flowers, in addition to being beautiful on the plants, are useful for cutting. A tank of a few feet square and of a depth of 3 feet, with a foot of good loam at the bottom and the remainder water, will suit them. *Dracænas*, *Palms*, and other ornamental-foliage plants employed in conservatories, must be returned to the stove before the foliage suffers from the cold, or they will be irreparably injured; similar remarks applying to flowering plants, such as *Dipladenias*, *Ixoras*, *Allamandas*, *Bougainvilleas*, *Clerodendron Balfourianum*, *Ste-*

phanotis, &c., being careful not to keep them too moist or too warm and close when returned to the stove, or the probability is they will be excited into fresh growth.

Ixoras that have yet flowers to open should be carefully treated, not syringing them, as their flowers will be very valuable. *Allamandas* may continue flowering for months to come without injury to the next season's bloom, but water should be given in diminished quantity so as to prevent sappy growth. Our planted-out specimens of *A. nobilis*, *A. cathartica*, and *A. Hendersoni* are never out of bloom, a portion of the plants being cut back at different periods so as to insure a continuity of bloom. *Rondeletias* will afford flowers for some time longer, and should be treated similarly.

Roman Hyacinths potted some weeks ago along with double Roman and Paper White Narcissus will have rooted and should be placed near the glass, in order to keep them as dwarf as possible, and not be brought on too quickly, a temperature of 55° to 65° being suitable.

Ferns having for the most part completed their growth will need considerably less moisture both at the roots and in the atmosphere, but should not be kept too dry or thrips will appear, and should be eradicated where they exist by moderate fumigation on two or three consecutive evenings. Plants of *Adiantum cuneatum*, &c., wanted to give fronds early for cutting, or the plants for decoration, should be somewhat dried off, and be given a rest for a few weeks in a temperature of about 50°, afterwards placing in heat and moisture to encourage growth, and when mature gradually harden them. Plants so treated are far more enduring for decoration or cutting than those taken direct from a warm moist atmosphere to a cool and dry one.

THE BEE-KEEPER.

BEE-KEEPING FOR BEGINNERS.—No. 6.

SWARMING VERSUS NON-SWARMING.

EXPERIENCE and close observation strengthen our conviction that the swarming system of managing bees is better and more profitable, healthier and more natural, than the non-swarming system. In unfavourable seasons for honey-gathering the non-system is better because less expensive than the other. This was fully stated in our last letter on this subject, in which it was said that in investigations of this kind many points should be noticed—viz., large and small hives, good and bad seasons, early and late localities, spring and autumn flowers. By noticing these points briefly we shall cross, but not cover, the whole field of inquiry before us.

1st, Large and small hives. By common consent the superiority of large hives is admitted. The most advanced bee-keepers are using them. Some ten or twelve years ago some teachers said they were a delusion and a snare. Be this as it may, large hives in good seasons yield the largest swarms, gather most honey, and give the largest returns. Smaller hives yield proportionately large first swarms, but their second swarms and turnouts are very small and comparatively worthless, and they never yield a large return in honey. In good and bad seasons, and in early and late localities, large hives are advantageous. In bad seasons small and weakly hives suffer most.

2nd, Good and bad seasons. In good seasons the swarming system of management is incomparably the best and most profitable. In such seasons we have had records of notable and remarkable success by management on the non-swarming principle, and such records we like to read and rehearse, though in most instances they are solitary. Just a few hives here and there, well managed and kept from swarming, yield to their masters extraordinary results. But the actual and almost unavoidable loss of swarms in good seasons, if managed on the non-swarming principle, is disastrous and discouraging. The stories of lost swarms from such apiaries are seldom told. In good seasons we take, and advise others to take, all the first swarms that can be had in May and June. As apiarians gain experience and better understand the natural habits or history of bees, they take broader views of swarming, and advantageously use it in various ways which they never thought about before. Hives that swarm in May are empty of brood in three weeks after swarming. Their queens have not begun to lay. By driving the bees out of them into empty hives, and putting swarms into them, the later swarms are made equal to

the earlier swarms for strength and activity. In a week, or ten days at most, they are filled with brood and ready for supering. Meanwhile the turnouts with young queens fill their hives, and, generally speaking, make excellent stocks for keeping. Thus the eggs of pregnant queens are used in hives empty of brood.

In good seasons strong hives managed on the non-swarmer system are ready for supering before supering should begin. The honey gathered from fruit trees, Sycamores, and other early-flowering plants, is too dark in colour for supering. It does not look well in any kind of supers. In early summer, too, how difficult it is to keep brood out of supers. At this season bees are bent on multiplying their numbers, and show by their conduct that "excluders" are useless, and that they can carry eggs wherever they go. They sometimes—nay, often, cut down honey-comb in supers, and empty the cells to make room for brood. By having strong hives in autumn and spring, early swarms are obtained in good seasons, many of which will be ready for supering at the proper time. In bad seasons bees themselves instinctively shrink from swarming, and, generally speaking, few colonies are sent off. To swarm bees in such seasons is undesirable; indeed, it would be about as unnatural as it is unnatural to prevent swarming in good honey seasons.

3rd, Early and late localities. In some high and cold districts there are no orchards or fruit trees, no early spring flowers. In such districts bees are late in commencing to work and breed; swarming there does not commence till June under ordinary management. In some districts there is no Heather or autumn flowers. The honey season ends with the white Clover about the end of July. In the absence of Heather, or, in other words, if bees are not taken to the moors in August, swarming should be prevented about and after the end of June. My native village in Lanarkshire is a cold late place without orchards and Heather, but the bee-keepers there remove their bees to the orchards on the Clyde in spring, and to the moors in autumn. By so acting they get early swarms and have long summers. In that cold district swarms are obtained about as early as they are in the warm districts of England. This is owing to the excellent mode of managing bees in autumn at Carlisle. The swarming principle is adopted and followed there. In autumn all the bees of the honey hives are preserved and united to the stocks, making them doubly and trebly strong. Herein we have the secret of great success, and an instance of modern bee-keeping unsurpassed for worth and excellence. If bee-keepers generally will see that their hives are made strong in autumn by additions of bees and proper protection, they will soon be proud of their apiaries.

In cold late districts we approve of covering hives well, and gentle stimulating feeding in the spring months. Attention to these points and autumn treatment, bee-keeping, even in high-lying districts, may be a source of pleasure and profit to all who resort to it.

Looking at the advantage of having hives with young sweet combs in them and young queens, and other points which cannot be had on the non-swarmer principle, we feel quite certain that the teachings of experience will lead most bee-keepers at no distant day to adopt and follow the practice now indicated—viz., of having strong hives in autumn and early swarms.—A. PETTIGREW.

BEEES IN WINTER.

IN your August number, page 137, Mr. Pettigrew says:—"Owing to last winter being open and warm, bees, generally speaking, consumed most of their stores," &c. On the same page you give an extract from the *Bienenzeitung* of one of Dr. Dzierzon's articles, thus:—"The milder the winter is the more complete will be the repose of the bees . . . whilst increasing cold stimulates them to breathe more frequently and consume more food." Can these two statements be reconciled, and if not, to which should a beginner give credence? I have just read up your bee articles for the last eighteen months, so did not sooner notice the apparent difference of opinion between two acknowledged authorities.—EAST RIDING.

[Dr. Dzierzon, and most scientists, on the principle that all saccharine matter is heat-producing and stimulative, adhere to the theory that bees in cold weather both require, and actually consume, honey in larger quantities than they do in warm, in order to keep up the necessary heat of the hive. In proof of this they allege the well-known fact that two stocks of bees united in the autumn will exist and thrive upon the same quantity of food which one stock alone would have required for its sustenance. Although this subject resolves itself into a question of chemistry chiefly, it is, nevertheless, one for experiment; and we trust that some of our able contributors on bee culture will institute ex-

periments forthwith, the present time of year being especially favourable for carrying them out.]

WHAT TO PLANT FOR BEES.

MANY have applied to us to know what plants are best to put in small gardens for bees, and therefore we take this opportunity of stating what experience has taught us regarding this subject. It is a well-known fact that bees do not depend upon the comparatively few plants we can tempt them with in our gardens. Their supply of food is drawn from more extensive sources—from the forest trees, the fields of blossoming corn, Clovers, Buckwheat, Mustard, Charlock, or from acres of purple Heather. At the same time there are many plants which can be placed in a bee-keeper's garden upon which the bees delight to feed, some of which yield, comparatively speaking, great quantities of honey and pollen, and fill up intervals between the blossoming of various field crops. It is likewise always pleasant to see bees working, and to be able to walk round our garden and watch the manner in which our little favourites load their pollen baskets. There is, moreover, another reward which the bee-keeper has who plants for his bees. Many of the plants which we have proved are most acceptable to the bees are also most remunerative to the planter, and inasmuch as he who keeps bees is certain of manifold more fruit from the plants than he who has no bees, there is a double inducement to take some little trouble to give up some part of our garden space to plants specially suitable to the production of pollen or honey. There are many flowers which are most acceptable to bees, and which give pleasure to the eye only of the bee-master, such as Crocuses, Arabis, Wallflowers, &c. Of these we will in this paper say nothing, but only treat of such as shall be remunerative both ways to the bee-keeper—viz., such as will yield honey from their flowers, and be of market value as to their fruit, or of utility for kitchen purposes. In another paper we will take in their order of flowering some of the plants which are only pleasant to the eye, and from which the honey alone is the remuneration obtained.

Of the former class the Gooseberry should be placed first, as it flowers early in the year. Wherever an odd corner can be spared, or a border by the side of a walk is available, plant Gooseberry bushes. If space be limited, then train them to wire netting fastened to stakes. Many bushes can thus be planted in a small space, and the fruit from such will be fine, and easily protected, where required, from birds. We have grown splendid crops of this fruit in seasons when our neighbours have hardly had any. With every gleam of sunshine our bees revelled on the tiny blossoms and thus set the fruit, and we have always had to thin out well; never the annoyance of fruitless bushes. Strawberry blossoms are also much frequented by the bees, and where space can be allotted to them a bed is much more productive, if near hives, than at a distance from them. It is a delightful study to trace the marvellous adaptation of insects to the fertilisation of flowering plants; and the Strawberry plant, among many others, is a striking example of the dependency of flowers on insect life for their means of producing fruit in proper season. Those of our readers who would like to know more of this subject should purchase the plates published under the auspices of the British Bee-Keepers' Association, showing the anatomy of the honey bee and its relations to flowering plants. An explanatory key is published with the diagrams, and the subject under our consideration is thus explained:—

"For fertilisation insects are required, since the stigmas are ripe long before pollen is produced. Bees especially, walking over the bloom seeking honey, carry pollen to the stigmas. Where fertilisation takes place the Strawberry develops, but if it fail in part we have there a hard, shrunken, and greenish mass. Any dish of Strawberries examined will give instances. Without this fertilisation no crop appears. To produce a single perfect Strawberry from one hundred to double or treble that number of independent fertilisations must be accomplished. In the Blackberry or Raspberry every little rounded mass (drupel) has had its stigma which an insect has visited. How clear it is that our fruit crops are aided not a little by the presence of bees!"

Other fruits are produced by aid of the bees in a more or less elaborate manner, and with this slight digression from our immediate subject we will proceed to point out other profitable plants for small gardens. We do not remember seeing the Radish specially noted by any bee-keeper before, but we have found it a wonderful favourite with bees. It is our practice to leave a few roots in each Radish bed to run to seed, and those who may try this plant will be surprised at its attraction for bees, also at the enormous amount of seed that will set on each plant. Towards autumn the seed vessels if not ripe can be cut off and hung in a warm dry place, where the seed will be quickly harvested.

Another useful plant of which bees are very fond is the French Runner Haricot Bean with white blossoms. After giving employment to the bees the useful vegetables will be the more productive the oftener the weather has permitted our insect friends to visit them. The flowers of all the Cabbage and Cauliflower tribe are ever wooed by the bees; but then they occupy much space, and perhaps look somewhat untidy. Two herbs we have found ever covered with bees when in flower, and we intend to place them in every vacant nook and corner this next season. The one is the ordinary garden Thyme, a neat pretty plant, looking well as an edging to borders and flowering late in the year when most other flowers are over. The other herb is Pennyroyal, its trusses of lilac flowers at the present date being alive with all kinds of bees whenever the state of the weather permits. We have said nothing here about the various kinds of fruit trees which are found in large gardens, and all of which yield honey. Even in small gardens they can be grown as dwarf bushes or pyramids, and near bees will readily set their fruit in favourable weather. The plants we have mentioned can be grown in every garden, even near the smoke of London.—P. H. P.

BRITISH BEE-KEEPERS' ASSOCIATION.

At a recent meeting of the Committee the following report was received from the Examiners appointed to conduct an examination of candidates desirous of gaining certificates of competency in the modern system of bee management—viz.

"In presenting to the Committee of the British Bee-keepers' Association a brief report of the first examination of candidates for the certificates of competency in bee management held at South Kensington on the 7th and 8th days of August, 1882, in connection with the annual metropolitan Show, we have to state that twenty-one candidates appeared for examination, and were examined by us in the appointed subjects as laid down in the books recommended by the Committee, by written papers, *vis à voce*, lecturing, and manipulation of living bees; that twenty of the candidates were deemed by us as qualified to receive certificates, eight being placed in the first class, nine in the second class, and three in the third class, only one having failed to satisfy us.

"We could have wished that the printed questions had been more fully considered, many of the candidates having treated them in too cursory a manner. We express a hope that future candidates will bestow more care and energy upon their preparations for the delivery of lectures to audiences composed of cottagers, and to the manipulation of living bees.

"With the theory of apiculture all appeared to have a fair general knowledge and acquaintance, and as a first attempt or experiment we deem the examination to have proved eminently successful, and to have so far produced most satisfactory results.

"Herewith appending the class lists.

"We remain, Gentlemen, your faithful Servants,
 "THOS. W. COWAN, F.G.S.,
 "HENRY BLYTH, M.A.,
 "GEORGE RAYNOR, M.A., } Examiners."

CLASS I.

C. Brown, 49, High Street, Dudley.
 J. Stevens, 10, Montrie Terrace, George Lane, Essex.
 F. Cottman, 23, Western Road, Olney, Bucks.
 C. T. Overton, 7, New Street, Three Bridges, Sussex.
 G. Stothard, Welwyn, Herts.
 G. H. Baines, 33, Western Road, Tring.
 Rev. E. Davenport, The Manse, Hungerford.
 I. Lake, Cantley School, Doncaster.

CLASS 2.

G. St. John, Holly Cottage, Quinten, Birmingham.
 J. Arnold, School House, East Molesey, Surrey.
 J. Best, Witham Apiary, Boston.
 R. H. Stonhill, Stekeley, Leighton Buzzard.
 R. W. Davies, Manor Street, Braintree.
 A. W. Rollins, Stourbridge, Worcestershire.
 R. J. Tomlin, 2, Albion Villas, Park Grove, Leytonstone.
 J. Taylor, Cooper's Green, Buxted, Sussex.
 T. C. Edmonds, Caistor, next Yarmouth.

CLASS 3.

J. Alsford, Market Place, Blandford, Dorset.
 N. Atkin, The Grange, Welwyn, Herts.
 J. Perry, Banbury, Oxford.

The next quarterly meeting of the Committee and conversazione will be held at 105, Jermyn Street, on October 18th, when a paper will be read by Mr. G. D. Haviland on the "Social Instincts of Bees, their Origin by Natural Selection."

TRADE CATALOGUES RECEIVED.

William Paul & Son, Waltham Cross, Herts.—*Catalogue of Roses, Fruit Trees, and Miscellaneous Plants.*

James Gray, Danvers Street and King's Road, Chelsea, London. S.W.—*Illustrated Catalogue of Horticultural Buildings.*

** All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Late Nectarine (J. E. R.).—You cannot add a better variety for continuing the supply to those you have named than the Victoria. It is large and of excellent flavour, while the tree grows well and bears freely.

Vines at Longleat (Vitis).—Mr. Taylor's manual will be ready in a few days. The price will, we believe, be 1s. exclusive of postage. Full particulars, however, will probably be announced next week.

Golden Feather for Spring (A. Boyle).—Certainly if you had stated your requirements we should have advised earlier sowing. Your letter implied you desired the plants for summer, not for spring bedding. Procure the larger plants to which you refer, they will answer your purpose, while some of the smaller will probably also be useful.

The Cucumber Disease (J. Penton).—You do not appear to read the Journal attentively, or you would have found much matter from time to time on this subject. On page 284 of our last issue you will find a reply to a correspondent that is equally applicable to your case, and to that paragraph we direct your attention. Melons are much less liable to be attacked by this malady, but they are not invulnerable.

Ampelopsis Veitchii (A. M. B.).—Yes, we endorse what Mr. Luckhurst said on page 242 relative to this most useful climber. For summer and autumn effect you cannot plant anything better and needing so little attention; in fact if you plant it in good soil near a building it will take care of itself. It is perfectly distinct and greatly superior for forming a close surface to the old Virginian Creeper. We doubt the advisability of your planting other climbers with it, though we have seen a pretty effect produced by adding Clematis Jackmanni. This, however, must be secured to the wall and trellised; so also must the Jasmine which you name, but the Ampelopsis adheres with tenacity to almost everything with which it comes in contact; we have seen it adhering to glass. Thanks for your letter, and we shall be glad to hear from you at your convenience.

Roses for Buttonholes (F. J.).—Tea Roses are among the most suitable for this purpose, and there are few gardens where the soil is good and the atmosphere pure in which they, with a little protection, may not be grown. Free and good are Niphotos, Madame Falcot, Homère, Madame Van Houtte, Madame Lambard, Safrano, Perle des Jardins, Comtesse Riza du Parc, Madame Jules Margottin, and Souvenir de Paul Neyron. The old crimson China Rose and Cramoisie Supérieure are good for your purpose, as also are the Noisettes Triomphe de Rennes and Aimée Vibert, with Baronne de Maynard, Boule de Neige, and Louise Darzens. Moss Roses are indispensable—the common, crested, Moss de Meaux and Little Gem (W. Paul), the latter being very charming. Among the most free and suitable of the Hybrid Perpetuals are Jules Margottin, Général Jacquemiuot, and La France. We have probably named sufficient for your purpose. The advisability of digging-up and planting your established Roses deeper depends on the depth at which they are planted now. If they grow and flower freely we should let them alone; if not, you might try the plan you suggest, but on this point we cannot advise, since you have not stated the length of the stocks.

Muscadine Vines Unsatisfactory (Idem).—The foliage indicates that the roots are in ungenial soil. No doubt the Vine would be benefited if the roots, or some of them, were raised and placed in good turfy loam, covering them 4 or 5 inches deep, and keeping them regularly moist. Thus treated, fresh fibres would form, which would appropriate the food within their reach and invigorate the Vine.

Lime for Light Soil and Vine Border (Inquirer).—Half a bushel is a sufficient quantity to apply per rod (30½ square yards), and unless the soil be rich—full of humus from heavy dressings of vegetable and animal manures, such as are essential to the production of high-class vegetables—a peck per rod is a sufficient quantity to apply at one time, which we do about every third year; but as your soil has not been limed for ten years the larger quantity may be applied. It should be put on "quick," and during dry weather in autumn or spring, preferably the latter. For a Vine border half a bushel per rod is a sufficient and suitable quantity, but with the soil very rich from surface dressings double the quantity may be applied. In every instance it should be equally distributed and pointed in with a fork.

Earth-closet Manure (Idem).—The manure when stored must be kept dry, as the ammonia, &c., would be liberated by moisture. Charred or burnt garden refuse, including soil, will be suitable for using instead of earth, and the more valuable from the increased quantity of potash contained in the manure.

Strawberry for Light Soil—Raspberry for General Use (Idem).—President is unquestionably the best Strawberry for a light soil, giving an abundance of large highly flavoured fruit. Of Raspberries Baumforth's Seedling is very free and fine, and when more generally known must become a great favourite. Of established varieties Carter's Prolific is very good, and so are the Prince of Wales and Fastolf. The first of the three last named is grown by the acre in Kent, and gives great satisfaction.

Insects on Pansies and Ferns (An Old Subscriber).—These are specimens of a common Myriapod, the Julus terrestris, in a young or immature stage. Both are identical, and the difference in colour arises from the fact that those

of the species living above ground become darker by exposure to the air and light. Although occasionally injurious, as described by you, it is also a destroyer of other insects. It might be killed by an application of the compound of paraffin, soft soap, and water, the proportions of which have been repeatedly given in these pages. Or many of them might be snared by strewing in the earth small pieces of apple or pear, of which they are very fond.

Treatment of Belle de Chatenay and Queen of Violets (C. R. W.).—Mr. G. Abbey writes as follows in reply to your query:—"These, when the blooms can be had fully developed, are perfect rosettes, Belle de Chatenay being purest in colour. Sometimes, as you observe, they bloom splendidly, and at others it is only by chance we get a good bloom, the rest being quite undeveloped and scarcely possessing a petal. This tendency results from the plants flowering too profusely, more buds being produced than the plant can develop. It is the same under whatever condition the plants are grown—in pots with the flowering accelerated by warmth, in frames, or outdoors. Even now the plants have a great number of deformed buds, being devoid of petals, and cannot under any possibility be developed into well-formed full flowers. The only remedy that I know is to examine the plants frequently, and remove all the flower buds that do not appear to be perfect. The removal of these will mostly result in the best-formed buds developing satisfactorily. It is the first buds that show the tendency to petal-defect. Such are marked by short footstalks, and are common to all double Violets in the first or early buds."

Fruit for August and September (Constant Reader).—If you have a warm position out of doors we should not plant Apricots in the house, but should add the Moorpark to those you name and plant against a wall with south aspect in the open air. Some of the best Plums for exhibition are Goliath, also called Emperor, end of August; Pond's Seedling, end of September; Kirke's, middle of September; Jefferson, middle of September; Transparent Gage, beginning of September; Huling's Superb, end of August; Denniston's Superb, middle of August; and Washington, middle of September. The exact period of ripening depends on seasons and districts; we have given the usual times of ripening in the open air near London. It is for you to determine in accordance with the climatic character of your district whether you plant any of the trees under glass or not. You may graft the Black Hamburg, Alicante, Gros Colman, or Madresfield Court on the Lady Downe's stock provided it is healthy.

Arums (Lorrimore).—None of these plants is difficult to grow, and the three following are quite hardy, and would be the best suited for your garden. Ordinary garden soil is all that is needed, but a little manure applied in spring will render their growth much stronger and the spathe larger. A dry position is the best fitted for them, and in any situation they require abundance of water during the summer. They can by no means be considered as strictly handsome, but they are curious, and possess a certain degree of attraction,

Fig. 49.—Arum crinitum.

Fig. 50.—Arum italicum.

chiefly owing to the peculiarity of their forms, for their odours are far from agreeable. *A. crinitum* (fig. 49) is of very singular appearance, the spathe being broad and shovel-like in form, the upper surface being dotted with bluish purple airs. *A. italicum* (fig. 50) is more in the way of our common *A. maculatum* as regards the shape of the leaves and spathe, also in its habit, but the spathe is yellowish and contrast strikingly with the rich green foliage. *A. Dracunculns* (fig. 51 page 307) is one of the largest-growing sorts, and forms a prominent object in a mixed border, the foliage being handsome. The spathe is long and tapering, of a blackish-purple colour, and for a short time after they have expanded they exhale a most fetid odour, but that soon passes off.

Raspberries for Autumn Bearing (Anon).—October Red is the best, withstanding wet better than most others, Large Monthly being dwarf-growing and an abundant bearer, but the fruit is not so large as October Red or Belle de Fontenay. Orange d'Automne is very large, yellow or orange, and good in flavour; but October Yellow, though less in size of fruit, is more prolific. By double bearing we presume is meant the fruit borne sometimes on the canes of the current year's growth, which is usually most common when the season is moist and the canes make vigorous growth. These have been scarce with us this season, but have been usually sufficient to give a supply as an accompaniment for Red Currants in tarts and dessert until the autumn-bearing sorts continued the supply until the approach of winter.

Roses for Greenhouse (Harborne).—Your request implies that you need Roses for training up the roof, but you do not say so. For this purpose we doubt if any will give greater satisfaction than Maréchal Niel and Gloire de Dijon; the best red variety for the same purpose is probably Reine Marie Henriette. As a rule they are far better planted in good soil than kept in pots. Two good Roses for growing in pots for forming bushes are La France and Niphetos, of which strong plants well cultivated give a wonderful quantity of acceptable flowers.

Second Crop Figs—Paulownia imperialis (Ramallo).—It is not possible for you to preserve the Figs, which are now larger than Filberts, on a tree in the open air so that they will ripen next year. They will all shrivel and drop off whatever you may do to secure them. Nor is it practicable to protect the flower spikes of this tree so that the blooms will expand at this late season of the year. The nights are too cold for that to be accomplished, and such buds as you have sent will shortly fall. We are not able to state definitely the cause of the brown patches on the leaves. If you have not had a shower of hail in

your district they have probably been caused by the puncture of an insect. The red Apple you have sent is Fearn's Pippin, the other Keddlestone Pippin.

Melons Failing (J. E.).—Even if you had supplied us with some particulars relative to the treatment your plants have received and the weight of the crop, we suspect it would have been difficult for us to state the cause of the evil; without some such information it is impossible. The fact that your plants have produced a second crop suggests that they are more or less exhausted; this, with possibly some little inattention in watering and ventilating, would cause the foliage to collapse and the stems to shrink as in the specimens before us. Withholding water when the fruit is approaching maturity is often carried to excess, and many crops are thereby impaired if not ruined. Whether this is the cause of your failure we are unable to say, being quite without data for determining the point, or, in fact, for comprehending the case in a satisfactory manner.

Grapes not Colouring (Idem).—The chief cause of Grapes failing to colour is undoubtedly defective root-action or insufficient support; injury to the foliage, either by insects or scorching, also contributes to the evil. You do not think the Vines have been overcropped because one of them is not bearing more than 8 lbs. of Grapes, but you omit to state either the age or size of the Vine, which information, as you must perceive on reflection, is absolutely necessary for us to form an opinion on that point. We have seen hundreds of Vines overcropped with 8 lbs. of Grapes on each, and hundreds more undercropped with thrice that weight of fruit. Everything depends on the constitution of the Vine, the activity of the roots, and the fertility of the border. We strongly suspect that, although the crop may appear light, it is really too heavy, and that more vigorous root-action with fresh soil are needed to bring the Vine into a healthy condition that will enable it to finish the crop. This opinion is founded on the assumption that the foliage of the Vine is clean, not overcrowded, and apparently healthy. If we were acquainted with the actual condition of the Vines and border and the leading points of your treatment, we should have no difficulty in answering your letter, but with a lack of knowledge on these points we cannot reply satisfactorily to ourselves.

Traders versus Amateurs Exhibiting (R. B. Barratt).—The schedule with rules to which you refer has not reached us, and consequently we are placed at some disadvantage in answering your letter. We, however, have no difficulty in stating that the individual in question is not a nurseryman, neither is he an amateur according to the ordinary meaning and acceptance of that term. He is a trader, and as such not eligible for competing in amateurs' classes. An amateur is, briefly, a person who grows his own produce for his own use. If growing it for sale is his chief object, he is, as we have stated, a professional trader. If there is nothing special in your rules on the subject admitting such an exhibitor in the amateurs' classes, the protest to which you allude is well founded and is worthy of consideration.

Repotting Pines (J. C.).—The plants having been transferred to the 9-inch pots in May will not now require repotting, as the shift then given them ought to be the fruiting one. To repot now would defer the fruiting for some time, but, well attended to, the plants should throw fruit early next year and ripen in early summer. Instead of shifting now apply weak guano water in a tepid state, but it should never be given until the plants need it, and then a thorough supply. When the roots of Pine plants have fairly hold of the soil after repotting weak liquid manure may be given each time water is required until the fruit is near the colouring stage; not afterwards.

Vines in Pots (Idem).—The Vines no thicker than a lead pencil will be of no use for fruiting next season. They should be as thick as the middle finger or thumb, and have hard, brown, well-ripened canes, with eyes like nuts, and be in 12 or 13-inch pots. The Vines should be cut down to a couple of eyes, and when they have produced a few inches of growth next season shake out and repot into 7 or 8-inch pots, and when these are filled with roots, and before they become matted around the sides, shift into the fruiting pots.

Budding Cherries on Mahaleb Stock—Madresfield Court Grape Cracking (Idem).—The early part of July is a proper time to bud this stock as well as the common Cherry stock. The most probable cause of the Grapes "splitting" is an insufficiency of nutriment during the early stages of swelling and an over-abundance when the Grapes are approaching the ripening stage, along with a moist atmosphere. This Grape is liable to crack, and requires a rather dry well-ventilated atmosphere, with a drier condition at the roots when ripening than most other Grapes. Well grown it is one of the finest of autumn Grapes both in appearance and quality.

Alternanthera Cuttings (Miss A. Peel).—We are not able to state where you can purchase cuttings, it being quite contrary to our custom to recommend dealers, as you will perceive if we were to recommend one we should be acting unfairly to others of equal repute. Plants can be obtained from most of the nurserymen who advertise in our columns. A few plants obtained now and kept in a stove through the winter would afford hundreds of cuttings for striking in the spring and planting out in early summer. They cannot be wintered in a cool greenhouse, nor will they grow and colour satisfactorily in districts where the summers are cold and wet.

Turf Litter (C. D.).—No one could have supposed that the above term applied to such matter as you have sent us. In the great mass of correspondence that passes through our hands it is impossible for us to remember the contents of letters sent a month ago, and you ought to have re-stated your request. We can only say that the "litter" you have sent possesses little or no manurial value, and can only be of use for mixing with very strong soil to improve it mechanically for certain kinds of plants for which it may be unsuitable in its original state. We will readily answer any questions you may submit if we can understand them, but you are one of those correspondents who, with the best possible intentions of affording us the least trouble in reading long letters, err on the other side, and afford us no data for replying satisfactorily. Write more fully, explaining clearly the nature and condition of anything on which you need information, and your letters shall at all times have our best attention.

Plants for Cold Greenhouse (J. Martin).—To furnish an unheated house well of the dimensions of yours would cost nearly as much as heating it with hot water, and quite as much as by a flue of sanitary pipes. For rendering such a structure ornamental in the winter you would have to rely mainly on choice evergreens and fruit-bearing shrubs. Amongst the former small variegated Hollies, Enonymuses, and Ivies; and the latter *Skimmia japonica*, *Pernettya mucronata*, and *Aucubas*. Small Rhododendrons would be refreshing in winter and gay in spring. Some of the Veronicas, such as *V. Andersoni* variegata and *Blue Gem*, might be suitable, also Christmas Roses, such as *Helleborus niger* and the fine variety *maximus*, *H. olympicus*, and *H. purpurascens*. For

early spring all bulbs that are grown in gardens would be useful, such as Hyacinths, Tulips, Scillas, and Crocuses, with Hepaticas and Winter Acouite (*Eranthis hyemalis*).

Preserving Scarlet Runners (*Idem*).—They may be preserved by being placed in layers in large stone jars alternately with layers of dry salt. First cover the bottom with salt; then place in the pods, which must not be wet, about an inch thick, which just cover with salt, and continue the process until the jar is filled, finishing with a thick covering of salt. The beans when taken out should be soaked for several hours before being cooked. We have had beans thus preserved that were fresh, green, and of good flavour throughout the winter. If any of our readers know of a better plan for preserving the pods we will readily publish it.

Tomatoes Diseased (*Witherby*).—The disease which has attacked your plants is similar to the Potato disease. It has been extremely violent in some districts, and quite ruined the plants and crops. It is much worse in wet than in dry positions, and does not commonly affect plants under glass. There is no remedy, but the evil may be evaded by affording the plants the shelter of walls or glass.

Fig. 51.—*Arum Dracunculoides*.

Gordius aquaticus (*G. U.*).—The above is the name of the singular creature which children call horsehair worms, and we suppose many thousands of horse hairs have been placed in water by them under the erroneous notion that they be converted into the worms; hence the common name that is applied to them. They are found in many parts of Great Britain, but whether "all over" it or not we are unable to say. Their distribution, however, is general, not partial merely.

Zonal Pelargoniums (*J. H.*).—We perceive you are on the way to success, and you will in a short time achieve your object. Your plants from spring-struck cuttings are of full average quality, and next season you will probably have plants and trusses extra fine. Young plants raised from strong well-ripened cuttings, healthy root-action always, rich soil, and full exposure to the light and air, are the chief essentials for producing large trusses. If you add to the loam a fifteenth part of bonemeal, and give liquid manure occasionally when the pots in which the plants are to flower become filled with roots, you will have strong growths and thick dark green foliage, and these being secured large trusses are inevitable. There must be no check to growth at any time, either by permitting the plants to become root-bound before being shifted, or inattention in watering at any time. Your varieties are good, and the following, selected from Mr. Canuell's collection, may be grown with confidence. They produce at Swanley enormous trusses, quite twice the size of those to which you refer. This, however, is doubtless in a great measure due to superior cultivation, and are top-dressed frequently with the "Invigorator" that is used in the nursery. Newer varieties.—*Crimsons*—Metis, Mrs. Gordon. *Rosy Crimson*—Celia, Hermia. *Scarlet*—Future Fame, General Graut, Manfred. *Magenta*—La France, Eva, Hebe. *Salmon*—Cercs and Mrs. J. Gibson, Madame Colson. *Purple Pinks*—Eurydice, Mrs. Strutt, Jean III. *Rosy Pinks*—Constance, E. V. Sembry, Paul Baur, Lady Bailey. *Whites*—White Clipper Improved, Eureka, and Prima Donna. *White, Pink Eye*—Mrs. Moore.

Names of Fruits (*R. Warner*).—Jefferson Plum. (*P. J.*)—1, rotten; 2, La Jnive; 3, Fondante d'Automne; 4, Nouveau Poiteau; 5, Beurré Rance; 6, Probably Beurré Clairgeau from a late blossom, not Emile d'Heyst. (*C. J.*)—1, 2, and 12, Beurré d'Amanlis; 3, Dunmore; 6, Urbaniste; 8, Elton; 10, Beurré de Capiaumont; 11, Catillae. We cannot name more than six specimens. (*W. H. Ashwin*).—The Apple is Lady Henniker. Pear is not known to us, and it is worthless. (*Erdington*).—Kerry Pippin. (*H. P.*)—1, Not known, probably local; 2, Beadnell's seedling Plum Isabella. (*Captain H.*)—*Pears*.—6, Pitmaston Duchess; 8, Williams' Bon Chrétien; 9, Marie Louise d'Uecl. *Apples*.—10, Winter Hawthornden; 11, Court Pendu Plat; 12, ReINETTE de Canada.

Names of Plants (*T. F. L.*).—1, Ajuga reptans; 2, Saxifraga aizoon; 3, Sedum hispanicum glaucum; 4, Sedum acre; 5, Lysimachia nummularia aurea; 6, Antennaria tomentosa. (*G. P.*)—1, Streptocarpus floribundus; 2, Much shrivelled, but apparently a form of Pteris tremula; 3, Swaiusonia galiegifolia alba; 4, Pellaea rotundifolia; 5, Begonia ania. (*H. Osman*).—The specimen with yellow flowers is Hypericum Androsæmum, the other is Pittosporum Tobira. (*W. C. S.*)—*Calecolaria glutinosa*. (*Inquire*)—1, Unrecognisable; 2, Maxillaria squalens; 3, Adiantum tenerum scutum; 4, Gymnogramma chrysophylla; 5, Selaginella Wallichii; 6, Croton undulatus. (*H. B.*)—1, Pteris cretica; 2, Pteris serrulata; 3, Habrothamnus fascicularis; 4, Cestrum aurantiacum; 5, Epidendrum vitellinum. (*W. R. S.*)—1, Maranta zebra; 2, Maranta arundinacea; 3, Tradescantia discolor; 4, Tradescantia zebrina. (*N. O.*)—1, Cosmos bipinnatus; 2, Bidens tripartitus; 3, Bidens pilosus; 4, Dahlia glabrata; 5, Cosmos diversifolius atrosanguineus.

COVENT GARDEN MARKET.—SEPTEMBER 27TH.

POULTRY AND PIGEON CHRONICLE.

THE INFLUENCE OF CLIMATE ON CULTIVATION.

(Continued from page 285.)

WE must now point out somewhat more in detail the climatic elements which should decide the special advantages of each system of cultivation; but this can only be done beneficially by bringing into contrast the requirements of the various crops, and with particular regard to cultivation and manuring under the varied conditions of climate. One of the most peculiar and clearly defined variations in the cultivation of cereal crops in moist and wet climates is strongly indicated by the position which the growth of Wheat occupies in the rotation. In moist climates it is found to thrive best after a bare fallow or fallow crops, such as Vetches, Trifolium, and Mustard, or early root crops fed off by sheep; whereas in dry climates it succeeds best after Clover lea if properly manured and seeded. Nearly all over Scotland, Ireland, and the western districts of England Wheat is a rather uncertain crop when seeded after Clover, and in consequence Oats of the best white and early varieties are usually grown in lieu of Wheat, especially in the higher and more exposed situations, where the latter is found not to ripen at all. Although it may be difficult to account for this well-known fact, yet there are two principal causes in operation, for in the moister climates the straw of Wheat, except in the valleys and more favoured aspects, hardly ever assumes a clear and bright healthy colour when sown after Clover lea. The action of decaying vegetable substances like Clover roots has no doubt the effect of producing luxuriance to a certain extent in the plant, which is not counteracted by the superior effect of direct sunshine which prevails in drier climates. The surface of the straw is, therefore, subject to mildew, which often extends to the ear and reduces the yield of grain both in quantity and quality. In such climates as we have referred to conditions are less favourable, but the growth of the Wheat plant is greatly promoted in its early spring growth when the land had been fallowed before seeding. It must be admitted that land which has had the benefit of cultivation, which is insured by the growth of root crops, is generally in a much better state for allowing the young plants to root freely through the soil and gather food to a greater extent than when grown after Clover lea, and this will be seen especially when Wheat is sown after green crops.

There is a further advantage resulting from the fallow or fallow crops upon strong soils, for we are assured by the experiments of Sir J. B. Lawes, who is the greatest authority we recognise in such matters, that some considerable amount of ammonia is deposited in the land by the rainfall, especially in the summer months. Besides this, it is confidently stated that the soil condenses an unknown quantity of ammonia, which is afterwards converted into nitric acid, and that also a certain additional amount is liberated from the soil during cultivation. This scientific view of the benefit

derived from fallowing on heavy land clearly corroborates all that the practical farmer has ever claimed as the advantage to be obtained by the fallowing or the growth of green crops, irrespective of the cleansing and attrition of the soil under preparation for autumn seeding.

We find another strong reason for Wheat not answering so well after Clover lea in moist climates, which is the greater vigour of the grasses which may have been turned under in ploughing the lea. These are more difficult to overcome, and any couch which may be found remaining in the soil is not kept in check by the Wheat plant either in spring or early summer. These grasses in consequence grow up amongst the Wheat crop, and the land is left in a more foul and impoverished condition. We must, however, here remark that, as a matter of farming under such climatic conditions, the home farmer is not justified in either sowing his Wheat broadcast or in drilling it with narrow intervals, and the only way under the circumstances above related that he can ever be master of his position will be by drilling or press-drilling the seed at from 10 to 12 inches between the rows of corn, in order that room may be afforded for horse and hand-hoeing.

Let us now consider the alternative, for when Oats follow the grass crop the result is very different, especially if the seed is sown over the land broadcast or drilled at close intervals, because a liberal allowance of seed goes far to insure a thickly planted crop, and this having the start of the grasses or weeds smothers them, or at any rate prevents their injuring the cereal crop. Upon this subject it is stated on the farming of Somersetshire in Mr. Ackland's report in the Journal of the Royal Agricultural Society, that after grass ploughed down Oats are taken "to clean the land," as the farmers say, and permit its being sown with Wheat the following year. In contrast to the foregoing observations we find Mr. Hannam states most decidedly the advantages of vegetable decaying substances as manure for the cereals in all dry climates, for he says, as stated in Morton's "Cyclopædia of Agriculture," that—"It is only after a good crop of depastured seeds that a full crop of Wheat can be grown upon the high and dry wolds and the limestone and chalk hills that have been brought into cultivation in this country and in the south-east of England." Now this decaying of vegetable matter appears to improve the soil, not only by its attraction for moisture, but it also to a certain extent regulates the supply of ammonia to plants by only slowly yielding it—a matter of immense economy in the feeding of plants.

Mr. C. S. Read, in his writings upon the farming of the county of Norfolk, with his great practical knowledge and experience, remarks:—Holkham is not the natural soil for Wheat. In those wet seasons, when there was so poor a Wheat crop throughout the kingdom, the nitrate of soda here produced the greatest results." With regard to spring sowing of Wheat this is entirely a matter of climate, where soil and cultivation are equal, for in the western counties, Wales, and Scotland, the climate is quite favourable to the growth of spring-sown Wheat. The less forcing temperature by day, and greater humidity, prolongs the growth of the plant, and develops it more grossly, and with a broader blade so as to produce much heavier crops with the same amount of manure. Light soils also in the west of England sustain its growth in a most remarkable manner, and in consequence it almost resembles Barley in its quickness of growth; and when contrasted with Barley the comparison is favourable to the growth of Wheat, for it is not so liable to fall or lodge with rains as Barley.

In a general report of the Agricultural Society of Scotland by Sir John Sinclair, which aptly illustrates the effect of the Scottish climate, it states that during a series of years the Wheat crop brought in the largest money return, as compared with Barley and Oats, to the Scottish farmer, but more particularly in the Lothians and certain eastern districts; and we can say that practically the same returns hold good comparatively now as was true of them many years ago, for it is founded upon climatic influence, which is the same as ever, although it may change from year to year, for it is still found that Wheat is not grown above a certain altitude in the highland districts. The period of sowing Barley seems very wisely to be regulated by the influence of climate. A most important point here arises—viz., the seedtime for Barley; for it is found in the eastern and southern counties that it succeeds best when sown as soon as the land can be got into working condition, whether it happens in February or March; whereas Mr. Read, in his "Report of the Agriculture of South Wales" states, that "The season for putting in Barley is generally from the first week in April to the middle of May." Although it is necessary to sow Barley early in any districts where the soil is dry and the climate forcing, but in the late districts where the rainfall is greatest, although Oats succeed best, yet on the kindest soils Barley may be sown. It is, however, considered the best

practice to sow in April and May; but it is usually sown after the Wheat crop, the rotation being—1st, Turnips; 2nd, Wheat; 3rd, Clover; 4th, Wheat; 5th, Barley.

We find it pointed out by nearly all writers upon the agriculture of Wales, the western counties of England, and moist climates of Scotland, that Barley, like most other cereals, the later it is sown in spring the less manure it requires to produce a given quantity of grain. Where the custom of late sowing prevails, and it is the practice to take repeated crops of grain, it is invariably resorted to as a means of augmenting the produce. The influence of climate on the productiveness of the Oat crop is well known; it will not, therefore, be necessary for us to dwell long upon the matter. It is, however, a plant that requires a larger amount of moisture than any other cereal, but especially of Barley or Wheat; these both become plumper and thinner in the skin when the temperature is moderately high during the ripening season: on the other hand, Oats lose their plumpness under a high temperature, for they often become thin and light in weight. Hence the success of Oat culture in the highlands of Scotland, where they are grown successfully upon soils at altitudes which preclude the growth of Wheat entirely, and Barley also. We may, however, here notice that both white and black sorts of winter Barley—a Russian produce originally, and called Berc and Bigg—may be sown with success in our northern latitudes and moister climates; and we can recommend the experiment of their growth as against that of Oats. We must now conclude for the present, but we have much to say and many points to illustrate as regards the influence of climate upon the pulse crops, root crops, &c., which we hope to do on a future occasion, as other subjects now demand our attention.

WORK ON THE HOME FARM.

Horse Labour.—The harvest has now, even in the late north-western districts, been nearly finished, except in the highlands of Scotland, where the Oat crop is grown on high mountain sides in preference to other cereals; and fortunately the weather has lately proved favourable, so that but little delay has occurred in the late districts, being a great contrast when we think of the delay and difficulty of harvesting the crops of last year. Although the harvest in the earliest counties has not been exceptionally forward, still, the weather having set in fine at and after its conclusion, has proved favourable to the cultivation of those fields intended for roots, Potatoes, Mangold, and Swedes next spring. By the use of steam during the past month—that is, by cultivating a fair depth longways and crossways, and followed by horse labour, using Howard's self-lifting harrow, removing any couch, weeds, or rubbish, will have completed the surface fallow, so that after the Wheat seedtime is over the land may be deeply ploughed and allowed to lie thus during the winter. Instead of ploughing again in the spring, the bunches of grass and couch, if any, may be removed by the women with forks, which will be money well expended, because it will save the great expense of horse labour otherwise often necessary to complete the fallow in the spring. By this time all the seeding has been done for Trifolium, Rye, and Vetches, and the next work will be seeding of winter Beans and winter Barley, so that all these crops may be sown in good season before the seeding for Wheat commences, and especially is this desirable upon anything like strong flat-lying soils. Preparation, however, should now be made for seeding the Wheat land, particularly where it comes in after fallow or roots or green crops, such as Vetches fed off, Mustard ploughed in, otherwise after the autumn rains set in it is difficult to obtain a good seed bed for Wheat on such land until the spring, when it must be sown with Oats or Barley, for cold heavy land does not answer for spring Wheat in the majority of seasons. The Clover and grass leas may be left until all the before-named crops are seeded, and also all autumn fallows are completed, which, if it cannot be done by horse labour only, should be done by the hiring of steam power.

The next work will be laying out and spreading the dung upon Clover leas, and spreading as fast as laid out, especially upon dry kind soils on the vale farms, because the seedtime may be delayed for Wheat out of lea until the last week of October and the first week in November. But on the hill farms of light soils and cold aspects the Wheat should be got in the first week of October, or earlier if the land is strong soil, such as clay upon chalk and strong red soils in red sandstone districts.

Hand Labour.—Trenching in the water meadows should be continued until completed in readiness for the reception of flood water arising from the first heavy volume of autumn rain. Filling and spreading manure from the farmyard or heaps will now employ some labour. The roots of certain kinds are very foul with weeds and should be hoed, or the weeds hand-pulled in order to prevent their seeding, remembering that "One year's seeding means seven years' weeding." The hedging and cleansing of the dykes should now be done, especially on those farms where much under-draining has been effected, so that as soon as these begin to discharge freely there may be no accumulations or stoppages at the outlets of the main drains.

Live Stock.—In speaking of sheep stock for this period we must refer first to the horned Dorset and Somerset stock; these, as well

as other breeds of sheep, are very high in price, and are likely to continue so unless we should be surprised by an early winter. The horned ewes are now especially dear to purchase in lamb, showing how favourable the season has been and how beneficial it will prove to those farmers who have held over a portion of the ewes by taking a second crop of lambs from them. We must here notice the practice in this respect. The plan of doing this in the south, south-eastern, and home counties is by some of the most experienced farmers who usually supply early lambs to the metropolitan market in the winter and early spring. It has now for many years, since the forward ewes have been so much in request, been the practice to hold over one-half or a third portion of the ewes bought in, and which will now begin lambing in the course of a week or ten days, and breed from them again, and they are selected in the following manner:—All the earliest lambing ewes being put to high feeding and sold with their lambs fat in the winter and spring. Those ewes which lamb late, say after the 20th of November, are kept in good stock condition, and mated with the ram the following month of May. There are several advantages in this system. The ewes—speaking of Dorset and Somerset stock—that do not lamb early, and not until after the period named in November, do not pay for high feeding, but it is found by experience that the ewes which lamb early will always get fat, if well fed, whilst suckling their lambs, but those which lamb late will not, as a rule, prove fat and fit for sale when their lambs are sold, although the food they may have consumed may have been of the same kind, quantity, and quality, and during the same number of weeks as the early lambing ewes. It is, therefore, not deemed profitable or desirable to feed the late ewes with cake or corn or any other costly food, but to keep them only in such a state as will enable them to furnish a good supply of milk for their lambs, which is done by feeding with first-rate hay and roots only. In the spring, afterwards and during the summer, the ewes are kept in fair stock condition, turning the ram with them first week in May, and removing it away from the ewes the end of June. This will give all the lambs for the season by the 20th of November; any ewes not proving in lamb to be sold fat as soon after as possible. The new ewes purchased, which lamb at the same time, are fed and kept with the old stock which lamb early, but it will be found that the latter will generally make lambs of the choicest quality, and better than those derived from the new stock, although they may fall at the same date. The Hampshire and cross-bred lambs intended for early slaughter should now be well fed on cut roots, cake, and bean or barley meal. The young cattle intended to be killed as baby beef should now be forced on by liberal feeding in the boxes, both by roots such as Cabbage or Carrots and early Turnips, with 4 lbs. of cake and 2 lbs. of beanmeal per day, but without hay, for if plenty of sweet straw is available they will thrive well. It is not much even of the best grazing districts which will maintain the fattening bullocks in full condition unless cake is given freely, but if fat the sooner they are sold the better, as good beef has lately been selling at a high figure. If intended for Christmas beef they should be put into the boxes immediately.

THE HOP CROP.—Messrs. W. H. & H. Le May's annual report on the state of the Hop crops of the world states that after a careful and thorough examination of the Hop gardens of England they are of an opinion that this will be the shortest crop per acre ever known, and will not produce more than £32,000 old duty, or an average of 1 cwt. per acre. They have calculated that there are at least 30,000 acres that will not produce any Hops; 20,000 that will not exceed 1 cwt. to the acre; 10,000 that will not exceed 2 cwt. to the acre; and 5500 that will not exceed 5 cwt. to the acre; or a total of say 65,000 cwt. The best district is East Kent, where the vermin did not attack so early or so severely, but mould is now ravaging the more promising grounds.

AN AGRICULTURAL NOTE FROM NORTH DURHAM.

HARVESTING operations are now in active progress in this neighbourhood; another week of fine weather will see most of the corn in the stackyards. Quality is fairly good, but the yield is not above the average, although much better than the last four or five years. Some samples of new Wheat have been shown in Sunderland market in good order.

Potatoes are being lifted as rapidly as harvesting will allow; quality is very good, but the crop is as a rule light. Disease has not yet done much damage, indeed little of it is seen as yet.

Turnips are improving, and bid fair to be the success of the season. Second crops of Clover, which are very heavy, are being cut both for making into hay and for green food, an article in much request among the dairy farmers in this populous district.

A great number of farmers in this neighbourhood are turning their attention to dairy farming, the large manufacturing centres ensuring a ready sale for any quantity of milk; in fact the supply never seems to equal the demand.

Pleuro-pneumonia has broken out at several places; one dairyman has lately lost some twenty cows through getting an affected animal into his byre. Many districts are completely closed against the moving of cattle either to or from.

It is disappointing to learn that the Show of the Durham County Agricultural Society, although held at Leechmore, in the midst of this rich mining, manufacturing, engineering, and ship-building neighbourhood, was a financial failure. Almost ruined as it was by the failure of the Show, owing to two extraordinary rainy days last year at Jarrow, the Society could ill afford another loss.

Farmers in this neighbourhood complain greatly about the loss of the old-fashioned ashpit manure from the large towns, all the fertilising agents being now sent down the sewers to the rivers or the sea, nothing but ashes and *débris* being left.—PETER FERGUSON.

THE SEED HARVEST OF 1882.—Messrs. James Carter & Co., High Holborn, London (and Mark Lane), write as follows:—"We are now in a position to give some reliable information as to the probable seed crop of the present season, the results in many cases of personal observation. The English crop of Red Clover will be better than last year, both in quantity and quality. Of German and French Reds the crop is also expected to be fairly good. Our reports from America, on the other hand, are very unsatisfactory, the prospects being very poor. It must be remembered, however, that the stocks generally of Red Clover held over are unimportant, so that values will be firm on that account. Of Alsike and White Clovers some very good samples of English seed have reached us. We have also handled a few samples of English White of fine quality; the quantity of the latter will be limited. Of Swedish and German Alsikes the crop is reported to be very moderate, and the quality below the average. Of German White Clover we have received a few samples, for which last season's full values were demanded. We are of opinion, however, that this seed will be better both in quantity and quality than last year, and we expect easier prices in consequence. The English Cow Grass crop is very limited in quantity, and we anticipate that last year's prices will be fully maintained. Of German and American Cow Grass there is promised to be a fairly plentiful crop, but the quality of this will not bear comparison with the English seed. Respecting Italian Rye Grass very favourable reports reach us from the home districts, and the French crop is reported to be also an abundant one. There was no seed, however, carried over, so that prices will be firm, at any rate for some time to come. Crested Dogtail is a much better crop than last year, and we have already secured some very fine samples. Lucerne is expected to be a fair average crop. Trefoil is a light crop; quality variable. Broad-leaved English Rape is a good average; quality very good. The crop of Perennial Rye Grass is a good average one, but as there was no 1881 seed carried over, prices at present are very firm. Sweet Vernal, Foxtail, Fescues, Poas, and other natural Grasses are short in fine qualities; considerably higher prices than last year's values are readily obtained. Swedes and Turnips have come in very satisfactorily, notwithstanding the inclement season that we thought at one time would prejudice the crop. It will be seen from the above report that the seed harvest of 1882 is generally satisfactory, and in almost every respect superior to that of its predecessor."

POULTRY AND PIGEONS

JUDGING AT POULTRY AND PIGEON SHOWS.

WE have at times found it our duty, by no means a pleasant one, to take exception to the way in which poultry and Pigeons were often judged at shows. The fault we had to find was fortunately almost always not with the integrity of judges or with the manner in which they, under the circumstances, performed their duties; but with the circumstances under which they were called upon to perform them. Far too frequently a number of pens was allotted to a judge which it was perfectly impossible for one man to go through carefully and critically in a single day; but more than this, a judge was often sent into a show tent full of some four or five hundred pens at 10 o'clock A.M., with the request that he would finish making his awards by noon or one o'clock, so that on the admission of the public the pens might at once present a proper appearance, gay with their many-coloured prize cards, and exhibitors could not complain of any delay!

As we have in the past commented severely on this state of things we are particularly anxious now to acknowledge that a great change for the better has taken place. In the schedule of almost every large show is published an imposing array of judges' names, not two or three as formerly, and generally particulars as to the classes upon which each adjudicates. Some of them, too, only take one or two breeds, their own special fancy. This is an excellent arrangement, and one which we should be glad to see, as far as possible, further extended. As a rule, no man is a really good judge of a variety which he has not himself bred. It is easy enough to learn

points of excellence, but very difficult to know where to look out for faults or tendencies to faults, the detection of which is one of the nice points of judgment, without a thorough acquaintance with each variety acquired by daily observance of the growth and development of birds in the home yard. At the same time, when once some experience and confidence in judging has been gained by one who begins with special breeds in which he is quite at home, his critical faculty improves in a wonderful manner. He acquires a power of observing and appreciating distinctive points in other varieties, and of picking up information on them from other judges and breeders hardly comprehensible before. It is thus that good all-round judges are made, and we know that one or two of the very ablest we now have, both in the poultry and Pigeon lines, have thus gained their skill and discrimination.

Exhibitors are often too ready to exclaim loudly at any supposed mistake in judgment. With prize list in hand it is easy enough to pick holes in the awards, but we can assure our readers that the position of a young judge who for the first time finds himself before a long row of pens is by no means an enviable one. The birds look more alike than any lot have ever looked before. He walks once down the line, and one or two seem to stand out a little before their neighbours; they change their positions, and on the second view others seem decidedly their superiors. Haste is almost certain to cause bewilderment. It is only after a quiet and undisturbed survey of the class from different points of view that the judging faculty asserts itself. It is quite enough for a beginner thus to be tried in his own particular breeds. It is not long since the paucity of good Pigeon judges was specially deplored. The committees of two or three shows have gone to work in the most sensible manner to remedy this increasing difficulty. Mr. Bulley has once or twice been invited to judge the Toy varieties, of which he has been so successful a breeder and exhibitor; and quite lately at Bingley, where specially good classification was given to Turbits, Mr. G. Webster adjudicated on them—his special fancy. We would gladly see these examples further followed, and feel sure that in the future only really well and carefully judged shows will continue to be popular and successful. It is hardly necessary to enlarge upon the advantages of employing so many judges that none may be overtaxed. We know well from experience the great evil of a judge being overworked. Only those who have undertaken the office fully realise the combination of bodily and mental fatigue entailed by continual pacing up and down long halls or tents for several hours, while every power of thought is exerted to carry at once in the mind's eye many far-divided specimens, and to place them all in their proper order of merit. Only those who have experienced it know the great difference between the feeling that a certain number of awards must be made within a given time, and the contrary feeling that no awards must be made till there has been time thoroughly to study each class and to master it. The one makes judging an irksome task, the other to a real fancier a great pleasure.

Practice makes perfect, and some judges become extremely quick in taking in a class, and extremely accurate in remembering each bird as they pass, and carrying it on in their mind's eye for comparison; but there are limits to this rapidity. We are always suspicious of the boasts we hear of those whose eyes comprehend a whole class at a glance, and who make their awards with a few dashes of the pencil. The quickest eye can at best only take in what the birds look at the moment. A class to be thoroughly well judged must be seen from various points of view—must almost be watched. A feed makes the greatest difference to some birds, or a little rest after a long journey. For many reasons we dislike a system pursued at some shows of starving all the exhibits till they have been judged. It gives an advantage to exhibitors who live near. The strong birds and last fed look best and show themselves to the most advantage; while perhaps the best, just penned after a long journey, may be faint, ruffled, and peering eagerly about for food. It is the part of a good judge to observe the birds so carefully as to take into account these almost unavoidable advantages and disadvantages of different exhibitors. We have often seen the prizes apparently well placed in the morning, but by the afternoon it appears that some decided mistake was made—viz., one of the best birds passed over for want of condition, simply because it was tired or not at home in the pen. A little more time would have enabled the judge to recognise its merit.

Such a real study of a class as we have described is only practicable where the judges' work is well and judiciously distributed. It requires, too, nerve and a clear head in the judge. An incompetent and ignorant person generally becomes more puzzle-headed from delay. He had better place the birds as best he can from first impressions. However, only such a moderate and appropriate share of work as can thus be thoroughly done is now at most good shows given to each judge. We are greatly pleased to hail the change,

and feel sure that nothing is more sure to please exhibitors and to extend the fancy. All must make occasional mistakes; for these all reasonable people make full allowance. But after much care has been expended in bringing birds to perfection, or when large sums have been given for them, it is extremely provoking and disheartening to see their merits passed by solely because a judge is pressed for time and hurried and cannot do his best. We really believe that it is possible for one who thoroughly understands the breed before him, and has plenty of time and confidence, so to make his awards in a class as, barring particular fancies and idiosyncracies, almost to defy reasonable criticism and complaint.—C.

CHICKENS' FACES SWOLLEN.—Will any of your readers kindly state the cause of swollen faces in Turkeys and chickens, and what treatment they require to remedy the ailment?—J. C.

OUR LETTER BOX.

Weeding a Hedge (*Hortus*).—The bottom of the hedge to which you refer as producing weeds which spread to the adjoining roadside can be best kept within bounds by paring off the turf, or turning a sod from the roadside to the bottom of the hedge, which will probably prevent any weeds or running grass spreading into the road. If the hedge is properly trimmed twice a year no manure or other application will be required, nor can any weeds seed and spread over the roadway.

Farm Account Book (*W. B. Butler*).—You can obtain Webb's Farming Account Book by application to the office of W. H. Smith & Son, booksellers, &c., 186, Strand, London, W.C.

Milking Cows (*John Ross*).—The number of times a cow should be milked in four and twenty hours will depend, even during the first few weeks after calving, upon the quantity the cow gives. In the case of great milkers, when milked only twice a day they will sometimes drop and waste their milk between the periods of milking, in which case they may be milked three times during the twenty-four hours, otherwise it often leads to the cows being wasteful of their milk ever afterwards more or less. In the event of cows not being milked dry each time, the milk, or cream rather, which may be left in the udder will coagulate and form what are called can-bagged udders, and in such cases they frequently lose one or more teats; besides which they will not only not continue to yield milk for the full period, but will also be subject to the downfall in the udder, or puerperal fever, which not only endangers their life at calving time, but renders them useless as dairy cows ever after. In the case of a heifer with her first calf it is a good plan to keep the calf sucking the dam for two or three months, the calves being the best and cleanest milkers. This plan has an excellent effect on the milking value of the cow in the future.

Cropping Land—Lucerne Culture (*J. W.*).—If you could find a ready sale for Lucerne you may grow it with profit in the following manner:—Plough and press the present Oat eddish, sow 3 cwt. Peruvian guano, or 4 cwt. dissolved bones per acre, and three bushels of Rye immediately after the presser, then work it in together by the harrows, and in the spring sow 20 lbs. per acre of Lucerne seed, and drag or harrow the land sufficient to bury the seed. The crop of Lucerne would be ready to cut several times the next year. If there is no sale for Lucerne as green fodder, which there is not in some districts, then plough and sow the Oat eddish next spring with four bushels of early field Peas per acre, drilled 14 inches apart, and sow behind the drill the same dressing as above stated and harrow in; the land will then, if clean, be in good order for a crop of Wheat or Barley. The next year, if not clean, make an autumn fallow after the Peas are off.

PLANTS FOR MOIST POSITIONS.

IN former notes I described my method of making a bog garden, I now purpose noticing a few useful plants suitable for such a position. It must be understood that a thoroughly made bog garden admits all moisture-loving plants; thus a great variety can be grown. By varying the height of the soil above the general level such plants as *Androsace carnea*, *A. Laggeri*, *Houstonia cærulea*, and some of the better alpine *Primulas*, can be suited with a moist but well-drained position, as can also *Gentiana bavarica* with a swampy one. Those who have seen Mr. Whitehead's famous garden at Bickley, Kent, can testify to this. I have never seen *Lobelia fulgens* in such magnificent condition as in a wet peaty bog, where its noble branched spikes exceeded 5 feet in height. A moist but well-drained position suits *Allium pedemontanum* better than any. It is desirable that it should be planted so that its heads of purple-blue pendant flowers could be seen on a level with the eye. I have tried this plan, but have not been very successful. Planted on elevated or dry positions they are affected by short seasons of drought in early spring. Watering will not compensate for insufficient rain, and I have in my mind a case of planting on a ledge, when injury resulted which took more than two years to rectify. It is a rare and most desirable plant, and the best of all the *Garlics* known to me. Seeds are very slow to germinate, and are better kept in a cool frame until they do. It scarcely admits of division, and needs careful watching, as garden pests, especially slugs, are fond of it. It is quite hardy, and fully repays any attention given it.

Some of the better alpine *Anemones* will probably find a better and more comfortable home in a well-drained part of the bog than any other position. No doubt they are more in character planted in somewhat elevated fissures, but the question gardeners in this country have to consider is, Will they grow there? We have no melting snows to keep the higher alpine moist and cool. Rock gardens seldom receive a top-dressing of leaf soil, peat, or other decayed vegetables, however often the necessity of doing this suggests itself. Probably our ideas of neatness in this as often in other matters prevent it, and it is in consideration of the vast amount of decayed vegetable matter—yearly top-dressings, so to speak—which supports mountain plant life that I recommend the culture of alpine *Anemones* in the drier parts of the bog garden. To impart a general porosity or sweetness to the soil broken stone may be used. Besides the above-mentioned, the following and almost any other dwarf *Anemones* may be grown under conditions as above described. *A. narcissiflora*, a species producing

branched leafy umbels of proportionately large white globular flowers from amongst pedate, hairy, radical leaves, is a most desirable acquisition, but difficult to increase, seldom producing more than a single crown. Seed of this will sometimes be in the pans for three years before germination. I have never been able to raise more than a single plant from hundreds of seeds, and my impression is that the seed ought to be sown as soon as gathered. This is not a bulbous or tuberous-rooted species, but one which dies back to an enormous crown, in which are contained all the essentials for next year's growth and flowering.

Anemone alpina var. *sulphurea*, though not so fastidious as the Siberian or *Narcissus*-flowered species, is, perhaps, nowhere seen to such advantage as planted in shaly peat. I believe, however, that in the more salubrious climate of the western counties it does not need very considerable attention. On the eastern shores an almost yearly period of drought in spring time has to be taken into account. In May, sometimes earlier, large sulphur-coloured flowers are produced, subtended by pinnately divided almost Fern-like leaves. In age a semi-woody rootstock develops above ground, which needs earthing-up with peaty soil and small stones. This, together with the vernal species, the *Pasque-flower*—in fact all which form this woody rootstock, delight in having their roots along the face of some stone or boulder for instance; and to meet their requirements in this way stones may be placed 1 foot or so beneath the surface before planting. Seeds sown in autumn should germinate the following spring. I have seen a very good patch of *A. thalictroides* which came from an undeniable source, but can only describe it as a bracteated and very pretty form of the common Wood *Anemone*. Another neat little species in the way of *A. nemorosa*, coming from Columbia, named *A. deltoidea*, might be added to the list. For this a little shade is essential.

Asters furnish few species worth growing in the peat bog; only one occurs to me now, *A. confertus*. I have searched for some record of it, but have been unable to find any. It came to us from the Rev. Harpur-Crewe, so there can be little doubt about the correctness of its name. It is a very stout-growing species, answering well to its specific title, being very compact; attains the height of 5 feet in the wettest parts, and is very showy, having flower-heads individually of the type of *A. Chapmani*. *Astrantia carniolica* would make a capital companion to the latter. It is never seen so much to advantage in any other part of the garden. Its light rosy heads are produced in umbellate fashion, subtended by leafy bracts.

Epigæa repens, the New England *Mayflower*, ought to be in every good garden. Its culture is not difficult; all that is needed is sandy peat, good drainage, never being allowed to become dry on the surface. When its little bunches of *Stephanotis*-like flowers expand a handlight, whitewashed inside, ought to be placed over it as protection from frost. In the moister parts of the bog it grows luxuriantly, increases rapidly, and is quite an attractive plant. Being a member of the *Lily* family it dies back in autumn to a bulb-like crown. A fine larger-growing plant is *Camassia esculenta*. This is also a border plant, but is better seen in the bog. It is a true bulbous plant, bearing fine spikes of blue upwards of 2 feet high. *Chrysosplenium alternifolium*, though a common plant, is generally admired by all visitors. Nothing surpasses it as a carpeting for larger plants: It will grow in the swampiest parts, and

blooms from early spring until autumn. Another useful plant, giving no trouble whatever, though only a biennial, as it sows itself so freely, is *Claytonia siberica*; there is only the danger of getting too much of it. Some who saw it as grown in one of the very best bog gardens in this country admitted never having recognised its beauty so fully before. In this case it had strayed away from its first habitation amongst a rather dense carpet of the lovely *Equisetum Drummondii*, its stars of lovely rose alone peeping through here and there in patches. *Comarum palustre*, or *Potentilla Comarum*, need only be mentioned as a Strawberry-like British plant for the wettest parts.

If any low bush or trailing shrubs be wanted the *Daphnes* will furnish some of the most easily adapted. In planting trailing species, either *D. Cneorum* or *D. rupestre*—relatives, the latter being rarer—a good plan to adopt is to just cover the bottom of a boulder; place your plant to hang over this to south, east, or west, and back the bare stems, if any, with another large stone, filling the intervening space with peat and stones. *Daphnes* do not like limestone.

All the American Cowslips are at home in well-drained peat. The varieties of *D. Meadia* do almost anywhere, but *D. Jeffrey-anum* and *D. integrifolium* nowhere so well as in peaty soil with stones. *Erpetion reniforme*, the New Holland Violet, is, as generally grown on the rock garden, only an annual; but in a shady position amongst stony peat it becomes so much a perennial that at least a patch may be preserved for a very considerable time. Its seeds are carried about, and it appears in various places away from the parent patch, but in the case of such a lovely little plant that is not objectionable. The Dog's-tooth Violets, especially the better kinds, are at home in company with the *Erpetion*; like it they grow in any moist well-drained soil. It is generally noticed amongst growers of these special kinds—to wit *D. americanum*, *D. albidum*, *D. giganteum* var. *grandiflorum*, and *D. grandiflorum* (the lovely dwarf twin-flowered species), that planted amongst ordinary alpine they yearly dwindle away both in quality and numbers; the reverse, however, is the case in the bog. *Gagea lutea*, a British plant, if allowed to ramble about—a curious thing for a bulbous plant to do—is quite an interesting acquisition. The habit and character reminds me of *Ornithogalum umbellatum*, the flowers opening and closing with the sun, but they are yellow.

It will be seen from the above that my idea of a bog is the inclusion of all, or nearly all, plants of merit which prefer a moist situation, whether well drained or swampy, and which prefer peaty soil in this part of the garden. To meet the various requirements soil and position can be easily altered in all the cases I have mentioned. I am writing principally for residents of the drier east coast, where my experience has generally been gained. I intend giving some further notes upon suitable plants for the bog garden.—M. B.

MUSHROOMS FOR THE MILLION.

MARKETING THE CROPS—PUNNETS.

(Continued from page 217.)

As previously observed Mushrooms are packed in punnets, and a few particulars relative to these articles that are sold by millions annually at such a cheap rate will not be uninteresting, but, on the contrary, may be serviceable to many readers of this treatise. Vast numbers of gardeners even know little or nothing about the manufacture of the small, handy, and cheap chip punnets that are seen in nearly every green-grocer's shop and fruiterer's window; and if they were asked where they could be obtained, and at what price, it is certain that not one in twenty would be able to give an accurate reply. This being so, and the statement cannot be controverted, the need of information on the matter becomes apparent. Among other places where these useful articles—indeed indispensable to the Mushroom grower—are made, Brentford and Hammersmith must be named as “seats of manu-

facture,” and it appears as natural for the industrial population, the old and young of both sexes, to make them there as it is for fowls to scratch in seed beds or boys to take Apples when they are offered, or when “nobody is looking.” It is only by much practice and dexterity that the thick shavings can be so deftly worked into baskets, as, when sold at the current rates, to leave a margin of profit behind them. Many, however, are made in the evening after the regular labour of the day has ended, and thus odd moments are commendably turned to account, while children are taught habits of industry and are content to earn a few pence at the work in question. Thus it is that the punnets cost so little as often to be given away with fruit that is sold in them. But they are not quite given away with Mushrooms, as it is the practice in weighing them into pounds to throw a punnet into the scale and not on the side containing the weights; still, if the scales were balanced with the greatest exactitude, the purchaser would not give more than a farthing for a punnet, and it is worth that for the convenience of carrying the Mushrooms home, apart from any use to which it may be applied afterwards. But in practice the weighing cannot be done with such great nicety, and as the “draw” of the scale is always in favour of the purchaser he practically gets his little basket for nothing. They are sold in rolls of three dozens, as represented in the annexed sketch (fig. 52), which also affords an idea of the number required and used in a Mushroom-growing establishment. They are employed in three different sizes—namely, for “buttons,” 5 inches in diameter and 3½ inches deep, and known as “deep pounds;” for “cups,” 6½ inches in diameter and 2 inches deep, known as “flat pounds;” and for broilers, 5½ inches across and an inch deep, sold as “halves.” The price of course varies with the size, deep pounds and flat pounds being usually obtainable for 6s., and halves 4s. per gross. With the object of rendering these notes substantially useful it may be stated that the stock from which the figure was prepared was obtained at the prices quoted from Mr. P. Nicholls, 377, Goldhawk Road, Hammersmith. It may be that other makers may sell them even cheaper, and if so they need have no difficulty in making the facts known; in the meantime Mr. Nicholls will presumably not seriously object to the mention of his name in connection with this apparently simple yet certainly not unimportant subject, for the question of punnets is one of the essentials in the industry of Mushroom-growing for market purposes.

PACKING MUSHROOMS.

When large quantities are gathered it is customary for two men to be engaged in weighing and packing—one sorts them from the hampers, quickly divests them of any loose particles of soil or manure from the tops or roots, and weighs them into pounds; the other places them in the punnets and ties them down. Packing must be neatly done, as a little care in this respect adds materially to the saleable value of the stock, while scarcely any more time is incurred in the process than by doing the work roughly and without thought. It is not the habit of experienced growers of garden produce for the London market to place the best samples at the bottom. If the produce is good all through, as it ought to be and often is, still care is exercised to select either fruit or Mushrooms of uniform size for

the uppermost layer. It is from this practice that the very expressive word "topper" originated as denoting anything of exceptional merit; and though the term is perhaps not found in all dictionaries it is much more than a provincialism, as it is widely used and well understood over the greater part of the country. In packing Mushrooms, then, do not forget the "toppers,"

Fig. 52.—Punnets.

but let the work when done appear as represented in the figures on pages 216, 217. Provided the whole produce is saleable, as it ought to be, and must be if a vendor is to maintain a position, there is no more deception in arranging the specimens neatly and attractively than there is dressing a horse for the fair, or legs of mutton or poultry for the market. But all must be done fairly and honestly. The man who fails in this respect by hiding unsaleable produce will sooner or later be inevitably shunned—unable to dispose of whatever he has to sell, and serve him right. The best of garden produce may be seriously deteriorated, because made more or less unsightly by rough usage and defective packing. In fact, it may be stated without hesitation that hundreds of pounds are lost annually by want of care in this respect, and vendors are disappointed while purchasers are dissatisfied. It becomes necessary, therefore, to emphasise the importance of placing whatever is good in the market in the best manner, including Mushrooms, as by this course purchasers are attracted, whereas by the opposite habit of careless preparation and arrangement they are certainly repelled.

PACKING THE PUNNETS.

After the Mushrooms are papered neatly and secured with raffia, which is the best and cheapest tying material, the punnets are packed in light yet sufficiently strong boxes, such as anyone can make who can use a saw, hammer, and nails, appearance here being of little moment. Neither is it material that the boxes be of a particular size; still, it may be submitted that those of the following dimensions are found convenient

for moving and arranging in vans without loss of space—3 feet 2 inches long, 1 foot 11 inches wide, and 1 foot 4 inches deep, an inch batten being nailed across the inside of each end 8 inches from the bottom. This is for supporting a floor or shelf after the bottom of the box has been occupied with punnets. From fifty-six to sixty punnets can be accommodated in what may be termed the two layers in a box of this kind; and a little clean hay being used if needed for making the punnets firm, with a few strips of deal tacked across the top for protection, the produce may be sent any reasonable distance without fear of injury. Salesmen in London are glad to dispose of good Mushrooms, and the leading greengrocers in the large provincial cities and towns can rarely obtain sufficient to meet the demands that already exist, while if the supply were greater a further demand would without doubt be created. But if by chance the supply should be excessive, of which the probability is extremely remote, even then the successful cultivator can not only ensure himself against loss, but can realise a fair profit by the manufacture of ketchup—pure, honest, genuine, unadulterated ketchup. This is always in demand, and it is not generally known that Mushroom-growing well conducted on the system described is lucrative, even if the whole produce is what may be termed "melted down" into this favourite condiment.

CONCLUSION.

In the preparation of this treatise, which in its serial form now terminates, endeavour has been made to give the several details of culture by which alone success can be achieved. Trivial some points may appear to the uninitiated, but the experienced cultivator will recognise their importance. It is by attention to small matters that great results are accomplished, and the advice that was given to the writer many years ago by one of the greatest and best

Fig. 53.—Packing Mushrooms for market.

of men in the ranks of horticulture, and found useful, indeed most valuable, may not inappropriately be given to others, as, to the young especially, it may prove useful too. "In whatever you do," said Mr. G. W. Johnson, the founder and late Co-Editor of the *Journal of Horticulture*, "either in writing or working, do not ignore the simplicities that bear on your object,

but attend to what are termed small matters and master them. . . . 'I promote,' said Napoleon, 'the man who is capable of utilising small details; any elephant can lift a hundredweight, few can pick up a pin.' Let that advice be followed, and the sentiment be remembered by all who wish to excel; it applies strictly to the subject in question. Master the small matters, and what is truly great will be attained—success.—J. WRIGHT.

P.S.—By special request the above treatise, with such additions as will be appropriate, will be embodied in a pamphlet. This will be published at the lowest possible cost consistently with defraying the expenses of publication, remuneration being neither sought for nor expected, the sole object being to place sound information on an important subject within the reach of all who are in a position to turn the plain teaching to profitable account.—J. W.

STRAWBERRIES IN POTS.

STRAWBERRY plants should now have their crowns large and plump, the pots being well filled with roots. But much may yet be done in furthering their development, and careful cultivation during the next month is as important as in any previous period. The freedom with which the Strawberry fruits in pots often causes these plants to be neglected after they have attained a fair size. Often large plants prematurely developed are not so good as those of a smaller size with thoroughly ripened crowns. The plants during the whole season should be placed so that they are freely exposed to light and sunshine; at the same time weak stimulants may be given each time the plants require water. Stimulants are often given too early in the season while the plants have ample food in their pots if a good compost was employed, yet in autumn they are neglected when they most need attention. It is from this time onwards that feeding is of the greatest importance, when the pots are or should be well filled with active roots.

To satisfy myself as to the importance of liberal feeding these plants until thoroughly matured, I took two batches of plants of the same variety, equal in every respect as far as appearance when selected. One lot was watered well and as frequently as required with clear water, while the other batch was supplied with weak guano water every time watering was necessary. At the end of the season the latter batch had a little the finest crowns. In spring the treatment of the two batches was exactly the same, but those supplied with stimulants had flower-stems very much stronger than the other plants, and the difference in the size of the fruit was equally conspicuous. Our plants were layered in their fruiting pots early; they grew rapidly without a check, well filled the pots with roots, and liberal feeding has been practised for some time. This has been the most sunless season I have experienced since I took charge of the gardens here. Rain fell so frequently that at one time before the pots were full of roots we feared the soil would be saturated. In spite of the weather, however, the plants are now of a large size, with well-developed crowns and abundance of roots—in fact, so full that with the majority of the plants it is impossible to discern the drainage at the bottom.

Those layered first and kept in 5-inch pots are in a well-ripened condition, and already showing signs of rest. But those in pots of a larger size are not so forward, although some of them were layered at the same time. I have always been able to produce fruit earlier and better from plants confined at their roots early in the season. When in large pots they continue growing for several weeks longer in the season. To bring these plants into a resting state by drying them at the roots and placing them under glass as practised in some gardens is a great mistake. How can plants be expected to fruit and do well when forced to rest while their growth is not mature? To place them under cover for the purpose of sheltering them from autumn rains is a disadvantage rather than otherwise. The protection of glass is not needed for Strawberries, as it only induces them to keep moving slowly until late in the autumn. Cold induces complete rest sooner and more naturally than any artificial treatment. A few sharp frosts are very beneficial to those plants required for early forcing, and the plants start with greater freedom and vigour into growth when introduced into the forcing house or pit. I used

to fill shelves in my early Peach house when closing it for forcing, but have discontinued the practice, as the plants are better outside for the three weeks or a month before fire heat is applied. Forcing here is commenced gently when the Strawberry plants are introduced, and we can gather earlier under this system than by placing them under glass early in November. The change from the cold and complete rest they enjoy outside to the gentle warmth of any house in which they are to be started soon starts them. But the secret of early forcing is, early runners to commence with, early matured growth, which can only be obtained by employing small pots in a wet locality, and early rest.—W. BARDNEY.

SINGLE DAFFODILS.

DAFFODILS have already begun to put out new roots in preparation for their spring flowering, and will continue in active growth all winter, so that the best time for dividing and transplanting them is already past; but as many gardeners have not yet ordered their bulbs for spring flowering it may not be too late to say a few words about them. The single kinds are most in favour now. Some of the more elaborate bulb catalogues offer a list of them quite perplexing from its length, and it becomes more difficult every year for beginners to make a selection. We find them offered at all prices, from 5s. or more to 2d. or 3d. each, and some of the best are to be found amongst the cheapest.

The genus *Narcissus* may be divided for convenience into five sections, though the limits of each section are by no means definitely marked. They are, first, the Daffodils proper, called pseudo-*Narcissus* or False *Narcissus*, because they wrongly claim to be the flower into which the youth *Narcissus*, who died of admiring himself, was fabled to have been transformed. Of this section the common single wild Daffodil of our meadows and orchards is taken as the type. The second section is the *N. incomparabilis*, the Nonsuch or Nonpareil Daffodil, with a broad open flower and shallow crown, of which there are now a very large number of varieties, both double and single, though scarcely one of them is handsomer than the old type of the section with yellow petals and rich orange-coloured crown, of which the origin is unknown. Next comes the Jonquil section, the name of which is derived from the French form of the Latin word *juncillus*, a little Rush, because many of them have Rush-like leaves. The type of this section is *N. odoratus*, the large Campenelle Jonquil. The fourth section comprises *Narcissus* proper, or Poet's *Narcissus*, which passes through the well-known form *N. biflorus* into the many-flowered section—the *Polyanthus-Narcissus*, called by Linnaeus *N. Tazetta*, a class which contains florists' or local varieties of perhaps older standing than those of any other section. It is of the first section, or the Daffodils proper, and of the single forms of them, that it is proposed to speak more particularly in these notes.

It is very difficult, and botanists almost despair of being able, to define accurately the limits of the different species of the genus *Narcissus*. Some treat of the Daffodils proper as if they all belonged to one species, of which, as I said above, the type is *N. pseudo-Narcissus*, the common wild Daffodil; but from a gardening point of view the forms of the species are so very distinct as to make their specific distinctions a matter of little importance to gardeners. In catalogues they are often classed as the "Ajax" section, as a writer on the genus at the beginning of the century distinguished the members of it by the names of the Homeric heroes. It is also called the "Trumpet" section, from the trumpet-like form of the central tube. The number of varieties in this section is now very large, and as they are the handsomest of the tribe I propose to mention separately about ten of the single varieties, including those most distinct from one another in form and colour, and selecting those which may be bought from any large bulb shop at a low price—from 2d. to 6d. each. I will first mention *N. Bulbocodium* (which means "bulb with a small trumpet"), the Hoop-petticoat Daffodil, not because I can give much hope of its being successfully cultivated as a perennial occupant of English gardens, but because it is so pretty and may be bought so cheaply that it is worth trying. It is peculiar in its requirements of soil and climate, and none of us know what they are. As it flourishes well in some parts of Northumberland it cannot be cold alone which causes it to fail.

The others I shall mention as nearly as I can in the order in which they flower. The earliest of them is generally *N. nanus*, the common old dwarf Daffodil of gardens, often sold under the name of *N. minor*, which begins to flower soon after the Snowdrops and continues a long time. It is not more than 3 or 4 inches high, and should be planted close to the edge of the bed. In good soil it increases fast. Next comes *N. obvallaris*, the Tenby Daffodil, which has been established abundantly in some meadows near

Tenby for many generations. In height it is about the same as the common double Daffodil, in colour nearly uniform dark yellow. It has a flower of great substance, which lasts for a long time, sometimes more than three weeks. In my garden it increases fast, flowers freely, and is one of the best of the single Daffodils. The next two, *N. maximus* and *N. spurium*, flower about the same time—a few days later than the beginning of Daffodils. The former is one of the largest in flower and in height, and one of the brightest in colour, being of a very rich golden yellow, elegant in form, and with a stalk sometimes 3 feet high. It is called in some catalogues *N. obvallaris maximus*, but is imported from Holland as *N. maximus*. *N. spurium* is also sold as *N. Telamoni*, and is often considered to be the single form of the common double Daffodil, though the parentage of that is uncertain.

N. bicolor Horsfieldi is a grand Daffodil, which I have selected as the representative of the Daffodils which have a white corolla round a yellow tube, because it is the most vigorous as well as the cheapest of the section. It is the handsomest Daffodil in common cultivation, though the flower does not last so long as that of *N. maximus*. *N. lorifolius*, having a bright primrose corolla round a tube of bright yellow, is a well-formed and fine flower, and is intermediate in colour between *N. spurium* and *N. bicolor*. It is strong in growth and increases fast. The last I shall mention is added because of its distinctness, being of a nearly uniform cream colour. It is rather dwarf in growth, and has not the vigour of the others, nor does it increase as fast. Still it should be added to the collection I have named, which comprises the most distinct as well as the cheapest single Daffodils to be found in the catalogues.

There are several points of importance in the cultivation of Daffodils. Those purchased should be obtained as soon as possible after they have lost their leaves, and be out of the ground as short a time as possible. The soil for Daffodils cannot be too rich, provided it is of good substance. It is well not only to mix manure with the soil, but to give a top-dressing of riddled manure just when the leaves appear above ground, and again when the flowering is over. The soil should be well and deeply dug, but should not be left too loose beneath and round the bulb, but be pressed to a firm consistency. The top of the bulb should be about 6 inches beneath the surface, and a handful of coarse sand should surround it. A position sheltered by bushes or a wall from the north-east is best, because Daffodils flower at a time when east winds prevail, and the delicate white calyx of such kinds as *N. Horsfieldi* is easily injured by a combination of sun and parching wind after frosty nights. Many of the taller kinds require some support, and it is better to arrange sticks in a triangle, so as to make a cradle with tying material, than to tie all the stalks to one upright rod. When full grown the leaves may be tied in a bunch to save untidiness, but should on no account be removed until quite decayed. The bulbs should never be lifted except to divide them, which in no case will be required oftener than once in three years; and they should be then moved directly the leaves are dead, and replanted immediately.—C. W. DOD.

FUCHSIA RICARTONI.

THIS is a fine old plant, and flowers with such profusion in autumn that it should have a place in every garden. Its slender shoots laden with flowers are very effective when arranged with other flowers for decorative purposes. When planted singly in shrubby borders it brightens them wonderfully at this season, but its effect in this position is nothing to a large bed planted with it. Where a garden of hardy plants is required gay as long in autumn as possible, one or more beds should be filled with this useful old plant. It contrasts well with beds of Pentstemons, Antirrhinums, and such plants that flower profusely in late autumn. The growths during the season will require a little regulation, but not much. Slightly thinning the shoots may be necessary, and stopping others that are likely to outgrow their neighbours. It is easily managed when grown in beds, and only requires to be cut close down to the ground annually any time after the foliage and flowers have been destroyed by frost. Whole beds of such plants are much more effective than a miscellaneous collection of hardy plants filling the same space, some of them always being untidy.—B. N.

WASPS.—I have waited till the end of September to record the year's experience (in this district at least) of the abundance of spring and autumn wasps. In the spring we had a most extraordinary quantity. Up to July 30th we had a few about, much under the average. I then left home till August 19th, and on my return found more than I had left, but far less than usual. They increased some-

what up to September 11th, though never appearing in any quantity. On that day a rain of thirty hours began, and since then I have seen scarcely any. So much for a heavy-land country.—DUCKWING.

THE LONDON PARKS.

BATTERSEA.

UNDENIABLY this is one of the most popular of the London parks, as it is the most diversified both in what may be termed its structural character and floral embellishment. Its bold shrub-clad banks with many hues of foliage not only form a fine background to the flower border and beds, but are beautiful in themselves, with in one part their carpet of Ivy and another an undergrowth of Ferns disposed in the most pleasingly natural manner. There are carpet beds, but not in great numbers, in one part; floral panelling in another; subtropical groups luxuriantly picturesque; long stretches of herbaceous borders; deep lawn recesses curving into the shrubs, conducting the eye to some fine *Musa* or specimen Palm, with ribbon borders forming bright margins to the shrubberies, and mixed beds of flowers in appropriate positions on the lawns.

Many visitors reach the park by rail from Waterloo to the Queen's Road station. At this, the east entrance, they see in the season a fine bed of Roses—the old Moss and Crimson Bedder, which show by their health that these are good "town Roses." Now the bed, with borders stretching on either hand, are brilliant with *Calceolarias*—Gaines' Yellow, which is the only one that gives satisfaction, and hence must be regarded as a good "town *Calceolaria*." But the greater number of sightseers take the river route, and enter the grounds from the park pier. They there at the outset see a bright arrangement of flowers, and pass on into the centre of the park—the subtropical garden. Perhaps a preferable landing place is the railway pier, as the park is then entered at the north-east corner, and its whole extent can be traversed without the necessity of going over much ground twice.

Turning suddenly to the left on entering the gates the wilderness is first passed through. At the very approach, however, a bird's-eye view of the park should be had from "Mount Pleasant." This eastern walk is new, and in the spring is beautiful by the fine collection of flowering shrubs, while dells here and there add to its attractiveness. One of these has been greatly admired this summer. At the base of a weeping Poplar roots have been piled, and these covered with *Clematis Jackmani*. From the soil that was added the common *Bracken* sprung, and was cherished. This has formed a graceful margin to the *Clematis*, which formed a Brobdignagian bouquet fringed with this handsome Fern. The effect was most pleasing. Other dells of hardy Ferns, the green and variegated *Comfrey*, *Helianthemums*, *Cistuses*, *Pyracanthas*, *Sedum spectabile*, *Coreopsis*, *Tritomas*, *Vincas* and *Ivies*, the graceful and distinct *Tamarisk* planted on the banks in several, overhanging the smaller occupants, and constituting most picturesque and tasteful portions of the scenery. Before leaving the eastern side of the park the visitor will notice a large bed of single Dahlias bordered with a very handsome scarlet *Pentstemon*, which, as it is unnamed, we can only refer to as the Battersea Park Scarlet. It has large and richly coloured flowers, which are produced very freely and continuously over a considerable period. This, with purple and rose-coloured varieties, both of great merit, have been obtained by careful selection, and are now propagated exclusively for this park.

Quitting these beds the visitor should proceed towards the lake, taking the path to the right of the boating station, and then turn to the left; a charming walk along the margin of the lake is here found, which passes the "waterfall," the "rocks," and other features of interest. Indeed, on a fine day this is the most attractive walk in the park, and the full beauty of the lake can be admired from several points. At one rather prominent corner some large boulders have been covered with a luxuriant growth of *Clematises*, *Sweet* and *Everlasting Peas*, and *Tropæolum peregrinum*, which have been allowed to trail and twine about unrestrained. The combination of rose, white, crimson, and purple Pea flowers, with rich blue *Clematis* and bright yellow *Tropæolum*, was most striking. Nearer the subtropical garden are the "snow-clad" mounds thickly covered with the silvery white *Antennaria tomentosa*, at the base being a dense carpeting of *Leptinella scariosa* and the dwarf *Pyrethrum*, which possesses what the ladies term a "dreadful" name—*i.e.*, *Tchihatchewi*. Both these, however, are useful little plants where it is desired to cover a bed with close greenery as a foundation; but they do not appear to have been tried much for carpet beds, and it is doubtful if they would equal either the Gibraltar Pennyroyal or the *Herniaria* for that purpose. On these mounds also numerous succulent plants impart a distinctive appearance to them, large-growing *Crassulas*, *Portulacarias*, *Echeverias* of the *metallica* type, and many others being notable. A few yards from the mounds are two carpet beds of simple yet striking design. One, the better of the two, has a ground of the soft grey *Sedum acre elegans* edged with *Echeveria pumila* and *Cerastium tomentosum*, with panels of *Alternantheras*. The centre is *A. versicolor grandis*, very richly coloured; and in others of irregular form are *amabilis latifolia*, *amœna*, *paronychioides major*, and *aurea*, all being of excellent colour, and contrasting admirably with the neutral *Sedum*. The bed corresponding to this has a rather undue proportion of Golden Feather as a groundwork, with *Mesembryanthe-*

mum cordifolium variegatum, in which are panels of *Alternanthera amœna* and *A. paronychioides major*.

Passing the ferneries, where during the summer graceful *Cyatheas*, *Dicksonias*, and other Tree Ferns are placed in company with smaller Ferns and fine-foliage plants in a shaded recess, the subtropical garden is entered on the north side, and one of the great features of Battersea Park is at once in view. During July, August, and September there is always much to admire in this department, and in favourable seasons like the present the beauty continues far into October. The usual occupants, such as Palms, Musas, *Monstera*s, *Wigandia*s, *Ricinus*, *Cannas*, and *Solanums*, are well represented; but by far the most striking bed of this kind is one filled with *Polymnia grandis*. This plant is very useful where a bold effect is needed, and might well be more generally employed than it is at present. It is suggestive of the large-growing *Solanums* in habit, but is not related to them, being a member of the Composite family. It is of very quick growth, attaining a height of 5 or 6 feet, and bearing large pinnately divided leaves 2 to 3 feet long and about 2 feet broad. The *Polymnia* and *Wigandia* are two of the most imposing plants for a subtropical garden.

Especially deserving of notice is an elliptical bed prettily planted with a groundwork of the variegated Vine (*Vitis heterophylla*), from which arise numerous healthy plants of *Grevillea robusta*. Around the central portion is a neatly trimmed band of the Golden Honey-suckle (*Lonicera aureo-reticulata*), next to this a band of *Alternanthera amabilis latifolia* well coloured, followed by the Golden Spurrey and *Sedum acre elegans*. Another bed of distinct design is of oblong form, having circles of *Mesembryanthemum cordifolium variegatum* and *Sedum Lydium*, in the centre of the former being single plants of *Pincenectitia tuberculata* and *Dracœna marginata*; while in the *Sedum* circles *Pandanus Veitchii* of moderate size is planted. The last-named plant, however, is not quite satisfactory, as after it has been out a short time the leaves assume an unhealthy yellowish tinge, indicating that the conditions are not suitable to it. Angles of *Sedum dasyphyllum*, with plants of *Rochea falcata* and a margin of the above-named *Sedum*, Golden Feather, *S. glaucum*, and *Echeverias* complete the bed. Two circular beds nearly opposite the above are marked by very pretty carpet designs. One has a scroll of *Alternanthera paronychioides major* margined with Golden Feather on a ground of *Mentha Pulegium gibraltarium*, the outer band consisting of *Alternanthera amœna*, with angles of the same. In the other bed is a central cross of *Alternanthera aurea* edged with *Leucophyton Brownii* on a ground of *Mentha*, in the centre of the cross being a quadrangular figure of *Alternanthera versicolor grandis* also margined with the *Leucophyton*, the outer bands of the bed being *A. amœna* and *Sedum acre elegans*. Several other carpet beds are pretty; but these two, though very simple, are the most effective and pleasing.

The ordinary flower beds are well represented, those near the Albert Bridge entrance to the park being the most showy; but in various suitable portions of the park gay beds and borders are observable. The borders round the shrubberies, especially those by the chief roads, are tastefully planted, the white and red Japanese *Anemones* being freely employed with excellent effect near the river. Beds of mixed herbaceous and ordinary plants also serve to break the monotony too frequently prevalent where bedding is largely employed; in fact, every portion of the park bears testimony to the skill and care exercised by Mr. Roger in rendering it a charming resort both horticulturally and popularly instructive.

FINSBURY PARK.

What Victoria Park is to the east of London, and Battersea to the south-west, so is Finsbury to the north, each in their particular districts enjoying an equal and well-merited popularity. The northern park, however, is comparatively young, and it is surprising how rapidly it has been advanced to a foremost position amongst such metropolitan pleasure resorts. The situation, though somewhat exposed to the northerly and easterly winds, is in other respects admirably fitted for the purpose, commanding extensive and varied views; but the prospect in one direction is being seriously obstructed by the fast-extending buildings. Fortunately, however, the valley to the north-east is so low the view that way is in no danger. The shrubs, notwithstanding their exposed position, are becoming well established, the common *Laurels* appearing very luxuriant in some parts, while in the more sheltered portions *Rhododendrons* are thriving most satisfactorily. Amongst the trees the Black Italian *Poplars* succeed by far the best, growing fast and strongly, and within ten years a handsome avenue of considerable length has been formed. In other parts of the park this tree has also been freely planted with good results.

Bedding is not extensively represented, but wherever it is attempted it is thoroughly well done, much care being exercised to obtain vigorous plants of good size before placing them out, so that the beds never have a bare appearance. The principal flower garden occupies a position at the highest portion of the park, but well sheltered by an encircling belt of shrubs, a walk passing through the centre, with an equal number of beds on each side. These are not of elaborate design, being chiefly oblong, elliptical, or circular, with a few angular beds between them. The front row on each side consists of oblongs and small circles alternately, the latter filled with *Herniaria glabra* or *Veronica repens*, and central circles of

Alternanthera aurea, *A. versicolor*, or *A. magnifica*, the oblong beds being devoted to the bronze *Pelargonium Marshal MacMahon*, which succeeds very well there, or the tricolors *Macbeth* or *Lady Cullum*, the last named colouring well. These beds are margined with *Iresine Lindenii*, *Mesembryanthemum cordifolium variegatum*, and *Echeveria secunda glauca*. Two of them are filled with *Princess Alexandra Pelargonium*, which is unquestionably one of the best white variegated forms, but unfortunately rather difficult to increase. At the back are several large circles of *Cannas*, around which bands of *Abutilon niveum aureum maculatum*, *Waltham Seedling Pelargonium*, *Ageratum The Queen*, a free-flowering variety of fine colour and vigorous habit, *Lobelia Omen*, and *Echeverias*. In another bed *Edward Sutton Pelargonium*, a rich dark scarlet variety, is surrounded by *Crystal Palace Gem* and *The Bride Lobelia*, a very good white form, free, compact, and pure in colour, forming a pleasing contrast. But perhaps the most effective beds of all are those planted with *Verbena venosa* and *Centaurea ragusina* and *Cineraria maritima* mixed, the purple flowers of the *Verbena* and the silvery white foliage of the other plants harmonising most agreeably. Mrs. Turner and Mrs. Holden, two good pink *Pelargoniums*, are noteworthy. Amongst other varieties represented, *Lobelia Finsbury Park Blue*, a rich-coloured variety of good habit, and *Calceolaria Little Gem*, very dwarf and free, are similarly deserving of notice, for they both succeed remarkably well. The ribbon border skirting the shrubs consists of the pink *Cleopatra* and scarlet *Bonfire Pelargoniums*, margined with *Golden Feather*; and another pretty ribbon border near a dell devoted to Palms and other subtropical plants during the summer is planted with *John Gibbons Pelargonium* and *Centaurea* in semicircles.

Subtropical gardening is not attempted on a large scale, but a number of small beds are so planted in the more sheltered walks, and have a pleasing effect; circles of *Eucalyptus*, *Acacia lophantha*, *Solanum marginatum*, *Abutilon Lemoinei*, *Abutilon niveum aureum maculatum*, and others being margined with scarlet *Tropœolums*, one seedling form of the latter being very meritorious, *Santolina incana*, *Lobelia pumila magnifica*, and similar dwarf plants. Long ribbon borders near the shrubberies are also occupied with herbaceous plants in considerable variety, the early-flowering *Chrysanthemums* being just now the most attractive, well indicating the value of these plants in autumn. Indeed, in several instances where it has been considered prudent to remove the larger specimen subtropical plants, such as Palms, under cover, their places have been filled with these *Chrysanthemums* plunged in pots.

Though the glass houses are not very numerous, a large quantity of bedding plants are raised there every season, over 140,000 being required, as Southwark Park and the gardens on the Thames Embankment are supplied from Finsbury. The *Chrysanthemums* which have within the past few years become so attractive a feature in this park are making most satisfactory progress, and bid fair to surpass the previous season's displays. About 1500 plants are grown, and their condition at the present time is most encouraging, fine vigorous growth being well matured—better, indeed, than any we have yet seen. The structure assigned to them for exhibition has been improved, the roof being glazed, and all due provision is made for a show of great interest and beauty.

In every department the condition of this park indicates most thoughtful management, and Mr. Cochrane well deserves the many compliments he receives from visitors.

GRAPE GROWING AND SHOWING.

I HAVE a few remarks to make under the above heading. Of late years it seems to have been the fashion to grow and exhibit heavy-shouldered bunches of Grapes, and at exhibitions in the provinces several doubtful cases have come under my notice as to whether the examples have been single bunches or what may be termed twin bunches. At the late Crystal Palace Fruit Show, in the first-prize dish of *Alicantes*, there was in my opinion a most decided case of two bunches on one shoot represented as one bunch; and it was the strongly expressed opinion of some bystanders that the bunches in question should have been disqualified. I am fully aware that we cannot always get bunches to grow so symmetrical as we could wish, but I do think that if the Royal Horticultural and Royal Botanical Societies of London were to take the subject up when framing the next issue of their schedules of prizes, by stating in a footnote that preference would be given to symmetrical bunches, and that any doubtful cases of twin or double bunches would be disqualified, that we should have more creditable displays of Grapes. I am aware that this is a vexed question, and I may be told that the bunches under notice were above suspicion. If so, I can only say they were open to a censuring public, and I feel the matter should not be passed in silence. I have only to add that I was not an exhibitor at the Show referred to, nor have I any interest in those who were.—G. R. A.

LACQUER TREE OF JAPAN.—In a report to the Foreign Office, which has just been issued, our Consul at Hakodadi gives a full and

interesting account of the lacquer industry of Japan. From this it appears that vast plantations of the Lacquer Tree (*Stagmaria verniciflua*) are grown for the express purpose of extracting their sap, which is usually done when the trees have attained the age of ten years. One province alone sends out no fewer than 1500 workmen, whose business it is to tap the trees and collect the sap which exudes from them; and when it is borne in mind that this process is going on all over the mainland, it will at once be seen that the industry is very extensive. Each tree yields sufficient juice to fill a 3-oz. bottle, and each workman during a season of about four months is expected to bleed about one thousand trees, the total yield of sap amounting to between 120,000 and 140,000 gallons. For his services during the season a first-rate workman is paid the munificent sum of £13, though inferior men get considerably less. The wholesale trade is entirely in the hands of two or three large merchants, who dispose of the raw material to the manufacturers. These prepare it in a manner which they keep secret, and contrive to sell it in its manufactured state at the same price which they paid for it, from which the Consul not unnaturally concludes that it has to undergo considerable adulteration before it finally reaches the hands of those who use it in artistic work.

WHAT IS THE MANURIAL VALUE OF PHOSPHATE OF MAGNESIA?

IN my last letter on this subject, page 290, I brought forward certain facts which appeared to me to show that the question of the valuation of different forms of phosphoric acid was in a very unsatisfactory condition; and I concluded that letter by pointing out that, if so slight a degree of solubility as Dr. Voelcker found to be possessed by phosphate of lime in guano was sufficient for all the wants of plants, and if the solubility of precipitated phosphate of lime was so materially increased, as he found it to be, by dilute solutions of ammoniacal salts, we are able better to understand why Jamieson obtained, with finely ground mineral phosphates, the results which have astonished the agricultural world. Ground coprolites are by no means insoluble in distilled water, and must be appreciably more so in solutions of ammoniacal salts or of carbonic acid. I cannot here forbear quoting the opening paragraph from your able review of the Report of the proceedings of the Sussex Association for the Improvement of Agriculture (*Journal of Horticulture*, page 110). "Dogmatism in things scientific is not worth indulging in, for what is accepted as fact to-day is to-morrow shown to be fallacious. A year or two ago phosphates in manures were reckoned as of little or no value, and only acid-treated phosphates were considered of use for plants. The Aberdeenshire experiments, conducted by an able and original chemist, Mr. Thomas Jamieson, dealt the first blow to the old theory—for it never was more than a theory, though universally accepted as proved fact, and acted on as such." Four years since a little work on artificial manures was published by Mr. Alfred Sibson, who was formerly an assistant in Dr. Voelcker's private laboratory, and was subsequently the Assistant Professor of Chemistry in the Royal Agricultural College, Cirencester. At page 91, second edition of the work, he writes: "Nevertheless, as manufacturers do not appear disposed to press their rights on this point [the identification and estimation of precipitated phosphate] some modification of the foregoing scale ('in which precipitated phosphate is reckoned at seven-eighths of the value of soluble phosphate') is necessary to render it generally useful and applicable in those cases in which the precipitated phosphate is not shown, either from the refusal on the part of the analyst to recognise it, or from a simpler and less complete analysis only being desired." Now if the results obtained by Voelcker by acting on precipitated phosphate with distilled water in comparison with those obtained by acting on guano, which Dr. Voelcker considers to be "sufficiently soluble for the wants of plants," are to be relied on we shall not be disposed to quarrel with Sibson's valuation. From guano one gallon of distilled water dissolved 2.52 grains only of phosphate of lime; of precipitated phosphate, whilst the precipitate was still moist, 5.56 grains per gallon; and when the precipitate was burnt and finely ground, 2.20 grains. In practice, precipitated phosphate of commerce, though far more soluble than it would be after burning, would not be as soluble, undoubtedly, as when freshly precipitated; but we might safely assume that it would be considerably more soluble than phosphate of lime in guano.

At page 90 "Artificial Manures" Sibson says that precipitated phosphates are now determined by more chemists than formerly, especially on the continent, yet there is and has been great hostility shown towards its recognition in some quarters for reasons which need not be entered upon here. "At the same time, I should plainly state," he adds, "that I consider it [precipitated phosphate] distinct from soluble phosphate;" and no doubt it is so, for the soluble phosphate in acid superphosphates is undeniably

injurious in soils deficient in lime to neutralise the acid, and in clay soils there is greater chance of loss of phosphoric acid from excessive rains; whilst, on the other hand (see review of the Report on the Sussex proceedings, page 110 *Journal of Horticulture*), one of the ascertained benefits resulting from the use of dissolved phosphate over undissolved is that it gives the plants the advantage of a quicker start where only chemical manures are used;" but "although this is the case, it is shown in the report before us that dissolved phosphate has a tendency to fail towards the end of the season, whilst the undissolved holds on, and in the end gives equal and in some instances superior results."

The results obtained by Jamieson in Scotland led to a controversy between Voelcker and himself, in which, whilst Jamieson argued that crude phosphatic materials finely pulverised were very nearly as valuable as superphosphates for the growth of Swedish Turnips, Voelcker, "viewing the matter from a different standpoint," after quoting numerous experiments made by himself and others, enunciates his opinions in the following eight propositions, which I extract from the *Journal of the Chemical Society*, No. ccxiv., page 640, vols. xxxix. and xl. Amongst these propositions I beg that the reader will particularly take notice of the first, as it alludes to a remarkable fact, the knowledge of which is essential to the comprehension of the *rationale* of plant food. It appears, strange as it may seem, that the soluble phosphate of our manures (as well as their ammonia, potash, &c.), again becomes insoluble, generally speaking, before being taken up by the plant; and that their activity is dependant upon their thorough diffusion through the soil in this physically fixed condition, as Liebig termed it.

1, Phosphates are not readily taken up by plants in a soluble form, but must be returned to an insoluble condition before they yield their useful properties.

2, The efficacy of calcium phosphate corresponds with the minuteness of division in which it is found in a manure.

3, The finer the particles in a phosphatic material the easier it is dissolved in water, and the more energetic its action in a manure. Coarsely ground coprolites and other minerals are less useful than the same materials in fine powder.

4, Calcium phosphate in porous soft bones is more soluble and energetic than in hard bones, and is more available in bone meal than in crushed bones.

5, Calcium phosphate in crystallised mineral phosphates—Norwegian, Canadian, and Spanish apatites, for example—is less soluble and energetic than the same amount contained in porous phosphatic materials, such as certain descriptions of phospho-guano.

6, Treatment with acids renders the material completely soluble in water, and the so-formed superphosphate when put into the ground is precipitated in a very fine state of division.

7, In this precipitated state the insoluble phosphate is immeasurably more finely divided than it could be obtained by mechanical means, and is consequently more energetic than any raw material mechanically ground.

8, The author's conclusion is that the chemical treatment with acid is the cheapest and best way of rendering mineral phosphates useful for agricultural purposes.

With these propositions I believe few authorities on the subject will be found to disagree, excepting perhaps with the last. I would, with deference, suggest for Dr. Voelcker's consideration whether to them might not be added with advantage a ninth proposition to the following effect:—"If, after a phosphate has been dissolved by treatment with an acid, the phosphoric acid is precipitated in combination with a base by which the acidity produced may be neutralised, whilst the precipitated salt possesses a sufficient degree of solubility to ensure thorough distribution through the soil, perfect conditions are attained for rendering the phosphoric acid useful in plant nutrition."

"Precipitated phosphate," says Sibson in "Artificial Manures," page 123, "is therefore as valuable as soluble phosphate, except in so far that it has lost the power of spontaneous diffusion possessed by the latter; and this lessens its commercial value, since it is this condition of solubility which it is wished to secure, and for which we chiefly pay in buying superphosphates." It is my contention, I may here state, that in precipitated phosphate of magnesia we have a substance "reduced to a degree of minuteness infinitely surpassing anything obtainable by grinding," accompanied by a degree of solubility such as all agricultural chemists, when they will take the trouble to think about it, must admit to be sufficient for the attainment of perfect diffusion.—INQUIRER.

FLOWERS IN AUTUMN.—Some of our plants are still attractive. We are gathering at this time *Viola odorata* and *The Czar Violet*

from the open ground, reminding us of the spring time. Crocuses are very beautiful in the September sun. A collection ought to be in every border, their lovely flowers repay us for all our care. The Cyclamens, too, with their various-coloured flowers are always admired, and they are so easy to manage I wonder they are not more sought after. *Sedum spectabile* will shortly be in its full beauty, and to be seen to the best advantage must be planted in large masses. *Schizostylis coccinea* is just coming into bloom, in a little time will be very beautiful. *Caltha palustris plena* is flowering freely. *Comtesse Hericart de Thury Strawberry* is in full bloom. Apple and Pear trees are in bloom; many of the spring bedders are also forward. *Triteleia uniflora* is producing its leaves in the open border. *Colchicum autumnale* will soon be in full beauty. The Michaelmas Daisies are fast coming into bloom, and many other old favourites will interest for some time to come; then we shall have the Forget-me-nots and a host of others through the winter.—NORTH YORK.

FRUIT-JUDGING AT EDINBURGH.

YOUR correspondent "H. B." has good grounds for his objections to the adjudication of the prizes in at least one of the classes to which he referred on page 289. I, in company with other gardeners, examined most carefully on the night previous to the Show the collections of twelve dishes of fruit after they were arranged. Every dish was examined and its merits estimated, as much time being spent in this inspection as no doubt was given by the Judges the next morning. The result of this critical examination was an unanimous opinion that either Mr. Austin or Mr. Godaere would be first, as some of the Hutton Hall fruit was considered unripe or not fit for table, the Pines for instance; while the small dishes, such as Figs, Nectarines, and Apricots, were certainly inferior to any in the other collections. The Grapes were indeed splendid in appearance, but for quality bore no comparison with the others.

Amongst those who acquiesced in the decision arrived at were some first-rate fruit-growers, the representatives of two of the gardening journals, and one of the Judges of the Show. Opinions were about equally divided as to the merits of the Ashton Court and Elvaston collections, but not one individual considered the table quality of the Hutton Hall fruit sufficiently high to secure either first or second honours.

I have not the slightest idea who the Judges were, nor have I any acquaintance with the competitors; but I have a very strong opinion that if the collections had been judged by the Fruit Committee of the Royal Horticultural Society the awards would have been different.

If size regardless of quality is to be thus honoured, exhibitors must cease growing Muscat of Alexandria and Madresfield Court Grapes, even if they can stage handsome bunches weighing 2 to 3 lbs., with large berries excellently finished, perfectly ripe, and of splendid quality, and what owner of a garden would tolerate that?

Had all the Grapes been placed on a dessert table it is certain the Gros Guillaumes and Trebbianos would have been left till the last, and so would both the Pines in the first-prize collection.

Unless "H. B.'s" letter is answered it will be considered unanswerable by the majority of gardeners who visited the Show, and excellence of quality in fruit with good appearance will stand officially condemned. Is this right?—A SCOTCHMAN.

THE GREENHOUSE AND ITS INMATES.

No modern house is complete without its conservatory or greenhouse however small it may be; but although giving in the following notes some hints on the greenhouse and its inmates, we shall devote more attention to the latter than on the house. At one time the village carpenter was the only tradesman to whom anyone could apply, but since glass houses have become so common their erection has become a distinct calling. This has led to the principles on which such houses should be constructed and heated being properly understood; therefore no one need fear to trust any of the numerous hothouse builders, for as a rule they thoroughly understand their work.

We may, however, properly say a word on the situation best suited for greenhouses. This does not seem to be very well understood. The fact that plants must be freely exposed to light, and that they will not otherwise thrive, is in a great number of cases ignored. In winter plants die often from no other cause than that they are too much shaded. Conservatories are frequently placed in positions where they are shaded for the greater part of the day by the house. This should not be done if it can possibly be avoided, for in houses of this kind the highest skill will not produce satisfactory results. Plants in such shady houses grow tall, unsightly, and flowerless in spite of any care taken over them. Sometimes, and more especially in crowded localities, no other positions are available. When this is the case Ferns and other

fine-foliage plants should be largely grown, and only a few of the more floriferous plants chosen for the lightest positions.

There is another point to which we would draw attention, and that is the heating of such houses. There is no doubt but that the most satisfactory as well as the most economical plan ultimately is to use hot-water pipes and boilers. There are very many different kinds of boilers, but we think that none surpasses the ordinary welded saddle for small houses. For larger structures either the welded flued saddle or upright or horizontal tubulars answer well. A flow and return pipe round the house are quite sufficient for an ordinary greenhouse. In the case of very small houses the slow-combustion boilers, which with the necessary piping attached are advertised, suit very well. In the smaller houses, such as we often see attached to the houses of artisans and small shopkeepers, a flue either built with bricks or constructed with earthenware pipes properly jointed to prevent the escape of smoke, suits better than anything else, and costs much less in the first instance than boilers and pipes.

In the use of fire heat, in whatever way applied, some care is necessary. Nothing delights a young beginner more than being able to raise a great heat the first fine still night which looks like frost, and nothing, except the admission of frost, is more injurious. We remember being asked to see a very small house in December, which the owner, a working man, had erected and was attempting to force Hyacinths in. The whole floor was the top of a flue, and the fire was almost directly underneath. The outside registered nearly 20° of frost, and the individual in question had a heat of 75° inside the house, and exulted in the fact that he could, with so little trouble, turn winter into summer!

Now this is just the idea that influences many beginners, greatly to their chagrin, when they find out the destruction which such courses lead to. Growth during the dark days of winter should not be encouraged. Forcing is not the easy process persons having no knowledge of the matter suppose it to be. With suitable plants properly prepared, and in the best appointed houses, it calls forth the skill of practised gardeners to the utmost to secure success; but with ordinary greenhouse plants the best gardener in the world would fail utterly if he had them in houses when the temperature was high enough to keep the plants growing.

This is a very important point, and is the rock on which numbers of beginners founder. During dull cold weather from November to February a temperature of from 45° to 55° is quite sufficient, and a greater heat is dangerous. The lower figure is the more suitable one for the hours of darkness and the higher for daylight. When the sun shines and the weather is fine a few degrees more will do good if there is a little ventilation on, for superfluous moisture will then be dried up, and such occasions should always be taken advantage of for this purpose. Stagnation and dampness should always be guarded against, but especially so during November and December. During the spring and autumn months the temperature should be considerably higher—something like 55° by night and 65° by day. In cold weather the temperature should be allowed to recede, and when it is fine and bright higher day temperatures will do no harm, but good.

Ventilation is a very important point, and a circulation of air should always be maintained except in very cold or very damp weather. In summer shading during the hottest part of the day will prove beneficial. At this time the top and bottom ventilators should be very nearly always open night and day, but of course the discretion of each cultivator should be called upon to know when to ventilate and when to close the ventilators. We advise plenty of air, however. Fire heat will very seldom be necessary when the summer should be excessively cold and wet. In that case a little fire heat during the middle of the day to raise the heat and expel damp may prove of great benefit. Even when fire heat is necessary it is well to ventilate a little at the same time, and not to exceed 65° even at midsummer.—J. H.

(To be continued.)

A PLEA FOR PINKS.

"DON'T follow everyone's advice, but listen to it." So wisely counsels Mr. J. E. Ewing in last year's "Rosarians' Year Book." To my brother amateurs, however, I now give advice which I hope they will not only listen to but act upon. If you have not at least a few Pinks procure them. To your other jewels you will find you have added gems of the first water. Of good habit, exquisite beauty, delicious fragrance, and easy culture—I cannot say too much in their praise. For three months at least, and till yesterday (October 1st), when a storm of wind with occasional blinding showers destroyed almost every flower in the garden, I have had in their continuous profusion of bloom full inducement to cut and come again. With plenty of yet unopened pods, I

look forward to have beautiful flowers from them till frost comes. In fact, if anyone asked me to recommend one flower for his garden I would say, Grow the Pink Modesty.

But be advised to get them now, or as soon as possible. Those obtained in spring have with me made comparatively little growth, and have been some time out of flower, while near are strong bushy plants, miserable enough looking as to bloom this morning after the storm of yesterday, but which by the end of the week will, I expect, like the æsthetics, be "existing beautifully." These, with all my other sorts, are from the collection of Messrs. William Paul and Son, Paisley, and I can specially recommend the first six:—Modesty, John Facer, Lady Isabel, Vanessa, William Murray, William Paul, Clothilde, Corinne, Louisa, Oimara, Premier, and Teaser.—A NORTHERN AMATEUR.

MR. SHIRLEY HIBBERD will give a lecture on PLANT LABELS at the next meeting of the Royal Horticultural Society, October 10th. His object will be to point to a few practical conclusions resulting from the recent competition for the Society of Arts' medal and Mr. G. F. Wilson's money prize.

— GEORGE F. WILSON, Esq., Heatherbank, Weybridge Heath, writes:—"In 'N.'s interesting note on ERYTHRONIUMS (p. 293), under the head *E. grandiflorum*, he speaks of varieties which may be specific forms. We have bloomed *E. giganteum* alongside of *E. grandiflorum*. It is certainly constantly more distinct."

— MESSRS. J. CARTER & Co. send us flowers of PYRETHRUM ULIGINOSUM, which they correctly describe as "one of the finest of autumn white-flowering plants either in pots for conservatory decoration or for affording cut blooms out of doors." In borders the plant is very handsome, attaining a height of 5 or 6 feet, and bearing great numbers of flower-heads with long white outer florets. The suggestion as to its usefulness for the conservatory is worth attention.

— FROM Messrs. Rawlings Brothers of Romford we have received blooms of their NEW DAHLIAS HARRISON WEIR and JOHN HENSHAW, both show varieties of much merit, the last-named having been certificated at South Kensington at the September meeting of the Royal Horticultural Society. Harrison Weir is a fine bloom, very symmetrical and of good substance, bright clear yellow in colour, the lower florets being tinged, spotted, or streaked slightly with crimson. John Henshaw is even more symmetrical and compact than the other, slightly smaller, and of a rich crimson-purple hue—a very distinct and beautiful shade.

— IN reference to the late STORM IN IRELAND, "W. J. M., *Clonmel*," writes:—"One of the most destructive storms—a hurricane—I can remember passed over this locality on Sunday last. The damage must have been enormous. Houses were unroofed, chimney stacks thrown down, and slates sent flying in town, while in the country I saw enormous trees, especially Elm, Ash, and Beech uprooted, and the roads stopped for traffic. We had an immense Elm turned right around and lifted out of the ground without bringing a root with it. As to the vegetable garden, I saw Cabbages and Cauliflowers twisted out of the ground and carried considerable distances. Lastly, as to the flower ground, Dahlias, Hollyhocks, Gladioli, Scabious, Helianthemums, and Roses are spoiled for this season." At the time the storm was raging in Ireland in London the weather was calm and bright—one of the most pleasant days of the year.

— AN American paper states that the PEACH CROP IN TEXAS has been unusually large this year, the largest and best fruits

being sold at 15 cents. per bushel—that is 7½*d.* English money. It is stated that on one day fifty cartloads of Peaches were disposed of in Boston.

— THE series of articles by Mr. Taylor on THE VINES AT LONGLEAT that have appeared in our columns are now published in the form of a small volume, which we know by the many inquiries we have received will meet with wide acceptance, and especially as the price, 1*s.*, is the reverse of prohibitive. We do not suppose that everything stated by Mr. Taylor will meet with unanimous approval; indeed we know that his work is variously estimated. One correspondent, A, describes it as "needlessly prolix;" another, B, as "much too condensed;" C says it is "most valuable and original;" D suggests the author is a "copyist," and the matter "very commonplace;" while E, and a very good judge he is, observes that "Mr. Taylor seems to have made several mistakes in his practice, but has come right at last." It is in the latter respect—the free recording of mistakes and how the author came "right at last"—that renders the work different from most others, and on that account certainly valuable. We could adduce a column of estimates of the same contradictory nature as those of which we have given examples; but even those who oppose the author's views appear amongst the most anxious to possess the book, which implies there is something in it. Without endorsing all the details of the author's system of Vine culture, we do not hesitate saying that every chapter in the book is worthy of perusal even by the experienced, while young gardeners and amateurs may with great advantage read and read again the notes on "Giving Air," and if they become as competent in this important work as the author is they will in time be ready to admit that this chapter alone is worth much more than the amount they have invested in the book. A gardener who has just returned from Longleat says, "The Vines are in splendid condition, and bear satisfactory testimony to the excellence of Mr. Taylor's practice." It is that practice that is detailed in the neat little volume that is now submitted to the world, and which merits a place by the side of other excellent works on Vine culture that are found in most gardeners' libraries.

— A CORRESPONDENT writes:—"The WEATHER NEAR LIVERPOOL has lately been very fine in the daytime, but usually very wet at night. On Monday the wind was extremely boisterous, and the Chrysanthemums were spinning about the walks like ninepins; they will be placed under glass at once. The plants are fine, but it remains to be seen what effect an unusually wet and cold season will have on the character of the blooms."

— A WRITER in the "Journal of Forestry," describing a FOREST RAMBLE IN FIJI, thus refers to the principal features of the vegetation:—

"Port Ngaloa is a lovely bay, capacious enough to afford anchorage to a fleet, and perfectly land-locked on three sides, whilst on the fourth the enviroing coral reef acts as a breakwater to the long rollers of the Pacific, whose ceaseless thunder affords a vivid contrast to the perfect calm of the lagoon. This lake-like expanse of light green water is fringed with Cocoa-nut Palms, which throughout Fiji grow luxuriantly wherever the trade wind can reach them, and in the form of copra supply one of the principal articles of export. These Palms actually overhang the broad expanse of sand which fringes the islands, and in many places one sees their graceful fronds dipping into the still waters of the lagoon, whilst the shore is everywhere littered with fallen fruit. In some parts of Viti Levu this Palm does not thrive, owing to the ravages of a small caterpillar which feeds on the leaves, and thus materially weakens the bearing capabilities of the tree. This disease is now being inquired into, the wants of the native population, as well as the pockets of the exporter, demanding that there be no falling-off in the supply of nuts if by any possible means such a calamity can be averted. The verge of the forest is, as a rule, guarded by Palms, their smooth trunks entwined with the tendrils of Convolvuli, whose superb crimson blossoms, often from 3 to 4 inches in diameter, show up vividly against the cool green shade of the undergrowth. Here and there, however, one comes across the Breadfruit Tree (*Artocarpus incisa* or *integriolia*), a native of the South Sea Islands, and a thoroughly

well-to-do native too, with its spreading branches of dark green glossy foliage and its large Melon-shaped fruit, which is being constantly produced and ripened during nine months of the year. So prolific is the Breadfruit that a single tree will suffice to keep a man supplied with nutritious food for a twelvemonth. Striking up the mountain slope from the shore the wild Banana or Plantain everywhere meets the eye. There are no fewer than twenty-five varieties of the Plantain found in Fiji, and as, according to estimates made, a pound of Bananas contains more nutriment than 3 lbs. of meat, while as a food it is equal if not superior to good wheaten bread, the value of this product to the natives of the South Sea Islands can hardly be over-estimated. In nearly all parts of the forest, but especially in the neighbourhood of the 'koros,' or villages, the graceful light green fronds of the Plantain, with its huge pendant branches of fruit, tell of the rich store of food which Nature provides for the islanders. One of the numerous wild varieties is the *Musa troglodytarum*, the plant from which the Manilla hemp is obtained in the Philippine Islands. The white Plantain, which Mr. Cooper takes to be the *Musa textilis* of botanists, is cultivated in the group, and yields a fine bright and strong Manilla hemp, valued at from £30 to £40 per ton in Sydney; and, when proper machinery has been imported and set up, this export will in all probability be rapidly developed."

— No. 12 of Mr. Auguste Van Geert's "ICONOGRAPHY OF INDIAN AZALEAS" contains coloured plates of *bignoniæflora plena*, a deep rose-coloured double form raised from seed by Mr. C. Schulz, and sent out in 1879; *Königin Cleopatra*, a single or semi-double form, white, striped with carmine and blotched with yellow. This is another of Mr. Schulz's varieties, and is said to be the result of a cross effected with *Rhododendron Edgeworthii*; and Heinrich Heine, also a seedling raised by Mr. Schulz, having large semi-double rich purple flowers.

— A CORRESPONDENT sends us the following relative to PEAS AND COCOA-NUT FIBRE:—"This day, October the 2nd, I have gathered a dish of most delicious Peas—British Queen, sown late in June and mulched well with cocoa-nut fibre obtained from Messrs. Chubb, Round & Co. of Millwall. I use this fibre extensively all over my garden; amongst flowers, fruits, and vegetables, and find it amply repays for the outlay, the fibre acting well both as a mulching material and manure. I still expect a few more dishes of Peas."

— THE *Manchester City News* as the following note:—"A GREAT PLANTER OF TREES.—The Duke of Athole is one of the most extensive tree-planters in the world. There are already vast woods and plantations in Athole and Dunkeld, and as, of course, they exist for use as well as ornament, large numbers of trees have to be planted annually to maintain the woods. Indeed every year the Duke plants from 600,000 to a million trees. During this season a plantation covering 2000 acres has been completed. It may be remembered that the Duke of Athole's plantations were thinned of 80,000 trees by the gale which destroyed the Tay Bridge. When the planter Duke began operations on a large scale in 1774 the Dunkeld Hills were almost bare. During his life the Duke, who may be described as a true benefactor to his country, planted 27,000,000 trees, covering 15,000 acres."

— WE have received Parts 40, 41, 42, and 43 of Messrs. Cassell's "FAMILIAR GARDEN FLOWERS," and Parts 63, 64, 65, and 66 of "FAMILIAR WILD FLOWERS," both of which works are being continued in the same popular but instructive manner that has been previously noted. In the former the plants represented are *Lathyrus latifolius*, *Petunia phœnicea*, *Lilium croceum*, *Rhododendron ponticum*, *Bellis perennis fl.-pl.*, *Iris Xiphion*, *Begonia Mont Blanc*, and *Campanula turbinata*. The wild flowers illustrated are *Calluna vulgaris*, *Trifolium procumbens*, *Erica Tetralix*, *Impatiens Noli-me-tangere*, *Bartsia Odontites*, *Meconopsis cambrica*, *Carduus Marianus*, and *Hypericum hirsutum*. Many interesting historical particulars are given concerning some of these plants, and the plates are all fairly accurate.

— REFERRING to the CULTIVATION OF PLANTS IN FERTILISED MOSS, the American "Gardener's Monthly" states that

"Mr. C. J. Power of Framingham, Mass., made a magnificent display at the Massachusetts Horticultural Society's Exhibition in Boston on the 30th of June, of plants grown in the Dumesnil moss. We are not informed in what manner this moss differs from moss prepared by Mr. Peter Henderson, which is simply moss mixed with any fertilising substance. But there are large numbers of people in all large towns and cities who do not care to have the trouble of mixing fertilising substances with moss, or who have not the opportunity of doing so. To all these the ready-prepared moss will be a great boon. It is cleaner and more easily handled; and those who, like Mr. Power, are making efforts to introduce it, by showing practically what can be done with it, deserve the thanks of the community. Henderson's fertilising moss was for mulching only. These plants are grown wholly in the moss."

— WE have received a schedule of the NATIVE GUANO COMPANY'S SHOW to be held at Aylesbury on Thursday, October 19th, for farm and garden produce grown with native guano; and we observe that, in addition to numerous prizes for ordinary farm crops, such as Mangolds, Swedes, Turnips, Cabbage, Wheat, Barley, Oats, and Potatoes, prizes are also offered to market gardeners, gentlemen's gardeners, amateurs, and cottagers for vegetables and Grapes. These prizes range in value from £6 to 2s. Messrs. Sutton & Sons offer a prize of five guineas, Messrs. Carter & Co. offer one of similar value, and Mr. C. L. Perry of Banbury one of two guineas for collections of Mangolds and Swedes. The Hon. W. F. B. Massey Mainwaring also offers a prize of £5 for the best collection of twelve foliage or flowering stove and greenhouse plants; and the Company contribute a second prize of £2.

— THE *Walsall Observer* has the following respecting a MODEL COUNTRY SEAT:—

"Harefield Grove, near Uxbridge, is one of the most remarkable gardens in England. It is the seat of George Webster, Esq., and lies about half-way between Watford and Uxbridge. The park is very extensive and beautifully wooded, and the mansion nestles amongst trees, ornamental water, and surrounding flower gardens and shrubberies. Attached to the house is a spacious handsome conservatory of light construction and elegant in appearance, a model of what such a structure should be. It is, however, of the kitchen and fruit gardens we wish to say a few words. The gardens are very extensive, and are now under the charge of Mr. John Gough, the late able Superintendent of the Crystal Palace Grounds, Sutton Coldfield. Throughout the winter he had a staff of about seventy men to get the place into order, and to assist in forming a new fruit garden, which occupies 13½ acres, on the south side of the kitchen gardens. This ground was a large grass field in October last, and within three months it was converted into a spacious and well-arranged fruit-growing garden of the extent we have named. Broad grass walks, along which there is ample room for driving, have been formed. In this new garden five thousand pyramidal Apple, Pear, and Plum trees, twenty-five thousand Gooseberry and Currant trees, and five thousand Filberts have been planted, and the whole of these trees were procured from the nurseries of Messrs. Richard Smith & Co. of Worcester. Passing from this garden underneath rustic arches or over a rustic bridge, the kitchen garden is entered, and here there is a town of glass. There are thirty-seven glass structures, eleven of which are vineries, some of great length, one new range being amongst the finest in the country. There are three long low span-roofed Cucumber houses, with beds on either side, each house 110 feet long, and with strong healthy fruit-bearing plants about 2½ feet apart, the foliage being most remarkable in size, substance, and health. Running parallel with the Cucumber houses is a Melon house, 110 feet long, planted on both sides, and the plants are in fine health. One of the Peach houses has a curvilinear roof, is 112 feet long and 22 feet wide. Long houses over 100 feet in length are devoted to Tomatoes, of which excellent vegetable there are nine hundred plants now growing. In addition to the vineries existing at Harefield Grove previous to Mr. Gough taking charge other spacious new vineries have been built, necessitating the planting of 180 strong young Vines, and this has been done since the 1st of March last, and they are doing well. In other houses are seven hundred fruit trees in pots, such as Peaches, Nectarines, Figs, Cherries, Plums, Pears, &c.; so that some idea of the magnitude of the fruit-growing operations here may be formed. Then, in addition to these houses there are others devoted to Orchids, one large house to Gardenias only, whilst others are filled with Ferns, stove plants, and a fine collection of other plants. The culture of forced French Beans is a great item here, row after row the whole length of the

houses being planted, and these have been in use since February last; many of them now are pulled up, the crops having been gathered, and are cleared away. Mushroom-growing is also practised on a large scale here."

— A SMALL HERBARIUM OF PLANTS THIRTY-FIVE CENTURIES OLD must be an object of considerable interest. Such a one has recently been formed by Dr. Schweinfurth from garlands found on the breasts of mummies discovered last year at Deir el Bahari by MM. Brugsch and Maspero. Two garlands on the body of the King Aames I. consisted (according to a letter of the Doctor's published in "Archives des Sciences") of leaves of Egyptian Willow (*Salix salsaf*), folded twice, and sewed side by side along a branch of the Date Palm, so forming clasps for separate flowers inserted in the folds. The flowers were those of *Acacia nilotica*, of *Nymphæa cærulea*, with isolated petals of *Alcea ficifolia*, and of a *Delphinium* believed to be orientale. The garlands of the other kings contained flowers of *Carthamus tinctorius*, and the folded leaves were those of *Mimusops Kummel*. Leaves of the common Water Melon (*Cucumis citrullus*) were also found on the body of Neb-Seni, a high priest of the twentieth dynasty. Dr. Schweinfurth managed to preserve many of the leaves and flowers by moistening them, then putting in alcohol, then spreading out and drying. A remarkable thing is the preservation of colour of the chlorophyl, violet in *Delphinium*, green in the Water Melon leaves. All the species named are still found in the East; and they afford examples of both spontaneous and cultivated plants continuing for many centuries without variation.—(*Nature*.)

— IN regard to giving LIQUID MANURE TO ORCHIDS a correspondent of the "Gardener" writes as follows:—

"The question of whether liquid manure is beneficial or injurious to Orchids is far from settled; but my own plan is to give pure rain water to all Orchids which have permanent or long-lived roots. Those Orchids which produce annual roots only—such as deciduous *Calanthes*, *Pleiones*, and *Phajus*—may not be injured, indeed I am quite sure *Calanthes* are benefited by liquid manure waterings; and I am equally confident that *Vandas*, *Cattleyas*, and many other Orchids of a similar habit, have been much injured by its application to their roots. Only the other day I saw a plant of *Vanda Batemanii* 4 feet high, and once the picture of health, spotted and disfigured by a dose of liquid manure having been given to it by a man who was deputed to water some *Gardenias* in a stove wherein it grew. When we think of the splendid specimens of Orchids which a judicious use of pure water has sufficed to produce, the wonder is that anyone can be found willing to risk valuable plants by making experiments of this kind. I even question whether throwing an occasional can of weak liquid manure on the flooring or stages of the Orchid house is productive of any permanent good, albeit that a deeper tint of verdure may thus be gained. Mere greenness in Orchids, however, is no sure test of healthy long life or of free flowering, and I earnestly advise all who grow Orchids to pause ere they even think of giving liquid manure to valuable Orchids."

RENOVATING OLD VINES.

MANY gardeners think that the best thing to do with old Vines is to throw them out. It may be in some instances; but in most cases good results may be obtained by renovating them. In many gardens young Vines are planted, cropped heavily for a few years, the border becomes exhausted through inattention, the Grapes degenerate in size of bunch, berry, and colour, also shank; but if better attention had been paid to the Vines and borders the result would have been different.

Most vineries have the borders both inside and out, and when it is the case good Grapes can be obtained from the same Vines for many years—indeed, during a lifetime, by judicious cropping, timely attention to the borders, lifting the roots, and relaying them in good fresh soil every six or seven years. It is not well to lift the roots both inside and out at the same time. The safe plan is to do one portion one year and the other two or three years afterwards; the Vines will not then feel the check in the least, but continue year after year producing good Grapes. Generally when Grapes are a bad colour and shank the roots are in exhausted soil or the Vines too heavily cropped. Artificial manure in such a case is not like good fresh loam, which is the best remedy in the case of exhausted borders. Some may say that they have old Vines that do well and bear good Grapes annually that never have the roots disturbed or the border touched. In such a case the feeding

roots are not in the original border, but have rambled outside into better quarters. In some places where there are several vineries, removing old Vines and planting young is a matter of little consequence, as the supply would not be diminished, but where there are only two or three houses and a good supply of fruit is required it is a different matter.

Having had some experience in renovating old Vines that were pronounced worn-out I will state how I managed it with very fair results. The Vines are, I believe, between fifty and sixty years of age. The time they were lifted was from this period of the year onwards, as there were three or four vineries to do. The first thing I had done was to get some turf cut and have plenty of wood ashes and lime rubbish ready. The Vine borders were both inside and out, so I kept the inside border well supplied with moisture. To keep the roots fresh and active each border was done as the Grapes were cut. Where the roots were outside we did not know, so a trench was dug 6 feet from the front wall of the vinery, and a few black-looking roots were found among the drainage. We worked the old soil away, placed about 18 inches of brick rubble for drainage, and relaid the roots near the surface (which had been protected as well as possible during the operation by damp mats) in the fresh soil, notching them at intervals of 1 foot, and covering the borders with dry litter to keep all comfortable for the winter. The house was kept close, and the Vines syringed two or three times a day for a week or two. After they were lifted the vinery was afterwards well ventilated, a little fire heat being afforded to ripen the wood. After the leaves had fallen the roots were examined, and in all cases the cut parts were callused over. In some new roots were being emitted. Whilst the roots were being lifted the weather was dull, or we should have had to shade the roof, as there were not many roots inside to support the Vines. It is by far the best plan to lift the Vines whilst the foliage is on them; but good results may be obtained after they have fallen, as long as the work is done as soon after the fall of the leaf as possible.

The early Vines were started in February, as a good crop of Grapes was expected the same year. They grew gently in a temperature about 55° at night, so as not to exhaust the stored-up sap. After the shoots had grown about 12 inches, and I could see by the appearance of the leaves that new roots were starting, a little more heat was employed. The shoots were not stopped until they had grown four or five leaves beyond the fruit, and those at the top of the Vines were left to ramble to keep up root-action. That season the berries swelled twice the size they had previously been, and coloured fairly well, although they had been regarded as a distinct variety—Red Hamburgs. During the past two seasons they have been quite black, and are good Grapes for old Vines. The Muscats are a better success than the Hamburgs, the bunches being of large size, and the berries very fine.—A. YOUNG.

PLEIONES.

OUR *Pleiones* are flowering rather early this year, although the treatment they have had has differed in no way from that usually given except in the time of potting. It is usual to repot these plants directly the flowers have faded, so that the shift shall not interfere with the growth which follows immediately after the flowers, nor injure the roots, which are pushed almost at the same time as the flowers. Thinking last year that by repotting the bulbs before the flowers had developed I should avoid breaking young roots, which almost unavoidably takes place if the potting is deferred until the flowers are past, I shook out the greater part of our pseudo-bulbs after they were ripened, and repotted them in the usual compost. I was careful that neither more water nor heat should be given than they would have under the ordinary method; yet in spite of this the flowers never expanded, although some of the buds grew to a good size, all fading, and the growth pushing at once. Of course, it is possible that the treatment was at fault; but as far as I could make out the early shifting alone was the cause of the flowers failing, and in future I shall wait until the flowers have disappeared before I repot *Pleiones*.

One species, *P. Hookeriana*, has not done well with me this year. It is a small, round, smooth pseudo-bulbed species, bearing beautiful little flowers, which last for at least a fortnight. A characteristic feature of this species is the appearance of the leaves with the flowers. It is a cool species, and last year succeeded very well on a block with sphagnum moss and suspended near the roof in a cool house. Another cool species and very pretty one is *P. humilis*, which has smooth bottle-shaped pseudo-bulbs about the size of Damsons. *P. lagenaria*, *P. Wallichiana*, and *P. maculata* are the best known kinds, all easily managed, and very free-flowering. We grow them in a warm stove on a shelf through the summer,

placing them in a light airy greenhouse in the autumn to ripen their growth. Abundance of water, with a little weak liquid manure occasionally, should be given during the growing season, and a good syringing at least twice a day keeps them clean and assists their growth. As the leaves fade the syringing should be discontinued, and less water at the root should be given, withholding it altogether when all the leaves have faded. As the flowers advance a little water may be given, but not much, or the roots will get too long to make the potting operation easy and safe. *P. lagenaria* is so easily grown and requires so little heat that anyone possessing a greenhouse may venture to grow it. Few Orchids are more pleasing than these pretty little plants—Indian Crocuses as they are called—and they come in at a time when Orchid flowers are rather scarce. In the Himalayas, where these plants are found, they must form beautiful pictures; clothing, as I am told they do, old tree trunks, rocks, with a perfect carpet of pink and white.—K.

SOILS FOR POTTING.

MUCH of the success attending the cultivation of plants in pots depends on the soils at the cultivator's command. This is, therefore, a point demanding attention and much knowledge, which can only be gained by experience and partially from written or printed instructions. The two chief articles needed are loam and peat.

Loam.—The best kind of loam is that made from turf taken from an old pasture, and cut 3 or 4 inches deep, or as deep as the fibres or the grasses hold the soil firmly. But some pastures—good old ones, too—are on very heavy clay, and others are on gravel or sheer sand. Either of these are better than nothing, but neither make the best kind of loam for most purposes. True, some plants, such as Lilies among flowers, and Melons among fruits, delight in heavy loam, while very sandy loam, pure and simple—which is generally all fibre, as the loose soil shakes out easily—is just what *Lapagerias* and some other plants delight in. Nevertheless, loam from a fertile soil of a medium texture is best. At the same time very few people, even among those who live in the country, have a choice of soils. If only heavy loam can be obtained it should be cut and stacked (under cover if possible), with layers of horse droppings and charred refuse sandwich fashion between the layers of turf. The manure will enrich, and when chopped up and mixed with it tend to lighten the loam. At potting time leaf soil may be added with advantage for many plants, and also sharp sand. These will further lighten it. For other plants, and especially such as are in large pots, pieces of freestone, charcoal, or even tough peat, will further tend to improve such soils.

This lightening and mixing process must not be overdone, though. Very light loam should be stacked in the same way, but cowdung should be placed with the turves instead of horse droppings. The charred refuse should also be kept out, and a little heavy soil be added instead. In chopping it up for potting any light loose soil should be shaken out, and mixing sand with it may be altogether unnecessary. When it is used for plants in large pots large pieces of the turf should be used, and firmly packed into the space between the roots and sides of the pots. Leaf soil may be quite unnecessary, and the decayed cowdung sufficient for enriching it. Instead of lumps of porous charcoal and sandstone we would (and do) substitute lumps of fresh bone.

By such process, and the different employment of different materials, very dissimilar soils may be made to answer the same purpose. Medium loam requires nothing more than stacking with a little manure of some kind, and any admixture required by the different plants to which it is to be applied.

For loam we have often used partially decayed "rack" (quick grass roots) from off fields; and for small plants in small pots, or for rapidly growing annuals, such as Balsams, Cinerarias, and similar plants, it is very good, especially if mixed for some time before using with horse droppings or such like, and a little bone meal when put into the pots. For large plants of *Lapagerias*, Oranges, Vallotas, Lilies, and Camellias, we always endeavour to secure proper turfy loam, as such loam as rack makes soon become earth, and is then apt to get too solid and sour, in which state nothing can thrive in it.

Peat.—It is not every district that possesses good peat for plant-growing purposes. Moreover, different plants require different kinds of peat. Ferns delight in that spongy kind which is only decaying mosses and other kinds of vegetation. Heaths, Azaleas, and similar plants demand peat from the surface of dry ground, and it is much better if it is full of grassy fibres and is dashed with sharp sand. It is only rarely that such is the case, however, and the sand has to be supplied by the cultivator. The peat should be cut in turves like the loam, and stacked in the

same way, but without manure. Both loam and peat should be stacked some months before they are required for use.

Leaf Soil.—This is simply leaves which have been laid in a heap until they have decayed. It is best when it is just decayed enough to pass through a sieve and remain in a flaky condition.

Decayed Manure should be made similarly, and used in the same way, but we very much prefer applying any manure required for pot plants in a fresh state among the soil at stacking time in the way described. Placing manure in heaps dissipates its best properties, which are washed out by the rains or escape into the air. When placed in the soil in a fresh state the latter absorbs it, and is benefited and enriched.

Charred Refuse is the remains of any fires which may be made annually for the sake of getting rid of prunings, old Pea and other sticks, Cabbage stumps, &c. It is very valuable on the potting bench; and to make as large a heap as possible any earth which adheres to the roots should be charred, especially if the soil is clayey, along with the other materials.

Sand.—Everybody knows what sand is, but it may be necessary to state here that close adhesive sands are of no use for mixing with potting soils, as sand is only used to make the soils with which it is mixed more porous. Pure white sharp sand (silver sand) is best, but clean sharp river or other washed sand is good, no matter what colour it may be. Pit sand often contains much iron, and is then worse than useless.

Bones.—Quarter-inch bones and bonemeal when judiciously mixed with soils at potting time are of very great value to all plants which love to grow in loam. Ordinary manure, well decayed, soon loses much of its nutritive value, because it decays rapidly, and the repeated waterings, which are necessary for plants in pots, rapidly wash its nutritive substance out of the pots and beyond the reach of the roots. Bones, on the other hand, decay and give out their feeding substances slowly, and last until the plants want nourishment most—after the pots are full of roots. After this happens the roots literally absorb the substance of the bones, and so find sustenance, when, without their presence the plants would likely be on short commons. When a little bonemeal is added to the soil at potting time we find that the plants thrive for a long time in comparatively small pots, especially if a very little sulphate of ammonia is dissolved in the water which is given them. When no bones are in the soil we find that guano water or liquid manure made from animal dung is necessary to produce equal results. In numberless instances liquid manure with an offensive smell is not tolerated, and an odourless stimulant, such as a weak solution of sulphate of ammonia, becomes necessary if the very best results are expected.—N. B.

POTTS' SEEDLING APPLE.

I HAVE always considered Potts' Seedling Apple a most valuable variety. The fruit is clean, large, and excellent for either baking, boiling, or exhibition purposes. The tree is a very good grower, with splendid foliage and very distinct, which makes it the more prizeable. I used to exhibit a good deal at the various shows, and nearly always carried off first prize with Potts' Seedling, although I had Lord Suffield quite as large at the time. I cannot say with strict accuracy where nor by whom it was originated, excepting that when I used to go down into Lancashire collecting new Gooseberries, &c., I came across it at Oldham in the garden of a small cotter, a Gooseberry grower, who had two small young trees of it; and he stated that he had just procured these from a Mr. Potts, who had raised it. I presume he was a neighbour, but do not know for a certainty. I think it is about thirty years ago, as near as I can remember. After hearing such a glowing description of the Apple by the individual named I was very anxious to procure the sort, which I did, and have every reason to think it one of the best kinds in cultivation. If anything that I have said will be of any service I shall be very pleased.—JOHN NELSON, *Nurseryman, Catcliffe, Rotherham.*

[We have received very fine fruits of this Apple from Riverdale near Sheffield, and it appears to be admirably adapted for exposed localities and northern districts.]

BOMAREAS.

CLIMBING *Alstromerias* would not be an inappropriate title for Bomareas, for they are very closely allied to those plants, differing from them simply in habit and in the form of the seed pod, which is triangular. So nearly, indeed, are the two genera related that many of what are now known as Bomareas were at one time classed with the *Alstromerias*; but the formation of a separate genus was necessary and judicious when the number of species

described was largely increased by every traveller in the northern parts of South America. As to the extent of the genus, some idea may be gathered from the fact that in Kunth's "Enumeratio Plantarum," published in 1850, no less than sixty-one species, besides many varieties, are described, and since then several new forms have been discovered and introduced to cultivation. It should, however, be remarked that few of the total given above are at the present time grown in England, and it is only in quite recent years that some of the most handsome have been obtained, such as *B. conferta*, and these are still confined to comparatively few establishments. At Kew a good representative collection has been grown for some time, and the beauty of the plants has often attracted the attention of horticulturists, to whom they were comparatively unknown, as few nurserymen seem to have duly appreciated the beauty of the genus, and thus they have not been

brought so prominently before the attention of the public as many other less useful plants. That they are useful no one can question who has any experience of their attractiveness as greenhouse climbers, and of the ease with which they may be had in satisfactory condition.

Either in pots or planted out they are equally beautiful, but the latter method is preferable where it can be practised, as the fresh green foliage is pleasing even when the plants are not in flower, and when they are bearing abundant handsome trusses of showy flowers they are scarcely rivalled by any cool-house climbers. There is little difficulty in providing a soil to suit them. A compost of loam and peat, or good fibrous loam alone, with a small proportion of sand, will meet their requirements, provided the pots or position in which they are to be planted are thoroughly drained. Liberal supplies of water and occasional assistance with liquid

Fig. 54.—*BOMAREA OLIGANTHA*.

manure will produce a vigorous growth, which, if the shoots be trained in a sunny portion of the roof, will mature and flower as freely as can be desired. It is surprising how rapidly some of the stronger-growing sorts, such as *B. Carderi* and *B. conferta* advance; and this sometimes is an evil rather than not, for when they become excessively vigorous flowers are seldom produced. An instance of this kind may be now noticed at Kew, where the latter of the two species just mentioned is thriving as prosperously as could be desired, but at present it gives no sign of blooms, though elsewhere the same species flowers without any trouble. Proper measures have, however, been adopted to restrain its luxuriance, and no doubt this attention will soon yield better success.

As one of the oldest introductions, though not for its beauty, the first deserving notice is the *Bomarea edulis* of Herbert, which is the *Alstromeria Salsilla*, figured in an early number of the "Botanical Magazine." This has small flowers borne in threes or fours, the outer segments rose and white, the inner green spotted with reddish brown. It has not the remotest pretensions to beauty, but is interesting for the fact that its tuberous roots

are edible, and are said to have been at one time used in St. Domingo like Potatoes are here under the name of "Tapinambours blancs." The plant was also designated *B. Salsilla* by the Spanish colonists from its resemblance to Sarsaparilla, while some record that it bears the name of "Coyolxochite," which will no doubt recommend itself to the attention of those who are so partial to native names. The plant designated *B. Salsilla* by Herbert—who, it should be observed, is our principal authority on these plants—is totally different from the above, being more slender and graceful, with small rosy-purple flowers produced in umbels of six or more each. *B. Salsilla* var. *obtusata*, *Herb.*, is the *Alstromeria oculata* of the "Botanical Magazine," a really pretty form, with rosy flowers blotched with black in the centre of the tubes.

Turning to more recently introduced species, we have two charming forms in *B. Caldasiana* and *B. oligantha* (fig. 54), which in some degree resemble each other, both possessing much beauty to recommend them to the attention of cultivators. The first-named has the exterior segments of the perianth red, the inner orange-yellow spotted with a darker shade, the flowers being numerous in moderately compact trusses, the peduncles being

1½ inch or 2 inches long. *B. oligantha* has closer umbels and shorter peduncles, the colour being orange-red spotted with brown. Both are of moderate growth, free-flowering, and extremely graceful trained to the roof of a greenhouse or conservatory, the trusses of brightly coloured flowers showing to much better advantage when pendulous above a path, as the markings of the tubes can then be seen.

Two of the larger-growing species may be similarly compared—namely, *B. Carderi* and *B. conferta*. The former was introduced about six years ago by Mr. W. Bull, having been discovered by Mr. Carder, who was then travelling in South America collecting plants. It was also, I believe, introduced to Kew about the same period, but was grown under the name of *B. Jacquesiana* for some time, before it was identified as the same as Mr. Bull's. It has flowers between 2 and 3 inches long, of a pleasing rosy tint, spotted near the points with brownish purple. They are borne in large trusses of thirty or more, and the fruit when ripe is of a fine rich yellow colour. *B. conferta*, though long known to botanists, has been only recently introduced by Messrs. Shuttleworth, Carder & Co. of Clapham Park, who have already added several beautiful forms of this genus to those previously in cultivation. It has large trusses like *B. Carderi*, the blooms being of a clear bright rosy crimson hue. Both are of strong growth, as already noted, and are especially suitable where there is a large space of roof to be covered.

Other forms introduced by this firm, which I have not yet seen, are *B. vitellina* and *B. Shuttleworthi*, both said to be attractive in no ordinary degree. Several older species not referred to in the above notes, such as *B. acutifolia*, are well worth attention, but those named would form a good representative collection.—L. CASTLE.

"WOMEN FLORISTS."

In an article bearing the above title, "Vick's American Magazine" gives the following:—

"There is now a lady florist in Quincy, Mass., who, to indulge her own love of flowers and improve her health, built a small green house, and took the care of it and a garden beside. People wanted to buy flowers, and the business grew upon her hands, till now she has four forcing houses, a Fern house, and large garden crowded with flowers, herbs, and splendid fruit. She has three young women in training, who find it easy to do all the work of the place, the only other help being a boy in the busy season. The sight of Mrs. Packard's dwarf Cactus and leaf plants, her thicket of Roses and screens of Ivy, her Pears and Lawton Blackberries, and the Fern house draped with clouds of greenery, would lead any unoccupied woman to resolve to devote herself to floriculture.

"That gardening pays everywhere was shown by the success of a German woman, out on a newly settled prairie in Wisconsin, some twenty years ago. Her husband, a nursery gardener, was struck with paralysis, when his stout-hearted wife took up the business, and made it support them well for years. In a neighbourhood twenty miles from market, and where houses were a mile apart, she raised all the seeds and plants in demand, all the Onion and Cabbage seed, Cabbage and Tomato plants, Pie Plant and Horse-radish roots, Currant and Blackberry sets, and Strawberries. People stocking new gardens for fifteen miles around went to Christina Johnson for these things, and while they were about it were often tempted to add a Flowering Currant and Prairie Rose, a Pæny root and Snowball for the door yard.

"Every established florist knows of modest ventures made by women which advanced to gratifying success. I can recall more than one in a small way, like the two old maid sisters who kept a greenhouse built from the sitting-room of the old homestead, which added to their slender income for years, and the quarter-acre of Amaranths, which brought in most of an old woman's spending money, to keep her in the long winter. The 'Fern farm' in Connecticut, which supplies the trade in the region, is largely known to enthusiastic cultivators; and there were the two friends, one a school teacher, the other a needle-woman, who went to Michigan and made themselves a home and an independence, with a capital of 300 dollars, off a fruit farm, worked, all save the ploughing and harrowing, by their own hands."

ALPINE FAVOURITES.

Linaria pallida is frequently called *L. Cymbalaria major*, although I do not see the reason for such a name, for it is certainly very distinct from that species. In my opinion it is much nearer *L. hepaticæfolia* and *L. pilosa*. It is a very pretty plant, creeping beneath the surface, and it is very apt to crop up where it is unwelcome; but for all that it is really an alpine gem. Very dwarf

in habit, with crowds of purple and white flowers twice the size of those of any of the above-named species, extending over several months of the year—in fact I have known it in flower this year from May until September. If it is planted on the rockery, which most certainly is the proper place for it, select a dry position, when it is not so likely to spread so rapidly. In a mass it is a charming little plant.

Linaria Anticaria is one of the more erect-growing species, or sub-trailing, with stems 6 to 9 inches high, covered with narrow glaucous leaves and terminal racemes of white flowers marked with two bars of deep purple. Sometimes the bars are absent, but the flowers are very much prettier when they are present. This species I obtained in the first instance from Frœbel and Co. of Zurich, and now it exists in several gardens. I am rather doubtful as to the correctness of its name; but it is a pretty alpine, flowering very freely, and is quite hardy and perennial, although I have seen it noticed in a contemporary as an annual. It is easily increased by dividing the roots, or raised from seed, which it produces freely.

Arnebia echinoides is an extremely interesting Boragewort, quite hardy and perennial, with large lanceolate leaves. It flowers early in the year—during April and May, and again in August and September. The flowers are produced in racemose cymes on stems about 9 to 12 inches high, sometimes higher, according to the position it occupies, of a bright primrose yellow, with brownish-purple spots when first expanded, but which gradually die out, and on the third day after the flowers are open they are scarcely visible, so that the heads present a very peculiar appearance with flowers quite clear of spots, and others with them in varying degree; and as it is particularly free-flowering it is a very showy plant. It does well in a warm border, but most cultivators will find a place for it on the rockery, where it flourishes extremely well. I have not raised it from seed, although Mr. Max Leichtlin of Baden-Baden has, seed ripening freely with him; and I learn from three sources of seed having been saved in this country this season. Side shoots will strike if taken off with a good heel and placed in a cold frame, although rather slow in doing so, yet if treated carefully they are sure to root. It is a plant which will be much more frequently seen when better known.

Campanula Allionii.—This is certainly one of the prettiest of the Bellworts, very dwarf, with small rosettes of foliage, from which spring the large solitary blue flowers, nearly equal in size to a Canterbury Bell. These are freely produced when the plant is thoroughly established, and a most handsome little carpeting it makes. It seems rather capricious, for I have heard of many failures with it, though I have had no difficulty with it. If it grew with everybody as with Mr. Ewbank of Ryde it would find a place in the garden of all alpine fanciers, for it thrives admirably in the rich rather heavy loam in which it is planted, and in which it delights. A cool, moist, and rich loam is the soil it requires to establish itself, and in which it gives satisfaction.

C. Raineri is a scarce and very pretty species, but very frequently misnamed, *C. turbinata* and its varieties being often supplied to purchasers as the true form, from which, however, it is quite distinct. It is much dwarfer in habit, very woolly, and the flowers are more bell-shaped, being deeper, on short foliaceous stems, whereas the flower-stems of the *C. turbinata* section are all but naked. The flowers are pale sky blue, and very large for such a diminutive plant. It delights in rich gritty loam and leaf soil, in a sunny position. At the foot of the rockery I have known it to do well. Slugs are extremely fond of it, leaving other species untouched near it, and they will clear it quite away if not disturbed.

C. Tenorii has slender trailing stems, with racemes of more or less contracted blue flowers, pendulous in disposition; it is extremely pretty and well suited for drooping over a ledge on the rockery. Easily raised from seed.

Neja gracilis, although not quite hardy, is nevertheless well worth the trouble of keeping in a frame or cool greenhouse, as it is very showy for the rockery and warm borders during the summer, blooming for a very long time. The leaves are very narrow and deep green, and the bright yellow capitula are produced upon slender stems, and about an inch across, copiously produced. It is most easily grown, and cuttings striking freely any time of the year; a store pot kept through the winter in a house would be quite sufficient to make a good show in the following summer if they were potted off early in spring, and planted out in April or May. It is very striking, and certainly well worth growing.

Potentilla dubia is a comparatively rare species, although a very free grower, for when once planted it always maintains its position, forming neat masses, of dwarf habit, and when such are a desideratum it is well worth having, as it is very bright and lasts for some months in bloom. The flowers are bright yellow, round, and

rather larger than a sixpenny piece, while the foliage is deep green. It is most easily increased by division.

P. nitida alba is a very scarce and pretty variety, with deep green shining foliage and pure white flowers, nearly as large as a shilling. The plant is tufted in growth, and not nearly so free as the last—in fact it is really a slow grower, but very distinct and showy. I had it from Froebel & Co., and am quite pleased with it, after having been frequently disappointed with *Potentillas*.

Edraianthus dalmaticus.—This is a charming Bellwort, growing in close rosettes, with slender leaves and axillary racemes of light blue flowers freely produced. It is very easily grown; some chippings of limestone should be mixed with the soil in which it is planted, and I have found it do well in a sunny position. It has a tendency to throw up a terminal flower-stem, and this frequently ends its existence if allowed to develop. I always pinch it out, and thus lengthen the life of the plant. It is easily raised from seed, but the roots cannot be divided, and, as far as I know, cuttings will not strike.

E. serpyllifolius—another species—is a lovely little gem, producing solitary deep bluish-purple bell-shaped flowers. It is also a much smaller plant, with very narrow leaves. It may be divided if planted in very sandy soil, and I have also rooted cuttings taken from it on more than one occasion. It also enjoys a sunny position in rich loam, leaf soil, and sand.—ALPINA.

THE CHEMISTRY OF MANURES.

IN a correspondence extending over several weeks there is danger of losing sight of the precise questions originally raised unless attention is now and then recalled to them. Permit me, therefore, to remind you that in my first letter on earth-closet manure (pages 120-121, *Journal of Horticulture*) I expressed my belief that "Dr. Voelcker's opinion of the trifling value of earth-closet manure was substantially correct." As "J. B. K." (at page 218) acknowledges his acquiescence in "the real value of the manurial value of the addition to a ton of soil" being 2s. instead of the price of £1 usually charged for it, we appear to think alike so far; but I went on to ask whether "a better system of manuring than by earth-closet manure" (supplemented by a little wood ashes, occasionally a few half-inch bones, and also a little of Standen's manure) "may not be employed for Vine borders?" and "J. B. K." apparently does not concur in this. He thinks that my inquiry, or suggestion, was unnecessary, and, I may add, misleading. He also says that the first of the questions (which, however, he is good enough to reply to) asked in my letter (p. 244) "hardly expresses any practical question arising out of the discussion." I accept this dictum "without prejudice," as the lawyers say, and return to the real question of difference between us, or what I conceive to be such.

In "J. B. K.'s" last very interesting letter on the chemistry of manures he gives a tabular statement showing the rate of application per acre of the three important fertilisers—nitrogen, phosphoric acid, and potash—which follows from Mr. Taylor's recommendation. I accept this statement as correct, for it evidently has not been put forward without careful calculation. Again, in his first letter (p. 218) he informs you that the principal manurial ingredients in the Longleat recipe are equivalent to an application to the soil of 14 cwt. of sulphate of ammonia, 4½ cwt. of bone meal, and 10 cwt. of muriate of potash per acre. Lastly Ville, whose authority ought to carry great weight on a point of Vine culture (though he makes an error, as I believe, in his omission of magnesia from his formula), supplies us with the quantities which he recommends as the best for this object—viz., 528 lbs. of calcic superphosphate, 440 lbs. of potassic nitrate, and 352 lbs. of calcic sulphate per acre.

Comparing the amounts of nitrogen, phosphoric acid, and potash which would be used in the above three cases per acre, I find them to be as follows:—

	1.	2.	3.
	The Longleat application, calculated by "J. B. K." to supply to the soil (see p. 298)	Longleat application, supposed by "J. B. K." to equal (see p. 218)	Ville's formula for a manure for Vines.
Nitrogen	256 lbs.	say 310 lbs.	57 lbs.
Phosphoric acid ..	120 "	" 130 "	79 "
Potash	60 "	" 560 "	193 "

It will be observed that the supposed Longleat application (2) does not differ very excessively from Ville's formula (3) in the relative proportions of phosphoric acid and potash; but what shall we say of the proportion of potash in the soil (1) calculated by "J. B. K." to result from the manure used and recommended by Mr. Taylor? Can it be said to supply in requisite proportion the universally acknowledged dominant manurial constituent for Vine cultivation? I may, perhaps, be told that "the small quantity of wood ashes" which Mr. Taylor uses supplies the potash; and if

so I have nothing more to say, excepting to apologise to that good gardener for again introducing his name into the discussion, and to express the hope that he will at least try a manure at Longleat very much richer in potash than that which he has hitherto used. If hereafter he is enabled to inform your readers that he has gained nothing by the change I shall regret having suggested what has turned out of no advantage; but my *amour propre* will be untouched, as my suggestions were derived from recorded and authoritative observations, and not from my own experiments; and Mr. Taylor will have the satisfaction of proving to others that it can no longer be said of his "high estimate of the value of earth-closet manure" that it "does not rest on any solid foundation."—INQUIRER.

HARDY PLANTS—A DELIGHTFUL GARDEN.

MANY who have no convenience to grow the ordinary tender bedding plants to render gardens attractive during the summer months, may keep them gay and delightful for a long time with hardy plants. Although the latter never produce such a blaze of colour as the former, yet they possess an interest, beauty, and fragrance that ordinary summer bedding plants do not. Hardy plants are also preferable for cutting, and flowers for the decoration of the dinner table and rooms are always in request. They possess another great advantage over *Pelargoniums* and *Calceolarias* by not being rendered unsightly for any length of time by a few heavy showers, but soon brighten up, and are as beautiful as ever.

To render gardens gay and delightful for a long time selection is of great importance, and it is preferable to employ a few good plants in quantity than to aim at having a collection. A collection is interesting to the botanist, but to cram as many different kinds as possible into a given space for the mere sake of having them, is a great mistake where beauty and effect are the objects to be attained. Only a few kinds of hardy plants are necessary to keep a garden gay; these should be grown in quantity, and when once obtained may be kept and propagated without either cold frames or glass houses. This is important to many; at the same time it must be admitted that many hardy plants can be increased more quickly with the aid of frames and handlights than without them.

I have seen in many parts of the country gardens entirely devoted to hardy plants, but the most satisfactory that has come under my notice has been pronounced by all who have inspected it as the most "delightful" little garden they have seen during the season. The whole garden devoted to flowers is not more than 30 yards in length, and is protected with a bank of shrubs at the north end, the west side being also moderately well sheltered. Two beds run the whole length, and are 7 to 8 feet wide, with a walk up the centre and on the opposite side of the beds. Running parallel with the outside walks are borders about the same width as the beds, or probably a little wider. At the end of these beds there is another bed 30 yards in length and 1 yard wide. These plain beds and borders are more appropriate for the style of gardening employed than any geometrical design. Fancy-shaped beds are objectionable for producing an effective display with hardy plants.

Each bed contains three rows of Roses, a choice selection only finding a place of both dark and light varieties. La France is evidently a general favourite, as the outer rows of one bed are entirely planted with this variety. The majority of the Roses are upon their own roots, and have produced some remarkably fine flowers. Two rows of seedling Carnations are planted on each side of the centre row of Roses in each bed, the Carnations being strong, robust, and flowering abundantly, promising to continue until cut off by frost. Alternately with the Roses in the centre row is one plant of *Gladiolus brenchleyensis*, which are now highly effective. Each of these plants rise out of a small patch of Mignonette. The beds are edged with Ten-week Stocks and dwarf Asters, which are planted alternately, the latter being in full beauty; the Stocks having passed their best now have just been removed. Between these and the Carnations are dotted in the open spaces between the Roses in the outer rows of taller growth, Phlox Drummondii, and a few double Zinnias. These beds are a thorough mixture, but not crowded, yet gay and diversified, affording an abundance of flowers for cutting. The beds are gay in spring with clumps of Alpine Auriculas, Hyacinths, Tulips, Narcissus, and other early-flowering plants. The bulbs are planted deeply, so that the beds can be forked over without injuring them, and they can also be avoided with the trowel when planting the summer occupants. The end bed is entirely devoted to seedling Carnations, and a finer lot of bloom I have never seen.

The side borders are also gay in spring with bulbs, Pansies, Aubrietias, and other early flowers, and their places afterwards planted with Intermediate and Ten-Week Stocks (the former

wintered in a frame), Dianthus, Zinnias, Candytuft, Asters, and other suitable annuals. After the early-flowering plants have ceased flowering the borders are gay with a good collection of double and single Pyrethrums, *Narcissus poeticus flore-pleno* being freely planted and very effective, as they flower about the same time as the Pyrethrums; in fact, the latter are in their full beauty just when the *Narcissus* are past their best. These, however, are at once succeeded by the double white Rocket (*Hesperis matronalis alba plena*), which are freely planted, and in full beauty with the Pyrethrums, which are amongst the best plants that can be employed for mixed borders, because they produce their flowers in succession from early season until cut off by frost. Sweet Williams are also employed, and come usefully into flower when many of the earliest Pyrethrum blooms are getting over. Spanish Irises are also planted, and are very effective with their slender stems and delicate flowers rising out of and above the other plants. Delphiniums and French Paeonies with their large fragrant flowers have a place towards the back of the side borders.

Phloxes are grown in quantity, especially the early-flowering varieties. Miss Robertson, Princess of Wales, Mrs. Downie, Max Kobb, Wm. Kirkpatrick, and Madame Rendatler are amongst the best. These are planted over the entire borders, so that they alone render them gay when the earlier-flowering plants are over or considerably past their best. Many of these Phloxes are propagated annually from cuttings, and throw up one large spike and then break into growth from below, and in due time flower freely again. This is especially the case with Princess of Wales and that beautiful pure white variety Miss Robertson. The late varieties are also included, and from their taller habit of growth are kept near the back of the borders. *Lilium candidum*, *L. auratum*, and the varieties of *L. lancifolium*, as well as a good quantity of Pentstemons and Antirrhinums, with *Gladioli brenchleyensis* (planted rather late), keep these borders gay until the approach of winter.

The object in planting a good number of plants of a few kinds is the means by which the borders are kept attractive over the longest possible period without any serious break. With a greater number of kinds the borders could not be made so effective.—L. D. W.

LIFTING PEACH TREES.

THE practical notes that have appeared on this subject of late are in every way sound and seasonable; but the practice of periodically lifting Peach trees is not general, and the operation is only undertaken by many when some circumstance compels them. Lifting, then, is regarded as both serious and critical; in fact, failure or partial failure is looked forward to as a certainty. When trees have remained undisturbed for a number of years it is not unreasonable to expect failure, because the trees are not in a good condition to start vigorously into growth the following season and bear a good crop of well-flavoured fruits. In whatever soil trees may be growing, if undisturbed for a number of years they are characterised by absence of fibrous roots. Without abundance of these necessary feeders fruit of the first quality can scarcely be expected. But when trees are annually lifted, instead of having long woody fibreless roots they have more the appearance of door mats or box bushes. In the one case there is a difficulty in finding the roots, and in the other in working out and removing the soil from amongst a complete network of feeders. I am but little surprised at Peach trees having the "yellows," mildew, or other diseases they are subject to when planted in deep borders and left unattended for years as far as the roots are concerned. Our immunity from these annoyances is the result of annual lifting and working amongst the roots a few barrowfuls of fresh compost, or merely returning the soil removed in lifting if in a fertile state.

Labour is often unnecessarily spent when making borders for Peach and Nectarine trees; in fact, large deep borders are too often made and filled with fresh soil, not only being a waste of labour, but also of material. Deep borders are not needed for Peach trees, and if a depth of 18 inches of soil is given with abundance of drainage below it is ample to grow trees of a very large size. Mr. Iggulden says, page 168, "The old surface soil, may be disposed at the bottom of the hole made, allowing a depth of 18 inches for the fresh compost." Would it not have been wiser to have removed entirely the whole of the spent surface soil and filled up the border while lifting the trees with broken bricks, clinkers, or other suitable material, leaving only a space of 18 inches for compost? What are deeper borders needed for?

I have frequently seen quantities of broken bricks used in Peach borders, and have been at a loss to know what service they are. I could understand their use in soil of a very heavy nature, yet Peach trees like heavy soil, and it is almost impossible to make

it too firm or too heavy for them. But "brickends" are used in some gardens where the soil is comparatively light; a good application of clay would prove of greater service to the trees than filling the borders with rubbish. Perhaps he, or someone else, will say if Peach and Nectarine trees derive any benefit from their application.—A. B. C.

HARDY AND TENDER OUTDOOR FLOWERS.

HARDY herbaceous plants are now considered quite as necessary in gardens as Grapes in fruit houses or Maidenhair Ferns in the plant house. Comparison between ordinary bedding plants and these is out of place, because there can really be no reasonable comparison between the two classes. There is not only room for both kinds of plants in most gardens, but one is as much required as the other. Herbaceous plants may be omitted and only bedding plants grown, or the former may be grown to the exclusion of the latter, but in either case a desirable feature in the decoration of the garden will have been overlooked. Without doubt we can secure a succession of flowers with hardy flowers from earliest spring to latest autumn, and with a series of gardens to be effective at various given times the display can be regulated to any season; but with gardens as they are at present, and as they are likely to remain at least for some time, such a series of arrangements would hardly be possible. Scarlet Pelargoniums and Calceolarias have obtained a standing from which it would be difficult to displace them, even were it desirable to do so. The garden of lawns and flower beds have done duty for so long, and have been so greatly the means of increasing the practical love of flowers amongst all classes, that they cannot be ignored. Gardeners may be conservative, but not so much so as the owners of gardens. It is not necessary to dispute the one great fault against these beds, that the period of their beauty is a limited one. If it is a fault it is one shared by all kinds of plants. The sameness as to the kind of flowers used to fill these beds has been very greatly altered and the primness relieved.

The disinclination of owners of old gardens to change even objectionable features is an obstacle which cannot be overcome. We can point out the want of taste in cutting out beds on lawns in shapes which are too common—hearts, crosses, initial letters, scrolls, and beds with many points, which can be treated in planting only in the best style, and then can only be managed effectively by good taste. But even in cases where the beds are of the simplest outline there is room for improvement in the planting. The habit of cutting up beds into divisions cannot be considered attractive when judged by the result. There may be a certain prettiness in detail, but as a broad feature of arrangement there is failure. No mode of planting is so satisfactory as that of planting in blocks either of one colour or in mixture, having an edging to each bed—white, grey, or brown is best, and according to size of bed, one or more bands of harmonising colours between the edging and main block. Flatness is broken by the free use of fine-foliage plants. With carpet bedding we have slight sympathy. Artists like a Roger or a Graham no doubt make studies which ordinary gardeners feel their utter inability to copy; and it is here that the ordinary gardener fails. Most likely he is not an artist, and if he is he finds his material utterly inadequate to carry out his designs to a successful issue. A want of taste and insufficient labour to keep the beds in first-rate order are not so noticeable in ordinary flower gardening; in carpet bedding these are everything.

With regard to the adaptability of certain flowers to different soils and climates, there is no doubt about these varying greatly. Take Pelargoniums for example. If we commence at the south of the highlands of Scotland, draw a line through the centre of the lowlands southward through the backbone of England till we reach the line of the Humber or the Mersey, we might state that northwards and to the west of that line it is not advisable to grow Pelargoniums at all as they are so generally unsatisfactory, while eastward it will be safe to do so, and away to the south. Tuberous Begonias appear to succeed very well where Pelargoniums are a failure. Then, in addition to flowers which are already common in flower gardens, such other good flowers should be introduced as *Vittadenia triloba*; Japan Anemones, which do not require any edging, nothing surpassing their own foliage. *Tritoma Uvaria* is one of the grandest plants for large gardens; *Sedum spectabile*, very valuable. *Oenothera prostrata*, *Stenactis speciosa*, *Helianthus multiflorus fl.-pl.*, *Salvia patens* and *S. fulgens*, Chrysanthemums, Pentstemons, and Phloxes may one and all be employed with good effect. Of course some of these require large beds and a large open space around them, but they are worth any attention. Tritomas are at the present time glorious in effect, and can be seen half a mile distant. An herbaceous border in the autumn

flower garden should be planted with those flowers which are at their best in autumn.

In commencing the culture of hardy plants both annuals and ordinary bedding plants may be employed, but with a sufficient number of plants perennials should be strictly kept to themselves. They require a mode of treatment inimical to the well-being of their shorter-lived relatives. A word of warning may be here given to beginners or those who have not had a long experience of these plants, and that is this: A system of merely striking the plants in the ground and leaving them unattended, with the exception of tying up stragglers, cutting over dead stems, and an annual doing-up of the border, is not the sort of cultivation to do these flowers justice. It has been our experience that more labour is required to keep them in good order than is needed for ordinary bedding plants—that is, to keep them in the same condition. To do justice to the plants we find it necessary to lift them every second or third year, well manure, and either dig the ground deeply or trench it. The plan we have found best has been to propagate as many plants of each kind required at this season. During winter the remainder of the plants are destroyed, with the exception of bulbs which are merely transplanted, being also divided if required at the same time while the ground is being cultivated. In spring the plants are put in these places closely enough to be effective the first season. The majority of the plants are divided, and the divided pieces laid in like Box in a trench along which a little manure, such as that used for Mushroom beds, has been placed. Cuttings are also inserted at this time, being covered with old sashes. Seeds of such things as Aquilegias and Alpine Poppies sown now, and the young plants obtained kept growing through the winter, also do well to place out with the others.

It is strongly advisable to limit the time of the display. If you have a good decorative effect from March till July, then trust to tender bedders after that time. It is possible to have a continued display until winter sets in, but the majority of gardeners cannot do so. The cultivation must be of the highest order, early-flowering plants kept free from seeding in order to flower again in autumn. A large place in the ground must be occupied with Tritomas, Michaelmas Daisies, and other late-flowering plants, necessitating a broader space of ground than can generally be obtained for this purpose, and above all an amount of attention which it is often impossible to secure.

Just a few words as to the kinds of plants to grow. I have seen more than one so-called collection of hardy plants bought at a somewhat heavy expense, and not over 20 per cent. of the plants were worth growing. To those who are unacquainted with these flowers it is of course difficult to decide as to the sorts to purchase. Such improved flowers as Antirrhinums, Delphiniums, double Pyrethrums, English Irises, and Phloxes should be very largely employed, as they are sure to give satisfaction, afterwards the commoner hardy species may be added. Curiously enough forms of British wild plants are amongst the very best of hardy plants.—B.

LORD NAPIER NECTARINE AND HALES' EARLY PEACH.

I GATHERED from the warmest end of my early house Royal George Peaches on the 23rd of May, and the first fruit of Lord Napier Nectarine on either the 14th or 15th. This tree is situated in the middle of the house and is young, not having filled the space allotted to it. The fruit it bore this year was its first crop, and I was perfectly satisfied with the results. I first saw this Nectarine fruiting freely on a very small tree at Court Hey near Liverpool, and in consequence obtained a tree. The Court Hey tree grew rapidly and fruited freely each season, having ripe fruit in May. Mr. Elsworthy considers it a fortnight earlier than Royal George Peach in his house. This is only two examples of success with Lord Napier, and Mr. Elsworthy's experience with it is much greater than mine, and I shall be pleased to see the opinions of others who have established trees, and have fruited them with other varieties in May.

Like Mr. Taylor I have always had a dread of large-flowering varieties for early forcing; but since I found out the deficiency that appears most marked with those varieties, the fear of not obtaining a crop from them is passing away. I find they are short of pollen at a time when it is wanted, and the pistil is too far advanced before the pollen appears on the stamens. Lord Napier is not so badly affected in this way as some, but I carried the pollen to it from my Royal George trees in the same house. I have a tree of Noblesse in my third house, and have failed more than once in securing a crop, but never since I discovered it required the aid of pollen from neighbouring trees.

Hales' Early Peach I can say but little about. I have a young tree from which, from its size and quantity of blossom, I anticipated a dozen and a half or two dozen fruits, but it only ripened six. The tree is still in a temporary position.

Two years ago I was recommended to obtain a tree of Early Alexander, as being the best and most satisfactory of all the early Peaches. It is a large-flowering variety. I shall be pleased to see stated the merits of this Peach, for I shall hesitate to destroy a good tree of Royal George to make room for it until I know more about it, and it can only stand one more year in its temporary place. I do not expect it to fruit next season, as the position in which it is in is not very satisfactory.—W. BARDNEY.

LORD NAPIER NECTARINE is one of the most valuable Nectarines ever raised. I am sure Mr. Taylor need not fear to plant it in an early house, as it sets its fruit very freely indeed in our orchard house. I have grown first and last at least thirty varieties of Nectarines, and if I was allowed to select three varieties only for planting they would be Lord Napier, Stanwick Elruge, and Pine Apple. If by any chance there could be room made for another one it would be Victoria. By substituting Victoria for Stanwick Elruge the season would be prolonged, but then you would omit a much more beautiful variety, for appearance is of great importance, although it will scarcely do to place it before flavour. But from the market-growers' point of view high colour would be placed before flavour, and Stanwick Elruge would always command a higher price than Victoria. Besides, high and rich colours look best on the table when the fruit is arranged for dessert. The good old Nectarines Violette Hâtive and Elruge are out of it now, and Hunt's Tawny, which used to be the earliest, is nowhere.—J. DOUGLAS.

IN reply to Mr. Taylor's inquiry respecting the earliness of Hales' Early Peach compared with Royal George and others. My experience of it is that, growing in a second early or midseason house facing east, it ripens from a fortnight to three weeks before Royal George, and nearly as much before Early York. I certainly consider it far before Early York in size and appearance, and better than Royal George, except, perhaps, the vigorous constitution and free-bearing properties of the latter.

With regard to "LANCASTRIAN'S" inquiry respecting Lord Napier Nectarine, I find it to succeed well in a late house. Upon taking charge of these gardens in July of last year I found the border of one of the late Peach houses in a particularly bad state with regard to drainage, and the trees in a poor condition. I lifted the whole of them, drained the border, carefully replanting. Two of the trees were Lord Napier Nectarine. I allowed one of the above and one Peach to carry a crop this year, which they finished well. The change in the appearance of all the trees in this house is very marked this season. If I were going to plant Nectarines in a late house I should certainly give Lord Napier a place. My employer says there is no Nectarine like it.—W. JENKINS, *Aldin Grange, Durham.*

SOME USEFUL PALMS.

DURING the last half dozen years our knowledge of these valuable decorative plants has been considerably increased by the large number of new and rare species which have been introduced by enterprising nurserymen, in whose houses one may see thousands fast approaching that size which is most desirable in plants for decorating the dinner-table. Few cultivators are unacquainted with the value of such Palms as *Cocos Weddelliana*, *Areca lutescens*, and *A. Verschaffeltii*, which from their graceful and robust habit are so well adapted for decorative purposes. The rough treatment these, and in fact almost all Palms, will bear with impunity renders them of especial service. It would be difficult to find any plant even among Palms which would surpass such as the above for general purposes, yet among the newer introductions there are many, the claims of which are quite equal to the best of the older kinds; and as there is a great range of variety of character in the members of this large order, it will be found that some of these less known species possess both beauty and distinctiveness that must win for them general favour.

To commence with the genus *Cocos*. We have in addition to *C. Weddelliana* a very ornamental and rather rare species in *C. plumosa*, which is perhaps one of the most graceful and noble Palms known. One of the most effective groups ever arranged by Mr. Wills owed much of its beauty to the presence of several noble specimens of this Palm, their dark green plume-like leaves, towering up and curving over the smaller plants, having a most beautiful effect. Along with this species may be mentioned another almost similar one—viz., *C. flexuosa*. Both these kinds are

erect-growing plumose-leaved Palms of rapid growth and healthy robust nature. They are stove species, both being natives of the New World tropics.

A Palm which is yet rare, and the name of which seems somewhat undecided, is that known as *Glaziova insignis*. Whatever this Palm may be it is certainly closely allied to *Cocos Weddelliana*, with which in foliage characters it is almost identical, the only distinction being in the terminal pinnule, which in the *Glaziova* is broad and in the *Cocos* very narrow. The name *Glaziova* has long ago being given to another plant, so that it cannot be retained for this Palm. A plant at Kew labelled *Juania australis* seems to be in no way distinct from the Palm known as *Glaziova*. However, be the name what it may, this is a very handsome species, quite as handsome as the *Cocos*, and likely to become as popular.

Amongst *Geoninas* there are several very graceful species, notably *G. Carderi*, *G. gracilis*, *G. Seemanni*, and *G. Schottiana*. These are all deserving of a place in the stove, *G. gracilis* being already well represented in a few collections; whilst *G. Seemanni* is very rare, Mr. Williams of Holloway possessing perhaps the finest cultivated specimen of it.

Brahea filamentosa, now known as *Washingtonia filifera*, is a handsome fan-leaved Palm, clothed with long silvery threads which add considerably to its attractiveness. This species thrives well in a greenhouse or conservatory, and if liberally treated soon develops into a noble plant.

The genus *Calamus* contains many beautiful species—in fact every one is worthy of cultivation, their graceful pinnate leaves and handsome habit even in young plants being especially serviceable. The best of them are *C. ciliaris*, which I consider to be the most beautiful Palm known; its Fern-like pale green foliage arranged alternately along the stem are most attractive. This species is rather delicate, but in a moist stove there is no difficulty in keeping it in good health. A character possessed by this Palm is that of throwing up young ones from the base, sometimes before the stem is a foot high, which may be taken off and grown on in separate pots. *C. asperrimus*, *C. calilepis*, *C. fissus*, *C. Lewisianus*, *C. palembanicus*, *C. periacanthus*, and *C. melanochætes* are other beautiful kinds, some of which are known as *Dæmonorops*.

Amongst the *Chamædoreas* there are *C. elegantissima*, a graceful *Cocos*-like species; *C. elegans*, with broader pinnules; *C. glaucifolia* and *C. graminifolia*, with plumose pale green foliage; and *C. tenella*, a pretty little dark green species, interesting from its being the smallest Palm known, plants not more than 6 inches high flowering and fruiting yearly.

Deckenia nobilis is one of several beautiful Palms which are found in the Seychelles Islands, and which are becoming great favourites. This species, along with *Acanthophœnix crinita* and *Nephrosperma Van Houttii* are remarkable for their graceful pinnate foliage, and a stem and leaf-petioles thickly covered with long stiff spines. They are really beautiful stove species, and thrive well in a moist atmosphere.

Verschaffeltia splendida, *V. melanochætes*, and *Stevensonsonia grandifolia* are noble simple-leaved Palms, also from the Seychelles. The first is a rather delicate Palm, but when well grown it is undoubtedly one of the very best exhibition plants. The *Stevensonsonia* is a very large-leaved Palm, remarkable in that the foliage is thickly marked with brown spots on a dark green ground. The stem of this species is also thickly clothed with long spines. There are some very fine specimens of the *Stevensonsonia* in the Kew collection.

The *Euterpes* were once more largely cultivated than they appear to be now, especially *E. edulis*, the Cabbage Palm, as it is called, from the hearts or young undeveloped crowns being largely used as food by the natives of South America. It is a graceful free-growing species, with pinnate leaves and smooth erect stem. The same may be said of *E. oleracea*, or perhaps even more, for this Palm is a very handsome table plant, the gracefulness of its foliage being very attractive.

Heterospatha elata is a dwarf pinnate-leaved Palm, handsome when well grown, but rather miffy, and perhaps somewhat too stiff for table work. A noble plant for the stove or warm conservatory is *Hyophorbe amaricaulis*, closely resembling *H. (Areca) Verschaffeltii*, but of stronger habit, and with reddish stem and leafstalks.

Amongst *Kentias* there are several very attractive and useful species, the best known being *K. Fosteriana* and *K. Belmoreana*, both very elegant table plants and valuable to the exhibitor. Others equally good are *K. Wendlandii*, with broadish dark-green pinnules and a robust grower. *K. australis*, which is not unlike *K. Fosteriana* and *K. Lindeni*, a robust broad-pinnuled species, and especially remarkable for the deep shining purple of the young leaves as they are unfolding. Several new *Thrinaxes* are also deserving of mention, as also are *Sagus vitiensis*, *Rhapis*

humilis, *Phœnix rupicola*, *P. sylvestris*, and *P. reclinata*, all very desirable species, and eminently adapted for furnishing and exhibition purposes. Other species might be mentioned which are also to be seen in large quantities in some of the London nurseries, but sufficient have been enumerated to show what a host of useful Palms have been recently introduced by nurserymen and others interested in this noble order.

With very few exceptions the cultural requirements of Palms are such as need not puzzle the merest tyro, given of course the necessary temperature. A rich loam is the best soil to use for them, though almost any sweet and fresh soil will do. A liberal supply of cow manure either in the fresh or liquid state is a capital food for all Palms. Most of them require plenty of water all the year round, and in the event of any becoming root-bound, and it not being desirable to transfer them into larger pots, they may be grown for a considerable time in such a state by keeping the roots well supplied with water and liquid manure. The seeds of most Palms retain vitality for a year or two, so that there is little trouble in importing and growing them, the principal difficulty being in procuring them from the natives. This difficulty is, however, rapidly being met by the large numbers of fruiting specimens which are now to be found in our colonial botanic gardens, from whence abundance of seeds of many hitherto rare kinds are now to be procured, so that we may hope to soon be in possession of other Palms which will prove as serviceable as the few we have known for some time.—W. W.

FRUIT HOUSES.

Vines.—As heavy and cold rains may now be expected, covering late Vine borders will be necessary to insure the fruit keeping satisfactorily. Wooden shutters are the best, but tarpaulin or a thick thatch of straw or bracken sloped so as to carry off the water answers well. Mats, or a light covering of straw, placed on inside borders will to some extent prevent moisture rising, as well as prevent the border becoming too dry. The Grapes should be frequently examined, removing all decayed berries, as if left others are soon affected; but if thoroughly ripened the thick-skinned varieties will give little trouble if the house is watertight. The houses should be kept as cool and dry as possible, only employing fire heat to secure a temperature of 50°, or when the external atmosphere renders it necessary. Have the ventilators closed in damp weather, opening only when the outside air is dry, at the same time applying fire heat. Turn off the heat early in the afternoon, so as to have the pipes cooled before night.

The earliest Vines must be pruned, and the house receive a thorough cleaning, the border being top-dressed as advised in a former calendar. The outside border should be covered with a good layer of dry fern or straw litter, with shutters or tarpaulin to throw off heavy rains or prevent the border being chilled by heavy rains or snow. Where fermenting materials are obtainable in quantity to admit of their renewal when necessary, preparation should be made of these for placing on outside borders at least a fortnight before closing the house, and a bed of the same materials introduced inside at starting time will aid the Vines.

Where new ripe Grapes are required very early preparation should now be made for starting the earliest Vines in pots, and if a slight bottom heat, such as that of three parts leaves to one of stable litter, their starting regularly will be the better insured. The pots should be raised on pedestals of brickwork, so as to prevent the pots sinking with the fermenting materials, the materials being brought up about the pots, but not to cause the heat about them to exceed 75°, between that and 70° being suitable. The soil in the pots must be brought into a thoroughly moist condition by soaking or repeated watering at 80°. The canes should be slung in a horizontal position. The temperature at starting must not exceed 55° artificially, but as the Vines break it should be gradually increased to 60° or 65°. Syringe the Vines in the morning and early afternoon.

Melons.—The last fruits are swelling well, and will need supporting in good time. Remove all superfluous growths as fast as they appear, it being important that the plants have the advantage of every ray of light, and the fruit be exposed to the sun as much as possible. Only moderate supplies of water will be needed, and the syringe must be used very sparingly over the foliage. A light sprinkling on bright afternoons, with damping available surfaces occasionally, will be sufficient, as too much moisture at the roots or in the atmosphere tends to encourage canker, for which a vigilant watch should be kept, and upon its appearance quicklime must be pressed well into the affected parts. The temperature should be maintained at 70° to 75°, with an advance to 85° or 90° from sun heat, closing early. Maintain the bottom heat steady at 80°.

In dung-heated pits or frames watering should cease, as a dry condition at the roots will accelerate the ripening and improve the quality of the fruit. Linings will be necessary to maintain the heat of the beds, and the lights should be covered with mats at night. The fruit from exhausted plants not yet ripe should be cut with a good portion of stem attached to each, and be placed in a sunny position in a warm house.

Cucumbers.—Liberal attention must be given the autumn fruiters to insure a strong growth, as much of the after-success depends on the foundation now laid. Remove all male blossoms and tendrils, avoiding overcropping, and do not allow the fruit to hang too long on the Vines. Syringe only on bright warm afternoons, gradually reducing the atmospheric moisture as the days shorten, continuing to earth up the roots from time to time, pinching out the growing point every week or ten days, reserving only as much growth as will have full exposure to light and air.

The plants for winter fruiting should have a light position, so as to keep them sturdy, and the fermenting bed—if such be employed—be prepared. Good stable dung and Oak or Beech leaves well incorporated and turned over every three or four days, moistening if necessary for a fortnight, form a good bed, and next to this tanners' bark, which should be had fresh, thrown into a heap, and when fairly warmed through it can be placed in its final quarters. The plants for fruiting at Christmas should be placed in the beds without delay.

FLOWER GARDEN.

Pelargoniums of the tricolor, bronze, and other ornamental-leaved varieties are difficult to winter if at all affected by frost; it is, therefore, necessary to have suitable quarters, and preparations should be made for potting them quickly directly a change in the weather necessitates their removal. From their slow growth it is not desirable to cut them back much, merely removing any crowded branches and stripping them of their leaves. The remaining shoots may with advantage be left their full length to afford an early supply of cuttings in spring. A little frost will not much affect the green-leaved varieties. They should be cut well back and potted singly after the roots have been trimmed, or they may be packed close and stored away in boxes. Coleuses, Iresines, and all tender plants should be placed under cover at once. The tender succulents, such as *Echeveria metallica*, *Pachyphytums*, *Kleinias*, and *Sempervivum tabulæforme*, should be removed, or if it be desirable to continue them out a time longer it will be necessary to have some light protecting material to place over them when frost is expected. Where winter or spring bedding is contemplated let all the plants be in readiness and fully arranged, so that no delay may occur when it is necessary to clear and refill the beds.

In the mixed border many of the autumnal plants will still be attractive, and a little extra attention to ensure neatness will compensate in some measure for the paucity of flowers. Dead and decayed leaves and flower stems should be removed as the plants cease blooming. Hollyhocks which are cut down will produce cuttings, which may be taken off with a heel and struck in slight heat. Seedlings of these may be potted singly and wintered in cold frames; they will make strong plants for next season. Any gaps in the mixed border should be filled with Brompton Stocks, Wallflowers, Canterbury Bells, Antirrhinums, and other biennials or perennials, Pansies, Pinks, Carnations, and Picotees may yet be planted out, the earlier the better, firming the soil well about the roots. Most of the

Rose buds will ere this have taken, and all ligatures should be removed and the Briar shoots reduced in length.

PLANT HOUSES.

Orchids.—The temperature for the East India house must be kept at a mean of 70° by day and 60° at night, *Cattleya* house 65° by day and 55° at night, and for the *Odontoglossum* house 55° by day and 45° is advisable at present. Very little ventilation will be needed except during mild weather. The atmospheric moisture must be reduced and syringing discontinued, except in the case of plants making growth to restore plants becoming shrivelled, and in the case of newly imported plants, in which cases syringing will be necessary. *Phalænopsis* must be very carefully supplied with moisture, as the leaves at this season are liable to decay. *Calanthes* now producing their flower spikes should have every encouragement with heat and moisture. *Dendrobiums*, *Cattleyas*, and any other Orchids which have completed their growth will require very little water; but *Zygopetalums* and other plants commencing to grow will need moderate moisture, and the most favourable position in the house for growth—plenty of light and moisture, repotting if necessary or surface-dressing with fresh material. Some of the *Oncidiums* are useful for autumn and winter flowering, especially *O. aurosum*, *O. bicallosum*, *O. flexuosum majus*, *O. macranthum*, *O. incurvum*, *O. ornithorhynchum*, and *O. tigrinum*. These will bear a cool dry atmosphere when in flower, and the flowers last much longer than when in a moist atmosphere. Sufficient water only should be given to prevent the plants suffering. *Vanda cærulea*, with *Odontoglossum grande* and the *Pleiones* when in bloom, will also bear a cool dry temperature (50° to 55°). Let the glass and woodwork in all the houses be thoroughly cleaned both inside and outside, taking advantage of wet weather to give the plants a thorough cleaning, neatly staking all young shoots. Search for slugs by lamplight, as they are very destructive to the young growths, flower spikes, and roots of Orchids.

GREENHOUSE.

Camellias that have been outdoors should at once be transferred to their winter quarters, and the plants thoroughly cleaned. Plants that have not been out should likewise be similarly treated.

Plants of *Cassia corymbosa* that have flowered may be cut back and placed at the warmest end of the greenhouse, where they will commence growth slowly. Any plants which have a number of heads to open should be placed in a house slightly warmer than an ordinary greenhouse, in which the bright yellow flowers will open and be very useful. *Neriums* are not so much grown as they deserve to be, nor are they treated in such a manner as to make the most of them for decorative purposes. Cuttings now taken from plants that have the wood thoroughly ripened and their flowers set, and struck, as they will readily in a good bottom heat, and shifted into 6-inch pots, will form beautiful plants very useful for decorative purposes.

Some of the most forward and promising plants of *Daphne indica* may be placed in a temperature of 50°, and they will not only flower earlier, but admit of more bloom being cut from them than later-flowered plants, which when cut hard do not break again freely.

Croweas bloom nearly two months at this season, and yet they are seldom seen, their pretty star-shaped pink flowers contrasting well with most other plants. They are not difficult to grow, and in a conservatory slightly warmer than an ordinary greenhouse they bloom freely. *Witsenia corymbosa*, with its beautiful though small bright blue flowers, is too much neglected, its colour being rare at any time, especially at this season.

Mignonette grown in pots for winter flowering should have the growths neatly secured to stakes as they advance, and have a light airy position in a house with a temperature of 45° to 50°. The plants, if the flower spikes are not cut as they become fit, must have the seed vessels removed; or they will impair the vigour of the plants more than a similar number of flower spikes. If the plants are not as large as required, the bloom as it shows should be pinched out until the size of specimen desired is secured. The plants are impatient of fumigation, hence if it be resorted to for the destruction of aphides it must be moderate, but it is better to syringe with clear tobacco water. *Heliotropes* that have been prepared for autumn and

winter flowering by liberal treatment during summer, and fully exposed, with the flowers pinched off, and supplied with liquid manure, should now be placed in a light airy house with a temperature of 45° to 50°, in which they will bloom freely.

Abutilons now are so numerous and varied in colour as to be quite useful for winter flowering. Young plants struck in spring and grown on through the summer will be stout well-furnished plants in 6-inch or larger-sized pots, and with a little extra warmth will bloom through the winter, being alike useful for furnishing and for affording flowers for cutting. Weak liquid manure should be afforded the plants, with a light position and a temperature of 50° to 55°.

THE BEE-KEEPER.

THE STEWARTON AND THE BAR-FRAME HIVE.

THE Stewarton hive had once and for many years an enlightened and able advocate and patron in the person of the "RENFREWSHIRE BEE-KEEPER," and since his retirement no one has come to the front to take his place. This I regret much, for the principle of the Stewarton hive cannot be too well known, and there are reasons for thinking that its advocacy at the present time would be valuable to a great number of apiarians. Many people like to follow the fashions and go with the majority. They readily spend their money for things last out, hence new inventions are the order of the day. Many bee-keepers are going to extremes just now. The bar-frame fever is reaching to its height. Dealers and hive-makers seem at their wit's end to get something fresh to offer for sale. Old hives receive new and various shapings and remodellings in their reproductions. The markets and show tables are full of novelties. For many years I have privately advised many bee-keeping friends to introduce to their apiaries the bar-frame hive and give it a fair trial; nay, I have been anxious to see this hive spread over the land and become well known, believing that when this happens we shall have a reaction, and see men trusting less to hives and more to their own management. To those who follow the fashions bee-keeping is rather an expensive recreation. This statement is made, not with a view of disparaging any kind of hive or any system of management, but simply to let the readers of this Journal know that novelties are not always improvements, and that changing from one system of management to another is not the shortest road to success. The fact that so many bee-keepers are seeking new hives and new ideas proves that the past has not been successful and satisfactory; indeed, we all know that those who follow others are always behind.

Now let us examine the principal feature of the Stewarton hive, which is one of surpassing excellence—namely, its constructive arrangements for supering. The arrangements to this end in all other hives that we have seen are faulty and inferior if compared to those of the Stewarton. The Stewarton hive is made of wood in several parts, octagonal in shape and 14 inches wide. The several parts consist of three breeding boxes, each 6 inches deep, and three supers the same width 3 or 4 inches deep. All are made with bars across their tops, from which the combs are built. There is no crown board, so that if all the six boxes were placed on one another we could see through the skeleton from top to bottom down through every bar. If a swarm of bees were cast into an empty Stewarton they would not know where to settle and begin work; the hive being without crown-board, the bees could get out at the top as well as by the door. But there are slides used in the Stewarton hive which answer the end of a crown-board, and these slides are made to run in grooves in the cross bars of all the sections of the hive. This is a wonderful arrangement, well contrived, but difficult to explain to those who have never seen a Stewarton hive. If we begin to people a Stewarton two breeding boxes only are used, the slides going between the bars of the uppermost box. If the third breeding box be used it is placed underneath the others, and the slides remain as they were. When supering begins the slides are withdrawn from the breeding box and placed between the bars of the super, and if a second and third super be used the slides are moved to the top one, or crown of the hive.

This simple description of the hive is imperfect, the hive itself being so unlike all other hives. But the reader will see that the Stewarton hive complete with three supers piled on the breeding boxes is about 30 inches deep, giving the bees free access to every part of every section of the hive from bottom to top. The leading

or main principle of the hive now becomes apparent—namely, the absence of crown-boards or partition walls between breeding boxes and supers. This is the great characteristic of this valuable hive. The bars of all the sections being filled with combs, the interstices between the bars run from bottom to top, and thus the hive is without complications, and the bees have no hindrances when at work. In such a hive bees are capable of doing much work and amassing great stores of honey. Have we no fault to find with the Stewarton? None with the principle or distinctive feature of the hive, which is its peculiar adaptation for supering, and none with its size and shape. But I disapprove of wood as materials for hives of all kinds, and the Stewarton is made of wood. By reading the report of the Bee-keepers' Association I learn that an attempt is being made to introduce the Stewarton principle on the straw hive. If the attempt be successful—and there is no reason to think otherwise—the straw Stewarton, in my opinion, will be the hive of the future. I hope the hive will appear and be sold at a moderate price, and never be patented.

The prices asked for some hives are exorbitant and far beyond their value. When I was in Scotland lately, and travelling through a bee-keeping county, the train by which I was travelling halted for an hour at a railway station near which a first-rate straw-hive maker lives. I found him and family engaged at their work, making at the rate of about four hives a day, or say twenty a week. I asked if he was constantly employed in making common straw hives. He said "Yes." The hives he was then making were 14 inches wide—just the width of the Stewarton hive, and they were so well made and so low in price that I ordered a dozen of him. I am quite certain that straw Stewartons can be produced at prices low enough to tempt even cottagers to use them.

The Stewarton hive can be managed on both the swarming and non-swarming systems, and its mode of enlargement is far more likely to prevent swarming than the mode of supering through a hole on bar-frame hives about 3 inches wide. This hive has no separate apartment, all the work is done in one room, and when enlarged the outer walls are simply elongated and the roof raised a storey higher. But why object to the wooden sides of the present Stewarton hive? Wood is not a proper material for hives. It may answer well enough for summer, when bees can drive out the moisture of the hive; but in spring, autumn, and winter they have not the power of doing this, and therefore the moisture condenses on their wooden sides and rots the combs. When men have a little more experience wood will go out of fashion and straw will be employed. No less than seven prizes were offered for straw hives at the last show.—A. PETTIGREW.

TRADE CATALOGUES RECEIVED.

V. H. Hallock, Son, & Thorpe, Queen's, New York.—*Catalogue of New Plants.*

Jacques Vigneron, Orleans, France.—*List of Roses.*

Cranston's Nursery and Seed Company, King's Acre, Hereford.—*Catalogues of Roses and Forest Trees.*

E. Webb & Sons, Wordsley, Stourbridge.—*Illustrated Catalogue of Seed Corn.*

William Rumsey, Waltham Cross.—*Catalogue of Roses, Trees, and Shrubs.*

TO CORRESPONDENTS.

** All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Lemon (J. D.).—The fruit you have sent is not the same as the kind that is imported, but the plant has probably been raised from seed saved from an imported fruit, seedlings being subject to great variation. The variety does not, at least as represented by the fruit you have sent, possess any merit.

Peach and Nectarine (C. A. J.).—The aspect you name is suitable for the trees, and you cannot probably plant two more useful varieties than the

Royal George Peach and Lord Napier Nectarine. It is immaterial which has the warmest position, but you will not err by devoting it to the Nectarine, with the object of securing early fruit. The centipede is not beneficial in the garden.

Flue Heating (*Anxious*).—If your flue answers well except at the end near the chimney we should only remove that part and there fix glazed pipes, which, being thinner we presume than your paving tiles, would conduct the heat from the flue more quickly. Glazed tiles placed near the fire are apt to split at the sockets; at a distance from it we have seen them used with perfect safety.

Flower Garden Boxes (*A Young Gardener*).—There is no "average" size for such boxes as those to which you refer. The size of the boxes either is or ought to be stated in the schedules in which prizes are offered. We have seen boxes 3 feet square, 4 feet square, 4 by 3, 5 by 4, and even longer. We are not aware that there is any book published with coloured designs for flower gardens.

Material for Mushroom Beds (*J. D.*).—We have no doubt that London stable manure where the horses are bedded with cocoa-nut fibre refuse would do for Mushroom beds if mixed with ordinary decayed stable manure. Even sawdust that has been used as bedding in stables has, when largely mixed with the material in question, produced excellent Mushrooms. We doubt if either sawdust or cocoa-nut fibre refuse used alone would answer the purpose, as the former especially is liable to promote the growth of small fungi.

Removing Sub-laterals from Vines (*East Berwickshire*).—Provided the principal leaves of the Vines are fully exposed to the light the laterals now being produced will not do any harm. If they shade the large foliage remove them gradually as you suggest, not by armfuls at once. You do not say whether you have cut the fruit of the Black Hamburgs; if you have and the growth is strong you may remove the laterals, but do not remove them otherwise except for the purpose referred to of exposing the original foliage to the light and air. The production of sub-laterals when Grapes are ripening is a favourable symptom, as it indicates that the Vines are not overcropped, but have a surplus store of energy for future work.

Gros Maroc Grape (*W. J.*).—Although we have had no experience with grafting this variety on a healthy stock of Lady Downe's, we should not hesitate to try it if we desired to add it to our collection. You might well try it with the rest, and if it does not answer your expectations you can readily remove it, and train an additional rod of whatever variety you find most useful in its place. Gros Maroc is a strong grower, does not as a rule produce very large bunches, but the berries are fine, colour beautifully, and possess an agreeable sprightly flavour that is pleasing to most palates.

Early Potatoes for Market (*H. M.*).—We doubt if there is a better or more profitable early variety for the purpose in question than a true stock of Myatt's Improved Ashleaf, which is synonymous with Rivers' Royal Ashleaf. Beauty of Hebron is also profitable in some districts, and in light soil and rather dry and warm localities the Early Rose crops freely and is of good quality. If any of our readers have found other varieties more profitable than those we have named we will gladly record their experience.

Shelter for Garden (*R. P. O.*).—If you want a tall sheltering screen we know of nothing that will afford it so quickly and inexpensively as a hedge of Lombardy Poplars. They can be cut to any width and height you like, from 2 feet in diameter to 20 feet or more high. Hornbeam forms a good hedge, and is well adapted for a screen of moderate height. Evergreen Privet is liable to be injured by frost during very severe winters. As an evergreen screen Thuia Lobbia forms one of the best.

Standard Fruit Trees (*Idem*).—You do not say whether you want dessert or culinary Apples, so you must choose for yourself from the following. *Dessert*.—Devonshire Quarrenden, *Cox's Orange Pippin, Wyken Pippin, and *Wormsley Pippin. *Culinary*.—Keswick Codlin, *Cellini, Golden Noble, *Blenheim Pippin, and Dumelow's Seedling. Those prefixed by an asterisk are useful for both dessert and culinary purposes. *Pears*.—Jargonelle, Louise Bonne of Jersey, Hessele, and Swan's Egg. *Plums*.—Rivers' Early Prolific, The Czar, White Magnum Bonum, and Victoria.

Eccremocarpus scaber (*Surrey*).—This is doubtless the plant to which you refer. It is a native of Chili, and has rough leaves and orange-coloured flowers. It is hardy in most districts, and when established needs no protection; but it is advisable to place a little cocoa-nut fibre refuse or other suitable material over the roots of young plants. The plants die down on the approach of winter like Hops, but fresh growths start from the fleshy roots in the spring. We presume your plant is established in the soil—not in a pot, and the roots will only need the protection indicated. If the plant is in a pot winter it in a frame or cool greenhouse. Fresh seed germinates quickly when sown in heat in the spring and kept moist, the plants flowering the same season.

Oak Spangles (*Idem*).—These are produced by insects, species of *Diplolepis*, some of which produce very pretty galls—red or orange and fringed. In most museums they can be seen, and in the British Museum a very good collection will be found.

Violets in Frames (*A. D.*).—In all probability the soil in which the Cucumbers were grown will be suitable for the Violets, but it must be thoroughly moist without being saturated. An addition of decayed vegetable matter and burnt refuse would improve the soil if it is heavy. As you have not stated the distance that the present soil is from the glass we are unable to advise you on that point; but you will, we think, find all the particulars you require in an excellent article on Violets in Frames on page 224, September 7th, 1882. If you do not possess this number it can be had from the publisher, post free, for 3½d. in stamps.

Conifers for Border (*A Leeds Subscriber*).—We think you are attempting far too much in a border only 7½ feet wide. So far as we understand the case, we think a row of Conifers of one kind to form a screen or hedge would be decidedly preferable to a mixed assortment, and we should plant Thuia Lobbia. It is hardy, close yet feathery, bright green, and very hardy. In the front of these you might furnish the border with Rhododendrons if the soil is suitable, interspersed with variegated Hollies, Boxes, and Aucubas, leaving a margin as you suggest for flowers. Large deciduous trees in such a border would spoil both the Conifers and evergreens, and very few, if any, of such trees should be planted, unless indeed you prefer them to the others.

Decayed Manure (*C. D.*).—The material of which you have sent a sample is such as many gardeners would be glad to have for mixing with strong loam for such plants as Fuchsias, Pelargoniums, Cinerarias, Calceolarias—indeed, nearly all kinds of softwooded plants and bulbs; it would be also valuable for surfacing flower beds in the summer. Added to strong soil at the rate of about a sixth of the bulk it would make an excellent compost. If used similarly with light soil it would make the mass too light, but that in a measure might be

obviated by potting very firmly. Rubbed through a sieve it would be excellent for the purpose of raising seedlings of all kinds of flowers in the spring. It would not be suitable for hardwooded plants such as Azaleas.

Plumbago capensis (*Idem*).—The old foliage is liable to be attacked with mildew, and this is no doubt the "white substance" to which you allude, but which was rubbed off the leaves you sent in transit. Dissolve 2 ozs. of soft-soap in a gallon of water, in which mix a small handful of sulphur. With this solution at a temperature of 120° syringe the plant thoroughly, but prevent by some means much of it draining into the pot. Several leaves usually turn yellow at this season and fall, the plant being semi-deciduous, like Azaleas. After it ceases flowering reduce the supply of water, and during November and two following months keep the soil almost dry. In February prune it closely, and when growth commences remove a portion of the old soil from the roots and add fresh loam. If you do not possess our "Greenhouse Manual" you might with advantage obtain it; its price is 10d. post free. We do not consider you have given us any trouble, and we shall always be glad to aid you in obtaining proficiency.

Roses for Towns (*R. W.*).—If the soil in your garden where you contemplate making a bed for Roses is not good you had better remove it to the depth of 2 feet. This will be ample if the ground is well drained, which is essential for the successful cultivation of Roses. When the soil is cleared out good fibry loam of a rather strong nature should be obtained, to which add one barrowful of good half-decayed manure to every eight barrowfuls of loam. If soil only of a light nature is available add one-seventh of clay, and incorporate it well with the soil before placing it in the bed. The clay should either be dried in some suitable place or over a fire made for the purpose, which will enable you to break it up easily into small particles. To break it well up before mixing it with the soil is much better than chopping it into pieces with a spade; for if mixed into the soil in lumps it will remain in that condition, except what little is turned to the top, which will fall by the influence of the weather. This is all the preparation needed to form a bed for Roses, but the soil should not be allowed to become into a wet saturated state before wheeling it into the bed. The following varieties may be safely planted:—La France, Général Jacqueminot, John Hopper, Jules Margottin, Duke of Edinburgh, Comtesse d'Oxford, Capitaine Christy, Abel Carrière, Souvenir de la Malmaison, Edouard Morien, La Duchesse de Morny, Magua Charta, Princess Louise Victoria, Sultan of Zanzibar, Sir Garnet Wolseley, Victor Verdier, Boule de Neige, and Louis Van Houtte. If only six varieties are required plant the first six named. It is much better to plant a quantity of a few kinds that will flourish than a greater number of uncertain varieties.

Vines and Melons (*J. E.*).—If the roots of the Vines are confined to the 6 feet-wide border, which appears to be very shallow—too shallow—in the front, you cannot expect superior Grapes unless there is a network of fibres near the surface of the border, and these are well supplied with food in the form of frequent top-dressings of fresh loam and manure. In many Vine borders there are no fibrous roots within a foot or more from the surface, and in such cases top-dressings are of little use. We suspect this is the condition of your border, and if so the sooner you remove the old soil, or most of it, raise the roots as much as possible, notching several of them by making a deep vertical cut half through the main roots and a sloping cut upwards to it, the better. If wood ashes are added freely to the loam fresh roots will be emitted the more freely. The roots must not be allowed to become dry during the process of raising them; they should be covered with soil 4 or 5 inches deep, this to be mulched with manure. A top-dressing of manure is of great service during the summer, as if the border becomes dry at the surface the roots at once leave it and penetrate downwards; neither will they permeate the surface of a border that is loose by being forked over periodically. In another column you will find what has been done by renovating Vine borders, and you cannot do better than follow the practice there detailed so far as it applies to your circumstances. In reference to the Melons, we presume you had fermenting materials in the pit, but you do not say so, and hence the roots were not dry at the bottom of the bed; if they were dry there that circumstance would account for the failure. We have seen not a few plants collapse from the cause indicated, and we have also seen them wither, this season especially, under skilled treatment by being affected with a disease, the origin and nature of which at present appear quite obscure. Melons, too, are apt to fail in the manner you describe when grown in too light soil. So far from troubling us with your second letter we are glad to receive it, as in regard to the Vines especially, and Melons possibly, it has enabled us to give you a reply that may be useful.

Names of Plants (*Rosa*).—The plant of which you obtained seeds from Ceylon is *Cassia corymbosa*; it succeeds in a greenhouse, or planted out in the open ground in summer to be taken up and potted in the autumn. The plant raised from seed sent from Bengal is an inferior form of the African Marigold. (*J. F. L.*)—1, *Herniaria glabra*; 2, *Meutha Pulegium gibraltaria*; 3, *Stellaria graminea aurea*; 4, Insufficient.

Names of Fruits (*J. Winter*).—1, Louise Bonne of Jersey; 2, Urbaniste; 3, Marie Louise d'Uccle; 4, Stirling Castle; 5, Tower of Glamis; 6, King of the Pippins. (*Alloa*).—1, Dumelow's Seedling; 2, Gloria Mundi; 3, Warner's King; 4, Beauty of Kent. (*Winchester*).—1, Court Pendu Plat; 2, Bcurré Diel; 3, Beurré Sterckmans. (*J. P.*).—1, Lord Lenuox; 2, Cellini; 3, Duchess of Oldenburg; 4, Cellini. (*S. L. D.*).—1, Emperor Alexander; 2, Wyken Pippin; 3, Wormsley Pippin; 4, Norfolk Bearer; 5, not known, probably a local variety. (*L. L.*).—You ask for the names of six fruits, but we have only received three; 1, specimen poor and insufficient; 5, King of the Pippins; the large Apple, from which the number has been lost, Dumelow's Seedling. (*G. R.*).—The Apple is the Gravenstein. (*Four Pears*).—1, Beurré Charneuse; 2, Beadnell's Seedling; 3, Fondante d'Automne. All the fruits were over-ripe when dispatched, and decayed before examination. The sender's name of these four Pears has either not been received or been misplaced. No. 4, which cannot be identified, is a very round fruit. Our correspondent will have no difficulty in recognising the reply as the one pertaining to the fruit he has sent. Some other fruits will be named next week.

Naming Fruits (*C. J.*).—Although the greatest possible care is taken to keep the fruit separate, yet with such a number of specimens it is not impossible for an accident to occur by misplacement. In many cases, too, the numbers sent with the fruit are not attached to them firmly; several, no doubt, are apparently secure when packed, but get displaced in transit. We do not remember whether this was so with your parcel or not. Quantities of fruit reach us with tablets either simply placed on or under them, not attached at all. This always causes inconvenience, and it is sometimes impossible to determine to which fruits the numbers apply. We find it imperative to adhere to our rule only to name six sorts at one time; and when we state that it is not unusual for several boxes containing from twenty to fifty and even a hundred specimens to reach us in the course of a week, the impracticability of retaining

surplus fruits for naming in future issues will be apparent. Pears should only be sent when approaching ripeness, as when green we are deprived of an important test, that of the palate, in determining their names, and we cannot undertake to keep the specimens until they are ripe, although under special circumstances we sometimes endeavour to do so. When Pears are quite ripe when packed they are usually rotten when examined. All this we have stated more than once, and we repeat it in order to induce our correspondents to exercise judgment in sending fruit to be named. No specimens were retained from any parcels that were examined last week.

COVENT GARDEN MARKET.—OCTOBER 4TH.

TRADE quiet, with a fair demand for late wall fruit, Kent Cobs selling freely at lower rates.

POULTRY AND PIGEON CHRONICLE.

SEED CORN FOR AUTUMN SOWING.

THERE is no subject connected with practical agriculture of more importance to the home farmer than the selection of cereal seeds which may be required for autumn sowing. But the difficulty of obtaining first-class true samples adapted to particular soils and climates is generally very serious. Although we may in favourable seasons grow large crops of good quality, we have no right to assume that we have the cleanest, the heaviest sample, and best millers' grain as regards quality unless it will bear comparison with the choicest sorts of Wheat which are now to be obtained from the seed-corn merchant. Again, one of the most important points in seed corn is that it should be free from the seeds of weeds as well as free from grain of other varieties. This is seldom attainable when seed corn is purchased of the farmer who grew it, even when he has grown it from the best and purest sample; for under ordinary circumstances, the corn being often threshed by hired machinery, it is frequently the case that the remains of other varieties which have been threshed just previous are left in the machine, and become mixed with the next sort which may be threshed. We must, therefore, look to the seed merchant, whose especial care and business it is not only to select the best grain, but the purest and truest of its variety, and there never was a time when it has been so easy to obtain selected sorts of Wheat of the highest value in every respect as at the present. Major Hallett of Brighton led the way with his pedigree grain of various kinds, but for some years it had little influence on the mind and management of the

ordinary farmer. It has, however, gradually been "pushed into notice by the seedsmen, a few of whom have with great care improved the various kinds of grain by selection and otherwise, and their endeavours deserve every encouragement.

We must ask the home farmer to consider the nature of his soil, its situation and aspect, as these are the three chief points to be considered by him in choosing the variety of Wheat best suited for his use. Our experience in this matter commenced many years ago, and enables us to say how very difficult it is to decide which of the many varieties offered to our notice is most suitable. We, therefore, recommend the growth by actual experiment and comparison of sorts under the like circumstances; and as the most important farmers of the district in which he may be farming will recommend him varieties which may have succeeded best with them, these ought also to claim his attention. Still, when other varieties are offered it is well to make the comparison, and prove to his own satisfaction which is best—the favourite kind of the locality, or some of the choicest sorts recommended by the seed-corn merchant. Few men will be deterred from this when they know that the most valuable sorts can be obtained in very moderate quantities, although at a somewhat higher price than the ordinary millers' grain, as it will not entail a heavy expense in making the experiment and comparison. If it succeeds he will be in possession by his own growth of valuable seed corn for his own use in the next and following seasons if due care is taken by keeping the grain unmixed in threshing, after which he may be his own judge upon the important question of seed corn.

At the present time we have the advantage of a choice of seeds which did not exist formerly, for the first Wheat we sowed in 1826 was a Scotch Wheat very much like our present variety called Nursery, except that it was of a pure white berry, but strong in character. We have a sample now grown by us in the year 1835, the produce being 52 bushels per acre; weight, 66 lbs. per bushel old Winchester measure. We also have a sample of our own growth of Chidham Wheat, the produce of the year 1844. It is of splendid quality and very true in character, and at that time was much sought for by millers intending to make the highest quality of flour required by the pastrycooks and confectioners, and it always commanded the highest price, especially in the markets of Guildford and Uxbridge, at that time the two highest markets in England. Although we grew this Wheat in one of the finest seasons ever known, the yield did not meet our expectations, as we only obtained 40 bushels per acre, although the straw was a very full crop. Our next sample which we have preserved was called Morton's Red Straw White, and introduced by Lord Ducie on his farm at Whitfield in Gloucestershire. The redness of the straw, however, disappears when ripe. Our sample is a fine white grain of excellent quality, weight 67 lbs. per bushel; and as we do not know the origin of Oakshott's Champion White it seems to us probable that it was selected from Morton's White, as it resembles it both in growth and grain.

We must now refer to sorts which we have grown within the past twenty-eight years, and we shall refer more particularly to the varieties which have proved to be advantageous, and which can at present be obtained from the seed-corn merchants of superior and selected stocks. The Red Nursery is a good millers' grain, and well adapted for sowing on those soils which are subject to loss of plant, as it is a very hardy variety, and can be obtained now as a selected sample. The Rough Chaff Essex, more particularly the Dwarf Clubhead variety, we have found ever since its introduction the most profitable sort we have ever grown, but more especially on the best soils in a high state of cultivation. It is shorter in straw by 6 or 8 inches than any other variety we have ever grown. It is very hardy and maintains a thick plant in severe seasons, at the same time tillers very freely if thinned out by wireworms or otherwise. Some exception has been taken to it

on account of the thick velvet-like covering on the chaff, it being said that it is more subject to mildew; but we find this refers to the chaff only, and not to the straw. It is also credited with sprouting sooner in wet weather. This may be the case in certain western and northern climates, but not in the south and eastern districts of England. We have, however, a good set-off to any difficulty, for the thick close chaff preserves the grain from shedding in windy weather in exposed aspects—a matter of great importance in all seacoast districts.

The above variety can be obtained of the various seed merchants. But Mr. Oakshott claims to have introduced an improvement in the Rough Chaff varieties, and offers us his selected Imperial White or Velvet Chaff Wheat, and describes it as having more length in the straw with less velvet on the chaff than the original, and this we are willing to accede to him as better for growth on light land or land not in first-rate tillage. But we prefer the Dwarf Essex to any other when a full crop of straw is expected, as it never suffers from falling or lodging on land correctly tilled. During the three years past we have the following crops of this sort grown on very thin gravelly soil and seacoast district:—In 1880, fourteen sacks per acre; 1881, twelve sacks per acre; and in 1882, thirteen sacks per acre—of great weight and fine quality in each instance; and we here call attention to the advisability in any selection of the Velvet Chaff of maintaining in all its advantages the short straw and the thick coating of velvet on the chaff, irrespective of any other possible improvement. In making these observations we by no means insinuate that the Imperial Velvet Chaff is not best in some districts, especially on soils not usually throwing much straw, and upon light soils in the midland or sheltered districts, for we should rather prefer it, for the special reason that on such land it is sure to yield full crops of straw and grain of the very best millers' quality. But still we do not name it to the exclusion of the Champion White under the like circumstances of soil and climate.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—The season has been generally favourable for carrying out autumn tillage either by horse labour or steam power, and those who have not completed the cultivation of land intended for either Barley, Potatoes, Mangolds, and other root crops next year, may not have the opportunity in the spring should the weather then prove adverse. If we view this matter in another way it must be admitted, in the event of the spring being propitious, there is not time for fallowing and cultivating without a serious delay occurring to the seeding of the crops in the spring. Besides, every practical farmer ought to know that, although the labour of fallowing as regards tillage may be carried out, yet the result and effect will be very inferior compared with that arising from autumn tillage. For instance, if we have couch in the stubbles, unless it is cleared off in the autumn it cannot be so effectually done in the spring should the weather prove ever so favourable; because, in the act of tillage, when the ploughing or cultivating follows closely upon the previous one, the couch is not killed, but is in fact transplanted by being mixed with the soil, and will certainly make its appearance at a future time. We will now suppose that the land intended for Trifolium, Vetches, Rye, and winter Barley has been seeded upon land which was clean; some of these crops, however, have, we find, been eaten by slugs, in which case the sooner another seeding takes place the better, especially as regards Trifolium, for in the second seeding not less than 30 lbs. of seed should be sown per acre; and it is advisable, too, not to sow the same land from which a first seeding has been destroyed by the little white slugs, as they will be surely awaiting another opportunity of feasting on the young and tender plants as soon as they show above ground.

In all cold and flat-lying land the seeding of Wheat and winter Beans must now be anticipated, and the land prepared, so that when the time arrives for seeding it may be done without delay. In the case of Clover or grass leas the land should be ploughed and pressed, using the skim coulter, by which the turf will be buried under the furrow when the ploughman has done his work effectually. We, however, advise that in those cases where the leas were foul and have been broken up with the view of cleaning and destroying the couch, that such land should not be sown with Wheat unless it is ploughed, pressed, and press-drilled at the same time, because if the land is worked down and drilled in the ordinary way the crop is nine times out of ten injured by becoming root-fallen in the summer, caused chiefly by shallow seeding and shrinking of the land, leaving

the rootlets bare. Rather than sow such land with Wheat we should allow the land to remain in the fallow state after being ploughed or ridged until the spring, and then sow with either Barley, Oats, or drege according to the nature of the soil and the climate of the district.

Hand Labour.—The hedge-trimming, especially the White Thorn, should be completed as soon as possible. In some of the enclosed heavy land districts, however, where the ditches are deep, the banks high and broad, and the borders wide, in order to prevent shading of hedges, these, instead of being trimmed, should be cut as closely as possible to the bank, so that the fagging hook or Gorse-cutting scythe may be used for cutting the growth, not only of grass, weeds, and herbage, but also the Maple wood, the Hazel, the Black Thorn; in fact every kind of wood found thereon may with great advantage agriculturally in respect of everything (except fencing) be cut and cleared away twice a year—in May and September. This we have found yields good green fodder for young cattle, dairy cows for the sale of milk, breeding sows and store swine in the yards, so what they do not or cannot eat will still tread into a manure by the animals; in this way we not only obtain food for stock, but by closely trimming the banks and borders effectually keep down and prevent the seeding of all noxious weeds and coarse injurious grasses which contaminate our fields under ordinary or careless management. The women should now be employed in weeding the root crops by hand-pulling and heaping the weeds, for the showery summer has in various cases produced weeds which during the harvest months could not be destroyed by the hoe and are seeded, but by pulling and heaping the weeds will decay, but by hoeing only they drop their seed and keep up a succession. The irrigated meadows should now be got ready to receive the first heavy rains, which are so valuable by flooding them. There is still, we notice in our travels, some aftermath hay about in the cold districts on the meadows; on the arable land Clover seed, too, is still out in many cases. These matters will require men's labour and women also in attending to them and making the most of every hour of sunshine now the days are shorter.

Live Stock.—The contrast in the requirements and management of the different breeds of sheep will now be apparent; for although the tupping season for the Hampshire and other breeds of down ewes as well as the long-wooled breeds is not yet over, still we find that the Dorset and Somerset horned ewes are beginning to drop their lambs, and with liberal feeding will require but little attention as regards shelter if they obtain a dry night lair. We find in our visits to certain districts that the management of swine is frequently very much neglected, not only as regards the mode of feeding and the accommodation for the animals by night as well as by day, but also that the breeds peculiar to certain localities are still maintained, without reference oftentimes as to the improvement which may be effected either by crossing or choosing a new breed of stock. With regard to the capacity of certain breeds for producing numbers and rearing them for killing at an early age of the best quality, it is important to consider these as the leading points or basis of profit; and as far as our experience reaches we find that first crosses are better than the correct maintenance of any pure breed (except for sale as a speciality), and no cross that we have ever met with has exceeded in profit for fattening than the cross of the Berkshire sow mated with the large white Yorkshire boar. These sows are notoriously good mothers and bring large farrows of good-sized stock as a pure breed, but when crossed with the Yorkshire they still bring large and numerous farrows, and as weight for age they cannot be equalled in any way, for the quarter pork as well as the bacon obtained will always supply a good proportion of lean meat of any age or size.

THE METROPOLITAN DAIRY SHOW.

THE seventh Exhibition of the British Dairy Farmers' Association, which opened in the Agricultural Hall on Tuesday last and closes to-morrow (Friday), is probably the best of its kind that has ever been held. The animals are on the whole of high quality, the dairy products excellent, and the appliances almost bewildering by their variety. In the class for Shorthorn cows the Lord Mayor's cup and first prize was won by Mr. Newton Edwards of St. Albans with Daffodil, Mr. Walter, M.P., securing the chief honours in the class for heifers with Duchess V. The Channel Island cattle are prominent by their numbers and quality, the prizes for cows going to Messrs. J. Cardus, Southampton; Le Brocq, Jersey; and Mr. George Simpson. For heifers to Messrs. Corbett, Beckworth; Arnold, and Brideaux of Jersey in the order named. For heifers bred in the Channel Islands the prizewinners were Messrs. Arnold; Simpson, Jersey; and H. A. Rigg, Walton-on-Thames. Messrs. James Fowler, and Welford and Sons, are large exhibitors of splendid animals. The Lord Mayor's cup for any other breed was awarded to an Ayrshire shown by Mr. G. Ferme of Roupell Park, Streatham Hill. Mr. Good was the most successful exhibitor of Kerries. Goats, poultry, pigeons, ducks, and bees with apiarian appliances are admirably represented, but the prizes were not awarded when we left the Exhibition.

THE REMEDIES FOR THE AGRICULTURAL DISTRESS.—Mr. A. J. Burrows in his recently published book, "The Agricultural Depression and How to Meet It," thus sums up the remedies for the agri-

cultural distress which has been felt so keenly during the past few years. 1, A fair amount of sun, genial springs, hot summers, and dry autumns. 2, Increased produce obtained by means of larger outlays on a smaller acreage. 3, More home breeding of live stock, and less danger from disease. 4, Keeping only the best classes of stock, and aiming at early maturity. 5, A thorough readjustment of local taxation. 6, More drainage, better accommodation, more care of manures, &c. 7, The reduction of holdings and employment of more capital per acre. 8, Close supervision and more task work. 9, More personal attention to buying and selling, and more care in selecting seeds, manures, &c. 10, Better accommodation for young stock and feeding cattle, and for the making of manure. 11, A fair and equitable Tenant Right Bill, or an improved Agricultural Holdings Act. 12, Longer leases at fair rents, and with proper freedom of cultivation. 13, The introduction of improved labour-saving machinery. 14, More roots and forage crops, more pastures, and consequently more stock and more manure. 15, Greater confidence between different classes, and a determination to work together for the good of all.

POULTRY AND PIGEONS

POULTRY SHOWS AND ENTRY FEES.

We have never concealed our opinion that there are now far too many poultry shows—*i.e.*, far too many large shows open to the world, and to which all comers are invited. Of local shows confined to particular counties or particular districts and groups of parishes there can hardly be too many. The former, if carried to excess, promote overshadowing of birds, and so impair their health and productiveness. The latter encourage just those classes who need encouragement in poultry-breeding—*viz.*, amateurs who are just taking to the pursuit, farmers and cottagers who wish to know the relative worth and excellence of their stock and how to improve it. Especially are these shows useful when held at the same time as, or in connection with, agricultural meetings. Their further advantage, too, is that they seldom extend beyond one day.

The evils, however, of the over-multiplication of open shows have often been pointed out in our columns, and we are not going to weary our readers with a general repetition of them. Exhibitors have the remedy entirely in their own hands. No one is compelled to overshadow his birds.

The point to which we will now confine attention is the absurdly high fees which are frequently charged for the entrance of birds. This is one of the consequences of there being too many shows. At one time any exhibition of the kind was well attended by the public (they are still so attended in some districts, especially, as we have lately observed, in the south-western counties and South Wales), and the money paid at the gate sufficed to meet most of the expenses. The promoters of them could then afford to be liberal. Now this is all changed. We have beautiful shows of the best birds the kingdom can produce, well arranged and managed in light airy halls of such towns as Bristol and Southampton, yet almost empty. Where the inhabitants of the neighbourhood take so little interest in them they cease to do good. However, ardent local fanciers will seldom recognise this fact, and often, at great sacrifice of time, trouble, and money, attempt to keep them up when the public refuse to do so. This can only be done by raising the entry fees; in fact, by practically making the classes a combination of sweepstakes, with a handsome deduction for the general expenses and management.

We have lately been specially struck by some schedules sent us. We do not for a moment wish to discourage the efforts of any committee; it is seldom that they are not personally losers, and so it would be unjust indeed to write harshly; but we do candidly say what we think—that it is a great mistake to get up schemes for shows when they can only be floated by enormous entry fees utterly disproportionate to the prize money. Many a breeder is deterred from this cause from making a beginning in showing, and a species of gambling in poultry and Pigeons, is promoted by it. If there were only one or two schedules which we could instance we should hardly like to call attention to them; but the mistake is so general that without risk of being invidious we may, by way of comparison, review several. We put out of consideration such great and famous meetings as Birmingham, the Crystal, and the Agricultural Hall. The entry fees of 8s. or 7s. 6d. for poultry are dear enough, but immense expenses are involved in exhibitions of such magnitude. A "highly commended" or "very highly commended," which is considered a barren honour at most places, is valued in such competition, and adds value to the

noticed specimen; besides, the opportunities of sale offered are not to be despised, and the fact that the exhibits necessarily come under the gaze of thousands of eyes.

We will take some schedules of lesser exhibitions lying before us. Among the more liberal of them we note that of the Manchester and Liverpool Society, probably because the poultry show is a part of the general agricultural show. The prizes in each class (and the classification is good) are £3, £2, and £1. The third prizes are added by some local committee, so we will not take them into account. This leaves £5 for the aggregate of prizes in each class, and the entry fee is 5s.—*viz.*, 5 per cent. on the prize money; this seems to me a very fair proportion. Again, we take Tredgar; here the prizes are £2, £1, and 10s.—*viz.*, £3 10s. in the aggregate; but then there are specials of two guineas given in addition to the prizes for the best specimen in every two or three classes of adults, and of one guinea for every three or four classes of chickens. The entry is 5s., not a much higher proportion than that of Preston. At Nottingham we find a rather higher rate of entry—*viz.*, 3s. 6d. for three prizes amounting to 35s., but then there are many specials from three guineas downwards to be awarded in addition to first prizes. On the other hand, we find that at Merthyr Tydfil the entry fee is 4s. 6d. for each bird, with prizes of 30s., 15s., and 5s., and no extra premium—*viz.*, 9 per cent.; and at Exeter the Committee value as highly the honour of a prize at their first forthcoming show, where a like fee is charged for an equal amount of prize money in the aggregate though distributed rather differently. We might point out further the great difference in the proportion of entry money to prize money between show and show. The cases cited are enough for our purpose. Where a committee do not see their way to arrange a schedule in the proportion of 5 or 6 per cent. entry on the prize money we doubt very much if it is worth while holding a separate show. It is very well to talk about the honour and glory of a poultry prize card being sufficient, but the people who are satisfied with such decorations are as a rule the rich; and glad as we are to interest all classes in poultry-breeding, those who can afford to buy winners are not the class for whom we primarily write. Many a poor man has been led by a first victory with his home-reared chancicleer to turn more attention to and lay out more money on his poultry yard. Whatever discourages such people does harm, and absurdly high entry fees necessarily do discourage them. The possessor of "certain winners" pays them as a speculation. The diffident beginners hesitate risking so much on a hazy chance.—C.

OUR LETTER BOX.

Rabbits (T. J.).—It is contrary to our practice to recommend dealers; besides, we are not acquainted with the breed you name. Is not the designation a local one?

Victoria White and Uxbridge Wheat (Bailiff).—These are distinct varieties and both very good. The Victoria grows rather taller than the Uxbridge White and has longer heads, but does not always give a better yield of grain.

REMARKS.

24th.—Fine pleasant day, but not very bright.

25th.—Fine bright day.

26th.—Cloudy day, with one or two slight showers.

27th.—Cloudy day, with a shower in the afternoon.

28th.—Beautiful spring-like day; cloudy evening; rain at night.

29th.—Heavy rain early; dull damp morning; fair afternoon; cloudless night.

30th.—Damp cloudy day, with frequent slight rain.

On the whole an unsettled and rather showery week, but not so wet as would appear from the total rainfall, as a very large proportion of it fell during the night of Thursday. Temperature very near the average, and remarkably accordant with that of the preceding week.—G. J. SYMONS.

VARIETIES OF PEACHES AND NECTARINES.

AS the time has arrived for planting these from the nurseries, it has occurred to me that a few remarks upon the merits of old and new varieties might prove acceptable to many readers. At any rate I shall open the subject, both because I always enjoy writing upon and comparing the relative values of different varieties of fruits or vegetables, and also because my remarks may elicit the opinions of others corroborative of or in opposition to my own experience: I do not propose to confine myself exclusively to present experiences, but shall allude to what has come under my notice in former situations and also in the gardens under the charge of practical men.

There is no doubt the introduction of late years of remarkably early varieties of these two fruits has much simplified their culture, as we are now able to secure very early crops without much hard forcing, this in some instances amounting to a considerable saving in fuel. Unfortunately the fruit of several of the Peaches more especially, for which we have to thank the late Mr. Rivers, are small in size—in fact are oftentimes below medium, this consequently rendering them of much less value than would otherwise be the case. There is no disputing the fact that not only must we grow heavier crops than of old, but the size of the fruit must in nowise be diminished. Small and colourless fruit are of comparatively little value, especially in the markets, and for this reason such varieties as Early Beatrice, Early Louise, Early Albert, and Early Alfred will never be grown extensively. At the same time one or more of them ought at present to be included in every collection, whether where early forcing is resorted to, where only one house is devoted to Peach and Nectarine culture, or where they are grown exclusively on the open wall, simply because their extreme earliness insures a more lengthened supply than was possible at one time.

On the open walls in Middlesex I have grown good-sized specimens which perfected fair crops of the four varieties above mentioned, but taking into consideration our limited space, the conclusion arrived at was that we had at least two varieties too many. Early Beatrice, being decidedly the earliest, was retained; so also was Early Louise, this being about a week later, larger fruited, and of superior quality to the former. Early Albert and Early Alfred ripening about the same date as the latter did not equal, so far as quality was concerned, the glowing descriptions given of them by competent authorities; in fact, to form a succession to Early Beatrice I now prefer Hale's Early, this to be followed by Early Grosse Mignonne. Hale's Early has proved disappoint-

ing to some growers, simply because they received a spurious form. The true variety, such, for instance, as has been grown for several years by Mr. Austin of Ashton Court near Bristol, grows freely, is very early, and the fair-sized fruit are highly coloured and agreeable, though not remarkably rich in flavour. This and Alexander, another American variety, if all accounts are true, will eventually supersede the early English-raised varieties. I find Alexander grows most satisfactorily, and have confidently planted it in the early house to take the place of worn-out older kinds. Early Rivers I am unacquainted with. It is described as being the "finest early Peach in cultivation," and I should be glad of further information concerning it, and also the extremely handsome *À Bec*. Early York does not succeed well in the open here, as it is much attacked with mildew, and the fruit lacks sweetness. This and Acton Scott, which at one time was particularly useful for an early supply, may well be struck out of the catalogues, as they are not now required. Crawford's Early is very distinct, the fruit being large, of a rich lemon colour, tinged with pale red next the sun; but I am not favourably impressed with the quality, as, although melting and juicy, it appears to lack briskness—in fact, is rather flat. Exquisite, also of American origin, much resembles it in general appearance, but is a fortnight later. I recently found on testing that it was scarcely so exquisitely flavoured as the name would suggest. Both look well on the exhibition table.

Of the various main-crop varieties I am acquainted with I am of opinion that few equal and none surpasses Grosse Mignonne. I have grown it and its synonyms Neal's Purple, Royal Kensington, and Padley's Purple under glass and in the open in four widely separated counties, have seen it growing in many more, and in each instance it proved most serviceable. It possesses a good constitution, sets freely, the fruit swells to a good size, is highly coloured, and sufficiently melting, rich, brisk, and juicy. Bellegarde, slightly later, is more popular among exhibitors and growers for market, and no collection may be said to be complete without this extremely highly coloured variety. According to my experience, however, it is less vigorous and scarcely so good in quality as the foregoing. Royal George is, perhaps, the best known second early or main-crop variety, and probably when in good condition there is no higher-flavoured delicious Peach cultivated. Unfortunately this again is very liable to mildew both in a young state and also when well established. This is especially the case when grown in unheated houses and on the open wall. One of the best and most profitable trees we have in a late house is labelled Millett's Mignonne, and this I find to be synonymous with Royal George. Noblesse is one of the most delicious Peaches grown, but it often lacks colour, and appears to be of weakly constitution. Like other large-flowered varieties the blooms are deficient in pollen, and a good set is not easily secured. I have seen it very good in second early and late houses, but never particularly good on open walls. Chancellor is now seldom met with, and I am not surprised at it, as I find it comparatively worthless; in fact, this and Lord Palmerston have turned me against varieties the flesh of which is very deep red next the stone. I have given both a second trial, but although the trees have the best positions in the houses they are both rooted out. Lord Palmerston is remarkably handsome when in flower, and the fruits grow to a great size; but for dessert purposes it is worthless, and not particularly

good in tarts. I may be somewhat singular in my experience with it, as I hear it secured first honours at the recent grand fruit show at Edinburgh. The decision, however, I was informed was a surprise to many practical gardeners. Red Magdalen here forms a handsome healthy tree, and is very productive. The fruits do not attain a great size, and are not remarkably good in quality. Princess of Wales proves excessively vigorous in a second early house, and good crops are not easily secured. The fruits attain a great size, but are a rather sickly yellow in colour, and not always of the best quality. It is of somewhat the same parentage as Lord Palmerston, and very red at the stone. In our case it will be gradually cut away in favour of Walburton Admirable. The latter, though presumably a late variety, succeeds admirably in the second early house. It grows vigorously without the growth attaining objectionable grossness, sets fairly well, and swells a heavy crop of large handsomely formed fruit; colour, however, is generally wanting. All who have tasted fruit from this tree express themselves delighted with its superior quality. It is rich, juicy, and melting, and deliciously cooling in a marked degree.

Barrington is grown for a late supply both under glass and on the open wall, but I am not particularly enamoured of it, as many of the fruits are in the habit of falling before being quite ripe, and in this state prove quite sour. Synonymous with this variety is Buckingham Mignonne, but the tree we have under this name behaves no better than the rest. Sea Eagle I hear highly commended, and should be glad to learn further of this presumably good late variety.

As will be seen, I have not attempted to minutely describe the distinctive flavours of the different varieties of Peaches; and although Nectarines still more widely differ in this respect, I must not trust to memory, nor indeed to my taste, in describing these. The best well-known variety is Elruge, but I prefer the Downton to it, as this I find more robust, the fruit larger, very highly coloured, excellent in quality, and it will continue to be grown to succeed Lord Napier. The latter I consider to be the most valuable of Mr. Rivers' introductions, as it is found the earliest and very good wherever grown. It is not so highly coloured as is desirable, green largely predominating, especially early in the season, and I have seen but few notable exceptions. The flesh is melting, juicy, brisk, and sweet; Pine Apple, however, is the most delicious of all Nectarines, and it also possesses a good constitution. It is rightly said to be an improvement on Pitmaston Orange, as with us the latter is inclined to crack, and is not so highly coloured or richly flavoured as the other. White Nectarine seldom ripens to perfection, and is not worth growing. Balgowan is one of the best for wall culture, especially as it is hardy and vigorous. The fruits are large and attractive in appearance, and generally sweet and juicy. I have not tried it under glass. Prince of Wales, I am credibly informed, is not a very robust variety, but is much liked by a friend who grows it on a light soil and in a warm position. The fruit is rather deceptive in appearance when ripe, as the skin is nearly green, with a little red next the sun; I was, however, agreeably surprised on tasting it, as it is much better than it looks. For a late supply Victoria is much liked by some. At Wilton House, near Salisbury, it proves very free-growing and serviceable, and is considered much superior to the Stanwick. Hunt's Tawny, unfortunately, is of poor quality, otherwise it has much to recommend it, especially for open-wall culture. I have known it to succeed where all others failed.—W. IGGULDEN, *Frome*.

CONSERVATORIES IN SUMMER—GESNERIAS.

As a rule, conservatories and other structures in which flowering plants are expected to be found are the least satisfactorily furnished during the summer and early autumn months. In winter there is no lack of plants for rendering those structures attractive, while in the spring the chief difficulty is often how the plants at disposal can be arranged effectively, so great are the numbers; but as summer approaches its zenith and merges into autumn the plants that are usually flowering in conservatories may generally be found in better condition in the open air.

It will not be denied that conservatories, to be to the fullest extent agreeable, should be furnished with plants dissimilar from

those which abound in the flower garden. Even Roses, beautiful and admired as they are in pots in the spring, are not longed for under glass in summer, such having at that time a thin, worn, and washy appearance in contrast with the health of the examples, massive and rich, which luxuriate at the same time in outdoor beds and borders. It is the same with Pelargoniums of the zonal type; bright and varied these useful plants are, but to see them in fullest beauty under glass we must have them in their best garb from November till June, not from June till November. Rich, luxuriant, well-cultivated examples during what may be termed the dull period of the year command admiration; but crowded in conservatories in the summer, dried and drawn, with withered leaves and dropping petals, they do not invite a second glance. Instead of being attractive there and then they are repellent. Plants of a totally different character are requisite for furnishing houses effectively from July onwards, and thus we have recourse to Ferns and sundry fine-foliaged plants, with, in their season, Tuberous Begonias, which combine elegance with brightness and chasteness; Achimenes, cool yet cheerful; and Gloxinias, incomparably the most beautiful of all dwarf-growing plants, but seldom fresh after July. In addition to the plants named, and to continue the display beyond them, so as to meet the Chrysanthemums and winter zonals, we want something, not as mere makeshifts for filling a blank and occupying space, but plants possessing intrinsic and undeniable elements of beauty—pleasing habits, handsome foliage, and elegant yet rich and variedly coloured flowers in abundance. These we have in Gesnerias, or, as they are known by continental nurserymen who have raised so many beautiful varieties, Nægelias.

No one who has seen the establishment of Mr. Van Houtte near Ghent during August and September, and inspected the thousands of Gesneriaceous plants there flowering, can fail to have been impressed with their beauty and precise adaptability for summer decoration. Stately yet sturdy in habit, with the central stem and branching spikes covered with flowers—crimson, scarlet, orange, yellow, pink, rose, blush, and white—relieved by magnificent foliage, these plants are candelabras of beauty. Yet how seldom we see them grown as they should be in this country. Possibly they may be kept in the background, because they are rarely staged at public exhibitions, less seldom submitted for certificates, and thus are not being constantly "mentioned" in the press. But Gesnerias, or Nægelias, are not exhibition plants—their nature is too fragile to enable them to travel well. They are essentially home plants, and those who have them and grow them well possess a great advantage over those who do not possess them, and who desire to have attractive houses during the period in question. Yet while they will not endure the rough treatment that is inseparable from exhibiting, they are by no means transient when grown for the home stage and kept there; on the contrary, they continue attractive for weeks, and with a sufficient number of tubers, and starting them periodically, flowering plants may be had if needed all the year round. Indeed, although prominent attention is now given to the plants for summer decoration, some of them are not surpassed by any plants in existence for rendering cool stoves and warm conservatories brilliant in the depth of winter. Those who have not seen a houseful of such forms as *G. cinnabarina*, *G. exoniensis*, and *G. refulgens* during January and February have a floral treat in store if they will obtain these kinds, the former especially, and grow them well. They will have fiery pyramids surpassing even Poinsettias, dazzling as a mass of those plants is admitted to be. This, however, is a digression, but will be pardonable as showing the great usefulness of these too much neglected plants.

Only those who have hothouses can have a display of Gesnerias in winter, but all who have a Cucumber frame in which to start the tubers and establish the plants, and a greenhouse or close pit to grow them in, may have a rich late summer or early autumn display just when indoor flowers are scarce, while the plants will fade and can be removed by the time the space is required for storing for winter plants that have until then been kept outdoors or in cold frames. Thus, while Gesnerias are attractive and serviceable they are also accommodating, as after growth has ceased and the plants withered the pots can be stored under the stages until the time for starting the tubers again comes round. In their dormant state, however, they are not safe in a very cold position, and should not long remain in a house where the temperature falls below 50°.

As to culture, they require the same general treatment as Gloxinias—namely, light, free, gritty soil for starting the tubers, and care in watering the young plants; stronger and richer soil afterwards, subdued light, a moist genial atmosphere, no sharp dry currents of air, and never to permit the plants to be rootbound before they are placed in the pots in which they are required to

flower. For summer flowering the tubers should be started with Gloxinias and Achimenes, or a trifle later, say in April; for winter and spring flowering in July or early August.

As to varieties that are good they are very numerous, and as long lists are not infrequently more perplexing than useful, only half a dozen varieties for summer shall be named now—the most distinct in the collection now flowering at Chiswick. It was the inspection of the bright group there that prompted these notes; and thus the old garden proves its usefulness in not only testing things that are new, but in showing the merits from time to time of plants that are generally overlooked or neglected. There is nothing now so attractive under glass in the Royal Horticultural Society's Garden as the Gesnerias or Nægeliias, and the following are among the best in the collection.

Penelope.—Salmon rose tube, deep rose segments, white and mottled crimson throat; fine spikes and good habit. Very effective.

M. Pollux.—Rich glowing rosy crimson tube, with paler mottled segments; fine symmetrical spike. Very pleasing.

Franklin.—Deep velvety scarlet tube, throat and lobes mottled with white. Neat habit.

Horace Vernet.—Orange scarlet, brighter than the preceding with whiter lobes; dwarf habit. Rich and glowing.

Brèguet.—Pale rose tube with deeper lobes mottled with white. A strong grower with good spikes. Very useful variety.

Jeannot.—Flowers rich uniform chrome yellow, symmetrical spike; very rich dark velvety foliage, the contrast in colours being very striking.

It should be remarked that all the varieties named have handsome foliage, this adding materially to the attractiveness; indeed it is a question if there are any plants that possess in combination the three qualities—beautiful leaves, bright attractive flowers, and a pleasing habit of growth, more markedly than those under notice; hence they are worthy of record here, and for growing for the better embellishment of conservatories in summer.—EXPERIENTIA DOCT.

NOTES ON PEARS.

To have Pears in good condition through the winter months they must be grown on walls, except the early kinds, which to my mind produce fruit of much better flavour, if not quite so large, on espalier and pyramid trees. Pears that are in season from November onwards should be grown on walls having south or west aspects. I think an east aspect—although I have had the management of Pear trees on such aspects—had better by far be planted with Plums, as it must be a favourable season to obtain good crops of Pears there. The ground for Pears should be prepared in the same manner as recommended for Apples in a former article (page 291), and the trees planted in the same position of the garden as recommended for Apples.

As to the stocks employed for planting, I shall recommend the Quince, as in my experience it is the best stock, and comes into full bearing much sooner than trees do that are worked on the Pear stock; but the trees must be well attended to. Some people think that Pears on the Quince are short-lived. If the trees have not been worked low enough or not planted in properly prepared soil they are; but if the ground has been well prepared before planting, and the trees well attended to as regards surface-dressing and adding fresh soil to the roots when needed, they will succeed. Be careful to select trees that have been worked low enough, so that the union of the stock and scion is beneath the surface.

Some persons may say they have handsome trees on the Pear stock that bear annually large crops of fruit. No doubt they have. I have seen such trees, but they require a much larger space than the others; besides, as I have mentioned above, they do not commence bearing nearly so soon. Some kinds I would plant on the Pear stocks, as they do not succeed so well on the Quince, such as Williams' Bon Chrétien, Winter Nelis, Easter Beurré, Knight's Monarch, and Beurré Clairgeau. The latter as a rule is not worth eating, but it does for a show Pear. Marie Louise succeeds both on the Quince and Pear stock.

Pears on the Quince stock for walls or espaliers should be planted 12 feet apart, pyramids 6 feet apart, and when they almost touch each other every alternate one may be taken out. I would also recommend a cordon Pear wall to those who require the greatest number of varieties in a given space. These should be planted 18 inches apart. The first season train them at an angle of 60°, the next season bring them down to 45°, or at least all that have grown freely. These may be kept in good health for a number of years if not overcropped, the roots being at the same time surface-dressed, and at intervals of a few years have

good turfy loam placed round them after the old inert soil has been removed.

The following are useful kinds for succession. Early Pears for pyramids or espaliers—Beurré Giffard, Williams' Bon Chrétien, Beurré d'Amanlis, Beurré Hardy, Beurré Superfin, and Pitmaston Duchess. The following for south or west walls—Marie Louise, Doyenné du Comice, Beurré d'Aremberg, Josephine de Malines, Winter Nelis, Glou Morceau, Passe Crassane, Knight's Monarch, and Bergamotte Esperen.—A. YOUNG.

SINGLE DAHLIAS AT TOTTENHAM.

FIVE acres of single Dahlias in bloom has not yet become so common a sight as to rank amongst the things which tire by their sameness and repetition. Probably, indeed, the display now provided in Mr. T. S. Ware's Hale Farm nurseries has never been equalled either in extent and beauty, and it may therefore be fairly considered as unique. It is doubtful, also, if so extensive a display will be again seen, for the object of planting so many has been simply 'a utilitarian one—that of selection—which, having been accomplished, those excluded from the place of honour will be promptly destroyed. Thus another season the stock will be much smaller, including only the finest and most distinct amongst hundreds of seedling forms, many of which are the results of crossing with the best of the types now in cultivation. As might be readily imagined, the variation in colour and form of the flowers, habit, &c., is very great; all shades of colour, from the deepest maroon through scarlet, orange, and yellow to white, are represented, the flowers varying in form from the star-like earlier type to the broad rounded florets and symmetrical flower of the handsome White Queen. In habit, too, there is every gradation from the most slender and graceful to the most robust and compact; but all the selected forms agree in a remarkable floriferousness, though even amongst the best some surpass others in this respect. It is not easy, however, to select a few where all are so good, but the following amongst the novelties are especially worthy of note:—Darkness, rich deep crimson; Duke of Teck, fine mauve tint, dwarf; Francis Fell, warm deep purple; Harlequin, deep rose banded with purple; Lutea grandiflora, Sunflower and Yellow Queen, the best yellows, of great excellence, fine flowers, and very free; Mauve Queen, beautiful shape and soft tint; Nora, pink, bushy; Thalia, rosy, very free and dwarf; William Gordon, pink and mauve shaded; Rob Roy, brilliant scarlet; and White Queen, the finest white. Of several seedlings raised from Paragon Pantaloon is the best variety, very distinctly marked, tipped with white. Amongst the older but not less beautiful forms the following dozen include the leading varieties: Ascalon, deep rosy purple; Beauty of Cambridge, intense crimson, very handsome; Fusilier, white shaded pink; Painted Lady, delicate pink; Pompeii, rich crimson; Gracilis, ardens, elegans and perfecta, scarlet and crimson forms of that elegant Dahlia; Orangeman, deep orange; Paragon, maroon edged with purple; and Wilmott, peculiar rosy tint. To these may be added the Dahlia Zimapani, also known as Bidens atro-sanguinea, and Cosmos diversifolius atro-sanguineus, a small-flowered form which is not considered as a true Dahlia, though it much resembles that genus in all respects. It is similar in habit to *D. glabrata*, but has deep maroon, almost black flowers.

An experiment has been made in this nursery, the success of which deserves attention, as a similar practice might be advantageously adopted in many gardens. A number of the single Dahlias were planted in a bed, and when the shoots became of sufficient length they were pegged down closely to the surface. The lateral growths subsequently made, with the points of the stems turning upwards as they advanced, have now clothed the bed with abundance of flowers a foot to 18 inches or 2 feet above the soil. In this way they are seen to excellent advantage; and further good results are observable, for the strong-growing varieties, which under the ordinary system are frequently so luxuriant that few flowers are produced, are sufficiently restricted by pegging them down to greatly increase their floriferousness. Some charming examples of autumn bedding might be produced by various applications of this idea, which will be more extensively tried at Tottenham another year.—VISITOR.

THE ROSE ELECTION, 1882.

It was rather to be expected that any attempt to arrest the introduction of "too much alike" Roses would not be universally popular. This, I doubt not, many feel. Having all of us our own likes and dislikes, and with the natural pertinacity of us islanders for our own opinions, I suppose some of us think that one or other of the bracketed "too much alike" Roses of the National Rose

Society's catalogue is hardly dealt with. Personally I rejoice that some attempt has been made to stay the introduction of novelties at novelty prices, that are scarcely to be distinguished from old friends except by their clothing. If we say that two persons are very much alike we mean that the face and features are similar;

and however dissimilar the clothing and dress may be, we still consider them alike. So it seems to me with the Rose: if the blooms are so similar as to be taken for the same, the habit and foliage are surely secondary matters. Personally, then, I congratulate the compilers of the National Rose Society's catalogue on their attempt and the lines on which they have gone. To small growers it would indeed be an advantage if every Rose worth cultivation and not considered "too much alike" was certificated from the National Rose Society's Committee, and, at any rate as regards new introductions, some such scrutiny might be advantageous.

This present election will serve to show out of this class of Rose the most generally useful, and this will certainly prove advantageous to all beginners. Those limited in ground and pocket may select the better of the set and discard the rest. The catalogue of the National Rose Society must, however, as it appears to me, become an annual or biennial at the least, and taken as an exhibition catalogue it will surely need some additions. Only 166 H.P. Roses are named in the whole catalogue, counting all those named "too much alike" or not. In former elections the number of Roses named has amounted to close on two hundred varieties; and although by the sub-Committee's first resolution very tender Roses or those of "extremely delicate growth" are almost excluded, yet it seems to some amongst the electors, and I confess to joining the number, that the list of exhibition varieties must be extended if the catalogue is to be considered complete. Whilst stating this as evidence on the part of some electors that the list of Roses considered exhibition varieties should be more comprehensive, I may also state that some of the electors have urged that future catalogues should go further in the way of classification on the "too much alike" plan.

It will, I think, be generally conceded that A. K. Williams is by far the greatest acquisition that rosarians and Rose-lovers have received for many years. Last year, when under five years old and probably but slightly known by some electors, it nevertheless at the first attempt obtained a position amongst the leading dozen. This was no slight proof of its excellence. From the tenor of some electors, and my experience agrees with them, it is not as robust as one could wish, but others have advanced an opinion exactly the reverse. I trust the future will prove the fears groundless, for certainly this variety is a glorious flower, perfect in form and brilliant in colouring. In commenting on the election of 1881 in the "Rosarians' Year-Book" I expressed the thought that this variety would be that which would in a few years contest with the faultless Marie Baumann the pride of place. I little thought the prediction would so speedily be verified. For many days the returns placed the pair neck and neck, and only at the end of the papers was the old queen reinstated in that position which she has held for some years. Even the greatest admirers of A. K. Williams will allow that in one respect the lady is superior—she gives a larger proportion of exhibition blooms throughout the season. So amongst the Roses as amongst the human race, "*place aux dames*."

Altogether there are sixty-six electors, the following counties being represented—viz., Kent by nine; Surrey, eight; Hereford, five; Essex, Herts, and Sussex have each four; Cambridge, Cheshire, Devon, and Oxfordshire are represented by three; Glamorgan, Norfolk, Notts, Wilts, Warwickshire, and Yorkshire have each two; whilst one return has been received from each of the following counties—viz., Bedford, Berks, Derby, Durham, Gloucester, Leicester, Lincoln, and Somers-

RESULT OF THE POLLING.

Position in General Election 1881.	No.	Name of Rose.	Date of Introduction.	Paisier's Name.	Amateurs' Votes.			Total.	Nurserymen's Votes.			Total.	Grand Total.

* The Roses bracketed together here are considered as "too much alike." The first named in all cases receives the greatest number of votes.

set. So that no fewer than twenty-four counties are represented. To obviate the difficulties felt by some exhibitors in comparing the relative merits of Teas and Noisettes with the other varieties of the Rose the two classes have been kept distinct. Note must be taken of this, as some of the Roses not of Tea character will necessarily rank rather higher than in the election of 1881.

Thanks to the National Rose Society's catalogue the few missing dates and raisers' names are now nearly complete, and I think these elections may lay claim to the idea of fixing the ages and raisers of many of the varieties.

The table is now well known, and it is only necessary to remind our readers that the first, second, and third columns of figures under both amateurs and nurserymen mean respectively that the votes given represent first twelve, second twelve, and next twenty-four.

Three other Roses received 9 votes, five 8, five 7, six only 6, eight were only named five times, six had 4 votes, nine only 3, twenty-nine had 2 votes, whilst forty-one only received a single vote; and in summing up, counting the "too-much-alike" as a single Rose, 187 Roses have been named. It will be noticed by those persons who possess the catalogue of the National Rose Society that in the seventy-five Roses tabulated are two Roses not to be found in the catalogue—viz., Constantin Tretiakoff and Mrs. Jowitt. The former is with me very distinct; the latter is thought by some to be too much like Marie Rady. Time will show.

As in the last election, the test of first-class votes only, shows a very rapid falling-off; still, this is not so marked as last year. This proves that after all there are but few Roses that command universal homage. I give the first-class votes.

E. Y. Teas			

In each case of the "too much alike" Roses only the highest is mentioned.

It only remains for me to mention the names of the electors, to whom we are all indebted for making returns. It is a stereotyped phrase that I tender them my sincere thanks, but it is truth; to one and all I tender them, and to not a few I feel grateful for their kind appreciation of the work.

Amateurs.—Miss Bulmer, Broadlands, Hereford; Revs. W. Ager, Faringdon; H. B. Biron, Lympne Vicarage, Hythe; C. H. Bulmer, Credenhill Rectory, Hereford; A. Cheales, Brockham, Reigate; H. H. D'Ombra, Westwell Vicarage; E. L. Fellowes, Wimpole Rectory, Cambridge; J. M. Fuller, Bexley Vicarage, Kent; L. Garnett, Christleton Rectory, Cheshire; W. J. Jackson, Stagsden Vicarage, Bedford; F. J. Jenyns, Knebworth Rectory, Stevenage; J. H. Pemberton, The Round House, Havering-atte-Bower; F. Roberts, Scole Rectory, Norfolk. Messrs. G. Baker, Holmfels, Reigate; J. Brown, gardener to G. A. Waterlow, Esq., Great Doods, Reigate; Burnside, Farningham; Burrell, Heighington, Darlington; J. Choyce, Pinwall Grange, Atherstone; Evans, Marston, Oxford; Fewkes, Tyburn, Erdington, Warwickshire; F. H. Gall, Hope Cottage, Hitchin; W. J. Grant, Hope End, Ledbury; T. Graveley, Cowfold, Sussex; T. B. Hall, Larchwood, Rock Ferry; W. Harrington, Corbels Tay, Romford; T. B. Haywood, Woodhatch Lodge, Reigate; Hinton, Warminster; E. Mawley, Lucknow House, Addiscombe, Croydon; W. Moore, The Gardens, Coedriglan, Cardiff; G. Mount, Harbledown, Canterbury; L. C. Norris, Trumpington, Cambridge; F. C. Pawle, Northcote, Reigate; J. D. Pawle, Wray Park, Reigate; Ridout, Reigate; A. Slaughter, Jarvis Villa, Steyning; A. G. Soames, Waltham Hall, Grimsby; Sparke, Rooklands, Torquay; J. Tranter, Upper Assenden, Henley-on-Thames; W. H. Wakeley, Macklands, Rainham; E. R. Whitwell, Barton Hall, Darlington—forty.

Nurserymen.—Messrs. Bunyard & Co., Maidstone; Cant, Colchester; Cranston & Co., Hereford; Curtis, Torquay; Davison, Hereford; Dickson & Son, Chester; Durbin, Englishcombe, Bath; Ewing & Co., Eaton, Norwich; Farren, Cambridge; Francis and Co., Hertford; Frettingham, Beeston, Notts; Keynes & Co., Salisbury; Kinmont & Kidd, Canterbury; Jefferies & Son, Cirencester; Laing & Son, Forest Hill; Mack & Son, Catterick Bridge;

Mitchell & Son, Uckfield; Merryweather, Southwell, Notts; Paul and Son, Cheshunt; Perkins, Coventry; Piper, Uckfield; Prince, Oxford; Proctor, Chesterfield; Rumsey, Waltham Cross; Tresseder, Cardiff; and Walton, Exeter—twenty-six.

Messrs. Cooling of Bath also made a return, but it arrived too late—after all the placing was complete—and only their return of Teas could be used. Their return scarcely altered the position of the leading twelve. The Tea Rose election will be published next week.—JOSEPH HINTON, Warminster.

NORTHWARDS.

WHEN we consider that upwards of twenty express trains have rushed from the metropolis to Scotland laden with their living freight every day for the last two months there is some reason for London being what is termed "empty," although a stranger would not know that it is so, and the great rendezvous of tourists in the north full; and when we consider also the wear and tear of London life, and the at times stifling murky atmosphere, there is no wonder that all who can do so should make their escape from it for a time and enjoy the pure breezes of the Heath-clad hills.

Fig. 55.

My escape from the "Modern Babylon" was by the favourite morning express from St. Pancras, a choice that left no regrets, as on the new Settle route is seen some of the grandest, wildest, loneliest scenery that is to be found in England, while at the same time there was no lingering, only four minutes of time being lost in the four hundred miles between London and Edinburgh. I had thought enough had been said about the great Show there, but there appears a disposition to say more. I, however, will leave the debatable theme, and record a few memories of a northern tour.

Edinburgh and its nurseries merit a note in these pages, which are scanned by many a "canny Scot;" but these nurseries will be described by another pen than this, wielded by one to whom the establishments are familiar, while I pass on and record brief jottings on the woody slopes of ancient Keir, the mountain gorges of the Trossachs, the wondrous picture of Grapes at Clovenfords, the grandeur of Drumlanrig, and, to change the theme, a scene of sadness—the sick bed of one whose writings in this Journal have awakened a large share of interest during the past few months—"SINGLE-HANDED."

That familiar signature has been missed of late by many, but few can know the reason of its absence, and all will now regret the cause—illness protracted and dangerous. The once strong man, physically and mentally, is stricken down. His gigantic frame is wasted, but

his mind is as clear as ever. Composed, even cheerful, one almost forgets his critical state. Of all who fear he fears the least the issue, whatever it may be. Some words of his I cannot forget—"You may never see me in the flesh again, but I would like to live a few years longer for the *puir bairns'* sake." It is hard to think that one just in the ripe vigour of manhood will not survive his affliction. We will all hope earnestly that his strong constitution will prove the victor over the serious internal malady; and he may now be assured that on the appearance of these lines a bond of sympathy will be flashed on a thousand breasts towards him and with his family in their lonely Scottish home among the hills. Before proceeding further, as he would be the last to wish us to tarry, and casting aside any depressing feelings since he is so cheerful, we will register an earnest and united wish and prayer for the restoration of "SINGLE-HANDED." And now we change the scene, and in thought go back to

EDINBURGH.

In situation perhaps unequalled, in appearance imposing, this is emphatically a city of contrasts—one part, as Sir Walter Scott has said, "exhibiting the full tide of existence, pressing and precipitating itself forward with the force of an inundation; the other, dark with the smoke of ages, resembling some time-worn anchorite," with the "misty mountain" of Arthur's Seat overshadowing all. In gardening we find contrasts too, at least as violent as can be found elsewhere, for we have close together perhaps the best examples of roof gardening and ditch gardening that are to be found in the kingdom—the former on the top of the Waverley Market, the latter in the grand ravine (once the protecting fosse of the frowning old castle) that stretches along the south side of Prince's Street.

Wonderful is the improvement that has been effected here during the past few years by the skilled city gardener, Mr. McLeod. The deep steep slopes of the great ravine, once covered with scrub and rubbish, are now smooth velvety lawns, with bright groups of colour, chiefly in the carpet style, surrounding the trees, and filling in angles where they show to advantage. This system of decoration when imperfectly carried out or displayed in incongruous positions no doubt merits the scoffs of those whose life work would appear to be to pedantically write it down, but to assail it when well done in positions such as this is vain. The clearly defined bright lines and circles of colour are far more effective as viewed from distant and elevated standpoints, as is the case here, than any mixtures of herbaceous plants could be. There are proper positions for both examples of garden adornment, but the right place for the latter is not in this fine ravine—yept the Prince's Street gardens of Edinburgh.

The roof gardening, too, is of its kind excellent. The great Waverley Market, it must be stated, is in a fringe of the ravine, the roof of the building being level with Prince's Street. This is laid out as a garden, and so admirably is it done that a stranger would never suspect that the fine promenade of cement walks, the long curving borders of flowers, the carpet beds, the patch of lawn, and numerous well-filled vases along the balustrades, were arranged on the top of what may be termed a gigantic hall. But they are, and the effect is most pleasing. All forms of decoration are represented here—ribbon gardening, panel gardening, subtropical gardening, carpet bedding, excellent in design and execution, with annuals and herbaceous plants in suitable places in the borders. The bronzed vases, numbering considerably over a hundred, are a fine feature, relieving the flatness that would otherwise prevail. They are not trim and formal, but clothed with a floral drapery of Tropæolums, Sweet Peas, and similar free-growing plants that surround the Cordylines or Aloes that occupy the central position. The character of these vases is fairly represented in fig. 55, and the appearance of such a number in an enclosure of about 150 yards by 60 can be better imagined than described. The garden is surrounded by palisading, and the drainage from the beds is conducted into pipes close to the roof inside the building. They are not seen unless sought for, and the whole arrangement is a great success.

We hear, from time to time, of roof gardening in London as represented by a small conservatory; but all the roof gardens in the metropolis put together bear no comparison with this solitary example at the top of the Waverley Market, Edinburgh. Even in one of the nurseries—Messrs. Downie & Laird's—there is a better, and decidedly more useful, representation of housetop gardening than is to be found in the possession of any "city" firm, but this will be more fully referred to in the following notes that have been placed at my disposal. The civic authorities and Mr. McLeod are to be congratulated on the success in rendering their fine city so attractive, and it is gratifying to learn that their excellent work is widely appreciated. There are other public gardens in the city, but those alluded to must suffice as a type of what is accomplished in the direction indicated.

THE PILRIG AND REDBRAES NURSERIES.

These belong to the well-known firm of Messrs. Dickson & Co. This nursery and seed business has been established in Edinburgh for one hundred years. The great Loudon spent many of his youthful days as an operative here; and it may well be surmised that the nursery occupied a prominent position then, but not more so than now, as all kinds of indoor plants, fruit trees, forest trees, shrubs of every description—in short, everything connected with the garden, forest, and farm, are to be found here extensively and well cultivated. Only some of the main features of the business can be briefly noted. From

the seed warehouse of the firm, No. 1, Waterloo Place, trams run down Leith Walk to the Pilrig Nurseries. Telephone communication also exists between the two, which are a mile or so apart, and this is found to be of the greatest convenience to the firm and customers generally.

The Pilrig Nurseries stand on a fine open space, and there the principal houses and pits have been erected on a commodious scale, alike convenient for working and comfortable for visitors, as a lean-to corridor facing the south-east extends to a length of 180 feet, and from this access is obtained to seven span-roofed houses, which are arranged at right angles, and are 70 feet long each. No. 1 is the Camellia house, and it contains plants from one year old to splendidly furnished specimens 16 feet high clean and healthy. There are also many splendid specimens of Tree Ferns in this house arranged along the centre, and have a very imposing effect. There are also some fine plants of the Himalayan Rhododendrons, and one of the best examples we have seen of *Phormium tenax Veitchianum*. It flowered profusely throughout the summer, and has produced a fine lot of seed. A *Maréchal Niel* Rose, worked on the Briar seven years ago, covers a large area on the roof of this house, and produces large quantities of useful blooms early in spring. No. 2 house is devoted to *Ericas*, *Epacris*, and other hardwooded greenhouse plants, all unusually clean and healthy, and the edge of the stage on each side was fringed with a white *Lobelia* named Pilrig Park. It is a compact grower, good in colour, and a most profuse flowerer. No. 3 house is in two divisions, both compartments being devoted to Ferns, one for propagating young plants, and the other for containing them in a more advanced stage of their growth, all the best known kinds being represented. No. 4 house contains young stove plants—healthy *Crotons*, *Dracænas*, *Aralias*, *Palms*, &c.; and besides many small plants of the popular *Eucharis amazonica* there are some splendid specimens which produce large quantities of their charming flowers two or three times annually. Of climbers there is a choice variety, and a healthy and varied batch of Orchids occupy one part of the stage. A fine stock of the variegated Pine Apple also deserves notice, as it is one of the finest varieties of the kind we have seen. No. 5 house is well filled—in one part with *Gardenias*, or small healthy plants well set with flower buds; and here we found a batch of new *Coleus*, which for size of leaves and chasteness of colours outdistance most other members of this numerous family, and no doubt more will be heard of these in due time. No. 6 house was gay with *Liliums* and double-flowering *Primulas*. The red variety of the latter, known as *Stewartii*, is noticeable for the robustness of its constitution and its free-blooming properties. In this house are also fine batches of *Solanums*, winter-flowering *Heaths*, *Fuchsias*, *Pelargoniums*, &c. The last house in the range, No. 7, is devoted to a miscellaneous collection of hardwooded greenhouse plants, choice in variety and excellent in quality.

The corridor, before referred to, is in four divisions. The first division is filled with a large quantity of young Indian *Azaleas*, brightened with well-flowered *Begonias* and autumn-flowering *Chrysanthemums*. The second is full of various kinds of fine-foliaged plants; and the third is a fernery arranged in a natural style, most of the tables being faced with cork bark, which associates well with the Ferns, and has a very effective appearance. The back wall of this house is also very beautifully decorated with *Lycopods*, Ferns, *Begonias* of the *Rex* section, *Anthericum*, &c., and the result is in every way pleasing. The fourth and last division is filled with a choice assortment of greenhouse *Rhododendrons*. In addition to the glass houses just noticed there are extensive ranges of span-roofed pits in several divisions of 50 feet each, which are used chiefly for the propagation of the finer Japanese and other Conifers, newly grafted *Rhododendrons* and *Camellias*, which are here worked on an extensive scale. There is also a large seed warehouse here, and an office containing the nursery end of the telephone. Long rows of frames are attached to the general buildings, and are completely filled in autumn, winter, and spring with young stock of Show and Fancy *Pansies*, bedding *Violas*, *Pentstemons*, *Phloxes*, *Pinks*, *Carnations*, of which many fine varieties have originated here, *Picotees*, and all kinds of florists' flowers. Plants of a new class of *Pinks* are noteworthy for their dwarfness. They are of various colours, and can be grown without tying or staking. They open their first flowers with the dawn of spring, and never cease their production until the autumn frosts come.

An extensive piece of ground is devoted to hardy flowers and herbaceous plants of all the popular kinds, with a fine collection of single and double *Dahlias*. American plants, *Kalmias*, *Ghent Azaleas*, *Menziesias*, and hybrid *Rhododendrons* are largely grown. Hardy *Heaths*, too, are well represented in many large beds, and in a collection such as this some are always in bloom; as many of them flower as freely in December as others do in July. They should be largely grown in private gardens.

A portion of the nursery is occupied with beautiful specimen *Hollies*, including *Golden Queen* and all the best sorts; also other evergreens of all kinds, an excellent assortment of Conifers and deciduous trees, flowering shrubs and fruit trees in varieties, which are found to succeed in the north. *Bothwell Bank Prolific Strawberry*, which we have found superior to *President*, a new variety lately distributed by this firm, was growing in large quantities, and the demand for it is very great.

Redbraes is the name of another Edinburgh nursery belonging to this firm. It is very ornamental in aspect, having a fine pond in the

centre, with an island here and there; and the banks which slope to it are planted with choice specimens of Conifers, but the main quarters are filled with large batches of *Rhododendron ponticum* for game coverts, and Laurels of various kinds, including *colchica* and *rotundifolia*, two of the hardiest and most vigorous varieties of the common Laurel. Japanese Coniferæ were plentiful here, the Golden Box (*B. Fortunei*) being very conspicuous. A number of houses are devoted to the rearing and growth of young Vines, and just now they are full of well-developed canes, short-jointed and well matured, for planting or fruiting in pots. The walls which surround the whole were covered with well-trained healthy Peach, Apricot, and other fruit trees.

The forest tree department is a great and important feature of the firm. The trees are grown in various nurseries on the outskirts of the city, one of the principal places being on the farm of Liberton Mains, three miles to the south of Edinburgh. This farm of 400 acres is occupied by Mr. Robert Black, who, along with his farming, combines market gardening on an extensive scale; and the system adopted by Messrs. Dickson & Co. is to take a piece of land from which some green crop has been cleared, plant it with one or two-year-old seedlings of Larch, Scotch Fir, Oak, Chestnut, Beech, or any other sort of tree they grow in large quantities, and after these have been grown there for two or three years they are ready for the market, and the ground from whence they are cleared is given back to be cropped as farm land. By this system the trees are always planted and reared on fresh ground, which keeps them clean and vigorous. The trees are here also allowed plenty of room for healthy development. We never observed finer plantations of forest trees, but probably some share of this may be attributed to the selection of seed, as the firm gives special attention to this; their Scotch Firs, for example, being collected in one of the finest old forests in the Highlands. At Liberton they also grow their Roses, of which they have a healthy and extensive stock. Some of those budded last autumn have made shoots 5 feet in length.

Notes on other nurseries will appear in a future issue.—J. W.

ORCHIDS IN OCTOBER.

THIS is a good time to examine the *Masdevallias* and repot them. Where large masses have died in the centre they should be shaken out, all the decayed parts removed, and the healthy pieces potted separately. The best material for potting these in is a mixture of peat, leaf soil, broken crocks, and rough sand, with a surface dressing of live sphagnum moss.

Odontoglossum Alexandræ, *Pescatorei*, and others which may require it, should be repotted, or top-dressed with good fibrous peat, surfacing with sphagnum, and just giving sufficient water to keep it fresh.

Plants of *Lælia Dayana*, *L. præstans*, *Cattleya marginata* and *C. pumila*, which have their young growths well advanced, should be removed to the *Cattleya* house, as they will be greatly benefited by a little heat now.

Plants of *Odontoglossum vexillarium* which have not been removed ought also to be shifted to the *Cattleya* house, and likewise *Cælogyne barbata* and *crinata*, which are showing, as the flowers are apt to suffer from the damp atmosphere of the cool house. The night temperatures should now be as follows: East Indian house, 60°; *Cattleya* house, 55°; and cool house, 50°.

Though this is a dull season for Orchid blooms, yet the houses are enlivened by a few plants, amongst the most notable of which are the following:—*Aerides nobile*, with its long pendent spikes of large creamy-white flowers spotted with rose. *Barkeria elegans* with rosy lilac blooms, with a rosy white lip with purple blotch; it lasts in perfection for nearly two months. *Cattleya Schilleriana* bearing olive green flowers sprinkled with brown, with a white purple-veined lip; this does well either on a block or in a pot. *Odontoglossum vexillarium Leihmanii* is a variety bearing smaller but darker-coloured flowers than the other varieties of *vexillarium*. *Oncidium curtum* has chocolate and yellow blooms, with large, bright yellow, chocolate-margined lip. *O. flexuosum* has brown-spotted bright yellow blooms. *O. Forbesii* is bearing numerous yellow-margined chocolate-coloured flowers. *O. oblongatum* has long spikes of bright yellow blossoms; and *O. tigrinum* has yellowish green blooms, with large citron-coloured lip, exhaling a Pine Apple-like odour.—ORCHIDIST.

VALUE OF EARTH-CLOSET MANURE.—“INQUIRER” has drawn attention to the circumstance that on two occasions I have given different amounts of the ingredients to be found in this substance. I may perhaps be permitted to recall that these were arrived at in two different ways. On the first occasion I took Dr. Voelcker's estimate (modified by Dr. Gilbert's) of the value added to soil by passing through a closet in a particular instance; but the soil itself in that case contained a considerable amount of potash, and I credited a portion of this to the excreta. In the second instance I calculated from the average ingredients of excreta alone, with a

small proportion of urinc. Hence a discrepancy, which is, however, trifling, except in the matter of potash. Whether Mr. Taylor's soil contained potash or not cannot be told till it is analysed; but my sole purpose was to show that, whether his soil was rich or not, it at all events received an addition which made it a rich dressing when applied in the quantities which he has informed us he used. Having shown this in two different ways I have nothing further to add.—J. B. K.

ALPINE STRAWBERRIES.

PERHAPS it may be serviceable to some of your younger readers if I give a short account of a very useful little Strawberry that is grown here—the Alpine, its value consisting in its continuous fruiting. I gathered the first dish in May, and there has not passed one week since but I could have gathered a dish more or less large. I have this day (October 2nd) gathered fruit, of which I send you a fair sample; and if the weather continues mild I shall be able to obtain several more dishes from the same bed. In size and quality the Alpine is, as most persons know, inferior to the general garden Strawberry, but on account both of its earliness and lateness I think it is invaluable and worthy of a place in many gardens where it is not at present grown. The plants of which I write were raised from seed supplied by Messrs. Suttons of Reading three years ago, and their treatment since then has been of the roughest. They were planted in the first piece of vacant ground that was available, which happened to be on a south border; and there they have been ever since, nothing having been done to them except clearing off the runners at different times; but in future I intend for them to have more attention, for I think that a dish of Strawberries at the present season from the open ground is not to be despised. I daresay they would not do equally well in all places, but at least I think they are worth a trial.—J. S.

[This communication reached us with the following note, which we print for the information of other correspondents who may have sent fruit through the post and lost it.

“Returned Letter Office, General Post Office, London.
“Oct. 4, 1882.

“SIR.—I have to inform you that a packet addressed to you containing fruit from which liquid was escaping, injurious to other correspondence, has this day been destroyed, it being contrary to regulations to allow such matter to circulate through the Post Office. Cover and letter sent herewith.—G. R. SMITH, Controller.”]

PHOSPHATE OF MAGNESIA, WHAT IS ITS MANURIAL MONEY VALUE?

IN my first letter on this subject (p. 290) I alluded to the part taken by salts of ammonia and organic matter in aiding the solution in water of phosphates, and in my last (p. 317) I alluded to the wonderful fact that all fertilising elements in the soil must, before they can be absorbed by plants, be again fixed and rendered insoluble by water, or, as Liebig terms it, be physically combined with the soil. In my present communication I propose to enter more particularly into this phenomenon, and inquire into the existing theory of plant-nutrition as taught by Liebig, Voelcker, and other chemico-agricultural writers, for without entering into this question I should be unable to pursue advantageously, particularly to the non-chemical reader, my examination into the value in agriculture of phosphate of magnesia.

In the first of the propositions put forward by Dr. Voelcker to make his present views on phosphates clear, which I quoted in my last, he distinctly refers to his opinion on the physical-combination theory of plant-nutrition; but I shall make use of the writings of Liebig to lay the question before those sufficiently interested in the subject to follow my arguments thus far, not only because he was the first, as I believe, to propound these truths clearly, but because I cannot hope to find any other exposition of them which puts the matter so simply. I cannot do better than refer the reader to Liebig's treatise on the “Natural Laws of Husbandry” or his “Letters on Modern Agriculture” for a perfect view of his reasonings, and I must content myself here with making a few extracts from them. I ought to state, however, that the first discovery of the surprising fact of the fixation by soils of potash, ammonia, phosphoric acid, &c., is due to Professor Thomas Way.

“We have hitherto believed,” says Liebig in explaining the present view of the nutrition of plants, “that plants received their food from a solution, and the rapidity of its effect was in direct proportion to its solubility.” “We believed that water was the carrier of the most remote elements of the soil to the immediate presence of the plant.” “But all this has been a great mistake. We have inferred, from the effect of water and carbonic acid on rocks, a similarity of action in soils; but this conclusion is false.”

"By the simplest experiment anyone can satisfy himself that rain water filtered through field or garden soil does not dissolve out a trace of potash, silicic acid, ammonia, or phosphoric acid." "The soil does not give up to the water one particle of the food of plants which it contains. The most continuous rain cannot remove from the field, except mechanically, any of the essential elements of its fertility." "If rain or other water, holding in solution ammonia, potash, phosphoric and silicic acids, be brought in contact with the soil, these substances disappear almost immediately from the solution; the soil withdraws them from the water. Only such substances are *completely* withdrawn by the soil as are *indispensable* articles of the food of plants; all others remain wholly or in part in solution." "If freshly precipitated *phosphate of lime, or phosphate of magnesia*, be dissolved in water saturated with carbonic acid, and filtered in like manner through soil, there will not be found a trace of phosphoric acid in the filtered water. A solution of phosphate of lime in dilute *sulphuric acid*, or of *phosphate of magnesia and ammonia* in carbonic acid water, comport itself in the same manner. The phosphoric acid of the phosphate of lime and the phosphoric acid and ammonia of the magnesian salt remain in the soil." "Charcoal reacts in a similar manner with many soluble salts; it removes colouring matter and salts from solution;" "but the constituents of the soil take part in its action, and hence it must in many cases be quite different from that of charcoal."

"Potash is found in all our land plants, but soda forms only an exceptional constituent of their ashes. From sulphate and nitrate of soda the soil withdraws only part of the soda, but the whole of the potash from the corresponding potash salts." Liebig convinced himself that in a garden soil, rich in lime and $2\frac{1}{2}$ acres in extent, 10,000 lbs. of potash would be absorbed from a solution of silicate of potash, and retained for the use of plants. "A similar experiment," he says, "made with a solution of *phosphate of magnesia and ammonia* in carbonic acid water, showed that a $2\frac{1}{2}$ -acre field would withdraw 5000 lbs. of this salt from such a solution. A loam (poor in lime) produces the same effect."

"These facts give us some conception of the powerful action of soils, and of the strength of their attraction for three of the chief elements of the food of our cultivated plants, which, in consequence of their solubility in pure and carbonic acid water, could not be retained in the soil did the latter not possess this power of attraction."

"There can be no doubt, from the action just described of soil on potash, ammonia, and phosphoric acid, that the majority of our cultivated plants cannot receive out of a solution from the soil their essential mineral constituents." "These substances are present in the soil somewhat like colouring matter in charcoal or iodine in starch, fit for absorption by the rootlets of plants, but not by themselves soluble in rain water or removable by this solvent until the soil is saturated with them. It is more than probable that it is assigned to the majority of our cultivated plants to receive their nourishment directly from the portions of the soil which are in immediate contact with their rootlets, and that they die when their food is presented to them in solution." "From the action of soils already described, it follows that plants must themselves play some peculiar part in the absorption of their food. As organised living structures, their existence is not quite dependant on external causes." "They select from the soil those substances which they require, but which can only pass into the interior of their organisms by the co-operation of a cause which resides within the rootlets."

"By its decomposition in the soil humus forms a source of carbonic acid, by which the fixed elements of food are rendered soluble and capable of being distributed in all directions." "Like carbonic acid water, the sulphate, as well as the other soluble salts of ammonia, possesses the property of rendering the earthy salts soluble in water."

"We know of no other way in which the earthy phosphates are dispersed through the soil than by means of carbonic acid water. If it is true that one of the chief effects of humus, or the decaying remains of plants in soils or in manures, consists in its forming a source of carbonic acid, with which the air and the water of the ground is enriched: if it is also true that this carbonic acid water renders the earthy phosphates soluble, and thus contributes to their distribution in the soil, then there can be no doubt that the salts of ammonia, which possess the same solvent property, can in this respect replace the organic matters, and thus exert an equally favourable influence on the growth of plants." "The same solvent property is also possessed among the salts of soda by Chili saltpetre and common salt. It has been recently shown that these two salts, even in the most dilute solutions, dissolve earthy phosphates to a very appreciable extent, and that consequently they must play a part in the process of the nutrition of plants similar

to that which is ascribed to carbonic acid and water (to the humus) and salts of ammonia."

"The seeds of the cereals, particularly Wheat, contain phosphate of lime, and in preponderating quantity phosphate of magnesia. In many kinds of Wheat the quantity of phosphate of magnesia is four times, often ten times, greater than that of phosphate of lime; and in like manner in the grain of Rye, Oats, and Barley the magnesia salt exceeds very greatly the phosphate of lime. These proportions are so constant that they cannot be ignored in the cultivation of these plants. The comportment of the salts" (nitrate of soda and common salt) "above mentioned towards phosphate of magnesia and ammonia and phosphate of magnesia appears, therefore, of special interest."

Liebig goes on to show that the solubility of tribasic phosphate of magnesia is, in a solution of nitrate of soda, 4.5 grains in a gallon; and, in a solution of common salt, 5.3 grains in a gallon; and that the solubility of phosphate of magnesia and ammonia is much greater—viz., in a solution of nitrate of soda, 9.8 grains in a gallon; in a solution of common salt, 8.6 grains in a gallon; in a solution of sulphate of ammonia, 8.6 grains in a gallon. "It is quite conclusive from these facts," he adds, "that water containing a very small quantity of common salt, nitrate of soda, or sulphate of ammonia acquires thereby the power (which alone it does not possess, or only in a slight degree), of dissolving phosphoric acid in the form of earthy phosphates. These feeble solutions, therefore, react towards earthy phosphates like solutions of carbonic acid in water."

It also appears to me to be equally conclusive that to estimate the value of phosphates of lime and magnesia without reference to the salts of ammonia, or to the organic matter capable of yielding carbonic acid which is present in the manure, must be incorrect; and that, "like the salts of ammonia or a watery solution of carbonic acid produced by the decay of organic matter in manures, a solution of these salts" (nitrate of soda and common salt), "wherever they come in contact with spots containing accumulations of earthy phosphates not fixed by the soil, must become saturated with these phosphates, and thus convert them into a condition in which they can be diffused through the ground."—
INQUIRER.

AT a general meeting of the ROYAL HORTICULTURAL SOCIETY, held October 10th, Geo. F. Wilson, Esq., F.R.S., in the chair, the following candidates were unanimously elected Fellows—viz., Mrs. Gilbert à Beckett, Dr. M. F. Anderson, A. F. Govett, H. Herman, Mrs. Montagu, Mrs. Frank Schneider, and Dr. J. P. Stratton.

— THE "Belgique Horticole," referring to ERYTHROCHÆTE PALMATIFIDA, of which we recently gave an illustration, states that the plant was introduced from Japan to the St. Petersburg Botanic Garden about 1864 by M. Maximowicz.

— AT a meeting of the Horticultural Club, Ashley's Hotel, Henrietta Street, Covent Garden, held on Tuesday night, a very excellent PORTRAIT OF MR. JOHN LEE, the Chairman, was uncovered. It was subscribed for by the members of the Club, and suspended in the room as a mark of the high esteem in which Mr. Lee is held by a large circle of friends.

— MR. GEORGE BOOTHBY, Louth, has sent us flowers of a SEEDLING FUCHSIA, which he considers an improvement on any others of the type. The flowers are certainly very large and double, the petals broad and nearly pure, the sepals elegantly reflexed and deep coral red. If the habit of the plant is good and the flowers are freely produced, the variety will be valuable for decorative purposes.

— A CORRESPONDENT desires to accord the following word of praise of SINGLE DAHLIAS:—"For effect in masses they are charming, and as single specimens they are very telling. In groups, with colours blended, they make showy beds, and are

considered by many superior flowers to the double varieties. For use in vases and dinner-table decorations, they have the advantage over all other Dahlias, being more graceful. They ought to be grown in all gardens. The following sorts I find good—Paragon, lutea, coccinea, alba, Cervantesii, Stella Bianca, and Painted Lady.”

— WE are glad to hear that the FREEHOLD OF THE OLD FULHAM NURSERY of Messrs. Osborn & Son, which was offered for sale at the Mart, Tokenhouse Yard, by Messrs. Protheroe & Morris on Thursday last, has been bought by Messrs. James Veitch & Sons of the Royal Exotic Nursery, King’s Road, Chelsea. This nursery is the oldest of the existing metropolitan nurseries, and was founded in the beginning of the last century. It has always had a high reputation for its fruit trees, its collection of ornamental trees and shrubs, and at one time it possessed the richest collection of herbaceous perennials which was to be found near London. It is well to know that this historic nursery, so closely associated as it is with the history of English gardening, is not to be handed over to the tender mercies of the enterprising builder, but will become an adjunct to that equally notable firm of James Veitch and Sons, who will in future carry on the Fulham business in conjunction with their own at King’s Road, Chelsea.

— THE Commissioners of Her Majesty’s Works have issued the customary autumn notification that they intend shortly to distribute SURPLUS PLANTS FROM THE LONDON PARKS among the working classes. If the clergy, school committees, and others interested will make application to the superintendent of the park nearest their respective parishes, or to the Director of the Royal Gardens, Kew, or to the Superintendent of Hampton Court Gardens, in the cases of persons residing in those neighbourhoods, they will receive early intimation of the number of plants that can be allotted to each applicant, and of the time and manner of their distribution.

— MR. GEORGE RUDD of Undercliffe, Bradford, is now sending out his new PICOTEES MRS. RUDD and SARAH ELIZABETH. The former is a heavy edge, described by the raiser as a seedling from Edith D’Ombrain, with deeper colour and smoother edge than that fine variety. It has a large broad petal, free from spots or bars, and the nearest approach to a self-dressed flower he has yet seen. The latter is a light red-edged seedling from Thomas William; a large full flower with a true wire edge, and is a strong grower. The new white Clove Virgo, which has been recently described, is also now being distributed by Mr. Rudd.

— A SCOTTISH correspondent asks a question RELATIVE to EARLY ROSES which we shall be glad if any of our readers can answer:—“Please name a Rose or two having all the good qualities of Gloire de Dijon, but a month or two earlier in blooming.” We should like a few Roses of the nature indicated, but almost despair of finding any flowering a “month or two” sooner than the old favourite.

— WHEN any kind of tropical fruits become plentiful upon the London hawkers’ barrows it may be safely concluded that the culture of that kind has been largely extended in some suitable part of the world. This would appear to be the case with POMEGRANATES, which every year seem to become more abundant in the metropolis, and it is quite common at this time of year to see large barrowloads in the streets. The fruits, too, are offered at a merely nominal price, some fine ones being sold at two for a penny, such as a few years ago could not have been purchased for less than 3*d.* or 4*d.* each. Like the Pine Apples and Bananas, these are now evidently imported in large quantities, some of which must be sold in the first instance at exceedingly low prices.

— THE peculiar but brilliantly coloured ANTHURIUM ANDREANUM appears to be advancing in favour, judging by the fact that

in one of the florists’ shops at the Covent Garden Market we recently observed about a dozen handsome spathes. We have previously noticed a few small samples on several occasions, but these were unusually fine, of great size, and the glossy scarlet hue most striking, the white base of the spadix seeming by contrast to render the richly tinted spathe even more prominent. That this species will ever become as popular or as generally useful as *A. Schertzerianum* can scarcely be expected, yet the strangely puckered appearance of the spathes and the unrivalled colour will doubtless cause it to be largely grown.

— A BRISTOL correspondent writes:—“However deserving of commendation LORD NAPIER NECTARINE may be for cultivation under glass or in a warm soil, it has proved a great disappointment to me here on a coldish clay soil even so far south as the neighbourhood of Bristol. I obtained a tree from Messrs. Rivers four years ago, which now covers about 100 feet of brick wall with a good aspect, where Peaches and Nectarines in general are of excellent quality; but it has so entirely failed to ripen its fruit the two years it has borne, that I am about to destroy it and plant a second tree of Hale’s Early Peach, which I find a first-rate variety.”

— RELATIVE to the VALUE OF MANURES Mr. A. Boyle writes:—“In answer to Mr. Peter Ferguson, page 298, he appears to be unaware that the richer the food of animals the more valuable the manure, even though the diet of both may be classed under the same head. For instance, that from animals who get oilcake is much more valuable than what comes from those which do not.” This is no doubt correct; hence in some counties it is customary for the incoming tenant of a farm to pay a large share of his predecessor’s cake bill of the previous year on proof being submitted that the cake has been consumed on the farm.

— THE October issue of the “Botanical Magazine” gives a very good plate of *LILIUM PARRYI*, a charming South Californian species now well known to most lovers of such plants, as it was discovered about six years ago, but it is as yet very scarce in cultivation. The beauty of the plant has been admirably shown at Kew this summer, where a specimen on the new rockery has flowered grandly and attracted the attention of many who had not previously seen it. The flowers are of moderate size, the petals narrow and slightly recurved, of a bright yellow colour, the anthers being brownish. The stem is about 3 feet high, with lanceolate leaves in whorls. The raceme is a foot or more in length, also having the flowers in whorls of three to six. Sir Joseph Hooker states that “*L. Parryi* is a native of the San Bernardino mountains, Southern California, on the borders of the Arizona desert, at an elevation of 4000 feet. It was found in the Potato patch of a settler in a boggy soil.”

— THE schedule of the KINGSTON CHRYSANTHEMUM SOCIETY announces that the sixth annual Exhibition will be held in the Drill Hall, Kingston, on Thursday and Friday, November 16th and 17th of the present year, the usual liberal prizes being offered in numerous classes. There are, however, two classes of special interest—namely, those in which the champion challenge vases are offered, and the competition in these alone will undoubtedly render the Show one of the most important of the season. It will be remembered that the first vase has been won in the three years—first by Mr. G. Harding, gardener to T. Galpin, Esq., Putney Heath; second by Mr. W. Tunnington, gardener to Chas. MacIver, Esq., Liverpool; and third by Mr. F. Faulkner, gardener to F. R. Leyland, Esq., Liverpool, the competition this year being confined to those exhibitors. That all will try their best for the final success this year there can be no doubt, and it appears extremely probable that the contest will be exceedingly close and keen. A second vase of equal value to the first—*i.e.*, twenty-five guineas,

with £3 in money, is offered this season also for forty-eight Chrysanthemum blooms, comprising twenty-four Incurved and twenty-four Japanese, the three winners of the first vase to be excluded from competing for this one. Thus some others of the many good growers will have an opportunity of testing their strength.

— THE *Chambre Sydicale des Horticulteurs Belges* of Ghent have issued a circular in six languages, stating that the following resolution has been agreed to in reference to an INTERNATIONAL CONGRESS OF HORTICULTURISTS:—"In order to give to the representatives of horticultural industry of all countries the occasion to extend mutually their commercial relations and discuss their common interests, an international meeting of horticulturists will take place at Ghent in April, 1883. The programme will be published in due time. As this meeting will coincide with the great quinquennial international flower show organised by the Royal Agricultural and Botanical Society, interesting entertainments will be offered to the Congress members."

— BORDERS OF HARDY PLANTS are still attractive where proper attention has been given to including in the collection late as well as early-flowering plants; and though the numbers of the former are more limited than those of the latter, yet the great family *Compositæ* affords abundance to select from. One of the finest borders of this kind we have seen recently is at Kew near the T range, which has been greatly admired by all visitors. As a background numerous clumps of the floriferous and beautiful *Pyrethrum uliginosum* are particularly fine, bearing a profusion of their large pure white blooms. Near these the early-flowering varieties of *Chrysanthemum indicum* form a pretty contrast, the bright rosy crimson form *Adrastus* being especially good. Dwarf and tall purple, blue, and rose *Michaclmas* Daisies are freely employed, together with the dwarf yellow *Compositæ*, such as *Coreopsises*, *Chrysanthemum segetum*, *Helianthus multiflorus*, and many others. Single Dahlias are similarly planted in suitable positions, and a most satisfactory effect is produced, which will last until the frosts become sufficiently severe to injure the plants.

— IN the ORCHID HOUSE AT KEW several plants are now flowering that are worth the attention of growers. Conspicuous amongst them is the charming *Comparctia macroplectron*, for a plant of which it will be remembered that Mr. Heims, gardener to F. A. Philbrick, Esq., Oldfield, Bickley, obtained a certificate at one of the Royal Horticultural Society's meetings this year. It has drooping racemes of mauve-coloured flowers, the sepals, petals, and broad rounded lip being spotted with bright rose—a pleasing and delicate contrast. *Spathoglottis Fortunei* is a pretty dwarf species with neat bright yellow flowers that are produced very freely, and would be extremely useful for cutting. The remarkable *Cypripedium Spicerianum* is bearing one of its striking flowers, the large white dorsal sepal having its margins revolute, and appearing almost funnel-shaped. Near it is the neat and bright purple *C. purpuratum*, which is not too frequently seen in collections. As a curiosity may be noted the peculiar *Gongora Bufonia luteochilum*, which has a pendulous spike of reddish flowers with yellow lips, the structure being very peculiar. In the porch *Pleione Wallichiana*, *P. lagcnaria*, and *P. maculata* are flowering profusely, near them being the richly coloured *Pinguicula caudata*, which has again commenced flowering. This beautiful species, as we have frequently noted, is almost constantly in bloom, and the fine crimson hue of its flowers is unrivalled.

ROSES AT THE AUTUMN SHOWS.

Now that the principal shows of the year are over, and before arrangements are made for next year, permit me to call attention to a grievance of Rose-growers which a stroke of the pen may set right to the mutual advantage of show managers and exhibitors.

In the schedule of prizes at a show held in September there are liberal offers for Roses—forty-eight varieties in bunches of three

trusses, or 144 flowers; twenty-four varieties and twelve varieties, both in bunches of three trusses, or six dozen and three dozen in the respective classes. "Why were you not at the show?" was asked of a Rose-grower whose name is well known as a prize-winner at metropolitan shows. "Simply because I was excluded," said he. "Who is able to find three really good flowers of each of forty-eight, twenty-four, or even twelve varieties at this season of the year?" "Certainly not those who exhibited," I replied, "for there were not more than three or four really good triplets even in the first-prize stands."

Now at a season of the year when really fine flowers are so few and far between that we may reasonably regard any one of them as "the last Rose of summer," surely it would answer best to confine every class to single flowers or trusses, not simply because even the largest growers must then find it difficult, almost impossible, to stage an entire stand of triplets worthy of a prize, but rather that it would be quite certain to materially increase the number of entries, and, what is even more important, secure the exhibition of many more good examples of such general favourites.

"Can that possibly be *La France*!" said a lady to me at the show in question. Yes, it was undoubtedly *La France*, but not easily recognisable under its autumnal guise, the small flowers having none of its attractive summer brilliancy. "Not bad for this season of the year" perhaps, and in point of fact is, often said in reply to such strictures. But the wisdom of offering what may be fairly termed unreasonable prizes for any flowers is certainly questionable. Rather let them be so modified to what is possible in autumn as to secure for the Rose as high a place then among the other exhibits as it has in summer, and this can only be done by the exclusion of triplets.—EDWARD LUCKHURST.

A TOMATO TRAP FOR INSECTS.

I HAVE lately found out something in this way which is new to me. In washing out some Tomato seed the other day I was called away, and left a teacup half full of seeds, pulp, and water. To prevent this from moulding I placed the cup close to a hot-water pipe in one of the vineries, and next morning the cup was almost full of dead woodlice, crickets, earwigs, and all kinds of insects which are fond of harbouring in warm corners or about glass houses. They were all mixed up together, as if there had been a general scramble as to which was to get in first. Owing to this little could be seen of our valuable seed, which we had lately brought from Scotland; but the satisfaction of securing such a haul of those general garden pests so unexpectedly fully compensated for the loss of the seed. The following night and other nights afterwards we repeated the dose with some worthless Tomatoes, and the result was the same as in the first instance. Now we are using this trap about the pits and where the pests indicated are troublesome, and to all appearance they will soon be all caught. We have never been able to find anything which took them in so completely before, and I would be pleased to hear of anyone trying it as successfully as we have done.—J. MUIR, *Margam*.

FRUIT-JUDGING AT EDINBURGH.

THE gentlemen who acted as fruit judges at the late International Fruit Show were as follows:—Messrs. D. Thomson, Drumlanrig Castle; A. F. Barron, Chiswick; J. Smith, Mentmore; G. Smith, Vice-regal Lodge, Dublin; A. Fowler, Castle Kennedy; Z. Stevens, Trentham; A. Henderson, Thoresby Park; J. Webster, Gordon Castle; T. Lunt, Ardgowan; W. Bennett, Rangemore; and J. Dell, Stoke Rochford. If no other fact than the above had been mentioned I think enough would have been said to satisfy most of your readers that justice was done to every exhibit set before them. However, "H. B." seems to think otherwise (see page 289), and attributes the result to the deception of the eye "in the grey of the morning." The fact is, the Veitch Memorial medals were awarded to the finest Grapes and the best collection of fruits at about nine o'clock, when the sun was high and shining brightly. So much for "the grey of the morning."

Nothing can possibly be more distasteful to me than even seeming to praise my own and disparage the exhibits of my respected brethren; but as "H. B." has considered it part of his duty to question the verdict of the Judges and the excellence of my exhibits, allow me to say a few words in reply.

In the first place, the Society offered the prizes in the premier Grape class for the best twelve bunches, and the Judges did award the first prize to the undoubted best twelve bunches in the competition. In cases like this it requires something more

than simply the best varieties ripe and fit for table "early in September."

Your correspondent seems to have made a great hit when he discovered in the class for twelve dishes of fruits that the third-prize collection ought to have been first, also that Charlotte Rothschild Pine Apple in the first-prize lot had a few green streaks round some of the pips. Well, it did have the blemish of wanting another day or two to finish it perfectly; however, the fruit being in every way symmetrical, and weighing 8 lbs. 9 ozs., no other fault could be urged against it. I wonder "H.B."

did not see the Queen Pine at the other end of the collection; this was as perfectly finished as any Pine in the Show, and weighed 5 lbs. 6 ozs., or about the weight of the two Pines in the third-prize put together.

Again, "H. B." says every dish in the third-prize was fit to put on the table of a prince. On the exhibition table there were staged seventeen collections of twelve dishes each, and in my opinion any or all of the 204 dishes might be fit to put on the table of a prince. It was a matter of common comment on the spot that perhaps the poorest dish of fruit on the whole table

Fig. 56.—ÆSCHYNANTHUS SPECIOSUS.

was the dish of Nectarines in the said third-prize collection. The Muscat of Alexandria Grapes in this lot were indeed far from first-class. "H. B.," I think, ought in fairness to have mentioned the fact that it took three bunches to cover a very moderate-sized stand, and these had their shoulders padded with wool in order that they might appear presentable. The colour, too, was somewhat different from those that won the Veitch Memorial medal.

Apples in a class like this, be they ever so good, are somewhat common, and I think "H. B." in criticising the decisions of the Judges in some other cases would have done well to have noticed the Figs as well as the Peaches. Here in the small competition the large Figs were passed over, they being from the same source

as came the Figs in "H. B.'s" fancied third-prize collection.—J. MACINDOE, *Hutton Hall*.

[This is equally a reply to "A SCOTCHMAN," on page 318, and shows that "H. B.'s" letter is not "unanswerable."]

ÆSCHYNANTHUSES.

GESNERIACEOUS plants are some of the most brilliant ornaments of our stoves, the majority of them producing very gaily coloured flowers in abundance, and these seem even more attractive in comparison with the rich diversity of foliage which Palms, Crotons, Dracenas, Alocasias, and innumerable others present.

Gesnerias, Tydæas, Gloxinias, Achimenes, and Streptocarpus include many handsome plants of great value not only for the stove but for cooler houses also, though the majority are more at home in a rather high temperature.

The genus *Æschynanthus*, to which especial attention is now called, similarly comprises several species of much beauty, particularly as basket plants, for which their epiphytal and pendulous habit well fits them, and in gardens where they are carefully grown no better plants for that purpose could be desired. The rich scarlet and orange shades distinguishing their flowers are unrivalled, and the blooms, being produced in large trusses or clustered closely along the stems, have a very imposing appearance when pendulous from elegant baskets near the path of a stove. They are not more difficult of management than many other epiphytal plants; but it is no use attempting their culture in any house where a high and moist temperature cannot be maintained with regularity, and perhaps most failures that occur in the growth of these plants is due to a misapprehension of their requirements in this respect. The baskets should be prepared in the ordinary way with a layer of large potsherds and some pieces of charcoal, over which a layer of rough moss or peat can be placed, upon which the plant should rest, with good fibrous peat in lumps placed firmly round the roots. Water must be liberally but judiciously supplied; and if at any time the temperature becomes unduly reduced the amount of water given must be proportionately limited, or the plants will soon become extremely unhealthy, and when once they get into that state it is very difficult to ensure their recovery.

A few of the species are adapted for culture in pots, the best of these being the one represented in the engraving, as it is of more erect and sturdy growth than the majority, and the large trusses of flowers being borne at the apex of the stems in an erect manner, and are seen to much better advantage in that way than when in baskets. Some cultivators prefer peat alone for this species under pot culture, with thorough drainage, but I have found a little turfy loam incorporated with the peat is beneficial. But in that case sand should be also used, unless the peat contains a large proportion. Both the basket and pot plants must have a warm position in the stove, and then little difficulty will be experienced with them.

Of the species in cultivation, that shown in fig. 56—viz., *Æ. speciosus*, is one of the most handsome, its large scarlet and orange flowers being produced in trusses of sixteen to twenty, and with several of these on a plant of moderate size in a 48 or 32-size pot the effect is most striking. Another valuable quality it possesses is the remarkable durability of the flowers, which last in good condition for some weeks. Like several others of this genus, we are indebted to Messrs. Veitch & Sons for the introduction of this plant, which was found by Mr. Thomas Lobb growing upon trees in damp woods on Mount Asapan in Java at an elevation of 2000 feet. *Æ. fulgens* was also collected by Mr. T. Lobb in Moulmein. It approaches the above in habit, but is more drooping. The leaves are large and ovate, the flowers being 3 inches or more long, scarlet streaked with yellow in front, and are borne in large heads.

Æ. cordifolius, obtained by the same collector, is a native of Borneo, with leaves and flowers of moderate size, the latter about 2 inches long, deep scarlet streaked with black in the throat, and produced in pairs or triplets in the axils of the leaves. This is well suited for a basket, as also is its near relative *Æ. tricolor*, both being of slender habit. The last-named is similarly a native of Borneo, whence it was obtained by Messrs. Low of Clapton. It has small ovate leaves, the flower being about 1½ inch or 2 inches long, scarlet streaked with yellow and black, being borne in the axils of the leaves. *Æ. javanicus* is a showy form, with deep scarlet flowers streaked with yellow, and borne in the axils of the leaves near the point of the stems; while *Æ. Lobbianus* ought to be included in every collection, its rich scarlet corollas contrasting so well with the deep purple calyx. All these succeed best in baskets.—L. CASTLE.

SCRAPS ABOUT FRUIT.

LAST year under the above heading there appeared a miscellaneous collection of very interesting information which I had been hoping to be commenced again this year, as there surely must be much more for many of us to learn. By way of starting the train again I would bring under the notice of your readers a few fruits.

THE PINE APPLE RUSSET APPLE.—This is a most delightfully aromatic-flavoured Apple. It ripens well here even in unfavourable seasons. It is small, but makes up for that in its extra good-

ness. It somewhat resembles in flavour the Cornish Gilliflower; but as it ripens earlier and in more unfavourable seasons I think it is a superior kind to grow, and no one will regret adding it to his dessert list.

THE DYMOND PEACH.—Has this Peach borne out the high character it received last year for hardiness and certainty of crop? for if it has stood its ground in such a bad Peach year as this it ought to be better known. Messrs. Lucombe & Pince of Exeter kindly favoured me with a few buds in summer, but unfortunately they were not sufficiently matured; and coming in dry cotton wadding, they were so shrivelled that, though the bark of the bud has taken well to the stock, I am afraid the buds will fail to push in spring.

SENDING BUDS BY POST.—On this subject of budding some may not know that in having buds sent by post the blade of the leaf should always be cut off, leaving only the stalk; the scion with the buds on it should then be rolled in damp wadding. It will in this way come a long distance, even in hot summer time, without injury to the buds; but before working them the scion had better be put in rain water till bark and buds have plumped up again, if they have been at all withered.

REINETTE FRANCHE APPLE.—Two or three years ago I bought in a fruiterer's in Paris a most excellent deliciously flavoured Apple, somewhat above medium size, round and without ribs; skin greenish, turning to brownish yellow on the sunny side, and covered by light grey russet—answering, as far as my memory goes, to the description in the "Fruit Manual" of Reinette Franche, but on asking the name all I could learn was that it was Reinette. Now I want to know, Is this Apple grown any place in England? If it can be grown as good as I ate it in Paris no garden should be without it, as it was far superior to any American Apple I have ever tasted; and yet, though I have consulted the fruit catalogues and many of the chief growers in England, and written about it to numbers of nurserymen, I cannot hear of it being procurable anywhere.

THE COLUMBIA PLUM.—This is stated in the "Fruit Manual" to be sometimes as much as 2 inches in diameter and an excellent fruit; yet no nurseryman seems to think it worth while growing, and outside of the "Manual" it seemed to be unknown.—IRISH RECTOR.

[The description in question of this Plum was of American-grown fruit. We have found that the fruit does not attain the same size in this country, and the variety does not appear to be well adapted to our climate.]

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 10TH.

ONE of the largest and most interesting meetings that has been held for some time was that of Tuesday last, when plants, flowers, and fruits were shown in large numbers, the Council-room and vestibule being well filled. The single Dahlias, Roses, and large collections of Apples and Pears were the great features of the display.

FRUIT COMMITTEE.—Harry J. Veitch, Esq., in the chair. Mr. R. Gilbert, The Gardens, Burghley House, Stamford, exhibited a green-flesh Melon of moderate size named Burghley Pet, said to be a cross between Netted Victory and Dickson's Exquisite. The flesh was deep, juicy, and of an exquisite rich flavour. A first-class certificate was awarded for it. A letter of thanks was also accorded to Mr. Gilbert for bunches of Gros Maroc, Gros Colman, and Black Alicante Grapes, the berries of good size and beautifully coloured. A certificate was also awarded to Mr. Taylor, gardener to J. McIntosh, Esq., Duneevan, Oatlands Park, Weybridge, for a Codlin-like Apple erroneously named Landsberger Reinette; the fruits of pyramidal form, the apex of the fruit pentagonal, the eye deep, pale yellow with a slight rosy tinge on the side next the sun. Mr. C. Howe, The Gardens, Benham Park, Newbury, sent some handsome Cucumbers named Challenger, a cross between Freeman's Yard Long and Telegraph, and said to be very prolific. A fruit was also shown of Melon Eclipse, a cross between Benham Park and William Tillery, described as useful for culture in pots. Messrs. J. Veitch & Sons, Chelsea, sent some fine samples of Neapolitan Curled Kohl Rabi. Mr. A. Pettigrew, Castle Gardens, Cardiff, was awarded a cultural commendation for fruits of Cardiff Castle Cucumber of moderate length but very even. Mr. T. Laxton, Bedford, sent several dishes of Runner Beans, The Czar and Girtford Green being the finest. Messrs. James Veitch & Sons sent a fine collection of Apples and Pears, comprising 180 dishes, representing a large number of varieties. Some Apples were extremely fine, all the best varieties being shown, and well merited the silver medal awarded for them. Mr. Goldsmith, The Gardens, Hollanden Place, Tonbridge, was awarded a bronze medal for a collection of sixty dishes of Apples and Pears, the Pears being of great merit

large, and finely ripened. Messrs. H. Lane, Great Berkhamstead, were adjudged a similar honour for a collection of Apples and Pears comprising ninety dishes; and a bronze medal was also adjudged to Mr. A. G. Bridgeman for a collection of merit. A letter of thanks was adjudged to the Rev. Canon Smith, Great Marlow, for several dishes of fine Apples and Pears.

FLORAL COMMITTEE.—G. F. Wilson, Esq., in the chair. Messrs. J. Veitch & Sons, Chelsea, exhibited a group of new plants, several of which were certificated and are described below, but the following were also worthy of notice. The rosy scarlet *Impatiens Sultani* was represented by a number of small plants a few inches high and flowering freely, indicating the value of this plant in a decorative point of view. Several early-flowering *Chrysanthemums* were also shown, amongst them being a pure white-flowered variety named Mrs. Cullingford, extremely free and of great size. Messrs. Heath & Son, Cheltenham, had a group of *Dendrobium formosum giganteum* in grand condition, the plants being grown in shallow pans and on pieces of cork. The healthy sturdy growth of the plants was surprising, nearly every shoot terminating in from three to eight large white flowers, the tips of which are dashed with pale yellow. The Burmese variety of *Vanda cœrulea*, a very deep purplish-blue-flowered form, the spike having nine large flowers, and a freely flowered specimen of *Oncidium ornithorhynchum* were also shown, together with several *Saccolabiums*. Mr. L. F. Davis, Ogles Grove Nursery, Hillsborough, Co. Down, Ireland, had a collection of varieties of *Pernettya mucronata* in fruit, which attracted much attention. The rich crimson, purple, mauve, and white-berried forms were represented by compact little specimens, and several were certificated. In addition to those so honoured the following were noteworthy:—*Rosea lilacina*, rosy purple, which was certificated last year; *purpurea macrocarpa*, large deep purple fruits; *atrosanguinea major*, very dark scarlet fruits; and *coccinea*, deep rich scarlet fruits. The utility of these plants for decorative purposes was admirably shown by this group, the fruits being so thickly clustered on the branches. Mr. Davis also had some varieties of *Cupressus*; *Lawsoniana erecta viridis*, of fastigate form, deep rich green, and *erecta alba* being the best. The last-named was certificated.

Mr. B. S. Williams, Upper Holloway, had a group of Orchids and new plants, comprising several well-flowered plants of the pretty rosy-purple-flowered *Dendrobium superbiens*; fine varieties of *Odontoglossum Alexandræ*; *Oncidium oblongatum*, with large panicles of pale yellow flowers; the rich purple-flowered *Zygopetalum Clayi*; *Odontoglossum madrense* with white flowers, the narrow sepals and petals brown at the base, and the triangular lip yellow in the centre; the bright purple *Pleione Wallichii*, and the rich purple-tinted *Cypripedium barbatum biflorum*. The well-flowered examples of *Dendrobium superbiens* especially attracted attention, as it is reputed a difficult Orchid to grow satisfactorily. A vote of thanks was awarded; also to Mr. E. Spary of Brighton for a vigorous plant of *Gymnogramma Sparyana*, one of the Golden Ferns, with very large fronds. A similar award was also granted to Messrs. J. Carter & Co., High Holborn, for two large plants of *Pyrethrum uliginosum*, 4 to 5 feet high, and bearing large numbers of their white flowers. The same firm showed a large-leaved *Croton* named *Bealii*, the leaves marked with yellow, crimson, and dark green. Mr. Charles Turner, Slough, exhibited a collection of Show and Fancy Dahlias, comprising a number of large and handsome blooms. A vote of thanks was accorded for these and collections of single and Pompon varieties, the last-named being very fine. A vote of thanks was also accorded to Mr. Turner for a collection of seedling Tree Carnations, scarlet, rose, salmon, and maroon. Mr. T. S. Ware, Tottenham, had a beautiful collection of single Dahlias, white, yellow, orange, scarlet, crimson, maroon, and other shades being represented. Several of the best were certificated.

Messrs. William Paul & Son, Waltham Cross, sent eight boxes of fine Rose blooms, remarkably handsome for the time of year. Especially noteworthy were the Tea Roses *Madame Barthelmy Levet*, *Souvenir d'Adolphe Tiers*, *Victor Verdier*, *Pierre Notting*, *Alfred Colomb*, *Countess of Rosebery*, *Niphotos*, *Louis Van Houtte*, *Duke of Teck*, *Fisher Holmes*, *Marie Baumann*, and *Pride of Waltham*. A medal was recommended for this collection, which was one of the features of the meeting. Mr. C. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury, sent several handsome seedling *Crotons*; one, a narrow-leaved form, a cross between *Weismanni* and *Johannis*; two crosses between *C. majesticus* and *Johannis* were also good, a narrow-leaved form being certificated. A vote of thanks was adjudged to Mr. R. Dean, Ealing, for some bunches of single Primroses of diverse colours.

Messrs. H. Cannell & Sons, Swanley, had a large and beautiful group of single Dahlias and miscellaneous hardy flowers, such as *Pyrethrum uliginosum*, *Pentstemons*, *Marigolds*, &c. A vote of thanks was accorded. A vote of thanks was accorded to Messrs. Dixon & Co., Hackney, for blooms of Japanese *Chrysanthemums* and plants of *Gymnogramma Laucheana grandiceps*, an elegant variety with tufted fronds. The Japanese *Chrysanthemums* were mostly new, and comprised the following of special merit:—*Chinaman*, flower large; margins of narrow florets revolute, deep purple, under side whitish. *François Delaux*, also a narrow-floret form of a rich maroon colour. *George Gordon* with flat florets of a claret colour on upper side, yellowish below; and *Madame Bouchardat* creamy white, large. Mr. Smith, The Gardens, Oakfield, Wimbledon, exhibited plants of a *Begonia*, said to be a cross between *B. semperflorens* and *B. Schmidtii*, plants of both parents being shown for comparison. It was evidently

intermediate between the two named, the hybrid having the red stems and dwarf habit of *B. Schmidtii* with the white flowers of the other parent. A vote of thanks was accorded to Messrs. Rawlings Brothers, Romford, for a large collection of Show and Fancy Pompons and single Dahlias, comprising many fine varieties. Mr. Taylor, The Gardens, Longleat, Warminster, sent two trusses of a large-flowered *Vallota* of remarkable rich colour. Colonel Clarke sent a *Begonia* named *Aurora*, one of the tuberous type, with very abundant deep orange-coloured flowers, for which a vote of thanks was accorded. A tastefully arranged group of Gesneriaceous plants and Ferns was contributed from the Society's Gardens at Chiswick, a collection of *Ceanothus* blooms being also shown.

First-class certificates were awarded for the following plants:—

Mormodes unicolor (Veitch).—A Mexican species, with narrow tapering leaves 18 inches long, the spike being nearly a foot long with about thirty deep yellow fragrant flowers. The sepals and petals taper to a sharp point, the points being incurved, and the flowers closely placed.

Rhododendron Sir Beauchamp Seymour (Veitch).—One of the greenhouse hybrid section, with large beautifully formed flowers; the lobes rounded, of a peculiar distinct pale buff yellow, the stamens being rosy-coloured.

Rhododendron Sir Garnet Wolseley (Veitch).—Another handsome form, of similar type to the above, but having much larger flowers, the limb being over 3 inches in diameter; the lobes rounded, and of an orange or reddish salmon hue. Eight or ten flowers are borne in a head.

Cypripedium Arthurianum (Veitch).—A hybrid between *C. insigne* and *C. Fairrieanum*, a distinct and pretty form. The dorsal sepal broad, undulated at the margin, white at the apex, pale green ground spotted with deep purple; the petals being similar in colour, waved on the upper margin, and the lip of moderate size, purplish brown.

Ornithogalum thyrsoides (R. Veitch & Son, Exeter).—A dwarf free-flowering species, with short broad leaves and dense corymbs of pure white flowers on peduncles a foot or more in height.

Pentstemon Mr. McFarlane (Cannell).—A very distinct variety, with large wide-tubed flowers, the outer part of the tube and border of lobes being rose-coloured, the inner part of the throat being blotched and streaked with deep crimson on a white ground. The spikes are large and dense.

Pernettya mucronata, vars. (Davis).—The following varieties were certificated of this well-known small-leaved dark green shrub:—*macrocarpa*, a strong grower, with very large deep crimson fruits; *sanguinea*, small fruits of a scarlet hue; *alba*, white fruits of small size; *nigra major*, very deep crimson, nearly black; *carnea nana*, pale purplish-pink fruits; *purpurata*, pale purple fruits.

Rose Earl of Pembroke (Bennett).—A pedigree Hybrid Perpetual Rose, shown by Mr. Bennett of Shepperton, Middlesex. The blooms are an extremely deep rich scarlet-crimson tint, the petals broad and revolute.

Cupressus Lawsoniana erecta alba (Davis).—Similar in habit to *erecta viridis*, but with light green foliage approaching white. Very elegant and pretty.

Phalenopsis Esmeralda (Williams).—A botanical certificate was awarded for the plant, which has very diminutive flowers white, purple, and orange near the top of spikes 2 feet or more in length.

Croton Eyrei (Ross).—A cross between *majesticus* and *C. Johannis*, with large narrow drooping bright yellow leaves, slightly voluted, the upper parts of the older leaves being streaked with green. This would prove an extremely valuable plant for table decoration, being most graceful in habit and bright in colour.

Dahlia Harrison Weir (Rawlings).—A Show variety. Large, full, compact, deep, and symmetrical; rich clear yellow.

Dahlia Duchess of Albany (Turner).—A Fancy variety, with large compact blooms of an orange-yellow ground, streaked and spotted with scarlet. *Nymphe*.—Very neat, the florets yellow tipped with orange. This and the three following are Pompon varieties shown by Mr. Turner. *Little Princess*.—Compact and small blooms, the florets pale mauve tipped with purple. *Isabel*.—Very neat blooms, intense scarlet and very free. *Little Duchess*.—Pale mauve, nearly white tipped with deep crimson.

Dahlia White Star (Ware).—This and the five following are single forms. A small-flowered variety, but very neat and extremely free. *Francis Fell*.—Deep rosy crimson florets, broad and rounded. A very telling colour. *Cherry*.—Rose, shaded crimson, very distinct shade. *Mrs. Burbidge*.—Deep purplish plum hue, neat rounded florets, and flowers of good outline. *Mrs. Goldring*.—Pale rose, very broad florets, circular and handsome. A useful and distinct variety. *Pantaloon*.—Small flowers, white or pale centre edged with deep maroon.

Dahlia Marguerite (Cannell).—This and the two following are also singles. Deep rose, shaded lighter at margins of florets; flower symmetrical. *Tyro*.—Rose shaded purple; very free. *Yellow Gem*.—Rich yellow, very handsome flower of moderate size; broad florets. *Constance*.—A white form of the Juarezi type; pure white, large, and free.

During the afternoon Mr. Shirley Hibberd gave a lecture in the Council-room upon plant labels, with especial reference to the results of the recent competition for the prizes offered by G. F. Wilson, Esq., through the Society of Arts. Upon this subject the lecturer delivered a humorous and instructive discourse of about an hour's duration, discussing the respective merits of the substances employed for labels and the various modes in which they are utilised. He stated that

Mr. Wilson's object in giving the prizes was to obtain a label that should be legible, durable, and cheap; and he considered that those were the chief points requiring attention. Unfortunately it was difficult to find one which combined all these qualities, and in consequence at the first competition no prize was awarded. At the second, however, a label was selected as worthy the award. This consisted of an oblong wooden blade, through two holes in which a strong galvanised wire was bent, so as to form two prongs, as it were, which was the part inserted in the soil. He described at length the merits of metal, glass, paper, and wood as substances for labels, and after explaining the good and bad qualities of a large number of those shown at the Society of Arts Exhibition he concluded by describing one of his own design, in which the body consisted of metal—either sheet iron or Bessemer steel—and upon the blade was fixed a small sheet of sized paper, on which the name of the plant or tree had been previously printed. This was then covered with a coating of copal varnish, and the label had the merits of being practically indestructible, very legible, and easily altered or renewed. Mr. Wilson, the chairman, in proposing a vote of thanks to Mr. Hibberd, stated that he had also offered a prize for the best wooden label, which he hoped would bring some good results, as he considered that if one could be found to stand the weather it would far surpass metal or any other substance. One he had tried which had been boiled in paraffin (not petroleum) for twelve hours had proved satisfactory. Unanimous votes of thanks were accorded both to Mr. Shirley Hibberd and Mr. G. F. Wilson.

CHRYSANTHEMUM CORONARIUM.

I WONDER if there are many readers of the Journal who know or who grow *Chrysanthemum coronarium*. It is an old-fashioned annual, and used to figure half a century ago among all collections of flower seeds, and it might have been seen adorning the borders of all gardens where flowers were cherished. But, like many other good old things, it has been crowded out by the novelties by which we are ever too ready to allow ourselves to be led captive. Other *Chrysanthemums* there are which have forced themselves on public favour, and which under the names of Paris Daisy and Nice Daisy have of late become universally grown. But "Daisy" we may not use now-a-days. They must now, forsooth, be called *Marguerites*! and it is these *Marguerites* which, pretty as they are, may be supplemented as decorative plants by this neglected flower.

Last year I procured some seed of *C. coronarium*, which was sown in the open border, and when the plants came up they were thinned, and then left to themselves. They began to bloom in July, and continued to supply a profusion of large yellow, white, and cream-coloured flowers, some double and some single, all through the autumn, and, the winter being mild, they supplied us with cut flowers well into the spring from the open ground. This year I sowed some seed of my own saving, and some of the plants which were allowed sufficient room have grown into handsome bushy forms 2 to 3 feet high, of a pyramidal habit of growth, and covered with a profusion of large flowers, some of which are nearly 3 inches across. Some of these I had potted into 24-pots, and placed in the conservatory, and anything more ornamental it would be difficult to find. It is not only the flowers, but the foliage which is so ornamental, the latter far surpassing that of the Paris Daisy, which I always think is thin and meagre; and then the flowers are so useful for cutting, as they will keep fresh in vases for a fortnight or three weeks without having the water renewed.—SUSSEX.

MILDEW ON PEAS.

COULD any of your numerous correspondents state their experience with respect to mildew on Peas? I have always understood that it was generally attributable to wet, but I am inclined to think that on our land here Peas suffer more from mildew in dry weather. The early part of the summer with us was wet. Peas grew very fast, and were as clean as they possibly could be. A period of dry weather set in, and all the rows were seriously attacked; but in August and September rain again came, and washed them quite clean—in fact, they are quite as fresh now as the early Peas were in June. If it would be of any interest to your readers I could give you my observations on the varieties of Peas new and old (about twenty-five varieties) I have grown during the past summer.—J. S., *Darlington*.

[Your notes on varieties of Peas will be very acceptable to our readers.]

SALVIA HEERI.—We find this *Salvia* the most useful of all for winter-blooming. It is most easily managed. We take the cuttings early in April, which soon root, and are then potted and pinched back from time to time, and then in June are planted out along any unoccupied border in the kitchen garden. Here their growth is regulated by occasional pinching, and they form bushy plants, being lifted and potted about Michaelmas and taken into a cool vinery, where

they begin to bloom towards the end of the year, when they are most useful to bring into the conservatory to take the place of the *Chrysanthemums*. Their brilliant scarlet flowers are highly decorative during the months of January and February—a period when conservatories are often found comparatively destitute of bright flowers in elegant sprays. They last well until they give room to the early *Azaleas*. We have never tried the white *Salvia Heeri*, but if it flowers as freely as the scarlet one the two would make a pretty contrast.—M. A. M.

NAMING FRUIT TREES.

NOT long ago I began to buy fruit trees, and being without experience I did not know what to do about labels; so the labels that came on the trees from the nurseries were allowed to stay on them until they gradually dropped off, and the names of the trees were lost. I would therefore advise all inexperienced tree-planters to replace the paper labels at once with labels of zinc, which they can hang on the trees by means of thin lead wire. The names written with a chemical preparation, which is sold with the zinc labels, by means of a quill pen seem never to fade. This may seem a trifling matter, but it would prevent the annoyance which is felt at not knowing the names of the fruits in the garden, particularly when some are much liked, and in consequence there is a wish to grow more of them. The possessor is then driven, as I have been, to trespass on the kindness of the Editor of the *Journal of Horticulture*, and trouble him to remedy the effects of my own carelessness.—J.

[We emphasise the above advice. The matter is far from being "trifling;" on the contrary, it is a question of importance. Scarcely anything causes greater disappointment and involves more trouble in after years than neglecting to secure and preserve the names of fruit trees.]

SILKWORMS AND SILKWORM REARING.—17.

(Continued from page 294.)

WE have stated that the silkworm, *A. Yama Mai*, has been found to be subject to diseases when kept in cages, or at least restricted to a small space. Such a life is necessarily more or less artificial, and it is as liable to be unwholesome to these worms as it is to human beings who are similarly circumstanced. The common silkworm of the Mulberry seems as yet to have taken to confinement better than any of its relatives, thriving in every land if proper care be taken. Indeed so thoroughly has this insect been domesticated or tamed, that it has been observed the worms when kept in trays will die of starvation rather than wander beyond them in search of food, trusting entirely to man for their food supplies. Probably even when leading a life of freedom the *Yama Mai* suffers sometimes from each of the three diseases specified, since the breeders in Japan have noticed them all, though their losses by these are small compared to the percentage of worms that have died under the management of our experimenters. The Japanese have also noted the curious fact that in their country a creeper with a dark stem, and leaves resembling the *Convolvulus*, occasionally climbs up the young Oaks. If one of the *A. Yama Mai* worms chances to eat a small portion of this creeper it dies almost immediately.

Our apparent non-success in Britain with this Japanese species Dr. Wallace and others attribute to an insufficient trial of rearing the worms in the open air upon young Oaks, growing with a moderate amount of shelter from high winds, and where the climate is rather moist. *Yama Mai* is reared to profit upon this plan within a certain district of Japan; it is also fed elsewhere upon twigs or branches taken from some species of Oak, and placed in water very much in our method. Mr. Adams, of Her Majesty's Legation in Japan, made a tour some years ago through that region, which has at present sent the largest quantity of this particular kind of silk into the market. From the town of *Matsumoto* he was directed to a village situate in the heart of the silk district, and was fortunately able to lodge at the house of one of the principal persons engaged in this industry. He, it seemed, belonged to a society or association comprehending members from a large number of villages, which had the greater part of the trade in their hands, although some silk was produced by outsiders. By a rough estimate this man calculated that his society must on an average sell at least twenty million of cocoons yearly. The demand for the silk of *A. Yama Mai* had of late become greater than the supply: a much larger quantity, so Mr. Adams thought, might have been obtained by improved methods and more attention; "the general principle there of letting things take their course and of leaving the issue to Providence, being painfully manifest."

Several species of Oak grow in that district, but one is chosen

for the food of *A. Yama Mai*, called by the natives *Kunogi*, ascertained positively to be *Quercus serrata*. Many plantations of this tree were seen by Mr. Adams; very frequently they were made on the slopes of hills, but not carried to any height or in the valleys between the hills. The soil was mostly sandy, and the spring is so cold that the early leaves often suffer from frost. Separate nurseries for young Oaks were formed, in which acorns were sown, and the seedlings afterwards replanted in suitable positions. It was also usual to cut down the Oaks to the roots every four or five years to allow them to develop young shoots. Following the change from winter to spring is a rainy season, "when still it rains day after day," and then hot weather usually sets in. The worms have hatched out, as a rule, before the down-pour commences, but the continued moisture does not harm them, for it is one of the peculiarities of *A. Yama Mai* that leaves well besprinkled with water suit its constitution. These silkworms, indeed, both old and young, have been observed to sip drops of water or dew with a relish, as our English "drinker" caterpillar, *Odonestis potatoria*, has the credit of doing, only rarely, I believe.

In order to obtain the eggs the moths, when they emerge in

July or August, are enclosed within small cages of bamboo, which are subsequently hung up under the eaves in dry corners. About the end of the year the eggs are moved by the finger and distributed over wooden trays; these are then placed in some cool position till the time of hatching has arrived. An ingenious plan is next put into operation: the eggs in little batches are pasted on slips of paper, which are tied to a small branch facing the north. By this arrangement the juvenile worms can easily reach the leaves, and from that time until the cocoons are sought after no special care or attention is bestowed upon those so placed. In the case, however, of worms brought up on boughs or twigs of Oak inserted into bottles a regular renewal of the food is necessary, as they feed both by night and day; but then, probably, the return in cocoons may be calculated upon with more confidence. Yet the majority of Japanese breeders incline to the plan of giving the silkworms their freedom.

Mr. Adams inspected many trees or shrubs upon which these were feeding at large, and he particularly observed the close resemblance they bore to the twigs and leaves upon which they rested, so that the eye was apt to miss them until accustomed to

Fig. 57.—CATERPILLARS OF *ATTACUS YAMA MAI* ON *QUERCUS SERRATA*.

distinguish their shape and attitudes (fig. 57). As the silkworms were then nearly full-grown this is a natural protection, doubtless, afforded to them at an age when they would prove tempting morsels to birds. He was told, however, that it was believed many of them were destroyed by sparrows or other birds at some period of their life, on account of which scarecrows had been put up, which the birds appeared to treat with cool contempt. Caterpillars of several other species not recognised by this gentleman were seen to be feeding amongst those of the *Yama Mai*. Ants red and black were said to be noxious to the silkworms, especially the red. Mr. Adams did not observe these. The black he noticed in crowds upon some of the Oaks colonised by *Yama Mai*, though he looked in vain to see them attack the worms. Possibly they drag the young and feeble ones to their nests sometimes.

The average time of growth in Japan is sixty days, varying a little with the warmth of the season. Spinning begins in ten or eleven days after the last change of skin, and the worms are allowed to form their cocoons on the trees and bushes. These are carefully cut off, with a portion of the branch attached to them, and placed within doors upon shelves. Several days having been allowed for the silkworms to change to chrysalids, they are next removed from the vegetable matter and shaken separately. Those that do not rattle are presumed to contain only dead insects.

A selected number of those that do rattle are set aside for breeding, upon the calculation that each female moth will deposit from 150 to 250 eggs. The rest of the cocoons have the enclosed chrysalis killed by the heat of fires or by exposure to the rays of the sun during two or three days. Winding the silk is said to be performed with facility by means of a wheel very simply constructed. At a suitable time the women and children go in search of wild cocoons of *A. Yama Mai*, which are to be found scattered over woods or hedges.—J. R. S. C.

STANDEN'S MANURE.

I THINK it only due to the manufacturers of this manure (Corry, Soper, Fowler & Co.), after seeing it spoken of in the *Journal of Horticulture* as not being quite equal to its former quality, to state that I use it largely, and honestly affirm that its effects on plants are really marvellous. I use it abundantly on Palms, Ferns, Azaleas, Camellias—in fact, plants of all descriptions; and the vigour with which they grow, the rich appearance of their leaves, is evidence that it is a most powerful stimulant and invigorating food for plants. As a highly finished Grape-producer it is, I believe, truly a gardener's friend. I am certain that anyone who will apply it as a top-dressing to a Vine border

previous to forcing will be astonished at its good results, likewise for Peach trees. Another point is its cleanliness in use—a great consideration where greenhouses are frequented by ladies interested in plants, no disagreeable smell being caused by its use. This is my testimony regarding it as a manure, and I am stating my opinion simply as a duty towards the manufacturers.—*WM. IRVINE, Gardener, Lord Howard's, Glossop Hall, Manchester.*

HARDY FRUIT GARDEN.

GATHER Apples and Pears as they become ripe, and place them thinly upon the shelves of the fruit-room, which ought to be kept cool and dry. Avoid anything like rough handling in gathering and storing Apples and Pears, the latter being exceedingly susceptible of injury. Late Plums, such as Coe's Golden Drop and Ickworth Impératrice, though still hanging, will generally be quite ripe and likely to fall. They should, therefore, be gathered and placed singly upon the shelves of a light airy fruit-room, where they will keep good for a considerable time; and although they may shrivel, many prefer them in that state to using them fresh from the trees. Filberts and Nuts of various sorts should be gathered now, and spread out very thinly upon shelves in any airy but not too dry room, or it is likely the kernels will shrink. The nuts must not be divested of their husks, as they are generally placed upon the table for some time to come in their natural covering.

Wherever it may be intended to form plantations of young fruit trees, whether to be trained to walls, &c., or as standards, the ground should be prepared for their reception. The preparation needed will depend in a great measure upon the nature of the soil and the subsoil. All soils overlying a heavy and retentive subsoil will, in the first instance, require thorough and efficient drainage. Light sandy soils very frequently have water lodging in the subsoil, and this must also be removed by drains with a proper fall and outlet, whilst soils resting on a gravelly subsoil may not require drainage. In most instances trenching as deeply as possible without bringing any of the bad soil to the top is essential to the well-being of the trees, especially if surface-rooting be encouraged by keeping the surface mulched. In order to increase the depth of shallow soils, that immediately below the good top soil may be loosened to admit of the percolation of water through it freely. Heavy soils will be improved by a free admixture of burned clay, ashes, old mortar or lime rubbish, and road scrapings. A good liming will materially improve the texture of heavy soils, and charred vegetable refuse is a good application to the soil for all fruit trees. Soils that have long been under vegetable culture will need little beyond liming and an addition of fresh loam. Soil of a light sandy nature should be improved by adding turfy loam and a liberal dressing of well-pulverised clay, applying some well-decayed manure to the surface.

Intending planters must now select their trees, making choice of such as are clean and healthy, have short-jointed well-ripened wood, and are not unduly vigorous or weak. The trees should not be moved until most of the leaves have fallen; then they should be lifted carefully, the roots being protected by careful packing, and, all being in readiness, planting should be done as soon as they come to hand, spreading the roots carefully, and making the soil firm about them. Water must not be given unless the soil be dry, and to retain a genial condition of the soil a mulching of partially decayed manure may be given over the roots.

FRUIT HOUSES.

Peaches and Nectarines.—Planting trees from walls or houses against or in which they have been grown and trained for two or three years and have become well furnished must be attended to without further delay, especially if they are intended to be subjected to forcing from an early period of the coming season. If the trees be lifted carefully, even whilst the foliage be quite green, and well attended to in shading and keeping the house rather close for a short time when the sun

is powerful or the outside air dry, also having the soil in a moist condition, the roots will soon become active. They should not, however, be started so early as trees that have been subjected to the process in previous years.

The border for Peach trees that are to be forced early should be for the most part inside the house, though there is no objection to the roots having some extent of run in an outside border. Fruit-tree borders, especially those for trees under glass, are made too wide, too deep, and too rich, being out of all proportion to the wants of the trees. If the root space of fruit trees were restricted half, and in many instances two-thirds, much would be accomplished towards increased fertility of the trees, and the need for summer pruning, to say nothing of root-pruning, considerably lessened.

A Peach border in the first instance should not be wider than one-third the height or breadth of the trellis; 30 inches is a sufficient depth, 6 or 9 inches being occupied by drainage, and the rest soil—strong loam of a calcareous or marly nature—placed together as firmly as possible, without any admixture whatever. If light, well-pulverised clay or marl may be added with advantage, and if the soil be devoid of calcareous matter one-sixth of old mortar rubbish or chalk may be thoroughly incorporated. The border must have proper drains to carry off superfluous water passing through it. In planting make the soil firm about the roots, apply water thoroughly to settle the soil about them, and mulch over the surface with partially decayed manure about 3 inches in depth. For very early forcing Alexander, Hale's Early, and Royal George afford a good succession, and are reliable sorts; Lord Napier and Elruge Nectarines being suitable for planting in the same house. To ripen by June and onwards in succession houses Royal George, Grosse Mignonne, Noblesse, Dymond, Bellegarde, Barrington, Stirling Castle, and Late Admirable are the best, with Nectarines Elruge, Violette Hâtive, Pine Apple, and Victoria.

Pines.—Young growing plants should be arranged so as to derive the fullest benefit from sun heat, and as this diminishes during the daytime a corresponding diminution of temperature should take place at night, and gradually until it reaches the ordinary winter minimum—viz., 55° to 60° at night and 65° by artificial means in the daytime. Ventilate freely whenever the weather is favourable, giving particular attention to watering, discriminating between those grown or plunged in fermenting beds, as such afford more moisture to the roots than plants have in shallow beds of plunging material heated by hot-water pipes; hence no particular time can be given for watering, but under all conditions a weekly examination of the plants should be made, and whenever water is needed it should be given copiously at about the same temperature as that of the bed.

Fruiting plants require a night temperature of 70°, or 5° more when the weather is mild, 75° artificially by day, and ranging between 80° and 90° from sun heat, closing at 85°, maintaining a genial condition of the atmosphere by sprinkling the pathways as they become dry, with an occasional syringing over the plants on fine afternoons. Keep the bottom heat steady at 85° to 90°. Do not overwater at the roots, as this, along with a low temperature, tends to cause a serious defect in the ripe fruit—i.e., their cutting black at the centre.

PLANT HOUSES.

Stove.—Allamandas intended for early flowering, and consequently required to be cut back and started early in the year, should not receive more water than will prevent them flagging excessively, withholding it to such an extent as to check growth and insure well-ripened wood. Keep the plants near the glass, with a warm dry atmosphere; but the air of the house must not be so dry as to injuriously affect others, Ixoras especially being affected by a dry condition of the atmosphere.

Large specimen Ixoras may now be cut well back into the old wood, and if infested with scale or mealy bug they should be cleansed with an insecticide, repeating the operation every third day for ten days to effectually eradicate the pests before the plants form fresh growth, which would be likely to be injured by an insecticide strong enough to kill the insects. An opinion prevails that when once mealy bug has seriously infested stove plants it cannot be exterminated; but such is a mistake, as continuous perseverance and considerable

labour will accomplish it, but the half-measure attempts at cleansing are of no use. One washing does good, but it is effectual or otherwise according to its thoroughness. The insects must not only be reached on the most exposed parts of the plants, but in every crack and inequality from the top of the plants down to their roots. A simple dressing will not effect this, but it should be repeated at least half a dozen times, and at intervals of two or three days. Every particle of material likely to harbour the pests should be removed from the house; the woodwork, &c., washed three times with petroleum in solution with water (as used by Mr. W. Taylor in cleansing vineries). During the next two months is the best time to destroy mealy bug.

Urceolina aurea is now throwing up its flower stems, and though it flowers without the leaves it must not be allowed to become dry at the roots. Its fine pendant flowers—yellow, with green tips—render it very attractive and acceptable at this season. *Hippeastrum pardinum* is also flowering freely, and needs to be kept moist at the roots.

THE STEWARTON HIVE.

THE members of the British Bee-keepers' Association who read the article on this subject in your last number, must have been surprised at the statement made by Mr. Pettigrew, that "since the retirement of the 'RENFREWSHIRE BEE-KEEPER' no one has come to the front to take his place" in advocating the claims of the Stewarton hive. On the contrary, this hive formed the subject of a paper and a very full discussion not long since at one of the quarterly meetings of the British Bee-keepers' Association; and the Rev. E. Bartrum, who read the paper, published it with additions by the "RENFREWSHIRE BEE-KEEPER" and others, only last year. His little work, "The Stewarton, The Hive of the Busy Man," has had, I believe, a considerable sale. Messrs. Longman are the publishers, and the price is 6*d.*

Mr. Pettigrew will be interested to learn that in the new edition of "Modern Bee-keeping," about to be published by the British Bee-keepers' Association, the straw skep, in all probability, will not be wholly ignored, as the Committee will be asked to add a chapter, if not on the straw skep, at all events on sections arranged on the top of straw skeps. As many skeps cost no more than 1*s.* 6*d.*, whereas a good bar-frame and its appendages cannot well be obtained under something like 7*s.* 6*d.* or 10*s.*, it seems very advisable that the British Bee-keepers' Association should at all events recognise the skep, and by means of sectional supers lead those who are willing to aim at higher things. If they would do this they would, I am convinced, conciliate a considerable section of the bee-loving public, who consider that the bar-frame hobby is sometimes driven too hard.—A MEMBER OF THE BRITISH BEE-KEEPERS' ASSOCIATION.

PREPARING BEES FOR WINTER.

EVERY bee-keeper should now take advantage of the earliest opportunity that offers to prepare his bees for passing the long winter months in comfort and safety. At the risk of repeating advice oftentimes given before, we would endeavour to impress upon our readers the necessity of giving great attention to the proper arrangements of the exterior and, interior of their hives while fine weather still permits such attention to be given. Many bees are still kept in the straw skep, and, compared with the wooden bar-frame hive as a winter domicile, the straw skep requires by far the least amount of trouble bestowed upon it to make it a snug and healthy winter residence. But the bar-frame hive has so many other advantages over the straw skep that we willingly give the extra labour and attention required to prepare it for the winter. Even the well-made skep ceases to be a healthy home for its much-neglected inmates in the hands of the careless bee-owner. We have seen straw skeps in a cottage garden left to pass the winter with the only protection a decaying sack and broken milk-pan. But let us hope that such a state of things will soon be unknown, now that so many are competent to give kind advice to the thoughtless or ignorant.

In preparing bees to pass the winter there are two things to attend to: First, the interior preparation of the hive; and secondly, the exterior. In the straw skep something may be done as to the interior arrangement. Stocks that have shown signs of being queenless should be examined and the state of the bees

ascertained. Stocks that are weak in numbers, as well as queenless stocks, should at once be united to healthy stocks standing nearest them. If the hives contain sweet young combs after the bees are cast out they should be well wrapped up to secure them from mice and moths, and utilised the following year for hiving swarms into them. If left as they were both the weak and the queenless hives would die out and the combs become a prey to vermin, or, being attacked by stronger colonies, be the cause of much commotion, and perhaps slaughter, in the early warm days of spring. Floor-boards should be scraped and placed slanting forwards, so that water may not lodge on them. If the bees have not sufficient food to carry them through the winter, say from 12 to 20 lbs. weight, then food must be given rapidly and by night by means of a feeding-bottle inverted over a hole cut in the crown of the skep. How to do it has been so often explained that we feel it a trespass on time and space to repeat directions; yet we are constantly meeting with beginners who ask the questions, "How is the syrup to be made, and how applied?" Therefore once more we will ask pardon for repeating the recipe.

For rapid autumn feeding put a pint of water to 3 lbs. of best loaf sugar and a tea-spoonful of salt. When boiling take off the thick scum which collects on the side of the pan farthest from the fire, the stew-pan being drawn back when the syrup begins to boil. Add a table-spoonful of vinegar, and let the whole simmer for ten minutes, then pour it off into a jug to cool.

To feed the bees with this syrup, place over a hole in the crown of the skep a piece of tin or zinc in which eight or twelve holes have been pierced with the point of a small French wire nail. Do not let the holes be large, or the syrup will run through and flood the hive. Fill a wide-mouthed bottle (a pickle bottle will answer the purpose) with the syrup; have a piece of flat zinc, or, better still, a child's toy dust-pan, place this on the top of the bottle filled with syrup, steadily invert the bottle and dust-pan. Now place the dust-pan on the perforated zinc over the hive, withdraw the pan, and the bottle of syrup is in position for the bees to feed from. Take great care that the zinc over the feed-hole is perfectly flat, and that the syrup be not made too thin. Over the bottle place an empty skep or large flower pot, and over this a pan or a hackle to shed water. As soon as the bees have increased the weight of their stores to that advised above wrap the skep up warmly, and disturb no more until the following February. There are many ways of doing this which will suggest themselves to bee-keepers in various forms. Some means should be employed to prevent the rain and snow from drifting against the skep. Anything waterproof gathered at the top and bottom, and drawn up under the pan and round the post on which the hive stands, leaving an entrance in front and ample ventilation under the pan above, will answer the purpose. This latter point should ever be attended to, otherwise the straw of the skep will become a sodden mass, and the bees killed by too much kindness (?). Entrances should be narrowed; half an inch long and a quarter inch high is ample space for a winter entry.

Now we come to bar-frame hives. When properly constructed these may be made as snug and as healthy for the bees during winter as the warm skep. The interior arrangement shall first be attended to. The space occupied by the bees for wintering should be much contracted. For a strong stock five or six combs at the most will be sufficient to leave, placing those with most honey on the outside of the allotted space at each end, and giving the more empty combs to the centre, that the bees may not have to cluster on cold honey, but be able to creep into the empty cells, and thus only have their cluster divided by the thin waxen bases of the cells. Winter passages should be made through all the combs; a small tube of tin or zinc will cut these out neatly. Hives should always be made sufficiently long to allow of the use of two dummies either in winter or summer. All our hives are so made, and as far back as the year 1875 we tried the experiment of working such a hive, using a perforated zinc divider in summer for working sections on either side the brood nest. These moveable dummies should now be drawn up close to the outer combs at both ends, and the spaces between them and the hive walls packed with dried sphagnum moss, chaff, or any other warm material.

The same system regarding queenless and weak stocks should be carried out as with skeps. Some hives will have more honey than they need, and others will have too little. We need not feed in the case of bar-frame hives when this happens, but take from the stronger and give to the weaker, only allowing to either sufficient to last until spring, and carefully keeping the other combs for expansion of the hives as breeding advances. Entrances, as with skeps, should be narrowed, and all made snug over the frames; a piece of ticking or canvas first, then either three or four squares of flannel, or, better still, a quilt made of any coarse stuff and filled with moss or chaff, leaving a hole in the centre to correspond with

the feeding hole over the cluster. When not required for feeding this central hole should be covered with a separate pad. It is better not to place too much covering above the frames—sufficient to keep the bees dry and warm, but not so much that evaporation is stopped. It is the accumulation of noxious vapours in the body of the hive that causes so many diseases that bees are heirs to. This moisture must be allowed to pass away first through the quilt, and then into the outer air through holes covered with perforated zinc made under the eaves of the roof. Care, therefore, should be taken to make the roofs sufficiently high to leave a space above the quilts. On no account should the roof rest on the latter.

If these directions be carried out no amount of cold or wet weather will hurt the bees; and providing they have been put up with plenty of young bees, which is a great desideratum, they will come out strong and well in the spring, when we will all look forward to a more propitious summer and a more profitable autumn than those which have passed away.—P. H. P.

TRADE CATALOGUES RECEIVED

Edward George Oakshott, Reading.—*Illustrated Catalogue of Cereals.*

G. J. Alberts & Co., Boskoop, Holland.—*Catalogue of Plants.*

S. Owens & Co., Whitefriars Street, Fleet Street, London, E.C.—*Illustrated Catalogue of Hydraulic Machinery.*

William Farren, How House, Cambridge.—*List of Roses.*

Joseph Schwartz, Lyons, France.—*Catalogue of Roses.*

L. Delaville, 2, Quai de la Mégisserie, Paris.—*Catalogue of Bulbs and Miscellaneous Plants.*

* * All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (C. L. P.).—Our "Garden Manna" contains sound and reliable information on the kitchen, flower, and fruit garden, and the best evidence of its usefulness and acceptability is its large and constant sale, upwards of thirty-six thousand copies having been disposed of. The price is 1s. 6d., post free 1s. 9d.

Early Alfred Peach (F. C.).—We are much obliged to you for your reminder, also for your notes. We have, however, investigated the subject, and find it is only occasionally that the leaves have glands; these when they are produced are round, but usually the leaves of this variety, are however, glandless.

Landlord and Tenant (J. C. S.).—We do not know of a previous case of the precise nature of the one to which you allude, nor is it possible for us to comprehend the case satisfactorily from the letter before us. Our view is that the tenant, after receiving the proper notice to quit, must relinquish his holding, and cannot claim any compensation. The question is one that can only be properly dealt with by a solicitor.

Incrustation on Flower Pots (B. D.).—The white incrustation to which you refer is incident to the material of which the pots were made, and, as you say, cannot be removed by washing. It is carbonate of lime. You may cover it with paint, but, so far as we know, cannot remove it. The best course to pursue is to procure pots from a source where there is not so much lime in the clay of which they are manufactured.

Renovating Vines (A. Z.).—An excellent method, and one which proved highly successful, of "refreshing" a Vine border was described on page 321 last week. If the same practice is not applicable in your case we will readily give you the best advice we can, if you will supply us with particulars of the age of your Vines and the size, character, and position of the borders. At present you afford us no data for answering your inquiry satisfactorily.

Lifting Fruit Trees (A. S.).—The time for lifting and adding fresh soil can only be determined by the condition of the trees. When trees make luxuriant growth and have little disposition to form fruit buds the roots are usually correspondingly strong and fibreless, and taking up and replanting such trees, adding fresh soil, and making it firm round the roots, would result in the production of a network of fibres near the surface, and the succeeding growth will be shorter-jointed, healthy, firm, and fruitful. Old trees that do not make sufficient growth through soil-exhaustion are similarly benefited by removing the old soil and applying fresh of a fertile character. The cultivator to whom you refer (Mr. Young) has had great success in renovating fruit trees, and has grown some of the finest fruit in the kingdom.

Liming a Garden (Idem).—So far as we understand the condition of the soil we believe a dressing of lime would be of much greater advantage than a further application of manure, but a mere dusting will be of no use—at the least half a bushel should be applied to each rod of 30½ square yards; indeed you may with advantage apply 8 bushels to the extent of ground you name. The lime should be obtained in lumps fresh from the kiln, placed in heaps, and covered

with soil as if covering Potatoes. In a few days the lime will swell and fall; it should then be spread and forked into the land, not, however, covering it deeply. It is an excellent plan to dig the ground roughly in the autumn, and to apply the lime and fork it in in early spring.

Araucaria Unhealthy (Aylesmore).—We have seen many such instances as the one you bring to our notice, and in almost every case where injury has not been caused by frost the degeneration of the specimens has been due to soil-exhaustion. The remedy is to remove the old soil down to the roots and beyond them, and if these are in a medium almost as dry as dust to apply pure water copiously, following a day or two afterwards with liquid manure. After the soil has been rendered sufficiently moist cover the roots with fresh compost, turfy loam, wood ashes, and decayed vegetable matter in equal parts, and surface the whole with manure. We have seen many specimens invigorated by this practice, and you cannot too soon apply the same remedy. In some cases the decay of the branches results from the roots having penetrated stagnant soil, and in this case drainage must be afforded as well as top-dressing.

Cropping Land (P.).—If you have had no experience in the work to which you allude you may be easily led astray by merely working from books. "What crops to grow" depends entirely on the demand for produce. The most practical reply we can give is to suggest to you the advisability of securing the services of an industrious man who has had experience in growing farm and garden crops for market, this being the only trustworthy plan for securing satisfactory results. Much money has been lost and disappointment caused by persons working by books alone, as none of them can compensate for the absence of experience in the work in question. You may clean your Carrot seed by rubbing it through sieves.

Pears Unsatisfactory (Gloucestershire).—If the varieties are good and the trees not old and worn-out they can without doubt be greatly improved by removing the old soil from the roots, adding fresh loam and wood ashes if procurable, and surfacing with rich manure. This would induce the emission of fibrous roots near the surface, and the good food they would absorb would result in healthier growth and finer fruit. In all probability many of the old spurs would also need removal, and the trees cleansed from any moss that may have grown on the branches by applications of lime, applied in the form of paint, and the colour toned with soot. Not knowing the precise condition of the trees we are unable to give the requisite details of management. Cannot you induce a good gardener in your district to inspect them and give you advice on the subject of their renovation? If you can do this we think it advisable, as you cannot make the exact state of the trees clear to us.

Celery Fly (Idem).—The maggots may be prevented by dilute applications of petroleum or frequent dustings of soot in the summer at the time the fly (*Tephritis onopordinis*) usually deposits eggs on the leaves. The only method of destroying the maggot when it exists is to crush the affected leaves with the fingers, removing the worst portions and burning them; this will limit the attacks of the enemy next year. Some small works such as you appear to require are published at 170, Strand, and can be had through a local bookseller.

Heating Unsatisfactory (A. E. B.).—Had you sent a sketch showing the connection of the pipes with the boiler and their arrangement, we might possibly have found some error causing defective circulation. If there has been no mistake in the setting of the boiler and disposition of the pipes, we are unable to suggest a remedy other than that of more steady firing. If you can get the pipes sufficiently hot without boiling the water violently, why fire so hard? If you cannot so heat the pipes, then proper provision is not made for heating the house satisfactorily. If you can supply us with fuller particulars, supplying the requisite data for our comprehending the matter, we will give the subject further consideration.

Spergula pilifera aurea (W. H.).—This is a pretty plant for carpet bedding, and is hardy or nearly so. Plants may be wintered in pans or boxes placed near the glass in a light frame from which frost is just excluded, ventilating freely during all favourable weather, occasionally removing the lights; or they may be placed on a shelf of a cool greenhouse. Unobstructed light is, however, essential, or the plants will become drawn and worthless. The *Spergula* belongs to the family Illecebracea, being related to the *Herniaria glabra*, also used in carpet bedding.

Insects on Potatoes (Farnham).—We wish our correspondents generally showed as much care in packing specimens sent us as you have exhibited with your insects. The species is a Myriapod, named *Polydesmus complanatus*, not unusually found eating Potatoes, Carrots, and Onions, as noted by you, also Anemones and Pansies. Probably the moist summer has favoured the increase of this and other Myriapods. We have recently recommended for destroying these a solution of soft soap with paraffin. This, however, cannot always be conveniently applied, especially on an extensive scale. Soot and lime are popular remedies amongst some gardeners. But these creatures are admitted to be difficult to deal with without hurting the plants.

Caterpillars Destroying Cabbages (Mrs. St. John).—The specimen sent is a caterpillar of *Tryphaena prunibo*, the great yellow underwing moth, about half-grown. Caterpillars of this species feed upon the roots and underground stems of many plants in the kitchen garden, being discoverable from August until May. They become more or less torpid during winter. It has been recommended to hunt down the moth in its season—viz., July and August, as it moves sluggishly by day, and is conspicuous owing to its yellow "under wings." Frequently it flies to the lights in houses or public buildings. Amongst the Cabbage rows, where the insect is known or suspected to be doing mischief, the application of soot to the roots well dug in has been of proved utility. Some advise the careful application of gaslime which has been kept for a time; but probably the best application at the present time would be a solution of petroleum, half a fluid ounce of the oil being dissolved in a gallon of weak soap-suds, a little of this being poured round the plants; it will not injure them provided they are established. Plants that are being planted should have their roots immersed in a puddle of soot and soil in equal quantities before insertion.

Planting Vines (W. G.).—The right time for planting Vines in an outside border is in the spring after the Vines have fairly commenced growth, great care to be exercised in not injuring them. The roots also require care, and must not be dried by exposure. They should be spread out straight from the stem, covered quickly, watered with warm water, and mulched with litter. A rather low temperature should be maintained in the house until fresh roots are produced, 50° by fire heat being ample. We do not know whether you are aware of the fact that it is of little use planting young Vines in old borders—that is, without making stations of fresh soil. There is no better Muscat than the Muscat of Alexandria, but unless you are a skilled cultivator you will possibly not have highly finished fruit for exhibition in July. If you want Grapes next year you should get additional Vines, and either fruit them in pots or planted out, as it would be very unwise to crop the newly planted Vines that are in-

tended to occupy the house permanently the first season. On the contrary, they should be shorteued now to a height that will not, when they are planted, reach above the base of the rafters, and then allow them to make strong growth under the full influence of light and air. If they mature stout canes they may carry a bunch or two the second season. If the canes are not shortened until late in the spring bleeding will ensue, therefore shorten them now, and you are far more likely to cr by leaving the canes too long than pruning them too low. A length of 2 feet is better than 6 feet when young Vines are planted.

Keeping Grapes (Trickest).—No one can say whether your Grapes will keep the longest by allowing them to remain on the Vines or cutting and "hottling" them. Everything depends on the equability of temperature in the house and the adaptability of the room for preserving the fruits. We have seen so many failures by "hottling" Grapes that we hesitate to advise amateurs to adopt the practice unless we are well acquainted with the circumstances of each case. You will not err, however, by letting the Grapes hang until they show signs of decay or shrivelling, as they are not late-keeping sorts; you can then cut them and try the alternate plan of preserving them. Whether your Vine border needs enriching or not it is impossible for us to say. If it does not, cover it with litter during the winter; if it does, top-dress with good manure.

Stapelia not Flowering (Idem).—The soil has been too rich, or food too abundant hitherto. Do not replot the plant, give it little or no water during the winter, and keep it in the sunniest position you can on a shelf near the glass, and it will probably flower next year. We are unable to account for the state of your Amorphophallus. Keep it dry or nearly so throughout the winter, and try the effect of placing it in gentle heat in the spring.

Alnwick Seedling Grape not Setting (C. E.).—We have seen several examples similar to those you have sent and many others in the most satisfactory condition. The bunch before us shows undoubtedly that the fertilisation has been defective, and there is at least a probability that this variety does not produce pollen freely. A safe course for ensuring a crop is to dust the bunches with pollen from a Black Hamburgh or Alicante. There is usually a superfluity of these for shaking over the others, and if not the pollen can be collected on a soft camel's-hair brush and thus applied. Shaking the rods when the Vines are flowering, or drawing the hand or a rabbit's tail gently over the bunches, greatly facilitates the setting of the fruit. This variety is worthy of a little aid in this respect, and we believe Mr. Bell of Clive House adopts some such course as we have suggested and never fails to secure excellent crops.

Extirpating Worms (Lady Trevelyan).—In this case the safest remedy will undoubtedly be clear lime water, as this will neither discolour the paths nor injure the Box; indeed, it will be beneficial rather than otherwise to the edgings, as Box must have lime to maintain it in health. Place a few lumps of fresh lime in a tub, which fill with water; let it remain until quite clear, removing the scum that will form on the surface, then apply it to the walks copiously through the rose of a watering pot, and shortly afterwards the worms will rise to the surface and can be swept up, or at any rate if they do not come to the surface they will otherwise take their departure. By applying lime water to the paths as often as is needed they will be kept clean. The quantity of lime used is not material, as if half a pound to the gallon is used the lime water will be as strong as if twice that quantity were placed in the vessel; thus there is no danger or possibility of making the preparation too strong, or so strong as to injure Box edgings.

Hippophae rhamnoides (H. C.).—This shrub, also known as the Sea Buckthorn, is a member of the natural order Elaeagnaceae, and is found wild in this country. Its bark is considered astringent; its berries, which are numerous, small, and red or orange-coloured, have an acid taste, which is owing to the presence of malic acid. They are much eaten by the Tartars, and the fishermen of the Gulf of Bothnia prepare a rob from them, which imparts a grateful flavour to fresh fish, and they form the principal food of pheasants about the Caucasus. It has been discovered that the fruit contains a fatty matter of narcotic properties, 12 grains of which given to a moderate-sized dog prostrated its strength in a few hours. This confirms the opinion of the inhabitants of Dauphiné, who have always regarded them as poisonous. The shrub is planted in gardens, especially near the sea, as its silvery foliage and brightly coloured fruits are ornamental, and it is not injured by exposure to the sea air.

Names of Fruits (Spero).—1, Lincoln Codlin; 2, Norfolk Bearer; 3, Bess Pool; 4, perhaps a small fruit of Bedfordshire Foundling. (P. J.).—1, Williams' Bon Chrétien; 2, not known; 3, Flemish Beauty; 4, Autumn Nelis; 5, Belle Julie. (J. H.).—Jersey Gratioli. (Reader).—The large Pear is probably Gilogil; the Apples are worthless, probably never had names, and they certainly are not worthy of them, nor of space in the garden. (Beverley).—Although we stated last week that Pears should only be sent when approaching ripeness, as when green we are deprived of an important test, that of the palate, for determining the names, yet you have sent quite hard specimens, the numbers of which are not attached to the fruit as they ought to be, while it is impossible for us to undertake to keep fruit until it is ripe, or to guarantee that the numbers are not misplaced that are not made secure by the sender. At present your fruit is not in condition to be named. (G. B.).—1, Cellini; 2, Alfriston; 3, Beauty of Kent; 4, Wyken Pippin; 5, King of the Pippins. (S. O.).—The Pear is Beurré Superfin, the Apple Blenheim Pippin.

Names of Plants (J. G., Wantage).—Your plant is Lycopodium volubile, a native of New Zealand; it is interesting botanically, and we should be glad if you could send us a small living plant of it. The name Supple Jack is usually applied to a species of Paullinia. (H. C., Huddersfield).—The Orchid is Pleione lagenaria; the plant with orange-coloured berries is Hippophae rhamnoides, of which particulars are given above. (Shropshire).—1, Limnathes Douglasii; 2, Chrysanthemum segetum. (F. H.).—Desfontainia spinosa, of which an engraving was given in this Journal September 25th, 1879.

COVENT GARDEN MARKET.—OCTOBER 11TH.

OUR market has been well supplied during the week, growers sending their produce early, and Apples are slightly easier. Kent Cobs in good supply and selling freely.

POULTRY AND PIGEON CHRONICLE.

SEED CORN FOR AUTUMN SOWING.

(Continued from page 333.)

IN again alluding to the sorts of Wheat we do not intend to remark upon every one in use for growth in all districts, for many varieties are recognised only by a local or provincial cognomen. We have, however, yet to notice certain varieties which are highly approved by some of the most practical and experienced farmers, and although a statement of their successful growth must be estimated as valuable, yet it is frequently the result of exceptional circumstances, so that it is found extremely difficult to say which is really the best unless proved by experiment under the supervision of the home farmer himself. The success which certain sorts may have attained in some localities is often the result of influence of soil, climate, or cultivation, the extent of which cannot easily be ascertained. It is, therefore, very desirable that in the catalogues of seed-corn merchants, wherein the names of successful growers of certain cereals are given, that not only the name of the farms should be stated but the county also, because it is generally understood what are the climatic characteristics of certain counties or districts throughout the kingdom.

Still referring to white Wheat, we must name a very valuable white variety commonly grown in the home and southern counties upon gravel or sandy soils called "Trump," and we recollect perfectly the admirable samples which obtained the prizes at Guildford market in Surrey some twenty-five years ago; it was at that time a special favourite and esteemed as fine millers' Wheat, the growth being also in the interest of the farmer, doing well as it does on poor land, especially when sown out of Clover lea, because it is sure to tiller well in the case of loss of plant in an adverse winter. Hunter's White and Hertfordshire White are two very useful sorts of Wheat, but require warm soils, liberal cultivation and manuring, and are, strictly speaking, fairly adapted for enclosed and sheltered districts. They, however, as we have found them, are apt to grow unevenly at head, which affects the yield injuriously as compared with some of our more recently introduced sorts, such as Champion White and Imperial White Velvet Chaff. We have several white bearded sorts now offered, called Sheriff's, Pringle's, &c., of very good millers' quality, and they are well suited for growth in exposed districts, for they do not easily shed the grain under the influence of high winds, and will frequently answer best for late sowing or in early spring, as they are extremely hardy. Hallett's Pedigree White is of high reputation, especially as to cropping, because it represents the system by which it was produced—namely, from the

selection of the longest and most productive ears. We must not, however, be led away by the origin, for frequently samples are offered for seed without selection or care having been taken to prevent the mixture with other sorts, which is certainly of the highest importance, especially when we know that some dealers in seed-corn never attempt anything beyond selling what they buy. That style of business is, however, fast declining, to make room, let us hope, for those intelligent and enterprising men who offer nothing to our notice except it has been grown and selected under their own care, and we seriously advise the home farmer to accept the latter style of business only, as likely to yield satisfactory results.

We must now make one more reference to a sort of white Wheat called "Talavera," as being especially adapted for spring sowing, for when the season and harvest are favourable it is sometimes equal in quality and millers' value to the best Dantzic Wheat. It is said to be suitable when spring-sown for warm climates and light soils; but this is only correct when the climate is moist as well as warm, for in the western counties and parts of Scotland the climate is much more favourable to the growth of spring-sown Wheat than the eastern and south-eastern counties, in which it is an uncertain produce owing to the dry cold springs and often drought in summer, especially on all light soils. Before leaving the consideration of white Wheat, the question of straw grown per acre is now a matter of far more importance than it has been at any former period. Although red Wheat is said generally to produce more straw than white Wheat under the like treatment, yet it must be remembered that latterly our best selected white Wheats, such as Champion and Imperial, frequently produce from 8 to 10 cwt. more straw per acre than many other sorts, and of more value per cwt., especially in the cattle-grazing and dairy districts of the kingdom.

The advantage of growing red Wheat next deserves consideration, for it must be remembered that the growth of red Wheat is not confined within such narrow boundaries as the white, which can only be grown with success where the climate is favourable, whereas certain varieties of red Wheat can be grown wherever the growth of Wheat is possible. Probably we have no variety of Wheat yielding red grain which is so generally esteemed by farmers as the Red Nursery, if we consider the sorts of soil upon which it will flourish, and also further consider the preparation and cultivation of the land also. It is not only important that this Wheat is excellent for the miller, but that it will likewise maintain a plant with greater regularity under adverse circumstances than any other variety, and yield a full crop of grain upon the poorest hill farms, both on chalk and limestone soils. This Wheat is often, especially on some soils under a fallow or green crop preparation, more likely to be laid or lodged than some other sorts, being weaker in the straw under high cultivation, but nevertheless it usually fills the bushel well at threshing time. We must not forget, however, the celebrated Golden Drop Wheat, to which farmers in general are much attached, especially under moderate cultivation, for it yields a long strong straw, stands well, and yields well, and is a grain of great importance to the miller, because the grain is strong and heavy when well harvested, and valued for admixture in grinding with the weaker sorts or with foreign Wheat. Another good sort of red Wheat called Browick is also patronised by some farmers, and is so much like Golden Drop that it is entitled to the description just given of that sort. Red Lammas is a very old variety which we grew more than fifty years ago, and found it specially adapted for the thin soils on chalk and limestone. It yields fairly well, and the grain is strong but thin in the bran; the straw is long, but not strong, and readily goes down under high cultivation. Scholey's Square Head is an inferior light-weighting variety, and we cannot recommend it in the face of the red Wheats we have named. Professor Buckman's experiment in 1881 is an apt illustration of its use and value in comparison with some other sorts, being as follows in produce:—"Oakshott's Champion White, ten sacks per acre; Scholey's Square Head, six sacks per acre." As far as our experience goes this statement represents completely our estimate of the latter variety. April or Bearded—This is red Wheat strong in colour, and weighs well if properly harvested. There is a peculiarity about this variety which we find in no other, because it will bear later sowing, and is adapted in preference for growth upon newly broken-up soils out of woodland or inferior pasture. We have sown it in April on poor soils such as peat and sour woodlands, producing as much straw as it is possible to grow; and for sowing the first year upon newly broken land no cereal can equal it in value for that purpose—in fact no other cereal will produce a profitable crop until the land has been chalked, limed, or marled.

Such cereals as are commonly grown for fodder or mixed with

fodder crops may be now discussed, taking Rye first. There are two sorts—The Giant or St. John's Day, and the ordinary sort usually grown for folding-off with sheep. The ordinary sort is the best, because the most hardy. The St. John's Day Rye is, however, a better and heavier grain, and if the winter proves mild will yield a heavy crop of fodder at the earliest period, and is now very valuable for all purposes where the best straw is required. Winter Barley is of two sorts, called Bere and Bigg. The former is a white grain, the latter is black. The former is well adapted for mixture with Vetches to protect them in winter and hold them up in the spring. The latter is the earliest winter cereal we know, and has a strong broad flag, which makes it specially adapted for mixing with the small early winter Vetches. Winter or Tawney Oats have also a value for growths as fodder or mixing with green crops. All these fodder cereals, although they vary somewhat in their habit of growth, are more or less valuable to ripen as a salc crop, especially in consequence of the land being available after harvest for root crops of various kinds. After the removal of the cereal crop the securing of both grain and straw (the latter being very valuable) in first-rate condition being almost a certainty even in our uncertain climate.

We must now refer to the seed of leguminous plants, such as winter Beans and winter Vetches. The home farmer should consider the advantage of sowing the Improved Winter Beans of a selected variety in comparison with the ordinary samples on the market, in which it has been often found that the common Horse Bean has become mixed, which may not, however, be always detected until the winter frosts have destroyed a portion of the plant, entailing great loss as well as disappointment. The Improved Winter Bean, when true, will endure any adverse weather in this kingdom. It is in this respect of great consequence, for although our midland, western, and northern districts are favourable to the growth of spring Beans, yet the mixed soils situated in our southern and south-eastern counties are more uncertain in the produce of spring Beans: hence the value of the winter variety, for these will generally succeed where the spring Bean would fail through the difference of climate. It is a matter of great consequence that the Bean as a fallow crop should succeed, in order that the great expense of a long fallow may be avoided. The same or similar advantages are to be derived in the case of winter Vetches, which, as a fallow crop, are correctly estimated by those agriculturists who maintain a large summer flock upon strong land, where it is impossible to carry out a system of sheep-feeding on arable land in the winter months; and as winter Vetches frequently fail in consequence of the seed being mixed, it becomes extremely desirable that the seed should be obtained from persons who are responsible for its purity through selection.

WORK ON THE HOME FARM.

Horse Labour.—Much of this work is required at this time of year, especially where land is farmed under the Norfolk or four-course rotation of cropping, for the Wheat being all sown out of Clover or grass lea, the whole of the land intended for Wheat has to be manured from the farmyard or boxes. At this time it is, however, a good plan to anticipate this extra work to some extent, by manuring the Clover seeds in the first winter or early spring, as it makes use of the manure whilst it is fresh and strong, and at the same time equalises the horse labour of the year, and reduces pressure at certain periods of the year. In ploughing and pressing Clover leas drilling is best accomplished by the press drill, which deposits the seed in the grooves formed by the rings of the presser, or, as weeds seldom injure Wheat sown after Clover lea, the seed may be well sown broadcast, and the greater portion of which will then fall into the presser grooves, and will surely be buried a good depth and be more likely to secure a regular plant. We, however, object to working down the lea ground and then drilling the seed with the ordinary drill, for in that case the seed is never buried deep enough to give the plant a firm hold on the soil. Besides which, it is more subject to the attacks of wireworms and other insects, and when severe frost occurs the rootlets of the plants are more exposed and injured than when the seed is put in with the press drill or sown after the presser, in which case less seed is also required. Fallowed land, or land after fallow crops intended for Wheat, and where the land lies flat and cold, should now be ridge-ploughed, and if the land is very dry it may with advantage be treated in the same way as recommended for the Clover lea ground; for unless the land is close and heavy after the autumn rains it will be sure to shrink, and the plants in the next month of May will frequently become root-fallen and the crop lodged or laid. But under any circumstances the fallow preparation always encourages the growth in the spring of those weeds which are indigenous to the soil and hurtful to the Wheat crop. It is, therefore, necessary, whether the seed is deposited by the press drill or ordinary drill, that it should be done at from 10 to 12 inches apart between the rows. We view this as the only way for the home farmer to be master of the position, for weeds are sure to occur, and besides which, on strong soils the Wheat plant will often look yellow and sickly at the end of the month of April. In either case, if the Wheat land

cannot be horse-hoed and hand-hoed between the drills, the crop will be injured past recovery, the effect of hoeing being not only to destroy the weeds, but also to break up the close cold surface of the land to give renewed life and growth to the Wheat plants, without which the application of nitrate of soda will only make the weeds grow and stifle the Wheat plants. If the seed time should be delayed let it be upon the Clover lea ground, as the first fortnight in the month of November on warm soils is quite soon enough. Lifting the Potato crop should now be completed, and where there is a considerable acreage to take up it is greatly facilitated by the lifting frame attached to the ordinary plough with the turn furrow detached.

Hand Labour.—Let the hedge-trimming be now completed, as well as cutting the coarse grasses on banks or borders of the dykes, and also in the newly planted Fir plantations, because these materials are useful for covering Mangolds and Potatoes in the store heaps; and in the absence of seaweed, which is best of all coverings for root heaps, it saves straw, which is now a more important produce than at any former period. Hence the advantage of carefully ricking the straw cavings and chaff at the time of threshing the grain, for it should be as carefully thatched and preserved whether for sale or for feeding on the farm as if it was the best of hay. As soon as the odd horses and carts have completed the removal of couch, stubbles, and rubbish from the autumn fallows, the work of taking up the Mangold crop may proceed at once, in fact, without horse labour at first, if the land should be soft and not able to bear the treading and tracking of the horses and carts. In fact, it is only necessary to employ the men and women, as we approve the heaping and stacking in the field by clearing a space of about 10 yards each way in forming each heap, and we neither sow Wheat after Mangolds or recommend it to the home farmer, because we prefer to sow Lent corn in the spring. It is, therefore, at present a question of hand labour only; the horses are not required for the purpose during the busy seed time, and the heaping of roots in the field may be quickly done. In the future, whether the roots are required to be fed on the land either in whole or in part, they are well placed, and may be removed if required to the cattle yards, or any part of the farm when convenient and in suitable weather. If allowed to remain in the field beyond a certain time the heaps may be covered with straw or seaweed and a little earth; in this way they never heat or decay as is sometimes the case with large store heaps. The greens and tops of the Mangolds may be carted away for feeding store cattle, breeding sows, &c., in the yards.

Live Stock.—The young calves and yearling heifers intended for the dairy in the future should now be removed into high and dry pasture for their night lair, letting them feed in the daytime in the good aftermath of the low-lying meadows; but at night they may be given with advantage 2 lbs. each of cotton cake, this will tend to keep them healthy until the time for hay-feeding with roots arrives. The cattle which were grazing during the summer have now been sold, we will suppose, and those not yet ripe for slaughter should be put into the boxes and well fed in readiness for Christmas. On those farms where the bullocks are purchased for winter feeding and fattening we do not like to buy poor low-conditioned stock, preferring to attend the various cattle markets and select the best-conditioned animals, but especially those just beneath the butcher's quality, for at this time many animals half fat are offered and refused for killing. Let the home farmer buy these and feed them in the boxes liberally, buy them as low as possible in price, but buy them, for they will pay more than by any other plan—at least this is the result of our experience. The dairy cows now the grass generally is become stale in their summer quarter should have the run and aftermath of fresh pastures or parkland, or otherwise have a supply of Cabbages or other roots to eat with cotton cake meal in their troughs at milking time, night and morning; in this way they will continue to furnish a supply of milk until the latest period. Those cows which have been grazed and sold fat this autumn may now be replaced by the purchase of a corresponding number of first-class cows just ready to calve or with calf at foot. The sheep stock, whether of ewes, tegs, or wethers, are more healthy and in finer condition at this time than we have known them for many years. Those intended for root-feeding should whilst in grass have a few cut roots mixed with cake or bean meal in troughs daily; they then do not find any ill effects from being removed suddenly from grass-feeding entirely to root-feeding entirely. This is especially important for the health of the sheep.

OAKSHOTT'S CHAMPION WHEAT.—We are requested to state that this Wheat was not selected from Morton's White, as suggested on page 332, but is the produce of one ear (variety not named) selected by Mr. E. G. Oakshott in Essex.

AGRICULTURAL LECTURES.—Courses of lectures on the "Principles of Agriculture" will be delivered during the autumn, winter, and spring months by Mr. Bernard Dyer, F.C.S., F.I.C., in connection with the City of London College (Monday evening, 7 to 8); and also in connection with the East London Union for Advanced Education at Stepney (Monday evenings, 9 to 10). Particulars may be obtained from the Secretaries of those Institutions, at 66, Leadenhall Street, and at "The Schools," Dempsey Street, Jubilee Street, E., respectively. The classes at Stepney are open to ladies as well as to gentlemen.

POULTRY AND PIGEONS

POULTRY NOTES AT THE DAIRY SHOW.

THE Exhibition at the Agricultural Hall is always regarded with considerable interest, as being the first occasion when the quantity and quality of the chickens of the year can be estimated with any certainty. This year it was some weeks later than in 1881, and the birds are consequently more matured. There was an increase of about a hundred in the poultry entries, but a slight decrease in the number of Pigeons. The classification, as usual, commenced with Dorkings. These had 125 pens in six classes, and were, on the whole, of good quality. The first for Coloured cockerels went to a very large raw-looking bird of Mr. Parlett's, too long in leg for our taste. We much preferred the Earl of Winterton's second-prize cockerel, a squarely built short-legged one of true Dorking type. The winner was not without admirers, as, though entered at £10, his owner had to bid up to £22 for him at the auction to prevent a sale. Of the rest we much liked Mr. Butler Smith's and Mr. Cresswell's birds. The former was v.h.c., the latter quite unnoticed. In the pullet class Mr. Cranston stood first and second with good birds rightly placed notwithstanding some slight duskiess in foot. Third (H. R. Peel) pressed the winners pretty closely. Mr. Cranston was again to the front with Silver-Grey cockerels; indeed, most of the prizes for this variety went to the north. The Dorking medal went to the winner here, which we thought a mistake, as, although of good size and silvery, he was splashed on breast and seemed a trifle round-backed. Of the actual winners we thought Mr. Annand's first-prize Silver pullet most worthy of the distinction, though the second-prize Coloured cockerel would have been our choice for the medal. The prizes in the variety class went to Whites of no special merit.

Cochins had eighty-eight entries in six classes. Buffs were good. The winning cockerel (Mitchell) also took the medal. He was the most finished of the lot, but wanted more size and carried rather too much tail. Second and third (Proctor), though a trifle light in breast and showing a few false feathers on foot, were fine all-round Cochins of the right sort: v.h.c. (Lady Gwydyr) very shapely. In pullets Mr. Proctor again stood second and third with birds of the true type, round and fluffy. First, though of even colour and good in profile, wanted width to make a Cochin. The Partridge cockerels were hardly ready. The winner (Brett) was large and promising, though showing a white feather or two in tail. Second (Mrs. Turner) in better bloom, but smaller. Third (Nicholls) will take time to develop. We could not agree with the awards in the Partridge pullet class. First (Southern), though nicely marked and of good colour, had a very ugly tail. Second (J. Wood), in a small degree, and third (Mrs. Goodall) to a much greater extent, showed white edges to the plumage. This we regard as a very great defect. Mr. Wood's highly commended pullet easily topped the class for size and shape combined with fair marking; while Mr. Nettlefold's unnoticed bird, though young and unformed, showed good promise as to other points, and was splendidly marked. The variety class was entirely composed of Whites, which call for no special comment.

Brahmas had 127 entries in five classes. Dark cockerels were not of exceptional quality. Sir Henry Thompson's birds were first and third, and the Brahma medal also went to the winner here. His best points are his head and comb; his worst, length of leg and want of shank feather. For the rest he is of average merit. Third, very like first, though better on shank, but tailless at present. Second (Breeze), good in most points, but very loose in wings. The pullets were better as a lot than the cockerels. There were thirty of them, and no less than nineteen were mentioned. Sir Henry Thompson again headed the list here with a well-shaped beautifully marked bird, whose only faults were brown, and plenty of it, on shoulders, and want of middle toe feather. Second (Mitchell), of pure light grey ground and fine shape, but wants distinctness of marking. Third (Maddison), large, shapely, and well-feathered, with a very well-marked breast, but showing a mixture of two colours on body: v.h.c. (Comyns), pure colour, but wants just a little more marking. Light cockerels were only an average lot. The winner (Breeze) was good in most points, but seemed rather overshadowed. Second (Sir H. Thompson), also a good one, though not up in tail and a trifle long in leg. Third (G. H. Wood) we liked as well as any in the class but for his black hocks. The pullets were much better than the cockerels, and showed a distinct advance in purity of white. The winner (Birch) was best in size, shape, and feather, though hardly distinct enough in hackle marking. Second (Mitchell) was the best of the class in hackle. Third (While), another good pullet, though showing rather much black on back: 311 (Nettlefold) a really beautiful pullet, but without a tail.

The Langshans still seem in want of a settled standard. First in cockerels (Harris) was large, long in leg and back. Second (Rippon) was small, short in leg, and had a short cochiny back; while third (Orme) was wanting in the one point common to first and second—lustre. Spanish cockerels were a better lot than we have seen for some seasons. The winner (Le Sueur) had a face and lobe of beautiful quality, and but for a fold in the lobe at the ear would be hard to beat. Third (Brown) was our choice of the class. His face is some-

what larger than the winner's, while he has a large fine lobe well spread out. He was not, however, well shown. Second (Street), another good face and lobe, but not laid on so well. Pullets after the winner (H. Brown) were not a remarkable class. Andalusians were few. The first pair (Boissier) were in fine condition and nicely laced, though the pullet was somewhat mixed in ground colour. The winning Minorcas (Harwood) had fine white lobes, red faces, and good glossy plumage. Second (Physick) were somewhat rough in lobe, though otherwise good.

The classification of the French breeds was not so liberal as might be expected in a show where useful qualities are supposed to claim special attention. The winning Houdan cockerel (Jennings), to which also the medal was awarded, did not suit our taste. His plumage was beautifully glossy, but he was hollow-chested, and what with crest and a huge comb he was almost blind. Second, belonging to the same owner, was a grand bird in all points, and far before the winner. The class generally was good, as also were the pullets. First here again easily went to Mr. Jennings with a very fine pullet. Second (Mrs. Lane) not so large, but good in points. Third (Lee) too light for a pullet. In the other French class first (Jackson) and third (Ward) were good Crèves, while second (McMorland) were La Flèche of good size with clear lobes.

Hamburgs, though few in numbers, were of good quality throughout. The medal went to Mr. Fielding for a neat well-marked pair of Gold-pencils. Premier honours also went to Mr. F. Heap for Golden-spangled, to Mr. Jagger for Silver-spangled, to Mr. Rawnsley for Silver-pencils, and to Mr. Ryman for Blacks. These last were in a bad light, which perhaps prevented Mr. Kellaway's beautiful pair from taking the position which we thought their due. The Game classes were very poorly filled, and the exhibits were of no great merit. The most noteworthy were Mr. C. Gibbs' Black Red cockerel which won the Game medal, and Mr. Garne's pullet of the same colour claimed at £20. The winning Malay cockerel (Rattinshaw) was an exceptionally good bird in all points, he was of dark red colour. The Polish classes contained some very good birds. Mr. Beldon's winning Golden-spangles were quite free from white in crest. The winners in the variety Polish class were both white-crested, and we specially noted the length of the cockerel's crest feathers.

Leghorns hardly seem to advance in favour so much as formerly. There seems to be a difficulty as to the lobes. Yellow was the prevailing colour, and if the white is so very difficult to obtain it seems a pity to sacrifice other points to lobe. The winning Browns (Hurst) were not quite free from the prevailing fault though otherwise good. In the White class we much preferred second (Keen) to first (Bradbury), as being clearer in colour and better in lobe though younger. Plymouth Rocks had twenty-one entries, and were of good quality. First (Turner), second (Ainsworth), and third (Bradbury), were of good colour and were rightly placed, although none of the cockerels had their tails up. In the Any other variety class first went to Mr. Beldon for Sultans, second to the Hon. and Rev. F. Dutton for Aseels, and third to Miss Rose Hubbard for Scotch Greys.

The Bantam classes were fairly filled. We have only space to note that the chief prizes in the Game classes went to Mr. Morgan for a smart Black Red cockerel, to Mr. Nelson for a tiny pullet of the same sort, and to Mr. Waters and Messrs. Stretch respectively for a Pile cockerel and pullet. Mr. Phelps won in Blacks with a neat clear-lobed pair, while Messrs. Crowther's Whites stood at the head of the variety class.

The cross-bred table poultry class had twenty-three entries and was well judged. Mrs. Dent took first for a pair of Dorking-Game pullets of fair size, plump, and hard in feather; second (Mrs. Hayne), were Dorking-Houdan pullets; and third (Metcalfe), Dorking-Brahma cockerels. In Ducks Pekins were most numerous and had twenty-seven entries. First (Kellaway) were of fine colour and good shape. The winning Rouens (Wakefield) also deservedly took the medal for Ducks. Messrs. Fowler headed the list in Aylesburys with a specially fine pair, while the Embden Geese shown by these gentlemen were of such great size as to provoke some unfounded doubts as to their being of this year's growth. Turkeys were well represented.

The awards were made by Messrs. Burnell, Leno, Teebay, and Tegetmeier. Mr. Nicholls acted as Steward. The penning, feeding, &c., were undertaken by Spratts' patent, and were all that could be desired.

THE CRYSTAL PALACE SHOW.

THE great schedule is before us, increased to 308 classes! If an average of twenty entries be allowed to each class—no improbable number—there will be an exhibition of over six thousand pens of birds! There seems no great novelty in the poultry department. Dorkings, Cochins, Brahmans, Spanish, French, and Hamburgs and Game have as nearly as possible the same classification as last year. There is a class for Indian Game, but none for Aseels. We cannot understand why "Black and any other colour Polish," which are all shown together, should have but two classes, while Golden and Silver each have four.

Sultans and Silkies have disappeared from the list. It seems a pity that the promoters of a show on such a grand scale cannot

afford to recognise every well-known breed of poultry, even though the loss of a few shillings may be entailed by a small entry; even this would hardly be the case were the chief fanciers of such breeds invited to aid.

There is a twenty-five-guinea challenge cup for the best Game Bantam, which will become the absolute property of anyone who wins it three times in seven successive years. We are much puzzled with the Duck classes, for in addition to the open classes there are four for drakes and Ducks "bred in 1881." This must surely be a misprint for 1882.

There are again two cups (presented by the proprietors of the *Live Stock Journal*) and other prizes for respectively "the heaviest pair of chickens cross-bred, or any pure breed suitable for the table," and "couple of cockerels or couple of pullets cross-bred table fowl."

The Pigeon division is the most wonderful part of the schedule. There are twenty classes for Pouters, seventeen for Carriers, twenty-three for Dragoons, sixteen for Antwerps, and thirteen for Turbits. The classification for the latter variety is a great improvement on former years. By degrees the Toy varieties are getting their due; we hope in time to see them as well subdivided as are Pouters and Carriers. The chief novelty, however, in the Pigeon list is the addition of classes for several varieties which have never or seldom before had them. Among these are Turbiteens, Blondinettes, Satinettes, Fire, Frillbacks, and German Toys. We regret to miss the classes for collections, which we have often admired at the Palace. It is, on the whole, a wonderful schedule, and we look forward to seeing a show worthy of it.—C.

THE POULTRY CLUB.

A MEETING of the Committee of the Poultry Club was held on Wednesday, October 4th, at the Charing Cross Hotel. There were present the Hon. and Rev. F. G. Dutton (in the chair), the Earl of Winterton, and Messrs. G. B. C. Breeze, A. Comyns, H. R. Dugmore, S. Lucas, and L. Norris.

ELECTION OF MEMBERS.—The following new members were elected: Lord Grimston, Cell Barnes, St. Albans; Rev. Chichester A. W. Reade, M.A., LL.D., Chaplain's House, Banstead Asylum, Sutton, Surrey.

STANDARD OF EXCELLENCE.—Several dates were fixed for meetings of the Sub-committee having in charge the preparation of the Standard of Excellence.

SHOWS UNDER CLUB RULES.—The Secretary reported that the following Shows were to be held under Poultry Club rules: Banbury, Dorchester, Exeter, Kendal, Market Rasen, Stanhope *via* Darlington, and Southport. Subscriptions were granted in aid of the funds of Banbury and Dorchester Shows.

NEXT MEETING.—The date of the next meeting was fixed for Wednesday, October 25th, at the Charing Cross Hotel at 2 P.M.—ALEX. COMYNS, Hon. Sec., 47, Chancery Lane, London, W.C. October 7th, 1882.

OUR LETTER BOX.

Cows Eating Beans (*A Cow-keeper*).—In the event of cows eating whole horse beans in any considerable quantity they would injure the health, and probably in some instances prove fatal, precisely in the same way that acorns have often affected cows, for being ruminating animals they cannot be digested if taken in large quantities in the whole state.

MICHAELMAS DAISIES.

PERENNIAL Asters, or, as they are popularly termed, Michaelmas Daisies, are late this year. Michaelmas-day found more of them in bud than in flower. Many of the plants in this second week of October have not yet opened a flower, and some, strange to say, show no signs even of a bud; still the splendid weather we have lately had has made some of them very gay. The name Michaelmas Daisy belongs properly, it is said, to one of the North American species, *Aster novi-belgii*, but is generally applied indiscriminately to all the many forms of perennial Aster, *Boltonia*, *Galatella*, and some other names, of which some of the species flower early in summer and are over long before Michaelmas. Generally, however, the class is characteristic of early autumn, and the most desirable of them are in average seasons at their best about the beginning of October.

The ease with which they may be cultivated, even in town gardens, is one of their chief merits; but it is a mistake to think that they do not require any attention. Though they may exist and flower in any soil or situation, a good rich soil and a warm sunny situation adds greatly to their beauty. They also require to be pulled to pieces after flowering—the stronger kinds every year, and other kinds according to their increase—and replanted, not more than three stalks being planted several inches apart in the same bunch. In this way the lateral branches find room for development, and the flowers are not all crowded together at the top of the stalk. The increase of some Asters is prodigious. We have seen wonderful calculations of the produce of a pair of rabbits in two years, reckoning by a sort of compound interest, but a single shoot of a vigorous species of Aster may be made in the same time to produce a sufficient number of plants to stock all the gardens in a county. Some of them, if left to themselves, become troublesome weeds, though others, it is true, require encouragement to persuade them to grow; but these are exceptions.

It is easier to obtain a collection of plants of Asters than to get their right names, and it is better to select Asters for purchase by sight than by name. It is said that Professor Asa Gray is the one special authority for their names, and that a monograph of the genus is now being prepared by him, to which many of us are anxiously looking forward. At present it is hardly possible to get Asters correctly named. I have been guilty occasionally of sending the same flower to three different authorities, each of whom have given it an entirely

different name. Out of about sixty species or varieties grown in this garden there are hardly ten about the names of which there is anything like a general consent. Many Asters are worthless as ornamental plants; other kinds are of bad habit, but are useful for supplying cut flowers, and a vase filled with well-selected and well-arranged Aster flowers will not be despised as a decoration by those who have good taste. Though I cannot guarantee the correctness of my names, I will mention twelve of the best of the large collection of Asters now in flower in this garden.

The first and best I bought two years ago from Mr. Robert Parker of Tooting by the name of *Aster amethystinus*. It has large semi-double flowers of a clear pale slate blue. It is tall, with spreading branches, and the flowers are well displayed. It increases so rapidly, that besides having it all over my garden I have distributed it to at least twenty other gardens. Next I place the form I call *A. novi-belgii* No. 1, the best variety of that variable species. It has flowers of nearly the same colour as the last, but more thickly set, and with a single row of outer rays. It is rather earlier in flower. These two grow from 5 to 6 feet high, according to the situation, the first being the taller by a foot. Then comes *A. Amellus* and its variety *bessarabicus*, closely allied to one another, and having relations hardly distinguishable, sold to me under the names of *cassubicus* and *amelloides*; but for gardening purposes I class these four as one. The height is about 2 feet, the flower heads broad and thickly set with flowers, and the colour light purple. The fourth and fifth places I assign to the two best forms of *A. novæ-angliæ*, the purple and the pink, sold as "*ruber*," but being in reality a good bright clear rose colour. There are several varieties of both these forms, differing in colour, in the time of flowering, and in the mode of opening their flower. All of them are liable to the objection of being too tall, and of flowering only at the top of the stalk, not making many lateral branches.

Next comes *A. lævis*, a fortnight earlier in flower than the last, and having the merit of flowering from the summit, which is 5 feet high, nearly to the ground; but the spikes are loose, and the flowers look better when gathered and massed together than when growing. *A. versicolor* is a most effective plant for garden display, perhaps beaten by none. It grows 8 feet high, and the mass of flowers is immense. It changes each flower from white to light purple, but neither the white nor the purple is very pure. Next in merit comes an Aster for which I have never been able to get a name at all, though it resembles one sent to me by Mr. Lynch of Cambridge, which he calls *A. æstivus*. I have had it from three or four sources, mostly cottage gardens. In habit it resembles *novi-belgii*, and in colour *Amellus*.

These eight are all large-flowered, and I now mention an Aster about 4 feet high with an elegant curved feather-like growth and abundant small flowers, either pale mauve or creamy white, for there are two distinct forms. It has heart-shaped leaves, and is sometimes wrongly called *cordifolius*—a name which belongs to a coarser plant. I suspect that *paniculatus* is its right name. It is common in cottage gardens, and worth growing in any garden. *A. nivus* is a plant with large nearly pure white flowers. It was given me with that name by Mr. Harpur Crewe, who expressed uncertainty about its correctness; but the flower is good, though not produced in long succession. It grows about 3 feet high. *A. Chap-*

manni must not be omitted on account of its very elegant growth. It is about 5 feet high, with horizontal pendulous branches, and well-dispersed light mauve flowers of no great size or merit in themselves; it is, however, a very distinct kind. After looking through a long list, the claims of *A. horizontalis* seem to deserve the last place in the dozen. It comes into flower late, and forms a dense bush from 3 to 4 feet high, covered with small flowers with a red purple centre and dull white outer rays. It lasts a long time in flower, and is not like any Aster before described, though it claims several other names.

Besides these there are many curious and distinct Asters, amongst which are *A. oblongifolius*, very broadly branching, with irregular-shaped flowers of dull purple. *A. sericeus*, with silvery satiny leaves and weak wiry stems; more elegant and delicate than ornamental. *A. sikkimensis*, which sends out its stems few and far between, but surmounted with good broad umbels of very regular flowers like those of a *Cineraria*. *A. sibiricus*, having the largest flowers of any, like those of *Stenactis speciosa*, but bearing very few of them. *A. ericoides* with linear leaves, and smothered late in autumn with small white flowers. Two occur to me which I saw in flower at Kew in the beginning of August, neither of which I possess: *A. japonicus*, chiefly remarkable for its earliness, and *A. saluginosus*, a fine ornamental flower, which I cannot find in the catalogue of any English nursery, or I should at once buy it.

I cannot tell why I have forgotten *A. longifolius*, surnamed *formosus* (the beautiful), of which I have more plants in my garden than of any other Aster, and which I think is generally the most admired. It is certainly entitled to the third or fourth place in the best dozen, the thirteenth being added to compensate for carriage. But those who have an opportunity should study the Asters now in flower at Kew, where they are correctly named. We who live a long way off envy those who have the chance of doing so.—C. WOLLEY DOD, *Edge Hall*.

[The large bunches of flowers which accompanied these notes afforded satisfactory evidence of the great value of perennial Asters for garden adornment at this period of the year.]

SELECTIONS OF FRUIT.

MANY owners of small gardens desirous of growing some fruit will be much exercised in the approaching planting season as to what is best to plant, weighing the merits of various sorts as set forth in the long puzzling lists, and at length ordering what may very possibly prove unsuitable to their tastes or requirements. I for one must plead guilty in this matter, and by way of atonement will try now to turn Mr. Wright's hint of picking up a pin to account by pointing out a few varieties of fruits of sterling merit suitable for the wants of a very numerous class of Journal readers.

Strawberries ought to have been planted long ago—in July or August, but I may usefully note here a few of the best. By the way, which is the best variety of Strawberry? If I name President many will agree with me, perhaps more than if I chose Sir Charles Napier. Either sort may safely be taken for a general crop, and if a very early one is wanted take Black Prince, and for a late one Frogmore Late Pine. These three will suffice for ordinary purposes, for they are of proved excellence, and will not fail. But for a novelty or two, equally good in their way, take for flavour Dr. Hogg, and for size Cockscorb. See that the soil of the Strawberry bed be well drained, deeply stirred, thoroughly enriched with manure, and if at all close or heavy in texture rendered sufficiently open by a liberal admixture of coal ashes, and there will be no difficulty in obtaining crops of excellent fruit.

Apples for early use in the kitchen will be afforded in abundance from a tree or two of Duchess of Oldenburgh, or say one tree of it, one of Keswick Codlin, another of Warner's King, and another of Hanwell Souring for a succession of good cooking fruit. If there is room for two more take Small's Admirable and Striped Beefing, and you will have half a dozen of our most useful Apples. You may only be able to indulge in one tree for dessert; if so, Margil will be the one to plant. It hardly ever fails to bear a full crop of its handsome richly flavoured fruit, comes into bearing early, and continues doing so upon very small trees. If an earlier sort is wanted Kerry Pippin is excellent, and for a second later sort Cox's Orange Pippin.

Pears are so much affected by local circumstances of soil and

climate that not many varieties may be recommended with any degree of certainty, but there are more than enough for our purpose. Williams' Bon Chrétien is an autumn gem of the first water, closely followed by Fondante d'Automne. Plant the first if you have only room for one autumn Pear. Jewess will afford some good Christmas fruit, and Bergamotte Esperen a later supply. But several more are required for a regular succession of fruit, and to secure these much may be done by planting single cordons 18 inches apart against a house or any outbuildings, then you will be able to indulge in such delicious fruit as Comte de Lamy, Doyenné du Comice, Marie Louise, Louise Bonne of Jersey, Dana's Hovey, Huyshe's Victoria, Glou Morceau, Seckle, Easter Beurré, and Winter Nelis.

Plums.—Rivers' Early Prolific is quite indispensable in every garden. Victoria comes later, and is a sure cropper; and Autumn Beauty affords a supply of late fruit. For dessert there are three kinds to be highly recommended—McLaughlin's Gage, Green Gage, and Reine Claude de Bavay, ripening in the order they are named, and all most delicious. If you can afford space for Coe's Golden Drop and Blue Impératrice do so, for they are invaluable for a late supply of delicious fruit.

Cherries.—May Duke, Kentish, and Morello are so useful that one of each should at least be planted.

Peaches.—If only one tree is required plant Grosse Mignonne—it will seldom fail. If more are wanted, then for earliness take Early Beatrice, which I find much better flavoured in the open air than under glass. Next to it Rivers' Early York, and for later fruit Barrington and Walburton Admirable.

Nectarines.—Balgowan is probably the best sort to name if only one is wanted. It is a little late, but ripens perfectly upon an open wall, makes a fine tree, and is very healthy and robust. For earliness take Advancer, which though small is of most delicious flavour, then the large and fine Lord Napier, followed by such excellent kinds as Pitmaston Orange, Downton, and Pine Apple.

Figs.—The best Fig for an open wall is Brown Turkey, a sure and abundant cropper. For large fruit of delicious sweetness take Brunswick, and for a rarity often fruiting well upon walls Grizzly Bourgasotte, but I am sorry to say it has failed me this year for the first time.

Of Raspberries there is none to surpass Prince of Wales for large and abundant fruit. Carter's Prolific is also very good. Red Currants—Knight's Large Red and Victoria. Black Currants—Lee's Prolific; and of Gooseberries Early Sulphur, Red Champagne, Pitmaston Green Gage, and Red Warrington.

I may add that no Grape is so suitable for an amateur as Black Hamburgh.—EDWARD LUCKHURST.

ROMAN HYACINTHS.

HYACINTHES of all kinds are much valued as winter and spring flowers, but none of them deserve to be more generally grown than the Roman Hyacinth. It is as fragrant as any of them, and comes into flower far earlier. In December it is most appreciated; the choice pure white fragrant flowers are then of the utmost use for floral decoration. One batch of them is never sufficient, but a quantity early in December, another at Christmas, and a third after the new year would not be too many. To have them in bloom at the earliest mentioned time the bulbs should be potted at once; in fact the whole of them may be potted now, and their time of blooming may be regulated by their introduction to heat. A compost of loam, half-decayed manure, and plenty of silver or river sand suits them well. The pots should be well drained, and only a little of the crown of the bulb should be visible above the soil when potting is finished. Sometimes we put single bulbs into 2-inch and 3-inch pots, and in other cases half a dozen or so are placed in a 6-inch pot. As soon as potting is finished the soil is watered if it is very dry, otherwise they are not watered, but plunged under coal ashes to the depth of 6 inches. Here they remain undisturbed for about a month, and then they are brought out to the light, when it will be found that young growths have pushed up from the crowns, and if placed in a temperature of 60° the leaves and spikes will soon develop. Those not wanted in bloom at the earliest date should be placed in a cold frame and introduced to heat as they may be required.—M. M.

THE ROSE ELECTION.

THE TEAS AND NOISETTES.

IN the general elections of previous years the Teas and Noisettes can scarcely be said to have come off very favourably. In last year's table, when no fewer than eighty-eight Roses were tabulated, only eleven Roses of this class obtained a place, and these held

the following positions, Nos. 8, 21, 32, 35, 39, 42, 43, 65, 72, 80, 84. I suppose that with most admirers of our national flower, if two Roses—a Hybrid Perpetual and a Tea—were equally good, the latter would carry away the votes. There is no gainsaying their exquisite beauty; they have a charm peculiarly their own, and they have one quality vastly in excess of their Hybrid Perpetual brethren—they, in sporting phrase, can stay. Who has not wished on the eve of an exhibition that some of his Perpetuals would retain their glories for the judge? Alas, how often have the hopes and wishes been blasted! and yet of Teas one might safely predict that the morrow will find the bloom in as great perfection as to-day. Now, too, that additional colours are being found amongst the newer varieties, and that it is gradually being established that they are not after all so very delicate, there is little doubt their admirers will increase.

Gradually various electors have stated their opinions, maintaining that it was unfair to these varieties to expect them to compete with the others, and urging that they should enjoy a separate election. This has now been accomplished, and I here give the result. Sixty-four electors have voted—thirty-nine amateurs and twenty-five nurserymen. The table contains first the position in the present election, the name, date of introduction, and raiser of the Rose, the amateur first ten and second ten votes, and the nurserymen's first and second-class votes.

RESULT OF THE POLLING.

* The asterisk denotes "too much alike."

Three other Roses had six votes, two others only five each, four were named four times, eight had three votes, seven two votes, and twenty-five received only a solitary mention. Altogether just seventy-nine were mentioned, counting the "too much alike" as single; but counting these in each case as a Rose, the number tabulated in the Tea portion of the National Rose Society's catalogue only amounts to fifty.

Possibly in this section my returns show more demurring to the Roses named as "too much alike." I quote from one of these as regards Madame Bravy and Alba Rosea:—"For instance, Alba Rosea is a thin-petalled papery Rose, beautiful in shape and colour; Madame Bravy is a thick-petalled waxy flower, less good in shape, much stronger in colour." I pass over the foliage, as the compilers have tested only the blooms. This gentleman is a close observer. But it may be asked, Do we not find on the same tree two blooms of some Roses, apparently distinct, influenced probably by some atmospheric condition?

In both the elections there is but one Rose whose certificate has invariably been endorsed A1—that Rose is Catherine Mermet. She is indeed most captivating, deserving her position.

In former elections many electors when naming Devoniensis have added in brackets "climbing," and my own ideas certainly were that it would distance its lesser counterpart, on the principle that if two things are equally good the quantity obtainable would decide in favour of one of them. To my surprise up to almost the last my own return was the only one favourable to the climber.

The electors are the same, with the exception that Messrs. Gall, Frettingham, and Proctor have not voted on the Teas; and Messrs. Cooling's list could with some little trouble be added, and therefore was included.

In the next issue I hope to compare the lists as arranged from the voting papers, with the opinion entertained by the great rosarian of America, Mr. Ellwanger.—JOSEPH HINTON, *Warminster*.

A NOTEWORTHY HARVEST FESTIVAL.

SEEING how wide-spread is the most commendable practice of holding harvest thanksgivings, it would be out of the question for the *Journal of Horticulture* to take more than a general notice of them; at the same time our old friend is read by great numbers who are either interested or take an active part in decorating the sacred buildings where these services are held. For this reason, I hold, especial mention should be accorded noteworthy examples of decorative art; and further, if some of those who frequently

give the readers of the *Journal* the benefit of their experiences would make seasonable suggestions as to what may be done in the way of decorating places of worship on special occasions they would, I feel certain, be widely appreciated. Each festival, such as Christmas, Easter, and Whitsuntide, and last but not least harvest thanksgivings, has its appropriate style, or at all events certain kinds of material for the purpose; and, if I might be allowed to suggest it, why not depute a competent writer to offer timely suggestions upon each? Mr. Luckhurst, in particular, is well qualified for the task, and it is certain his hints would be acted on by some, and probably supplemented by others.

It generally happens this class of decorations is a "labour of love" to those concerned, and in this case it is apt to be overdone—that is to say, they make their wreaths, festoons, and devices too neatly; in fact, spend too much time over them, thus spoiling the effect, owing to the churches more especially being large and heavy, requiring a heavier style. Or, again, if the structures be light and permanently and extensively adorned, by decorating too freely they hide or disfigure the admired features of the internal constructions. Both these extremes are offending to good taste.

At the grand old church of St. John's, Frome, however, the ladies and gentlemen interested contrive to create a most beautiful effect without marring the features of one of the most richly decorated churches in Great Britain. Freely were the requisite plants, flowers, and fruit provided, and freely yet most tastefully were these grouped and arranged, the whole with the splendid service in connection therewith being most vividly impressed on my memory. On each side of the altar were disposed beautifully flowered plants of *Begonia insignis*, these being fully 3 feet high and of proportionate circumference, and were particularly effective in the evening when the church was lighted. About the altar

itself were disposed miniature sheaves of corn and magnificent bunches of Black Hamburgh Grapes, and more of the latter with a background of coloured Grape foliage were suspended to the ends of the choir stalls. Most beautiful was the low carved stone chancel screen. This was surmounted with neat well-flowered pot plants of *Begonia Weltoniensis* and *Knowsleyana*, on each side of the gates being pretty groups formed with a mixture of the plumes of Pampas Grass and flowering spikes of *Gladioli*. The screen was further festooned with Ferns, Dahlias, *Allamandas*, *Bougainvilleas*, and other flowers. The pot plants were surrounded with Apples, Tomatoes, Grapes, and crosses formed with corn were freely interspersed among the wreaths. At the base of the pillars on each side of the chancel were disposed handsome groups of fine-foliage and flowering plants.

The pulpit was tastefully decorated with black and white Grapes and other fruits and cut flowers in variety, and many plants, fruits, and vegetables were effectively grouped at its base. Nothing but white flowers, fruit, and Ferns were employed in the baptistry, and the effect was most chaste and pleasing. Floral

designs laid on moss surrounded the base of the font, while the pillars were festooned with Ivy and white Clematis, and the basin hung with Roses, single Dahlias, Anemones, Begonias, and other flowers, as well as choice fruits. The whole was surmounted with a cross formed with Grapes, Aucuba leaves, and a semi-double Dahlia which I do not remember having seen before. Groups formed of flowering and fine-foliage plants, fruit, and cut flowers were disposed in each window sill, and all the gas standards were wreathed and otherwise decorated. By daylight the general effect was good, but in the evening when lighted up it was most beautiful, and we could but heartily wish the clergy of every church or place of worship could command such ready help from the owners of gardens, and such a staff of willing workers as are to be found among the ladies and gentlemen of Frome. It ought to be mentioned the fruit and flowers are subsequently distributed among the sick poor.—SPECTATOR.

ALNWICK SEEDLING GRAPE AT CHISWICK.

A CONTRAST.

LAST year complaints were not infrequent that this comparatively new and undoubtedly good late Grape was a "bad setter." The fruit unquestionably failed to set in many instances, and unsatisfactory bunches containing a number of pea-like berries were too numerous; even where artificial fertilisation had been resorted to, but perhaps imperfectly performed, the bunches were not so full nor the berries so regular as is desirable. The impression, however, that such aid is requisite for securing a good crop of any Grape is an obstacle against its free cultivation, and with the object of testing the character of Alnwick Seedling as a "setter" it was determined, wisely under the circumstances, Chiswick being an experimental garden, to treat this Vine the same as others in the same house—the Black Hamburgh, Gros Colman, and Alicante—that is, not to have recourse to any artificial means for setting any of them. The result was that the last three named—and there is a great number of Vines of the two later sorts—set their fruit perfectly in every instance, all the bunches being full, and the berries well formed, large, and regular. But it was different with Alnwick Seedling. Of this there were, and are, three or four Vines of the same age and strength as the others planted at intervals along the house, and in every position the formation of the berries was most unsatisfactory, the bunches being practically worthless. This fact being recorded in the press at the time gave to the variety a rather bad character (which some persons, however, did not think it deserved), and without doubt was the means of limiting its culture.

While it was perfectly right and proper to record the Chiswick experience of last year, however unfavourable it was as affecting the value of any particular variety, it is equally fair, and only just, to record the condition of Alnwick Seedling in the same house this year. Last year the crop of it was the worst in the house, this year it is the best. Last year there was not one bunch of this Grape that was half furnished, this year every bunch is full and the berries regular, of good size, and well coloured. Of all the Vines of Gros Colman and Alicante in the same structure not one of either can be found bearing such excellent crops as are borne by each Vine of Alnwick Seedling. Last year there was not one bunch of this Grape in the house under notice that could have been placed on the table at a cottagers' show; this year there were no examples at even the late International Show at Edinburgh equal to those now hanging at Chiswick—not even those, and they were good, exhibited by Mr. Bell, who brought this Grape into notice, and obtained a first-class certificate for it from the Royal Horticultural Society.

The reason for the striking difference alluded to is that this year the bunches when in flower were fertilised with pollen from Alicante. This, then, appears to be the safe method for securing full and regular bunches.

So superior is the crop of Alnwick Seedling both as regards weight and quality over the others, that not only will additional rods be trained from the Vines that are doing so well, and so commence the extension system, but it is not unlikely that it will be increased by grafting. Even if artificial aid is needed for setting the berries, it will be time well spent and labour well invested if such a satisfactory return can be had as is produced this season.

The experience recorded suggests that if we should not hurriedly praise neither should we hastily condemn anything that is new, but await the teachings of experience under differing conditions. The failure of this Grape last year at Chiswick was so complete that not a few persons who pride themselves on their "quick judgment" would no doubt have cut it out. But the manager there has seen too much of what may be termed the vagaries of vegetation to act on the impulse of the moment. He has learned the

wisdom of watching and waiting, and, by cultivating the virtue of patience, has had a reward.

It would be interesting to know how this excellent Grape—an improved Alicante—has behaved in other places. It has no doubt been rather extensively planted, and many canes must have fruited this year. If they are like those at Chiswick their owners and cultivators will be satisfied, and the merits of Alnwick Seedling will be more firmly established.—J. WRIGHT.

POTTING PLANTS.

THIS is an operation which every beginner considers himself skilled in, but which is, nevertheless, often badly performed even by practical gardeners. The first point to be noticed is properly draining the pots. When a suitable outlet for the superfluous water is not made it is hopeless to expect success, for no plant can thrive in sour soil. In draining the smallest-sized pots one crock (piece of broken pot) over the hole in the bottom, with the concave side downwards, covered with the roughest of the soil, is generally enough. Indeed, a little rough soil in the case of strong-growing strong-rooting plants is often enough. For plants in 6-six pots one large crock covered with rough lumpy soil may be enough for Balsams, or even Fuchsias, when growing rapidly. For Heaths and plants of a similar nature small crocks carefully arranged to the depth of fully an inch should cover the central one, and over the small crocks a little moss, or the fibre from the peat or loam, is necessary to prevent the soil stopping the drainage. For a 12-inch pot from 3 to 4 inches depth of drainage will be necessary, and more according to size.

Having drained the pots, the next thing is placing in the soil. When the smallest pots are used for potting cuttings or seedlings enough soil should be placed in the pots, and pressed firmly down, that when the roots of the plant to be potted rest lightly on it the part of the stem which was at the surface of soil before may be fully a quarter of an inch below the rim of the pot. Holding the plant in this position, in the centre of the pot, with the left hand, soil should be placed into the pot with the right, and pressed down firmly and level, the surface of the soil being a quarter of an inch below the rim of the pot. This space is for holding water. When the plants are to be taken out of cutting boxes each should be lifted out carefully with a good ball of earth, and only as much being carefully removed without bruising the roots as will reduce the ball so that it may be easily introduced into the pot intended for it.

When plants are to be shifted the same rule should be observed. Plants do not need shifting unless the soil in the pots is well occupied with roots, and it is considered desirable or necessary to increase the size of the plants. When the plants are turned out of the pots the drainage should be removed, and any unoccupied soil carefully picked off. It should then be placed on the soil (which has been put in the pot and well firmed down previously), and fresh soil packed, either with the fingers or a blunt piece of wood, rather firmly. Loose soil holds too much water, and when plants which are potted loosely are turned out there is danger of the ball breaking, and so destroying the roots. When a plant is potted the new soil should always be put in as firm as the old ball is, or when the water is applied it will run through the loose soil and leave the firmer portion, where the roots are, too dry.

In potting large plants soil as full of fibre as possible should be chosen, and rammed into the pots or tubs rather firmly. The reason for choosing turfy material for soil is that it lasts a long time without becoming sour. When large quantities of soil, in which there is neither fibre nor roots, are packed into large pots or tubs, to remain there for years maybe, it is sure to become sour, soddened, and unhealthy, in which state no plant can grow well in it.

Repotting generally takes place in spring, when plants that have rested through the winter have been pruned and started into growth require partial saking out and repotting in the same or similar pots. Fuchsias should be thus dealt with in spring, and so should any scarlet and other Pelargoniums which may have been brought over the winter, and which may be intended for growing on. Fancy Pelargoniums require this treatment in autumn, when they have made fresh growth after having been ripened and pruned. Plants which have thus been treated do not need larger pots until some growth has been made, but the partial removal of the impoverished soil and supplying fresh soil is always accompanied with good results. In such cases the old balls should be turned out of the pots and reduced as much as will allow of this being easily placed in the pots, and new soil along with them. Any loose roots should at the same time be cut back.

"Potting-off" is when plants in a small state are placed into pots for the first time. "Potting-on" is shifting plants into larger pots

than those they occupied; and "re-potting" is turning plants out of their pots, reducing their balls, and placing them in the same or similar pots. When plants are potted enough room should be left in the pots as will hold as much water as will thoroughly saturate the soil contained in them. A quarter of an inch is enough to leave in a 3-inch pot, half an inch in a 4½-inch pot, 1 inch in a 6-inch pot, and 2 inches in a 10-inch pot, and so on.—N. B.

THE MANURIAL VALUE OF PHOSPHATE OF MAGNESIA.

IN my first letter on the manurial value of phosphate of magnesia (page 290) I said that the point mainly regarded by chemists in assigning values to different combinations of phosphoric acid was their solubility in water. With this quality their diffusibility through the soil is manifestly intimately connected, for on their diffusibility the activity of fertilisers ultimately depends. The solubility of a phosphatic material is largely promoted by fineness of division, and so also is the completeness with which it can be intermixed with the soil whilst it remains a powder, or distributed thoroughly through the soil afterwards when brought into solution. Generally speaking, therefore, in respect of manures, we may consider solubility and diffusibility as expressing the same quality in them; but this is not always true. If perfectly soluble acid phosphate of lime be added to a chalk soil the phosphoric acid undergoes immediate neutralisation, and is fixed in the mere upper crust of the ground. Diffusion is thus checked until this crust is saturated with phosphoric acid, when the process of diffusion may again go on and carry some of the phosphate a little deeper in the soil, and so forth. On the other hand, when the soil is a clay deficient in lime the perfectly soluble phosphate may sink below the reach of the roots of plants before it is physically fixed in the manner explained by Liebig to be necessary, as quoted in my last letter, page 341.

It is manifest, therefore, as it seems to me, that there must be a degree of solubility between that of the so-called insoluble phosphates and the perfectly soluble acid phosphate of lime, better calculated than either of these two extremes for diffusion through soils in general, and such a compound, I believe, we have, as I hinted in a former letter, in phosphate of magnesia. Voelcker ascertained (see table of solubilities, page 190), that a gallon of distilled water dissolved about 0.56 grain of a specimen of Cambridge coprolite, and that when 1 per cent. of sal ammoniac was added to the water 1.52 grains were dissolved per gallon. Of Suffolk coprolites, soluble to the extent of 0.56 grain per gallon, he found that when a per cent. of sal ammoniac was added to the water the solubility rose to 1.12 grains. Roughly speaking, therefore, we may say that the solubility of coprolites is more than doubled by the addition of the sal ammoniac; but Voelcker concluded that neither nitrate of soda nor common salt materially modified the solubility of phosphate of lime, a conclusion opposed to the general opinions of chemists as well as to that of Liebig. Jamieson states that the solubility of coprolites finely ground is in water, 1.13 grains; in nitrate of soda, 1.33 grains; in sulphate of ammonia, 1.46 grains; whilst Liebig found that in the case of water with one part of sulphate of ammonia in 540 parts by weight of water one gallon dissolved 4.4 grains of tribasic phosphate of lime; with one part of common salt in 500 of water one gallon dissolved 2.2 grains; and with one part of nitrate of soda in 333 of water one gallon dissolved 2.5 grains. It will be readily understood that owing to differences in the mechanical state of aggregation of the particles of phosphate of lime, and in the strength of the solution, identical results could not reasonably be expected even if the errors of manipulation which necessarily affect such determinations could be eliminated, but the following points may be considered to be satisfactorily proved.

1st, A very slight degree of solubility in water will enable a phosphate of lime to feed plants with phosphoric acid.

2nd, The slight degree of solubility possessed by phosphate of lime is considerably increased when sal ammoniac or sulphate of ammonia, even in very minute quantities, is added to distilled water. Carbonic acid solution produces similar results in the solubility of phosphatic materials. This point is so well understood that it will not be disputed. Phosphate of lime is also soluble, in no inconsiderable quantities, in liquids which contain in solution various organic non-acid substances, and when recently precipitated it is readily soluble in carbonic acid. A saturated solution of carbonic acid will dissolve fifty-two grains per gallon of bone phosphate, whereas distilled water will dissolve only 5.4 grains of it.—(*Lassaigne Ann. Ch. et Phys.* (3.) 25.348; and *Voelcker, "Solubility of Phosphatic Materials," p. 10.*) I may here state that freshly precipitated phosphate of lime was found by Voelcker to be dissolved by distilled water in the proportion

of 5.66 grains per gallon; but when this had mixed with it a per cent. only of sal ammoniac the solubility was increased to 21.7 grains, or fourfold.

It is, therefore, evident that chemists ought to make some allowance for the increased value of phosphates when organic matter yielding carbonic acid on decomposition, or salts of ammonia, are mixed with the manure; but on the present system of valuation nothing whatever is allowed for organic matter, though formerly a different system prevailed, £1 per ton being allowed for it: this is little enough. No additional value is given for phosphoric acid when associated with ammoniacal salts, though its value is so much increased by their action. Voelcker says in this paper on the solubility of phosphatic materials, "The various conditions which affect the solubility of lime in water, therefore, have a direct practical bearing on the application of bone manures in agriculture;" has not Jamieson shown incontestably that this observation may be extended with truth to coprolites, if not to even less soluble mineral phosphates?—INQUIRER.

AMATEUR'S VINERY.

I WANT a small cheap house in which I can grow Grapes and also a few plants, some of them rather tall, such as Palms and Ferns, therefore the stage must not be made on the orthodox plan for having the plants "close to the glass." Can you throw out an idea that will help me in this matter? I think I have seen something of the kind in the Journal, but have been too negligent to preserve all the numbers. I am an attentive reader, nevertheless, and shall appreciate whatever assistance it is in your power and disposition to render in this matter.—J. P. BOUSFIELD.

[Mr. Luckhurst's "idea" may possibly be of service in this case; but he broaches it with the condemnation of "cheap houses, because they are not durable," and observes—"The accompanying

figure is a section of a light, strong, and durable vinery suitable for any garden, but peculiarly adapted to the requirements of an amateur by the arrangement of the interior. The roof is a fixture; air given as shown. Its dimensions are:—Height of back wall from floor, 9 feet 6 inches; apex of roof from floor line, 12 feet; height of the front wall from the bottom of the Vine border, 2 feet 8 inches; height of the glazed part of the front, 4 feet 6 inches; width, 16 feet; extreme height of stage, 3 feet; width of stage, 5 feet; the interior retaining wall is 4½ inches, or a single brick in thickness. The iron pillars require to be placed about 10 feet apart, and an iron bar passing along under the roof from pillar to pillar imparts great strength to it. The whole surface of the floor should be paved or concreted and faced with Portland cement. The Vines should be planted in the narrow interior border, the roots passing through arches to the outside."

HARDY PERENNIALS FOR MASSING—A PLEA FOR A BETTER NOMENCLATURE.

THERE is no doubt that hardy perennials, or, as they are generally called, "herbaceous plants" (from the fact of some of them being herbaceous), are still slowly gaining favour. The singular beauty of some of them, their great adaptability for supplying cut flowers, and the amount of admiration lavished on them by people of taste when the plants happen to be placed in telling positions, is gradually forcing some persons who have hitherto tried to ignore them to now learn some of their long ugly names, and to cultivate a few of the more showy

varieties. Their names are certainly a great drawback, and as if one of such was not sufficient you can scarcely find a good plant without at least two or three names. It is, however, a comforting fact that aliases in the plant world are generally indications of merit, and convey altogether a different impression to aliases borne by men and women. But an alias or two is not the only drawback—we find totally different plants under the same name. In some cases, if you order the same from three different nurseries you will get three distinct sorts of plants, not one of which is the thing you want, and there is no recognised authority to tell us which is the right name or the right plant. Who will start a society for the purpose of making a collection of useful hardy plants with systematic classification, and an English as well as a botanical nomenclature, such as would be generally received? We do not want the collections of weeds we see in botanic gardens—these may or may not have their uses there (I am not sure about this part of the subject)—but we want collections of plants which are really decorative, and with names such as nurserymen would recognise when we give them an order.

As it is at present nurserymen are under a disadvantage, and private gardeners have demands on their time and resources which they can ill afford to comply with. A lady or gentleman sees a collection of plants in a private establishment; he or she if not a novice knows that the same plants are not to be obtained in a nursery under the same names, takes notes, and asks the proprietor to supply pieces of plants there and then. Of course a refusal is out of the question, and it frequently happens that when there is only one choice example of a new arrival it has to be divided, and perhaps spoiled, when it ought to be easy to procure the same plant at the nearest nursery for 9d. or a shilling if the nomenclature was trustworthy.

But I have slipped away from the part of the subject I intended to write about. Within the last three or four years I have used some of this class of plants for massing in formal beds in the flower garden, and I find they are very popular. The proper place for herbaceous plants generally is where they can have a background of shrubs, and where there is little or no formality in design; but the few plants I shall name are admissible in circles and ovals amongst the strictly geometrical designs, and as they pretty well take care of themselves their use is advisable on the score of economy, as well as for giving variety in colour and habit.

Rudbeckia speciosa (syn. *R. Newmanni*, syn. *Centrocarpha grandiflora*) is the best of all for this purpose. I have self circles of it on the grass, also circles on a groundwork of Purple King Verbena, and it is very effective both ways. The colour is bright yellow, with a black centre. It grows about 2 feet high, and has the habit of clothing itself with flowers quite down to the ground. It is very beautiful for cutting, and has been used in thousands for church decoration during the late harvest festivals.

Anemone Honorine Jobert (syn. *A. japonica alba*, syn. *A. vitifolia*) is the next best, and the pink variety, *A. japonica hybrida*, is very little inferior to it. The white one especially is useful for cutting. The larger the masses of these are the better they seem to look. I have self beds of each of them some 10 or 12 feet across. The older *A. japonica*, with dark red flowers, does not grow so well with me.

Lobelia syphilitica and its varieties make attractive small beds, but for the dark varieties with blue shades they must not be too large.

Of Michaelmas Daisies the best for this purpose is *Aster Amellus*, about 18 inches high, of a bright purplish-blue shade. This also must not exceed 5 feet in the mass.

Many other occupants of the herbaceous border are quite as beautiful as these in their present positions, but from their straggling or tall habit they are unsuited for formal beds.—WM. TAYLOR.

BETTER INFESTING STRAWBERRIES.

RESEARCHES amongst a considerable number of books treating of horticulture or of insects fail to disclose any records in the past concerning attacks made by the ground or carnivorous beetles upon the fruit of the Strawberry. That such is the occasional habit of several species is sufficiently proved. "E. D.," a correspondent of this Journal, was the first to notify the fact, since confirmed by Mr. Cornhill and others. The species in the first instance published was *Harpalus ruficornis*; species in the genera *Pterostichus* and *Amara* also prove to be offenders, and very likely we shall find more species by-and-by. This discovery may be regarded as one result of the greatly increased cultivation of the Strawberry of late, possibly owing to the dexterous manner in which the beetles usually conceal themselves. Gardeners have

hitherto laid their damage to the slugs. Upon these it is certain several of these beetles prey, and upon a variety of insects, some of which are very harmful in gardens.

To the above tribe, at least occasional enemies, must be added the June bug (*Phyllopertha horticola*), as infesting the blossom of the Strawberry some seasons, and checking its development. Two of the *Otiorynchi* haunt the plant. The black Vine weevil (*O. sulcatus*) in its larval state is to be found at the roots as a whitish, frothless, hairy maggot from August to spring. The beetles come out in May. The red-legged weevil (*O. tenebricosus*) sometimes visits Strawberries, but it is rather a promiscuous feeder, attacking the roots of Currants and Raspberries, and also various vegetables. A far better plan than killing the maggots is to prevent their appearance by hunting up the weevils ere they have deposited eggs.—J. R. S. C.

AMONGST THE REIGATE ROSES.

UNLIKE Canterbury, Reigate has long been famous for its Roses and Rose gardens; indeed it has in all branches of horticulture been especially favoured, while in Rose cultivation it has occupied a very foremost place. Go back as far as we may in the annals of Rose exhibitions, and we shall find that the Reigate growers have ever been victorious. The names of such growers as Messrs. Waterlow, Heywood, and Sargent are sure to be found in the winning lists, while of late years others have joined them in the friendly strife; and the worthy Vice-President of the National Rose Society, Mr. Baker, and Mr. Wollaston have come to the front, and they are all not merely Rose lovers but Rose growers, and one is pretty sure in going amongst them to get information on some points and useful advice on others.

GREAT DOODS.

I have been to these gardens at various times, notably at the period of their Rose Show, and have recorded my impressions of what I then saw. My last visit was paid the other day, and most enjoyable it was to go with my excellent friend Mr. Baker and talk with those who had watched over and successfully cultivated the Rose for so many years. Great Doods, the residence of Mr. A. J. Waterlow, is noticeable not only for its intrinsic beauty but for the thorough excellence of the gardening all round. The Roses are, however, the special favourites of Mr. Brown, Mr. Waterlow's excellent gardener, and are cultivated with great success, and under by no means favourable circumstances as far as soil is concerned, which is light and hot; but withal that we know what splendid flowers Mr. Brown is in the habit of staging, and those who have advocated the non-manuring of Roses would find it somewhat difficult to get on in the same manner. Roses were grown here on the seedling Briar, on their own roots, and on a stock which Mr. Brown very much values, the *Rosa Grevillea* or Seven Sisters. It is impossible to see finer plants than were here on all these various stocks, those on their own roots being especially fine, two-year-old plants having shoots from 6 to 8 feet high. It was nearly the same on the other stocks. By-the-by, Mr. Brown mentioned that in planting his stocks he laid the roots on the surface and then earthed them up almost as is done with Potatoes; and thus when he came in the following year to the budding he had merely to remove the earth round the collar and then insert the bud, while in ordinary cases the earth has to be almost dug out in order to get underneath the surface for the purpose. It very evidently saved the back of the operator, and as one gets on in life these little matters are of some consequence. That it answered its purpose there could be no doubt after seeing the splendid plants that Mr. Brown had under his charge. Some persons have been complaining of this as a Roseless autumn. It was not so here, and flowers that would not have disgraced a stand in July were to be seen in considerable numbers, although a large bouquet of splendid flowers had just been cut for the Lord Mayor Elect.

HOLMFELS.

Mr. Baker's garden at Holmfels—not at all in the country, but in the centre of Reigate—is known to many a rosarian through its genial owner and the excellence of the plants which he delights in. One would hardly imagine from its situation what an enjoyable garden there is in the rear. A beautiful lawn with beds of *Pelargoniums*, &c., stretches up to the rear of the house, and beyond this is the Rose garden, and it is quite evident that however orderly and well-arranged the whole garden is, it is the Rose which is the grand object of affection and care. If a new piece of ground is broken up you may be sure that it is for Roses. If a bed is altered it is that it may be made into a Rose bed. And here again let me say to those who think that it is of no use growing Roses unless you have a good Rose soil, that Mr. Baker's is naturally a very

bad one. The garden rests on a bed of gravel, and hence there is great danger of the plants suffering from drought in summer; therefore infinite pains have been taken to make the ground. It is trenched to the depth of 3 feet. At the bottom is placed a layer of clay, then a layer of loam, then a layer of dung, then another of loam, and so on until the bed is finished. It will be seen that this is an expensive proceeding, but it is surely better to go to such an expense at first than to have miserable starved plants and to be obliged to continually replace them. And this I will say, that although I have visited this autumn many Rose gardens in various parts of the country, I have nowhere seen one that I can quite put equal to Mr. Baker's. The plants are vigorous without being "pithy," and care has been taken to thin out all the small and useless wood, so as to allow full play for light and air through the plants. This insures the ripening of the wood—one of the most essential points for success in the following year—success either for a display of Roses in the garden or for exhibition. Mr. Baker is a strong advocate for very hard pruning, and most certainly his Roses do credit to his system of culture. He also mulches very fully with old manure, except in the case of newly planted Roses, when he covers the surface of the ground with the decomposed lawn mowings, which has a certain amount of nourishment, but not too stimulating for the plants.

WOODHATCH.

Mr. Heywood's garden at Woodhatch is another which has made its mark in the Rose world, and of all the places about Reigate that I have seen is the most beautifully situated. The view of Leith Hill and all the country round about is simply magnificent. The eye is never tired, especially on a fine day, when the effects of light and shade amongst the foliage near and far off are to be seen; and no part of our island is more beautifully wooded than this part of Surrey, the greater portion consisting of gentlemen's demesnes, where trees are ever appreciated—different from agricultural neighbourhoods, where trees are regarded as "cumberers of the ground" and hindering the growth of crops. The garden at Woodhatch is beautifully situated on rising ground, and here is to be seen horticulture successfully practised in all its branches. Nowhere, for example, have I seen such grand plants of Chrysanthemums as here, "feathered down to the toes;" and those from which the exhibition flowers are to be cut, some 6 and 7 feet high, with splendid foliage. But here, too, the Rose has the place of honour. A house is specially devoted to the culture of Tea Roses, which were in a thriving condition, while borders and beds of Hybrid Perpetuals in a most satisfactory state were to be seen in every position. Mr. Heywood's excellent gardener, Mr. Ridout, has a large number of budded plants in the kitchen garden, which is at some distance from the house, and here all the best varieties are budded in considerable number—thirty or forty of a sort—and doubtless from these some grand blooms are to be expected for the next season. Mr. Ridout is a strong advocate for the Briar cutting, of which Mr. B. R. Cant thinks so highly.

Looking through all these gardens one could not but be struck with the number of plants which, by their abundance of flowers, thoroughly justified their title of being "remontantes," or autumn-blooming Roses. Teas, of course, were in flower everywhere. Charming blooms of Marie Van Houtte, Madame Lambard, Innocente Pirola, Souvenir d'un Ami, and a host of others were full of flower, and splendid blooms were gathered every day. Amongst the lighter-coloured Hybrid Perpetuals in flower were Baronne de Rothschild, Duchesse de Vallombrosa, Egeria, Comtesse de Sercnye, La France, Auguste Rigotard, Mabel Morrison, Marie Finger, Capitaine Christy, Marquise de Castellane, Madame Sophie Fropot, Duchesse de Morny; while amongst the brighter and dark-coloured flowers were Marie Baumann, Duke of Edinburgh, Charles Lefebvre, Marie Rady, A. K. Williams, Madame Victor Verdier, Duchess of Bedford, Dupuy Jamain, Général Jacqueminot, Charles Darwin, Etienne Levet, Madame Victor Verdier, Maurice Bernardin, Hippolyte Jamain, and Fisher Holmes; and, as far as my experience goes, these may be relied on as good autumn-blooming Roses. There are others which perhaps may be classed with them, while there are some which are hopelessly only summer-blooming. Only in this latter number I was some time ago inclined to include Madame Gabriel Luizet, but I am happy to say I maligned her; and Mr. Cant, than whom we have no better authority, says, "I hope when I can get strong cut-backs to find it much more free-flowering than at present."

Let me add that nowhere in the kingdom is there a more hearty and genial set of Rose-growers than at Reigate; nowhere is a real lover of the flower sure to receive kindness and hospitality; and nowhere are there a "straighter" set of exhibitors. The definition of "an amateur," which is now perplexing "committees," would be no difficult matter if all amateurs were like our friends here. There are other gardens here which I was not able to visit at this

time, such as Mr. Wollaston's; while from all I hear my excellent friend Mr. J. D. Pawle is likely to again enter the lists where he was once so successful a competitor. Altogether Rose-growing at Reigate is in a very flourishing condition, and I fully expect to see it coming to the front in the exhibitions of 1883.—D., Deal.

A MEETING of the General Committee of the NATIONAL ROSE SOCIETY was held at the Horticultural Club on Tuesday last, G. Baker, Esq., in the chair; at which it was determined that the Exhibitions for 1883 should be held at South Kensington on Tuesday, July 3rd, and at Sheffield on Thursday, July 12th. The idea of having a third show earlier than the other two at either Salisbury or Reading was also entertained.

— WE learn that the EXHIBITION OF CHRYSANTHEMUMS AT FINSBURY PARK will be opened on Saturday the 21st inst. Of course, at present only a few of the early flowers have expanded, but the show of buds and excellent condition of the plants augur well for a finer display than in the two previous years, beautiful as they were. About 1500 plants are grown, representing all the leading varieties.

— MR. G. GOLDSMITH, The Gardens, Hollenden, Tonbridge, writes that his collection of PEARS AT SOUTH KENSINGTON last week comprised sixty dishes of Pears, distinct varieties, no Apples being shown. As remarked in our report, the majority of these Pears were unusually fine for the season—large, handsome, and well ripened.

— MR. F. ORCHARD, late foreman at Warnham Court Gardens, Horsham, has been appointed gardener to E. Barker, Esq., Abington Hall, near Cambridge.

— RELATIVE to the competition for the CHALLENGE CUP AT THE KINGSTON CHRYSANTHEMUM SHOW, the conditions are that the three winners of the first challenge cup will not be allowed to compete for the second this year, but after this year they will be free to compete. This was not clearly stated in our note of last week.

— IN another column Mr. Shirley Hibberd appeals for support with the object of providing for an EXHIBITION OF PINKS, to be held in conjunction with the National Pelargonium Show next year. We readily publish this appeal, and shall be glad if it is responded to in such a manner as will enable the project to be carried out successfully. These chaste, sweet, hardy, and somewhat neglected flowers are at least as well worthy of encouragement as Zonal Pelargoniums.

— DAHLIA VIRIDIFLORA, shown by Mr. Cannell at South Kensington on October 10th, and which is by some considered to be a species, is only a variety, the same as any other double Dahlia, and was raised from seed in 1852 by the late Mr. John Salter of the Versailles Nursery, Hammersmith, so well known by his extensive cultivation of the Chrysanthemum; and it was then popularly called the Artichoke Dahlia, from the resemblance its green bracts gave the flower to the head of an Artichoke.

— WRITING on VEGETABLE MARROWS, a skilled gardener observes:—"They are among the first vegetables to be affected by the frost, and when once the leaves are cut down the fruit will cease growing. It may not be convenient to protect all the plants, but one or two of the most fruitful should be covered before frost has done harm. If it is desired to keep them on bearing for as

long a time as possible the marrows must be cut off before they are very old. To allow them to remain until they are full-sized and full of seed will prevent a constant succession. We grow two lots of plants—one to produce seed, the other to supply the kitchen. An open situation, close pinching, hard cutting, and good feeding throughout is the way to secure abundance of choice Vegetable Marrows."

— WE regret to learn that DR. THWAITES died at Kandy on September 11th, at the age of seventy-two. It will be remembered that he resigned the directorship of the botanic gardens at Peradenya, Ceylon, some time since, being succeeded by Dr. Trimen, who now holds that post. Dr. Thwaites was specially noted for his studies amongst the lower Cryptogams, Fungi and Algæ having particularly engaged his attention when in England. He was appointed Director of the Ceylon gardens in 1849, which he ably conducted until a year or two ago. His chief work is an enumeration of flowering plants found in Ceylon, which is useful for reference.

— A CORRESPONDENT informs us that "DAHLIA GLARE OF THE GARDEN OR FIRE KING, is now very effective in Croxteth Hall Gardens. A large bed of the single forms is near it, but cannot be compared to the above for richness of colour or free flowering. The single variety Avalanche is also effective, and these two varieties cannot fail to become popular, and will undoubtedly in a short time be largely and generally grown where either a display or cut flowers are in request in late summer and early autumn."

— MANY of our readers will be pleased to hear, as we have pleasure in recording, that a graceful tribute of esteem was paid last week to the REV. H. B. BIRON (whose name is so familiar as a successful exhibitor of Roses) in the form of the presentation of a valuable purse of gold, with a book containing the names of the subscribers, on his retirement from the curacy of Harbledown to the rectory of Lympne.

— MR. CHARLES SMITH of Wiggington, Tamworth, writes that from 1 bushel of 56 lbs. of CARTER'S MAGNUM BONUM POTATO he has dug 23 bushels of 80 lbs.; and one large set planted alone produced fifty tubers, all of them sound—namely, thirty large for table, five medium for seed, and fifteen small. He considers the results good, but does not suppose they excel those of other cultivators.

— THE reputed only specimen of CYPRIPEDIUM RETICULATUM in cultivation is now flowering in Messrs. J. Veitch & Sons' nursery at Chelsea. It is not remarkable for its beauty, having greenish flowers, the sepal and petals of semi-transparent texture, showing a network of fine veins, from which its name is derived. The lower sepals are broad and fitted closely to the lip, giving somewhat the appearance of an additional pouch at the back of the lip. A beautiful new species of Ladies' Slipper named *C. cardinale* is also flowering. In form of flower it is suggestive of *C. spectabile*, and it resembles *C. Sedeni* in colour, the lip being a deep rose colour. It is said to be equally as free as the last-named, which is represented in this nursery by a number of plants flowering abundantly.

— "J. W.," writing on LADY HENNIKER APPLE, says he saw a sample the other day grown by Mr. Smith at Mentmore, and its large size, symmetrical appearance, and bright colour suggests that this variety is worthy of attention. Compared with others in a large collection there was not one so handsome, and if the tree is a good grower and bearer the variety should be included in most collections. Information on these points, our correspondent suggests, would be serviceable, and he would be glad to have the experience of Mr. Smith or others who may have fruited this variety.

— THE "Belgique Horticole" observes that Baron Nathaniel Rothschild's gardener at Vienna has succeeded in crossing SCHOMBURGKIA TIBICINIS with pollen from *Lælia purpurata*, and plants have been raised which are making good progress. What the result will be if a cross has really been effected it is not easy to imagine.

— "S." WRITES, "Although the Floral Committee of the Royal Horticultural Society displayed at the last meeting an unusual anxiety to certificate all the plants they possibly could, yet they passed one of the best shown there—namely, IMPATIENS SULTANI. Their remarkable liberality in other respects attracted much attention and caused some criticism, and perhaps they were under the impression that they adjudged this beautiful Balsam a first-class certificate when it was exhibited at a previous meeting, as many visitors thought would have been done. The award of a botanical certificate with which the Impatiens was doubtfully honoured conveys to the public the idea that the plant is worthless for decorative purposes, which is far from the case, as in its free growth, perpetual flowering, and easy culture Impatiens Sultani is unrivalled amongst its relatives."

— MESSRS. J. JEFFERIES & Co., Oxford, send us a selection of SINGLE DAHLIAS, including several very distinct and handsome varieties, which we learn have been raised by Mr. W. H. Baxter, curator of the Oxford Botanic Garden, who has paid great attention to these plants, and has succeeded in obtaining a beautiful strain. Especially notable is one named W. H. Baxter, a medium size of good form, the florets $1\frac{1}{4}$ inch broad, rounded, brilliant crimson in colour and yellow at the base, which thus forms a central ring, imparting a most distinct appearance to the blooms. Some of the others are similarly characterised by this peculiarity, one being deep purplish crimson and the other bright scarlet, each with a yellow zone. Of the self varieties the best were the following, unnamed:—Magenta crimson, with broad rounded florets; orange buff, very neat flower of a distinct, but popular tint; white, very clear and good flower; creamy white, flower small, but symmetrical and graceful; claret red; ruby shaded orange; and several good shades of yellow. The flowers were admirably packed in damp moss, but their shattered condition indicated the one great defect of the single varieties—namely, not bearing carriage well.

— A CORRESPONDENT writes:—"Some Latin NAMES OF PLANTS have a great similarity in sound to certain English words, though the meaning is quite different. These occasionally give rise to rather amusing blunders, and one of the best examples of what may be termed literal translation recently came under my notice. I was inspecting a collection of plants, among which was one invested with interest on account of its rarity, and bearing the specific name 'nodatum.' My attendant seemed at a loss to understand the meaning of this term, but ultimately came to the conclusion that the plant had been so named because the collector had lost the date when the plant was discovered. It is evident that my informant might advantageously pay a little attention to the rudiments of botanical nomenclature."

— THE GREENHOUSE at the Royal Gardens, Kew, is still as gay as could be wished at this time of year. Salvias, such as Bruanti, Bethelli, and patens, have been freely employed with excellent results, *S. Bethelli* being particularly good, plants in 8-inch pots bearing numerous fine heads of rich purple flowers. The brilliant scarlet *S. Bruanti* and the unequalled blue *S. patens* are similarly effective. Very notable amongst the climbers is a plant of *Swainsonia Osbornii*, an extremely beautiful species that is by no means so well known as it deserves to be. This specimen has now been in bloom some months, and is likely to continue for a considerable time yet. The flowers are of a fine, clear, bright

purplish blue, with a white blotch in the centre of the standard, and they are borne in close racemes, which are produced very freely from the axils of the graceful pinnate leaves. *Lapagerias rosea* and *alba* are progressing well, one pendulous growth of the last named having about twenty handsome flowers in a length of about 2 feet. The deep orange-coloured *Cestrum aurantiacum* is still covered with its abundant trusses of flowers. *Tacsonias exoniensis* and *Van-Volxemi*, with *Passiflora racemosa cærulea*, being all useful climbing plants, the merits of which are well known.

— MESSRS. SAMPSON LOW, MARSTON, & CO. are about to publish a cheap edition of the illustrated re-issue of "GILPIN'S FOREST SCENERY," edited, with notes bringing it up to date, by Mr. F. G. Heath, author of "Autumnal Leaves."

A WINTER DRESSING FOR VINES—EXTIRPATING MEALY BUG.

WHEN I took charge of the gardens here a year and nine months ago I found the Vines very badly infested with mealy bug—so bad that the clusters of bug which hung to the rods looked very much like tufts of cotton wool. The Grapes had all been cut, and every bunch I have been told had to be cleaned. The first thing I did was to prune the Vines, but we did not bark them, a practice which I think is unnatural and one that cannot be too strongly condemned. We, however, gave them a good scrubbing with water as hot as we could bear our hands in and soft soap; then after they were dry we gave them a thorough painting with the following mixture, and for the two following seasons not a bug has been seen on the Vines, and we have had good crops of large and well-finished Grapes; and as the season for cleaning Grape Vines and other trees is close at hand perhaps the following receipt may be of use. To a gallon of water add 6 ozs. of nicotine soap, half a pound of sulphur, half a pound of tobacco, 1 oz. of nuxvomica powder, with sufficient clay and cow manure to make it of the consistency of thick paint; apply with a soft brush.—W. C.

NORTHWARDS—THE EDINBURGH NURSERIES.

No one can remain long in the "Modern Athens" without being impressed with the great number of hotels provided for the accommodation of a fleeting public; and if inquiry is made on the subject the visitor will find that nurseries are also numerous. Some of these are of established fame, worthy of a visit, and hence of record. Of a few that were visited the following notes are descriptive:—

THE LYNEDOCH AND CRAIGLEITH NURSERIES.

These belong to the young and rising firm of Messrs. Ireland and Thomson, and are different in some respects from most of the other Edinburgh nurseries. Until they were established some eight years ago there was no nursery in the north in which primary attention was given to Orchids and new and choice stove and decorative plants generally; but by this firm they are raised and grown with the most satisfactory results. The admirable display of plants at the late International Show was a good indication of the quality of the general stock, and a visit to the nurseries proved that the plants at the Show were only fair samples of the general contents of the houses. The Royal Exotic Nursery, Lynedoch Place, is only about three minutes' walk from the west end of Prince's Street, and is chiefly devoted to glass structures, there being three ranges, or thirteen houses. Here we found fine collections of *Camellias* and *Azaleas* luxuriant in growth and bristling with flower buds. Tree Ferns were well represented in several of the houses, there being many large plants of *Cyathea Smithii*, *Dicksonia antarctica* with stems from 6 feet to 9 feet high, *Cyathea dealbata*, &c. Palms are also growing in large numbers here, and amongst these we noticed great quantities of fine *Kentias* of sorts, *Arecas*, *Seafortthias*, *Latantias*, and all others of merit as decorative plants. *Cocos Weddelliana* and *Geonoma gracilis* also deserve special note, as they were excellently represented. In other of the houses there were large batches of *Primulas*, and a general collection of stove and greenhouse Ferns were very conspicuous by their clean healthy condition.

Further on over Stockbridge, and in a beautiful and open part, we come to the Craigleith Nursery, and this is on a much more extensive scale in the way of glass houses and nursery ground. The latter is filled with healthy batches of the most useful and ornamental evergreens and shrubs of every description, herbaceous plants in great variety, fruit trees, *Roses*, and in short everything to be found in a well-appointed nursery. The glass houses consist of eight span-roofed structures each 50 feet long by 15 feet wide. The first house, given up to East Indian Orchids, contains a selection of all the best of these in cultivation. Well-established pieces of such lovely and valuable kinds as *Cymbidium eburneum*, *Cattleya Trianae*, *C. Dowiana*,

C. Warneri, *C. Mossiæ*, and *C. gigas*, *Lælias*, *Phalænopsis*, *Dendrobiums*, *Cypripediums*, *Saccolabiums*, and all choice Orchids worth growing were to be found in quantity and in healthy and robust condition. *Calanthes*, which may well be included among the choicest of plants, filled a corner in the Orchid house, and their large pseudo-bulbs and fine foliage gave promise of a rich display of their favourite flowers. No. 2 house is devoted to cool Orchids, and was filled to overflowing with fine batches of *Odontoglossum Alexandræ*, *O. Pescatorei*, *O. triumphans*, *O. Rossii*, and the variety *majus*, with a quantity of *O. pulchellum majus* of the best variety. *Masdevallias* were in grand condition, such kinds as *M. Veitchii*, *M. Harryana*, *M. Chimæra*, *M. tovarensis*, and *M. trochilus* being grown in great quantities. *Lycaste Skinneri* is largely grown, and, like all the others, the plants of it are in fine condition. The old *Cypripedium insigne* was growing freely and blooming profusely, the largest of the plants having eighty blooms and buds on them. Many splendid young plants of the *Zygopetalums*, and some large and small potfuls of the charming little *Pliciones*, were doing remarkably well in the same cool atmosphere as the others.

In one of the plant stoves we found one of the finest collections of *Crotons* we have ever had the pleasure of seeing, their clean free growth, and, above all, their high colours, being most striking. The new *Croton Thomsonii*, certificated at Manchester last year, and previously noticed in these pages, was represented in grand form here; and also were other new varieties of value, including *C. Archibaldii*, *Lord Chelmsford*, and two new seedlings now being sent out by this firm. They are very long and narrow in the leaves, rich gold and crimson in colour, and most desirable for dinner-table decoration. Abundance of small and half-specimen plants of all the older varieties of *Crotons* are also kept in stock, and altogether form a remarkable collection. The same house also contains quantities of healthy *Dipladenias*, *Bougainvilleas*, *Stephanotis*, *Clerodendrons*, &c., and from the roof was suspended many Pitcher-plants, including *N. sanguinea*, *N. Mastersii*, *N. Henryana*, *N. Williamsii*, *N. robusta*, *N. Hookeri*, *N. Laurenceana*, and others. The smallest of them were carrying about twelve pitchers, and some of the largest had twenty-four. *Anthuriums* were doing well in the company of these, the new *A. Andreanum* being very plentiful, and the finest plant had eleven bright spathes. There were good batches of the new double-flowering *Bonvardias* in one of the houses, and hundreds of red and white *Lapagerias*, *Cyclamens*, and other winter-blooming plants. One house is entirely given up to the best kinds of greenhouse plants, and contains a choice and well-grown collection, a variety of choice Heaths being very prominent. Ferns are also grown in this nursery in large quantities. In the propagating house large quantities of new *Crotons*, *Dracænas*, and other choice plants were being rooted by the thousand. Young Vines in pots for planting out in borders and fruiting in the larger-sized pots were in a most satisfactory condition, the canes being very strong, the buds prominent, and all thoroughly ripened.

In this brief notice many good plants are necessarily omitted, but we would advise all interested who visit Edinburgh to go and see for themselves, when they will observe that cultivation is of an unusual high order here. The seed warehouse in Waterloo Place is under the superintendence of Mr. Ireland; Mr. Thomson, who is the only son of that widely esteemed gardener, Mr. David Thomson of Drumlanrig, looking after the nursery stock, ably assisted by Mr. Cole, a name known throughout the country in connection with high-class plant-growing.

MESSRS. METHVEN & SON'S NURSERIES.

Of these there are four, the principal one being in Leith Walk, the second at Warriston, the third at Inverleith, and the fourth at Gogar. There are few nurseries better known about Edinburgh than "Methven's in Leith Walk," as this nursery is entered from this popular thoroughfare, and the long walk which runs through the greater part of it in a straight line has a very imposing and inviting appearance. On each side there are many large beds filled with ornamental-leaved *Hollies*, *Rhododendrons*, and all kinds of hardy Conifers and shrubs, their condition all that could be desired, and the varieties choice and good. Amongst *Hollies* we were much impressed with the many fine samples of such valuable kinds as *Golden Queen*, *Shepherdii*, *Watereriana*, *myrtifolia*, and *Lawsoniana*. *Rhododendron ponticum* was remarkable for number, and other fine-flowering varieties of the Himalayan sorts appeared in a very luxuriant state. Many other bushes valuable as ornaments and useful for covert planting occupied much space, and every attention appeared to have been devoted to secure clean ground and compact robust growth. Here and there about the grounds there are brick walls very suitable for training juvenile fruit trees, and these were covered with healthy finely trained young *Peach*, *Nectarine*, *Apricot*, *Plum*, and other trees generally grown against walls. Judging from the growth of the generality of the trees in this nursery the soil must be unusually good, and no expense appears to be spared in keeping it in a highly productive state. The glass houses are more scattered here than in some of the other nurseries, but this does not interfere in any way with the condition of the inmates, as the many thousands of plants could not be in a higher state of cultivation. They consisted chiefly of *Azaleas*, *Camellias*, *Heaths*, and hosts of all other kinds of hard and softwooded plants of value for decorative purposes. The Vines in pots annually grown in this nursery have

Fig. 59.—INGESTRE HALL.

gained a special reputation for their quality, and the stock this year will certainly not detract from this, as the numerous canes of all the leading kinds have been particularly well grown and ripened in a sunny position.

In the Warriston nursery, which has its main entrance near the Botanic Garden gate, there are several glass houses, chiefly filled with softwooded plants for supplying cut flowers. *Eucharis amazonica* is planted out in one of the houses on an extensive scale. The plants were in perfect health, and bloom profusely several times throughout the year. The common plan of resting through lowering the temperature and withholding water is practised here, but only to a moderate extent, which is evidently the right method to pursue. Pelargoniums of the Fancy and French kinds were well represented here, the plants being numerous and in fine condition. Tea Roses are largely grown for cutting, and so are Ferns, Carnations, Heliotropes, Chrysanthemums, &c., cut flowers being in great demand in Edinburgh about this time, and on throughout the winter. In this nursery are found the chief stocks of Coniferæ, which are effectively grouped and well arranged to be seen to advantage by visitors. Varieties need not be named here, but it may be said that everything in this way worth growing is represented in excellent condition, while the many forest and other trees to be observed in the other nursery grounds of this firm proved how great the demand for them must be. On estates in England and Wales planting is being extensively conducted, and until Ireland commenced cutting her own throat there was a great outlet for forest trees there; but now, I was assured by more than one of the Edinburgh nurserymen, they leave it entirely out of their reckonings.

THE LAWSON NURSERIES.

These will be remembered by many of your readers in connection with the name of the late Mr. Charles Lawson, who brought them to a state of worldwide celebrity; but they are under a company now, and under the management of Mr. David Syme their reputation has been well sustained. Like all the other Edinburgh nurseries of any great extent, there are divisions in different parts of the city. Some might think this very inconvenient, but it is not so, as each is devoted to a particular branch. The Lawson Seed and Nursery Company have most of their plant houses in their Granton Road portion. The Bangholm ground contains the hardy ornamental trees and shrubs, and the Windlestrawlec is the forest and fruit tree nursery. To note all of interest in these vast and various departments would take more time and space than we can afford at this time, and only a few of the most prominent features can be pointed out. The glass houses in the Granton Road nursery number about two dozen, and are well constructed for the growth of all kinds of choice plants. Palms were very numerous, many of them being beautiful specimens. Crotons, *Dracænas*, *Dipladenias*, *Begonias*, *Caladiums*, *Camellias*, *Azaleas*, and in short all kinds of plants to be found in gardens, were well represented; but there is so much to be seen in the open air that the houses were passed through hurriedly, the Coniferæ, of which everybody has heard, being wonderfully attractive.

In the Bangholm nursery we were much interested with one specimen in particular. This was the original tree of that well-known and much-valued Conifer, *Cupressus Lawsoniana*. It is now about 24 feet high, and rather scraggy in outline, as well it may, as the stock which has been secured from this one tree must be enormous. However, it is in good health, and appears as if it would yet keep the propagator supplied for many years to come. But while this veteran will always command the attention of visitors, the admiration will be carried further to the great stock of all kinds of coniferous plants which are grown here. Trees of almost all sizes may be seen, but of course the bulk consists of plants from 1 to 4 feet high which have been transplanted frequently, and are being sent out from the nursery daily to the adornment of gardens. It is no use naming anything in particular here, as all kinds of vegetation which assumes the form of bush or tree are alike extensively and well grown.

THE WEST COATES AND PINKHILL NURSERIES.

These are the property of Messrs. Downie & Laird, and are widely known and noted for their valuable collection of plants generally, but more particularly the florist flower section. These are mostly grown at the Pinkhill Nursery, and include everything that is worth growing. Pansies, Violas, Phloxes, Carnations, Pentstemons, Dahlias, and all flowers of this kind of tried merit which have been raised by various firms and individuals are here; but prominence is given to this firm's own productions, and many of these are of the most valuable description, as the improvement of this class of flowers has long been made a speciality of here. The situation of this nursery is rather elevated, and at times may be too windy to be agreeable for the tallest-growing plants; but there was not much indication of this to be seen during September, as everything was in a most thriving condition, and the profusion of sturdy plants and the fine display of bloom on many proved at least that the soil must be excellent and the cultivators skilled. The place was in the best of order, and as many of the flowers were grown in large batches so as to fully represent each kind, the arrangement was most interesting and the display attractive.

Amongst Pansies and Violas which have been raised by this firm the following were noted as being of extra merit:—Flag of Truce, fine white; Yellow King, golden yellow; Perfection, yellow, deep purple belt; Tom White, yellow, bronze belt; Mrs. Melville, purple

maroon; Miss Milne, cream, purple belt; George Wood, crimson, very dark blotch; J. B. Downie, rich crimson laced with white; Lady Hay, very dark purple; Mrs. Crawley, rosy purple edged with white; Singularity, crimson, dark blotch; and Michael Scott, rose edged with white. These are mostly Pansies of the Fancy section, very extensively grown in the north, and worth growing everywhere. Phloxes, especially of the late-flowering section, were in splendid condition, the growth robust and spikes large. They are of nearly all colours and shades, and must rank amongst the most useful autumn-flowering plants grown. Hollyhocks, now so seldom seen in such fine condition as in bygone days, were growing luxuriantly here. Dahlias, especially the standard double-flowering kinds, were very fine indeed, and the small charming bouquet varieties were also most showy. As a cut flower for vase decoration they have much to recommend them, and there is certainly room for their extended cultivation. Pentstemons were far in advance of any we had previously seen, and Antirrhinums were effective in all the best named varieties. Besides the large quantities of flowers, trees and shrubs also form a large part of the stock in the nursery.

The West Coates Nursery is situated at the west end of Prince's Street, and is in a very commanding position. Here the finest glass house in any of the Edinburgh nurseries is to be found. It is called a winter garden, and well deserves the name, as it is a spacious structure where plants can be seen to much advantage, and there is ample space for visitors enjoying the treat thus afforded. Let one visit Edinburgh when they will, this house is always gay with flowers, and it must be a great boon to the Caledonians, especially in winter. Some of the plants are growing in beds, and many are in pots. Large Palms, Ferns, &c., give quite a tropical aspect to some parts of it, and it is altogether most enjoyable. Numerous other glass houses contain healthy stocks of all kinds of indoor plants. The nursery being practically in the town space is of the utmost value, and to economise it many of the glass structures have been erected on the top of the potting, packing, and other sheds. The ranges are extensive, and are entered by flights of steps at each end, the floors of the houses being of cement. By this method of house-top gardening a maximum amount of light and air is obtained. Instead of empty roof space we find here glass employed instead of tiles for covering, and thousands of plants of various kinds in the most satisfactory condition.

Other nurseries on a slightly smaller scale than the preceding may be visited about Edinburgh, and amongst these Messrs. Cunningham and Fraser, Comley Bank; Messrs. Gordon & Son, Coltbridge; and Mr. Peter Robertson, Trinity, will be found interesting on account of the variety and quality of their contents.

INGESTRE HALL.

THE destruction of an historical baronial residence always evokes interest, engenders feelings of regret beyond its locality, and incites sympathy towards those who have sustained so great a loss. The last calamity of this nature that has occurred is the burning, on the morning of the 12th inst., of the Hall in question. It will not be inappropriate to submit an engraving of the late structure at the present juncture, with the following particulars relative to the district and barony of Stafford and the surroundings of Ingestre Hall.

The Trent Valley is remarkable for the richness of its meadows, which in some places are barely elevated above the range of the floods, and therefore have very large breadths often submerged at the time when these prevail; in fact, the whole of the level land on both sides of the banks has no doubt arisen from an alluvial deposit, and it now forms some of the best land in the kingdom. The scenery, however, is neither bold nor varied, and the traveller in passing through it sees nothing near at hand to vary to any considerable extent the tameness of the prospect, as the rising ground on each side is too far off to be seen to advantage. But if he were able to examine the country more leisurely he would see that there is much to admire, and would learn that a well-directed industry has been at work in times past as well as at the present. When "Domesday Book" was compiled in the year 1081, this Staffordshire district was justly known as *Gestreon*, the Anglo-Saxon for production and riches. The district was granted by William the Conqueror to his follower Robert de Toëin, a relative of, if not himself, the Royal standard-bearer of that name. The King conferred upon him also the great barony of Stafford, and *Gestreon* was a part of its vast domains. Probably by marriage and without intermediate possessors it passed to the Mutton family, Eudo de Mutton being Lord of Ingestre, or Ingestren, as it was then called, in the reign of Henry II. Eudo gave lands in Ingestre to St. Thomas the Martyr Priory, then recently founded at Stafford, became one of its lay brothers, and left the remainder of his estates to his son, Sir Ralph de Mutton, whose daughter and sole heiress married to Sir Philip de Chetwynd. In the possession of their descendants it has ever since remained (the Earls of Shrewsbury).

Ingestre Hall stood on the right bank of the Trent, nearly in the centre of the county, a few miles from the county town of

Stafford, but nearer to the railway station Colwick. The ground slopes away from it on the east and north sides, while it rises to the south. On the western side is a large Italian garden, and to the south are the pleasure grounds, which rise gently until they blend in a wood. The kitchen garden is to the north of the offices, and in the same direction is the church of Ingestre, which had its origin as far back as the time when most dwellings of importance had their chapel. The mansion was in the Tudor style, a combination of brick and stone, the latter forming the window mullions and dressings, the other the body of the work. It was large and commodious throughout, and although ancient, both the stonework and brick had stood the test of time much better than many more recent buildings.

The fire, which so suddenly reduced this noble pile to ashes, is supposed to have been caused by overheating, and the loss, including many fine pictures and works of art, is irreparable. The gardens and excellent Grapes that are grown at Ingestre were described in our twenty-second volume.

FRUIT-JUDGING AT EDINBURGH.

I WOULD correct the false impression some of Mr. MacIndoe's words (p. 344) are likely to create on this subject with your permission. Mr. MacIndoe gives the names of eleven gentlemen who acted as judges as a guarantee of the justice of the awards complained of; and if the whole, or even the majority of those named, had been unanimous in their verdict in the cases under dispute nothing more could well be said on the matter, for it is hardly likely all could be mistaken. But was this the case? or were more than two or three responsible for the decision which created such marked dissent among the public at Edinburgh? Was it not the case that the work of judging was divided—two or three judges taking one class, and two or three another, and so on, and that hence the greater number of the eleven judges named had no more to do with the judging of the particular collections than any outsider? If this were so, then it would be impossible to accept the list of names given by Mr. MacIndoe as any guarantee. A more pertinent question is, Who judged the collections in question? How many judges were employed in the task? and were even the few who acted all agreed in the verdict? It may, perhaps, turn out the decision rested with an exceedingly narrow majority. At all events I do not suppose Mr. MacIndoe has any authority for assuming that *all* the judges he names were on his side.—UMPIRE.

MILDEW ON PEAS.

MY experience is that Peas suffer from mildew from two causes—namely, drought and damp, but as yet I have been unable to decide satisfactorily to myself which is the most active. I find that Peas do well in showery or wet weather if there are intervals of sunshine or drying winds to dissipate the moisture; but in weather such as we have had here this last fortnight (close, dull, and damp, with rain and slight fogs) I find that my Peas suffer much from the mildew, which after a few days causes the under growth to decay, although the leading shoots yet appear clean and healthy. I am fearful, however, that the mildew attack will prove fatal to what were a fortnight ago very fine rows of Peas. I shall be thankful if any of your readers can suggest a remedy.—J. S., Ripley, Surrey.

I CAN endorse all that "J. S." says on page 348 relative to mildew on Peas. My Peas did remarkably well in the early part of the season while the showery weather lasted, but when those few weeks of dry weather came in July the rows were very soon covered with mildew, and continued so till the rain set in again. I have not seen any since, as it entirely disappeared, and I have been able to gather good dishes of Peas up to the present time. This morning (October 16th) I gathered a fine dish of Ne Plus Ultra. If the present weather continues they will be in bearing a fortnight or so longer, as there is not the least sign of mildew on them, and are as green as possible. I have only had three varieties of Peas worth much this season, and they were Laxton's Fillbasket, Hundredfold, and Ne Plus Ultra. If "J. S." would kindly give his opinion on the varieties he has grown during the past summer it would be of much interest.—S. W., Derby.

THIS disease, as alluded to by "J. S., Darlington," is not induced by wet. It is always more prevalent in dry seasons, especially in the autumn, when the weather is hot; it is therefore more destructive to late than early Peas. The name of the fungus belonging to this mildew is Erysiphe Martii, a close ally of the Hop mildew. No cure has been published for the Pea mildew, but as the fungus grows equally well on various wild Peas, on

Beans, on Melilot, on the St. John's Worts, and on Umbelliferous plants, it is difficult to deal with, for if the garden Peas were freed from the pest there would be considerable chance of re-infection from numerous wild Peas and other diseased weeds.—W. G. SMITH.

LIFTING PEACH TREES.

WHILE cordially welcoming the criticism by "A. B. C." (page 326) of my remarks upon this subject, I wish to point out to him that the old surface soil I disposed at the bottom of the holes, (see page 168) was not necessarily "spent" soil—quite the reverse. How can it be rightly termed "spent," when during the previous nine months it had received one liberal top-dressing of short stable manure and three soakings with liquid farmyard manure, all of which was absorbed by the surface soil principally. If this had been full of roots it would have altered the case, but in reality there were few or no roots or fibres near the surface. Consequently, instead of being "spent" soil it was most fertile, and I made a mistake in not using it more freely with the turf, which after all was poor and not so good for root-forming. We have ample drainage already for our borders, and the more we add the more rapidly will they become dry. A depth of 18 inches may be sufficient; but the border may be 3 feet in depth for aught that I care, as when once I have the roots near the surface I know how to keep them there.

For my part I fail to see the utility of annually lifting Peach trees. It is unnecessary, is besides to a certain extent risky, and is laborious and expensive. If we have a border full of fibre, would not a surface dressing given annually and a trench cut round at a good distance from the tree, the roots partially lifted and replaced in fresh soil, say once in three years, be sufficient to maintain the border in a fertile state? At any rate this is as much as the majority of Peach-growers are able to do for their trees, and who will say the results in most cases are less satisfactory than is the case where annual lifting is resorted to?

With regard to the employment of "brick ends" at the wrong place, according to "A. B. C." it may be they are of no service among the soil; but I am inclined to think they are, not because extra porosity is necessary in a Peach border, but because they are to a certain extent root or rather fibre-formers. Every rambling root that comes in contact with them is at once arrested, and naturally commences forming rootlets. It may be almost impossible to make the borders too firm or too heavy, but I have yet to learn that brick ends materially affect either the lightness or heaviness of the borders. What does "A. B. C." mean by "filling the borders with rubbish?" It he means mortar rubbish, I ask, Is there no virtue in it, and are so many of us wrong in using it in moderation? Perhaps "A. B. C." considers turf generally contains every soluble or insoluble substance requisite for the successful culture of Peaches. Clay added to some soils is doubtless of greater service than the different materials I have suggested might with advantage be employed, but here we have too much of it already, and prefer all additions to be baked—that is to say, in the shape of brick ends. After all, the art lies as much in knowing how to treat them according to their construction. If a border be retentive of moisture—for instance if it has received a good application of clay, and also otherwise enriched—then much less moisture will be required; but if formed of lighter and poorer materials will the difference in the crops secured be very marked providing the requisite amount of moisture and fertility be constantly within reach of the roots? I say not; in fact the best crop of Peaches and Nectarines I have seen this season was at Orsett Hall, and on trees that I planted, while there in charge, in a comparatively light border. What would "A. B. C." say to a Vine border composed exclusively of brick ends, mortar rubbish, bones, and charcoal? Yet I have recently seen such a border, in which the Vines look even better than where growing in an orthodox border in the next compartment.—W. IGGULDEN.

CORN MILDEW.

THE following excellent article extracted from the autumn seed corn catalogue of Messrs. Edward Webb & Sons, Wordsley, Stourbridge, will not be less acceptable to gardeners than those who are identified with agricultural pursuits:—

The destructive pest of cereals known under the name of Corn Mildew attacks not only Wheat (*Triticum vulgare*) but Barley (*Hordeum distichum*), Oats (*Avena fatua*), and numerous other Grasses, both wild and cultivated. The most serious attack of the malady is, however, always on the Wheat, and from the very earliest historic times we find written records of Wheat being destroyed by mildew.

A few centuries ago the true nature of the Wheat disease was unknown; some persons attributed it to the bitings of minute poisonous insects, others to some baneful influence carried by the wind. It was not till 1767 that the blight was proved to be caused by a mildew or parasitic fungus. In 1799 our English botanist, Sowerby, illustrated the Wheat Mildew in "English Fungi," plate 140. At the very time that Wheat blight was shown to be of fungus origin, English farmers were most stoutly asserting that Wheat blight was always more virulent in the neighbourhood of Barberry bushes.

Against the connection of the Barberry and Wheat fungi it was reasonably urged that Wheat Mildew was quite as destructive in New Zealand and Australia as in Europe, whilst in the first-mentioned places there are no native Barberries to cause the blight. Moreover, it was urged that Barberry bushes were so rare in this country in comparison with the commonness of Wheat and its mildew, that under any circumstances it would be utterly impossible for Barberry bushes to produce sufficient baneful influence to infect all the corn. It was now soon observed that Barberry leaves were afflicted with a yellowish fungus not unlike the early state of Corn mildew, but botanists asserted that the fungus of the Barberry and the fungus of the Wheat were totally different in structure and nature. Many of our best botanists have kept to this opinion till quite lately, and it is indeed possible many may still adhere to the opinion that the Barberry and Wheat fungi have no connection with each other. Sir Joseph Banks, President of the Royal Society in 1805, however, was the first botanist to point out the true nature of the ailment of corn, and in a paper on Wheat Mildew, published in the "Annals of

Fig. 60.—Fungus of Barberry.

Agriculture," vol. 43, he gave in his adhesion to the views of the farmers. Sir Joseph Banks, after an examination of the parasite and all the evidence on both sides, printed his conviction that the fungi of the two plants were possibly the same species, and that the Barberry blight was probably transferred to the corn. At length Professor De Bary gave some confirmation to Sir Joseph Banks' views by stating that he had caused Wheat Mildew to appear artificially from infection from the fungus of the Barberry; but as De Bary failed to infect the Barberry back again from the corn fungus, and as other botanists could proceed no further, if indeed so far, the question stood in abeyance. One set of men thought the evidence sufficient, and sided with the farmers and Sir Joseph Banks, whilst other men were unconvinced, and were always asking for further and better evidence. No better evidence was, however, forthcoming till Mr. C. B. Plowright, surgeon, of King's Lynn, last year made a series of experiments which were at first laid before the Woolhope Club at Hereford, and more recently, with many new experiments, published in the "Gardeners' Chronicle." Mr. Plowright states that he has really gone a step further than other botanists, and produced the Barberry blight from infected Wheat. Some botanists may indeed reply that the fungoid diseases of the Barberry are so extremely few that, if the plant has any ailment at all, it is pretty sure to be the one under discussion, and that the Barberry leaves experimented upon would possibly have had the disease if left alone, or if brought into contact with any other organic or non-organic material.

In the light of Mr. Plowright's recent careful experiments, we will take the views first advanced by Sir Joseph Banks as now proved, that the fungus of the Barberry really is one potent cause of Corn Mildew. We propose to illustrate the entire subject, and may at once say that all our illustrations are taken direct from Nature and engraved to scale.

For convenience we will begin with the Barberry (*Berberis vulgaris*), a plant which is probably well known to all our readers. A group of three of its leaves, armed with thorns at the base, is illustrated at A (fig. 60). The leaves at B, B show their under surface to the spectator, and on this under surface is seen growing the Barberry fungus (*Æcidium Berberidis*). It grows in yellowish patches, and when these patches are carefully observed or slightly magnified they will appear as companies of minute yellow cups. C represents the upper surface of a Barberry leaf, and on this upper surface there are frequent companies of extremely minute black dots, as illustrated. These companies of black dots on the upper surface frequently correspond in position with the yellow cups on the under surface; and although the latter were at one time supposed to be fungi perfectly distinct from those on the upper surface, they are now known to be the same, for they spring from the same spawn inside the leaf. This tuft of leaves with its fungi is natural size. If we magnify the cups on the under surface of the Barberry leaf with a glass magnifying twenty diameters we shall see them as yellow cups or inverted open-mouthed bells, as at D. A much higher power, however, is required to understand these fungus cups. So if we cut the Barberry leaf in two across a group of cups and magnify fifty diameters we shall see them as at E, F. E represents the outside of a cup, and we now perceive it to be filled with yellow dust, which flies out like beautiful rows of beads in necklace fashion. At F we have fortunately cut right through the middle of a cup, and we now not only see the internal mass of bead-like seeds, but we see that the cup itself is built up of a mass of similar minute circular bladders packed closely side by side so as to make an enclosing skin. Underneath this illustration at G are three of the little black specks (termed Spermagonia by botanists) peculiar to the top of the leaf. These specks are now seen in section. They are minute flasks embedded in the leaf. Their mouths are like exquisitely fine bundles of threads or rods, and carried on and round these rods are numerous atoms of the finest conceivable dust as illustrated. H, H shows the thickness of the Barberry leaf, also enlarged fifty diameters. The round bead-like bodies seen flying out of the cups are spores, seeds, or ovules. The extremely fine dust round the rods at G are probably of the nature of pollen, as their name (spermata) imports. If we now desire to thoroughly understand the nature of Corn Mildew we must learn all about the spores and spermata, and a much higher magnifying power becomes necessary. If we examine the seeds or spores with a power giving six hundred diameters we shall see them as golden spheres as at J (fig. 61), dotted round the circumference with the little transparent granules derived from the black flasks at G. When ripe the spores readily germinate, and the first sign of germination is six slight protuberances from the sphere, one at each pole and four round the equator. Sometimes a thread is protruded from all the six positions, but it commonly happens that one thread only is protruded. This thread winds in a convolute fashion as at K, and the whole contents of the spore or seed is poured into the end of the tube as at L. The life of the fungus upon the Barberry here ends. At first we have seen it as a capsule or bell full of seeds living at the expense of the Barberry leaf; we have then seen its seeds fertilised by the minute granules attached at J; and lastly observed their germination.

The older botanists considered that these germinating seeds or spores reproduced the *Æcidium* fungus on other Barberries, but the newer school maintains that the *Æcidium* spores are incapable of reproducing the *Æcidium* direct upon other Barberries. It is confessed that they will germinate upon Barberry leaves, as, indeed, they will upon almost anything in damp air, but it is asserted that they speedily perish, and are positively powerless to directly reproduce the *Æcidium*. The newer school also maintains that when these *Æcidium* spores are placed on the leaves and other parts of Wheat and various Grasses they germinate with extraordinary vigour, and produce the fungus of Corn Mildew. The evidence in this direction we will now examine.

A less high power of the microscope is again sufficient, and at M an extremely small piece of the skin taken from the under side of a leaf of Wheat is represented magnified two hundred diameters; at N, N, are two seeds from the Barberry fungus, both germinating and sending their growing points into the substance of the Wheat leaf through the organs of transpiration of the Wheat plant seen at O, O; the dotted lines at P, P, show the growing points of the

Barberry fungus within the Wheat leaf. The minute organs of transpiration are small orifices on the under side of the leaves, and it is through these open places that plants part from water in the form of vapour, and it is through these natural orifices that the seeds of the Barberry fungus enter and attack the Wheat.

Mr. Plowright states that he has infected Wheat with Wheat Mildew by contact with these spores from the Barberry, and that "control" plants not experimented upon remained free from the disease. It is not necessary for us to enumerate all his experiments, but the general result is, that in ten or twelve days after infection the infected Wheat plants sickened with Corn Mildew.

The question now arises, What is Corn Mildew? Its general aspect in the spring is known to every farmer; the leaves of his Wheat are at first covered more or less with pallid spots and streaks, and these spots and streaks a little later on become yellow and orange. This condition is represented natural size at Q, and the fungus bringing about this result is known to botanists as

of the yellowish powder will be seen as at S. The powder consists of innumerable oval fungus seeds or spores, each borne on a slight stalk. As the yellowish spores continue increasing in numbers they cause the ulcer to burst, and then the spores fly out of the fissure as illustrated.

As we now have fungus seeds or spores produced of a different form and nature from those which arose from the Barberry, let us

Fig. 61.—WHEAT MILDEW.

Uredo linearis. It is said to sometimes result from seeds blown from Barberry bushes, the evidence for which we have already discussed. If we magnify one of these disease pustules to the same scale as the cups on the Barberry leaf—viz., twenty diameters, we shall see them as at R, elongated swollen ulcers under the skin of the Wheat leaf; the skin is cracked longitudinally down the swollen pustule, and the interior of the ulcer is filled with yellowish powder. If a transverse section is cleverly made across a pustule and magnified fifty diameters—i.e., to the same scale as the more magnified cups of the Barberry leaf, the nature

enlarge them to the same scale and see how they conduct themselves on germination. A group of three of these seeds is seen at T, enlarged (like the spores from the Barberry) 600 diameters; like the Barberry spores they are yellowish in colour, but instead of being round they are oval, instead of being smooth they have a granular surface, and instead of being free or in necklace or chain fashion, they are now all supported on little footstalks as illustrated. When ripe, if these *Uredo* spores from Wheat are kept for a few hours in a damp atmosphere they germinate as at V, much in the same style as the spores from the Barberry; the

spawn threads or growing points emerge from both sides of these Uredo spores; the places from which the threads are destined to emerge may be seen in the three seeds to the left. One of the threads is, however, generally aborted, whilst the whole contents of the spore is poured into the growing thread of spawn. A point of great importance here arises:—If these Uredo spores from the Wheat are planted again upon other Wheat leaves they germinate, enter the organs of transpiration at once, and produce other Uredo spores in the Wheat: this process is so exactly like the germination of the *Æcidium* spores from the Barberry upon the Wheat that it is unnecessary to illustrate it; for if oval spores are substituted for the round ones at N, N, the germination of the spores and the entry of the spawn into the organs of transpiration is precisely the same in both. The following point is now to be specially noted. The Uredo spores of Wheat will not effectually grow upon, or enter the organs of transpiration of the Barberry.

Before leaving this part of the subject we must call attention to the fact that if the yellowish ulcers of the Wheat leaves are examined with the microscope later in the autumn we shall find a new series of spores or seeds, and instead of the spores being all oval as at T, a large number of them (and in some instances all) will be found divided into two by a partition, as at W. This partition, which divides the spores, really doubles their number, for each of these pieces at maturity is capable of germination. The partition now seen across the spores or seeds is of the greatest importance, for it is one of the chief links in the series of phenomena seen in Corn Mildew, and prepares the way for the next and most important stage of the disease.

If we examine mildewed corn at harvest time we shall see the straw spotted and streaked with minute jet black patches, as illustrated natural size at X. This is another condition of the original ailment; it extends to the parched and withered leaves and even to the ears; it is also to be seen in perfection in stacked corn and straw six or nine months after harvest. These black spots are looked upon as the most perfect state of the fungus of Corn Mildew, and known to botanists as *Puccinia graminis*. If these black ulcers are magnified twenty times, as we have magnified the previous pustules, they will be seen as at Y, bursting through the skin of the Wheat plant. The burst and frayed skin is seen in the illustration all round each black ulcer. The ulcer is full of black dust, and the nature of this ulcer and its dust will be seen if a transverse section is made as before and magnified fifty diameters as at Z. It will now be noticed that the seeds, instead of being yellowish and round or oval, they are larger in size, oval in outline, dark brown in colour, distinctly divided in two by a partition, and each seed is supported on a transparent stalk; these seeds fly out of the pustule when ripe, and may break in two as illustrated. Now when these seeds or spores are magnified to the same scale as the previous spores—viz., six hundred diameters, or 360,000 times superficial, they are seen as at I. These seeds, although ripe in the autumn, will not germinate till the following spring; they are, therefore, resting spores destined to carry the fungus through the vicissitudes of winter. Too much moisture, too much dryness, or a slight amount of frost will destroy all ordinary fungus spores, but these autumn-produced spores are wrapped in thick coats, and the usual amount of drought, wet, and frost peculiar to Europe does them no injury whatever. In the spring of the following year they are ready for mischief, and they exist in uncountable millions on the old straw of stables, about pigstyes, dung heaps, and in all places where the previous year's straw is to be found. They germinate in April and May in the style illustrated at 2—both lobes of the compound seed throw out a transparent tube as illustrated—these tubes grow to a certain definite length, twist partly round like a shepherd's crook, three partitions form themselves in the crook end, the top three (sometimes four) pieces each protrude a slender tube, and each of these tubes carries a small yellowish seed or spore. The compound spores of two lobes have now by growth increased their power threefold, for there are now six spores instead of two, as at 3, 3. Unlike the brown compound resting spores of two divisions, these transparent little oval spores 3, 3, are ready to germinate at once as at 4; but will they blow on to the corn and reproduce the mildew? According to Mr. Plowright's observations they will not. If they are placed on young Wheat leaves they have no effect, but if they are put on Barberry leaves they germinate at once, their roots or spawn threads permeate the interior of the Barberry leaf in every direction, and speedily cause the production of the Barberry fungus (*Æcidium Berberidis*), described at the beginning of this article. The Barberry fungus soon gets ripe and produces myriads of seeds, these seeds are blown over the cornfields, and Wheat mildew is the result. All the phenomena we have described are once more

repeated, and so the fungus of Corn Mildew goes on from year to year.

NOTES ON PEACHES AND NECTARINES.

I WAS very much interested in Mr. Iggulden's article on varieties of Peaches and Nectarines, and wish to supplement two good varieties, especially as they are allied to two varieties he writes rather disparagingly of; and they are Rivers' Early York Peach and Albert Victor Nectarine. I know the old Early York very well, and I have the same opinion of it as Mr. Iggulden, but Rivers' Early York I think is all that can be desired for a Peach for the outside wall. Mr. Rivers correctly describes it as follows—"Medium size; skin marbled with red; flesh so melting and juicy as to dissolve in the mouth, leaving no fibre." Its flavour has a smack of the Stanwick Nectarine, and I will add the tree is very hardy and prolific, and fruit very highly coloured next to the sun.

Albert Victor I think is a Nectarine that should be grown by everyone if they only have an unheated house. It is a very heavy cropper, the fruit is of large size, the flavour delicious, and I find it much better if placed on a warm shelf two days before being used.

As most seasons are disastrous to Peach and Nectarine trees on outside walls, most people are recommending that they should be grown under Peach cases. But I think good results would be obtained if only the early varieties were planted and protected by tiffany at night whilst in bloom. I think the early varieties of Mr. Rivers and Hale's Early with the new American variety Alexander, if all that is said in its favour be true, might be so grown, as we must remember everyone has not Peach houses to grow this delicious fruit. I find Noblesse sets its fruit freely if assisted by pollen from Royal George.—A. YOUNG.

ALLOW me to say a word in favour of the Early York Peach. Mr. Iggulden at page 335 condemns it, and considers it should be struck out of the catalogues. Here it is grown in the early house with Hale's Early and Royal George Peaches and Rivers' Orange Nectarine, and never fails to carry a heavy crop of medium-sized, well-coloured, and good-flavoured fruit. As a proof of the latter quality, a dish of fruit was sent in May to a well-known nobleman, who described them as the best Peaches he had ever tasted.

Although a large-flowering variety it sets its fruit as freely as Royal George, and with us is not subject to mildew, and ripens about a week earlier. Hale's Early under the same treatment ripens fully ten days before Early York, the three varieties forming a good succession for the early house. Hale's Early I find does not open its flowers very freely when forced, but it does not fail to set a crop of large and well-coloured fruits. Prince of Orange Nectarine I am very pleased with. It also is a large-flowering variety, and sets its fruit very freely, is of good size, splendid in colour, and one of the best flavoured Nectarines.—G. S.

MR. IGGULDEN, in his notes under the above heading, page 335, says, "Small and colourless fruits are of comparatively little value, especially in the markets, and for this reason such varieties as Early Beatrice, Early Louise, Early Albert, and Early Alfred will never be grown extensively." I quite agree with the first part of Mr. Iggulden's statement, but cannot perceive why the two last-named varieties are included in the list given, because they are not colourless, and the last produces what might be termed large fruit. The fruit of Early Albert is not quite so large, but I have seen it a very deep crimson colour—in fact, nearly black, on the side fully exposed to the sun. Early Alfred also colours remarkably well when raised above the foliage. When well grown this is a rather beautiful Peach, the flavour being good.—L. D. W.

PROPOSED PINK SHOW IN 1883.

IF you do not utterly disapprove of my proposal I shall be pleased if you will permit me to appeal to readers of the Journal in behalf of an exhibition of Pinks, to be held next year in connection with the Pelargonium Society's Exhibition at South Kensington. I should long since have sought your aid in this matter, but I thought it best to wait for the programme of the Royal Horticultural Society, when having at command the date of the Show and other such necessary particulars. But the fixtures of the Royal Horticultural Society for 1883 are not yet announced, and I am fearful that if I delay any longer making a formal declaration I may prove to be too late, whereas for the sake of the cause I would prefer to be too early.

It is proposed, therefore, that we hold a show of Pinks in the later days of the month of June next year, and that a committee be formed to draw up the schedule and regulations, and that the friends of the movement communicate at once with the undersigned. A subscription of 5s. from every lover of Pinks will provide funds enough, for in truth we do not need a heavy purse, but money we must have. I now send round the hat, engaging to nominate the committee forthwith, and to announce the date of the show instantly upon obtaining from Major Mason an official reply to requests I have made anticipatory of this appeal.

To pronounce a panegyric on the Pink is not needful, and I would not burden your well-filled columns with a word more than I think I may fairly ask room for in the interest of a flower that has a name and a fame, but has for some time past shivered in the shade of cold neglect. All I wish to do is to give the Pink a new start by an exhibition in London. That accomplished, I shall gladly hand over the affair to better men, and hope to see the Pink show established as a respectable institution.

Lovers of Pinks, my hat is before you. Put in your crowns, and if things do not fit I will return the money. We must begin somewhere and somehow, and I propose that we form a society for the special purpose of producing one exhibition. As regards the farther future, we will leave that for the present to take care of itself.—SHIRLEY HIBBERD, 15, Brownswood Park, London, N.

VINES AT LONGFORD CASTLE.

To those who take more than an ordinary interest in Grapes and their culture it is at all times a pleasure to see Vines in a healthy and flourishing condition, no matter whether they are young or old, growing or at rest; for even if they are at rest, or, to speak more correctly, when they are not in active growth, it is not by any means difficult for the practical man to see what they have been doing, or to foretell with a certain degree of accuracy what they are likely to do in the future, supposing, of course, that all goes well. In a recent visit to the gardens at Longford Castle, Salisbury, I was highly gratified to find the most vigorous and promising young Vines of their age it has ever been my good fortune to see, and certainly such as we might almost with certainty venture to predict will at some future day render a good account of themselves. Indeed half of them, which are planted out as supernumeraries, are doing so now, each one carrying about four bunches and averaging something like 3 lbs. each, and this, too, when they were only put in as eyes eighteen months ago, and even now are not being cropped at their full capacity, it being intended to take another crop from the upper half of the rods next year. The Vines are planted in inside borders at a distance of 2 feet from each other. The permanent rods will be allowed to bear their first crop next year; and so strong is the wood—as thick as a stout walking stick, with leaves of that leathery texture and dark healthy green which is indicative of the best of health—that many gardeners would not have scrupled to have cropped them this year. This, however, if it had been done would doubtless have been a mistake, as many Vines are crippled for life through being overcropped in a young state. The range, which is a three-quarter span and with three or four divisions, is planted with all the leading varieties—Muscat of Alexandria, Mrs. Pince, Madresfield Court, Lady Downe's, Abercainey Seedling, Trebbiano, Gros Colman, Gros Maroc, Alicante, Black Hamburgh, &c. The berries of Gros Colman we noticed as being particularly fine, some of them measuring 4 inches in circumference, the largest I ever remember to have seen. Mrs. Pince and Lady Downe's were also conspicuous by their good colour and finish. Although the Vines are now growing in inside borders they are destined eventually to occupy an outside one about 14 feet in width, the front wall being built on arches for the said purpose. The soil in which they are planted is a strong yellowish loam, and contains a small percentage of iron, which is necessary to the well-doing of Vines—and has nothing incorporated besides animal manure, bones being excluded altogether, as Mr. Ward does not consider them absolutely necessary to produce good Grapes, and certainly the present state of the Vines would warrant anyone else in coming to the same conclusion.

For a few years past Mr. Ward has had an uphill task battling with the phylloxera, and almost all known remedies have been tried to exterminate it; but nothing short of what is generally known as the "stamping-out process" was successful, and that success has been attained one cannot for a moment have the slightest doubts. The almost continuous anxiety of mind resulting to the enthusiast from a visitation of this dreadful pest may be more easily imagined than described. Wherever it does appear, however, the best advice that can be given is to remove the Vines and destroy them without a moment's delay, clear away every

particle of soil, and thoroughly disinfect every inch of surface where the old soil has been taken from. Plant again Vines which can be warranted to be free from the insect, or put in eyes of the varieties required, and as soon as rooted and they have made a fair start in growth plant them out. Nothing short of this, so far as practical men are aware, has hitherto proved successful.—JNO. HORSEFIELD.

NOTES ON WASPS.

AS "DUCKWING" has given us his year's experience, which differs very considerably from mine, I must reluctantly trouble your readers with a few lines on a subject which by this time I imagine everyone must be tired; and, therefore, I will endeavour to condense into small compass, having kept my "eyes open" a little wider than usual in anticipation.

Queen wasps were unusually abundant in the spring, I may even say winter, for on January 19th last the first was seen and remarked upon by me. As the season advanced the cry became general; and, as I have before mentioned, I killed all I could, amounting to over one hundred round my own garden. Two nests were commenced in my arbour within a few feet, and notwithstanding my attention and energetic pursuit and destruction of queens many escaped, and with the result that I never was troubled with so many ordinary wasps as this autumn, in spite of all the wet weather during July and August. I have destroyed ten nests within a short distance, the wasps from which were constant visitors to my fruit and bees, as by careful watching (the wasps being fed on a little honey and water for the purpose) I traced out each nest. Some of the nests were very strong, and others the opposite. Several of the nests I have exhibited at our Amateur Gardeners' Society from the first about as large as a thimble, with one very small comb and the single queen, and others in different stages of development up till the present time, with the combs all cleared out and the queens ready to separate and seek out their winter's quarters.

One "byke" was exhibited just as it was taken from the earth with wasps intact, not as Tom Edwards' was—"in his shirt," but securely wrapt in a newspaper.

In my walks during the past summer I have never noticed so many nests in any season as the present. I counted twenty-three within a mile, and round one old marl pit four within 20 yards.

In one nest I could find no male wasps, although there were about fifty queens. Whether these would be fertile or barren queens I cannot say, but I have saved several alive if there is any means of ascertaining the fact either now or by keeping them through the winter, when I imagine their egg-laying capacity would be fuller developed. I have trespassed, I find, further than I intended, but must just say that I have not seen a hornet this season.—J. HIAM, *Worcestershire*.

KITCHEN GARDEN.

PLANT out, if not already done, the principal crop of Cabbage for early summer use, hoeing frequently about those for early spring use, drawing a little soil to them to keep them steady and prevent damage by winds. Dust occasionally with quicklime if slugs are troublesome.

Complete the planting-out of Lettuces and Endive for spring use, and see to the requirements of those previously planted as regards keeping them free from weeds, and applying lime, soot, or wood ashes as preventive of the attacks of slugs, worms in some instances being also extremely troublesome.

Run the hoe between the rows of winter Spinach, and thin the plants well to allow of large leaves being formed, and prevent damping off by well exposing the plants. Only the large leaves of this esteemed vegetable should be gathered at this season, as cutting too much enfeebles the plants and interferes with the continuity of the supply. Winter Onions should be kept free from weeds, and if too thick in the rows thin moderately. Cauliflowers will now require attention to protect the heads in case of sudden frosts; a few leaves broken down over the heads will be sufficient for the present, and will also keep them clean and white.

Measures being taken at the proper time to secure a supply of Lettuces and Endive ready at this season for lifting, it should not longer be delayed, as the quality of these is much deteriorated if injured by frost. In cold pits or frames with protection during severe weather, and ordinary attention to ventilation, these will keep in good condition for a considerable time.

Celery, a very important edible for winter use, must be given the requisite attention in earthing and protecting in case of frost; for when left too much exposed it sustains serious injury, decay being attributed to wet when it really is a consequence of previous damage from frost.

Roots of Carrots, Salsafy, Scorzonera, and a portion of the Parsnips should now be taken up and stored for winter use, being careful not to trim them too hard or to place in large stacks so as to induce fermentation, which causes decay. They should be packed in damp sand. Beet must be lifted and carefully trimmed, so as to avoid damage, or the colour will be impaired. In order to keep this root late a portion should be placed on a north border, the roots entirely buried and covered with a few inches depth of ashes, where the roots generally keep fresh and firm until next year's supply is fit for use.

Frame Ground.—Whilst favourable weather continues fully expose Cauliflowers, Lettuces, Endive, and Radishes in frames, being very watchful against the early frosts, as these are the most injurious. Remove decayed leaves and weeds, and stir the soil occasionally between the plants, dusting with lime to keep down slugs and worms.

Pits or houses that contain late crops of French Beans will require constant attention to prevent the plants damping, keeping the temperature from 60° to 65° at night, and 70° to 75° by day, with a little ventilation constantly. Successional sowings may be made in 9-inch pots, using moderately rich light soil. Periodical sowings of Mustard and Cress must also be made in heat according to the requirements.

FRUIT HOUSES.

Vines.—Where late Grapes are grown in sufficient quantity to continue the supply until late in spring Grapes may be had all the year round without the necessity for very early forcing. Lady Downe's is unquestionably the most valuable, it being a sure cropper and keeping in good condition until the end of May. Alicantes invariably finish well, and keep excellently. West's St. Peter's is a fine late sort, and keeps under favourable conditions in good order until April. Gros Colman is simply grand in appearance, its enormous berries and magnificent colour when well-finished being very telling. To ripen and colour this and Gros Guillaume requires more time than other late Grapes, and should as a consequence be started early, and encouraged from first to last with fire heat. Trebbiano and Calabrian Raisin are the best of the whites, large both in bunch and berry, and when well ripened good keepers and of fair quality. The last four are generally considered of second-rate quality, but this arises entirely from the fruit not being properly matured, and from their being contrasted with Muscat of Alexandria and Hamburgs at a time when their best qualities are undeveloped, which is effected by that which gives them their value—viz., late or long keeping.

Where late Grapes are not grown, dependance being placed on Hamburgs and Muscats for a late supply, which cannot under the most careful management be prolonged much beyond the new year, or new Grapes being required by the middle of April, no time must be lost in starting the Vines that have been pruned and dressed both at top and roots as advised in former calendars. If the roots have access to outside borders those should be covered with fermenting materials, three parts leaves—Oak or Beech—to one of stable litter well mixed being most suitable, from giving a mild and lasting heat. The inside border should be rendered thoroughly moist by supplying water or liquid manure at 80° to 90°, and fermenting materials of the description indicated in preparation for placing inside the house at the beginning of next month, alike as a means of warmth and to promote a good break of the Vines from the moist genial condition of the atmosphere occasioned by the presence of the fermenting materials. The house may now be closed, but no artificial heat should be applied for another fortnight, when the night temperature

should range from 50° to 55°, and 65° in the daytime from sun heat, syringing the rods twice daily.

Young Vines that have completed their growth should have a portion of the laterals removed to give light and air to the wood and induce earlier ripening of the wood, keeping rather dry at the roots; but an over-dry condition at the roots must be guarded against. Keep a sharp look-out for decayed berries in ripe fruit, ventilating freely in favourable weather, it being advisable to maintain slight warmth in the pipes when the atmosphere outside is charged with moisture.

Cucumbers.—Place the plants for winter fruiting out at once, planting on raised hillocks or ridges near to the glass, encouraging growth by a genial condition of the atmosphere. Examine the autumn fruited, removing bad leaves, thinning out exhausted and too crowded growth, removing all male blossoms. Maintain a night temperature of 65° to 70°, and 70° to 75° in the day, advancing with sun heat to 80° or 85°, admitting a little air at every favourable opportunity. The evaporation troughs should be kept charged with liquid manure. Employ the syringe over the foliage lightly on fine afternoons, and damp the floors about 8 A.M. and 3 P.M., reducing the supply of water at the roots, but do not allow the foliage to flag. Dust with flowers of sulphur against mildew, and fumigate carefully upon the first appearance of aphides. Keep the glass thoroughly clean to admit all the light possible.

PLANT HOUSES.

Azaleas.—Plants of the neglected *A. vittata* which have been encouraged by gentle warmth to make growth and set the buds early will now be in flower, and to enable them to open freely and enhance the size of the flowers a temperature of 50° to 55° will be more suitable than an ordinary greenhouse temperature. Plants of this that have been subjected to ordinary treatment will also shortly begin to open its flowers, and should, for the reasons indicated above, be given a slight increase of warmth. The plants will flower over a long period, as a second lot of flowers will be produced by the strong shoots providing the wood is not cut with the first blooms. The flowers of this are variously coloured, a few being entirely purple, others white-striped, and others blotched. Some of the earliest-flowered plants, and since encouraged to make growth and set their buds early, will now be in condition to place in heat, they coming on without much excitement, which will add to the durability of the flowers. Alba, amœna, A. Borsig, Fielder's White, Narcissiflora, and Raphael flower early without much excitement. Others which have been accelerated in growth and setting will also force readily. Some of the best are Jean Vervaene, Apollon, Eclatante, Roi d'Holland, and Reine des Roses, which have single flowers. In semi or double flowers Mlle. Louise de Kerchove, Kaiser Wilhelm, Dr. Moore, Triomphe de Wondelghem, Roi des Belges, and Madame Charles Van Eckhaute. The whole of the stock should be examined, and if there be any trace of thrips the plants must be washed with tobacco water, wetting the whole surface of the leaves and wood.

Chrysanthemums must be encouraged as much as possible whilst outdoors, keeping them well supplied with liquid manure, attended to in tying, using no more support than is absolutely necessary, and thinning the buds well in good time, so as to secure fine blooms. Whilst it is undesirable to house the plants too early, protection should be at hand to apply promptly in case of sudden frost, and when the buds begin to show colour the sooner they are housed the better, ventilating freely, and merely excluding frost.

Schizostylis coccinea grown in pots and liberally treated during summer will be throwing up its spikes, and should be moved to a cool house or conservatory, where it will make a fine display for several weeks. It is a moisture-loving plant, and well repays any extra attention in the application of liquid manure.

Tea-scented Roses grown in pots and not forced, but grown outdoors in summer, will be showing buds plentifully, and if moved to a house with a temperature of 50° will continue expanding them until a late period, liquid manure being given at the roots. Niphotos in an ordinary greenhouse keeps on growing and flowering throughout the year, and is unquestionably one of the freest and best. Where Roses are planted out and trained to the roof or otherwise, they

should be well supplied with liquid manure, keeping free from aphides by fumigation and from red spider by forcible syringings, applying flowers of sulphur for mildew.

THE BEE-KEEPER.

THE STEWARTON HIVE.

MR. PETTIGREW says, in his article on the Stewarton hive, that an attempt is being made by the Bee-keepers' Association to introduce the Stewarton principle on the straw hive. That has been done many years ago in Ayrshire, and is used by many bee-keepers, especially in the neighbourhood of Mauchline, where it was first introduced. This hive goes under the name of the Mauchline-Stewarton. The hive is circular, about a foot in depth, with bars the same breadth as those in Stewarton attached to a wooden rim 15 inches in diameter and supplied with slides. The principle of working is similar to that adopted in the Stewarton, a swarm being hived into one of the skeps. A Stewarton super is placed on the top when combs in the body of the hive are nearing completion. The two side slides are withdrawn, and should honey be coming in plentifully the other slides may be drawn an inch. By only withdrawing two side slides of the hive you are certain of getting honey-comb uncontaminated by brood or pollen.

In two instances when I assisted in removing a super when all the slides had been withdrawn, brood in the one case and pollen in the other was found. If the swarm is strong in bees and the weather is favourable other boxes may be placed over, first removing the lower super as soon as all the cells are sealed over. This may be known without raising super by merely drawing the shutters and looking through the window in front and behind. If all the cells are seen to be sealed it is ready to be taken away. If we wish to prevent a stock hive from swarming, as soon as the bees have thoroughly occupied the super a hive is placed underneath.—W. F.

PROGRESS OF APICULTURE IN THIRTY YEARS.

DURING the last thirty years great discoveries have been made in the natural history and general management of bees; and while the habits and instincts of the honey bee are the same to-day as thousands of years ago, the methods employed to develop and utilise their value and enable the bee-keeper to prosecute his business with intelligent oversight have been numerous and very valuable, because mainly practical in their application to the end sought—namely, the improvement of the stock; to acquire a knowledge of the habits of the bee; better to utilise their labour, hence greater profits, the latter mainly the greater desideratum of the Yankee mind.

The invention of the moveable-comb frame hive, introduced by Mr. Langstroth about 1850, opened up a wide field of study; in fact it was the invention of the age as regards intelligent bee-keeping, and upon it has hinged most of the progress that has been made since. By its use we were enabled to go inside the hive and prove those things at which naturalists had hinted. It enabled us to practise artificial multiplication of swarms, or prevent natural swarming when desirable. That bees, deprived in any way of their queen, had the means to rear another one, had long been known, but till now the knowledge was of but little practical value. Now we are enabled to rear queens at will, to become acquainted with their good or bad qualities, and to breed and perpetuate the one or discard the other; and also if another race of bees is thought to be superior to the ones we are breeding, the moveable frame enables us to introduce foreign stock without loss.

Science has also demonstrated that to elaborate and build comb causes bees much labour, and that it is at the expense of a large quantity of honey. Take an ordinary bee hive of 2000 cubic inches capacity, and to fill it with nice new combs requires labour sufficient to bring in 30 lbs. of honey, and the elaboration of wax to form material for the building of the combs requires 30 lbs. more. We find that 60 lbs. at least of honey has been the cost of filling each hive. Enterprising bee-keepers sought to obviate in some measure this outlay, and the result has been the honey extractor, whereby the newly closed cells are uncapped and the frames with combs attached are taken from the hive, the bees brushed off and then placed in the machine and rapidly revolved, emptying the honey from the cells, and then the combs replaced in the hive to be refilled, and the process repeated when advisable.

Twenty years ago, had some timid apiarist ventured to suggest the possibility of making artificial comb which the bees would readily accept and utilise the same as their own, he would have

been a fit subject for a lunatic asylum; but nearly as long ago as that the embryonic idea took root in the brain of the late Samuel Wagner, and the result has been the production of foundation comb that can be attached to the frame and placed within the hive and as readily used by the bees for all purposes as their own.

These are some of the wonderful results that have accrued by the application of certain principles in accordance with the no less wonderful instincts and habits of the honey bee.

But while the results of the new light that has dawned upon the bee-keeper's pathway has been to lead to grand achievements in summer management of the apiary, the successful wintering of bees has not yet come to be demonstrated by any set rules however carefully observed. Comparatively speaking it is easy to successfully manage the apiary during the warm months, for success hinges very much upon whether the season is auspicious for honey-gathering; but during the winter and spring the bee-keeper often finds all his wisdom at fault. There are a few rules it is well to observe, and these when put in practical use are as near right as any we have tried. To be brief, for this article has already exceeded its proper limits, let us observe—

1, Bees in the moveable-frame hive are not in their normal condition, hence some means should be adopted to prevent a low temperature within the hive. Such condition is best afforded by wintering in a dry cellar.

2, The larger the mass of bees consolidated together the less susceptible are they to a low temperature; hence by the 1st of November remove a frame and put the remaining ones farther apart, also cut passage ways through the combs to enable the bees to communicate freely through each sheet of comb.

3, Quietness is essential to their prosperity, hence the hives need to be placed in a dark cellar, and if the cellar is used for other purposes put a partition across the room so the light may not disturb them.

4, A current of air continually passing from beneath up through the hive is detrimental to the health of the bees; then contract the entrances and leave small spaces between the combs and bottom board; place quilts upon the top of frames, remove the caps from the hives and keep at a temperature of 40° Fahr.; higher than this will cause uneasiness, lower will do no harm.

5, Be sure that each hive contains at least 15 lbs. of honey, disturb as little as possible until spring. These rules followed, your losses will be less than in any other way.—L. F. ABBOTT (in the *American Bee Journal*).

FORMATION OF A BEE-KEEPERS' ASSOCIATION FOR WORCESTERSHIRE.

A MEETING, convened by the Rev. J. Ross Barker and Mr. A. H. Martin of Evesham, was held in the Guildhall, Worcester, on Saturday last, to take into consideration the desirability of forming a Bee-keepers' Association for the county of Worcestershire. There was a good attendance of persons residing in various parts of the county, including several ladies, who are desirous of spreading a knowledge of the improved methods of bee-keeping throughout the county. The chair was taken by Col. W. Stalland, the Mayor of Worcester. Mr. J. Huckle, Assistant Secretary to the British Bee-keepers' Association, attended the meeting, and gave information as to the mode of forming an association and the means whereby the association would be enabled to carry out its work.

It was resolved unanimously—"That it was desirable to form a Bee-keepers' Association for the county of Worcestershire," and that subscribers of 5s. and upwards be considered as members. Mr. A. H. Martin of Evesham was unanimously elected Honorary Secretary. Lord Beauchamp has signified his assent to act as President of the Association.

PLANTS FOR BEES.—A correspondent of the *American Bee Journal* states that his bees have gathered a large quantity of honey from the flowers of *Rudbeckia fulgida*, of which he states there were one thousand acres in his neighbourhood. *Pentstemon Digitalis* also grows abundantly in the district, and from these two a large portion of his honey is obtained. Both these are North American plants; but they are cultivated in this country.

TRADE CATALOGUES RECEIVED

Ernest Riemschneider, Altona, Hamburg, Germany.—*List of Bulbs and Herbaceous Plants.*

S. Dixon & Co., Amhurst Nursery, Hackney, and Moorgate Street, London.—*Catalogue of Chrysanthemums and Roses.*

Charles Turner, Slough.—*Catalogues of Roses, Fruit Trees, and Florists' Flowers.*

Francis and Arthur Dickson & Sons, The Upton Nurseries, Chester.—*List of New and Select Roses.*

Edmund Philip Dixon, Hull.—*Catalogue of Roses, Trees, and Shrubs.*

Henry Bennett, Pedigree Rose Nursery, Shepperton, Walton-on-Thames.—*List of New Roses.*

*** All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Book (Bryum).—You will find Tripps' work on Mosses, published by Messrs. George Bell and Sons, 4, York Street, Covent Garden, one of the best, but the price is higher than you named, and we do not know any reliable work published at so low a price.

Astrantia major (J. S. B.).—An herbaceous plant, which is very easily grown, as it succeeds in any soil that is not very heavy. It can be increased either by seeds or division of the plants. Several other species are in cultivation, one of the best being *A. carniolica*. A minor is rather more tender than the others, and one very large-flowered form is called *A. maxima*.

Pyrus japonica (Miss Tregoning).—The fruit is that of *Pyrus* (*Cydonia*) *japonica*. There are many varieties of this, producing various kinds and qualities of fruit. That which you have sent is a particularly handsome one, and worth cultivating. You can make marmalade of it in the same way as you would of the ordinary Quince.

Single Dahlias (W. B.).—The light flaked variety sent is worthless; thousands better will be thrown away this autumn. The only two varieties amongst the seedlings you have sent that we consider worthy of cultivation are the very dark one, and there are plenty similar, and the scarlet, which resembles *gracilis superba*.

Large Pears (G. H.).—We have no record of the heaviest Easter Beurré and Beurré Diel Pears that have been grown in this country. You have probably grown some of the heaviest. We will publish any records of heavy Pears that you or other of our correspondents may possess if they are forwarded to us.

Fruit Trees for Planting (Cheshire).—When you state you want Apples on Quince stocks we presume you mean Paradise stocks, and you must order the trees on this stock and not on the Quince. Suitable varieties for your purpose are of *Apples*—Lord Suffield, Cellini, Stirling Castle, and Ecklinville Seedling. *Plums*—De Montfort and Green Gage. *Cherries*—Early Rivers and Governor Wood.

Pears for Walls (G. P., Hants).—If you have the means for growing early varieties as espaliers or pyramids we should advise you to do so, as unless you grow the trees in the form of diagonal cordons you can only have a small collection on the wall. Read the notes on page 337 last week. You will find some of the best varieties there for both forms of culture. If you will let us know what your decision is in the above respect, and need further advice, we will readily attend to your letter.

Planting Tigridias (M. E. H.).—Spring is the best time for planting these bulbs, selecting fine weather either at the end of March or the beginning of April. Light rich soil suits them well, and if left out during the winter a little protection is advisable, though, perhaps, the preferable practice in cold damp localities is lifting and storing the bulbs in a dry position.

Mushrooms Decaying (J. C.).—The Mushrooms are rotting from a fungoid attack. This fungus, which is occasionally so destructive in Mushroom houses, is *Xylaria vaporaria*, and is usually introduced with particles of unpurified manure. When it once gets into a house it is a pest about as bad in its way as the phylloxera, and a clearing-out, disinfecting, and lime-washing process becomes necessary for its extirpation. Manure, where horses have had much medicine or have been fed with Carrots largely, would produce almost similar results; and in all likelihood if really suitable manure were used in a fresh place the same spawn would produce good crops of Mushrooms.

Sphagnum (S. B.).—We have received the samples of sphagnum moss, but do not understand what information you require. You say "No. 1 is from an Orchid received from a London nursery; No. 2 is from one of our Bristol nurseries, both growing on the same plant, both receiving same treatment. If you will kindly give me the reason at your earliest convenience I shall feel much obliged." We will willingly oblige you if we can, but further particulars are necessary for enabling us to do so, and better "samples" than these, which are crushed and dried by being enclosed in a letter.

Culture of Oncidium Rogersi (A New Subscriber).—This is a Brazilian species, and one of the most beautiful of those flowering in winter, bearing a large panicle of blooms, the lips being very broad, somewhat three-lobed, and rich yellow in colour. It requires warmer quarters than several of the species, and would not succeed satisfactorily in your cool Odontoglossum house. Many cultivators find that the *Cattleya* house suits it better, and if you have not such a structure or a warm Orchid house place the plant in a stove. The usual compost of peat and moss is needed if the plant is grown in a pot.

Fruits of Cycas revoluta (Inquirer).—You will find an engraving of the fruit of *Cycas revoluta*, with some particulars concerning their structure, on page 27, January 8th, 1880. The fruits are said to be edible, but we have never tried them. *C. circinalis*, which is nearly related to *C. revoluta*, produces similar fruits, and in the Moluccas these are eaten after being fermented and roasted. Sago is prepared from the pith of both plants. Specimens which have

fruited occasionally bear a weakly appearance for a time, but they soon recover under good treatment. It must, however, be remembered the fruits produced are not always perfect—indeed, that is seldom the case with cultivated plants, as fertilisation is seldom effected.

Annuals for Spring (F. S.).—You say the plants are "strong," possibly they are too strong, as if very forward and succulent, and especially if they have not been thinned so that each plant has had space for producing side growths, they are liable to be destroyed whether planted out or left in the seed beds. Assuming your beds are ready you had better plant them out now, as there is time for them to get established before winter. A few evergreen branches will afford them some protection in dry weather. If very forward the Virginian Stocks and *Nemophila* cannot be relied on for passing the winter safely; the others are quite hardy, but often made tender by overcrowding in the seed bed.

Trees not Bearing (C. B.).—You say the trees have borne little or no fruit for seven or eight years, but you do not say whether they are old or young trees, luxuriant or decrepit. Without knowing the condition of the trees it is impossible to suggest a mode of treatment. Are they young or old trees? are the branches trained thinly? and do they produce blossom freely? Many trees have failed to bear fruit during the past few years, not because of any constitutional fault of the trees, but because severe frosts and inclement weather have destroyed the blossom. If you can make the state of the trees intelligible to us we will give you the best advice we can on the matter.

Renovating Vines—Warts on Leaves (F. C.).—Your proposed plan is good generally, but appears to us to have one great fault. By being good generally we mean the plan of having the roots in a "sort of long box," which you describe will answer; but by elevating it 2 feet above the surface of the soil would render the roots liable to injury from drought in summer and frost in winter, unless soil were banked in a sloping manner against the front slabs. By taking precautions to prevent the contingencies indicated you may carry out your project with considerable hope of improvement resulting to the Vine. We have known Vines seriously injured, in fact nearly killed, when a border has been above the ground level, the front being supported by "slabs" as you propose, and these fully exposed to the weather. The warts on the Vine leaves in your case are the result of the foliage not being able to appropriate and elaborate the sap at this usually dull period of the year. No injury whatever will be done to the Vines by the few leaves at the top being thus affected.

Repotting Rose (Idem).—If the plant is healthy, and the roots also in a fresh active state, the pot being fairly filled without being firmly crowded with them, you will probably do well not to disturb them materially. All that is needed in such a case, and assuming the plant is required to flower in its present pot, is to dig out the soil round the sides of the pot half way down, more or less, and remove it with all that is loose which you can scrape off the surface, and add fresh turfy loam, enriched with about a fifteenth part of bone-meal and a tenth of wood ashes, working it amongst the roots carefully, and pressing it very firmly. Pruning should be limited to removing any soft unripe tips and shortening any weak or wiry-looking growths. Peach mildew is a fungus that attacks the shoots of the trees, and sometimes the fruit, in the same way that Roses are attacked. It is very injurious.

Planting a Row of Raspberries (T. J.).—Single canes are best, and they are always so sent from a nursery. Procure them early in November; cut off the upper part of each cane to within 18 inches or a foot of its base, according to its size, the weak canes being shortened most; and plant them a foot apart in the row. Before planting stir the soil deeply, and make it very rich with manure. Or, what is even better, make a trench 3 feet wide and 18 inches deep; fill three-fourths of it with old leaf soil or manure from an old hotbed, cover with good garden soil, and plant your row along the middle of the trench. We planted several rows in this manner seven years ago, and they still continue bearing heavy crops of excellent fruit. If you can give them frequent drenchings of house sewage during the season of growth you will be well repaid by growth of extraordinary vigour and fruit of proportionate abundance and size.

American Blackberries (Idem).—Treat these at first just as you do the Raspberries in planting and pruning, only you will probably find that the young plants have three or four stems of about equal vigour. Cut off any weakly stems; retain the others, shortened like the Raspberries. Do not attempt training the subsequent growth in an erect formal manner, for the long vigorous branches may be trained horizontally or diagonally as appears best adapted to retain it unpruned. We have a long row, with the growth interlaced into a perfect thicket, that is wonderfully prolific of fine fruit. A novel, useful, and attractive feature may easily be added to a garden by planting them 3 or 4 feet apart along the sides of a path and training them overhead upon arches; the long shoots may then be taken at will from arch to arch, connecting the whole into a pretty arcade. This plan will commend itself in all gardens where economy of space is important.

Pruning a Cluster Damson (Idem).—The Cluster Damson yields fruit abundantly, pruned precisely like the Plum, and trained as a pyramid. But if you can afford room for an unpruned tree or two do so, as you will eventually obtain most fruit from them. It makes lateral growth so thickly that pruning a few trees is a tedious business, always to be avoided if possible.

Planting Box Edging (Idem).—Box edging should be planted either in autumn or winter—not in spring. When a considerable length is required it becomes expensive; and it is a fact worth knowing that cuttings taken off any time during winter, and inserted as for a permanent edging along the margins of paths, make roots and grow freely during the next season of growth. Care must be taken to press the soil firmly about them by treading when they are put in, and due care must also be exercised to replace them securely after hard frost, which loosens, and sometimes causes them to fall out of the soil.

Dr. Hogg Peach (A. S.).—Mr. Luckhurst, who has had much experience with this and other Peaches, writes as follows:—"This fine Peach answers perfectly against an open wall if it is thoroughly screened from north-east winds in spring, to the baneful effects of which its foliage is so sensitive as to be often destroyed. The tree is a vigorous grower, and the fruit is large, handsome, highly coloured, and of delicious flavour. It is in the front rank of second early varieties, but owing to its tendency to suffer seriously from leaf blister in unkindly springs, the more robust Rivers' Early York should always be planted with it. This rule holds good also with both early and late kinds. With Hale's Early plant Early Beatrix, which is much better out of doors than in, and to follow Dr. Hogg there is none better than Grosse Mignonne, and for late sorts Barrington and Walburton Admirable."

Chionodoxa Luciliae and Freesia refracta alba (F. R. S.).—Particulars concerning the culture and history of both these pretty bulbous plants have been given in this Journal with illustrations, the first named on page 249, vol. ii., new series, March 31, 1881, the second on page 171 of the same volume,

March 3rd. From the descriptions there given you will be able to determine whether your plants are correctly named. The *Chionodoxa* is quite hardy, but a large quantity of *Scilla bifolia* has found its way into gardens under the above name, and beautiful though that bulb is, it cannot be accepted as a substitute for its charming relative. If grown out of doors the *Chionodoxa* can be treated similarly to the *Scillas*, and the same remarks apply to its cultivation in pots, which perhaps if you have only a few bulbs will be the best to adopt. One bulb in a small 60-size pot would be sufficient, and half a dozen in a 48-size pot. Rich light fibrous loam, with leaf soil, well-decayed manure and sand, form a suitable compost, well draining the pots. The *Freesia* may be treated in precisely the same manner. Both after having been buried in cocoa-nut fibre refuse and ashes should be grown in a greenhouse, though the *Freesia* should have the warmest position. This will answer the inquiry of another correspondent, "John George."

Bones as Manure (F. J. J.).—They form a valuable and lasting manure on account of the abundance of phosphate of lime they contain. They are sold in a broken state "as half-inch bones" by manure dealers for agricultural and horticultural purposes, also in the form of meal; they are further reduced to superphosphate of lime by the action of acids. For your Roses you cannot use anything better than bonemeal, mixing it with the compost at the rate of a fifteenth part of the bulk used, or one potful of meal to fifteen of soil. After the Roses are established further applications can be sprinkled on the surface of the pots as often as required for maintaining the vigour of the plants.

Alpine Strawberries (J. S.).—It is a wonder that the second packet containing fruit did not, as you say, "come to grief" like the other. Had the fruit been packed so that it could not move, which would have been the case had the box been firmly filled up with leaves, it would have reached us in good condition; but half filling a tin box with Strawberries and sending it through the post can only have one result—namely, the fruit by being dashed from side to side arrives little better than a mass of pulp: this was so in your case, and the escaping juice had converted a portion of your letter into a mass of pulp too. You have done well to direct attention to Alpine Strawberries; when well grown they are useful for dessert in the autumn, and to many persons are very acceptable. We regret the failure you have incurred. You cannot do better than continue the culture of a fruit you have found so serviceable, and we doubt not that you will, profiting by past mishaps, be able to send us good examples another year.

Variations in Apples (N. H.).—The three samples of fruits you send from the same tree represent an interesting case of bud-sporting. They are quite dissimilar, and a less observant person than yourself might have attributed the result to grafting, but the fruits before us are evidently variously developed (as to colour) forms of the same variety. Some varieties of Apples now in cultivation originated from bud sports. One instance occurs to us—namely, the Scarlet Golden Pippin, which sported from the normal variety in the garden of Mr. Mathew in the Carse of Gowrie about half a century ago, and was perpetuated by grafting. We have little doubt that if you were to graft some stocks with scions from the branch that produces the highly coloured fruit that you would establish a distinct and beautiful variety of Barton Freebearer, and which by its rich colour would probably be acceptable for market purposes. Both the dessert Apples are Court Pendu Plat, the slight difference in form being possibly the result of the influence of the stock. The other variety we recognise as the Irish Reinette of Lancashire. With the information relative to Dumelow's Seedling we were quite familiar. We are obliged by your letter in reference to The Domino and Lord Lennox Apples, and we shall be glad to know the origin of the varieties, or, failing this, the origin of their names.

Various (H. J. G.).—The seeds of Apples and Pears may be sown as soon as the ground is in a dry free-working condition in spring. The seedlings will do for stocks, but if you want dwarf early-fruiting trees the Apples must be worked on Paradise and the Pears on Quince stocks. The word "bothy" is Scotch, and applies to a plain dwelling on an estate for the accommodation of single men, of which the rooms or bothies in gardens for young men afford examples. "The Botanical Magazine" is published monthly by L. Reeve & Co., Henrietta Street, Covent Garden, London, price with coloured plates, 3s. 6d., uncoloured, 2s. 6d.

Names of Fruits (F. W. N.).—1, Thompson's; 2, Comte de Flandre; 3, Fondante d'Automne; 4, Beurre Charnense; 5, Dumelow's Seedling; 6, Lincoln Codlin. (S. M. K.).—1, Reinette de Caux; 2, not known, not Blenheim Pippin; 3, Gravenstein; 4, Reinette Diel; 5, not known, probably local. (W. N.).—The Apple is the Scarlet Pearmain, the Pear not known and worthless. (G. B. C.).—1, not known; 2, Pearson's Plate; 3, Hoary Morning. (A. S.).—The Apple is, we think, Lord Suffield, but the specimens are not quite characteristic; it is either that or a variety named Domino, which is a favourite in the midland counties. We do not recognise the Pears, both of which are inferior, and we should not consider worth the space they occupy.

Names of Plants (J. S. B.).—*Astrantia major*, see above. (S. H.).—The specimens were very small and not well packed, but we recognise the purple flower as *Aster amelloides*, and the rose-coloured one as *Aster novi-belgii rubra*. The other was quite withered. (J. S.).—1, *Begonia natalensis*; 2, *Begonia Weltoniensis*; 3, *Selaginella Braunii*; 4, *Nephrolepis tuberosa*. (G. P., Hants).—1, we do not recognise; 2, *Myrtus apiculata*; 3, *Abelia rupestris*.

COVENT GARDEN MARKET.—OCTOBER 18TH.

POULTRY AND PIGEON CHRONICLE.

THE DEVON BREED OF CATTLE.

CATTLE are generally divided into three varieties—The Short-horned, originally found in the northern and north-eastern counties of England; the Middle-horned in the western part of England, in Wales, Scotland, and Sussex; and the Long-horned in the midland counties and in Ireland, all agreeing that the Middle-horned, which includes the Devons, are descendants of the aboriginal breed of Great Britain. From the earliest records the Devons can be traced as the distinct breed peculiar to the county from which they derive their name, and of the portion of Somersetshire adjoining it, where from time immemorial they existed alone, their handsome red curly coats being so well adapted to protect them in the cold moist climate of their hill country.

Mr. Youatt, one of our earliest writers, in his excellent work on cattle says—"The slightest observation will convince us that the cattle in Devonshire, Wales, and Scotland are essentially the same. They are Middle-horned, tolerable but not extraordinary milkers, and remarkable rather for the quality than the quantity of their milk, active at work, with an unequalled aptitude to fatten. They have all the characteristics of the same breed changed by soil, climate, and time. We may almost trace the colour—namely, the red of the Devon, the Sussex, and the Hereford; and even where the black alone are now found the memory of the red prevails, and has a kind of superstitious reverence attached to it in the legends of the country. In many parts of Scotland and in Wales the milk of the red cow is considered to be a remedy for every disease, and a preservative from evil."

In viewing this choice breed of cattle as compared with other varieties, they may be placed amongst other cattle, as the South Downs are amongst other breeds of sheep; for as the South Down is the choicest of all the tribes, so are the Devon cattle in comparison with all other cattle. Whether we view them for grazing purposes and the profitable consumption of grass and other cattle food, or whether we take them as valuable for the butcher, they stand in the highest position. The South Down sheep always obtain the highest quotation in the mutton market, and it is the same with the Devon cattle—they always secure the highest quotation in the beef market; for not only is the flesh of South Down sheep of the best quality, but the joints are of moderate size and weight, in the same respects the Devon beef is specially noted for its beautifully mixed and marbled fat and lean. The size comparatively of the joints is small and of a moderate weight, which to the consumer is often a matter of great importance in household management.

In describing the style and outline of the Devon breed of cattle we cannot do better than quote from Mr. J. Tanner Davy's, as given in the "Devon Herd Book," he being the original Editor.

He says:—"The outline of a fat Devon very nearly approaches a parallelogram—angular bony projections are rarely found amongst the best bred ones, but their frame is level from the top of the shoulders to the tail. The belly is longitudinally straight and well filled out at the flanks, which should be easily found by the unbent fingers; the breast is wide, and comes out prominently between the fore legs, extending down to within two or three inches of the knee-joint and towards the udder in rolls of fat. The neck is rather long and thin, increasing towards the shoulder, which is tapered off to meet it where the neck-vein forms a sort of collar in front of the shoulders, connecting the fat of the shoulder with the fat of the breast. In the fore quarters the Devons probably excel all other breeds by the shoulders being placed so obliquely that there is no hollow behind them, but the part is well filled out with good flesh and fat, preserving an unbroken line, and promoting a uniform covering of fat throughout every part; commencing at the rump, over the pin bone, edge of the loins, ribs, shoulders, and on to the neck, without patch or excess of any kind. In breeding it is most important to get animals with shoulders placed obliquely, for it is found in practice to be much more difficult and to require a longer time to correct the fore quarter than the hind quarters. It is a remarkable fact in the form of the best Devons that their shoulders are so placed and packed that they can, like a similarly formed horse, go up and down the steep and rugged northern Devonshire hills with much greater facility than what are called the 'large Devons.'"

We do not dispute that the description here given is the pattern to be adopted, and has been the practice of the best breeders for a long series of years; but we say that the general character of the Devon cattle as a whole is especially defective in the fore quarter, very light without that prominence at the breast as is generally the case with the Herefords and Shorthorns. It is, however, extremely important that the fore quarter should be heavy and full, not only for the advantage of the grazier, but also for the benefit of those who work them in the fields, for it must be admitted that the weight and power given to the animal by heavy sound fore quarters is especially desirable whilst working in the collar or yoke. It is true that quite a revolution has occurred in the matter of working oxen since steam power has been introduced; but as we have often taken occasion to show the value of ox labour irrespective of steam power, we hold that the revolution is not yet complete, but must acknowledge the superior claim of early maturity, which induces breeders to turn their money more quickly by sending "baby beef" to the market in preference to feeding or rearing their cattle for working purposes, or for feeding at full age and heavy weights. We, however, hold the opinion that the question of ox labour is worth the consideration of the home farmer, if he will take the opportunity of purchasing Devon oxen broken-in to work, and use them for the summer months, and afterwards place them in the boxes for fattening during the winter months, the chief point being to keep them at the same cost as the horses during their labour, by which means they will be doing their work effectually, and daily growing into valuable animals for fattening in the winter months. The Devons are certainly noble animals for work on the farm in the absence of steam power.

In looking over the Devon cattle at the great fair at Bampton and others as well as at the cattle shows, we have been struck with the great difference in the animals although of the same origin and breed; for we find that large and bulky animals of the same character are co-existent with a warm climate and rich pasturage, whereas smaller types and styles and their varieties are met with in colder hill districts and on poorer soils. In proof of this we may direct attention to the larger class of Devons with long and softer hair, bred in the fertile vale of Taunton Deane, as compared with those bred amongst the hills of North Devon, so celebrated for their short rich curly coats, which they usually lose after a change to a better pasturage in a vale district, with its warmer climate and its richer grazing land, but which pleasing style of coat cattle brought from a distance generally acquire by the end of autumn after having been summer-grazed on those hill pastures. There can now be no doubt that the original seat of the Devon cattle was in the district bounded by the river Taw on the west, extending from Barnstaple to about the point where the South Molton Railway station is now situated, from thence to Bampton, Wivlescombe, Taunton, then turning towards Williton, and on to the Bristol Channel, which forms its northern boundary.

Vancouver, in treating of Devon cattle in his "Report of the Farming of Devonshire," published in 1808, says, "They are an important breed of animals, active at work, and their aptitude to fatten is unrivalled," but further states "they were then declining in their general standard of excellence and numbers," which he traced to the great sale for them to other parts of

England, where the purchasers (Mr. Coke, afterwards Earl of Leicester, and others), spared neither pains nor price to obtain those of the highest proof and beauty." A little later many breeders were tempted, by the excessively high prices offered during our wars with America and France, to sell even their best cows or heifers at great prices for slaughter, their fattening propensity being so great that then, as at present, even milch cows were in the autumn almost fit for the butcher. At this time, also, purchasers from a distance carried off many of the choicest animals at what were then considered enormous prices, to found new herds in various other counties. Fortunately there were some spirited and intelligent men in the country who were justly proud of their native breed, and who would not be tempted by high war prices and by other offers to part with their best animals, but retained and handed them with their offspring down to their descendants, in whose possession in various instances they still remain. Among these breeders were the Messrs. Quartly of Molland, Davy of Rose Ash and North Molton, Merson and Michael Thorne of North Molton, the Halses of Holland, and others. Seeing what was taking place, that the best cattle were being killed for beef or bought and carried out of the district, the late Mr. Francis Quartly, a most enterprising man, sometimes outbid the butchers in order to obtain a very superior beast possessing the qualification he thought most important; thus he selected the best from many hands, and by breeding from and intermingling them with his own, he brought the Champson herd to great perfection. Cattle shows were not at that period generally established, so that few, if any, opportunities occurred of testing the merits of several herds by actual comparison. Soon afterwards one was established at Torrington; further on, and about 1831, the Devon Agricultural Society was founded at Exeter, and soon followed by others at Barnstaple, Taunton, &c., all holding annual exhibitions, affording the public opportunities of comparing the relative merits of the various herds of animals more generally kept. Since then the establishment of railways and steamships have helped to bring out sales, giving increased facilities to purchasers from all parts of the world, including Canada, Australia, continental countries, and the United States of America. The reports from all parts are very satisfactory, stating "That Devon cattle are thriving, and are a profitable breed abroad as well as at home, and that they withstand the changes of soil and temperature well."

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—The late rains have enabled the Clover leas to be ploughed on the driest soils, so that ploughing, pressing, sowing, or drilling may be accomplished simultaneously—a matter of great importance when we consider the difficulties which may occur in the event of the rains continuing to be unusually heavy during the best period of sowing the hill and dry vale lands, which may be stated to be between October 1st and November 1st. Upon the strong soils, especially flat-lying fields, the October month is the safest month for seeding them with Wheat; and as these soils are usually prepared for Wheat by a fallow or fallow green crop, the management required is not so easy and straightforward as for lea ground. All, or nearly all, strong cold soils are subject to weeds, which in the early summer months frequently injure or ruin the Wheat crop unless the seed has been drilled at from 10 to 12 inches between the rows of plants, and which can be done most effectually at the time of ploughing, either by the presser drill or ordinary drill, as fast as the land is ploughed. In the event of the drilling being deferred to a future day we have on some occasions known that it never could be seeded at all until the spring of the year. We are strong upon these points, because the best managed farm in a certain county under our knowledge from the year 1833 to the year 1871, both strong land on chalk as well as light land, the practice was to drill all corn, both Wheat and Lent corn, at 12 inches apart between the lines, and this was done with the very best results, yielding the largest crops of the best quality, of Barley especially; and although we have noticed the agricultural practices in many counties, this farm of over 1500 acres was the best managed as regards growth of corn we had ever seen during the before-named period. The quantity of seed to be used, if not a vexed question, has not been decided by any rule as to quantity, but we consider 2 bushels in October with the land in good condition quite enough, but in November, dependant upon the weather, 2½ to 3 bushels is none too much.

With respect to sorts of Wheat adapted for certain districts, under the heading of "Seed Corn for the Autumn Period" we have treated the question fully, and based our advice to the home farmers upon our own knowledge and experience. There are, however, certain new sorts of Wheat now offered by Messrs. Carter, Messrs. Webb, and other seed merchants which are highly recommended, and are stated to have produced full outside crops, some of which have been grown under the directions of the Royal Agricultural Society of England. The successful growers, and the system of culture adopted upon the soils named, is well worth the attention of the home farmer, but

should be dealt with as experiments in the first instance, owing to the variation of soil and climate in the different districts of the kingdom. Upon all cold soils it is quite a matter of necessity to plough and seed the land daily, the seeding keeping pace with the ploughing. It was a rule we practised for many years, which secured us against the risks of delay in seeding.

Live Stock.—The dairy cows, and also young stock, both calves and yearlings, should now lie at night time on the driest pastures, and also receive a little cotton cake, the cows to get it at milking time as meal, mixed with Cabbage or early Turnips passed through Gardner's cutter; the young stock may get hay if they have a shed to retire to at night, or otherwise a little cake, with cut roots in troughs similar to the dairy cows. The bullocks which have been grazing for beef will by this time have been sold, or put into the boxes or stalls for fattening, to be sold further on—at Christmas or spring as the case may require. We have often advised the home farmer in regard to either cattle or sheep to rear all he requires either for dairy work or fattening for beef or mutton; and this year at any rate the advantage of having done so will prove more than usually to his benefit. All kinds of stock, both cattle and sheep, but especially the latter, are as dear to purchase as we have ever known them, and it is certain they cannot pay for high feeding, either ewes for lambing or tegs for mutton-making. It must at the same time be understood that justice cannot be done to fattening stock without consumption of cake or corn to a considerable extent. The hill farms with their breeding flocks will pay well this year, and so will the stock kept over for the second crop of lambs on the vale farms. But generally on the vale farms sheep of any sort are too dear to pay for fattening; nor should we hesitate instead of feeding our Turnip and Swede crops with sheep to plough in two-thirds of the roots after being passed through an old cutter, greens and bulbs together, the other portion to be removed for feeding young cattle in the yards, and also, together with the Mangold crops, to fatten the bullocks in the boxes or stalls.

POULTRY AND PIGEONS

THE PRODUCTIVENESS OF HENS.

IT may be useful to your readers to know reliable examples of peculiar productiveness in hens; I therefore think it worth while mentioning the following, for the correctness of which I can vouch. I have three Black Poland hens, not white-crested, but pure black. They were hatched in 1880, and in the autumn of that year were shut up in a small grass run, and have never since been out of it. It is about the worst of my enclosed runs, sloping towards the north, and somewhat exposed, on heavy sticky soil, with no scratching place, and no dry path through it. The house is a small portable one with wooden bottom. A little heap of lime rubbish in a corner is the only luxury of the birds. These three hens began to lay during last December, and from January 1st I have kept a record of their eggs, which is as follows:—January, 29; February, 19; March, 60; April, 51; May, 42; June, 21; July, 59; August, 59; September, 35—375 in all, or an average of 125 eggs per bird in nine months. Two of them are now in moult, the third is laying still on alternate days. This certainly is no mean performance for two-year-old birds in such quarters. They are fed regularly twice a day, and get occasional snacks at a third time as their feeder passes to a chicken yard near them.—O. E. CRESSWELL.

"THE PRACTICAL POULTRY BREEDER AND FEEDER."*

So much has been written of late years in connection with the subject of this little work, that one feels disposed to doubt whether there can be anything that is new to be told. Mr. Cook, however, takes up the subject in a somewhat different spirit to that of most writers. He states his object in writing the book to be "to endeavour to give in as few words as possible such plain and practical information as will enable anyone, who has little or no idea of poultry and only the smallest accommodation, to keep fowls and make them pay well." He disclaims any intention of dealing with fancy poultry, and states, as is undoubtedly the case, that birds reared only for the show pen seldom lay any large quantity of eggs. His idea in writing his book "is to describe the best fowls to keep for egg-producing and table purposes;" and he therefore has written very fully regarding the properties of the different crosses, all of which he has personally tried.

It is in the portion of the work relating to crosses that most that is

* "The Practical Poultry Breeder and Feeder." By William Cook. *Journal of Horticulture Office.*

new and interesting is to be found. The directions for management, feeding, &c., are plain and practical, but are necessarily much the same as those given by the best of former writers. He dwells on the necessity for personal attention, and further points out the advantages to be gained in laying qualities from a careful selection of the best layers only as breeding stock. We doubt, however, if he sufficiently indicates the extent to which this had been done in the case of the birds whose wonderful laying powers he instances. We fear this may have a twofold evil effect upon his readers. On the one hand, those who are ignorant of the subject will imagine that it is only necessary for them to procure birds of the crosses he names in order to have an equal result in eggs to that the author cites. On the other hand, those who have had considerable experience of fowls bred without any very special regard to their laying qualities, will be inclined to throw down the book with a sneer at the author's faith in the credulity of his readers.

Mr. Cook has apparently experimented in the matter of crossing the various breeds to a greater extent than any other writer. He advocates first crosses as being best, and here we may note a trifling confusion in his use of the word "pure," as applied to a cross. He speaks of pure cross-bred fowls when he evidently means birds bred from pure-bred parents on each side, and which are generally known as birds of a first cross.

As a rule, the author seems to have used Cochin in preference to Brahma crosses; but in his introductory remarks upon crossing he says that if it is more convenient such substitutions as Minorca for Spanish, or Crève Cœur for Houdan, or Brahma for Cochin, may be made. We cannot, of course, do more than select for mention one or two of the many crosses instanced.

Hamburgh-Cochins are described as very good table birds and enormous layers, averaging 240 to 250 eggs per annum. They do well in confinement or with a large run.

Houdan-Cochins are described as very hardy and easily reared, good table birds, and layers of large brown eggs. Six hens of this breed averaged in the winter of their first and second years twenty-six eggs per week, and the author considers 240 eggs per annum about a fair statement of their laying powers.

For table purposes the author recommends Game-Dorkings and Houdan-Dorkings, the latter being also spoken of as good all-round birds where there is an ample run.

We can safely advise a careful perusal of the entire work to such of our readers as desire to take up poultry-keeping with a view to the return in eggs or table fowls, and those who already do something in this line will also gain much useful information from the author's narrative of his experiences.

OUR LETTER BOX.

Incubator (Ramalho).—You can gain the information you require by writing to Messrs. Christy & Co, 155, Fenchurch Street, London.

Andalusians (Inquirer).—Yes, a fifth claw is an absolute disqualification in the hens of the above breed.

REMARKS.

- 8th.—Fog in early morning; fine calm day; much haze.
 9th.—Fog in morning; fine autumnal day; distinct solar halo in afternoon.
 10th.—Dull and hazy; rain in evening.
 11th.—Warm, dull, generally rainy.
 12th.—Rain in early morning, afterwards fine, but not very bright.
 13th.—Fog early, afterwards very bright during the morning; afternoon and evening cloudy.
 14th.—Fair but overcast.

A dull autumnal week, but the temperature still above the average. Very cloudy, especially at night.—G. J. SYMONS.

VINES IN POTS.

WHERE Grapes are wanted very early in the season to maintain a supply no one will question the value of Vines in pots. Not only are they useful for supplying a few early Grapes, and thus save permanent Vines the sharp forcing required to produce ripe Grapes in April, but for a midseason or late supply they are equally valuable where Vines require replanting and the supply of Grapes must not fail. Well-ripened canes allowed to start slowly and ripen their fruit from June onwards will produce some very serviceable Grapes if properly managed. Those ripened very early may not be quite equal in quality to those ripened later, still the produce may be very creditable indeed. Grapes produced from Vines in pots are generally regarded as of inferior quality, and on this account permanent Vines are forced onwards and fruited early for the purpose of maintaining the supply. This in time cannot fail to impair the health and energy of the Vines.

To produce fruit of average quality early in the season from Vines in pots it is important that they be early and well ripened, and to accomplish this there can be no doubt that "cut-backs" are the best for this purpose. I am persuaded that many failures occur in the culture of Vines in pots through premature ripening of the canes. Thousands of Vines annually that are raised in pots for forcing, when destitute of foliage and considered ready for forcing, should have been maturing their foliage, and thus developing their buds. I do not say that skilled gardeners who prepare a few Vines in pots for their own purpose tie them to some hedge or fence as soon as the wood is brown for the first wind to batter the foliage or early frost to clear it all off. Those who have to rely upon their Vines for fruit know the importance of preserving the foliage as long as possible and properly ripening the canes; but yet the barbarous system alluded to is largely practised.

Considering, however, that the Vines to be forced are in the best possible condition in autumn, the crop of fruit very much depends afterwards upon the treatment during the forcing season, whether the Grapes are of good or inferior quality. Heavy cropping is one cause of Grapes being of poor quality, and this is as marked in the culture of Vines in pots as with those planted permanently, and in many instances more so. How can a Vine in a 10-inch pot bring to such perfection ten or fourteen bunches as it could half that number? but even half that number are too many if the bunches are heavy. If the crop is too heavy, size of berry, quality, and general finish

are inferior, and Grapes that give but poor satisfaction are the result.

Many growers fruit Vines in the pots they were grown in; but I have satisfied myself that this is not the best or most satisfactory system. However good and rich the soil may have been, the young Vine must have exhausted it by the end of the season. Rich top-dressings of soil and manure will certainly help them, with a free use of stimulants, every time watering is done, but even this is not sufficient. When the fruit commences colouring liberal quantities of stimulants should be discontinued, or the fruit may possess but little flavour; but aid is actually discontinued under the above system at a time when the Vine requires liberal treatment, and the berries in consequence are comparatively small. I have failed at least to produce Grapes as good in berry and quality generally under the system described as I have by shifting the Vines into pots 4 inches larger than those they were grown in after they were well started into growth. This system has been previously described in these pages, and the Vines require little or no assistance with liquid manure while growing. The fresh soil given them will be ample to sustain them until the fruit is ripe, which will be of a superior quality.

I have read in reference to Vines in pots, "Fruit once, and that heavily." Now the question arises whether it is wise to do this or retain them for a longer period than one year. If cropped heavily they are useless after the first season. If cropped fairly and retained a second year they will produce better Grapes than in the first instance; but to accomplish this successfully they should be planted out in narrow borders of good soil instead of placing them in 14-inch pots. By so doing only one house is occupied with the Vines, which would not be the case if young canes were prepared annually, fruited, and then thrown out. This is important in the majority of gardens, as house room is often limited. Another advantage is that the Vines would have a good hold of the soil, and by being forced early one season would readily start freely and vigorously into growth the second.

Experience proves to me that this is by far the most satisfactory system. Some Vines transferred from 10 into 14-inch pots early last year carried an excellent crop of well-finished serviceable fruit. The Vines had six bunches each, the produce of one Vine weighing a few ounces less than 10 lbs. These Vines made fine wood, and were this season planted out in a narrow border of loam, to which was added a little fresh lime and a few small bones. The laterals were about 1 foot in length when the Vines were planted, and extra care was taken that they did not suffer by the want of water. The produce was again weighed from the same Vine, which this year carried the same number of bunches, weighing in all 11 lbs. Other Vines carried a greater weight of Grapes this year than the one alluded to, while none had less than 8 lbs., the number of bunches throughout varying from five to seven, according to their size. The berries were larger than last year, and would have been finer still if we had thinned them more liberally; but from the first swelling we concluded the berries would not be large, but were agreeably mistaken when the roots were fairly established in the new compost. The wood made this year is superior to that they produced last year, is well ripened, and the Vines will, I do not fear, produce some excellent early Grapes again next year.

This season we planted some small Vines amongst them that

will make good fruiting canes next year should they be wanted. From all appearances we shall not require to remove the Vines that have been fruiting for the next two or three seasons.—
W. BARDNEY.

NEW ROSES.

I HAVE been again looking through the new catalogues to see what the trade have to tell us about new Roses. The list of highly recommended is smaller than usual. It ranges, however, pretty widely from the two, which is all Mr. Prince admits to large type, to the twenty of Messrs. Wood and thirty-two of Messrs. Keynes.

Mr. Turner offers a select eleven. Mr. G. Paul tells of twenty-six Hybrid Perpetuals, seven Teas, and four Hybrid Teas; he also offers a single white and a single crimson Hybrid Perpetual. Single Dahlias are certainly very pretty, but I hardly expect to see single Roses in the boxes at present.

Putting together what is said, I certainly gather that Helen Paul is about the best of the new Hybrid Perpetuals. "Light tinted flesh, changing to pure white, perfect globular flower.—G. PAUL." "Beautiful white, very large and globular.—B. R. CANT." "Light tinted flesh, changing to pure white.—G. PRINCE." "Fine, white, large, and globular.—C. TURNER." While *Etoile de Lyon* as a Tea is equally highly commended. "Beautiful sulphur yellow, perfection in shape of flower and habit of plant.—G. PRINCE." "Very fine sulphur yellow, said to be one of the best yellows yet raised.—C. TURNER." I have had plants of both of these for the last four months, but do not feel able to say anything about them. Helen Paul has not shown much vigour.

May Paul appears another strong grower of the red *Gloire de Dijon* strain; of this I hope to know more next year. I can report very favourably of *Reine Maria Pia*, which is a most vigorous red Tea, and one of the sweetest Roses I know. I consider it, however, less of a Tea Rose than its sister *Reine Marie Henriette*, a real red climber, which has been relegated into the cold shade of the Hybrid Teas. Its pointed bud and foliage are very Tea like. I am glad to see that Mr. Turner and Mr. Prince both give it in their catalogues as a Tea. An endeavour should certainly be made to induce the National Rose Society's Committee to allow it to be shown as such. Since they turned out *Cheshunt Hybrid* a bit of red in the Tea boxes is sadly wanted.

I ought, perhaps, also to allude to Hybrid Perpetual White *Baroness*. It is very pretty, but we have not yet arrived at the much-to-be-desired pure white *A. K. Williams*.—A. C.

LABELLING FRUIT TREES.

YOUR correspondent "J." (page 348) does well to call special attention to the neglect of this operation, which is, as you both say, not by any means "trifling." It is indeed not trifling for a gardener to come into possession of a fruit garden or orchard where there is scarcely one fruit tree named, and where he has slight chance of finding anyone to name them except the local and commonest of the fruits. The higher-quality fruits, those of most consequence to him, are not easily determined, and it takes him years before he can get them all correctly named. I can give a recent and most forcible illustration of what I mean. When I came here there was scarcely one fruit tree that had a name to it. Those that had, the labels were found so faded that it was almost impossible to decide positively what was the real name. There were two Apples that were called by a purely local name, and a name that gave one no idea of their qualities. The consequence was that these Apples were treated as the most common of fruits. They went in to the cook just as they were wanted, and were peeled and used for the most ordinary culinary purposes, and I dislike having any tree or plant about me of which I do not know the name; so I made up a basket of fruit and sent them to you for naming, and this particular one proved to be *Sturmer Pippin*, one of the best and latest in use of all the dessert Apples, being, as I understand, a cross between the old *Nonpareil* and *Ribston Pippin*. Well, since it had its right name it has been put to its proper use, to the great pleasure and satisfaction of all concerned, and is raised from being anybody's Apple to the dining-room dessert dish, where it proves to be a very great favourite. I could give many more instances of this prostitution of high-class fruits to common purposes from ignorance of the name if necessary. It is not necessary.

I would like to warn those who are about putting zinc labels to their fruit trees to pause before they use lead wire to fasten them on with, as recommended by your correspondent "J." I know a young orchard that was planted on an estate and the labels were put on with this lead wire; and through the first winter

those labels that were in the swing of the wind were chafed through and scattered all about the orchard, and in the long grass many were entirely lost. Use either galvanised, or what ironmongers sell as annealed wire, or copper wire, to fasten the labels to the trees with. Such is my experience of lead wire, that I consider you might as well tie them on with ordinary string or with bast matting as with lead wire.

In addition to the method of naming each tree by a label, it is my rule always to make a plan of the orchard in my garden book—(every good gardener has a garden book full of all sorts of notes about his charges)—and dot the position of each tree in the book, and either put the name against the dot, or number the dot and put the name and number on another page. I contend that a plan of the orchard ought to be made at the time the orchard is planted, and kept with the other plans of the estate, and passed on from one occupier or owner to another, just as the other plans of drains, roads, fences, &c., are. We shall not get this done yet; but to my mind it is a thing that ought to be done.—P.

[Unquestionably it is, and we take care to do it.]

SUCCESSFUL VIOLET CULTURE.

THERE are but few places where Violets are not appreciated, and as a consequence the culture of these plants in frames is rapidly becoming fashionable; but if it became generally known how simple are the requisite cultural details to be observed still more would make the attempt. At *Crichel*, the beautiful Dorsetshire seat of Lord Alington, Violets are both extensively and well grown by Mr. Beck, the experienced gardener, and, as his fame had reached this district, on a recent visit I took careful note of his practice. When it is stated a pit was specially constructed for Violets, of which sixteen large lights are devoted to them during the winter, it will be readily understood how great the demand must be. Throughout the winter large numbers of blooms are picked daily, or at all events whenever the state of the outer temperature will admit of the pits being opened, and at times enormous quantities are available. On one occasion early in February, when Royal visitors were being entertained at *Crichel*, Mr. Beck states they could have picked nine thousand blooms had they been required. The variety relied upon for the autumn and winter supply is *Marie Louise*, and the blooms of this fine Violet generally measure $1\frac{1}{2}$ inch in diameter, and occasionally are still larger. To succeed these the old *Neapolitan* is grown, and is also particularly fine.

The pits above mentioned, which mostly face due south and are well sheltered, are constructed on a different principle than is usually the case, as they are about 5 feet high at the back and only $1\frac{1}{2}$ foot high in front. This extremely sharp pitch assures the Violets abundance of light, as the plants are disposed as near to the glass as possible without touching. No bottom or artificial heat whatever is given. The soil employed apparently consists of good enriched loam, which is trodden even and firm, and the plants are also firmly planted. No particular number of plants are disposed in each light, but the leaves just touch each other all round. This season they have made much less growth than usual, and consequently will be planted more thickly.

The method of preparing the plants is also different from that generally adopted, and it is certainly the best I am acquainted with. Large open well-enriched borders are devoted to them, and they are divided and transplanted in the spring before the pits are required for hardening off bedding plants. It must be understood the so-called plants when lifted are really clusters of plants, the strongest in the centre having produced good runners, which are pegged down about the end of August or early in September, and these prior to lifting about the first week in October are well rooted and yield some blooms. It is these rooted suckers which are separated and planted out singly the following season, the older central plants being then thrown away. A few strong crowns secured in this manner are found far superior in every respect to a greater number of weakly crowns.

As before stated, no artificial heat whatever is given to the Violets in pits, whether in pots or planted out as the case may be; on the contrary, cool airy treatment is constantly practised. The lights are drawn off at all times during mild weather, this checking both damping and exuberance of leaf-growth, two evils many find it difficult to counteract. The lights are sufficient to protect from moderate frosts, but if severe frosts are anticipated mats and litter are thrown over them. The pits during the prevalence of a very severe frost have been kept closely covered for about fourteen days; but in spite of this, and the blooms having been hard frozen, they, by being gradually thawed, have escaped apparently uninjured.

Judging from the success attending Mr. Beck's practice, the

greatest number of failures in frame culture of Violets result from excessive "coddling." Fairly well-prepared Violets, properly planted at the present time, having a light well-ventilated position, will certainly be found of great service in affording a continuous supply of blooms.—W. IGGULDEN.

CUCUMBERS AND MELONS FAILING.

WHEN I came here in February, 1881, there were some very weak Cucumber and Melon plants planted, but I soon found they made no progress in their growth, the bottom leaves continually decaying as if they were scorched. I obtained some strong plants and placed them in another house, but the leaves decayed in just the same manner as the others, and eventually died. I removed those, and I afterwards procured fresh plants and discontinued fire heat. These grew fast, and we cut a fine lot of Cucumbers from them until we recommenced fire heat, when all the plants died in the same manner. Last spring we experienced a similar trouble until we discontinued fire heat; since then we have had a good supply. We have every convenience that can possibly be had for growing them well, and they are treated suitably in every respect, notwithstanding they die in the manner I above stated. I think the fault must be the pipes, for it seems every two years they are painted with a brick-red paint, and probably this is the cause of the mischief. I should be glad to know the opinion of any reader on the subject, as well as the best way to cleanse the pipes. Melons and Cucumbers are not the only plants affected, for others, especially Maidenhair Ferns, die in the same way.—J. HEATH.

MANURES.

I PREFER good farmyard manure to all artificials, but it is not always obtainable. This year I tried the Crown Manure Company's improvers and complete manures, and perhaps your readers may be interested in the results. Unfortunately I received the Improver for mixing with farmyard manure and applying to Potatoes too late in the season to give it a fair trial. It was properly mixed and applied when earthing-up the Potatoes, with no result in the earliest Potatoes; with the second early Potatoes it prolonged the growth of the haulm and slightly increased the bulk of produce; with the later Potatoes, such as Improved Peachblow, it considerably increased the produce. Next year I intend to apply it at the time of planting, when I shall obtain a more satisfactory test.

Improver for Turnips I applied in two ways—by ploughing in and by harrowing in. I also tried it mixed with farmyard manure, and by itself. The half acre I ploughed in was one-half Improver mixed, and other half unmixed. The result is contrary to my expectation. I have a splendid lot of Carter's Early Jersey Lily all over, but they are better where no farmyard manure was applied. The tops are singularly small, but with fine Turnips beneath. They are all a garden Turnip should be for quality. Where I harrowed the Improver in without farmyard manure the tops are larger, the Turnips fine, and they decidedly grew much quicker. I give the preference to ploughing-in rather than harrowing when the season is not late.

Complete manure for Cabbages I ploughed-in, and planted Savoys, Brussels Sprouts, and Broccoli. I am much pleased with the results. They all look well; and although some of the Brussels Sprouts were planted as late as the 12th of July, yet I find there are some sprouts fit to pick now (October 16th). The manure seemed to push them on at an early date after planting.

In conclusion I may say that I should judge that if the Improver were mixed with farmyard manure and applied to Potatoes at time of planting the results would be satisfactory, judging from my imperfect trial. For Turnips I think very highly of the Improver. For Brussels Sprouts and the Cabbage family I think the manure excellent. This manure, I may add, I applied to one side of a bed of Onions, and native guano to the other side. The produce from the Crown Manure was far the heavier. You will observe I tried two classes of Improvers and one complete manure.—H. S. E., *Great Totham*.

POTATOES.—I have tried nearly forty varieties of Potatoes this year, and of these only twelve have satisfied me, and they are as follows:—St. Patrick, good cropper, free from disease; Wormleighton's Seedling, similar; White Elephant, great cropper, but diseased; Beauty of Hebron, excellent in all respects; Veitch's Ashleaf, good cropper and good quality; Wiltshire Snowflake, the best of all; Peerless Rose, handsome, good cropper; Vicar of Laleham, similar qualities; Improved Peachblow, great cropper; Trophy, very handsome, good cropper; Dalmahoy, best-flavoured Potato grown, and good cropper; Holborn Favourite, great cropper. Of these twelve I

prefer as an early Veitch's Ashleaf; medium, Wiltshire Snowflake and Dalmahoy; late, Wormleighton's Seedling. Beauty of Hebron, early, can well be added to these.—H. S. E., *Great Totham*.

"THE BLACK DAHLIA."

LIKE some other popular names the above has the merit of simplicity, and but for the fact that the plant to which it is applied is not a Dahlia, and the flowers are not black, it would be as suitable a designation as any other. It is true that the title botanists have honoured the plant with has not the first-mentioned merit, and doubtless there are some to whom *Cosmos diversifolius atrosanguineus* would appear almost as formidable as certain

Fig. 62.—*Cosmos diversifolius* var. *atrosanguineus*.

Mexican or Aztec names which so freely abound in unpronounceable combinations of consonants. Perhaps, therefore, as a kind of compromise between the correct and the incorrect, the few syllables and the many, "the Black Cosmos" might be suggested as a desirable equivalent or substitute for Black Dahlia.

Before, however, this can be considered as settled satisfactorily it will be necessary to explain how the title Dahlia was first applied to this plant and why it is incorrect. Mr. W. Taylor, in the last issue of this Journal, quaintly remarked that "aliases in the plant world are generally indications of merit, and convey altogether a different impression to aliases borne by men and women;" and if this be true our little *Cosmos* has an additional

recommendation in the fact that it has also other names besides those given above, such as *Bidens atrosanguinea* and *Dahlia Zimapani*, under which it is seen in several English gardens and nurseries. In reference to the latter Mr. W. Thompson of Ipswich writes—"Dahlia Zimapani was introduced by the collector Benedict Roezl, who gave the plant that name. I believe I sent it to the late Sir William Hooker for figuring in the 'Botanical Magazine' (tab. 5227, January 1st, 1861), but to the best of my recollection the seed came into my hands from one of the continental seedsmen about the year 1860. It is certainly close enough in external appearance to the Dahlias to excuse Roezl and others for having associated it with them; but I suppose the authority of such a botanist as Sir W. Hooker is not to be gainsaid."

Such in brief is the origin of the name, and the excuse urged above—*i.e.*, the general external resemblance to Dahlias, is quite sufficient; for, taking the *D. glabrata*, *D. Merckii*, and *D. gracilis* type, there is little to distinguish them on casual observation from the *Cosmos*. They are dwarf, with pinnately divided foliage, slender, tuberous, fasciated or bunched roots, and their flowers are borne on long slender peduncles, in all of which characters the *Cosmos* closely resembles them. The chief difference is in the involucre (the calyx-like green bracts surrounding the ray florets), which in the *Dahlia* consists of two series, the outer usually consisting of five bracts, strongly reflexed, dark green, and of thicker texture than the inner series, which closely surround the ray florets and consist of about eight thinner and lighter green bracts. The same portion of the flower in the *Cosmos* is also in two series—five bracts in the outer not reflexed, and eight in the inner—but of similar texture, both closely surrounding the ray florets, the inner series being slightly coloured like the florets. There are some other differences in the florets themselves, but they need not be repeated here. The foliage is of thicker texture and much less succulent than that of Dahlias. It, moreover, has a totally distinct taste, and though this cannot be considered as possessing much weight as a botanical character it is important in another respect—namely, it is obnoxious to slugs; and Mr. H. Cannell of Swanley, who has a large number of plants, states that he has never found one leaf injured by those pests—conclusive evidence, in his opinion, that it is not a *Dahlia*.

Having thus disposed of the nomenclature, the value of the plant as an occupant of our gardens may be briefly referred to. It cannot claim a high place for brilliancy of colouring, as its rich velvety maroon flowers are only seen to the best advantage when in contrast with the lighter or brighter flowers of its congeners, the single Dahlias, or similar dwarf plants. There is a peculiar richness of tint, however, that is very pleasing, and when associated with other flowers, as hinted, it has a striking effect. The long peduncles also admirably fit it for cutting, and the blooms continue fresh for several days in water. It succeeds well under similar treatment to the Dahlias, lifting the tubers in autumn and storing them in a dry cool place safe from frost; or if the roots are allowed to remain in the ground during winter, which, however, is scarcely a safe course, they must be amply protected with a covering of ashes, litter, or similar material.

It may be observed that the species (*C. diversifolius*) of which this is a variety, was described by Otto in Knowle's and Westcott's "Floral Cabinet" some years ago, but it has smaller flowers than the variety, of a rosy lilac colour not unlike *Anemone japonica*, the roots being tuberous as in the one now described. Another perennial *Cosmos* is known in gardens—*viz.*, *C. scariosoides*; but *C. hipinnatus*, figured in this Journal, page 265, September 21st of the present year, is an annual, and quite distinct from these, though Mr. F. W. Burbidge, usually so correct, appears to consider *C. hipinnatus* and *C. diversifolius* as synonymous.—L. CASTLE.

WOODS, FORESTS, AND LAND REVENUES.—The sixtieth report of the Commissioners of Her Majesty's Woods, Forests, and Land Revenues has been recently issued. In the past year, ended on March 3rd last, the gross sum that was credited as received from the rents and royalties, and the "thinnings of the plantations of the property," amounted to £346,560; but from that amount there have to be deducted various sums that were allowed to tenants, principally in consideration of the losses sustained by them from a succession of adverse seasons during the past six years. These allowances amounted to £20,652 17s. 10d.—equal to 21 per cent. on the rental. The report proceeds: "For the same purpose of assisting the tenants, and in order to enable them to cultivate their farms to the best advantage to themselves, nearly £130,000 have been expended by the Crown in the past six years in under-drainage and in the construction and enlargement of farmhouses and farm buildings and cottages, and in other works of permanent improvement of the land in my charge. In the past year the sum of £23,237 9s. 5d. was expended in works of that description and in repairs. The proportion of that sum which was expended in works falling under the definition of the

'Improvement of Land,' within the meaning of the Improvement of Land Act, 1864, amounts to £16,723 10s. 4d. The sum was paid out of capital in pursuance of the Land Revenue Acts, which provide that the cost of such works shall be charged to capital and be repayable by instalments out of income. The residue of the outlay, amounting to £6513 19s. 1d., was paid out of income."

THE ROSE ELECTION.

It may interest some of the readers of "our Journal" to compare the results of the present election with the matured judgment of the first rosarian in America, Mr. H. B. Ellwanger, a gentleman to whom I feel most deeply indebted; for in the earlier elections, when as yet the ages and raisers of the different varieties remained in cloudland, when mystery shrouded these interesting data, Mr. Ellwanger, unknown to me even by name, and therefore quite unsolicited, wrote from America, filling up many of the gaps in these columns, whilst from the pages of his catalogues I have learnt more on these points than from any of our English growers, excepting our old and departed friend the Rev. W. F. Radclyffe.

Few can appreciate the difficulty on these points in the earlier elections. Now that we have the catalogue of the National Rose Society the difficulty has comparatively speaking disappeared; but I desire to give honour where it is due, and the catalogue of Messrs. Ellwanger & Barry was, in this respect at any rate, an example to our own growers and an unvarying help to myself.

As the great authority on Roses and Rose-growing in America, I have thought that the contrast between the two lists might prove of some value.

THE ELECTION LIST.

1. Marie Baumann.
2. A. K. Williams.
3. Alfred Colomb.
4. La France.
5. Baronne de Rothschild.
6. Charles Lefebvre.
7. Marquise de Castellane.
8. Duke of Edinburgh.
9. Etienne Levet.
10. Marie Rady.
11. Capitaine Christy.
12. Louis Van Houtte.
13. Dr. Andry.
14. Ferdinand de Lesseps.
15. François Miehelon.
16. Madame V. Verdier.
17. Marie Finger.
18. Comtesse d'Oxford.
19. Mons. E. Y. Teas.
20. Madame G. Luizet.
21. Horace Vernet.
22. Sénateur de Vaisse.
23. Dupuy Jamain.
24. Marguerite de St. Amand.
25. Duke of Wellington.
26. Xavier Olibo.
27. Beauty of Waltham.
28. Annie Wood.
29. Duehess of Bedford.
30. Comtesse de Serenye.
31. Camille Bernardin.
32. Reynolds Hole.
33. Duehesse de Vallambrosa.
34. Princee C. de Rohan.
35. Star of Waltham.
36. Le Havre.
37. Fisher Holmes.
38. Countess of Rosebery.
39. Marie Verdier.
40. Abel Carrière.
41. Victor Verdier.
42. Pierre Notting.
43. Duehesse de Morny.
44. John Hopper.
45. Charles Darwin.
46. Duke of Teek.
47. Madame Laeharme.
48. John S. Mill.

MR. ELLWANGER'S LIST.

1. La France.
2. Alfred Colomb.
3. Marie Baumann.
4. Madame Gab. Luizet.
5. Baronne de Rothschild.
6. Marie Rady.
7. Mlle. Eugénie Verdier.
8. Louis Van Houtte.
9. Horace Vernet.
10. Xavier Olibo.
11. Pierre Notting.
12. Capitaine Christy.
13. Madame V. Verdier.
14. Mons. E. Y. Teas.
15. Marquise de Castellane.
16. Baron de Bonstettin.
17. Abel Carrière.
18. Jean Liabaud.
19. Alfred K. Williams.
20. John Hopper.
21. Comtesse de Serenye.
22. Fisher Holmes.
23. Annie Wood.
24. Charles Lefebvre.
25. Eliza Boëlle.
26. Princee C. de Rohan.
27. Beauty of Waltham.
28. Rev. J. B. Camin.
29. Charles Margottin.
30. Comtesse C. de Chabillant.
31. Countess of Rosebery.
32. Comtesse d'Oxford.
33. Egeria.
34. François Miehelon.
35. Etienne Levet.
36. Mauriee Bernardin.
37. Paul Neyron.
38. Victor Verdier.
39. Jean Soupert.
40. Mlle. Thérèse Levet.
41. Princee de Portia.
42. Boieldieu.
43. Helen Paul.
44. Gaston Levêque.
45. Mons. Noman.
46. Marguerite de St. Amand.
47. Abel Grand.
48. Hippolyte Jamain.

The comparison of these two lists is not without interest. It appears to me that the pronounced colours, whether very light or very dark, do better in America than in the old country. Our new acquisition of 1877, Madame Gabriel Luizet, stands very high; and La France, Eugénie Verdier, and Comtesse de Serenye all stand higher, as do amongst the darks Horace Vernet, Xavier Olibo, Pierre Notting, all these being in the first dozen, and in the second we find Baron de Bonstetten and Jean Liabaud, the former not named in our seventy-five, and the latter actually seventy-fifth. Baronne de Rothschild and Beauty of Waltham stand respectively Nos. 5 and 27 in each list, whilst most of us will wonder at the low position of Charles Lefebvre, perhaps our most constantly good dark Rose, which rarely burns as so many of the

darker do with us. I say *burn*; but though this describes the appearance, it certainly is not caused through burning as by the sun, for very frequently on sunless days this failing is more noticeable.

I also draw attention to the position of A. K. Williams and Madame G. Luizet. These two Roses almost exactly change their relative places in the two lists. Evidently A. K. Williams is not so highly esteemed in America, and since the publication of the first portion of this election I have received a letter from a gentleman in which the following passages occur:—"Since you mention A. K. Williams I cannot resist giving you my experience this season. I had between thirty and forty plants on Briar and Manetti, maidens and cutbacks. Eleven of them died right out in April, though they had shot strongly before, being pruned in March. Off the remainder I cut but one moderate show bloom all the season. They are well 'done by,' but made very weak growth. I think there was something in the season did not suit it. All Rose-growers in this county (Suffolk) were equally lamenting it." My experience, I confess, leans to the same view—plants have died so far as I could discover without any reason.

Of Helen Paul and Gaston Levêque, two Roses that are included in Mr. Ellwanger's second twenty-four, no mention was made by any one of the sixty-six voters in this country; the catalogue character of the former is excellent.

Let me now compare the two lists of Teas and Noisettes.

THE ELECTION LIST.

1. Catherine Mermet.
2. Maréchal Niel.
3. Souvenir d'un Ami.
4. Marie Van Houtte.
5. Souvenir d'Elise.
6. Devoniensis.
7. Madame Lambard.
8. Niphotos.
9. Madame Bravy.
10. Jean Ducher.
11. Perle des Jardins.
12. Rubens.
13. Belle Lyonnaise.
14. Souvenir de P. Neyron.
15. Comtesse de Nadaillac.
16. Madame Willermoz.
17. Anna Ollivier.
18. Innocente Pirola.
19. Madame Caroline Kuster.
20. Gloire de Dijon.

MR. ELLWANGER'S LIST.

1. Maréchal Niel.
2. Catherine Mermet.
3. Marie Van Houtte.
4. Madame Bravy.
5. Madame Lambard.
6. Rubens.
7. Etoile de Lyon.
8. Perle des Jardins.
9. Marie Guillot.
10. Comtesse de Nadaillac.
11. Marie Berton.
12. Madame Angela Jacquier.
13. Cornelia Cook.
14. Niphotos.
15. Souvenir d'un Ami.
16. Devoniensis.
17. Sombreuil.
18. Jean Ducher.
19. La Princesse Vera.
20. Madame Welshe.

The American list contains two Roses that I do not find in most of our English catalogues. No. 13, Cornelia Cook, thus described by Mr. Ellwanger:—"Cornelia Cook (Anthony Cook, 1855), a seedling from Devoniensis, pale yellowish white, sometimes tinged with flesh; flowers very large and very full, not a free bloomer, and often does not open well, but a superb Rose when well grown." The other, No. 19, La Princesse Vera, is a new Rose "(Nabonnand, 1878), creamy white bordered with coppery yellow, pretty buds."

Mr. Ellwanger has just published a new book on the queen of flowers entitled "The Rose." It is comprehensive, for it gives a list of 956 varieties, the date of origin, and name of raiser. It appears also to treat the subject fully, including the diseases and insects of the Rose. On the latter point most of us need enlightening, especially ordinary gardeners, who are only too ready to apply finger and thumb to any insects, forgetting, or more probably having never learnt, that many of the insects on the Rose are our best friends; and here I rejoice to see in Mr. Farren's (of How House Nurseries, Cambridge) catalogue additions on these matters. They will well repay perusal. Possibly he has scarcely drawn sufficient attention to the very pointed head of the larvæ of the syrphidæ, our greatest allies. The heads of all other grubs and maggots that eat the Rose are rounded or squarish, and the head is generally shiny and distinguishable from the rest of the body of the grub. Not so that of these most useful little creatures; it is roughly pointed, not distinguishable as a head. These untiring devourers of the green or black fly cannot be too universally known and recognised. They, with the larvæ of the ladybird and lace-winged flies which may escape destruction, being unlike grubs, are our most devoted slaves. It is a pity they so often receive the treatment meted out to our enemies.—JOSEPH HINTON, *Warminster*.

STANDEN'S MANURE.—I quite agree with Mr. Irvine in reference to Standen's manure and its effects on plants. I believe if it was more used many difficulties to be contended with in town gardening would be overcome. We all know how injurious town air is to plants, particularly to Roses. To grow these in gardens here is out of the question, surrounded as we are by thousands of habitations; even under glass few will succeed—not one out of ten. For five years I tried to grow Gloire de Dijon in a greenhouse, but failed every year

until the spring of 1881. I that year obtained a plant of the above Rose, and in potting it I used the manure as directed on the canister, quite expecting it to die as the others had done, but was surprised to find it growing vigorously. In July I planted it out, bringing the head inside and mixing with the soil half a 1s. canister of the manure. This spring I cut over two hundred blooms from it, and at the present time it covers over 100 feet of glass.—CHARLES WARING, *Prince's Park, Liverpool*.

RASPBERRY CULTURE.

To have this useful fruit in satisfactory condition good soil is essential. If the natural soil is not suitable it must be prepared. I managed a garden once where every other kind of hardy fruit was grown extensively and well except the Raspberry. The soil was a stiff loam and the cause of failure, so we marked off a piece of ground in an open quarter, and worked in plenty of decayed vegetable matter mixed with lime to make the soil light. The stools were planted, and the same season splendid canes were formed, and a good crop of fruit was obtained from the original canes.

When you are about to plant Raspberries choose an open quarter. If the ground is heavy work in plenty of vegetable refuse. If, on the other hand, it is too light well trench the ground and work in some stable manure. The best month to plant in is November. The rows should be 5 feet apart, and the stools 3 feet apart in the rows. The following February cut the canes down. As to training, the best way is to have a strong post at each end of the row and a wire strained to them, the canes being trained fan shape. When they are established mulch the ground with manure every season, but do not dig it in. It will help to keep the roots moist, besides affording them sustenance, as the Raspberry delights in a moist rich soil. There is another reason why Raspberries do not succeed at some places. They are surface-rooting, and the soil near them should not be dug at any time. In the winter hoe the quarter and remove the loose litter. They do not require very much pruning. After they have done fruiting cut the old fruiting canes away to encourage the suckers for next season, leaving about six to a stool. I do not recommend cutting the tops of the canes unless in the case of a straggler, as much of the crop is lost by doing so. The best varieties are Fastolff, Prince of Wales, and Carters' Prolific. Baumforth's Seedling is also said to be a good variety. Autumnal Raspberries do not bear good fruit on the canes of the preceding season. They should be cut down close to the ground in February and the suckers thinned.—A. YOUNG.

In the majority of gardens autumn Raspberries are almost indispensable, and this autumn they appear to be doing better than usual. The plants of the yellow variety in particular are still carrying a heavy crop of fine fruit, much heavier than the red. We commenced gathering five weeks since, and to all appearance will continue doing so until the frost comes. As is well known, these varieties fruit on the current year's shoots, the old wood being cut away during the winter and the stools well mulched with manure. It is advisable to transplant often, as by so doing much larger fruits are procured, and if done early it does not affect them, and they will carry a good crop of fruit the same year.—G. S.

SEWAGE, SOOT, AND ASHES—A CAUTION.

I HAVE been much interested with the discussion lately carried on in this Journal about benefits obtainable from what may be called home-made manures, such as sewage, soot, and ashes. Sewage both in a liquid and solid state is equal to any of the costly fertilisers in the market. As long as I can remember sewage has been known to me as one of the most beneficial and economical of fertilisers; indeed, it has often been a surprise to me that such a valuable article has been so wasted. "SINGLE-HANDED" and Mr. Taylor are national benefactors in stirring the minds of horticulturists to the benefits derived from its use. There is nothing new about it, but, as in cooking, the average Britisher will not look at the economical part of the subject. Home-made dishes of scraps what our continental friends would make a savoury meal of are thrown away for the large costly joint. So with home-made manures. We shall no doubt in time learn to study the application of those resources that are at hand, and to be had in most cases for the mere trouble, and a careful system of preserving and applying them.

Sewage, soot, and ashes I have always accounted amongst the gardener's best and readiest assistants, so much so that I have since I came here managed to obtain the whole of each for the use of the garden. In doing so I thought myself most fortunate. I used all unsparingly, but in most instances could not

detect the benefit I was led to expect from previous experiences; rather for some time there was not wanting indications that something was not as it should be. What could it be? In whatever way each and all these three articles were applied, and to whatever crops applied to, the results were the same—instead of invigorating the plants it impaired them, and in too many instances totally destroyed whatever they were applied to. I need not say I looked far and wide to account for the cause of this deteriorating and dying-out—Strawberries, Vines, Peach trees, Peas, Cauliflowers, Celery, bulbs, Chrysanthemums, Spiræas, and herbaceous plants. I had used sewage, soot, and ashes since I knew what they were with the best results, which puzzled me the more to account for the disastrous effects. We must bear in mind due care was taken in applying it. I was some time before I could persuade myself that to these I must look to for the mischief that had been done. Was it possible that an enemy was lurking within all three of those useful fertilisers? What could it be? It must be potent, and so it is. We have it in that useful article paraffin. In a large establishment with a number of careless servants this mischief can be done, and has been done, and by what means? I account for it in this way. Gardeners who are about the indoor establishment much cannot help noticing the peculiar liking Mary the housemaid has for the company of a tin can in her rounds to light fires. She is late in getting up, the wood is damp, and the paraffin can will be found to supply the quickest and readiest means of making a fire at once. Again and again have I seen it used the same morning. What is the result? Much of the paraffin falls through to the ashpit, and much again will pass away with the smoke before it is heated enough to burn and lodged in the chimney, and thus it finds its way to the gardens in both ashes and soot. The unlucky gardener is thrown off his guard, and it is well for him if he finds it out before it has done much damage. Truly is it said, "Protect us from our friends, from our enemies we can protect ourselves."

Now how are we to account for it in the sewage? Easily, I think. Go to the pantry in the morning, and you will find James or Charles trimming two or three dozen lamps, and they, too, know not the damage paraffin may do when thrown about carelessly. All refuse from the emptying and cleaning of the many lamps goes into the sink which leads to the sewage tank near the garden. This is one of the many channels. Another can be traced to a drain close to where the paraffin is stored. A can is turned over, the tap is left running too long, washing out the floor of the storehouse, careless tapping the cask, or it may be emptying out just the little that is left in the cask, are some more of the many ways in which it gets to the sewage tank. I once knew a large quantity escape into the drains, some of which leads to a fish pond, and the next morning I remember counting seventy-five dead fish floating on the surface of the water. Much of this, too, I afterwards traced to the sewage tank. All this was arrived at when it was too late, the damage being considerable. Since this I have some difficulty in placing that former confidence in what I thought three of my very best assistants. Still, we must remember that it is really not, after all, either the soot, ashes, or the sewage, but the paraffin that has done the mischief. What we wish to know before we use either is that there is no paraffin in them. I have now such a perfect dread of this oil that I care not to use it as an insecticide; though valuable in some respects, in others I have seen much harm from its use.—JNO. TAYLOR, *Hardwicke Grange.*

MARGUERITES OR PARIS DAISIES.

As this is the time for increasing these plants, a few remarks on their propagation may be useful. Choose the youngest shoots and those without a flower bud. Insert about nine or ten in a 48-size pot. Employ a compost of two parts fibry loam, one part leaf soil, and one part of silver sand, pressed firmly into the pots, with a surface layer of sand three-quarters of an inch deep. They should then be placed in a cold frame with a north aspect, keeping the frame close for a few weeks. The plants may then be transferred to a cool house. The frame should be kept quite close and covered in severe weather. At the beginning of April the young plants should be potted in large 60's and placed in the frame with a south aspect, ventilating as the plants improve. I plant them out in the beds and borders in May and June.—C. STEPHENS, *Lyne Gardens, Horsham.*

VAGARIES OF PLANTS.—I have at present (October 16th) in flower in my small garden *Lilium auratum* with seven large blooms, blue *Hepatica*, *Jasminum nudiflorum*, Christmas Rose just about to flower, *Helleborus lividus* in flower, *Auriculas*, *Laurustinus*, *Primroses*, *Pyrethrum uliginosum* just beginning to flower. In the kitchen garden Strawberries are flowering and bearing a second crop;

Currants against a wall have shed all their leaves a month or more ago, and show buds as if they intend to give a crop about Christmas; Gooseberry trees are the same. Can any of your readers explain why some plants are so premature and some so backward this year?—G. O. S.

VARIETIES OF PEACHES AND NECTARINES.

LIKE Mr. Iggulden (page 335) I am much interested in the culture of the above-named fruits, and I gladly give my experience on the subject. The soil here is very suitable for Peaches, being a strong holding loam, resting on magnesian limestone. When I say it suits them, I allude to the trees growing freely in it; in fact, too much so if left alone, consequently we have frequent recourse to root-lifting. In fact, we do this more or less annually, otherwise we should seldom have such heavy crops of good fruit as we usually do, especially during the late dull wet summers we have had here for several years. Our borders are both inside and out, and about 3 feet in depth. Were we constructing them now we should limit the depth to 2 feet 6 inches, and restrict the root space to 6 feet inside and about 4 feet outside, having the roots of the trees in the early house all inside. In pruning we make it a rule never to shorten the young wood unless we wish to fill up a vacancy in the lower part of the tree. We thin out all superfluous wood as soon as the fruit is picked, leaving but little to be done at the winter pruning. We have a quantity of shoots on the trees in our early house nearly 3 feet long covered with fruit buds their entire length.

A word now as to varieties. Our best and surest cropping variety in the early house is Royal George. The tree entirely covers a trellis space of 18 feet by 14 feet. Next to it is a tree of A Bec equally large. This is a splendid Peach as to size, colour, and flavour, but withers, and is a shy cropper. It usually loses quite one-half its flower buds, not in the usual way of dropping off, but they appear to shrivel and never open. Were we planting now we should plant it in a second house. Our next tree is an Elruge Nectarine, which usually bears good crops of fine fruit. We have not tried Lord Napier Nectarine under glass, but have a fine young tree on a wall. While on the subject of early Peaches I would just mention that Mr. Iggulden's remark respecting there being two varieties of Hales' Early is, I fear, only too true. We have on a wall a tree procured from a source where fruit trees are usually kept true to name that ripened a few fruits this year, but they were quite a fortnight later than Pine Apple Nectarine and Red Nectarine Peach growing on the same wall, so that ours cannot be the true variety. I have grown several varieties of the small-fruited early Peaches, but do not think them worth the room under glass. We have a good tree of Early Beatrice on a low south wall that ripened a fine crop of fruit this season. They were ripe the last week in July. In an early Peach house a few miles from here there is a tree of Early Victoria that has ripened fine crops of fair-sized fruit each year for the past eight years to my knowledge. It comes in fully three weeks sooner than Bellegarde in the same house, the latter being at the warmest end of the house too. Had we a vacancy in our early Peach house I should certainly plant a tree of Victoria to come in before Royal George. I believe it was originally sent out by Mr. Rivers of Sawbridgeworth. The tree I allude to came from that source.

In our second house we have four trees of as many varieties—viz., Belle Bauce, Grosse Mignonne, and Goshawk Peaches, and Violette Hâtive Nectarine. The first-named is a very fine Peach and a good cropping variety, its only fault being that it ripens about the same time as Grosse Mignonne, consequently we have not such a long succession of fruits as if we had either Bellegarde or Barrington in its place. Belle Bauce has ripened sixteen dozen fruits for several years in succession, many of them 7 ozs. each. Grosse Mignonne is in my opinion the finest midseason Peach we have, and I have grown it and seen it growing in four different gardens in as many counties and always giving satisfaction. Our own tree here has never produced less than twelve dozen fruits, and frequently more, for the past ten years, many of them half a pound each. Goshawk is growing on the back wall, consequently has not such a good chance as the rest, as all our trellises run parallel with and about 18 inches from the glass all up the roof; still, what few fruits we have had have been good, and we should not hesitate to plant it as a permanent tree had we a vacancy. Violette Hâtive Nectarine is too well known as a good standard sort to require any further remark than that it keeps up its well-known character with us.

In our late house we have two trees of Bellegarde Peach and a Balgowan Nectarine. The Peaches were, I believe, planted as Violette Hâtive and Bellegarde, but I cannot see the slightest difference either in fruit or foliage. They are fine Peaches, both

of them. Balgowan is a good late Nectarine, but were we planting now we would plant Pine Apple instead, as being rather later and larger. A tree of this latter variety on a south wall ripened a few good-sized fruits this year. The colour and flavour were fine. Our surest cropping tree on walls is an old one of Walburton Admirable, which I think a very good late Peach. Late Admirable is a fine-looking Peach, but scarcely ever worth eating either indoors or out, which in my opinion is the most important point in Peaches. Before concluding I wish to draw your readers' attention to a Peach I have already mentioned—viz., Red Nectarine. It is a hardy variety. The fruit is of a fine size and colour and splendid flavour both under glass and outside. It is not included in many catalogues; in fact the only place I have seen it mentioned, and from whence all the trees of it that have come under my notice have been procured, is the fruit catalogue of the Messrs. Veitch, Royal Exotic Nursery, Chelsea, where it is described as a new Syrian variety of great excellence.—H. J. CLAYTON, *Grimston*.

THREE USEFUL PLANTS.

GLADIOLUS COLVILLI ALBUS.

WHERE choice white flowers are in demand during May and June the above should be grown. To have a succession the bulbs should be potted from now until Christmas. The earliest could be grown in pots for the conservatory, and the later ones planted out in the borders in April, where they will soon commence blooming. Place about eight bulbs in a 48-pot, and keep them in a cold frame during the winter. I have never forced them, but when the flower spikes are showing I should think they would force well. It would be worth trying. This Gladiolus should be grown by everyone having a garden, and it is very cheap.

TRITELEIA UNIFLORA.

This is a pretty little bulbous plant. It is generally grown in the border, but it is very useful in pots. Place about twelve bulbs in a 48, and treat similarly to Crocuses, introducing a few pots at a time into an intermediate temperature.

SCHIZOSTYLIS COCCINEA.

This bulbous plant is generally planted out in the open and potted in September; but I find the best plan is after the plants have bloomed to place them in a cold frame until the spring, then turn them out and select the strongest plants, arrange them in 16-size pots about 2 inches apart, and stand them in the open until this time of the year, then place them in a cool house. When the flower spikes appear assist them with liquid manure.—X.

FRUIT-JUDGING AT EDINBURGH.

"THE Judges did award the first prize to the undoubted best twelve bunches" of Grapes "in competition" at the above Show, so writes the winner of the said prize. Now who ever heard a competitor express a doubt of the correctness of a decision that conferred upon him the distinction of being the winner of a first prize? It is, however, somewhat unusual for the person in whose favour a decision is given to be the first to come forward as a defender of it when its correctness is disputed by outsiders. The person most benefited cannot be admitted as an arbitrator in the case. Still, as he has thought proper to compare his own productions with those of his "respected brethren," I may be permitted to say a few words in reply.

Where, as at Edinburgh, a prize is offered for the best twelve bunches of Grapes, six varieties, two bunches of each, Mr. MacIndoe says "in cases like this it requires something more than simply the best varieties ripe and fit for table early in September;" and I would ask him to kindly explain what is the "something more" required. Perhaps the word "best" in this case means largest, and has no reference to variety, ripeness, or finish. If this is the meaning intended, then the sooner it is understood so by exhibitors of Grapes the better. This will simplify matters very much, as it will reduce the number of competitors to the few whose employers prefer as dessert fruit large bunches of coarse ill-flavoured sorts to the more symmetrical smaller bunches of the superior flavoured varieties.

About the twelve dishes of fruit. Mr. MacIndoe admits "that Charlotte Rothschild Pine Apple in the first-prize lot had a few green streaks round some of the pips," the fact, however, being that all the pips from top to bottom had a few green streaks round them. I noticed "the Queen Pine at the other end of the collection," which was, as Mr. MacIndoe describes it, "as perfectly finished as any Pine in the Show."

Mr. MacIndoe particularly refers to the three bunches of Muscat

of Alexandria Grapes as being small in the third-prize collection. True, they were small in bunch as compared with the bunch of Trebbiano in the first-prize lot, but they were of good average size both in bunch and berry for the variety, and they were ripe and fit to eat, whereas if the unripe berries had been removed from the Trebbiano more wool in the way of padding would have been required to make the bunch appear presentable than was employed in the case of the Muscats.

Then as regards the black Grapes in the first and third-prize collections. The latter contained a dish, three bunches, of finely finished Madresfield Court, and the former a dish, one bunch, of partially ripe Gros Guillaume. True, the one bunch of Gros Guillaume was of greater weight than the three bunches of Madresfield Court; but then, as a dish of dessert fruit the latter was much superior to the former. Mr. MacIndoe is mistaken if he supposes I "fancied" that the first-prize lot should have occupied the third place. The fact is, there were only nine dishes of fruit in the first-prize lot ripe enough to include in a first-class dessert, and therefore in my opinion—and I am not alone in this—it was not in the race from the first.—H. B.

THE storm of TUESDAY THE 25TH INSTANT, which was so violent in many parts of the country, was also very destructive in London and the metropolitan district. Suburban florists and market gardeners have sustained much loss by the breakage of glass. Trees have been battered and broken to a serious extent, and Dablias and similar tall plants in gardens have been swept off the ground. A driving rain prevailed, with sleet at times; but no snow fell as in some of the midland and northern counties. The hurricane subsided as suddenly as it commenced, and the evening was perfectly calm. The temperature is much lower, and it will be unwise to delay making everything safe in gardens for the winter. The first frosts, because coming suddenly and unexpectedly, are not unfrequently the most destructive.

— THE annual EXHIBITION OF CHRYSANTHEMUMS IN THE INNER TEMPLE GARDENS will be opened to the public to-day (Thursday), the plants being arranged as they were last year in a glass erection near the Thames Embankment, where there is a very convenient entrance for visitors. The plants are in good condition, healthy and strong, buds being plentiful, and a number of early flowers are fully expanded, so that there is already a display of some interest. A very important feature this year is the number of new varieties, chiefly of the Japanese section, represented in the collection, and some of these appear to possess considerable merit as far as can be judged at present. The majority have been recently sent out by Messrs. J. Veitch & Sons, Chelsea, and were raised by Mr. Salter. Very noticeable is Lord Beaconsfield, with flat florets of a rich bright red colour on the upper surface and yellow bronze below. La Charmeuse, of a fine crimson hue, is also good; L'Île de Plaisir, orange yellow; Reverie, deep red; Curiosity, yellow tipped with bronze; Dr. Macary, rosy tint; Mary Major, white; Rex Rubrorum, deep red; and others are similarly noteworthy, but will be more readily judged when their characters are fully developed. The best of the older varieties are included in the collection, such well-known favourites as Elaine, Mrs. G. Rundle, Empress of India, and Mrs. Dixon being very promising. With fine weather the interest of the display will now increase daily, and in a week to a fortnight's time will probably be at its best.

— A MAIDSTONE correspondent, "F. O. M.," sends us the following:—"In accordance with your request on page 375 of the Journal for records of HEAVIEST PEARS, I inform you that on a tree six years old of Pitmaston Duchess, I brought from Messrs.

Rivers, I picked twenty fruit, the heaviest of which weighed 1 lb. 6 ozs. There was little difference in the rest, but the first six selected as apparently heaviest we found of the weight stated. The fruit is now ripe and of excellent quality for dessert."

— A CORRESPONDENT informs us that "the tenth DURHAM FLORAL AND INDUSTRIAL EXHIBITION was held in the Town Hall and New Market, Durham, on Tuesday and Wednesday, the 17th and 18th of October. The greater part of the Show is devoted to industrial exhibits. The plants and cut flowers were generally inferior to previous years, but the vegetables in all classes were as good as they generally are in the north. The Hon. Sec., Mr. Graham Forster, and his assistant, Mr. Hutchinson, were indefatigable in their exertions in making the Show a success."

— AN experienced Fern-grower states that he has just succeeded in raising some young plants from spores of TRICHOMANES RADICANS, which he believes to be the first time this has been accomplished in cultivation. Prothallia have been previously obtained, and some of these lived for five years, then dying without producing fronds. The present batch is six years old, and the prothallia have only recently produced the characteristic fronds of the species, which are at present very small.

— WE learn from an American contemporary that the Georgia Horticultural Society condemns the practice of "RINGING" VINES as "not legitimate Grape culture," and will decline to take official notice of show bunches at their exhibition made unnaturally large by this process "to the injury of the Vine," and with the effect of "deceiving the public." The practice thus condemned seems to be very general in that State, but British gardeners contrive to produce excellent Grapes without resorting to such proceedings.

— A CORRESPONDENT writes that "at a meeting of the SALE BOTANICAL SOCIETY, held recently under the presidency of Mr. F. J. Broome, some time was spent in discussing the uses of bees in the fructification of plants and changing of colours in flowers, a number of specimens of plants or flowers being shown. It was incidentally mentioned that the single white Dahlia called the Queen, now so much in favour amongst florists, was grown in Bowdon forty years ago."

— GLASS structures in gardens are often profitably employed for mixed crops, but the practice of rearing PEACHES AND SALMON in the same house, as adopted at Culzean Castle and described in another column, is new to us. We have seen Grapes and early chickens grown in the same house and both profitably, but have not before heard of the method of rearing salmon in a Peach house. The practice described is worthy of record, and the system of trial in districts adapted for the increase of salmon in the rivers.

— WE have received few records of FULL CROPS OF APPLES this year, but the following extract from a letter from Lincolnshire shows that all orchards are not destitute of fruit:—"Sturmer Pippin has been the only failure this year, trees of almost all other sorts bearing great crops. Norfolk Bearer, King of the Pippins and some others we have had to prop to prevent the branches from breaking with their load of fruit. The trees, which are old, have each had about 65 gallons of liquid manure from a tank poured over their roots three or four times a year, and this, with thinning out the weak and dying wood, has greatly increased the quantity of fruit and improved the quality. The soil is strong and shallow, resting on limestone, and the position is dry."

— BOTANISTS will learn with satisfaction that the Cavaliere d'Amico has succeeded, not without considerable difficulty, in acclimatising a number of foreign plants in Sicily. They are being exhibited at the present time at the Agricultural Exhibition of Messina, and excite a great deal of interest among the

spectators. Amongst them are the Tea plant, *Persea gratissima*, *Cinchona succirubra*, *Indigofera tinctoria*, and *Myrica cerifera*. Cav. d'Amico intends to establish a Tea plantation of some extent not far from Messina, and it is hoped that Sicilian tea may in a few years become an important article of commerce.—(*Nature*.)

— FLOWER BEDS AND LOBSTER SALAD are not linked together in the ordinary style of describing the London parks, but there are writers in London equal to all emergencies. One of them remarks in a daily paper:—

"Few improvements have more completely justified their name than Battersea Park. With a lake of its own and the broad river flowing in its front, with picturesque Chelsea opposite, it is, now that the trees have grown, one of the prettiest places in London. Moreover, it has the precious adjunct of a subtropical garden full of forms strange and pleasing to the eye, hardy Palms and Aloes, and queer-looking plants not unlike a trophy of green bayonets, and suggesting anything but the idea of repose. Very little space is lost in the ornamental and subtropical garden. Persons whose taste tends in that direction cannot fail to admire the curious shapes and combinations of colour to which the bedding-out plants lend themselves. Varieties of Stonecrop and Houseleek make pretty enough designs in the opinion of many. They have at least the merit of being appetising, if one may judge by the remarks of a thoughtful gastronome, who compares some of the said beds to lobster salad and others to the rich combination of colour and symmetry found only in a dressed crab."

— A PLANT of BARBACENIA PURPUREA is now flowering in the Begonia house at Kew, and its beauty well merits all that was said in its praise by our correspondent "D." in the issue of this Journal, March 16th of the present year, page 219, when also figures were given of *B. purpurea* and *B. Rogieri*. It was then remarked that the former species is not in cultivation at the present time; it will, therefore, be satisfactory to "D." to know that it is included in the Kew collection, where so many beautiful old plants have been preserved. The flowers are of moderate size and of the richest velvety violet purple colour imaginable, the leaves being narrow, long, and drooping, something in the way of *Pandanus graminifolius*. The woodcut mentioned above well portrays the principal characters.

— A SUCCESSFUL cultivator and exhibitor of Grapes has conveyed to us his impressions of the VINES AT LONGLEAT. "I have seen," he says, "the best Grapes that have been exhibited in and near London for several years, but never saw Muscats with such large berries and so well finished as those in the vinery in question, but I have seen larger bunches; the crop, however, is splendid—so regular and so fine. Mrs. Pince's Muscat far exceeds anything that has ever come under my notice, and I doubt if such bunches have ever been produced. They range from 3 lbs. to 5 lbs. in weight, full and symmetrical, while the berries are coloured quite through the bunches as well as it is possible for Grapes to be. The Alicantes are superbly finished, but the Black Hamburg were all cut. The effects of the manure which Mr. Taylor has recommended are most marked, and he is fully justified in what he has stated relative to its superiority, the Grapes where the border was dressed with it being decidedly finer than those produced with the aid of a different fertiliser. I shall hope to visit Longleat again next year, and if the journey were a hundred miles further than it is I should not consider it a long one to see such a remarkable example of Grape culture, apart from the excellent practice that is visible in other departments of the gardens."

— A MEETING of the ROYAL CALEDONIAN HORTICULTURAL SOCIETY was held last Friday in Edinburgh, for the purpose of hearing a financial report by Mr. P. Neill Fraser, the Treasurer, in regard to the recent International Show held under the auspices of the Society. Mr. Syme presided. It appeared from the statement in question that the amount drawn at the gates during the two days of the Show was £1106 11s., a sum which represented 26,250 persons who passed the gates. This number, however, did not include ticket-holders, who, it was estimated, would make up

the total numbers of visitors to 30,760. A sum of £393 16s. had been obtained in subscriptions, which would make up the total receipts in connection with the Show to £1500 7s. The expenses, including the rent of the Waverley Market, Judges' expenses, cost of musical band, &c., amounted to £551 7s. 10d., which, added to £800 1s. 6d. that had already been paid in prizes, brought up the expenditure to £1351 9s. 4d. A comparative statement was submitted, showing that the total income of the International Show in 1875 was £1029, and that there was a loss on that occasion of £89; whereas this year, after paying all expenses, they expected that there would be a balance in favour of the Society of about £70. The probable surplus in the Society's finances at the end of the year would be £350, which would make the total amount at the credit of the Society about £1000. The statement was approved of, and a vote of thanks accorded to Mr. Fraser. The meeting then proceeded to vote various sums to exhibitors at the Show. A vote of thanks and an honorarium of 30 guineas were granted to Mr. Young, Assistant Secretary, whose exertions were stated to have contributed in no small degree to the success of the affair. Votes of thanks were also passed to the Lord Provost and Magistrates for opening the Show and otherwise countenancing it, and to Mr. Stewart, the Secretary, for his services.

— A CORRESPONDENT sends us the following NOTES ON DAHLIAS:—"At the Uplands, near Liverpool, all the new varieties that appear are tried, and the gardens under Mr. W. Woodfield's charge are brilliant with these fine autumn flowers. White Bedder is grand for bedding, the flowers being of the purest white, and in growth does not exceed 2 feet. Hender's Double Floret, or Hose-in-hose Dahlia, is not a very striking variety. Its greatest defect, probably, is its yellowish green centre, which shows very prominently, and the lower florets are gone before the centre expands. D. Juarezii should be grown in every garden. It is rather shy-flowering, but its large scarlet blooms have a very striking appearance. Glare of the Garden, or Fire King, is a gem, and too much cannot be said in its favour, and when well known will undoubtedly be grown in every garden where Dahlias are appreciated. The formation of the flower is Cactus-like in appearance, and we might safely term it a miniature Juarezii. Its flowers are brilliant scarlet, and are produced in abundance; in fact it is one of the most floriferous Dahlias I have yet seen, and for cutting purposes its flowers are unique. This variety massed in quantity in any suitable position would from its compact habit of growth and free disposition to flower produce a grand and imposing effect."

— THE small DOUBLE POMPON DAHLIAS are thus alluded to:—"White Aster is charming, and its pure white flowers of a suitable size for cutting for church or other decoration command for it a foremost place. The following Pompons are also good, distinct, and useful for supplying cut flowers. Triomphe, orange scarlet; German Favourite, white ground tipped with carmine; Pure Love, lilac; Northern Light, red; Osiris, lilac tipped with white; Little Nigger, deep maroon; Little Dear, and Nemesis, maroon crimson, and when tipped with white very beautiful. This marking does not appear constant, and it is only occasionally that properly coloured flowers are produced. However beautiful these forms are, they cannot be compared in my estimation with Glare of the Garden."

— OUR correspondent next refers to SINGLE DAHLIAS:—"Paragon is a lovely variety, but early in the season does not produce its flowers freely with that beautiful shade of purple round the edge of the petals. Towards the close of the season they are produced in large numbers, all displaying their true character. Some seedlings from the above variety Mr. Woodfield pointed out which were very effective, varying from orange scarlet, maroon, to nearly black; while one plant differs only in

having those rich purple stripes down the centre instead of round the edge of the petals as in its parent. All are of a similar habit of growth, and are as free-flowering. Avalanche is one of the single whites, and carries its flowers more erect than White Queen or Alba. Most of the named single forms were flowering freely, as well as many seedling plants, some of the seedling orange scarlets being gorgeous, having flowers of an enormous size. One seedling that flowered for the first time last year, which was noted in these pages, is very striking and distinct from any I have seen growing or exhibited. The ground of the flower is of a primrose colour, which forms a ring round the centre and again towards the outer portion of the petals, while the middle ring is heavily shaded with orange scarlet, the edge of the petals being lightly shaded with the same colour. Its habit of growth is similar to Paragon, and it is free-flowering. Where these plants are arranged in borders in rows this seedling and Paragon would associate well together planted alternately."

— A TELEGRAM to a daily contemporary has the following respecting the WINE-GROWERS' CONGRESS IN SARAGOSSA:—

"The Congress that has been sitting in Saragossa to discuss the best means of combating the phylloxera has been most interesting. Papers have been read which show that the insect has caused extensive ravages in the north of Portugal and the provinces of Estramadura, Malaga, and Catalonia in Spain, despite the severe legislation which enforces the isolation of infested vineyards, the destruction of tainted plants, and other precautions. The opinion of the savants and wine-growers assembled in Saragossa was divided on the question of American wines and on the remedies for the phylloxera. During the Congress some curious statistics were read, which show the vast increase in the culture of Vines that produce the common red and white less fortified wine, on account of the increasing demand for these qualities in France, the north of Europe, South America, and even England. I find that France, since the phylloxera has ravaged half of her vineyards, has imported since 1877 from 87,000,000 to 109,000,000 gallons of Spanish wines, chiefly for her own home consumption. Considering that she only exports to England a little over seven million gallons, and to the rest of Europe and America hardly three times that quantity, what becomes of the argument of Spanish diplomacy, that Spanish wines are mainly imported into France to be re-exported to England, owing to our alcoholic scale of duties? In reality France like England now-a-days imports steadily increasing quantities of light, natural, and less alcoholised wines, red and white, and an annually decreasing quantity of heavier and highly alcoholised sherry and strong wines."

— A CORRESPONDENT of "Vick's Illustrated Magazine" has the following respecting the WHITE PARTRIDGE BERRY (MITCHELLA ALBA), a North American plant allied to the Cinchonas.

"In one of my rambles in the Pine woods in our Canadian wilderness I found a wide plot of this charming evergreen plant, then covered with its white, waxen, double-eyed berries, which shone conspicuously among its darkly-shaded foliage. The fruit and leaves were larger than those of the sister plant, *Mitchella repens*, the creeping Partridge Berry of the Indian squaws, with its brilliant red fruit and sweet starry blossoms. On turning to Dr. Asa Gray's manual of the botany of the Northern United States I found no corresponding description of this, to me, new species. The only plant with the name Creeping Snowberry is *Chiogenes hispidula*, but this is not our White Partridge Berry. I am well acquainted with Gray's plant, Creeping Snowberry, and very pretty it is, forming mats of tiny evergreen leaves and greenish-white flowers, succeeded by small, round, white berries. It is found in black peaty soil in Cedar swamps and boggy shady ground, running over decayed wood and wet mosses. I do not think the fruit of this pretty graceful little creeper is poisonous, but it is flavourless and insipid. It would make a pretty plant for hanging baskets or pots."

SOME USES OF WILLOWS.—An American travelling in England is struck by the frequent occurrence in the landscape of the pollard Willows, the low rounded heads of which in some localities mark the watercourses for long distances. Willows thus treated—for the pollard is not, as sometimes supposed, a distinct kind of Willow—may be occasionally seen in some of our older States, but less frequently than formerly. The White Willow excitement of some twenty years ago was unfortunate, as many farmers, finding that the tree did not bear out the extravagant claims of speculators, became so disgusted with it that they overlooked its real merits. While the White Willow hedge will not be, as claimed, "the universal fence," the White and other Willows may be made most useful, especially to those who live in prairie regions. The question frequently comes

from the West and elsewhere as to the best method of preventing streams from encroaching upon their banks. Lining the banks with a row of Willows is a very ancient practice, and probably there is no better method. Their roots, especially in wet ground, form dense masses of fine fibres, well suited to retain the soil in place. The ease with which such a barrier is established is greatly in its favour. Cuttings of almost any size readily take root. These may be a foot or two long and as thick as one's finger, or they may be large enough for fence posts, according to the readiness with which they can be procured. While the roots are useful for preserving the bank, the tops may be turned to good account to afford fuel or poles for various purposes upon the farm. Another use for Willows is as a wind-break, to shelter the house and farm buildings, as well as to protect orchards and young forest trees from the prevailing winds. When planted for this purpose, as well as along the streams, the tops are made most useful by occasional pollarding. In growing Willows for basket-making the stem reaches barely above the ground, and the shoots are cut every year.—(*American Agriculturist*.)

TWO GOOD ORCHIDS.

Zygopetalum Mackayi.—To gardeners who require a useful plant this Orchid can be freely recommended as one of the best. Ladies are fond of its perfume, and the plant has the very great merit of being easy to grow. Ours are grown amongst Cattleyas, but it succeeds if managed like an ordinary cool stove plant. It is not particular as to compost, as we have it growing in peat, loam, and a mixture of both. Breaks on plants in all three kinds of compost or soils are producing a couple of spikes each. It is a free-rooting plant and requires plenty of root-space. A strong plant with one or two breaks should have a 9 or 10-inch pot. When the pots are too small for the plants one spike from each break is the rule, and very seldom more than one break is produced from a lead, while under liberal treatment more spikes and breaks are common.

Cymbidium Mastersii.—I had some dried-up pieces of this species in 1879, just as they had arrived from India, without roots and with scarcely any foliage. They were at once placed in small pots in a compost of half sand, half soil, being arranged in an ordinary stove. As the pots became filled with roots they were repotted into others 4 inches in diameter in a turfy sandy compost. Some were kept in a stove temperature, others in a cooler compartment in which *Odontoglossums* of the *O. grande* type, Cattleyas, &c., are grown. The cooler system has produced the finest plants. The strongest are now in 9-inch pots, and are producing two and three spikes of their very pretty white flowers. In the larger pots the compost is one consisting chiefly of turf with peat. The roots are very fleshy, and I think that abundant root room is better than keeping the plant too much confined.—B.

THE MANURIAL VALUE OF PHOSPHATE OF MAGNESIA.

It would appear, then, that there is every reason to suppose, judging by their respective solubilities in water (I take Voelcker's determinations, as they appear to be more complete and systematic than any others I am acquainted with), that the following would be the order of the manurial activity of the undermentioned phosphatic substances. Peruvian guano and bone dust have, associated with them, organic matter or salts of ammonia, which, as has been shown, materially increases the solubility of phosphate of lime.

1, Phosphate of lime, as it exists in superphosphates.....	perfectly soluble.
2, Precipitated phosphate of lime	soluble to the extent of 5.56 gr. per gal.
3, Phosphate of lime in Peruvian guano " " "	2.52 "
4, Bone dust, mean of the two extremes " " "	1.59 "
5, Coprolites	0.64 "
6, Estremadura phosphorite.....	0.10 "

The admixture of organic matter or salts of ammonia, whilst increasing the solubility of Nos. 2, 5, and 6, would probably have a decreasing effect from No. 2 (in which case it is fourfold) downwards.

In the cases of some of the field trials hereafter alluded to the term "retrograde" or "reduced phosphate" is used. It is perhaps therefore necessary to explain that this condition is brought about by the manure in which it occurs losing some of the soluble phosphate which it contained when first manufactured, and which afterwards appears, owing to the tendency of the soluble phosphate to revert to its original condition, as precipitated phosphate, with which it is assumed to have an equal value. The solubility of such reduced phosphate may therefore be taken to be 5.56 grains per gallon (page 361), and with water containing a per-cent. of sal ammoniac, 21.7 grains per gallon. This condition of phosphoric acid was alluded to in the remarks quoted from Sibson (page 317) when speaking of the unsatisfactory system of

valuation followed by many of his brother chemists. I should here, too, allude to another form of phosphoric acid which is sometimes met with—viz., the bibasic phosphate, also an unstable compound, with a strong inclination, if I may so express it, to become ordinary precipitated or tribasic phosphate of lime. Its solubility is, according to Malaguti, $\frac{1}{1000000}$, or 0.07 grain in a gallon; but although so insoluble in water it is soluble to a large extent in aqueous solutions of various salts, of many organic matters, and especially of sal ammoniac. This is of interest, as Otto remarks, since it is probable that this salt is left in the soil by the decay of vegetables. It is also dissolved by chloride of calcium.

Though less soluble in water than the tribasic phosphate of lime, Liebig found it much more soluble than this salt in weak solutions of sulphate of ammonia, common salt, and nitrate of soda; but, perhaps from its tendency to revert to the tribasic phosphate the difference between them need not longer here detain us.

I have now to show that practical field trials bear out the deductions which in this and foregoing letters have been drawn from laboratory experiments and theoretical considerations; and here we have such abundance of materials that it will be best, in order to avoid tediousness, to make a selection of some definite portion of them. The course which appears to be freest from objection will be to take the results of field practice recorded in the abstracts of papers from all countries given in the Journal of the Chemical Society during the last twelve months; but so far as the arguments which have been advanced are concerned, I might equally well have taken any one of the few preceding years during which such experiments have been extensively made.

1. No. ccxxviii., page 1072. At the experimental station of Kiel trials were made with Oats manured with precipitated calcium phosphate, Estremadura superphosphate, steamed bones, and dissolved bones. The superphosphate gave a heavier crop both of corn and straw than the precipitated phosphate, and dissolved bones than the steamed bones. At Renow-Dombrowo in Posen experiments were made with different manures on Potatoes. The soil was about 12 cm. deep, resting on a sandy subsoil, with large stones and marly loam underneath. Part of the manure was ploughed in with a subsoil plough, and the rest applied as top-dressing.

2. The relative yield was as follows: the plots contained each one morgen:—

	Potatoes.
No. 1.—2 centners Chili saltpetre	45 centners.
" 2.—1 " " and 2 centners nitro- phosphate	46 "
" 3.—1 " " and 2 centners bone- black superphosphate	48 "
" 4.—1 " " and 2 centners retro- graded phosphate..	50 "
" 5.—Unmanured deeply cultivated.....	32 "
" 6.—" cultivated in ordinary way	24 "

The result of the retrograded phosphate is, it is observed, remarkable.

3. By M. Maercker, p. 1073. Experiments were tried on Barley, Oats, Peas, Beans, Potatoes, and Beetroot. On the real Barley soils precipitated phosphate appeared to be of equal value with superphosphate, whilst on thin sandy soils the latter appeared to possess a slight advantage. In the case of Oats the results were reversed, as the precipitated phosphate was somewhat superior to superphosphate on sandy soils, and almost equal in value on loam. The experiments on Peas and Beans were so affected by bad weather as to be of no value. The Potatoes were also grown under very unfavourable conditions, but eleven experiments were completed; in these the superiority of precipitated phosphate in the lighter soils and of superphosphate in the heavier was established. In the case of Beetroot no special results were obtained, each form of phosphate having similar effects. On the whole, therefore, precipitated calcium phosphate appeared to give as good results as soluble phosphate, especially in lighter soils; this may be partially owing to the fine state of division of the former, by means of which it could be intimately mixed with the soil.

4. No. ccxxix., p. 1167. By Krockner and H. Grahl. The phosphates used were in the form of retrograde, precipitated, and soluble phosphoric acid and bone meal. They were employed in the proportion of 50 kilos phosphoric acid per hectare. The land consisted of a heavy clay soil well drained, and was sown with Oats, Beetroot, and Potatoes; the phosphates were applied both by themselves and mixed with ammonium sulphate to the extent of 200 kilos per hectare. Where ammonium sulphate was mixed with the manure a considerable increase was observed, especially in the case of the precipitated phosphate and bone meal. Similar differences were observed in the Beet, but not to so large an

extent, and here the soluble phosphate produced larger yields than the other kinds when given by itself or in conjunction with ammonium sulphate, although it proved inferior to bone meal in the first case. The bone meal contained 4 per cent. of nitrogen.

These abstracts of field trials are too numerous to be continued in this letter, and having brought them down to the end of the year 1881 it will be better to defer their completion until next week; but the reader will admit that, so far, the conclusions which I have drawn from theoretical considerations and laboratory experiments are by no means at variance with practical results in the field.—INQUIRER.

CULZEAN CASTLE.

CULZEAN CASTLE in South Ayrshire, the principal residence of the Marquis of Ailsa, is a place possessing great natural attractions and much that is interesting to lovers of horticulture. The Kennedys have long been the dominant family in Carrick, the

southern division of the county of Ayr; and along the stretch of coast extending from the river Doon to the mouth of Loch Ryan, a distance of over thirty miles, are still to be seen ruins of several old castles overhanging the sea, which in olden times were the strongholds of different branches of that family. The Marquis of Ailsa is the head of the Kennedys, and his splendid castle perched above the sea continues the traditional family connection with that rocky coast. The possessors of the title have not in recent times figured prominently in public affairs. They have resided chiefly at home, exercising the prerogative of chieftainship over their extensive estates and amongst their numerous tenantry. The present Marquis is best known as an enthusiastic yachtsman. Not content with the mere handling of craft supplied to him by famous yacht-builders, he has given himself to the study of the lines and proportions of yachts, so as to discover those most conducive to fast sailing; and in order to practically work out his ideas he has erected a yacht-building shop furnished with steam machinery in the vicinity of the Castle, and employs a number of

Fig. 63.—CULZEAN CASTLE.

skilled artificers. The drawings are all furnished by himself, and he spends a portion of each day in the shop when residing at the Castle. A 5-tonner turned out in the shop, named the *Cocker*, has this season beat everything she encountered on the Clyde. Another matter in which the Marquis takes great interest is the artificial breeding of salmon and trout, for which he has fitted up very ingenious apparatus in his grounds. His amiable Marchioness devotes herself to evangelistic and temperance work and to the care of her young family.

We took the opportunity during a recent visit to the north to pay a visit to Culzean Castle. Taking the train to Maybole, an ancient town about nine miles south of Ayr, a drive about three miles along a pleasant road skirted by plantations brought us to the entrance gate, from which an approach of about a mile and a half through richly wooded policies conducts to the Castle. We had not proceeded far till we reached a point where over the sloping foliage we caught a view of the sea away beneath us, its broad expanse, bounded on the opposite side by the island of Arran, fourteen or fifteen miles off, while at a particular point we descried above the tops of the trees, in which it appeared embowered, the upper turrets of the Castle whither we were bound. Many fine prospects were opened up as we gradually descended, and the sea breeze was very refreshing.

The site of the Castle has been finely chosen on a rocky emi-

nence in the centre of a small bay formed by two jutting-out headlands. It is a spacious building flanked by turrets and with battlemented parapets, its northern side resting on the edge of the rock, at the foot of which 100 feet sheer down the sea dashes itself when the tide is full. The outlook from the Castle is magnificent. It catches the island of Arran at an angle in which its noble features are brought into grand relief, while beyond is distinctly seen the Mull of Cantyre, and still further southward on ordinary clear days the north of Ireland. The great pile of Ailsa Craig standing solitary in the expanse of ocean is also seen with singular distinctness; while a continually changing interest is imparted to this noble panorama by the passing steamers and sailing vessels going to and from the busy ports on the Clyde. The natural advantages of the site have been well utilised by those who designed the place; indeed, one cannot fail to be struck with the evidences which exist of the care which successive proprietors must have bestowed by planting, and otherwise to make the artistic belongings of the place bear appropriate relation to its natural amenities.

From the rocky eminence on which the Castle stands the ground tends downwards all round. On the eastern side the crag terminates somewhat abruptly, and an easy access is thus had by a road to the shore beneath. On its western side, and separated from the Castle by a broad sloping lawn, is a battery of small

cannon overlooking the sea with tall flagstaff. One of the guns, fired every morning, gives the correct time as it flashes along a special telegraph wire connecting the Castle with the telegraph office at Maybole. On the south or landward side the ground descends from the wide quadrangle in front of the building by two terraces parallel to the Castle. These terraces are about 150 yards in length, with walls of about 12 and 14 feet in height respectively, the battlemented parapets at the top forming the boundary of the level above. These walls are covered with a variety of choice shrubs and climbers, while the borders at the foot (9 feet wide) are filled with a rich variety of bedding plants. The gravel walks are 12 feet wide, and access from one terrace to the other is provided by flights of steps arranged in keeping with the architectural plan. From the borders along the lower terrace stretches a trimly kept lawn, in the centre of which is a fountain in whose ornamental basin are multitudes of trout disporting themselves.

At the extreme end of the intermediate terrace stands what is called the higher conservatory, the framework of which is of stone rising to about 20 feet in height, of a light and graceful style of masonry in keeping with the architecture of the Castle. We learned from Mr. Murray, his lordship's experienced gardener, that this style of erection was not favourable to the growth of plants. It was filled with large Camellias, Azaleas, and a general collection of greenhouse plants. Some of the Camellias were from 14 to 18 feet high and well set with flower buds. The roof was covered with a good selection of climbing plants, and the stone columns outside were covered with Roses and *Tropæolum speciosum*, the latter doing remarkably well, and covered with seed-like small blue berries. In the lawn in front of the conservatory are some well-arranged flower beds and a good variety of flowering shrubs. Hydrangeas, Fuchsias, and Rhododendrons grow well everywhere about the grounds. A short footpath from there conducts us to the high conservatory, which is filled with a good selection of greenhouse plants in good condition; and in front of this is a neatly laid-out geometrical flower garden, enclosed on the west side by a Laurel hedge, and on the south by large Rhododendrons.

On leaving this we enter the main road which connects the Castle with the kitchen and other gardens. It is a magnificent avenue about 400 yards in length, bounded on either side by rows of Silver Firs, which surpass anything of the kind we have ever seen. As we pass along we notice in an adjoining park a large American ostrich, an emu, a herd of buffaloes, and a collection of Belgian goats, which testify, as do the herds of deer observable elsewhere, to the Marquis's taste for natural history, while the numerous breeding boxes of pheasants show that his lordship does not fail to provide woodland sports for himself and his friends. At the end of this splendid avenue we have referred to stands the entrance to the gardens, which is formed by an arched gateway, near to which is the gardener's house, a commodious dwelling two storeys high.

The garden grounds cover an area in all of 10 or 12 acres. The kitchen garden within the walls contains about 4 acres, and there is nearly an equal extent of cropping ground outside the walls. The flower garden is also of about 3 or 4 acres, and is bounded on one side by a long range of glass houses. The range of Peach houses is 132 feet long by 10 feet wide. The trees are planted in front and trained over the roof at a proper distance from the glass, and portions of the back wall are covered with Roses and Heliotropiums. The fruit had been mostly gathered at the time of our visit; the trees were clean and healthy, and showed signs of high cultivation. We were so much occupied with what is to be seen here that we neglected to note the different varieties grown. This range is utilised in an ingenious way in connection with the artificial breeding of salmon. Throughout its length are placed in direct line a series of oblong boxes covered with lids, rising in successive levels, so that a stream of water entering at the upper level falls successively from level to level until it escapes at the bottom. These boxes are filled with fine gravel, and many ingenious contrivances have been resorted to, to ensure a natural filtration, and that constant movement in the water and disturbances of its surface which observation has shown to be necessary for the successful hatching of ova. The water is brought in pipes from a reservoir in the grounds. The Marquis was guided in a great measure by the advice of the late Frank Buckland, who took a great interest in his experiments. At the proper season 300,000 salmon ova are introduced into the boxes, equally distributed amongst them. For a time the young fish were kept in ponds for a year after they were hatched; but latterly they have been taken at six weeks after hatching, in large cans specially made for the purpose, to the river Doon, some miles distant, and set free there to shift for themselves. There is evidence that the river is better

stocked with salmon since these experiments commenced. In a portion of the grounds about half a mile from the gardens are a series of ponds specially designed for the breeding of Lochleven and other trout. From these ponds the young trout are taken to the Marquis's lochs in the highland districts of Ayrshire, which are known to yield excellent fishing. All the operations in connection with the fish-breeding are under the charge of Mr. Murray.

Adjoining the Peach houses is a range of six vineries, 218 feet by 14 feet. The first is planted with Gros Colman and Muscat of Alexandria, varieties that do remarkably well when planted together in the same house. The second division is planted with Foster's Seedling, Golden Queen, Black Hamburg, and Raisin de Calabre; the third with Muscats and Gros Colman; and the fourth entirely with Lady Downe's Seedling. The fifth division is planted with a mixture of Foster's Seedling, Buckland Sweetwater, and Madresfield Court; and the sixth and last with Lady Downe's, Alnwick Seedling, and Black Alicante. The whole of the Vines looked clean and healthy. The late varieties were bearing good crops of finely finished fruit, both bunches and berries bearing evidence of great care and attention having been paid to them throughout all the stages of their growth. Mr. Murray is an advanced Grape-grower, and does not believe in keeping the Vine borders dry at any time. He informed us that at one time the Vines here were very much infested with mealy bug, but by dressing them after pruning with a mixture of coal tar and clay worked up to the consistence of cream, and put on with a painter's brush, he had got them entirely eradicated from the vineries without the slightest injury to the Vines. The coal tar recipe is by no means new; still we had our doubts about it, like many others, but after the assuring testimony of Mr. Murray we will have no hesitation in using it in future.

The Pine stove is 40 feet by 16 feet, and contains a healthy stock of fruiting plants. The varieties consist chiefly of Queens, Prince Albert, C. Rothschild, and Smooth Cayenne. Many of the Cayennes were swelling off large fruit that would weigh when ripe from 7 lbs. to 8 lbs. each. The succession Pine pit is the same length as the stove, but a little narrower. The succession plants looked strong and healthy, and free from all insect pests. The remaining houses consist of a plant stove 32 by 23 feet, and a greenhouse 36 by 16 feet. Each department—stove and greenhouse—are well represented with fine specimen plants.

Conspicuous in the flower garden, in front of the houses described, is a large Rhododendron ponticum, 56 yards in circumference, towering up at a regular angle from the edge of the grass to a height of from 28 to 30 feet, and in the best of health. It is the largest plant of the kind we have seen, and we question if it has its equal for size in the country. In its style of growth and shape it resembles Ailsa Craig. The likeness is so great that it has been suggested by some that by a little manipulation it could be made to form an almost perfect model of that picturesque rock in the sea. We found the kitchen garden highly cropped, and everything in it looked neat and orderly. The same remarks apply to the slip outside the garden walls, where all the taller varieties of vegetables are grown. Small fruits were plentiful and good, but Apples, Pears, Plums, and, in fact, all tree fruits, were a complete failure, the same as in most places in the country this year.

One other feature of the place remains to be noticed—viz., a large poultry pond, presenting a very extensive water surface peculiarly hemmed in with wooded banks, save on one side, where a long grassy slope affords recreation and feeding ground for an enormous collection of waterfowl. This collection embraces specimens of nearly every tame variety, from the smallest ducks to the splendid black Australian swan which, reversing the natural order of things, appear to lord it over their white native brethren. At the far side of the pond flocks of wild duck are to be seen skimming along together, but ready to take wing at the first scent of danger. A neat poultry house has been built on a small islet close to the shore of the lake. At the summit of the grassy stretch where the poultry of all sizes are basking in the sun stands an aviary in the form of a pagoda, in the various divisions of which are specimens of gold and silver pheasants, pigeons of fancy varieties, "gleds" or kites, and in one compartment a fine specimen of the hunting hawk. From the pagoda a short avenue through the trees conducts to a Heather-clad headland rising sheer up from the sea, from which a magnificent view can be obtained of the Channel, Ailsa Craig, and the far-stretching southern coast of Ayrshire. Making a circuit of the lake on our way back to the gardens we notice a party of Lord Ailsa's boat-builders testing the sailing qualities of a new model of a yacht, which, with a great expanse of white sail, flew across the water at a rate that left the men in the row boat far behind.

As we drove back through the wooded policies, and cast our eyes over the magnificent panorama in the quiet light of evening,

and recalled the many interesting things we had witnessed during our inspection, we confessed to ourselves that we had seldom seen a more beautiful or a better kept place.—A. PETTIGREW, *Cardiff*.

THE PARSLEY-LEAVED BRAMBLE.

THE above, which is, I am afraid, neither known nor grown in the majority of English fruit gardens, is nevertheless one of the most valuable and productive of late summer and autumn fruits, and is well worthy of notice in the *Journal of Horticulture*. A single row here 22 yards long, and trained to tall stakes after the manner of Raspberries, has been producing a constant supply of large and well-ripened fruits for six weeks now past, and looks as though it will continue to do so for another month should the weather continue mild. Up to the present time since the first gathering commenced an aggregate of more than two bushels of good fruit have been obtained, and employed by our cook in a variety of ways for pastry, also for making jam, jellies, cheesc, syrup, &c., till she tells me she appears to have an inexhaustible supply. It appears to be especially adapted for training over light wire arches or trellises spanning the kitchen garden walks, where it would be both useful and ornamental. Many of the fruiting rods with us are 10 feet long, and furnished with long racemes of fruit from the base to the summit. I do not know any other fruit-bearing plant or shrub which will produce an equally large quantity and long succession of fruit for the space occupied. Its cultural requirements are very simple, the main point being attention to training and tying out the young growths occasionally during the summer, and pruning after fruiting in the autumn, when a few of the oldest fruiting rods are cut away to make room for young growths, and those left have their laterals cut back to one or two eyes from the base, after which they are again trained to their supports and a liberal mulching of manure given to their roots.—W. K. W., *Oakbrook, Sheffield*.

EARLY WHITE GRAPES.

BUCKLAND SWEETWATER, though so extensively grown, I consider a comparatively worthless Grape. The reason why it is so often seen is because there are so few good white Grapes that ripen early under the same treatment as that best of all early Grapes the Black Hamburg. The variety in question answers this purpose very well, but as regards quality it is only second-rate. When its flavour is most perfect the fruit is only just beginning to colour, the quality even then being no better than Sweetwater, as its name implies; and at that stage would at an exhibition, on the ground of colour alone, be discarded by all good judges, whereas when fully ripe the colour is of an objectionable brown tint and the flavour insipid, while in many places the Vine is a very uncertain bearer.

Then the question arises, What other early white variety can we substitute as a companion to the Black Hamburg? The old Dutch Sweetwater, though small in both bunch and berry, is of far better quality than the above, and that is a property which should be sought for in preference to size; moreover, it is a sure cropper.

Ascot Citronelle is another superb early white Grape, having a rich aromatic flavour, and is a profuse bearer; but this also will probably be objected to by some on the ground of size, both bunch and berry being small, but in my opinion it is much preferable to the first-named variety.

Foster's Seedling is also an excellent early variety, and perhaps more largely grown than any other of the same class. The bunches are large, evenly shouldered, having medium-sized berries, and it has a delicious flavour.

Perhaps ere long someone will be the fortunate raiser of a Grape, the size of Duke of Buccleuch, but free from its defects as regards spotting and bad keeping. Whoever does this will richly deserve, not only the thanks of gardeners, but the large financial profit which he will be sure to reap.—W. L. H.

COLUMBIAN QUININE.—During the last two or three years a bark containing quinine and quinidine has been imported into this country from Columbia in such enormous quantities as to equal, or even sometimes exceed, the whole of the importations of Cinchona bark from all other countries. The botanical source of this bark, which is known in commerce under the name of Cuprea Cinchona on account of its peculiar coppery tint, has hitherto been a mystery. M. Triana, the well-known quinologist, has recently succeeded in tracing it out, and has stated in the *Pharmaceutical Journal* for April 22nd, that it is derived in great measure from two species of the nearly allied genus *Remijia*, none of the members of which were previously known to contain quinine. Several species of *Remijia* have leaves resembling those of the true Cinchonas, and of these M. Triana has determined

that *R. Purdieana*, Wedd., and *R. pedunculata*, Karsten, certainly yield Cuprea bark, the former being the species which contains the alkaloid Cinchonamine, recently discovered by M. Arnaud. It appears probable that other species also yield the Cuprea Cinchona of commerce; but definite information on this point is still wanting. The value of this bark has led, according to M. Triana, to great devastation of the forests in which the trees grow, and has produced a financial stagnation, business being neglected in order to follow the more profitable occupation of collecting the bark. Fortunately seeds of the tree have been received, and are now in cultivation at Malvern House, Sydenham. The tree is likely to prove valuable for cultivation in countries where malarial fever abounds, since it grows at an elevation of 200-1000 metres above the sea, at which even red Cinchona bark will not flourish.—(*Nature*.)

ROSE RÈVE D'OR.

IN looking through your interesting Tea Rose election I am surprised to see no mention made of a Rose which I consider should certainly appear in the first dozen if not in the first six—viz., Rêve d'Or. Is it because some growers say it is difficult to flower? All I can say is, if any grower will plant it in a cool house, and let it ramble over the roof inside, he will be amply repaid by having some splendid buds of great substance and in colour somewhat deeper than Safrano. As the buds expand they are very beautiful, although when full blown the Rose is thin. In the month of April I gathered hundreds from one plant budded on a Briar.—M. F. WOODLEY.

VEGETABLE SHOW AT AYLESBURY. NATIVE GUANO.

PRESUMABLY with the object of bringing before the public the merits of what is known as the A B C process of dealing with the sewage of populous districts and turning it to useful purposes, the Native Guano Company of the above town held an exhibition of farm and garden produce last Thursday. The preparations were on the most liberal scale, as not only were prizes to the amount of about £150 provided by the Company, but silver cups were offered by Messrs. Carter & Co. of High Holborn, and Sutton & Sons of Reading, for produce grown with the aid of the manure in question. Nor was this all. A special train of saloon carriages was chartered, and left Paddington heavily freighted with gentlemen, including the Right Hon. the Lord Mayor of London, who were interested in the Aylesbury process of sewerage-disposal, and its results as displayed in the marquee at the works. A bountiful luncheon was also provided for the invited guests, and these, to the number of about four hundred, sat down after having critically examined the A B C process and the splendid display of vegetables placed in competition for the prizes. I have no intention of giving a list of the awards, as these would be of limited interest, but may briefly describe the character of the Show and note the method by which the native guano is obtained.

The A B C, or precipitating process of treating the refuse matter of towns, has by name become familiar to most persons; but while the particular alphabetical designation is well understood by many readers of this Journal, it is certainly not comprehended by all. No doubt the familiar capitals are regarded by not a few who observe them in connection with this subject as symbolical of extreme simplicity, and that the precipitating method they represent is as easy as A B C. Simple, indeed, and easy the process is by which the solid and coloured portion of town refuse is collected and the liquid dispersed in a clear bright stream; yet the letters mean something more. They are typical of the manner in which the work is done, or rather are the initials of the chief ingredients employed in doing it—namely, Alum, Blood, and Clay. So much for the name, and now for the process. Here it is in a nutshell. The sewage as it falls into the tank is mixed with another mixture made of proper proportions of clay, charcoal, and blood, which at once removes all offensive smell; and then, when the whole is a thick opaque mass, a solution of alum is added, and the precipitation of the particles of solid matter suspended in the water commences at once—the clay, &c., quickly sinks to the bottom, dragging all the other impurities with it, leaving the water perfectly clear. Anyone can test the process for himself by pouring a solution of alum in a glass tube of muddy water, the solid particles will sink to the bottom of the glass and the water remain clear. At Aylesbury there are three tanks some 30 feet square through which the sewage passes, entering at one end in all its blackness, the effluent water passing out at the other over a channel of white porcelain as clear, to use the words of a speaker, as a "highland burn." Clear it certainly is, for in a tank of it fish appear healthy and happy; and this water tasted

—for I ventured to taste it—well, just a little “fishy,” that was all.

The matter precipitated at the bottom of the tanks—the mud—is pumped into a strong iron reservoir, and is then submitted to great pressure, the water passing out perfectly clear; the solid matter, a compound of sewage and clay, being compressed into the form of oil cakes. These, which are quite inodorous, the clay acting as a deodorant, are dried, then broken, next crushed or ground, and this, “the native guano,” is ready for use in farm and garden. During the entire process there is nothing even in the slightest degree offensive, in fact the air around is sweet in comparison with that floating over the Thames sometimes and other rivers that pass through towns.

From a sanitary point of view it is difficult to conceive that any method of dealing with sewage can be found better than this; indeed this was said in effect by the Lord Mayor after having made it his duty to become acquainted with the different processes of solving what is admittedly one of the problems of the age. He suspected that, after all the costly and elaborate methods of dealing with this subject, we must fall back on the simplicities of Nature, and separate the pure from that which is impure, sending the former into the rivers for the nurturing of fish, and placing the latter in the soil for the production of useful crops. As gardeners and cultivators generally always like to know as far as possible how the fertilisers are produced which they are invited to use, and as the whole question of sewage-disposal is so important to all, no apology is needed for devoting a little space to the matter, rather than by occupying it with a long list of the names of the individuals who have even had the honour of winning prizes for Turnips and Carrots. Most of these, therefore, will be passed in a brief reference to the Show.

Whatever the object of the Native Guano Company may have been in the great provision they made for filling their tents, it is hoped, while they will rightly demand and will ungrudgingly be accorded justice where it is due, they will not expect nor receive unqualified praise where it is not deserved. The system of disposing of sewage appears a splendid success from a sanitary point of view, but whether the Exhibition equally displayed the potency of their manure is another question. But did not the products staged prove this? They neither proved it nor disproved it. Granted the fine heads of corn with straw 6 feet long, the bright samples in sacks, the huge Turnips and Mangolds and Cabbages from farms, with the splendid collections of vegetables, the large Onions, huge Cauliflowers, good Potatoes, clear Turnips, Carrots, and Beet from gardens. Granted all this, we still know—all gardeners know—that equally good examples can be and have been produced on some soils where neither native nor exotic guano, or indeed any other so-called artificial fertilisers, have been employed. The native guano may be an excellent manure. It no doubt contains good food for plants—in fact, must contain it; yet we still want to know in what proportion it is used to produce given results, and also what other manurial matters the soil contains, before the true nature of the article under notice can be determined. Carefully conducted trials are needed in comparison with other fertilisers in different kinds of soils for testing its real worth. No doubt such trials have been made, but of these we have no record, and it is almost certain that this manure will be more largely tested. Let this be done systematically. Trials of fertilisers in private gardens are often conducted in a haphazard manner, and in a way that is not fair to one or the other of them. To test the native against imported guano, for instance, using both in the same quantity—say at the rate of 2 ozs. per square yard or 5 cwt. per acre—would be obviously handicapping the home-made article to a serious extent, for it is about four times less costly to purchase than the other. More than three times the quantity of the native fertiliser should be applied to the same extent of ground as the foreign, and to the same crops; then if the returns should prove equal or nearly so, the former will have proved its value in a substantial manner, and the demand for it will compel the authorities of towns to seriously consider the advisability of adopting the A B C process of sewage-disposal, thus rendering the streams clearer and land richer, the air sweeter and crops better; for at present the sewage of many towns and villages is worse than wasted, for too frequently it is allowed to ferment, and the disease germs that are then generated are distributed by air and by water into British homes of every class. If it can be proved by results that, say, 3½ tons of the native substance will produce as much food as 1 ton of the best foreign will, then neither special trains, lord mayors, nor sumptuous luncheons will be needed to bring the article into notice.

Very little has been said about the Show. It must suffice to say that in the fifty classes there were 400 entries and 7500

specimens, that Mr. De Fraine staged the finest collection of vegetables that has probably ever been shown by a market gardener, everything in season being represented, the whole covering a space of 15 by 9 feet; that the amateurs' and cottagers' collections were of wonderful excellence, equalling those staged by gardeners at our great shows; that Mr. Robins, gardener to E. D. Lee, Esq., won the chief prizes for collections of Potatoes with produce of unsurpassable quality; that Mr. Polley secured the first prize for the best bushel of round Potatoes with Arondinack, and the best bushel of kidneys with Pride of the Valley; that Messrs. Robins, A. Blake, gardener to H. Cazenove, Esq., and W. Finlay, gardener to Col. North, M.P., were the successful exhibitors of Grapes; that Mr. Blake won the Hon. W. F. B. Massey-Mainwaring's £5 prize for twelve stove and greenhouse plants; that Messrs. Suttons' cup for farm produce was secured by Mr. Beeson of Amersham, and Messrs. Carters' by Mr. Howard of Drayton Beauchamp; and that the produce in all the other classes was good, in most cases superior, and that the Show altogether was a great one and a great success.—J. W.

REMEDY FOR BLACK APHIDES ON PEACH TREES.

THE following I have found an effectual remedy for black fly on Peach and Nectarine trees:—1 quart of tobacco water to 3 gallons of warm water heated to about 120°; syringe thoroughly in the evening, and syringe with clear soft water the next morning, and there will not be many insects alive. If the trees are badly affected syringe on three successive evenings; but as prevention is better than cure, syringe once before the flowers open and again after they have set, and once again when the shoots are 2 or 3 inches long. In this way I have kept black aphides from the trees entirely for the season, but if two or three were seen I used to syringe at once. I am speaking of trees out of doors, as I was never troubled with fly in the houses; but these remarks are equally applicable to trees indoors and out. I have seen whole walls of trees entirely destroyed by not attending to them in time. I had as good a wall of Peaches as anyone could wish to see, whilst our neighbours' trees were destroyed with aphides.—G. G.

CARTER'S NURSERIES, PERRY HILL, SYDENHAM.

I HAD heard much of this nursery for some years, especially in connection with the periodical display of annuals shown by the firm, and as some hours remained after visiting the Holborn seed warehouses referred to on page 294, I went to London Bridge, whence Forest Hill station was reached in fifteen minutes, a few more minutes' walk bringing me to the nursery. On my arrival the great speciality of the season—Petunias, had just passed their meridian beauty, but enough remained to afford me a rare treat. There were ten thousand alone in pots. There were single and double sections, with plain, and laced, or barred corollas, with even edges, or scalloped or fringed, some chastely veined, and others curiously spotted. Some were miniatures, while others might be readily mistaken for one of Jackman's Clematis; and last, but the class I liked best, were the maculated and green-edged forms, especially the doubles—perfect flaked rosettes. Almost every colour was represented. Many beautiful and distinct varieties were named. It would have been interesting to all who love showy and beautiful annuals to see such masses of flowers grown in 5-inch pots. Many were grown in open frames, some in pits, and a number in low houses, but all were fully exposed, sturdy, and vigorous, having been removed under glass for perfecting their seeds and to keep them more under control during the process of hybridisation.

In the next house we came upon another present speciality of the firm—double Bouvardias, pink and white, Alfred Neuner and President Garfield. Remembering that the former was introduced and certificated so recently, I was surprised to find a house 100 feet long filled with plants, while the pink variety is being extensively propagated. Wherever beautiful waxy-white or pink flowers that will last a long time are in request those will be valuable additions. Several cool houses were devoted to Primulas, but for those I was too late, except to note the seed-harvesting process. One structure was wholly occupied with the “blue” Primula Holborn Gem advertised last spring. Large space, too, is given to Cyclamens; and though the plants were in comparatively small pots the foliage was beautifully marbled, vigorous, and fleshy, showing numbers of flower buds, that must make them desirable for winter and spring decoration. The striped giganteum persicum and the purple variety seem very robust, while perhaps the most desirable of all, White Swan, a pure white strain, will prove most attractive for special purposes. Gloxinias were resting, but Tuberos Begonias of the Crown Jewel strain were beautiful, valuable alike for pots and bedding.

Going out into the grounds and leaving a number of heated houses last, we wandered to a colony of succulents, which were as curious as they were beautiful, and which I was hitherto unaware were patronised here. Near these were some rare and hardy border plants, to meet the fashion in this direction. Here, too, was pointed

out the recently certificated Black Champion Currant, raised at Mr. Dunnett's, Dedham, the surprise of all who saw the berries. Nothing I had seen hitherto were to me more interesting than the large space devoted to Lilies, and I was fortunate in finding many, both of the Japanese, Martagon, davuricum, and lancifolium types in bloom. I find any time from this to the beginning of winter the best for planting the bulbs. I have some from imported bulbs obtained last year, and planted in ornamental wooden boxes about a foot square, and the same deep, in soil containing at least a third of peat, and I find the blooms 16 inches in diameter, and an average of six to the bulb. I have seen larger blooms in the borders with Mr. Burbidge, Trinity College Gardens, Dublin, a fortnight ago, but I consider this satisfactory, and not always obtained the first year of planting. I use those boxes and Lilies on Sunday for church decoration, and know of few floral ornaments so convenient to compare with them. As this use of Lilies is not common the digression may be pardoned.

I also noticed a large square of Tropæolum Empress of India, and I cannot remember ever seeing anything more brilliant, while the dark-tinted foliage showed the flowers to advantage. While I must pass many things, I cannot pass the new *Calendula officinalis* Meteor without commending it to your readers. It is perfectly hardy, very showy, with bright gold orange pencilling on each floret, and produces seed freely. Though I have already exceeded the space you are likely to have to spare, I have not even yet a reference to single Dahlias, Carnations, and their congeners of the *Dianthus* family, not a word of the beautiful tricolor *Chrysanthemums*, or any of the Composites, but I must stop to single out *Harpalium rigidum*, that you figured recently. There are two further houses yet to notice, and that I must dispose of in a line, devoted to a young stock of *Calceolarias*, including the new Cloth of Gold, and *Cinerarias*. We next arrive at the trial grounds for vegetable and farm seeds, returning by the Dahlia and Rose grounds, and could see through the shades of evening that the Tea Roses were remarkably fine for the season, and the Hybrid Perpetuals had commenced to wreath themselves a second time in their glorious tints.—W. J. M., *Clonmel*.

ANNUAL CHRYSANTHEMUMS.

I NOTICED in the *Journal of Horticulture* last week a few remarks concerning the beautiful *Chrysanthemum coronarium*, and I consider the plant fully deserves all that your correspondent "SUSSEX" has said in its favour; for in addition to its merits as a border annual or for lifting in the autumn for the conservatory, it may be grown with advantage for the conservatory in spring. I sowed a few seeds in February of the present year in a little heat, from which I had good plants in full flower in May. They were much admired, and nothing could have had a more pleasing effect than had these plants mixed with the ordinary greenhouse plants in flower in the latter part of spring and early summer. In addition to *C. coronarium* I would advise those who have not done so to try some of Messrs. Carter & Co.'s annual *Chrysanthemums* for the mixed border. Some of these, such as Dunnett's Golden, Dunnett's Snow White, Lord Beaconsfield, and some others, are extremely pretty. They will do well in any ordinary garden soil, and being of rapid growth they soon make an attractive display.—E. B.

TROPÆOLUM BEDFONT RIVAL.—This *Tropæolum*, which I have known the past ten years, is, I consider, the best for bedding purposes. At present, when *Pelargoniums* are quite without flowers owing to recent heavy rains, it is one mass of scarlet. It is quite distinct from any *Tropæolum* I know, and has a good formed flower, intense scarlet in colour, with light green foliage. On light soil it is at all times better than any bedding *Pelargonium* that I am acquainted with. Is this the same variety for which Mr. Dean received a first-class certificate last summer? I first saw it in 1872 in the gardens at Heslington Hall, York, but where it came from I am unable to say.—JOHN SHORT.

KITCHEN GARDEN.

CLEAR the ground of all exhausted crops, so as to have it in readiness for digging and trenching as may be found necessary. Where manure is required it should be placed on during dry weather, nothing being so prejudicial as working ground during wet weather. Soils of a heavy retentive nature should be thrown up in ridges, so as to expose as large a surface as possible to the action of the atmosphere during

winter. All soils under high cultivation, which means manuring after every crop and surface-mulching such as require it, along with deep stirring, will in the course of a few years have the soil very rich and liable to become close and soapy. Such must be trenched at least every third year, and a good liming given in the spring prior to the contemplated trenching. In trenching care should be taken not to bring much of the bad soil to the surface, but by loosening it at the bottom of the trenches seek to increase the depth of rooting and percolation of water through the soil. In the case of trenching manure must be applied afterwards, so as to enrich the comparatively poor soil brought up. It may be applied any time during the winter in favourable weather, pointing in spring prior to sowing or planting. Soils that do not require trenching and have the soil rich in decayed matter, consequently full of humus, may be given a dressing of lime, forty bushels per acre being sufficient for light soils, and double the quantity for heavy soils, whilst those that have not been dressed with lime for seven or more years may be given double the quantity. It should be applied in dry weather either in autumn or spring. Very light and shallow soils will not be improved by turning them and exposing to the action of the atmosphere during winter; in their case the ground may be manured so as to admit of the soil being turned in spring. If a good dressing of clay or marl could be placed on during frosty weather, and after being pulverised by frost or atmospheric influence dug in, such soils will be improved immensely.

FRUIT HOUSES.

Pines.—Plants on which fruit is now showing will be ripe at a time when other kinds of fruit are scarce, therefore such plants should be given a good position, where every advantage, both natural and artificial, may be obtained. Continue the temperature and treatment as last indicated in this calendar, but should the weather become cold and dull a fall of 5° in the temperature should be made. During the process of flowering it is not usual to wet the fruit, and should not be done through the winter months. The lights of all Pine houses or pits must now be washed. Plants expected to show fruit early in the ensuing year should now be rested for a time after having made growth, and as Queen plants do not generally start into fruit so readily as some other varieties it is advisable to treat the plants very carefully. The temperature at the roots should fall gradually to 70°, that of the house being kept at 65° by day and 60° at night. Houses which are naturally moist from being sunk, and having fermenting beds, must not be sprinkled, and water should only be given when absolutely necessary, which will not often be the case with plants plunged in fermenting beds. Ventilate at 70°, and freely above that temperature, closing at 70°.

Cherry House.—Dishes of fresh ripe fruit are not very plentiful in late April, May, and early June, hence Cherries afford an acceptable addition. A lean-to house from 8 to 12 feet in width is the most suitable, the last greatest width allowing a row of trees in front and the utilisation of the back wall by a row of trees, the front trees only occupying a part of the roof to the extent of about 10 feet up the rafters. For the front trees the trellis should be about 12 inches from the glass. The borders may be about 30 inches deep, with 9 inches of rubble at the bottom, and drain to carry off the superfluous water; 6 feet width is ample. Loam of a calcareous nature is necessary, and, if deficient of that, a tenth of old mortar rubbish should be incorporated, with a sixth of road scrapings. In selecting trees for planting under glass it is advisable to employ such as have been trained to walls for three or four years, as they come into bearing at once, and if carefully lifted and planted as soon as the leaves are falling they will afford early fruit the first season. The soil should be firm, and after planting a good watering must be given, mulching over the roots. *Empress Eugénie*, *May Duke*, and *Black Tartarian* are the best of the dark Cherries, and of the light-coloured *Early Jaboulay*, *Elton*, and *Governor Wood*. The house unless required for *Chrysanthemums* and similar plants, which will need mere protection from frost, with free ventilation, should not have the lights placed on for another month or six weeks. Trees in pots requiring a shift should be given pots 3 or 4 inches larger, and those requiring surface-dressing must be attended to at once, removing the mulching; and the soil near the sides of the pot as

deeply as can be done without much injury to the roots, employing rich compost, to be placed in firmly.

Peaches and Nectarines.—Unless the weather prove unusually wet the lights may remain off the house to be started early in December until the middle of next month, otherwise they should be placed on and the ventilators be open to the fullest extent when the weather is mild. The exposure of the trees to atmospheric influence after the wood is thoroughly ripe is of the greatest advantage, inducing a more complete rest than when the lights are kept on, the cleansing influence of rains and the thorough moistening of the borders being of considerable importance. Even in late houses the exposure of the trees is of the greatest benefit, but in no case should it be practised until the wood is thoroughly ripe. Trees in late houses that are not ripening the wood freely should be assisted with fire heat by day and a free circulation of air constantly.

FLOWER GARDEN.

When the beds and borders have been cleared of their summer occupants they should at once be prepared for refurnishing. If a display is wanted in winter dwarf evergreens are the most suitable, whilst for spring flowering plants will afford a more effective display. The great recommendation of plants for spring gardening is that they require no glass room or costly preparation to raise them, as an interesting display may be secured by the expenditure of a few pounds in bulbs such as Hyacinths, Narcissus, Tulips, Crocus, Scillas, Snowdrops, and Anemones, with Primroses, border Auriculas, Daisies, Violas, Wallflowers, Forget-me-nots, and early-blooming hardy annuals such as Candytuft, Limnanthes, Nemophilas, and Silenes. For edgings or marginal lines *Arabis albida variegata*, *Veronica incana*, Golden Feather Pyrethrum, Golden Thyme, *Stachys lanata*, and Dell's Crimson Beet are very effective. These and others that will suggest themselves to those intent on making a display in spring are readily increased when once procured. Before planting it will be necessary to manure the beds. Of shrubs few are more effective than the gold, silver, and plain-leaved Tree Ivies, the *Euonymuses* being distinct and bright in variegation. *Osmanthus*es with their Holly-like foliage have a telling boldness, and the *Aucubas* are equally noteworthy. *Skimmia japonica* well berried is superb, and *Vinca elegantissima* very graceful. The deep green dense foliage of *Mahonia aquifolia*, and its masses of gold flowers in spring, with the white flowers of *Laurustinus*, the rose flowers of *Erica carnea* and *Andromeda floribunda*, are fine as flowering shrubs. *Cryptomeria elegans* and var. *nana* with their chocolate, *Cupressus Lawsoniana* and vars., also *C. Nutkaensis*, *Retinosporas*, *Taxus baccata aurea* and *elegantissima*, *Thuia aurea*, and *Thujopsis dolabrata*, are a combination of gracefulness and elegance. Weeds on lawns, such as Daisies, Plantains, Crowfoot, grow fast in a wet autumn, and as they are a great disfigurement to a lawn they should be extirpated at once, so that their place may be taken by the natural grasses. The heavy rains have brought worms to the surface, their casts are also a great disfigurement, hence lime water should be poured over the lawn, which soon brings them to the surface, when they may be swept up and destroyed; this being repeated a few times after heavy rains will greatly diminish their numbers and save much labour in sweeping and rolling. Keep leaves cleared up, and roll walks and grass frequently. In the borders of herbaceous the *Michaelmas Daisies* (Asters) are still fine, and so are the perennial Sunflowers, Japan Anemones, and *Tritomas*. The stems of any varieties sufficiently ripened should be at once removed and the borders kept as neat as possible.

PLANT HOUSES.

Bouvardias.—For affording a continuous supply of flowers for cutting these are unsurpassable; but to induce them to afford their full quantity of flowers through the winter months they must be kept in a brisk heat. Plants from cuttings struck in spring and placed in pits or frames in good soil, and in September transferred to 6 or 8-inch pots according to their size, if now transferred to a house with a temperature of 65° at night, with a rise of 5° to 10° in the day, will soon be covered with bloom, and will continue for many months, an application of liquid manure being given once or twice a week. They should be placed as near the glass as possible.

Gesnerias of the *zebrina* section must have a light position, and a

temperature of 60° to 65° at night, with 5° to 10° more by day, which will induce a sturdy growth and free disposition to flower. Supply any plants in small pots with weak liquid manure.

Orchids.—Lowering the temperature has brought such plants as *Aerides*, *Vandas*, *Phalænopses*, *Saccolabiums*, and similar kinds into a partial state of rest. Just sufficient water should be given at the roots to keep the moss damp, for if allowed to become too dry the bottom leaves are apt to shrivel and fall off. Premature growth should be prevented by keeping the house comparatively cool and dry; but a little water must be poured over the paths on fine mornings. Open the bottom ventilators, though very little will be required except to keep down the temperature, as a cool system of treatment is most desirable at this season. Plants that have not completed their growth must be kept in a moist atmosphere and watered, those on blocks being examined and watered as needed. *Dendrobiums* will now be chiefly at rest, and should be kept cool and dry. *Cattleyas* require a long season of rest, and should be kept rather dry; but the pseudo-bulbs must not be allowed to shrivel, very little water being needed to keep them plump. *Lælia purpurata* not having completed the growth should be given a favourable position at the warmest end of the house. *Calanthe vestita* and *C. Veitchii* coming into flower should not be overwatered, or the buds are likely to fall before they expand, which is caused by too much atmospheric moisture and insufficient light; therefore keep them fully exposed in the driest part of the house. *Lycaste Skinneri*, though a water-loving plant, requires less at this season, but if allowed to become too dry the pseudo-bulbs shrivel in a few days; and the water must be kept from their base, or the flower buds will decay when an inch or so long. *Cypripediums* require liberal supplies of water, as they do not need any rest.

Stove *Begonias* of the flowering section should be afforded all the light possible, and no more heat than will enable them to open their flowers freely. Afford weak liquid manure occasionally. Easily grown as these are, it is surprising they are not more generally seen. *B. insignis*, *B. Ingrami*, *B. Saundersiana*, *B. fuchsoides*, and *B. semperflorens* are especially useful.

Richardia (*Calla*) *æthiopica* should now be placed in heat for early flowering. Plants that flowered early last season, and were liberally treated afterwards, are now throwing up their spathes. In a temperature of 50° to 55° they will develop perfectly, and in a conservatory be highly effective. By having sufficient plants started at intervals flowers may be had in bloom all the year round. It is spoiled both in leaf and spathes by being grown in too much heat. The general stock ought to be at once housed, and should be kept gently growing in a light house, a temperature of 45° to 50° suiting the plants.

Introduce more Roman Hyacinths, Double Roman and Paper White Narcissus to heat. Place them near the glass in a temperature of 50° to 65°, and do not accelerate the flowering too rapidly or they will be drawn weakly. Lily of the Valley is always acceptable. Plants that were forced this season and well attended to with water and liquid manure so as to complete a good growth, and been rested outdoors, will start readily on being placed in heat, the process being accelerated by a bottom heat of 90°. Single crowns inserted in rich soil a couple of inches apart over a bed with a temperature of 90°, kept moist, and the tops covered so as to draw the spikes up to a good length, in which state they are most useful, will afford flowers in abundance for cutting, the crowns being selected with flower buds.

THE BEE-KEEPER.

THE STEWARTON AND THE BAR-FRAME HIVES.

No. 2.

In a former letter on this subject I tried to explain the chief characteristics of the Stewarton hive and notice its best features. For supering purposes we hold that this hive is unequalled. The principle of the hive we highly commend; the material (wood) of which it is made we as unhesitatingly condemn. Those who try to improve the Stewarton will doubtless consider the question

whether three breeding boxes are essential to the completeness and efficiency of this hive, and whether one or two breeding boxes will not answer as well as three. If this question be fairly and fully considered I think that three sections of breeding boxes will be deemed quite unnecessary. The three supers for use over the breeding space are unobjectionable, for they afford ample space for great stores of honeycomb and give completeness to an admirable arrangement for expansion. Not so much can be said in favour of having three breeding boxes instead of one or two. In good seasons for honey, when supers become well filled, we invariably find that much honey is stored in the breeding space below. With three sections, as in the case of the wooden Stewarton, the top section can be removed for run honey, and the two bottom ones kept as a stock, and doubtless this is often done, though to my mind there is a better and more profitable way of management. Even if it were an advantage to winter the bees in the two bottom boxes we have to consider the disadvantages of a hive in three parts, which are expensive and inconvenient. I think the principle of the Stewarton hive could be well and satisfactorily carried into practice on a straw hive properly made, and sold at a much lower price than the present Stewarton. Some advanced bee-keepers of the modern school advise beginners to commence bee-keeping with inexpensive straw hives. This is good advice. I will go a step farther in the same direction, and advise beginners to commence with cheap wooden boxes rather than with expensive hives. Some amateurs and moneyed people can afford to go the whole round of fashion, but working men cannot. Buying costly hives is not the shortest road to success. The successful men in bee-keeping are those who can manage bees well in any kind of hive, and who also know that complications in bee hives, meant for the convenience of bee-masters, are often inconvenient to the bees themselves.

In supering the Stewarton hive there is a difference of opinion and practice. Some think that when the first super is nearly or partially filled the better way is to put an additional super on the top of the first, and when the second one is partly filled a third one should be put on the top of all, thus making the bees extend their stores upward farther from the breeding boxes. Some able advocates and patrons of this hive maintain that this is the proper way of supering the Stewarton. On the other hand, some enlightened apiarians think that the better and more natural way is to put at the proper time the second super below the first, and the third one below the second, and thus prevent the bees travelling through finished supers to work in others above them. The traffic of bees across virgin combs recently built would destroy to a certain extent the beautiful bloom on them when first finished; but the difference of opinion existing as to the better way of adding super to super does not detract from the excellence of the Stewarton principle of supering.

We have now to notice the bar-frame hive, which is much better known than the Stewarton. Indeed, it is so well known that any attempt on my part to explain its structure and mode of management would be unnecessary. It is the fashionable hive at the present time, and has the patronage of the bee-keepers' associations of England, and no expense is spared in commending its virtues and showing how it can be manipulated. Though I cannot endorse all that is said about its superiority and advantages, I will here mention some of its best features. The main feature and principal characteristic of the bar-frame hive is this, that its combs or bars are equal in size, moveable, and therefore interchangeable, and being so they can be removed from one part of the hive to another, or removed from the hive altogether, have their contents taken from them and restored to the hive again. Honey bars can be taken and brood bars left. For other and various purposes the moveable-comb system has advantages which no honest man will question. The frames facilitate the use of comb foundations, and if frame hives are made large enough to hold sixteen bars supering may be dispensed with, as the outside bars would answer for honeycomb or sections; and by having blind frames for partitions the hive could be contracted in winter, as is often done now. Notwithstanding all that has been and could be said in favour of the moveable comb system, I have never been able to fall in love with it. I get more and greater advantages from simpler and cheaper hives that are far more easily managed. Besides, frame hives like the present Stewarton are made of wood, which is, as has often been said, unsuitable material for bee hives. The ingenuity of bee-keepers has been taxed to find a method of letting the moisture of bees out of wooden hives, but, so far as I know, all have hitherto failed. The quilt was tried, and other schemes. Cavity walls are now being tried. Some of the American bee-keepers declare that hives cracked and open from top to bottom winter bees better than uncracked hives which have no ventilation whatever.

So far as I know, those that use and understand the Stewarton hive are quite satisfied with it, and this is certainly a proof of its

excellence. It is not a pretty hive, and its price, 25s., will and does prevent its being widely known. But if the Stewarton principle can be grafted on the straw hive and sold at a low price its usefulness will soon be known, and its fame travel fast and far. We have no hesitation in predicting that the Stewarton hive made of straw will take the lead in the supering apiaries of England.

The reader may now be ready to ask why I, who use common straw hives, commend the Stewarton principle so highly. This is a reasonable question. Many people keep bees for supering. Pure honeycomb is what they want. If supering were my only object in bee-keeping I would adopt the Stewarton principle. But I keep bees for profit, and can get as much honey from a common straw hive as can be obtained from either Stewarton or bar-frame hives, and I can sell run honey at about as high a price as honeycomb; and I wish bee-keepers to know and remember that in supering the bar-frame and the Pettigrew hive there is a loss of 2 lbs. of honey at least in every 7 lbs. gathered—that is, for every 7 lbs. of honey collected into a simple hive and there stored, only 5 lbs. are gathered into a supered hive. These facts go a long way to support the principle of simplicity as against that of complexity in hives. All complications, divisions, separations in hives are unnatural and artificial, and act as hindrances to bees at work, whatever advantage they may be to the hive-dealer and bee-master. Another consideration with me is this, that a Stewarton hive made of wood costs 25s., and for this sum I could get seven or eight first rate straw hives, which answer well all the purposes I have in keeping bees, and, moreover, I can afford to sell excellent stocks of bees at a price almost as low as the cost of an empty Stewarton. I am quite as satisfied with my straw hives as I was forty years ago. They are so cheap, servicable, and easily managed that I have no intention or wish to possess other kinds of hives.—A. PETTIGREW.

BRITISH BEE-KEEPERS' ASSOCIATION.

THE last quarterly meeting of the Committee and the representatives of county bee-keepers' associations for the present year was held at 105, Jermyn Street, on the 18th inst. In addition to the ordinary monthly meetings of the Committee quarterly meetings are held, at which representatives of the several affiliated county bee-keepers' associations are entitled to be present. There was a good attendance at this meeting, including Mr. Thomas W. Cowan (in the chair), Rev. E. Bartrum, Hon. and Rev. H. Bligh, Captain C. D. Campbell, Mr. J. M. Hooker, Rev. G. Raynor, Rev. F. T. Scott, Mr. D. Stewart, Mr. W. O. B. Glennie (Treasurer), Rev. H. R. Peel (Hon. Sec.), and the following county representatives—viz., Rev. N. Andrews, Sussex; Rev. W. E. Burkitt, Wilts; Messrs. G. Allen and G. Garratt, Kent; J. P. Jackson, Lancashire and Cheshire; and F. H. Lemare, Surrey.

The minutes of the last meeting having been read, confirmed, and signed, it was resolved—"That certificates be prepared in accordance with the copy submitted by the Secretary, and forwarded to the several candidates who gained first, second, and third-class honours in the recent examination held at South Kensington." The Honorary Secretary was requested to communicate with the Bath and West of England Agricultural Society, the North of England Agricultural Society, and the Royal Agricultural Society of England, and to take such steps as he deems advisable for the purpose of arranging exhibitions of bees, hives, honey, &c., at Bridgewater, Liverpool, and York in connection with the annual shows of the above societies during 1883.

The Rev. E. Bartrum, Hon. and Rev. H. Bligh, and Mr. D. Stewart were appointed as the sub-committee for the management of the honey market in London.

The Rev. E. Bartrum submitted the MSS. of a short chapter on the best methods of bee management with "straw skeps," and advocated the importance of such instruction being given in the next edition of "Modern Bee-Keeping." Mr. Garratt, Mr. Lemare, Mr. Jackson, and others supported Mr. Bartrum's proposal. It was pointed out that information in regard to feeding, supering, &c., with straw skeps was already inserted in the present edition of the work. The Rev. G. Raynor and Messrs. T. W. Cowan and J. M. Hooker were unanimously appointed as the sub-committee for the final revision of the new edition of this handbook.

The Rev. W. E. Burkitt brought forward several proposals relating to the prices and terms upon which hives and other goods should be exhibited at the annual show of the British Bee-keepers' Association. It was resolved that such suggestions be taken into consideration at the time the prize lists for 1883 were determined upon.

At the close of the above meeting Mr. G. D. Haviland read an interesting paper on "The Social Instincts of Bees: Their Origin by Natural Selection." Mr. Haviland treated his subject in a masterly manner, and was heartily applauded at its close. There was a large attendance of members, including several ladies. The Rev. F. T. Scott presided. The Honorary Secretary announced that Sir John Lubbock would have taken the chair on this occasion, but a prior engagement prevented him from doing so.

TRADE CATALOGUES RECEIVED.

Dickson & Robinson, 12, Old Millgate, Manchester.—*Catalogue of Fruit Trees.*

J. Cheal & Sons, Crawley, Sussex.—*Catalogue of Trees, Shrubs, and Bulbs.*

André Leroy, Angers.—*Catalogue of Trees, Shrubs, and Plants.*

Stansfield Brothers, 69, Percy Street, Southport.—*List of Herbaceous Plants.*

H. Merryweather, Southwell.—*Catalogue of Roses.*

John Laing & Co., Forest Hill, London, S.E.—*Catalogue of Roses, Trees, Shrubs, and Begonias.*

* * All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Tortoise in Garden (*L. T., Putney*).—We are not surprised to learn that your pet has not appreciably diminished the insects in your garden, the benefits of tortoises in this respect being as a rule much exaggerated. A greenhouse will be a good place for it in the winter, giving it a little bread and milk occasionally.

Gardener's Appointment (*Northampton*).—The letter you have sent us contains the names of your late and present employers, indeed all the particulars requisite for making the notification but one, this being your own name. As we have received no other letter of the same nature from Northampton you will recognise this reply.

Pruning Fruit Trees (*Amateur*).—The subject is too large for treating successfully in this column, and besides you do not state either the condition or names of the trees on which you desire information. We shall shortly publish notes on pruning fruit trees, and if after perusing them you desire further information, and will specify it, we will readily aid you if we can.

Pruning Climbing Roses (*W. A., York*).—The young growths will produce the finest flowers; but if the shoots are left several feet long they will probably be naked towards the base, as the lower buds will remain dormant. You had better shorten at least some of them, and not crowd any by securing too many to the wall, removing all decayed and much of the wiry-looking wood. We could have answered your letter more satisfactorily if you had told us the name of the Rose.

Slugs Eating Cabbages (*Idem*).—Dust the plants with newly slaked lime, applying it at night, when the plants will be covered with the enemy, and not in the daytime, when they are lurking in their haunts below the soil. Stir the ground frequently with a hoe. This will encourage the growth of the plants and check the movements of the slugs. A few ducks turned in the garden would probably be useful, but occasionally they assist the slugs to eat tender Lettuces.

Plum Leaves Unsightly (*Idem*).—Your Plum trees have been infested with insects that ought to have been destroyed early in the season. Dress the trees after pruning with Gishurst compound or nicotine soap, and be more watchful in preventing the increase of the insects another year.

Stoves for Heating (*R. S. B.*).—The stoves you name are useful for certain purposes, but we cannot recommend them for heating a vinery, and you had better not attempt to "finish" your Grapes with them. You say nothing whatever about the size of the vinery. Possibly it is too large to be safely heated by a stove of any kind. A small boiler and pipes constitute the best mode of heating, but a flue of earthenware pipes will be cheaper, and rightly made and managed will probably answer your purpose.

Temperature for Mushrooms (*H. C.*).—If the heat subsided gradually you may, if the spawn and material were good, expect Mushrooms in about eight weeks from inserting the spawn. The present temperature of 52° will suffice for the bed provided the mycelium has penetrated the mass. That, too, will be a suitable temperature for the house, and if it is too high for the plants you can reduce it by 5° without injuring the bed; the growth of the Mushrooms will be a little slower, that is all.

Training Vines (*A Reader*).—If the rafters are not more than 4 feet apart you had better train one rod up the centre of each light, not under the rafters. You may grow excellent fruit for table with the rods 3 feet apart, provided the bearing laterals are not too numerous. If the roof is short, not exceeding 12 or 14 feet, you may safely take two rods from each Vine. In his large houses at Clovenfords Mr. Thomson has two rods and upwards from his Vines, and it is questionable if finer crops of Grapes than his can be found at the present time in Great Britain. Foster's Seedling is the most free and certain white Grape for planting with the Black Hamburg. You might try a Vine of the Duke of Buccleuch, and if you succeed in growing it well you will not regret the experiment, while if you fail you can easily train an additional rod of one of the others in its place. It does not matter whether a Vine has one, two, or three rods, provided it can root freely in good soil.

Potting Plants (*F. J.*).—Plants generally should be shifted from smaller to larger pots as soon as the roots have taken possession of the soil sufficiently to just hold it together when the plant is inverted in the hand and the pot is

withdrawn. A very good index for shifting is the protrusion of healthy roots through the drainage. It is a mistake to allow plants to be very much root-bound before being shifted. Linnaeus is one of the most suitable varieties of Rhubarb for your purpose, it being small, early, and of good colour and flavour when cooked.

The "Musk Tree" (*Inquirer*).—The plant of which you sent a leaf is known under the above name, and is *Aster argophyllus*, a member of the natural order Compositae. It is a native of Van Diemens Land, whence it was obtained by Messrs. Lee & Kennedy at the beginning of the present century, and in a wild state it acquires the dimensions of a small tree. It is well worth cultivating in a greenhouse, as the leaves are very ornamental, owing to the silvery whiteness of the under surface, and their musky perfume is also very pleasant. Ordinary loamy compost suits it very well. Specimens are occasionally seen in a collection of old plants, but it is comparatively rare.

Culture of *Thunbergia Harrisii* (*D. D.*).—This handsome climbing plant succeeds best in the temperature of a cool stove or intermediate house, but it will succeed in a warm greenhouse, and being trained to the roof its fine purplish flowers when hanging in festoons are very ornamental. It can also be grown in a pot and trained to a balloon-shaped or other suitable trellis, but the most satisfactory results are obtained by planting it out. A compost of turfy loam with a little leaf soil and well-decayed manure is required, supplying water freely when the plant is growing or flowering. The chief pruning needed will be thinning the growths, removing the old shoots, and training in young wood.

Duke of Edinburgh Strawberry (*T. Mason*).—This is not so new as you suppose, as it has been in commerce ten years or more. Still, it is not

Fig. 64.—Duke of Edinburgh.

in place of Keen's Seedling and other large-growing leafy sorts."

Removing Raspberries (*E. B. M.*).—You will do quite right to shorten the canes which you remove, and to plant them as you propose, only the rows must be at the least 4 feet apart, and as the canes appear to grow strongly in your garden 5 feet distances between the rows will be preferable. You must remember, however, if you dig up the entire plantation you will have but little fruit next year, and a safe course to pursue will be to retain the old plantation, or sufficient of it for yielding the necessary supply of fruit until the new one is established. As your canes only bear at the top train them in an oblique manner as suggested in another column in an article on Raspberry culture. As you "know very little about the culture of the Raspberry" there will be other fruits and crops on which you need information, and you will find the investment of 1s. 9d. in our "Garden Manual" safe and profitable.

Trees Unfruitful (*C. B.*).—The old trees which do not make much wood would doubtless be benefited by having a portion of the old soil removed from their roots, say for a distance of 3 or 4 feet from the wall, fresh soil added to the depth of 5 or 6 inches, and a thick layer of rich manure, which should be left to decay. This would encourage the production of young surface roots, and the food they would absorb would improve the health of the trees. If trees grow healthily and blossom freely no assistance of the roots will ensure good crops of fruit. Aid must in such a case be given above ground, not below it, in the form of protecting the blossoms from inclement weather in spring. In addition to dressing your trees in winter, as you wisely propose doing, you must also dress them in summer before the insects become established. You will find a good method of destroying the black aphides in another column.

Late Pears (*S. H.*).—All the answers to practical questions that are given in these columns are founded on "real experience," but in compliance with your wish the gardener whom you named has supplied some of the following varieties as likely to answer your purpose; but we must remind you that if you limit yourself to large late Pears you will exclude some of the best and most profitable sorts in cultivation. On a wall so low as yours is you must train the trees horizontally; not, however, as soon as they are planted, as they will grow much more freely fan-shaped, the branches to be afterwards brought down and trained along the seams of the wall, and at the least a foot apart. They should be on the Quince stock, which will do well in such soil as you describe. The following are hardy, fruitful, and good late Pears, but not all of them of large size:—General Todtleben, Beurré Sterckmans, Marie Guisse, Nouvelle Fulvie, Marie Benoit, Passe Crasanne, Madame Millet, Glou Morceau, Beurré d'Aremberg, Eliza d'Heyst, Bergamotte Esperen, and Josephine de Malines. The three last are medium-sized Pears, but great bearers of excellent quality, and with good culture the fruit may be grown quite large enough for dessert or market purposes.

Mildew on Vines (*E. H., Barnet*).—Your Vines appear to have been attacked with unusual virulency, and your district would seem to be peculiarly favourable to the increase and development of the fungus that causes the evil. Why this should be so we are unable to say, but we certainly think you may

prevent the Vines under glass at least sustaining so much damage as they have suffered this year. As soon as the leaves of the Vines turn yellow collect and burn them, then after pruning wash and dress the Vines as recommended by a correspondent on page 365 last week for extirpating mealy bug. This washing must be thoroughly done. Wash also every portion of the woodwork of the house, coating the walls with hot lime in which sulphur has been mixed liberally, 2 or 3 lbs. being incorporated in an ordinary pailful of limewash. If the Vine border is inside remove an inch or two from the surface, and apply fresh soil. When the Vines are started in the spring paint the return pipes with sulphur, and afterwards the flow pipes when the Vines are in leaf and any specks of mildew is seen on them. These must be watched for daily, and the moment the first speck is seen dust with sulphur, and if this fails try Ewing's mildew composition. Keep the roots of the Vines moist and the house well and carefully ventilated, dry soil and a close murky atmosphere being favourable to the spread of the mildew and mimical to the Vines. If you permit the pest to become established, as you have done this year, you cannot destroy it without injuring the Vines, nor will the remedies we have suggested be effectual if they be not carefully applied.

Improving Lawn Tennis Ground (Old Subscriber).—It is not unlikely the lawn requires draining, and if so the first step to take is to put in drains 6 or 7 yards apart and 18 inches deep, with proper falls into a main drain and a clear outlet for the water. Three-inch pipes will be sufficient, and they should be covered 6 inches deep with rough cinders or gravel to render them permanently effective. Drainage, however, may not be needed—of this you ought to be the best judge; but whether it is done or not a heavy dressing of fresh soil, with a liberal admixture of manure, lime, and wood ashes spread over, so as to almost cover the grass, cannot fail to be of great benefit. Before applying the dressing comb off all the moss you can with a small sharp-toothed rake. This you may do at any time when the ground is dry very early in spring, and later, when the weather is genial, sow thickly seeds of a renovating lawn mixture. Rake it in and roll the ground lightly, and you may expect a greatly improved lawn a few weeks afterwards. If you state the extent of the ground to any seedsman or firm who deal largely in grass seeds the proper quantity of a suitable mixture will be sent to you. If the lawn is full of deeply rooting weeds you had better dig it up, forking and picking out all the rubbish, then make it level and firm, and sow it as before advised. In this way you may form a cleaner and better lawn than by taking up the old and laying down fresh turf as you propose, as, however clean the new turf may be, the roots of the weeds left in the ground will grow, and the new turf will soon be as unsightly as the old.

Removing Evergreens (E. Dawson).—The present is an excellent time for transplanting evergreen shrubs, and few that are of a suitable size and in good condition for removal will fail to grow if the work is properly done. First decide on the positions they are to occupy, and make the necessary excavations for the accommodation of their roots, the holes being a foot wider than the roots extend when they are spread out in them. Then tie up the branches, and take out a deep trench at such a distance from the stem as in your judgment seems suitable. Let this trench be deep and wide; undermine the roots, throwing out the soil as the work proceeds; remove also any soil that appears loose from the surface, and do not attempt to secure more round the roots than will adhere to them. Cut off any bruised roots, and place the shrub in its new position the same depth as it was in the old. Spread the roots out straight, placing soil on the bottom layer, then other roots on this, and so on, until they are all covered. Now, and before the soil is filled in, give a drenching of water to settle the particles round the roots, level in the remaining soil, making all firm, and the work is done. No more watering will be required until spring, and even then it is better to syringe the foliage to prevent evaporation than to saturate the soil when there are few active roots to absorb the moisture. Evergreen Oaks are amongst the worst shrubs to transplant, but still with due care and good attention they may be removed successfully.

Orchids for a Warm House (L. T. K.).—The book most likely to suit you is the "Orchid-Grower's Manual," published by Mr. B. S. Williams, Upper Holloway, price 7s. 6d., post free, 8s. The following are twelve of the cheapest Orchids suitable for a warm house, but their prices will probably exceed your anticipations, ranging from 5s. to 21s. each:—*Aerides odoratum*, *Calanthe Veitchii*, *C. vestita*, *Cattleya Mossiae*, *Dendrobium densiflorum*, *D. formosum giganteum*, *Dendrochilum filiforme*, *Laelia majalis*, *Odontoglossum vexillarium*, *Oncidium Forhesi*, *Vanda tricolor*, and *Zygopetalum Mackayi*. Two good Pitcher-plants are *Nepenthes Hookeriana* and *N. Rafflesiana*; while if you require more Orchids in your cool house you might add *Pleione lagenaria* and *P. maculata*.

Cordon Peaches (J. E.).—Cordons would certainly be likely to give you larger fruit with less expenditure of time and trouble than trees in pots. The pinching of the shoots, however, must be very persistent for furnishing the trees with fruiting spurs, and in all probability you would find the most satisfactory results by not adopting the cordon plan in its integrity, but planting the trees 2 feet apart and fruiting on the young wood, shoots being selected for their firm short-jointed character, and secured thickly on the trellis space between the trees, these bearing portions being removed when the fruit is gathered, and other growths that will then be plentiful secured in their places. This is the plan adopted successfully at Chiswick, and is the simplest and best we know where several varieties have to be grown in a limited space. In your case we should not think it necessary to incur the expense of concreting the borders, but provision should be made for carrying the water off the clay, above which we should make stations for the trees by placing 18 inches of good soil on a layer of rubble protected with turves. We should keep the roots near the surface by rich top-dressings, not digging the border, but having it firm. A border 3 feet wide would be sufficient for a year or two, and it could be added to as needed. Further, the trees could be easily lifted every two or three years if their luxuriant growth indicated that the roots were penetrating the subsoil. Assuming the borders will be well managed as to watering we should prefer them inside, but this is not a question of moment, and the trees may be planted inside or outside as may be most convenient. We should not plant Peaches and Pears alternately, but devote a portion of the house to each kind of fruit separately. A foot from the glass is a suitable distance for stretching the wires, but the trees will do equally well if they are 2 feet from the roof of a light house, and this is often more convenient for dressing the trees. You will find the necessary details for pinching fruit trees grown on the close spur or cordon system in De Breuil's work on fruit trees, published by Messrs. Lockwood and Sons. Your Vines will certainly be improved by the system you have adopted, but the benefit will not be so marked next year as the year after, as the wood on which you must depend for the next crop was made under unfavourable conditions.

Names of Fruits (G. P.).—We are obliged by the specimens of Lord Lennox. Of the other fruits you have sent No. 1 is Winter Majestic, a hardy, free-bearing, and good culinary Apple. No. 2 is a Costard, of which there are

several varieties; you may call it the Longhills Costard if you like, as we do not remember anything exactly like it. The Ribston Pippin is quite true and well grown. (*C. P., Herts.*)—1, *Maréchal de Cour*; 2, *Eyewood*; 3, *Josephine de Malines*, prematurely ripened. (*Beverley.*)—1, *Beurré Beauchamps*; 2, *Glou Morceau*; 3, *Baronne de Mello*; 4, *Winter Nelis*. We think the names are attached to the right numbers, but when these are sent loose the tickets are so liable to get displaced that we cannot guarantee accuracy in this respect. Numbers ought always to be firmly attached to the specimens.

Names of Plants (J. F. L.).—A and D, *Abies cephalonica*, the former a stronger variety; B, *Abies lasiocarpa*; C, *Abies balsamea*. (*Inquirer.*)—1, *Nicotiana glauca*; 2, *Aster argophyllus*, the Musk Tree (see reply above); 3, *Myoporum laetum*, an Australian shrub which thrives best in a greenhouse. (*H. S.*)—The plant of which you sent a spray is probably *Thunbergia Harrisii*, but why did not you send flowers when you had them? We could then have given the name with accuracy. (*G. P., Hants.*)—The spray No. 1 sent last week we have since recognised as *Escallonia montevidensis*.

Fumigator Defective (W. H.).—Your self-made fumigator appears to be good, and we think if you soak the rag or whatever you use in a weak solution of saltpetre and dry it sufficiently for use, that it will answer your purpose. If you use too much saltpetre the material will not only continue alight, but will burn too quickly. The strength suitable for your purpose can be easily determined by a few experiments.

COVENT GARDEN MARKET.—OCTOBER 25TH.

BUSINESS still keeps quiet, the late unsettled weather preventing any revival. Kent Cobs are active and well maintain their value.

POULTRY AND PIGEON CHRONICLE.

THE DEVON BREED OF CATTLE.

(Continued from page 377.)

In their original districts Devons have been largely kept by the tenant farmers, clearly proving that they are a good rent-paying breed in the cold hilly portions of the grazing districts of the county, where weightier animals would have fared badly; and experience proves that they will flourish anywhere under judicious treatment. Having purchased them of different ages for feeding and fattening under cover for many years, we have found them to average 10s. per week increased value both in winter and summer, which, under moderate feeding—such as 64 lbs. of Mangolds per day, with 4 lbs. of linseed cake, and sweet straw *ad libitum*—yields a fair profit. In the summer time we always feed in the boxes with Trifolium first, then Clover (of each as much as they will eat), with 4 lbs. of linseed cake per day. This plan of summer-fattening answers particularly well with Devon cattle at from two and a half to three years of age, because we can cut

Clover two or three times instead of risking the making of Clover hay. In this way the consumption of an acre of Clover will make double the amount of meat than when converted into hay, with all the expenses of cutting, making, rick, thatching, and risk of damage through adverse weather. On farms where large quantities of straw are grown, the box manure arising from Clover and cake-fed animals is superior to any arising in the case of winter fattening of the animals. We do not, however, value this breed to raise on the system of early maturity or for making "baby beef," because the Herefords or Shorthorns being more "growthy" would surpass them; but as calves for suckling in the making of veal they make the highest quality of veal compared with any other variety of cattle. Probably, however, the polled Angus or Aberdeen breed would equal them if reared under the same system and for the same purpose, but having never tried it we cannot speak positively. Upon the above-named system of box-feeding we have won numerous prizes with Devon cattle in contests with Shorthorns at the local exhibitions.

In looking back to a period of some forty or fifty years ago it is thought by many, and we agree with them, the Devons generally were larger animals than we have now. That they were gay-headed, upstanding, useful stock, especially the dairy cows, no one can deny. At the same time it is asserted by some experienced breeders who can remember them that they were deficient in those extra rich symmetrical "gems" which have since won our Royal Agricultural prizes, and in that high quality, perfect symmetry, and depth of frame now to be met with in our best herds maintained for exhibition purposes. It was not uncommon in former days to allow heifers to attain, and sometimes to exceed, the age of four years before calving. Thus their growth was unchecked; but at present, partly from the necessity of bringing them into profit earlier, and partly from the difficulty sometimes occurring in breeding from older animals, they are allowed to calve at three, sometimes at two and a half years old. In the latter case, without great attention and good feeding, the frame will be smaller and the growth of the horn checked, depriving the animals of their otherwise grand and imposing appearance. It is, we consider, quite impossible for such immature creatures to stand this unnatural drain upon the constitution without damage, and probably if the practice be continued, as well as that of breeding largely by the service of very young bulls, the general hardihood of the race will become impaired and their size reduced.

Many reasons exist why Devon breeders are seldom exhibitors at Smithfield or Birmingham fat stock shows, for they know it is useless to send any but a perfect animal to either; and having such a great demand for bulls, the best, and in fact nearly all the bull calves, are reared for that purpose instead of being steered for fattening, and good cows are mostly bred from up to an age when they would be too old to exhibit. Besides this their farms are more adapted for breeding than for feeding purposes, with which system exhibiting at fat stock shows would seriously interfere.

We find that there is to be met with in South Devon quite a distinct variety called the South Hams breed, and they have probably at some time been crossed with the Guernsey. They are reported to be good milkers, possessing large frames and coarse bones; but as dairy stock they are preferred by tenant farmers to the high and well-bred Devon, as they are very hardy, capital milkers both in quantity and quality, and the off-going cows make heavy weights, especially when fed in the rich and fertile vales of South Devon.

We will again refer to the period before the Herd Book was established; for it is a fact that until a comparatively recent period the existence and reputation of the Devon breed was chiefly sustained by tenant farmers and yeomen who could not afford to give the almost fabulous prices which are paid for Shorthorns. Previous to the publication of the Herd Book breeders were accustomed to speak of their best animals by some distinguishing name, often that of the donor of a prize it had won, as, for instance, the bull Sillifant was so called after Mr. Sillifant, who first gave the prize for a yearling bull at Exeter, or it referred to any accidental circumstance connected with its career, thus enabling farmers of the locality to indicate and recognise any particular beast alluded to. Strangers, however, found this more difficult; therefore Captain Davy of Rose Ash (to whom we are indebted for much information in his essay), observing the deficiency, and thinking they deserved to have their pedigrees recorded, and that it would greatly assist the public in tracing out different types and blood, compiled and published the first volume of the "Devon Herd Book" in time for distribution at the Royal Agricultural Show at Windsor in 1851. It contained the entries of 132 bulls and 483 cows, alphabetically arranged, and

numbered separately for the purposes of distinction and reference. Among the earliest entries was Prize (108), calved about 1819, bred by Mr. Quartly, and sold to Mr. Childe of Kiolet; Forester (46), also bred by Mr. Quartly in 1827, and his great grandsire, bred by the late Mr. J. T. Davy of Rose Ash; Oxford (89), bred in 1836 by the late Mr. Wm. Davy of Flitton, who gained the first prize at the first Royal Agricultural Meeting at Oxford; Cambridge (12), and Sillifant also were well remembered. The fifth volume of the Herd Book, which brought up the number of bulls to 977, and the females to 3143, was published in 1869.

The traditions of Devon cattle breeders take us back to a very early period. For instance, the far-famed breeder, Mr. Quartly, who relinquished business in 1836, had a sale, and was succeeded by his nephew, Mr. John Quartly, at Great Champson, in Molland, with whom he resided until his death in 1856, aged ninety-two. Mr. John Quartly writes, "Great Champson, the farm I now rent of Sir N. W. Throgmorton, Bart., has been in the occupation of my forefathers, my uncle, and myself for 170 years, and the cattle, I believe, now on the farm are of the same breed as those at the beginning of that time. The late Prince Consort first established a herd of Devons in 1856 selected from those of Messrs. Turner, Farthing, Mogridge, and Quartly. The prize lists of the Royal, Smithfield, Birmingham, and other agricultural societies testify how judiciously the managers of that herd have bred animals combining the extra quality and symmetry of the North Devon with the size of the Somersetshire Devon. The Royal stock was first entered in the third volume of the Herd Book in 1859. The Davy family have bred choice Devons for the last 150 years; they know that John Davy, who died at Rose Ash in 1790, aged eighty-four years, always bred them. Many noblemen and gentlemen have patronised the Devon breed of cattle. In Dorsetshire Lord Portman selected a capital herd from Messrs. Davy, Tapp, Dee, Merson, and Quartly. Mr. J. A. Smith of Dorchester had a splendid herd of Devons when we visited his farm about thirty years ago; also Mr. E. Pope of Great Toller, Dorset, whose herd numbered many prizetakers, and other gentlemen too numerous to mention."

The first recorded exportation of pure-bred Devons to America took place in 1817. Mr. Patterson of Maryland, Mr. Peters of Atlanta, Georgia, tried Shorthorns and Devons, but sold the former, finding the latter better suited to warm climates. Mr. Wainwright of Rhinebeck, New York, was a pupil of Mr. Turner at Barton, near Exeter, and purchased of him some of his prize-winning stock at the Royal and other shows, and subsequently with the offspring of these purchases gained high honours at New York shows. We have more than once laid stress on the marked improvement in quality, symmetry of the large-framed Somerset Devons produced by the use of the neatest North Devon bulls, and this view of the question is borne out by the late Mr. Henry Cline in his "Observations on the Breeding and Form of Domesticated Animals." He says, "When the male is much larger than the female the offspring is generally of an imperfect form. If the female be proportionally larger than the male the offspring is of an improved form. The proper method of improving the form of animals consists in selecting a well-formed female proportionally larger than the male. The improvement depends on this principle, that the power of the female to supply her offspring with nourishment is in proportion to her size, and to the power of nourishing herself from the excellence of her constitution." As we have thus traced the Devon breed from the earliest times when their existence was scarcely known beyond the then remote county from which they derive their name, we must notice the great advantage breeders of present day possess in having animals to breed from possessing such a long pedigree formed and maintained by a succession of intelligent and persevering men, who are not slow in availing themselves of the advantage, and now appear on the prize lists of Smithfield, Birmingham, &c., with splendid Devon bullocks—Mr. Bult, Mr. Kidner, and others, who do honour to themselves and benefit the consumers of meat throughout the kingdom.

WORK ON THE HOME FARM.

Horse Labour.—We suppose the winter Beans, Rye, Trifolium, and Vetches have been sown in good time; but in the event of failure of the plant of Trifolium it is not too late to sow again at the present time a larger quantity of seed per acre, not less than 30 lbs., upon a fresh piece of land, and if on a fallow surface so much the better, because the young plants are not so likely to be destroyed by the slugs as when the seed is sown upon a Wheat stubble, or whereon these pests have been able to maintain themselves until the present time. It will now be time to commence seeding the land for Wheat even in the vale districts of the kingdom; for on the hills or cold soils in the various counties we will suppose that the Wheat land has been for the most seeded before this time. If, however, the weather

is favourable for ploughing and drilling, there is no better time than during the next week or ten days from this date. If from unavoidable circumstances the seeding of Wheat should be delayed into the month of November, the home farmer should be prepared to do the work daily, so as not to trust the weather, for it is seldom that we obtain an opportunity to sow the seed in good condition at that time unless the ploughing, drilling the seed, and finishing the work is done simultaneously. This is the only way to be sure of a season, for it must be remembered that the English climate in November is either wet or frosty in the morning, both of which interferes very much with the work of seeding, whereas if sufficient horse power is judiciously employed in finishing off the work as fast as the seed is drilled, if rain sets in at any time of the day, the work done is secure against variations of the weather afterwards. The weather is now too uncertain for undertaking such work as threshing corn ricks in the fields, therefore when the horses cannot be doing day work connected with the Wheat season the winter fallow-ploughing may be done at odd times. The odd horse or mule will now have plenty of jobbing work to do, such as carting roots for the cattle in their boxes, hurdles and hay for the shepherd, also bay roots and straw for litter for the cart horses, straw for littering the pig pens, dairy-cow stalls, and cattle sheds as night lair for the calves and yearlings. We know farms where mules are kept to do the odd work, and they answer better than horses for all jobbing work on the farm all the year through, including hoeing the root and corn crops by the use of the horse hoe, it is found that the day is never too long for them when well fed. They are not subject to diseases like horses, are very long-lived, frequently outliving the home farmer, himself, but it is necessary to obtain an animal of the largest kind, which are costly, and cannot be bought for less than a cart horse of a good stamp and size. We hear a shipload is coming from Egypt of 350 animals; they would all find ready buyers if thousands were brought to this country of the right sort and size.

Hand Labour.—The heaping and storing of many Carrots and Swedes will now be going on, also the cutting and carting of border grass, seaside sedge, river sedge, and rough coarse grass in the plantations; also the collection of seaweed in the seacoast districts. All of these materials are extremely useful in the storing of roots, also in saving straw, an article now improving in value annually, especially in the grazing districts and in the immediate neighbourhood of large towns. Nor is this a matter of surprise when we know that nearly every tradesman now keeps a horse or horses connected with their advertising vans; in fact, the use of straw for feeding cattle is beginning to be better understood either as a substitute or in connection with hay for horses, hence it will answer better in the future to grow long-strawed crops of corn, as well as growing full crops by generous and liberal manuring. Labourers will now be required in the woodlands and hedgerows for cutting and making the hazel into hurdles and wattles, also the cutting and felling of Ash and Elm timber will be going on. The planting of Larch and other trees may now be provided for by cultivating and preparing the land, setting the young plants; and where the plantations have arrived at a size which make them valuable for the purposes intended, such as Hop poles and railway sleepers, they may now be cut and cleared, and the land either brought into cultivation for other purposes, or otherwise, as we have done on some properties planted the land again only by grubbing and planting between the old stools without removing them, as their removal is attended with heavy expenses in the absence of steam power. We can point now to plantations of Larch of splendid growth, for the old stools soon decay without injuring the growth of the young plants of succession.

The water meadows will be now, or shortly, in flood, and will require the constant attention of the drowners. Low flat-lying meadows should now be free of the cattle and the trenches taken out with care, and thus remain during the winter months whether they are to be grazed or cut for hay in the following year, for the herbage will be improved in quality by preventing all stagnant water from lying upon the surface of any grass land. Men will now be daily required in making out the water furrows upon the cold soils after the Wheat is sown; and it is important, too, that the land furrows between the ridges should be struck out with the double mould-board plough instead of the ordinary plough, which throws up the crumbs of earth from the furrow on one side only. Men will also be carefully employed in steeping the sown Wheat to prevent smut, &c., and we know no better material than Down's Farmers' Friend for the purpose, as it gives but little trouble, and with full directions for use but few mistakes can be made by the most ignorant workmen.

Live Stock.—The young sheep and wethers now feeding on roots will require cake in admixture with the cut roots. Some persons object to the cutting of common Turnips, but we prefer to do so always, as it is little trouble to prepare them for the cutter, and at the same time the waste is less than when eaten on the land; and this together with the advantage of mixing meal with the roots, and the animals having more time to lie down, makes it the most profitable method of management in open field feeding. In the southern and home counties where the horned Dorset and Somerset ewes are kept for producing early lambs for the metropolitan market they have commenced lambing and are yeaving numerous twins, and although they are very high in price, yet they will with high feeding and careful shepherding pay more than any other ewes, either Downs or cross-breeds, because they can be all sold off, both ewes and lambs, in first-

rate condition by Easter. These ewes as fast as they drop their lambs should have the best grass, such as young Clovers and Italian Rye Grass, with a dry night lair and some white heart Cabbages cut and mixed with linseed cake meal in the troughs. By this style of feeding the ewes will keep their twin lambs and themselves also in first-rate condition until they go with their lambs on to root-feeding. The manner of feeding from that time we will direct on another occasion. There are many half-fat bullocks forced on the markets now, and this is home farmer's opportunity to buy them for finishing off in the boxes; this has always been a favourite plan of ours, which we have found to answer a good purpose.

ILLUSTRATED BRITISH BALLADS.—Parts 17, 18, 19, and 20 of this work, now being issued by Messrs. Cassell, Petter & Galpin, contain some well-selected ballads, beautifully illustrated, and amongst them the following are noteworthy:—Browning's "Pied Piper of Hamelin," Peacock's "Pool of the Diving Friar," Praed's "Quince" and "The Red Fisherman," Kingsley's "Red King," Manson's "Robert the Bruce," "Robin Hood," and "Guy of Gisborne," with several others relating to Robin Hood; Davis's "Sack of Baltimore," Wordsworth's "Seven Sisters," "Sir Andrew Barton" from the Percy "Reliques," and Hogg's "Sir David Graeme."

POULTRY AND PIGEONS

BANTAM NOTES.

THERE is evidence that the Bantam fancy was the earliest phase of poultry-fancying in this country. Long before poultry were carefully bred up to ideal standards, and long before open poultry shows were dreamt of, there were private Bantam clubs in some districts, like columbarian clubs then and now-a-days, where rival fanciers met, compared notes, and showed the results of their breeding. Bantams, as we have often pointed out, are a suitable hobby for many who could not possibly keep Geese and Turkeys, or Brahmas and Dorkings. Nearly all the objections which occupants of small premises make to poultry in general are pointless in the case of these pigmies. They live where no other fowls could live, and thrive and luxuriate where others would pine. We are, therefore, very glad to see that the Bantam Club formed to breed and improve them is making some progress. Years ago an attempt was made at the Crystal Palace to establish a show of Bantams and Game birds in the spring. One pretty show was held, but it was not sufficiently successful to be repeated. Since then we have never seen anything like a prize list sufficiently complete to be any real encouragement to Bantam breeders till that of the forthcoming Kendal Show reached us this week. The Bantam Club has, we believe, for some time subvented such shows as have given a promise to give good classification to miniature fowls. Now for the first time it purposes to hold a special show of Bantams at Kendal in connection with the general poultry show there. The classes, twenty-eight in number, as follows, seem to us admirably arranged:—

They are: Game Bantams.—1, any variety cock over one year; 2, Black-breasted Red cockerel; 3, Brown-breasted Red cockerel; 4, Duckwing cockerel; 5, Pile cockerel; 6, any variety hen over one year; 7, Black-breasted Red pullet; 8, Brown-breasted Red pullet; 9, Duckwing pullet; 10, Pile pullet; 11, selling class, cock or cockerel; 12, selling class, hen or pullet. Bantams (other than Game).—13, Black or White Rose-combed cock or cockerel; 14, Golden Sebright ditto; 15, Silver Sebright ditto; 16, Japanese ditto; 17, Cuckoo or Scotch Grey ditto; 18, Booted (any colour) ditto; 19, any other distinct variety ditto; 20, Black or White Rose-combed, hen or pullet; 21, Golden Sebright ditto; 22, Silver Sebright ditto; 23, Japanese (any colour) ditto; 24, Cuckoo or Scotch Grey ditto; 25, Booted (any colour) ditto; 26, any other distinct variety ditto; 27, selling class, any variety cock or cockerel; 28, selling class, any variety hen or pullet.

Such a prize list as this gives an opportunity to many who have hitherto shunned exhibitions, especially the hazard of variety classes, to learn the comparative worth of their little birds and to enter them for a fair trial. It is not uninteresting to compare this comprehensive list with the catalogues of Bantams given in poultry books published years ago. Writing in 1850 Dixon enumerates Nankins, Partridge Bantams, Gold-laced and Silver-laced Sebrights, Black and White Rose-combed, Feather-legged, and Creepers or Jumpers. We fancy that he confused the old Gold and Silver-spangled with Partridge, as he describes them "almost miniatures of the Golden Hamburg fowls, both Pencilled and Spangled." We can remember the former, now we fear extinct, as extremely pretty birds. We fancy they were much used in the manufacture

of Sebrights. We have always believed Partridge to be nearly akin to Nankins, if not darker specimens of the same breed.

The list given by Wingfield and Johnson in 1853 differs little from Dixon's. It includes the Nankin Bantam, the Game Bantam, the Spangled Bantam, the Sebright Bantam, the Partridge ditto, the Black ditto, the White ditto, Creepers and Jumpers. It will thus be seen that Game Bantams, since so popular, were then newly produced and unknown three years before to a fancier of much research.

The lists, however, alike of poultry books and poultry shows, are surpassed by a private collection actually in existence. About a year ago we described the great Knighton establishment, its multitudinous birds, and their wonderful abodes. We have had the great pleasure of revisiting it, and took notes of the distinct varieties of Bantams which it now contains.

They are:—Game—1, Black Red; 2, Brown Red; 3, Piles; 4, Duckwing; 5, Birchen Duckwing; 6, White; 7, Wheaten. Other than Game—8, Black Rose-combed; 9, White ditto; 10, Nankin; 11, Silver Sebright; 12, Golden ditto; 13, Cuckoo (Rose-combed); 14, Scotch Grey; 15, White Japanese; 16, Dark ditto; 17, Buff ditto; 18, White Booted; 19, Black ditto; 20, Red or Partridge Tailless; 21, Speckled ditto; 22, White Booted ditto; 23, Red Booted ditto; 24, Speckled Booted ditto; 25, Black Frizzled; 26, Brown ditto (singled-combed); 27, ditto ditto (Rose-combed).

Besides these almost of Bantam size are—28, Japanese Silkies, white, dark-combed; 29, Japanese Silkies, red-combed; 30, Coloured Silkies; 31, White Frizzled; 32, Pile Frizzled, not to mention innumerable little birds of crossed breed, some of them approaching to new and distinct varieties. Pekins alone are absent from the exhaustive list.

It will be interesting to see what novelties this forthcoming Show brings forth. We have heard vague rumours of Polish Bantams in America and Brahma-Bantams in England. Every strain of Bantams must have had a beginning either through natural or artificial selection. We can see no reason why other liliputian families should not appear. Every fancier who possesses peculiar Bantams should contribute to the success of the Kendal Show, and yet after all we doubt if such variety can be there collected as we have just enumerated as flourishing in the Knighton aviaries.—C.

POULTRY NOTES AT WOLVERHAMPTON SHOW.

THE Oxford Show, which for many years has taken a leading position amongst the autumn chicken shows, having unfortunately become extinct, the Wolverhampton Committee wisely decided to alter their date to that of the old Oxford meeting, and to alter their schedule accordingly. This resulted in an entry of some 650 pens in fifty-eight classes, and the result would probably have been better, but that the date of Dorchester Show unfortunately clashed. This, we understand, will be avoided another year, and we have every hope that Wolverhampton will in a great measure fill the void caused by the extinction of Oxford. The schedule opened with the Game classes. The numbers here were pretty good, and the general quality above the average. Mr. W. Foster won the cup with a Black Red cockerel, which might well be selected as a typical bird except for a slight defect of colour in his under parts. The same gentleman stood first with a very good Black Red pullet. Mr. R. W. Warner and Mr. A. G. Potter also took first honours for a Brown Red and a Duckwing cockerel respectively, while Mr. Brierly was first in the Brown Red pullet class with a very smart bird in grand condition.

In Dark Brahma cockerels we could not agree with the awards. First and cup went to Sir Henry Thompson for, as we think, the Dairy Show third-prize bird. Sir Henry Thompson's other bird (62) was quite out of condition, and necessarily passed over, and the winner showed signs of overwork. He is too long in leg, and has not the true Brahma shape. Second far too long in back and lanky; third the Dairy Show second, not looking so well; fourth a grand body, but foul-coloured on shoulder, which should have thrown him out. We liked Mr. Fryer Bennet's very highly commended bird best in the class. He showed some white on breast and foot, but was a grand Brahma. The same exhibitor's other two birds hardly got their due either in a class which though large was by no means a good one. Pullets numbered thirty-six, and were a much better class. The winner (R. Holland) was large, shapely, and well feathered, colour and marking even throughout, but the latter wanting distinctness. She had also an old look, which should have made us hesitate to include her in the list. Second large and fairly marked, but showing a rich chestnut shade on parts; third held the same position at the Dairy Show, and might have gone higher here; fourth (Pritchard), and another pullet of the same exhibitor's, were the best in marking throughout, but much wanted shank and foot feather; v.h.c. (Henshall) one of the best in the class, though rather dull in colour. Light cockerels were not so numerous as the Dark, but better in quality. The winner (G. H. Wood) was, we think, the bird we liked at the

Dairy Show, and improved since then; second (Mrs. Holmes) very shapely and short in leg, but wants distinctness of stripe in hackle; third (While) we thought a mistake, as though shapely he much wanted size. The Dairy Show winner was here only v.h.c., which was less than his due. In pullets the Dairy Show winner added another to her victories by taking the cup; second going to Mr. Lucas for a pullet whose hackle was beautifully distinct in marking; third (While) and fourth (Mitchell) were also in the Islington list.

Cochins were good classes, and we were pleased to see that in many cases our comments on the Dairy Show awards were justified here. The cup Buff cockerel there here went down to third, and Mr. Proctor's seconds there deservedly headed the list in each class. Second for cockerels went to a large even-coloured bird shown by Mr. Stretch, a similar honour for pullets going to Mrs. Davidson for a broad shapely pullet poor in foot feather. Partridge cockerels were only a moderate lot. The winner (Mrs. Turner) is promising, though hardly ready yet. The winning pullet was Mr. Southern's beautifully marked bird which we selected at Islington. Mr. Darby took first with a Black cockerel of exceptional merit and in splendid condition. The same exhibitor's winning pullet was shapely but wanted gloss. In Whites Mr. Chase took the lead; his cockerels were hardly yet at their best, but his winning pullet was splendid in size and shape, though hardly so pure in colour as we could wish.

Dorkings were hardly so numerous as at Islington. In Coloured cockerels first (Smyth) was large and good in most points. His lobe was white, but the Judge, perhaps rightly, does not seem to regard this as a demerit. Second (Gardon) was dark and of good size. Mr. Cranston was third in cockerels and first in pullets with good birds, and the same exhibitor also stood first in Silver-Greys, which were a good class.

Spanish were small classes. First in cockerels (Brown) was the Islington third, which we much admired there. The first pullet (Aldridge) had a large face, though inferior in quality to second (Brown), doubtless thrown out through want of condition.

Houdans were good classes, the first cockerel (Thomas) and the first pullet (Jennings) being both good all-round birds. Plymouth Rocks were good classes. The winners were rather dark in foot and beak for our taste. Minorcas and Leghorns were good though not numerous classes, and the same remark applies to Polands. Andalusians were stronger in number, and Mr. Boissier here repeated his Dairy Show victory. Hamburgs were few though fairly good in quality, and most of the prizes went to the usual winners. Bantams had a liberal classification, and were well represented. The winning Pekin Ducks (Kellock) were especially fine in size, shape, and colour. In the variety poultry class Malays were first and third, and Crève Cœurs second and fourth.

The Judges were Messrs. O. E. Cresswell, J. Dixon, J. H. Smith, and Captain Heaton.

OUR LETTER BOX.

Canker in Pigeons (T. W.).—You hardly give sufficient information to enable us to advise you. Try the following remedy: Mix carbolic acid one part with glycerine eight parts. Scrape away with a knife the secretion on the diseased part, and apply the above mixture by means of a camel-hair pencil to the affected parts. Be careful not to let the acid touch the eyes. If your birds are of a small variety decrease the strength of the solution one-half for application inside the mouth.

Turnips and Frost (C. O. E.).—You have been rightly informed that large Turnips which have ceased growing are more liable to be injured by frost than smaller and later-sown examples that are yet in active growth. You had consequently better use the larger first, and not leave them till the last as you appear inclined to do.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

15th.—Fair, but very dull and cool; rain after 9 P.M.

16th.—Wet all day.

17th.—Damp and drizzly day, fine evening.

18th.—Dull hazy morning, fog in latter part of afternoon and in evening.

19th.—Cloudy dull day, rain after 4 P.M.

20th.—Fog early, fine pleasant morning, showery afternoon.

21st.—Wet all day and all night.

A wet week. Temperature about the average, but 5° below that of the preceding week.—G. J. SYMONS.

RENEWING AND INCREASING HARDY HERBACEOUS PLANTS.

IT is too commonly thought that all the care necessary for a border of hardy herbaceous plants is to plant them and leave them alone. This is considered by many to be the chief recommendation of these plants, as when once planted they require no labour in cultivation. It is quite true that by the use of hardy plants a gay garden may be had for ten months in the year at a far less expense than where a large number of tender plants are used; still, hardy plants will not do well without constant attention from the owner or his gardener. The work required may be divided into four parts—first, increasing and renewing the plants; second, renewing and dressing the soil; third, keeping it clear of weeds; fourth, tying up. The third and fourth items will suggest themselves to everyone, and little need be said about them. The mode of carrying out the second must depend partly on the nature of the soil, partly on the materials at disposal; but I propose here to make a few general remarks on the first.

For increasing and renovating stock October is, perhaps, the most important month in the year. Perhaps some may say, "I do not want to increase my stock, as I prefer large plants to small, and have already plants enough." Still, there are very few plants which will continue to flower in their best style if left alone for several years, and most hardy plants require dividing or renewing every two or three years or they degenerate. This is recognised in the case of spring gardens, the plants for which are more generally cultivated than the later-flowering perennials. Gardeners divide and replant, or grow fresh from seed, their Daisies, their Forget-me-nots, their Pansies and Aubrietias, or they do not expect them to do well; and the same ought to be done with Phloxes, Michaelmas Daisies, and similar plants. Some gardeners recommend entirely renewing and replanting a border once in three or four years; but I think this a very bad plan. Hardy plants in a mixed border do not all reach the stage at which renewal is desirable or necessary in the same time. There will always be many plants, such as Lilies and other bulbs, which are better left alone, and a border generally looks untidy the first year after such a renewal. Sometimes the encroachments of weedy plants, like the Japanese Anemones, may render a clean sweep necessary, but it is far better to assign to such plants their proper bounds and to confine them within these. I never dig my mixed borders, and venture to say that they never ought to require digging. Every time a plant is placed in the border

the soil is dug, and, if necessary, renewed round it, but no general digging is allowed.

Some store beds, more or less according to the size of the garden, are necessary, and in these a constant succession of young plants must be kept to replace those which are past their best. As for the frequency with which each plant is to be renewed, it is impossible to give any general rule. Not only must the habits of each plant be studied and watched, but the kind of soil makes a very great difference. Generally plants increase and arrive at their best, and degenerate and wear out themselves or the soil, far quicker in a moist and rich soil than in a dry and poor one; and plants, which in my garden cannot continue to flower well for three years if left to grow, will go on without any deterioration in a lighter soil for more than twice that time.

Let us begin with Phloxes. Those who grow them as florist flowers give special rules for their cultivation, which are, perhaps, too troublesome to follow for those who only grow them for mixed-border decoration; but we all wish to have what we grow as fine as we can, and Phloxes may be kept fine with very little trouble. Unless spring cuttings brought on under glass are grown the rooted side shoots taken off in September make the best plants; but if none of these is to be found, divide the plants in October and select a single well-rooted thin stalk with four or five shoots. These may be planted as close as convenient in a store bed for a year. Phloxes are so hardy that they may be transplanted any time during the winter. When you have the time dig up as many old and crowded plants as you have new year-old plants to replace. It is better not to put them in the same spot in which a plant of the same kind has already grown, unless the soil is renewed; but do not enrich it too much for Phloxes. I used to think they liked plenty of manure, but they became so succulent and sappy that the bark of the stalk would split. A top-dressing when they come into bud is the best way of manuring them. I advise that one-third of the Phloxes in the borders should be annually renewed. The finest heads of flowers are generally on the two-year-old plants.

Asters require the same treatment, except that amongst the many scores of varieties there are some weak and slow growers, which experience will discover. Others increase so fast that if not annually divided they over-run the border, and even some of the best kinds are amongst these rapid growers. These do not require any nursery bed to rear them, but may be divided and replanted at once, pulling the stalks asunder in October, and replanting one or two stalks according to the number of shoots they bear; but by all means let the soil be dressed. Friends give me Asters which in a year's time they cannot recognise from their increased size and improved appearance, because I give them real cultivation, which they have never done. Few plants respond to liberal treatment and attention better than perennial Asters.

The Monarda is a plant which is accustomed to die quite out if left alone, and yet a piece the size of a square foot is enough to fill a garden in a year if properly treated. A small rooted piece with three or four shoots planted in rich new soil in October will make a grand show in the following July.

Spiræas are the easiest of all plants to divide, as they may be cut with a spade into well-rooted clumps and never seem to feel the operation; but such plants as the double S. Ulmaria

(common Meadow Sweet), if left alone, become after two years so hopelessly clubbed as to produce nothing but mildewed stalks.

No plant after being divided and replanted is worse for a top-dressing of leaf soil. Upon some the effect of it in promoting vigorous growth is surprising. A few years ago, when the Japanese Anemones were not so common as now, and I wished to increase them, I covered their crowns in autumn with 2 or 3 inches of leaf soil a year old. I soon had them to give away by the sackful.

I have spoken of plants which are the easiest to divide, and which are divided more to protect them from overgrowth than to make new stock. Choice plants which it is desired to increase should generally be divided earlier in autumn. The worst time to divide a choice plant is when it is at rest, and the best time in most cases is before its leaves begin to show signs of turning. *Anemone narcissiflora*, *Jeffersonia diphylla*, and some of the choicer *Geraniums*, must be cut with a knife; but if green leaves and a piece of hard rootstock can be given to each division I find they will always grow without any recourse to flower pots, frames, or handlights. Coconut fibre and leaf soil mixed in the compost, shelter from sun, and regular watering, will generally ensure success. I repeat that different treatment suits different plants, and it must be found by experience what this treatment is.

Few things in gardening are more important than knowing how to increase plants. When I get a new plant I am never satisfied till I have found out how I can make two of it, and I have seldom failed. Of course there are many biennials and some perennials which are more easily and conveniently raised from seed than in any other way, and nothing need be said about the propagation of plants of this kind.—C. W. DOD.

SELECT PEAS.

IN making a few observations on varieties of Peas grown here during the past summer I will for simplicity arrange them in three classes—early, medium, and late.

Day's Early Sunrise, William I., American Wonder, Laxton's Alpha, Maclean's Little Gem, Dickson's First and Best, and Suttons' Emerald Gem were the early varieties selected for trial. The last-named variety has not been very satisfactory during a four-years trial. Alpha, First and Best, and Little Gem are tried varieties; the latter is very good in flavour for an early Pea. William I., though perhaps not so early by a day or two as some already named, is superior in flavour, and such an abundant cropper that it is entitled to rank amongst the best of early Peas. Day's Early Sunrise sown and gathered on the same day as Alpha grew 5 feet high, and produced at least one-half more Peas of decidedly superior flavour to that variety. American Wonder was undoubtedly the earliest Pea grown here. It has large well-filled pods of excellent flavour; it is, however, very dwarf, and is perhaps better adapted for pots. While it is difficult to say with certainty what is really the best, were I confined to one early Pea I should choose Day's Early Sunrise.

Having a desire to test which really were the best, a larger number of varieties of main-crop Peas than usual were grown, and in naming them I will simply notice what I have proved to be good. G. F. Wilson is a well-known Pea of excellent flavour; Electric Light, an abundant cropper; President Garfield, equal to the above as a cropper, superior in flavour, and likely to become a favourite; Dr. Maclean, one of the best; Maclean's Best of all is another very good Pea.

Telephone and Telegraph were grown side by side. The difference between them is not sufficiently great that they need both be grown in one garden. I prefer Telephone—it is in my opinion one of the very best if not the best Pea that has ever been sent out; Stratagem for quality and exhibiting is the best Pea I know, but it is not so bountiful a cropper as Telephone. The following were also grown:—Laxton's Supreme, Edinburgh Beauty, Dean's Dwarf Marrow, Kinver Marrow, and John Bull.

The late Peas were Veitch's Perfection, a good old sort, rather subject to mildew here. Walker's Perpetual Bearer is a new Pea of branching habit, a good cropper of great merit, and likely to be further heard of. Culverwell's Autumn Giant Marrow was raised, as the name indicates, by Mr. Culverwell, at Thorpe Perrow, and is, I believe, considered by him to be the best Pea he has raised. It grows here to a height of 8 feet, is a heavy cropper. Many pods on our plants this season had eleven and twelve large-sized peas. It is excellent in quality, but with us it

requires longer time to fill than any Pea I have tried; it does not commence bearing early. It was said to be a good exhibition Pea, but is not likely to win in the company of Stratagem or Telephone. Yorkshire Gem is a good late Pea, and so far has proved free from mildew. Omega is another excellent Pea, far too little grown; this is one of the best flavoured Peas I know. Ne Plus Ultra only needs to be named, being perhaps the best of our late Peas. The Prince is the hardiest and latest Pea, but is not easily obtained true to name.

While it is difficult to make a selection, as Peas do well on some soils and not on others, I would venture to submit six varieties that I feel sure would disappoint no one—Day's Early Sunrise, Telephone, Stratagem, Omega, Veitch's Perfection, and Ne Plus Ultra.—J. S., *Darlington*.

PLANTING ROSES IN AUTUMN.

WE have witnessed many revolutions in the culture of the Rose. We have, for instance, come to almost discard the standard (by this I mean those who really regard themselves as rosarians) for the dwarf. There will be always a number of persons who will grow standard Roses; but Rose-growers have come to regard the standard as ugly, expensive, and liable to be injured by frost to a far greater extent than the dwarf. We have come again to regard the Tea Rose as not nearly so delicate as we used to think. We have also to a great extent come to think hard pruning to be the proper way to treat the Rose, and instead of trussing to obtain symmetrical bushes, to cut down to within a couple of eyes of the root, and to depend on the strong shoots that are thrown up instead of the shoots of last year pruned back; and even in the case of Teas we have come to think that is the better plan. It used to be said, Merely shorten the tips; but personally I can bear witness to the fact that of two beds, one of which was treated on the old plan and the other pruned hard, that the latter were more satisfactory than the former and gave a larger quantity of bloom and for a longer time.

We now come to a matter which has, I think, to be ventilated, and that is whether the autumn is the best time for planting Roses; and I am induced to set the ball a-going in the hope that some of our experienced, and I may add scientific, growers will take it up. The question has suggested itself to me for two reasons. A discussion has been going on in the columns of a contemporary, originated by Mr. D. T. Fish, as to "Root-Disturbance in Autumn," and the pros and cons have been very ably stated; the one side maintaining that there is little root-action in autumn, that the ground is cold and wet and does not foster the growth of roots, and that consequently it is better not to disturb Roses then, and that they should be left alone; the other defending the practice, the former I think having decidedly the best of it. If this statement be correct it must surely have a great effect upon the present practice of planting out Roses now. There seems to be a good deal of reason in it, especially after such a season as this, when so much rain has fallen. The ground is sodden, wet, and cold—(perhaps our friend Mr. Mawley would tell us what the ground temperature a foot below the surface is)—and can be hardly conducive to the formation of roots. How would it, then, answer to get your Roses in from the nurserymen as usual and lay them in until February, get the beds all ready for planting, and then leave them until that time? It would be far easier to cover the Roses and protect them from injury by frost; and let it be remembered, too, that in other plants a change as great as this has been made. We used to be told to transplant Laurels, Hollies, and all evergreen shrubs and trees in autumn; but now the practice is altogether changed, and we are told that August is the best time for transplanting them. This is one reason for my asking the question. Another is, that when I was admiring some of those boxes of lovely Teas exhibited by Mr. Prince, he said to me, "Those are from plants that were only planted this spring, and which were in truth the refuse of my sales." Now if this is the result of spring planting of Teas, why not of Hybrid Perpetuals? I can see no reason why it should not be so, and I am quite sure if the practice proved to be sound it would be a great boon to many of us. It is disheartening to plant a new bed and then to find that there are gaps in it which we are inclined to attribute to the frost, or perhaps to the original badness of the plant, when it may have been that the coldness and damp of the ground had checked all root-growth and made the plant more liable to injury.

I perhaps need hardly add that I do not write as a botanist. My vegetable physiology may be all wrong; but I am by no means discouraged by this, for I have ever found that on most scientific subjects there are two sides. We get the most elaborate and convincing arguments in the high *ex cathedra* style, and we are in our ignorance inclined to say this must surely be right; but, lo!

"his neighbour cometh and searcheth him out." We get the most convincing arguments that A was all wrong, and that when B propounds the very opposite he equally avers that he only is right. One man says Nature is immoveable in her laws, and that all we have to do is to observe and give heed to them, as there can be no exceptions. Then comes out another who says that there is no law of physics, not even the law of gravitation, without great and growing exceptions, "and that, therefore, the boasted accuracy and permanency of so-called physical laws and theories is unfounded."—(Dr. Andrew Clarke.) To me, therefore, experience would be much more satisfactory than theory, and one such fact as that I have recorded in Mr. Prince's experience is worth a bushel basket of theory. But let all have their say, and I am very much mistaken if most valuable matter may not be obtained on a subject which I cannot but think is of considerable importance.—D., Deal.

ALNWICK SEEDLING GRAPE.

I HAVE sent you a bunch of Alnwick Seedling Grapes, together with a small piece of Gros Maroc and Alicante, grown in the same house under the same conditions. My experience, which is limited to one Vine of the first-named variety, is so very opposite to that recorded in the Journal of the 19th ult. that I will briefly state what I have to note.

This Vine of Alnwick Seedling was planted in March, 1880. I did not attempt to fruit it the first season, but expected to have a few good bunches the second year. Hearing of its shy-setting character I attempted to fertilise it, but failed. The house is a span, running north and south; it is 50 feet long, 20 feet wide, with one row of 4-inch piping all round. This spring, thinking an additional rod would help the Vine, I let a young cane extend 16 feet. To-day I measured it, and find it 2 inches in circumference—a very good serviceable rod. The Vine showed bunches well at every lateral; I pinched all off but ten, and when they should have been in flower I tried fertilising with pollen from Lady Downe's and Black Prince, but failed; nor do I see how the pollen is to reach the pistil, owing to a mass of jelly-like substance which covers it. I also left some bunches of the second crop, which were freely produced, but these did not set, as I had no pollen from another variety to apply; but I noticed very particularly there was the same fault as I note above. I was so disappointed that I cut the second crop as soon as they were past setting. I left some of the first crop—half a dozen bunches, the same as I send you, just to see what they would come to. You will note by the pieces of the two other varieties that the house will grow Grapes. Lady Downe's in this house does not do at all well, taking the Alicante as a standard.

My opinion of the Alnwick Seedling is that it requires more heat; still, as I did not use the Alicante pollen I should very much like to hear what other correspondents may say on this point. I have selected a position in the Muscat house for this Vine, but as this has now two large rods I feel reluctant to move it. Believing there was a deficiency of lime in the soil I specially selected this as a test plant with Alicante; the latter benefited very much by a heavy application of lime, but none was given to the Gros Maroc. I have seen one Vine of the Alnwick Seedling in this neighbourhood, and this was very little better than my own. The foliage of this is very beautiful now.—STEPHEN CASTLE, *West Lynn, Norfolk.*

[The bunch of Alnwick Seedling is a very good one, but only half a dozen berries attained their full size, some two hundred others resembling Black Currants. In this Grape, like the Morocco and the Muscat of Alexandria, the stigma has a tendency to exude a globule of liquid, which so effectually protects its tissue from the influence of the pollen that the ovary is not fertilised. This liquid exudation must be dissipated by agitating the Vine, or gently drawing the hand down the bunches, before pollen can effectually come in contact with the stigma. The exudation referred to is usually greatest in a low temperature, and we question if sufficient provision has been made for affording the requisite temperature for either this Grape or Lady Downe's without overheating the pipes. The Alicantes are very good in appearance, but would have been better in quality with more heat; and the berries of Gros Maroc are very fine, but not well coloured, nor so good in quality as we have frequently tasted this Grape. Lime would probably benefit this Vine, and more heat improve them all. We do not consider one row of pipes sufficient in such a house for growing late Grapes.]

FLOWERS IN AUTUMN.—Now that autumn has come, and with it the various-tinted leaves, we still have a few of the old-fashioned favourites in our borders to cheer us. *Anchusa italica* is still in full

beauty; its lovely blue flowers have a fine effect. *Centropus gracilis*, with bright orange ray florets and a black centre, is one of the finest of our late-flowering plants. *Jasminum nudiflorum* near a wall is beginning to unfold its yellow blossoms, and will afford us a display through the winter. *Erinus alpinus*, a lovely edging plant, is still in full beauty, and likely to be for a length of time invaluable for rockeries and edging. I prefer the rose-coloured to the white variety, but they are both beautiful. *Helianthus diffusus* and *H. multiflorus* are doing good service. *Delphinium cashmerianum* is a useful autumn flower from seeds sown in early spring, grown on in pots, and planted out in summer. Varieties of *D. consolida* of many colours are now very beautiful. *Salvia patens* is making a fine display. Then the charming *Aster elegans*, *A. Tradescanti*, *A. dumosus*, *A. trifolius*, and hosts of others, are charming. *Erysimum pulchellum* is commencing to flower; its pretty sulphur-coloured blooms are very pleasing. *Aubrietia deltoidea* will be in full bloom in a week or two, and will continue through the winter. The two varieties of *Rosa Lawrenceana*, used as an edging, are giving us a fine display of their lovely flowers; they deserve extensive cultivation. Another old favourite that I cannot dispense with is *Rosa semperflorens*, always welcome. *Primula farinosa* seems to have made a mistake; it is flowering now, and is very beautiful. I use it as an edging plant in the spring garden. The double sulphur-coloured Primroses are coming into bloom. The Alpine Auriculas are also throwing up their trusses, and some have already opened their flowers.—NORTH YORK.

THE GREENHOUSE AND ITS INMATES.

POPULAR FLOWERING PLANTS.

IN the enumeration of species and varieties suitable for cultivation in small greenhouses I have endeavoured to include only those which may be truly termed popular. Large numbers of plants suitable for greenhouses are in cultivation, and it would be an easy task to fill a volume with their names and the cultural requirements of each; but it is not so easy to write a short treatise such as this is, for it is difficult to decide which should be omitted and which included: but the following selection includes most of the plants suitable for an amateur cultivator. At the same time there are many others to choose from, although their claims have been set aside for the present.

ABUTILONS.

These are showy easily grown plants. They may be raised either from cuttings or seeds. Cuttings strike readily at any season of the year when there is heat enough to keep the plants growing, and seeds should be sown in spring. Possibly the best time to insert cuttings is about the month of August. If this is done the cuttings will root and be established before winter comes, and the plants will be ready for potting in spring, when they will commence growing, and flower as long as growth is maintained. Varieties do not come true from seed, but new kinds are raised in that way.

Abutilons grow very freely, and are by no means particular as regards soil. Ordinary loam with a little decayed manure and a sprinkling of sand suits them admirably. They may be grown as climbers or into large plants by shifting on and pinching and staking as may be needed. After the pots are full of roots liquid manure benefits them greatly. An occasional syringing is necessary to prevent small white aphides attacking them. Scale is also liable to be troublesome, but is easily disposed of if attacked directly it appears. The following varieties are good: *White*, *Boule de Neige*; *Yellow*, *Boule d'Or*; *Red*, *Darwinii elegans*; *Rose*, *Rosæflora*; *Variegated*, *niveum marmoratum* and *vexillarium*. The last-named is very beautiful in the form of weeping standards, which are obtained by grafting on stocks of the tall-growing varieties.

ACACIAS.

Acacias are very easily grown greenhouse plants. Soil composed of half loam, half peat, and a little sand suits them. After they have flowered they may be advantageously placed outside in the full sun with their pots plunged in ashes for the summer months. There are numerous species. For a neat-growing specimen *A. armata* may be recommended. As a climbing kind to furnish neat sprays for indoor decoration *A. Riccana* is worth notice, and the early-flowering *A. platyptera* should be also grown.

AGAPANTHUS UMBELLATUS.

The *Agapanthus*, or African Lily, is a good old-fashioned plant which anybody can grow. It may be had in small pots, say 8 inches in diameter, or it can be grown into large specimens. It roots strongly, and delights in strong loam and manure. In summer it should be placed outside and supplied with plenty of water. In winter it requires protection from frost, and not too much water. Large plants may be cut into small pieces with the spade, and potted with the certainty of their doing well. The

ordinary type is blue, but there is a white-flowered form and one with variegated leaves.

APHELEXIS.

These require to be grown in a compost of fibry peat and sharp sand, with a little leaf soil; or some prefer light turfy loam with sandy peat, and this is preferable if the drainage be good and a few pieces of charcoal be mixed with the soil. Great care is needed in watering these plants, as the slightest excess of moisture or a corresponding deficiency will produce most unsatisfactory results. After potting the plants should be kept in a rather higher temperature than usual for a short time until root-action has recommenced, occasionally syringing them lightly, but giving little water until it is seen that some advance is being made. Shading will also be then necessary for a time, though afterwards the plants must have as light a position as possible. During the summer a cold frame will be a suitable place; but in the winter, if there is no house specially devoted to hardwooded plants, the warmest position in the greenhouse should be assigned them. They are very useful, as the flowers last so long, and they are greatly valued for exhibition, as fine globular specimens can be readily obtained with ordinary care in the culture and training. The species and varieties in general cultivation are not very numerous, but the following four are the best known:—*A. Barnesi*, bright rose; *A. humilis grandiflora*, purplish rose; *A. macrantha purpurea*, rich purple; and *A. macrantha rosea*, of a pale but pleasing pink hue.

AZALEA INDICA.

This is a general favourite, and rightly so, for few hardwooded plants may compare with it. It is of easy culture, but nevertheless not many amateurs succeed with it. The chief reasons are that the plants are generally starved and rootbound or potted in unsuitable soil, and the foliage is allowed to be overrun with thrips. The best compost for Azaleas is peat and sand—good fibry peat, with a sprinkling of sand to keep it open. Peat may have to be purchased, for any kind of peat will not do, and it is rarely that good peat is to be obtained otherwise, more especially by urban growers.

The season for potting is just after flowering, or when new shoots start. Of course potting is not needed unless the pot they occupy is already full of roots or soured through over-watering. In the latter case it may be necessary to remove as much soil as possible without injuring the roots too much; in the first case the removal of the crocks and any loose soil will be quite sufficient. Too large shifts should not be given, for the new soil may become sour before the roots take possession of it, in which case they never will succeed in it. From a 6-inch to an 8-inch and from an 8-inch to a 10-inch pot are quite sufficient.

In potting Azaleas it must be carefully observed that the ball is not dry, or there will be no possibility of moistening it thoroughly afterwards without wetting the new soil far too much. It is therefore necessary to examine the plants twenty-four hours before potting takes place, and to steep them if dry for an hour or two, and then allow the ball to partially dry before potting. The new soil must be rammed quite as firm as the old ball. Hardwooded plants which have fine hair-like roots and are potted in peat are very liable to be injured, and in thousands of instances killed, through the neglect of the simple precautions I have endeavoured to explain.

After potting the plants must be placed in the greenhouse again, or in a warm structure if such be at command, a night temperature of 50° being maintained. At sunset or before, light syringings of tepid water will be very beneficial. Indeed, amateurs should begin not later than the middle of February to keep up such a temperature just for the sake of forwarding the Azaleas as well as for enabling spring bulbs—Hyacinths, Tulips, &c.—Primulas, and other greenhouse plants, to assume their best character. It is quite necessary for the Azaleas, as in greenhouses where frost is excluded and no more, they make their growth so late in the season that they do not ripen nor the flower buds set, and the consequence is a poor display of blooms. Where Vines are being forced these plants will do well, but I do not advise placing them in vineries, for they are very apt to introduce thrips and other insects.

By midsummer, after the buds can be felt between the finger and thumb, the plants may be placed out of doors with much benefit. The pots should be half plunged in ashes to prevent the sun scorching and unduly drying the roots. I recommend ashes because worms will not readily crawl through them into the pots. If worms enter pots the balls should be inverted into the hand and the worms removed. Lime water will dislodge them from ordinary plants, but lime water is injurious to hardwooded plants generally, and for none more so than Azaleas. Liquid manure may be occasionally given to root-bound plants.

Thrips are the great pest of this plant. Syringing with soft-

soap water will prevent its appearing, and hard syringings with water at a temperature of 140° and with a little softsoap in it will effectually wash them off if they appear. Tobacco water will also eradicate them. The thrips must be kept down, or healthy plants cannot be had.

Bush form is the simplest and most natural form for them, and for one unaccustomed to the intricacies of training is the best that an amateur can adopt; but pyramids are the favourite shape into which they are trained. The way to form a pyramid is to insert a stout stake the desired height in the centre of the pot; two cross stakes are fastened across the mouth of the pot to this central stake and to a stout cord tied under the rim of the pot; then a ring of copper or galvanised wire is fastened to these cross stakes of the desired width, and small wires taken from the rim of the wire and fastened to the top of the centre stake. To these wires the growth is trained.

The names of half a dozen kinds are appended, to which the cultivator may add after a little experience has been gained. The varieties are almost innumerable, but the following are good:—*Duchesse Adelaide de Nassau*, *A. Borsig*, *Iveryana*, *Flag of Truce*, *Punctulata*, and *Reine des Pays Bas*.—J. H.

THE FORMATION OF DEW.

I HAVE read Mr. Taylor's book on "Vines at Longleat" with great pleasure and profit. It carries to one's mind the word "thorough" in a very remarkable way. No labour too great to achieve the end in view; a genuine scientific spirit; patient keen observation; seeking out of cause and applying remedy, lightened up not a little by touches of real humour.

Before it passes to further editions there is one point which it might possibly be worth Mr. Taylor's while, to use an awkward phrase, to reconsider—namely, what follows on page 60 the words "The dew is caused in the following way." Our friend is perfectly right in his observations on page 61 that it is the "rapid evaporation which causes the complete chill," by what is known as the immense quantity of "latent" heat taken up during evaporation; but the cause of the original deposition of the dew is not, I think, precisely what he says.

The whole theory of dew was first pointed out by a Dr. Wells in a most interesting pamphlet, published, I think, thirty or forty years ago, which I wish I had to send to Mr. Taylor, but I will try and explain very briefly what I can of it; and it may be shortly stated by the broad fact that hot air can hold more moisture, invisible, than cold air, and that as the cooling process goes on the air becomes saturated—*i.e.*, can hold no more invisible moisture, but must deposit it or make it apparent in the form of fog, &c. If there is anything colder than the air itself, then dew is deposited on that substance. This is easily tried. Bring a tumbler of cold water, iced if possible, into a warm room; the tumbler chills the air round it below the point called the "dew point," at which it is saturated, and the moisture is condensed on the glass.

Now it seems to be a provision of Nature that plants have large powers of absorbing heat, and apparently a somewhat equivalent power of radiating—getting rid of it—also; doubtless the last to attract dew to refresh and invigorate them, as Mr. Taylor points out, and which power seems to be, as he says, in proportion to the vigour of the plant.

Well, to return to Mr. Taylor's house, which, as he says, is getting cooled during the night—that is, the air is approaching more or less to the point of "saturation." It is not the rise of temperature caused by the sun coming out which causes the dew to deposit on the Vines, slates, &c., because any rise of temperature must infallibly cause an increase in the moisture-carrying capacity of the air before it can cause much moisture to be evaporated from the ground in the house, or anything in the house; but it is the radiating power of the plants and other substances which have, so to speak, chilled themselves, and thus previously caused the air to deposit dew on them, just as on the artificially chilled tumbler. I think that just before sunrise a distinct and sudden drop in the temperature often takes place, and probably the dew may be largely deposited at this time, which may have led Mr. Taylor to speak of it as being caused by the sunrise.

The point is so small it may not be worth while troubling Mr. Taylor at all about it, but theoretically the cause of dew-deposit is an interesting one to gardeners, and he would, I am sure, be interested in watching a dry and wet bulb thermometer, by which the dew point can be at any moment calculated, and the amount of moisture in the air approximately seen at all times.—W. Y.

NOTES ON PEARS WANTED.—Have any of your correspondents any personal knowledge of the following Pears? Early and mid-

season sorts :—Duchesse de Brissac, Frederic de Wurtemberg, Buerré Lebrun, Soldat Laboureur, Grégoire Bordillon, Buerré Baltet père, Buerré Dubrusson. Late varieties :—L'Inconnue, Maréchal Vaillant, Emile Herpin, Bezi de St. Waast, Hébé, Madame Bonnefond, Madame Hutin, Marie Guisse, Lydia Thierard, Louis Vilmorin.—J. E.

LIFTING PEACH AND NECTARINE TREES.

I REVERT to this subject once more because Mr. Iggulden has thrown some light upon it in his last remarks ; but I am surprised when he knew the surface soil was in such a fertile state that he should place it at the bottom of the border.

My principal object in writing was to point out the waste of labour and material in making unnecessarily deep borders for Peach trees. Borders 18 inches deep are sufficient for trees with a spread of branches 30 feet, and from which good crops of fruit of first-rate quality can be produced. Mr. Iggulden does not object if the borders are deep, but that does not answer the question I asked. What are deeper borders needed for ? To keep the roots of his trees near the surface is Mr. Iggulden's object, as it is of

most cultivators ; and by what means can this be accomplished better than by annual lifting ? When trees are frequently lifted the operation is neither laborious nor expensive ; in fact, lifting three trees in a house say 60 feet in length occupies no more time than top-dressing the border, and is not more expensive. New soil is not needed every time the trees are lifted, for, as I said on page 326, the soil removed in lifting could be returned if in a fertile state. Annual lifting is the means of producing abundance of fibres, and the trees subjected to it would be in a better position in this respect than by a three-years lifting system and the addition of "brick ends," which are the rubbish to which I alluded.

Your correspondent is wrong in saying lifting is "to a certain extent risky." When done annually there is no risk attending the operation. Not a bud will fall from the trees, scarcely a fruit in stoning, and I have never lost a crop from any of my trees for several years since the annual-lifting system has been practised. Such appears to be the experience of Mr. Bardney (page 279), and Mr. Iggulden has referred in a contemporary to the success that attended the lifting of these trees. "S. N." also refers to

Fig. 65.—RENDLE'S ACME SYSTEM OF GLAZING.

the splendid condition of the same trees, and says, "Mr. Bardney thinks no more about digging up and replanting a Peach tree in July than of potting a Pelargonium." Surely he would not do this if the system was likely to be attended with risks or failure.

I have never seen nor heard before of Vines growing in the compost named by Mr. Iggulden, and therefore am in no position to pass an opinion about them. Perhaps he will give us more particulars, which I am sure will be interesting not only to me but many readers of this Journal.—A. B. C.

RENDLE'S ACME SYSTEM OF GLAZING.

INQUIRIES having reached us of late for information relative to this method of glazing roofs and for explanations as to the nature of the system, we submit from the patentees the annexed illustration, as without it the subject could not be satisfactorily explained, whereas it can now be easily understood. At C is the horizontal bar, designated the "Acme," which is screwed to the purlin that supports the roof. This bar, as may be seen, is constructed with perforations, through which any moisture will pass that may have condensed on the inside of the glass. E represents the "Acme" vertical bar, forming the junction of two squares of glass. The grooves carry off any water that may penetrate at this joint to the next square below, and so on from square to square. They also form a sufficiently strong bearing for the glass, G. It should be added that the vertical bars are firm, yet moveable, and thus provision is made for repairing the roof in case of breakages.

As will be apparent, no external painting is requisite by this system, while the roofs are very light and undoubtedly durable. Were they otherwise they would not be adopted by Her Majesty's Government, railway companies, and others, while in a number of gardens the system answers admirably. In a letter before us Mr. Gilbert of Burghley says :—"Rendle's houses for plants and Vines continue to give me great satisfaction ; but to see the system well tested go to Ketton Hall. They are there perfect structures, and everything grows well under the roofs in charge of Mr. Woodfield." In Messrs. Rendle's book of testimonials we find one from the gardener first named, so clever in its way that we cannot resist quoting one of the paragraphs—namely, "The span roof for plants has been most useful, and four first-class certificates for double Primulas, all grown in the house, bear testimony to their great superiority." The superiority of what ? The Primulas or the houses ? Oh ! Mr. Gilbert.

RASPBERRIES IN AMERICA.—Mr. Parry, who has long been a very successful grower of the Raspberry, gave the New Jersey Horticultural Society a statement of some of the large profits obtained when this fruit sold at high prices. He said the best American varieties, with fair treatment, will generally yield as many bushels per acre as corn, and generally bring five times as much in market, and when once planted remain for several years. A neighbour of his sent to market a one-horse waggonload of red Raspberries, and received \$220 (about £44) for the lot. A lady living near him rented out her farm, reserving a portion for a Raspberry and Blackberry

plantation, from which she sold in one year 43,000 quarts of berries, worth, at eight cents a quart, \$2440 (about £480), which was more than the tenant made from all the other crops on the farm.—(Prairie Farmer.)

MILDEW ON PEAS.

I AM glad to see this subject being discussed by your correspondents, and I trust something will be found to reduce if not destroy this fungus, although I fear, after reading Mr. W. G. Smith's article, there is not much to hope for. I quite agree with "J. S., Ripley," that it is caused by drought and damp, the former more especially; but I think as a rule late Peas are sown too thickly, and when grown up they are like a thick hedge, and in consequence when heavy autumn rains come they hold the wet for a long time and mildew soon attacks them, which is not the case with thin rows, at least such is my experience, and as a proof of that I will endeavour to explain an instance. On the 1st of June this year I sowed two rows of Ne Plus Ultra 9 feet apart; the seeds soon germinated, but early one morning I noticed several jackdaws fly from my Peas, and I found a quantity pulled out of the ground. I watched for and shot two of the birds, which I placed on the ground some distance apart between the rows of Peas. I thought this would frighten the others, but it was not so, for the jackdaws watched me too, and when I was gone they would pounce down for a few more Peas. In a few days, however, I noticed that for a certain distance away from the two dead birds the Peas were not touched; so I had them transplanted to make up the rows as far as I could, and they were very thin, but, however, I decided to stake them. The Peas grew very fast, and by the beginning of September were higher than the sticks, which were quite 7 feet out of the ground, flowered well, and they have continued bearing a fine crop of Peas since. In fact my employers say they are the best they have had this season; yet on looking through the rows this morning I could not detect the slightest spot of mildew; but they are as healthy as I could wish, and this day (October 23rd) I gathered nearly a peck of full pods. On the other hand, I have two rows of Omega in another part of the garden that are very thick, and the inside and under growths are affected badly with mildew. In conclusion let me add that Ne Plus Ultra and Omega are in my opinion the two best late Peas we have.—F. H., Oxon.

THE MANURIAL VALUE OF PHOSPHATE OF MAGNESIA.

(Continued from page 388.)

I HAVE now to bring down the abstracts of field trials on different forms of phosphate of lime to the October number of the Journal of the Chemical Society for the current year. My last letter finished with those included to the end of 1881.

5. No. ccxxx., page 89. Manuring experiments at the experimental station at Göttingen, by G. Drechsler. Little reliance can be placed on the results, which were very variable. This variation was most probably due to differences in the soil, and also to external influences on the growth of the roots (sugar Beet), which influences produced a greater result than the manures. However, taking the results as they stand, precipitated phosphate appears to have been the most beneficial.

6. Page 90. The experiments undertaken by the Rochester Farmers' Club on a 2-foot deep sandy loam (subsoil chalk), containing N.=0.21, K₂O=0.08, P₂O₅=0.12 per cent., were made with the object of testing the value of various forms of superphosphate as compared with insoluble phosphate on the growth of Swedes. The maximum yield was obtained by the use of dissolved bones, the minimum by the use of finely powdered raw bones. Several of the manured plots are below the unmanured plots in yield.

7. Page 91. Bone meal, dissolved coprolite, coprolite powder, precipitated phosphate, &c., were applied in equal money value as manures on plots $\frac{1}{2}$ acre by J. W. Kimber. Dissolved bones produced the best, and powdered phosphorite the worst crop. That coprolite powder produced a better crop than bone meal is explained by the fact that the latter, being very light, great difficulty was experienced in introducing evenly into the heavy soil. The precipitated phosphate was heavy and lumpy, and therefore it was less active than superphosphate or dissolved bones.

8. Page 91. Experiments on Turnips by E. W. Prevost. The plots were $\frac{1}{8}$ acre, and were in two sets, both in triplicate. When the manures were applied in quantities containing equivalent amounts of phosphoric acid, the increase in yield over the unmanured plots was, in the case of insoluble phosphate, about 18 p.c.; in the case of superphosphate, about 29 p.c. When the quantities of manure added were of equal money value, then the

increase over the unmanured plots were respectively 30 and 53 p.c. Analyses of the roots showed that those grown under the influence of the insoluble phosphate, though smaller, contained less water and more sugar than those grown with superphosphate. The soil contained 9.4 per cent. chalk.

9. Page 91, by M. Märker. In reference to the yield of corn and production of straw precipitated calcium phosphate is equal in manurial value to superphosphates with an equal quantity of phosphoric acid. Potatoes and other fleshy roots, however, gave the largest yields with superphosphates.

10. No. ccxxxii., page 331, by A. Petermann.

	Produce in kilos per hectare.
1. Unmanured	34.830
2. Superphosphate	34.380
4. Precipitated phosphate.....	34.380
5. Unmanured	33.840
6. Leather meal and soluble phosphate.....	37.890
8. Leather meal and precipitated phosphate	35.910
9. Unmanured	32.940
10. Sodium nitrate and soluble phosphate.....	43.380
12. Sodium nitrate and precipitated phosphate	43.880

The latter manure produced by far the best results. The experiments were made in sandy soil.

11. Page 333, by A. Emmerling. Experiments on clayey, humous, and sandy soils with bone meal steamed and with bone meal dissolved. The results confirm previous experiments in favour of the dissolved bone, and show marked increased production in each case wherein the manure was used.

12. No. ccxxxiv., page 550, by Hoffmeister. The plots were $\frac{1}{30}$ morgen in size, and the manures applied in triplicate, 1 kilo of phosphoric acid being applied in each case. The results showed that reduced phosphates were as good in their action as the soluble phosphates in the soil, which was a sterile sandy soil, very poor in lime.

13. No. ccxxxv., page 653-4, by G. Brown. Turnips were grown in five different localities simultaneously. The author thinks that the superiority of bone or coprolite to superphosphate, shown in seven of the experiments, is perhaps exceptional, and may be due to the exceptional dryness of the season from August 5th to September 10th, 1880.

14. No. ccxxxvi., page 767-8. Experiments at the experimental stations of the Highland Agricultural Society, by A. P. Aitken. Roots in 1878. At Harelaw Swedes were sown, and at Pumpherston yellow Turnips. The dissolved phosphates produced more than the undissolved, the increase averaging about 10 per cent. Although the quantity is increased by soluble phosphates, the quality is not improved.

Barley, 1879. At Pumpherston the season was cold and damp, so that the ripening period was much delayed. Soluble phosphates produced an increased yield of grain over crude phosphates of 14 per cent, and the amount of straw was also heavier. The equality of yield produced by the superphosphates is to be remarked, whilst the yield of the crude superphosphates is very irregular.

Hay, 1880. At Harelaw the soluble phosphate plots gave an increased yield over the unmanured of 6-7 per cent.; the opposite was the case at Pumpherston, and here the after-action of the insoluble phosphates was noticeable.

Roots, 1880. The $\frac{1}{12}$ acre plots were sown with yellow Turnips (Pumpherston) and Purple-top Swedes (Harelaw). The manures were the same as before, with the exception of the addition of crude and dissolved euraçao phosphate in the place of sodium nitrate and bone ash. This year again showed the superiority of superphosphates to the amount of 20 per cent., and although the percentage of dry matter is lower, yet the total quantity is higher.

15. Page 770, by Krockner and H. Grahl. Insoluble and soluble phosphates with bone meal were employed. These appeared to have no appreciable difference with Oats, but with Potatoes the action of soluble phosphate and bone meal was very marked. With ammonium sulphate the best crop of Oats was obtained from bones, the worst from superphosphates.

16. No. ccxxxviii., page 993, by L. Grandeau. On a soil of low quality various crops were grown for eight years. Taking the mean yield of all the crops, it was found that precipitated phosphate is equal to superphosphate, bone meal is but moderate, and phosphorite is poor in its action.—INQUIRER.

LIFTING AND STORING BEETROOT.—It is not safe to leave Beetroot out in the open after the end of October, for if frost comes it may be injured, and then it will not keep well. The first day when the leaves are perfectly dry should be selected for lifting it. When the plants are drawn up without the aid of a fork sometimes the bottom part of the root is left in the ground, and this allows the juice to

escape, which should not occur, as the main point in preserving Beet-root is to keep them whole, as bruised or broken roots lose their colour as well as their qualities. The roots when lifted should be laid on the ground to dry; then cut off their tops, but not too closely, for the same reason as we would avoid breaking the roots. In storing them the best way is to place them in layers in a cool shed or cellar, with a small quantity of sand between each. In a month or so hence they should be examined to see if any are decaying, and after removing these the others may be put back again in the same way. This may be repeated as it may be required, and in spring all growths on the crowns should be rubbed off.—A KITCHEN GARDENER.

NOTES ON POTATOES—THE CROPS IN IRELAND.

THE season that is now almost closed, as far as the crops are concerned, has been a strange one. It has been very wet and in a great measure sunless; yet notwithstanding the farmers have abundant crops of all produce except the Potatoes, which, although about half a crop compared with last year, are quite up to the average of the ten years previous to 1881, which year was said to yield a crop equal to those before the failure in 1847.

Amongst farmers here very few varieties of Potatoes are grown. The Scotch Champion has ousted all the Roeks, red and white, and last year was almost ousted itself by the Skerry. The good qualities of the Champion were not at all appreciated last year, as it grew strong and very many were hollow in the centre. Tons of them were sold in our local market for as low as from 1s. 5d. to 1s. 8d. per cwt., and these were for stock-feeding, very few were for culinary use. This year the Champions are being sold at from 3s. 6d. to 4s. per cwt. The Skerry resists the disease quite as well as the Champion, but if not allowed to come to maturity the tubers contain little starch. This year both were cut down in July—the Skerry not more than half-grown at the time—therefore it has lost its high place for favour this year. This early cutting has been most favourable to the Champion, for the tubers are a convenient size for the table and contain plenty of starch.

The season 1881 was not at all what might be called a dry one; yet the rain during the Potato growth was not excessive—just enough to keep them growing, never at any time saturating the soil, and, besides, the atmosphere was clear of fogs and mists. Fogs and much rain, I am convinced, are the chief causes of the Potato disease. I do not pretend to know the origin of the Potato failure, but I am sure from experience that it is now increased by wet foggy seasons; and, as I stated in this Journal years ago, it is only those Potatoes that have stout haulms and strong constitutions that can stand against such seasons. If the Skerry and Champion escape till about the 1st of September the haulms are strong enough to resist disease; but this year it came on them when they were very soft about the 12th of July. Still, although the Skerrys are small there are very few diseased tubers, even fewer than amongst the Champions; the latter have at least 20 per cent. bad tubers. The Magnum Bonum has only a few diseased; it is not generally known. I recommended it to my employer. We procured it, and it has proved very satisfactory. It has three valuable qualities—viz., it is a good cropper, cooks well, and is disease-proof. It deserves a place in every collection, and must force its way as a standard variety; but I think its shape is against it, most people being suspicious of kidney-shaped Potatoes.

The early varieties all surrendered to the disease at once, and as they are nearly all of the soft-haulm sorts they were much diseased. We have a variety which is grown amongst the early sorts, but is only a second early. It resists the disease remarkably well (proving my theory), having strong fibry haulms. The tubers are reddish, large, a good cropper, and good quality. It is named Wonderful.

I have the brightest hopes for the success of the Potato crop, and, one year with another, shall always have a crop with such varieties as we have, and even better ones I expect to come forward yet; so that with such a good, abundant, and early cropper as Myatt's Prolific to be out before the disease comes on, and such late varieties as I have named above able to resist the disease, we have little to fear.—B. G., *Co. Down*.

SEWAGE, SOOT, AND ASHES.

I WAS glad to see recorded on page 383, under the above heading, the experience of Mr. J. Taylor, for I also rely greatly on sewage water and soot for fertilisers, though, thanks to paraffin not being used, I have not suffered. I feel sure Mr. Taylor has found out the true cause of his failures, and has done a public service by bringing it under the notice of the readers of the Journal. I have on many occasions seen both butler and footman throwing the waste colza oil down the drains, and have often

wished it could have been seen by a more important person. Then the thought has occurred to me of what is to be done with such waste material. For my part I would like it to be disposed of in the ashpit, as my ground, being of a light nature, I only require the ashes for the paths, the cinders being used in the stokehole; in fact, I have asked that all broken glass and such-like stuff may go there to be run down to elinkers, which are of some service, while broken glass with me is abominable.—J. S. A.

NOTES ON THE ROSE ELECTION.

I DO not know when I have been more interested than with the two numbers of the *Journal of Horticulture* containing the Rose elections. The first six varieties of Hybrid Perpetuals are almost exactly as I should have placed them, but I should place Louis Van Houtte, E. Y. Teas, Marie Finger, and Abel Carrière higher in the list than the positions they occupy. I was surprised to find Felix Genero without a place, as it is a Rose which produces as large a proportion of perfect blooms as any I know; perhaps it is not of a fashionable shape. I am delighted to find Catherine Mermet at the head of the Teas, as it is a very old favourite of mine—in fact, except Gloire de Dijon, the first Tea-scented Rose I possessed.

Since writing the above I have received another most interesting Journal. I see that all the Roses I have mentioned get promotion in Mr. Ellwanger's list, but he puts Charles Lefebvre and Etienne Levet very low. I should have thought Madame Lacharme suited to the American climate.—A NEW READER.

THE annual meeting of the PELARGONIUM SOCIETY is announced to be held at South Kensington on Tuesday, November 14th, at 1 P.M. On the same day the promoter of the proposed Pink show will arrange a few preliminaries.

— AS a consequence of the high tides and floods MARKET GARDENERS IN THE VALLEY OF THE THAMES have suffered considerably, much land being under water and the crops in danger. One grower is said to have nine acres of Celery flooded.

— AN Oxfordshire correspondent writes:—"I have studied with much interest Mr. Iggulden's excellent article on varieties of Peaches and Nectarines. He must have overlooked the SALWEY PEACH, an excellent late variety. With us it has ripened with a most delicious flavour. It cannot be relied on if the autumn is dull and sunless."

— A GARDENER submits the following as his ESTIMATE OF LANTANAS:—"These plants are rising in popularity, as they are easily propagated, grow freely, bloom profusely, and the flowers are exquisite in shape and beautiful in colour. As seen in full bloom planted in flower beds or growing in pots they are most attractive, but their odour is most disagreeable."

— THE following are the fixtures of the ROYAL BOTANIC SOCIETY for 1883:—Spring Exhibitions, Wednesdays, March 28th, April 25th. Summer Exhibitions, Wednesdays, May 16th, June 13th. Evening Fête, Wednesday, June 27th, 8 to 12 P.M. Promenades, every Wednesday from May 2nd to August 1st, excepting May 16th, June 13th and 27th. Lectures at 4 P.M. Fridays, May 4th to June 22nd. General Meetings for election of new Fellows, &c., Saturdays, at 3.45:—January 13th, 27th; February 10th, 24th; March 10th, 24th; April 14th, 28th; May 12th, 26th; June 9th, 23rd; July 14th, 28th; November 10th, 24th; December 8th. Anniversary, Friday, August 10th, at 1 P.M.

— THE CHRYSANTHEMUMS AT THE INNER TEMPLE have improved surprisingly within the past week, and Mr. Newton now has a very pretty display, the flowers abundant, bright, and of clear colours. Of the new varieties recently noted Lord Beacons-

field was referred to as being particularly good, but its characters having now more fully developed, it may be observed that its appearance is somewhat spoiled by the florets being strangely infolded towards the centre of the flower.

— A CORRESPONDENT writing in reference to the INCREASED CONSUMPTION OF TOMATOES in recent years observes that "Though these fruits are so much more largely consumed now than they were ten or even six years ago, yet the production does not appear to have kept pace with the demand, and in consequence good Tomatoes are only procurable at about twice the price they formerly realised. A West End fruiterer assures me that ten years ago he sold Tomatoes for 6*d.* per pound equally as good as those for which he now easily obtains 1*s.* per pound. This, however, does not mean a larger profit for the retailer, as the wholesale price has advanced so much that less profit is really secured than when the prices were generally lower."

— "L'ILLUSTRATION HORTICOLE" states that a few small plants of a new Palm, *PRITCHARDIA NOBILIS*, are included in some continental establishments, and that it is likely to prove a rival to *P. grandis*, *P. macrocarpa*, and *P. aurea*. The Germans have named it *Bismarckia nobilis*. We recently saw some fine young plants of a new *Pritchardia* in one of the London nurseries with large, rounded, bright green leaves and vigorous habit, that appears to resemble the above in its chief characters.

— THE same Journal gives a coloured illustration of SIX NEW *SONERILAS* of considerable beauty, with diversely coloured leaves. In *Comtesse de Flandre*, *Madame Legrelle*, and *Madame Secrétan* the green body colour predominates, with silvery spots and marbling, the first and third having reddish petioles, and the under surface of the leaves is of a similar tint. The other three—viz., *Madame Alfred Mame*, *Madame Charles Heine*, and *Princesse Mathilde*, are of a silvery colour with green veins.

— A BEDFORDSHIRE correspondent writes:—"The GALE of the 24th ult., accompanied by heavy rain, hail, and snow, was severely felt in the Biggleswade district. The gale was severe but short, and happily the damage has not been so great as the memorable gale of the 14th October, 1881; but some fine old trees have been uprooted in Old Warden Park, and others were severely shattered by the violence of the gale. Several fine old Oaks have suffered very much, owing to their still being heavily clad with autumn foliage. Much rain has fallen since the 24th ult., consequently the ground is saturated, and the land in low districts is very much flooded. Gardening and farming operations are almost at a standstill."

— MR. J. CLARKE, Brynkinalt, writes as follows respecting a NEW MELON, *SIR GARNET WOLSELEY*:—"When visiting the gardens at Brogyntyn a short time since I was agreeably surprised by a new Melon grown there by Mr. Lambert, the head gardener. It is a handsome, oval-shaped, green-fleshed Melon, beautifully netted, of exquisite flavour, and very prolific. Mr. Lambert informs me he has grown ten good fruits on a single plant, but the average weight of fruits is about 4 lbs. It is a very free setter."

— MESSRS. JAMES CARTER & Co., High Holborn, send us some flowers of their CROWN JEWEL *BEGONIAS*—a strain of considerable merit, to which we have previously referred in commendatory terms. The flowers are white, creamy, yellow, rose, and scarlet of many shades; the white very pure, and the others rich, bright, and clear. They are of moderate size, except the scarlet and white varieties, which have blooms of good size and substance, the petals broad and rounded.

— To ascertain the amount of SUGAR IN THE STALKS OF COMMON FIELD CORN (*Maize*), some stalks of the *Waushakum* variety were stripped of leaves at the New York State Experi-

ment Station, September 15th, and crushed in a mortar. The juice removed by an ordinary jelly press amounted to 57.06 per cent. of the whole substance, and contained 2.77 per cent. of sugar.

— FEW persons except dealers have any idea of the enormous extent of CUCUMBER-GROWING IN AMERICA. It is estimated, says the *American Prairie Farmer*, that the Long Island farmers alone grow 300,000,000 per year, the average price in large lots being about one dollar a thousand. A Chicago commission man estimates that 100,000,000 of the abominations are handled annually by the trade in the city.

— A CORRESPONDENT who has visited MR. WITHERSPOON'S VINERIES at Chester-le-Street informs us that the crop of Grapes is marvellous, and he was not surprised to hear that Mr. McIndoe observed on inspecting the houses that "no man living could have persuaded him that such crops of splendid Grapes were in existence; but seeing was believing." We saw the first crop of fruit in these vineries, which was of extraordinary weight and quality, and are glad to learn of the continued success of this excellent amateur cultivator.

— MR. T. S. WARE of Tottenham sends us a collection of very beautiful MICHAELMAS DAISIES and SINGLE DAHLIAS, well showing the value of such plants in autumn as late as the last week of October. The best of the Asters were the following:—*A. ericoides*, a graceful species with small white flowers produced in great numbers at the points of short lateral closely set branches, thus forming wreaths of blooms. *A. Amellus bessarabicus* is one of the most telling varieties, having large purple blue flowers. *A. novæ-angliæ* has neat rose-coloured flowers very abundantly produced; *A. novæ-belgii*, bright purplish blue, large and free; *A. lævis*, lilac flowers of moderate size and numerous. The Dahlias included most of those recently noticed in these columns, together with others of great beauty, two of those certificated at the last meeting of the Royal Horticultural Society at South Kensington—namely, *Mrs. Goldring* and *Mrs. Burbidge*, both very handsome. The "Black Dahlia" (*Cosmos diversifolius atrosanguineus*), figured in the last issue of this Journal, was also represented by a number of its velvety maroon flowers.

— MR. BUNYARD of Maidstone has published an appendix to his useful manual on FRUIT FARMING FOR PROFIT. A great portion is devoted to comments on the press criticisms of that work. The great scarcity of fruit of the present year is alluded to, but still Mr. Bunyard is convinced that where different kinds of fruit are grown one or other of them will be sufficiently productive to prevent failure. On this point he says:—"As showing how little the crop is affected where a variety of fruit is grown in established orchards, I learn that one East Kent grower has this season sold his 'top' fruit for £1000, and this with the smallest crop ever known in this part, while his under fruit has brought £700 more, and I believe this is the experience of most growers on a large scale. And were landowners in a better position than they are, after the many bad years experienced by their agricultural tenants, I have no doubt that a very much larger area would be laid down in orchards; as such give, so to speak, three crops in a year—wool, mutton, and fruit. In sheltered spots our Cluster Damson has done well, one grower taking 2500 bushels, which realised 13*s.* per bushel. Fruit-growing is an occupation where there is some risk, but the prizes far outweigh the blanks."

— A DAILY contemporary gives the following particulars of the EXTRAORDINARY RAINFALL of the past fortnight:—

"It appears that in the west and south-west of England the amount of rain measured in the course of the past fortnight has been about double the average for the entire month of October, while over the midland and south-eastern counties it has been about half as much again as the monthly average. In London rain has fallen every day, and on five days out of the fourteen the amount has been at least

half an inch, the aggregate for the period being about $4\frac{1}{2}$ inches. Few persons are aware that an inch of rain over an acre of ground means 101 tons, or 22,623 gallons, of water. Accepting as correct the Registrar-General's estimate of the gross area of London and its immediate suburbs, it would therefore appear that an inch of rain over the London district weighs in round numbers 45 millions of tons, and amounts to the overwhelming volume of 10,000 millions of gallons of water. Estimating the total amount of rain in London during the past fortnight as $4\frac{1}{2}$ inches, and applying this amount to the above figures, we find that the weight of water which has fallen has exceeded 190 millions of tons, while in volume it has amounted to 42,500 millions of gallons. In attempting to grasp such enormous numbers the mind becomes lost, but some idea of the immensity of the volume may be gained by imagining it all to be concentrated into one reservoir or basin. Supposing such a reservoir to be quite square and 40 feet in depth, the sides of the square would be more than 13,000 feet in length, and a walk round it would entail a journey of very nearly ten miles. If we imagine the water to be enclosed in a cubic vessel, the sides of such a receptacle would be each about 1896 feet long."

— MESSRS. W. & A. GILBEY recently communicated an interesting letter to the *Times* on the vintage in France, from which we cite the following notes:—

"THE EXTENT OF LAND UNDER VINE CULTIVATION IN FRANCE affords striking evidence of the importance of the Vine to the prosperity of that country. The average production of wine in France is estimated at 184 gallons per acre. One-twenty-fifth part of the total area of France is appropriated to wine-production, and the number of acres under Vines, which a hundred years ago were just under 4,000,000 (four million), now exceeds 5,000,000 (five million) acres, and this notwithstanding the fact that 1,400,000 (one million four hundred thousand) acres of Vines have recently been destroyed by the phylloxera. At the same time, with this large additional extent of vineland, a state of things appears to have arisen in France something similar to that against which we hear a good deal of complaint in England at the present time—that is to say, the land is getting into the hands of a smaller number of holders; for although, as we have stated above, there are now a million more acres under Vine cultivation than there was a century ago, the number of the proprietors of vineyards, which in 1829 was 2,169,504, had fallen in 1878 to 1,932,573 only."

— RELATIVE TO THE PHYLLOXERA AND ITS ERADICATION it is stated that

"In the department of Herault, which produces between a fifth and a sixth of the entire French vintage, thanks to the energetic efforts of its Vine-growers, who have had recourse to American Vines for the purpose of replacing the Vines which have died from the effect of this insect scourge, this department is fast recovering from its first scare, and is rapidly regaining its old position and former confidence. In the Charentes, the great cognac-producing districts of France, unhappily the same is not the case. There the proprietors appear to have resigned themselves to what they have come to regard as inevitable, and cereals are fast taking the place of the Vine. On inquiring the reason for this we were informed that of the two most generally accepted remedies for the destruction of the phylloxera, one, that of the employment of insecticides, such as sulphur of carbon and sulpho-carbonate of potassium, has been found too costly; while, owing to the rocky nature of the soil and the small surface of earth, the land is said, on the other hand, not to be suitable for the planting of American Vines. In another of the large wine-producing departments above referred to—the Gironde—the phylloxera has undoubtedly also made some progress and created much alarm. Looking, however, at the wealth of the proprietors in this district and the importance of the interests at stake, it is quite certain that no effort will be spared, and hardly any expense found too great, to save the Vines of this department, which are regarded as the most precious of all the Vines of France."

— THE following shows the YIELD OF THE WINE-PRODUCING COUNTRIES OF THE WORLD:—

"It is estimated that the total average annual production of all the wine-producing countries of the world is nearly 3,000,000,000 (three thousand million) gallons, and that of this quantity about 35 per cent., or rather more than one-third, is derived from the vineyards of France. The total quantity of wine exported by France during the last four years has been 240,750,000 gallons; the value of the quantity thus exported for the year 1881 alone being nearly £10,500,000. According to French statistics, England in reality is the best customer of France, taking between a sixth and a seventh of the total quantity of wine she exports; the next largest consumers, in order of importance, being Switzerland, Germany, Belgium, Algeria, the Argentine Republic, and the United States."

ROSE RÈVE D'OR.

I QUITE agree with your correspondent M. F. Woodley in considering Rève d'Or to be one of the very best climbing Roses, its

principal merit being that, though it is excelled in power of growth on a warm wall by, perhaps, Climbing Devonensis alone of Teas and Noisettes, it yet keeps the base well covered with sprays and foliage, in this respect far surpassing any other Rose in my experience. But I cannot agree with him that it should be grown in a cool house. I find it perfectly hardy and evergreen on a warm wall in the severest winter we have had for the last five years. Yet, though covered with a mass of bloom in the spring, secondary flowers are with me comparatively few; and I think few who are acquainted with the whole class of Teas and Noisettes would place it among the first twelve, for Roses must be judged by their flowers, and a good bloom of Rève d'Or, though very pretty, is hardly first-class.—A. F. M.

PRODUCTIVENESS OF POTATOES.

To show what may be done with the Potato by cultivation I send you a statement of the produce of one tuber of Magnum Bonum planted whole in the garden at Glan-y-wern in March last, and this day raised with the following result:—

	lbs.	ozs.
7 Potatoes, each above 1 lb., weighed.....	7	9
9 " " " $\frac{3}{4}$ lb., "	8	2
10 " " " $\frac{1}{2}$ lb., "	6	7
7 " " " $\frac{1}{4}$ lb., "	2	13
6 small Potatoes	0	4
39 Potatoes weighing	Total	25 5

The stems of the haulm, instead of being allowed to trail upon the ground, were attached to stakes placed round the Potatoes, thus exposing both the surface of the ground and the foliage of the plant to the sun, air, and moisture. The seven principal stems ultimately attained the height of about 7 feet. The Potatoes were well formed and even in character, as an analysis of the weight shows, the heaviest weighing 1 lb. 3 ozs., while the remaining six of the first lot averaged 1 lb. 1 oz. each. The nine Potatoes of the second lot averaged $1\frac{1}{2}$ ozs., the ten in the third lot averaged $10\frac{1}{2}$ ozs., and the seven in the fourth lot averaged $6\frac{3}{4}$ ozs., the remainder were very small.

The parent Potato was moderate in size, planted on a bed of turfy loam without manure. Fresh soil was added as the tubers increased in size. A can of liquid manure was applied six or seven times, and water in very dry weather. The haulm remained perfectly sound to the last, the foliage throughout being very fine until the last fortnight, when the leaves began to die. The ground occupied by this Potato was about 4 feet square.—PHILIP S. HUMBERSTON, *North Wales*.

AUSTRALIAN ORCHIDS.

THE great Australian continent, though abounding in distinct types of vegetation and possessing a tropical climate over a large portion of its surface, does not include many representatives of that beautiful family the Orchidaceæ which a few degrees farther north are so numerous in the islands of the Malayan Archipelago. This is doubtless due to the comparative dryness of the climate and the peculiar conformation of the surface, which is somewhat basin-shaped, the higher parts being near the coasts, the large central portion presenting a flat extent of land, mostly arid and desert-like, but relieved in a few localities by slight elevations. In such a country we could not expect to find any remarkable luxuriance of epiphytal vegetation like the humid forests of Brazil produce, and we have instead an abundance of those peculiar dry-climate types, such as the members of the Rue family, the Eucalypti, the Proteas, and others, mostly distinguished by firm or leathery foliage, which frequently possesses powerful aromatic odours. In a few districts, however, Orchids are found, and these include several beautiful species. They are nearly all natives of some part of the east coast from Moreton Bay to Torres Straits, but the terrestrial species far exceed the epiphytes in number; and though outside the genera Dendrobium, Cymbidium, and Sarcochilus there are few of the latter class, yet the others are represented by such genera as Thelymitra, Cadadenia, and Pterostylis, which are scarcely known in English gardens, though two familiar terrestrial Orchids have been observed there—namely, Phajus grandifolius and Calanthe veratrifolia; but these can only be regarded as strays from more northern latitudes. With these exceptions the terrestrial Orchids of Australia do not possess much value in a horticultural point of view, and do not need consideration here; but the epiphytes well deserve attention, commencing with the

DENDROBIUMS.—This handsome genus, the species of which are so well known and admired in gardens, has about twenty forms that are either indigenous to or naturalised in Australia, and are

entitled to be considered the typical Orchids of that country. These are strangely varied in habit and other characters, some ranking amongst the curiosities of the Orchid family, and others

amongst the most beautiful. *D. cassythoides*, *D. linguæforme*, *D. teretifolium*, and *D. cucumerinum* may be taken as samples of the peculiar species, the names of which indicate their distinguish-

Fig. 66.—DENDROBIUM SUPERBIENS.

ing characters. The last in particular is a strange little Orchid, affording what Mr. Leo Grindon would term "an echo of the Cucumber," for the pseudo-bulbs or leaves, whichever they be, and it is not easy to determine the point, precisely resemble those small Cucumbers known as Gherkins in size, colour, ribbing, and

the small prominences on the surface. The Cassytha-like, the tongue-shaped, and the round-leaved Dendrobies named above, are in a measure similarly noteworthy for the characters expressed in these names. *D. linguæforme* is especially interesting in another way. It was first discovered in the Pacific Islands by

Sir Joseph Banks, who accompanied Captain Cook on his noted voyage. It has, however, since been found on the east coast of Australia at Port Jackson and Moreton Bay. It may be further remarked that this species is peculiar in its habitat, as it is said to be observed growing on moss-covered rocks on the coast—a rather remarkable position for an epiphytal Orchid.

Turning, however, to the species distinguished by the beauty of their flowers, which are of so much more importance to the gardener than the former, we have several that might be advantageously included in every collection; and prominent amongst these is that represented in the woodcut (fig. 66)—viz., *Dendrobium superbiens*. For this handsome Orchid English horticulturists are indebted to Mr. B. S. Williams of Upper Holloway, who obtained it through his collector, Mr. Goldie, about six years ago, and it has since become a great favourite, though some little difficulty has been experienced by a few growers in ensuring its satisfactory flowering. No such difficulty is, however, found at the Holloway nursery, where it flowers as freely as any other *Dendrobe*, and the blooms last for several weeks. The chief point in this successful treatment appears to be the temperature afforded, and this is worthy of note by all who have failed with the plant. *D. superbiens* is grown at Holloway in a small span-roof house extending from N.E. to S.W., in which a temperature ranging from 65° as the minimum to 80° as the maximum is maintained. The plants are grown in small shallow pans from 3 to 4 inches in diameter, the compost consisting of peat and sphagnum. They are suspended close to the roof and *never shaded*. In this way well-matured growth is obtained, and as a result the plants continue flowering over a long period, one with pseudo-bulbs about 3 feet long having borne ten racemes in succession. Some of the racemes even on small specimens have ten to a dozen of their rich rosy-purple coloured flowers. It may be remarked that both *D. Ainsworthi* and *D. formosum giganteum* succeed admirably under similar treatment. Of the other *Dendrobes* the two best are *D. bigibbum*, *D. Hilli*, and *D. speciosum*; the first dwarf, with bright rosy flowers in small racemes; the two others of much taller habit, especially *D. Hilli*, and bearing long racemes of creamy flowers. *D. bigibbum*, with its varieties *eandidum* and *superbum*, is much admired by orchidists, as, like *D. superbiens*, it supplies a rather uncommon tint in the genus, or, indeed, in the family.

Cymbidium reflexum, *C. suave*, and *Sarcochilus falcatus* are three of the best amongst the other Australian epiphytic Orchids; but even they are not very striking, and they cannot pretend to share the merits of the *Dendrobes*.

As might be expected, there is a great range in the temperature of so large an extent of land, the mean annual temperature varying from 60° in the south to 80° in the north; and the annual rainfall also varies considerably—namely, from 80 inches on some parts of the east coast to 12 inches, or even less probably, in the drier regions, so that it is of much importance to know the precise locality from which plants are obtained.—L. CASTLE.

SAND FOR PROPAGATING.

It is difficult at times both in gardens and nurseries to procure good sand for propagating purposes, as there is much difference in its quality. Sand should be tested before many cuttings are inserted in it, as an inferior material may be employed, and the consequence is batch after batch of carefully grown and prepared cuttings damp off. For over two years I filled the place of propagator in a large nursery in Scotland, where we had every opportunity of testing the various methods in propagating plants, and found it rather difficult in the dull days of winter to strike soft-wooded plants successfully, even under the best of treatment, in the early months of the year. We repeatedly lost numbers of cuttings. Some, no doubt, would say that was due to bad management, but in the first place the sand was of the worst description. A day or two after the sand was placed in the propagating chambers and cuttings inserted it was examined with a microscope, when innumerable small threads were observed not unlike spiders' webs on the surface of the sand, and when that fungus came in contact with the cuttings very few survived. Although the sand remained in the propagating chamber until it was dust-dry, after it was watered it gave the same result. Various methods were adopted to destroy the pest. A little salt mixed with the sand was a great preventive, still at all times it had not the desired effect. As the day lengthens light and heat increases, propagating becomes a much easier task.

Sometimes in private gardens very bad results may be seen in propagating plants. No doubt the cuttings are made and inserted correctly, watered, and due attention given, but more frequently sand from a river side is employed in those establishments, and

most of our rivers are polluted to an alarming extent. Sand from such sources must be neither adapted for the propagating nor the culture of plants. What is wanted is pure sand free from iron and minerals of any description. But in what parts of our country can such a sand be obtainable? There are various quarries of more or less importance. One which has come under my observation, and perhaps the purest white sand quarry in our island, is at Gateside, near Gourcock, as scarcely ever a cutting damps or fails in it. My trials extend over winter and summer. During January of last season we inserted a large number of tricolor *Pelargonium* cuttings in small boxes, and placed them in a moist plant stove more to test the property of the sand in the winter than the need of the plants, with the result that every cutting rooted much more quickly than ever I saw *Pelargoniums* root before, and a similar success attended my efforts with other cuttings during spring; our success this autumn is also very satisfactory.—WM. MUIR, *Bagatelle*.

AUTUMN-SOWN PEAS.

DURING the latter days of October and early in November is the best time to sow autumn Peas, and the advantage of doing this is often felt in spring, when a well-wintered batch produces pods some weeks earlier than the spring-sown rows. All know that many spring-sown Peas fail to make any satisfactory progress if the weather is unfavourable or vermin troublesome, and the same drawbacks are liable to occur in the case of autumn-sown Peas, but with both there are many chances of their doing well providing sowing is done at the proper time and necessary attention given afterwards. Only early kinds should be sown now, and those should be of the hardiest character. Round-seeded varieties must be selected. Wrinkled kinds are too tender; they are very liable to damp off in germinating, and they appear delicate when first they appear above ground in the winter side of the year. A spot well exposed to light and sun, but sheltered from winds, is a good situation for sowing autumn Peas. The ground should be deeply stirred and well manured, the rows not being nearer than the height the kind grows, and if a couple of feet wider so much the better; but while we approve of growing summer Peas in rows here and there and widely apart, we like the autumn and first spring-sown rows to follow each other and shelter one another.

Our Pea ground now is that from which we have lately cleared a lot of Cabbages. Manure was wheeled on the ground, dug over, and the drills opened, the Peas sown, and everything finished off in one day. When the soil is dry enough for digging, and in good working order in this way, it is surprising how well seeds germinate. The drills should be about 3 inches deep. The seed should be sown moderately thick, and the whole should be covered over firmly, and from the day the seed is buried until the stems are above being injured by mice and other vermin, constant attention must be devoted to trapping and killing, as one of the main points to success is to have the rows strong, entire, and even in growth. The many ways of destroying garden pests need not be pointed out here, but an impressive caution to beware may be given. As soon as the young plants are above ground a little earth should be drawn up on each side, but not close to them, the object being to afford a little protection. As growth advances, small twigs, such as birch from old brooms, should be put in on each side of them, and when 3 or 4 inches high stakes may be applied. If the weather is mild it may be necessary to do this before the new year, but if severe they may not be ready for stakes for some months. Frost or snow will not injure Peas sown now, and no attempt should be made to coddle them at any time, as this is sure to result in a relapse and loss.—A KITCHEN GARDENER.

SILKWORMS AND SILKWORM REARING.—18.

(Continued from page 349.)

It is one of the projects of the hour to introduce Chinamen to Britain for a variety of purposes, amongst them to show us how best to mix and combine teas of diverse flavours or strengths. Some persons may by-and-by suggest that we might obtain the services of Japanese natives of the Yama Mai district to instruct us in the art of tending and rearing this Japanese silkworm, concerning which such hopes have been entertained. No one can question the beauty and excellence of the silk that is yielded by its cocoons, but we have been as yet far from overcoming the difficulties which have impeded its successful rearing on a scale that would hold out the promise of certain commercial results. The Oaks of Britain have now ceased to be of the old importance to our navy; and, as Dr. Wallace remarks, it would be a famous

thing could we turn their leaves into a valuable silken fibre. Time, it may be, will yet bring this about.

My own experiment with *Attacus Yama Mai* was made some fifteen years ago on too small a scale to be of any moment, yet I succeeded in ascertaining a few facts tending to confirm what had been noticed or surmised by others. Want of leisure has prevented me since from trying the breeding of these worms under better arrangements, with a larger number to work upon, and in a summer less dry and hot than was that of 1868. A number of reports were published by persons who had fed the worms during the above season, showing many failures to be largely attributed to the weather of that very exceptional summer, for we have not yet had one that would rival it for uninterrupted sunshine and lack of moisture. Still, the truth must be told, that in summers more promising the caterpillars of *A. Yama Mai* have also shown a troublesome tendency to die off. I was unable to procure either Austrian or English eggs, so had to try some Japanese, which are seldom found to yield so strong a brood of worms. However, I got worms from two-thirds of the eggs; these emerged between the 6th and 21st of May. The intervals separating the changes of skin were generally nine or ten days, and it was about fifteen days after the fourth of these had been passed when the spinning commenced. On the whole it was evident my examples of the species grew slowly as compared with some reared by other naturalists, and Dr. Wallace may be right in thinking that the more rapidly the worms can be reared the greater will be the success, although he would not advise forcing.

My silkworms were fed upon Oak as succulent as I could obtain, the twigs being inserted in bottles of water. The nursery was a cool outhouse facing the north, without a current of air passing through certainly, but air was freely admitted in the daytime. The leaves were not allowed to remain until dry ere they were renewed, though, as I was resident in London, there was some trouble in getting fresh Oak during July, just when the worms needed abundant supplies. With some astonishment I one day saw a worm that had wandered crawl, not merely upon, but into a tumbler of water, and the liking the species has for occasional sips is a circumstance verified by many observers. Another liking, rather inconvenient, is that which some of them have for taking a bite out of a relative's back at a quiet opportunity, the wound so given being fatal sooner or later. On the near approach of anyone to the twigs upon which they are feeding, the caterpillars of *A. Yama Mai* cease to eat, so that visiting them too frequently might check their growth. This is a circumstance in favour of placing them in a position of comparative freedom upon young Oaks according to the Japanese plan, but then several circumstances have seemed to be against it, at least in this island. Some coaxing is required when they have to be shifted, as they are apt to cling very tenaciously to dry twigs and branches. By a gradual process of reduction I lost nearly the whole of my brood from disease, only a few surviving as mementoes of the trouble I had taken. Probably I should have saved more had I sprinkled the Oak with water, as some did, and others even went so far as to give their worms an actual ducking when the weather was very hot. Dr. Wallace does not seem to regard it of special importance that the leaves given should be chiefly young and succulent, for his worms fed well on Oak somewhat dry; his correspondents also differ in opinion upon this point. Their letters also show that these silkworms have been reared in and out of doors under such different conditions, as within glass buildings and exposed day and night to our climate in a plantation. Mr. Gascoigne, who succeeded in rearing a fine brood, argues in favour of an equable temperature for their room, an abstinence from water, and a free circulation of dry air. When newly hatched they have thriven upon oaklings in boxes of three or four years' growth, but their propensity to wander is always tiresome at this early age; it is less marked after the first change of skin.

To summarise those practical suggestions concerning the management of these silkworms that have arisen out of the patient experiments of naturalists scattered over these islands, it may first be remarked that, to start with, European eggs are preferable to those imported from Japan. If procured during the autumn the eggs should be kept until spring in a cool and dry place; even in the open air is not amiss, provided they are not subjected to a temperature that would freeze them. About the time the Oak is full in bud they may be laid upon blotting paper in plates and slightly damped, then covered with glass funnels or tumblers, upon which the newly hatched worms can be easily seen. By the aid of a stiff brush of camel or sable's hair they can be moved to young leaves of Oak. Dr. Wallace advises giving them a run on a moistened surface of earthenware before

placing them upon their food, as he thinks a "refresher" of this kind lessens their propensity for wandering. A proportion of them are sure to die in infancy. Should they be kept in the open air they must be guarded both from birds and spiders.

It does not seem to be a good method to keep these silkworms under bellglasses or in close boxes, but they will do moderately well in a plant house or room not too sunny. After they are half-grown they have been found to thrive if set free upon Oak saplings, where for security the twigs may be covered with gauze bags. Twigs and branches of Oak placed in water or sand will keep fresh for two or three days if the weather is not very warm. To remove the worms by the finger from stale to fresh food is hardly ever advisable. The plan is, having arranged your new Oak, to cut off the old sprays all the leaves or twigs unoccupied by the caterpillars. The remainder may be laid upon or put beside the new sprays, and they will soon shift their quarters. As a precaution against their wandering, trays and tables upon which bottles or jars containing Oak are placed ought to be round rather than square. Some stand these upon plates, the edges of which are greased, so that the silkworms are kept in check should they leave their food, as they will not crawl over this obstruction. Hasty moving while they are changing their skins is inadvisable, since a hurt is likely to be given by any rough treatment then. Although a little moisture on the leaves is rather beneficial than otherwise, it does not appear that the worms flourish if the foliage of the Oak given them is in a watery or over-succulent state. As they approach maturity an abundant supply of food is requisite, and the temperature of their room should be kept moderate if possible. Out of doors they should be shaded from too bright a sun. It is not needful to make special arrangements for spinning, as the habit of *A. Yama Mai* is to form its cocoons near the terminal twigs of the Oak. Of our native species Dr. Wallace recommends *Q. sessiliflora* as the best food.—J. R. S. C.

BUCKLAND SWEETWATER GRAPE.—I am rather surprised to see Buckland Sweetwater so much condemned in last week's Journal. It is very highly thought of here, and is in greater demand than Foster's Seedling. Buckland Sweetwater when well grown and finished realises a higher price in the market than Foster's Seedling. I consider Golden Queen well worth growing.—G. R. A.

KITCHEN GARDEN.

PEAS to afford an early crop may now be sown in a well-sheltered border of friable soil. A south border is the most suitable, having the rows north and south and about 4 feet asunder, with Lettuces between. Before sowing, the Peas ought to be either damped and coated with red lead, or damped with petroleum, to prevent the attacks of mice. William the First and Dickson's First and Best are the best early varieties in cultivation. Where space is available a sowing of the early dwarf varieties may be made at the base of a south wall, American Wonder being a good cropper. Slugs are frequently troublesome to Peas. Dress the ground with lime, and point in before sowing; and as a still further protection, give a dressing of a couple of inches thickness of sifted ashes after covering the Peas with soil, allowing the ashes to extend a few inches beyond each side of the row. Broad Beans may also be sown on a warm border, Early Mazagan being very early and hardy, but small. Seville Longpod and Early Longpod, though not so hardy, are much larger and early. Similar remarks apply to these in regard to precautionary measures against mice and slugs as advised for Peas.

Cauliflowers should be pricked out from the seed beds in pits and frames, and any remaining after due provision has been made by those means for a supply of plants for transplanting in spring may be pricked out on a sheltered border, where, if the winter does not prove unusually severe, they will survive. On a dry day lift Cauliflowers that are fit for use, and store them in a pit or sheltered position where protection can be afforded.

Complete lifting root crops such as Carrots, Beet, and Salsafy, and a portion of the Parsnips for immediate use; otherwise, and the

ground not being immediately wanted, these may remain in the ground for some time. Late-sown Turnips should be examined, those fit for use being stored in damp sand. This will improve the remainder of the crop, which may stand for later use. Complete the earthing-up of Celery, and where the soil is wet it will be preferable to employ ashes, sawdust, or cocoa-nut fibre refuse in preference to soil for this purpose.

FRUIT HOUSES.

Vines.—To have ripe Grapes in April the Vines, whether in pots or planted out, must now be started. Although bottom heat is not essential, yet when compelled to force early and quickly a bed of Oak leaves with a third or fourth of stable litter will hasten the Vines considerably, and with the Vines planted out in inside borders a good bed of Oak or Beech leaves with a little horse dung added will greatly facilitate the starting and be more beneficial to the Vines than fire heat alone. The inside border should have a thorough soaking with water at 90°, after which introduce the fermenting materials either on the border or floor to a depth of 2 feet, and occasionally turn them, the ammonia-charged vapour being highly favourable to the Vines. Syringe the Vines and house three times a day in bright weather. A temperature of 50° to 55° at night and 60° to 65° by day will not be too high to commence with, as the Vines will require a higher temperature than in December or January. The outside border must have regular attention as to covering.

Prune Vines in succession houses as soon as the leaves have fallen, the advantage of early pruning not being sufficiently appreciated—viz., earlier and complete rest. From all Vines bearing ripe Grapes remove the dead and decayed foliage. The wood of young Vines not yet hard and brown should have fire heat still applied, and this with free ventilation will soon ripen them.

Cucumbers.—The autumn fruiterers are now in good bearing. Maintain a night temperature of 65°, or 5° more in mild weather; 70° to 75° by day, and 80° to 85° from sun heat. Admit a little air at the top of the house on every favourable opportunity, which should never be done, particularly at this season, with a view to lower the temperature, but to prevent the temperature rising too high—to allow of rank heat and steam escaping. Ventilate cautiously on bright cold days, shutting off the top heat for a few hours at midday. Cease syringing the plants except on bright mild afternoons, but keep the evaporation troughs filled, damping the paths and walls morning and afternoon in warm clear weather. Take care that soil and water applied to the roots is of the same temperature as the house, and avoid sudden fluctuations in the temperature. Examine the plants once a week, stopping the shoots one or two joints beyond the fruit, removing bad foliage and superfluous growths. Upon the first appearance of mildew dust with flowers of sulphur.

PLANT HOUSES.

China Roses have passed out of general favour, but where these are grown, cut back and potted in spring after flowering, and plunged outdoors in ashes, they will now have abundance of flower buds, and if placed in a light house with a temperature of 45° to 50° they will open their buds and flower for a considerable time. Afford weak liquid manure, and keep them free from aphides.

Show, Fancy, Regal, and Spotted Pelargoniums must be kept as near the glass as possible, and as dry at the roots as can be done with safety, so as to prevent them becoming too luxuriant. Tie out the shoots neatly as they advance in growth. Zonals that have been grown and especially prepared for winter flowering should now be placed where they have plenty of light and a minimum temperature of 50°, just giving enough water to keep them slowly growing, supplying weak liquid manure.

Primulas should have a light position and be carefully watered, giving, however, thorough supplies when needed, and of a weak manurial kind. Ventilate freely on all favourable occasions, damp being their greatest enemy. A temperature of 45° to 50° is necessary.

Cinerarias sown early and grown on through the summer are advanced for flowering, indeed some of them are in bloom. The self-flowered sorts in various shades of blue, purple, scarlet, crimson, and white are very effective. They should have a temperature of 50°.

Other stock of these plants may be kept in a cool, moist, light structure, frost only being excluded, fumigating upon the first appearance of aphides. Shift successional plants into larger pots before they become root-bound, or when this is delayed too long the plants receive a check, generally resulting in their decaying at the base of the stem. Cyclamens producing their flowers should have a light position in a temperature of 50° to 55°, supplying them with weak liquid manure. Successional plants should be treated similarly, a little extra warmth being essential to their free growth and flowering.

Carnations for producing successional flowers through the winter must be well attended to, not allowing them to become dry at the roots. A temperature of 50° to 55° is necessary. Mignonette must have a light well-ventilated position, or the plants become weak; and keep the growths neatly staked and tied as they advance in growth. Those flowering should have a temperature of 45° to 50°.

Fuchsia cuttings struck in August should be shifted into 6 or 7-inch pots, and placed in a house close to the glass in a temperature of 50°, tying and stopping the leading shoots according to the habit of the plant. Old Fuchsias that have flowered should be partially dried off, but the soil must not be allowed to become dust-dry.

Herbaceous Calceolarias require potting singly, 3-inch pots being large enough at the first. Good loam, with a sixth of leaf soil or well-decayed manure and a little sand, is a suitable compost. Place them in a cool moist pit near to the glass where they will be safe from frost. Previous to potting the plants should be dipped in tobacco water, as they do not like fumigation.

Conservatory.—This structure is gay with Chrysanthemums, which should be kept at the coolest part of the house. With Primulas, Cyclamen, early-flowered Cinerarias, Zonal Pelargoniums, Salvia splendens and *S. gesneræfolia*, Epiphyllums, Epacrises, and Correas, a very effective display will be made, but avoid overcrowding. Free-growing roof climbers should have the shoots well thinned or cut back, for, however much shade may be desirable in summer, all plants require free exposure to light in winter.

THE BEE-KEEPER.

HIVES.

“THE markets and show tables are full of novelties. . . . The prices asked for some hives are exorbitant and far beyond their value.” Thus writes Mr. Pettigrew in the Journal of the 5th inst., and he has just cause for so writing. The reason why such novelties are produced and why they are purchased he gives in the opening sentences of his letter. “Many people like to follow the fashions and go with the majority. They readily spend their money for things last out, hence new inventions are the order of the day.” So far we go with him; and if people who take to bee-keeping as a pleasant pastime choose to expend their money on hives costing from £2 to £4, and to purchase appliances which quickly make away with a £5 note, we say, Let them do so by all means, it is good for the trade. But such hives and appliances are not within the reach of the cottager or artisan, who looks to his bees to help to pay his rent at Michaelmas. When Mr. Pettigrew would recommend the Stewarton hive in preference to the bar-frame hive we can go no farther with him. We do not for a moment doubt that straw is a superior material to wood for hives, but seeing that the difficulty has not been surmounted to make hives of straw which can have all the advantages of the moveable-frame system, for the present we must accept the wooden walls.

The question is how to make a hive of wood so as to keep bees and combs dry in it. Surely the bee-keeping readers of this Journal do not accept the inference that all bar-frame hives must have moisture condensed on the walls during the greater part of the year, and rotting combs! If such were the unhealthy state of colonies how could such grand results be obtained as the piles of beautiful sectional supers of honey, the breeding of healthy queens sent out by scores from our leading apiaries, the powerful stocks which store these piles of sections and produce these healthy queens? Great results can be obtained with the Stewarton in the hands of an able manager; but after all the product of

comb honey is in large shallow supers, and must be broken up to be retailed. Compare the comb honey in a Stewarton super with equal weight in 1 lb. or 2 lb. sections. Which is put up in the most inviting form? Which is the most portable? Which would be preferred by the salesman? One must be broken up and weighed out piecemeal, the other is already in a neat receptacle, and could be carried without any waste or trouble from one end of England to the other. When such honey is offered to the public, instead of the messy bulk in bellglasses or straw supers, as of old, is it a wonder that "the bar-frame fever is reaching to its height?" It doubtless is, and is likely to remain at its present height, until all who keep bees have learnt to adopt the system. But sectional supers can be filled over any kind of hive—over the straw skep, or box hives such as the Stewarton. The superiority of the bar-frame hive, therefore, does not depend on its system of supering. It is the hive which places the bees and combs entirely under the control of the bee-keeper. In a few minutes the whole of the combs can be separately examined, and their condition and that of the bees correctly ascertained. What we want to know about the queen, the brood, or the honey stores can at once be got at. Whatever may be the pros in the Stewarton or skep system, there must remain the contra that they are both systems of fixity, and therefore cannot be entirely under the control of the bee-keeper. The question then remaining is, How is a cottager or artisan who cannot buy an expensive hive to obtain one on the moveable-frame system at a reasonable cost? The answer is, Any man who can use a saw and hammer can make a substantial hive which shall be a healthy home for his bees at all seasons of the year.

We make our own hives during leisure hours, and their construction is so simple that we are certain that others can do the same during the coming winter, and thus start with good serviceable hives next spring. We will, therefore, endeavour to describe how our hives are made. Although measurement as to the length

S1, Dead air space. W1, Outer side wall. W2, Inner side wall. S2, $\frac{1}{4}$ -inch space round frame. Z, Zinc runner.

of the hive is immaterial, yet all the hives in one apiary should be in every respect alike, in order that all parts may be interchangeable. Brood boxes, frames, dummies, roofs, floorboards, and supers should be so made that any one may fit with another. We find that it is better to make the side walls of the hive hollow. The dead air space keeps the body of the hive warmer in winter and cooler in summer than single walls would do of whatever thickness. It will be presently seen that there is no need to make the front and back walls hollow, since the dummies take the place of the inner walls in those parts of the hive. Well-seasoned three-quarter-inch stuff is the best to use. If only planed on one side it will answer the purpose. To make the body of the hive saw off four pieces 9 inches wide, two of them to be 18 inches, and two $23\frac{1}{2}$ inches long. Those 18 inches long are to form the front and back of the hive, and those $23\frac{1}{2}$ inches long the two outer sides of the hive. Two other pieces 8 inches broad and 22 inches long form the inner side walls (W2, fig. 67) of hive. To these two pieces are to be tacked two strips of zinc, say $1\frac{1}{2}$ inch broad and the same length as the inner side walls, projecting a quarter of an inch above these walls, thus making $8\frac{1}{4}$ inches from floorboard to level of the zinc runners (Z, fig. 67). The frame bars (B, figs. 67

and 68) rest on these runners, and the bees are unable to propolise the frames to the hive. Mark off $7\frac{1}{4}$ inches on either side the centre of the inner sides of the front and back of the hive, in order that the interior breadth of the hive may be just $14\frac{1}{2}$ inches. The two inner walls may now be nailed on square, placing them outside the lines just marked off. Then nail on the outer side walls (W1, fig. 67), which are to overlap the front and back of the hive, so as to be nailed on square against them. Fit in strips of wood flush with the bottom and top of the 8-inch inner side walls between these walls and the outer walls, so as to shut in the space between them, and to prevent all draught through these spaces, as well as to exclude spiders, moths, earwigs, &c. Half an inch from the top all round the outside of the hive nail on strips half an inch wide and three-quarters deep, to be supports for the roof. In the centre of the hive front cut out a piece a quarter of an

Fig. 68.

inch high and 6 inches long as an entrance for the bees. Some arrangement should be made by which this entrance may be expanded or contracted at pleasure. Two strips with slots running on four tacks, as fig. 69, or two strips sliding in a groove or rebate above, will answer the purpose; but they should terminate with an inch of perforated zinc, in order that when quite closed together the bees may still have ventilation. At times it is useful to have some adjustment whereby the hive may be quite shut up—e.g. in case of troublesome robbing or when wishing to remove the hive to another position. A pent to shed the rain or shade during very hot weather may be made by screwing on a piece of wood or tacking a strip of painted zinc just above the entrance. Its width may be from 3 to 6 inches, and length the same as the front of the hive.

The floorboard (A, figs. 67 and 68) should be made as in fig. 67. A frame, A, is made of three-quarter-inch batten, and tennoned or made to overlap as to its separate pieces at the corners, as P, fig. 67. It should measure when put together $19\frac{1}{2}$ inches by $26\frac{1}{2}$ inches. The strip forming the front of the frame should be wider than the others, say 5 inches; the other three sides need not be more than $2\frac{1}{2}$ inches. This wide side should be bevelled off for 3 inches of its width, which part will form the alighting board for the

Fig. 69.

S, Slots. A, B, Alighting board. T, Tacks. Z, Perforated zinc.

bees. To this frame should be braded on both sides thin pieces of wood. If a stay be put across the centre of the frame quarter-inch deal will do very well to brad on. This will make a good reversible floorboard.

The frames are made as follows. For the top bars (B in figs. 67 and 68) strips of wood barely an inch wide, half an inch thick, and 18 long. Not having a circular saw to make a slot to carry the sheet of foundation or guide, we saw the bar through the centre lengthways for 15 inches of its entire length. Two pieces 8 inches long, half an inch thick, and three-quarters of an inch broad, form the sides of the frame. The top bar is nailed on to these side pieces so as to leave a quarter of an inch space between them and the sides of the hive, as S2, fig. 67. The bottom bar is 13 inches long, and need only be a quarter of an inch thick and three-quarters of an inch broad, and nailed on inside the side pieces of the frame, as shown fig. 67. When made the frame should hang clear of the frame and sides of the hive by a quarter of an inch. The ends of the top bar may be cut tapering from an

inch from their extremities, as shown at H, fig. 67. This will leave no chance of the bees propolis the frames to the sides of the hives. Two dummies or dividers should be made of three-quarter-inch stuff 14½ inches long and 8¼ inches deep, and should be nailed to the top bars similar to those made for the frames, only in their case the bars need not be slit up as for the foundation. A piece should be cut out of the centre of the bottom of the divider to correspond with the opening in the hive front, also to allow a passage at the back of the frames to the feeder, as T in fig. 68. In another letter we will speak of the roof, of the feeding arrangement, and of winter and summer arrangement of the hive.—P. H. P.

TRADE CATALOGUES RECEIVED.

Dickson & Robinson, 12, Old Millgate, Manchester.—*Catalogue of Roses.*

Bruant, Poitiers, France.—*List of New Begonias.*

J. L. Watson, Manor Road, Gravesend.—*List of Bulbs.*

E. Gill, Victoria Fernery, Lynton, North Devon.—*List of British and Exotic Ferns.*

Louis Van Houtte, Ghent, Belgium.—*Catalogue of Hardy Herbaceous Plants, Roses, and Fruit Trees.*

* * All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Black Hamburgh Grapes (*J. Gleave*).—The bunch, of which you have sent us a photograph, and which you stated weighed 4 lbs. 10½ ozs., and the berries good and well finished, was a very good one indeed, and highly creditable to you as a cultivator.

Plunging Hyacinths (*Doubtful*).—You have nothing to fear in burying the pots in the open air with cocoa-nut fibre refuse. They will be far better there than in the greenhouse. Nor is a cold frame necessary. The finest Hyacinths that are exhibited in London every year are buried 5 or 6 inches deep with the material above mentioned in the open air. Care must be taken that the pots are not stood on soil that is full of worms, but rather on a very hard surface impenetrable by worms, or on a thick layer of sharp ashes.

Gardener's Appointment (*W. D.*).—Your letter of last week was not preserved; and as you have not repeated the names of your past and present employers, we are unable to make the notification you requested. Full and accurate particulars, with plainly written names and addresses, are indispensable in cases of this kind. Last week you omitted your own name; this week you have omitted the name and address of your late employer.

Rose Catalogue (*Rosarian*).—We presume you mean the Catalogue of the National Rose Society, which we think can be had from the Rev. H. H. D'Ombra, Westwell Vicarage, Ashford, Kent, in return for seven penny stamps. We do not understand what you mean relative to the publication of "our observations in the spring." If you will explain the nature of the "observations" we will endeavour to answer your question.

Roses for Arches (*F. J.*).—The free-growing Ayrshire Roses, such as Alice Grey, Bennett's Seedling, and Splendens, are suitable for covering arches and arbours, as also are the Boursault Roses Amadis, elegans, and inermis. You may add also the evergreen Rose Félicité perpétué. These are all free, indeed more or less rampant growers, and are very effective when covered with their great clusters of flowers. If you desire Roses less floriferous, but produce better blooms over a longer period, plant such varieties as Gloire de Dijon, Belle Lyonnaise, Reine Marie Henriette, Cheshunt Hybrid, with the climbing forms of Victor Verdier, Jules Margottin, Bessie Johnson, and Charles Lefebvre, also the vigorous-growing Madame Clemence Joigneaux. You do not say how many you require, but probably we have named sufficient.

Vines and Brambles (*Idem*).—The instructions to which you refer on planting Vines are quite sound. A method of planting in summer which is not named in the work will not, we presume be suitable in your case. Both the mixtures to which you allude are good when properly applied, but we do not find it necessary to use either of them, nor to smear the rods with any pigment. You cannot err by planting the Parsley-leaved Bramble that was referred to last week.

Culture of Cyripedium Calceolus (*C. D.*).—The plant concerning which you inquire is a native of Britain, and therefore quite hardy; but it may be advantageously grown in a frame, and, if it is desired, in a cool house, as it may be then had in flower earlier in the season. The compost should consist of peat, fibrous loam, and sand, with a few pieces of rough limestone or sand, draining the pots thoroughly. The pots can be plunged in ashes, cocoa-nut fibre refuse, or other light material. During the winter very little water will be needed, but it is best not to allow the soil to become dust-dry. If it is desired

to grow the plant out of doors, a well-drained and moderately sheltered site on the shady side of a rockery should be selected, where with other hardy terrestrial Orchids it will give little trouble. The variety you name differs only from the species in the larger size of the flowers, and similar treatment suits both. They can be either planted or potted at the present time.

Culture of Cassia corymbosa (*Z. B.*).—The plant of which you sent a spray is a native of Buenos Ayres, and was introduced to this country at the close of the last century. It is a member of the natural order Leguminosæ, and bears the name given above. It succeeds well in a greenhouse or other cool house, and also does well out of doors in the summer; but it is not hardy, and it would not be safe in a border during the winter unless the situation is very warm and sheltered. A compost of turfy loam, a little well-decayed manure, leaf soil, and sand meets its requirements; but it will grow fairly well in almost any ordinary garden soil. Your plant is in excellent health, the foliage being remarkably vigorous. The best plan would be to transfer it to a conservatory, where it could be trained to a wall, pillar, or roof.

Exhibiting Berry-bearing Plants (*F. D. C.*).—It is impossible for us to answer your question without knowing the stipulations of the schedule of the show at which you propose to compete. The plants may or may not be eligible, everything depending on the intentions of the committee, which either are, or ought to be, defined in the schedule. For an answer to your other question write to Mr. Cannell, Swanley, Kent.

Grapes Shankling (*Sigma*).—There is no doubt the Vines would be injured by the ruthless defoliation of last autumn, and on that account ought to have been cropped more lightly and have had better attention this year. Overcropping in this case is the immediate cause of shanking. This, however, is a less calamity than the cause of it—illness. Cut off all the worst bunches, and remove the bad berries from the others promptly. Remove also all weak and superfluous growths or laterals at once, in order that the strongest and best can have full exposure to the light to facilitate their maturation. If you could also remove a portion of the soil from the border (if it is old) down to the roots, add fresh loam, and mulch with manure, you would do all that is practicable to restore the lost vigour of the Vine.

Cissus discolor (*Idem*).—This is the name of the plant of which you have sent an imperfect leaf. It is a stove plant, requiring light porous soil, such as equal parts of turfy loam, peat, and leaf soil, with a free admixture of charcoal. When grown in a shaded position in a moist warm stove the foliage is very beautiful in the summer. Most of the leaves fall in the winter, and the roots must then be kept rather dry, but by no means dust-dry, and the plants in a temperature of 60°. Repotting or top-dressing, whichever may be needed, should be done in the spring when growth is commencing.

Gypsum for Peach Border (*J. E.*).—It is not possible for anyone to state definitely how much gypsum you may incorporate with your Peach border without a knowledge of the constituents of the soil. If it is deficient in lime a quarter of a pound of gypsum mixed with each square yard of soil would be beneficial, or the same quantity spread on the surface and pointed in, but it will not act as a preventive of the Peach mildew. Brehaut's "Modern Peach Pruning" is published at this office, price 3s. 6d., post free 3s. 8d. Brehaut's "Cordon Training" is published by Longmans, but we do not know the price of the work.

Grape-growing for Market (*H. K.*).—Grapes for market are grown in the same manner as they are grown in private gardens. Mr. Taylor's work which you possess gives sound information on Vine culture, but it refers more particularly to Vines grown on what is termed the extension system, which, although very good when well carried out, may not be the form that you will adopt. Mr. Taylor grows splendid Grapes, but his crops are not so heavy as those of Mr. Witherspoon of Chester-le-Street, whose Vines are confined to single rods, nor of Mr. Thomson of Clovenfords, who trains two rods from the same Vine as a rule, and in some cases more, the rods being about 3 feet apart. Mr. Thomson has written an excellent work on Vine culture, which is published by Blackwood & Sons, and our Vine manual (3s. 3½d.) describes several methods of pruning and training Vines. Whether any one or all these works will be sufficient for making you competent as a Grape-grower it is impossible for us to say, as everything depends on your aptitude for turning published instructions to practical account.

Salting Asparagus Beds (*A. B. E.*).—We do not apply salt to our Asparagus beds in the winter as the soil is quite wet enough without it, but we dress the beds in spring and early summer, giving sufficient for preventing the growth of weeds. Before dressing the beds in November we carefully remove a portion of the surface soil, and the manure we add, being partially decomposed, is allowed to decay on the beds, thus forming a rich light medium in which Asparagus delights.

Culture of Chionodoxa Lucilæ (*M. H. R.*).—We have frequently answered queries concerning this plant, and can only repeat that it is quite hardy in the south of England and by no means difficult to grow, succeeding as well as the common hardy Scillas in ordinary light soil where it is not exposed to excessive wet. When grown in clumps in the borders it is very pretty and flowers freely.

Gardenias Unhealthy (*N. G.*).—If you have sent us a fair sample of the plants they are certainly far from being satisfactory. We should first of all repot them, removing any loose soil from the roots, and place them in clean well-drained pots smaller than those they are now in, using a compost of light turfy loam, fibrous peat, and leaf soil in equal parts, with a free admixture of charcoal broken small and silver sand. We should then plunge the plants if possible in a bottom heat of 85° to 90°, and apply water with great care, giving sufficient to keep the soil healthily moist without saturating it. This, with judicious syringings governed by the state of the weather, and a temperature of 70° as a minimum, would induce fresh root-action. This accomplished we should prune the plants rather severely, removing at least all such growths as you have enclosed, and should then expect healthy shoots and dark green foliage to follow. This effected, the plants could be kept clean and healthy by copious supplies of water, frequent syringings, and a very moist warm atmosphere.

Pears Cracking (*W. H., Eastbourne*).—The precise cause of the cracking of your Pears is not easy to determine. The fruit is usually most liable to be injured in this manner when the trees are growing in poor sandy soil, but we have often seen them seriously affected when the soil has been good. In this case we attribute the evil to frost in spring injuring the tissue of the fruit and depriving it of its elastic or expansive power; hence the ruptures, which injure if they do not destroy the fruit. Again, we suspect that imperfect fertilisation often results in the fruit cracking, as few fruits that are seriously injured have sound and fertile seeds, while those specimens which are sound on one side and split on the other, usually have more or less sound kernels on the sound side

and withered abortive seeds on the other. This is not always the case, but is undoubtedly so in by far the majority of fruits that we have examined, and it was so in the specimen you have sent. As a remedy we can only suggest that if the soil is sandy that the roots be placed in a heavier and more fertile medium, top-dressing with manure to keep them near the surface, and that the blossoms and embryo fruits be protected in the spring, both against excessive wet, which prevents the dispersion of the pollen, and against frosts and sleet that injure the enticle of the young fruit. By adopting these methods with a tree on a wall that had the fruits seriously cracked, we have not since failed to have good crops of fine smooth Pears.

Winding Rockery (J. T. W.).—We are very willing to assist you in this matter, but it is not easy to do more than give you a general idea for carrying out work such as your employer desires to have done, and we cannot better do this than by submitting a plan that was prepared by Mr. Abbey some years ago.

Fig. 70.

brought from the woods, and on some are seedling Ferns, Moss, and Lichens that impart an appearance of age to rockwork. Wood rots, and the stones that are above or on it fall, and the work has to be done over again at a time when the plants are about their best. Fix every stone firm, and lay them so as to leave some good-sized openings for soil (some large and some small), laying them in such a position as to be examined in case of an accident, and so go on until the whole of the rockwork is completed.

Names of Fruits (S. G. S.).—1, Passe Colmar; 2, Bergamotte Destrkyer; 6, Flemish Beauty. We do not recognise the others. They are perhaps local varieties, and one was quite rotten. (H. M.).—We have examined the specimens carefully, but all we can say is that 22 is not Nonsuch, 44 not Gloria Mundi, and that 57 is Hollandbury. The others we do not recognise. They are probably local varieties, of which there are so many in your district. (H. Knowles).—The cider Apple of which you have sent specimens in all probability never had a name, and if you have supplied us with a fair sample of the fruit it is certainly not worthy of one.

Names of Plants (H. K.).—Miltonia Clowesi. (L. B.).—Cassia corymbosa, see reply above. (J. W.).—1, Sednm spectabile, a Japanese species much used in the London parks and in gardens generally; 2, Polygonum vacciniifolium, a pretty dwarf species, very suitable for culture in pots or trailing over a rockery. (J. H.).—1, Quercus Phellos latifolia; 2, Quercus cerris; 3, Antennaria tomentosa; 4, Justicia speciosa.

COVENT GARDEN MARKET.—NOVEMBER 1ST.

THE supplies and character of the trade generally remain substantially the same as last week.

POULTRY AND PIGEON CHRONICLE.

NEGLECTED PASTURES AND WASTE LANDS.

ON former occasions we have alluded to subjects very nearly connected with our present one, but more especially we may refer the home farmer to our article on farming permanent pastures on February 5th, 1880, in this Journal, and again another article on the improvement and manuring of pastures on March 3rd, 1881. We wish, however, now to deal with neglected pastures, and also where farms have fallen into the hands of owners in consequence of the failure of tenants during the agricultural depression. It is especially desired to illustrate what has been done under such adverse circumstances in improving waste lands without the expenses being incurred of fallowing and cleaning.

Numerous entailed estates have been charged with heavy encumbrances by the "dead hand," the present or reputed owners have then unfortunately little or no means (in consequence of the reduction in the rentals and value of lands) to enable the home farmer or estate agent to adopt what has been frequently advocated by scientific as well as practical writers as being the best method of laying down arable land for pasture. Then arises a very serious question, at a very serious crisis, for "necessity knows no law," What is to be done with land left in a state of comparative waste by the previous impoverished occupiers? it being also in many cases extremely foul with couch and poor for want of manure. Under any circumstances, however, the question cannot be replied to off-hand, simply because we must ask other questions before the first can be answered. Is the land suitable for pasture? or is it better adapted for cereal culture, although suitable for pasture? If the latter, and it occurs that a farm comes to hand for the home farmer to manage, or for the agent to let, although the land may be foul and gene-

rally out of condition, the driest and best loamy soils must be cultivated for corn as well as roots, and must be managed or let for that purpose. If the land is of strong clay and flat-lying or hilly, if of a north or north-eastern aspect, it had better go into grass, except the altitude should be great, then a crop of timber offers the best opportunity for profit. But then we are brought face to face with the expenses of cultivation and planting, and, therefore, it must run to waste as hillside or mountainous land, and capable of rearing only a few forest ponies or horned sheep, such as those kept in the hill districts of Scotland, or the small white-faced horned sheep of Wales and some of the western counties of England; in this case no outlay will be required except for the first purchase of the stock.

Let us now refer to hilly strong land, as well as the flat-lying clay soils, and of these soils many thousand acres of them have within the past six or seven years fallen into or been returned on the hands of the proprietor. Supposing that the land is foul with couch or twitch, the distinction we make is that couch means the strong-leaved and white-rooted grass which lies deeply rooted in the soil; the twitch we consider is the creeping or narrow-leaved variety which runs upon the surface, with shallow bunches of roots which adhere to the surface soil from nearly every knot or joint in the stems of the grass, and thus forming a mat on the surface. In either of these cases, if we go to the expense of tilling the land it will be very costly to eradicate them. In fact on the cultivated arable land, if these grasses by bad farming have prevailed for some years their seeds will have been dropped and buried in the soil by the cultivation; and if we clean the land ever so well and sow the best kinds of permanent grass, still the couch or twitch will propagate from the seed and claim part possession of our surface, upon which we have made a large expenditure for the purpose of destroying them. When this occurs it is of the utmost importance to consider which will gain the ascendancy in the pasture, but this will entirely depend upon the course of management both as to manure and the system of feeding—in fact the general management of the turf, whether it should be cut for hay or be fed off only by live stock. Even then it depends upon the kind of stock which are kept and the food they consume, for it must be remembered that the feeding is also a manurial question, and must be allowed for and considered in any outlay made for artificial manures, or the value of farmyard or town manure, applied either by themselves or mixed with earthy compounds.

It is also necessary to consider in what state each field is as regards the last crop, whether it is now in stubble of corn crops or in Clover lea, or covered with weeds. Another point to be considered is, In what state is the surface? Does it lie in small ridges, or is it laid into the wide high-backed ridges peculiar to some of the midland and western counties with deep furrows? It is almost impossible to obtain an even sward or growth of turf on these small ridges, the furrows being only a series of hollows to hold water on the surface, unless it has been effectually under-drained with pipes in a judicious manner. The wide high-backed ridges, however, lie comparatively high and dry, and are more easily cleared of the water on the surface even though the land be strong, and if draining is required it is more easily effected by a pipe drain in each furrow. It is clear that if no cultivation can be done, or as little as possible, to produce a profitable turf in accordance with the capabilities of the soil, it is most important to understand which soils should be rejected as hopeless for the purpose of forming into pastures. We should say that sandy, thin, gravelly, peaty, and thin chalky land should be considered as unprofitable in pasture, and seldom worth the expenses of seed and tillage even under the best of management, unless production can be accomplished by irrigation either upon the ridge-and-furrow system with flood water, or upon the principle of catch meadows, where the position of the land enables the water with or without

flood deposits or liquid manure to be spread over large areas of land assisted by the peculiar incline of the surface. There can be no doubt that in various districts of the kingdom, but more especially in the western, midland, and north-western counties, there are large areas now comparatively waste, where farms and parts of farms of considerable extent can be turned to a profitable purpose as pasture, if the points to which we have previously alluded are considered in relation to the varying circumstances enumerated.

After these prefatory remarks we shall endeavour to describe land under varying conditions of profitless and wasteful occupation, and explain the means whereby they may be renovated and improved, to enable the home farmer to accomplish as much as may be possible under the circumstances by which he may be surrounded. It has been asserted, and even considered as a rule, that a good pasture cannot be maintained from the time it is seeded until it becomes a permanent pasture with a large accumulation of humus on the surface, without a break or period of barrenness after the first few years. But we deny that this is a matter that cannot be avoided, we only view it when it happens as resulting from want of care and intelligence in various ways. First of all, if the annual or even perennial grasses are used in conjunction with the best permanent meadow grasses, they will for a time promise well, but when they have decayed the surface is left bare to some extent, giving an opportunity for weeds or inferior grass to get possession. This vacancy, caused by the failure of the annuals and the time which may intervene before the permanent grasses can get full possession of the surface, is caused in several ways. First by the serious mistake of not sowing exclusively the permanent grasses and Clovers; also if the seed has been selected without judgment, and by trusting to others that which should be done by the home farmer himself, various failures may occur, such as old seed mixed with new, seeds uncleaned, and of sorts not suited to the soil. Still, much depends upon the condition of the land and manure applied as well as its fitness for the soil; also, if unsuitable stock are allowed to injure the young seeds, the pasture as a permanent one will be delayed. But the greatest cause of failure of the young plants of grass is because the land is not made rich enough with properly selected manures to maintain their vigorous growth.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—The weather has been very suitable for ploughing and pressing the Clover leas on dry soils for Wheat, because, although the late rains have been rather heavy for the strong flat-lying soils with a fallow surface, the greater portion of these soils intended for Wheat have been seeded before this date. Still, it is not too late if the weather should prove open and dry enough to drill the Wheat and work it off, and complete the work simultaneously; and this is really necessary in the month of November, for the records of our climate in this month are that slight morning frosts or rains prevail, both of which cause a delay of the operations of seeding for Wheat, and the work consequent upon it. Where the land is composed of dry loams, gravel, or sandy loam, the first fortnight in November is a good time for drilling Wheat, and especially if the land is in a high state of cultivation and situated in a warm and sheltered district. There is no fear of the Wheat becoming what is termed winter-proud if sown in November. It is, however, quite necessary to sow from 2½ to 3 bushels of seed at this time of the year, as the small birds and rooks are very likely to search for the grain when it shows the first blade, and they destroy much of it, especially after ordinary drilling, as the seed lies near the surface; but when the seed is deposited by the press drill it falls into the grooves formed by the rings of the presser, and is consequently buried a good depth under the surface, and is not so likely to be injured by the birds. The extra seed we advise is especially necessary, too, upon farms on an estate where the home farmer is called upon to conduct his operations when game is preserved thereon, particularly where rabbits prevail, for in this case there are frequently a large number of rats, which shelter themselves in the banks and burrows, and we have known large areas of Wheat destroyed by them, as they search for the grain as soon as germination commences. These, together with rabbits, are a sad nuisance where encouraged to any extent. We, however, do not object to rabbits being preserved and reared for profit upon rough and waste lands, but they should be confined by wire-net fencing

within certain limitations, to prevent injury upon the cultivated lands and valuable pastures. There is plenty of employment for the odd horse in carting roots for the cattle in their boxes, also Cabbages for the dairy cows, carrying hay for the farm horses, and also roots, such as red or white Carrots, and straw for litter for all the animals on the farm which are confined in pens, stalls, or stables.

Hand Labour.—The pulling and storing Mangolds will still be going on, and this may be best done by men, women, and boys, casting into heaps and covering with the leaves, the carting and storing to be done by the horses and carts at any time when the drying intervals of weather occur. Some little supervision by the home farmer is necessary as to the mode of taking up the roots of Mangolds, for we do not suffer the people employed to cut the greens off, so as to sever any portion the crown of the roots, but they should be cut so that all the leaves shall fall separate at the time of cutting. This mode will save the crown and heart of the roots untouched, and this we find necessary, because the roots are then capable of throwing out a little yellow leaf. This secures them against decay, because they have vitality in the root, as proved by the sprouting. If the field producing the Mangold should be at a considerable distance from the farm it is well to make the store heap on the margin of the field, so that the labour at this busy time may be diminished. Water-furrowing on the recently sown Wheat land should be done daily, in order that when heavy rains follow it may escape to the proper outlets and not sodden the surface, to the injury of the young Wheat plants. Hedging, ditching, and banking will be work for some men now, others will be required in the meadows at trenching, so as to prevent water lying on the surface, which breeds rushes or coarse sour grass. The water meadows, too, should receive the usual attention, for they should now be in flood and receiving the benefit of deposits from the hills left by flood water after the recent heavy rains. Cutting the wood in the hedge-rows for hurdles should now be done; also all the ditches which receive the spring drainage in the enclosed districts should be scoured to prevent stoppages at the outlets of the pipe drains.

Live Stock.—We never recollect sheep so dear before, especially the middling and lower grades, commonly termed calls; but it must be remembered that vast improvements have been made in the sheep stock of the kingdom, and that there are but few inferior animals now as compared with thirty years ago. This, therefore, tends to the higher average of prices. We have seen Hampshire Down lambs of nine months old sold from 77s. to 86s. each in lots of one hundred in number, but were sold for mutton weighing, as we estimated them, on the average at from 12 stones of 8 lbs. to 13 stones per hundred, some individual animals reaching the great weight, for their age, of from 14 to 15 stones of 8 lbs. each. Horned cattle are dear also, but not so dear after the rate as sheep; in fact, some of the importations from Ireland are really well-bred, show good outlines and deep long coats. We have noticed this specially amongst the young stock under a year old; these in good condition, both heifers and steers, selling at six guineas each. These, at the price, considering their breed and quality, will pay better for wintering than sheep. Dairy cows should now be given Cabbages on the driest pastures, as the grass is getting both stale and short. In order to maintain a full supply of milk some farmers, instead of encouraging the flow milk, allow the cows to go dry soon after this time. We object to this entirely, for it has the effect of cows laying on fat internally, and endangering success at calving time.

POULTRY AND PIGEONS

SPOILING THE DORKING.—No. 1.

IN your "Poultry Notes at Wolverhampton Show" in last week's number I find these words: "Coloured Dorking cocks, first (Smyth) was large and good in most points; his earlobe was white, but the Judge, rightly perhaps, does not seem to regard this as a demerit." Why should he? The true Dorking had a white earlobe, or very nearly so, and it was not until it was crossed with the Asiatic breeds that the red earlobe appeared. Then the wisecracks who had spoiled the Dorking in the crossing, in all its fine qualities as a table fowl, claimed as a point the red earlobe. For my part I look at the red earlobe as *one* of the proofs of the mongrelism of the present so-called Dorking. On no account would I purchase for breeding purposes a bird with a red earlobe. I should fully expect, and I have but little doubt that my expectation would be realised, that I should have chickens with sooty feet. The dark colour is another proof of the mongrelism of the present Dorking. Let us look at what the present breed has in common with the old and true. In the old, there were the Grey, the Brown, the Bay, the Silver-Grey, the Speckled, and the White, besides the Cuckoo. Now the judges have reduced the colours to the Dark (nearly black, never a Dorking colour), the Cuckoo, Silver-Grey (is now not a *silver* grey but a dirty brown grey), and the White. The angle of the carriage of the

Dorking was much more upright than the present, which tends towards the horizontal Asiatic carriage. They have got rid of the rose-combed variety as nearly as possible, and many of the single combs have sprigs at and about the large part of the comb, as could be seen at the Tonbridge Wells Show. They have produced sooty feet and white spotted with lead colour, as could also be seen at the same Show; and, as the reporter of this Journal noticed, even some of the prizewinners at the Dairy Show were tinted with dark colour. They have thick skins, yellow skins, yellow fat, instead of thin and white; and the flesh is a dirty colour by comparison, red earlobes instead of white, and they have got size and great coarseness of both flesh and bone, long fibre to the flesh instead of the short.

A few years back I knew a stock of good Brown Dorkings. In an evil hour the higgler who bought the young chickens of the henwife persuaded her to have a Dark Brahma cock to breed from. The result was much larger chickens at three months old, much darker in colour, with white legs. The Brahma was then got rid of, the cockerels were chosen from the home produce, the biggest being selected. Now, without any further cross, the whole of the stock have sooty legs and feet, or nearly so, and the colour of the hens and chickens is nearly black. I purchased a brood this year for table purposes; I found they all had dark legs, and the flesh was of a muddy colour comparatively to the original breed. The reason, no doubt, was this: The owner selected the largest (therefore those that most partook of the Brahma element), and so again and again, keeping to the dark colour because it was fashionable, not because it was better in any respect nor prettier; and so more and more Brahma without the feathers on the legs, but the *red* sides to the legs clearly showed that they had been so bred, instead of the pure white colour of the true Dorking. But how come the sooty legs and feet? Why, in this way: The Dark Brahma or Cochin has dark feathers on its legs, and when these are got rid of the stain of the colour remains in the leg, the more so when bred with a white-leg fowl. Yellow and white legs will often make darkish legs. This I have found by experiment with a Dorking and a yellow-legged Game, but more often they have been white. I am deeply sorry to find that there are those who act as judges still giving prizes to sooty-footed fowls. It is very wrong, and it is disheartening to the breeder who is endeavouring to restore the Dorking proper with all its points. Quality is not looked to, but size and colour. Why such a stress should be put on colour I cannot imagine. To me it appears utter nonsense when as a table fowl the Brown, Light Reds, Bays, and the old Grey were far superior in the colour and texture of fat and flesh. For my own part I ignore colour altogether. I intend to breed for the white legs, the full rounded breast, and thin skin, white fat and white flesh; and on no account will I purchase a cock bird to breed from that has a *red* earlobe or the slightest tint of sootiness on his feet, or a black toe-nail; for the latter proclaims its pedigree to my eyes, and I am most likely to get sooty-footed chickens as his produce. It is very uphill work to try and get back to the old sort, and it will take years of patient work; but it is to be done, and I for one mean to work steadily at it. I care nothing for colour; but, if any, I shall try and raise for my own keep the old, scarce, rich, red-brown colour, but that will depend on circumstances. I have this year bred several very dark birds with pure legs, feet, and toe-nails, and by careful selection and watching I hope to get more next year if I am spared.

I find on reference to the *Live Stock Journal* that Mr. Cresswell judged the Dorkings at Wolverhampton Show, and his giving the first prize to a bird with a white earlobe is no more than I should expect from him, as he knows, if anyone does, what a good pure Dorking should be, for I well remember birds of his that were shown long ago. Ah, me! yes, long ago, when Dorkings were Dorkings, and I hope and trust he still has some of the blood left.
—HARRISON WEIR. *October 28th, 1882.*

THE NEW STANDARD OF EXCELLENCE.

HEREWITH I enclose draft Standards of Excellence for Brahmas and Cochins. The Committee of the Poultry Club are anxious, if possible, that these, as also the Standards for Dorkings, Game, and the French breeds, which I shall send you next week, shall be considered and finally settled at the Crystal Palace Show.

The Committee will feel much obliged by your inserting the drafts.

I would remind fanciers that the Standard as now published is merely tentative, and I trust that all interested will aid in making the final Standard as representative as possible, by either sending me their views as to any alterations or additions they may think desirable, or attending the meetings of the fanciers of the various

breeds named above, which I am arranging for the Crystal Palace Show.

All comments published or sent to me, as also the comments of the leading judges, to whom I am sending copies of the drafts, shall be submitted to the fanciers who meet at the Palace. All are invited to attend, and I shall give as early notice as possible of the time and exact place of meeting.—ALEX. COMYNS, *Hon. Sec*, 47, Chancery Lane, London, W.C. October 30th, 1882.

BRAHMAS.

GENERAL CHARACTERISTICS—COCK.

Beak.—Short, curved, very strong.

Comb.—Triple or pea, erect and firmly set, as small as possible, the centre ridge slightly the highest; all three ridges perfectly straight and evenly serrated, fitting very closely to, and drooping behind to follow the line of, the head.

Head.—Small, rather short, of medium breadth, well rounded, with a slight prominence over the eye.

Eye.—Large, fairly prominent.

Earlobe.—Long in proportion to the size of the wattles, fine in texture, and free from feathers.

Wattles.—Small, well rounded, fine in texture, and free from feathers.

Face.—As smooth and free from feathers or hairs as possible.

Neck.—Long, well arched, covered with ample flowing hackles reaching well down to the shoulders, and free from twisted feathers. A depression should be apparent between the head feathers and the upper hackle feathers.

Breast.—Very full, broad and square, with great depth, carried well forward.

Back.—Broad throughout, short, flat or slightly hollow between the shoulders; the saddle to rise about half way between hackle and tail, and to continue to rise until it reaches the tail coverts.

Wings.—Of medium size, carried horizontally, free from twisted or slipped feathers, tucked up under saddle feathers, which should be of ample length.

Tail.—Of medium length, rising somewhat from the line of the saddle, but not quite upright; the quill feathers to spread well out, and the top quill feathers to form, if possible, what is known as the black cock tail (?).

Tail Coverts.—Broad, abundant, well curved, nearly covering the quill feathers.

Thighs.—Large and powerful, well covered with feathers, so set on that the lower feathers of the breast cover the thighs in front.

Hocks.—Amplly covered with soft rounded feathers, or with quill feathers provided the latter be accompanied with proportionately heavy foot-feathering.

Fluff.—Soft and very abundant, covering the hind parts and standing out well behind the thighs.

Legs.—Of medium length, powerful, with plenty of bone, wide apart, the scales to be as smooth as possible.

Leg Feather.—As profuse as possible, standing out well from the leg, and extending well under the hock feather and to the extremity of the middle and outer toes. Good foot feather without vulture hock to have a preference.

Toes.—Straight, large, and spreading.

General Shape.—When viewed in profile, very deeply and squarely built; when viewed from front or rear, broad and compact.

Carriage.—Lofty and bold, the breast bone to be carried horizontally.

GENERAL CHARACTERISTICS—HEN.

Beak.—Short, strong, curved.

Comb.—Triple or pea, erect and firmly set, as small as possible, the centre ridge slightly the highest; all three ridges perfectly straight and evenly serrated, fitting very closely to, and drooping behind to follow the line of, the head.

Head.—Small, rather short, of medium breadth, well rounded, with a slight prominence over the eye.

Eye.—Large, fairly prominent.

Earlobe.—Long in proportion to the size of the wattles, fine in texture, and free from feathers.

Wattles.—Small, well rounded, fine in texture, and free from feathers.

Face.—As smooth and free from feathers or hairs as possible.

Neck.—Short, well arched, covered with ample flowing hackles reaching well down to the shoulders, and free from twisted feathers. A depression should be apparent between the head feathers and the upper hackle feathers.

Breast.—Very full, broad and square, with great depth, carried well forward.

Back.—Broad throughout, short, flat or slightly hollow between the shoulders; the cushion to rise about half way between hackle and tail, and to continue to rise until it reaches the tail coverts.

Wings.—Of medium size, carried horizontally, free from twisted or slipped feathers, well tucked up under cushion feathers.

Tail.—Of medium length, nearly upright, the quill feathers to spread well out, those below gradually diverging like a fan.

Tail Coverts.—Full, and extending nearly to the extremity of the tail.

Thighs.—Large and powerful, well covered with feather, so set on that the lower feathers of the breast cover the thighs in front.

Hocks.—Amplly covered with soft rounded feathers, or with quill feathers provided the latter be accompanied with proportionately heavy foot-feathering.

Fluff.—Soft and very abundant, covering the hind parts and standing out well behind the thighs.

Legs.—Very short in proportion to size of bird, strong, and wide apart.

Leg Feather.—As profuse as possible, standing out well from the leg, and extending well under the hock feather and to the extremity of the middle and outer toes. Good foot feather without vulture hock to have a preference.

Toes.—Straight, large, and spreading.

General Shape.—When viewed in profile, very deeply and squarely built; the body carried very near the ground. When viewed from front or rear, broad and compact.

Carriage.—Sedate, the breast bone to be carried horizontally.

POINTS OF COLOUR IN DARK BRAHMAS.—COCK.

Comb, Face, Deaf Ear, and Wattles.—Bright red.

Head.—Silvery white.

Eye.—Orange-red, pearl or grey.

Beak.—Black or yellow and black.

Neck Hackle.—Pure silvery white, densely and sharply striped with brilliant black in the centre of each feather.

Breast.—Intense glossy black, or such black evenly mottled or laced with white.

Underpart of Body and Thighs.—Corresponding in colour with breast.

Back and Shoulder Coverts.—Silvery white, except between the shoulders, where the feathers should be glossy black laced with white.

Saddle.—Silvery white striped sharply with glossy black.

Wing Bow.—Silvery white. *Greater and Lesser Wing Coverts*.—Forming a distinct bar of glossy black. *Secondaries*.—White on outside web except at end, where there is a black spot. Black on the inside web. *Wing Primaries*.—Black mixed with occasional feathers having a narrow white edge on outside of web.

Tail.—Black.

Tail Coverts.—Glossy black, the upper two finely laced with white.

Legs.—Orange-yellow.

Leg Feather.—Black or black slightly mottled with white.

HEN.

Comb, Face, Deaf Ear, and Wattles.—Bright red.

Head.—Silvery white or white striped with black or grey.

Eye.—Orange-red, pearl, or grey.

Beak.—Black or yellow and black.

Hackle.—Silvery white sharply striped with black, or pencilled as on body.

Ground Colour of Body.—Pullets, any shade of clear grey. Hens, the same; or may be more chestnut in tint, if not too brown, but the former clear grey colour much preferable. The colour to be uniform throughout.

Pencilling.—Black or a darker shade than the body colour, very clearly defined, following the outline of each feather. As uniform in character as possible over the body.

Tail.—Black or black edged with grey.

Legs.—Orange-yellow, the feathers to be well pencilled.

POINTS OF COLOUR IN LIGHT BRAHMAS.—COCK.

Comb, Face, Deaf Ear, and Wattles.—Bright red.

Head.—Silvery white.

Eye.—Orange-red, pearl, or grey.

Beak.—Black or yellow and black.

Neck.—Silvery white striped with black, the striping being more dense at the lower part of the hackle.

Breast.—White.

Underpart of Body.—The surface to be clear white, but the fluff may be grey in the underpart.

Thighs (including hocks).—Clear white.

Back and Shoulder Coverts.—White.

Saddle.—White or white slightly striped with black; white preferable.

Wing Bow and Coverts.—Silvery white. *Primaries*.—Black or black edged with white. *Secondaries*.—White on outside web, black on inside web.

Tail.—Black.

Tail Coverts.—Glossy black, the two upper ones evenly laced with white.

Legs.—Orange-yellow.

Leg Feather.—White or black and white mixed.

HEN.

Comb, Face, Deaf Ear, and Wattles.—Bright red.

Head.—Silvery white.

Eye.—Orange-red, pearl or grey.

Beak.—Black or yellow and black.

Neck.—Silvery white striped with black, the striping being more dense at the lower part of the hackle; the black centre of each feather to be entirely surrounded by a white margin.

Breast.—White.
Back.—Pure white with or without grey underfeather.
Wing Bow.—Silvery white. *Primaries.*—Black or black edged with white. *Secondaries.*—White on outside web, black on inside web.
Tail.—Black.
Tail Coverts.—Black laced with white.
Thighs (including hocks).—Clear white.
Fluff.—White on surface, but may be grey in the underpart.
Legs.—Orange-yellow.
Leg Feather.—White or black and white mixed.

DARK BRAHMAS.

NUMERICAL VALUE OF POINTS.—COCK.

Points to be deducted for defects.

Bad head	3
Defective comb	6
Scanty hackle	4
Want of cushion	5
Want of fluff	4
Defective leg feather	6
Bad shape or carriage of tail	3
Splashes of white in tail	5
Primaries out of order	6
Pale legs	2
Curved toes	3
Stain of white in deaf ear	2
Breast patched or splashed with white	7
Impure colour of white	8
Want of stripe in hackle	5
Other defects of colour	6
Want of size	10
Defects of symmetry or carriage	10
Want of condition	5

100

A perfect bird to count 100 points.

DISQUALIFICATIONS.—COCK.

Trimming or dyeing of any kind; comb other than pea; twisted hackle; vulture hock accompanied with scanty foot feather (?); total absence of leg feather; deformity of any kind; twisted wing feathers; white legs; much red or yellow in plumage; great want of size in adults; total want of condition; much white in tail; if shown with a hen, birds not matching fairly well.

NUMERICAL VALUE OF POINTS.—HEN.

Points to be deducted for defects.

Bad head	4
Defective comb	4
Scanty hackle	4
Want of cushion	6
Want of fluff	4
Defective leg feather	7
Bad shape or carriage of tail	3
Pale legs	2
Curved toes	3
Stain of white in deaf ear	2
Streaky breast	8
Want of clearness and evenness in ground colour	8
White in foot feather	3
Shank feather not pencilled as the body	3
Want of uniformity in pencilling	10
Other faults of colour	4
Want of size	10
Defects of symmetry or carriage	10
Want of condition	5

100

A perfect bird to count 100 points.

DISQUALIFICATIONS.—HEN.

Trimming or dyeing of any kind; comb other than pea; twisted hackle; vulture hock accompanied with scanty foot feather; total absence of feather; deformity of any kind; twisted wing feathers; white legs; utter want of pencilling; patches of brown or red; great want of size in adults; total want of condition; if shown together, birds not matching fairly well.

LIGHT BRAHMAS.

NUMERICAL VALUE OF POINTS.—COCK.

Points to be deducted for defects.

Bad head	3
Defective comb	6
Scanty hackle	4
Want of cushion	5
Want of fluff	4
Defective leg feather	6
Bad shape or carriage of tail	3
Splashes of white in tail	5
Primaries out of order	6
Pale legs	2
Curved toes	3
Stain of white in deaf ear	2
Black in breast	4
Black in fluff	3
Impure colour of white	8
Want of stripe in hackle	5

Striping on saddle	2
Other defects of colour	4
Want of size	10
Defects of symmetry or carriage	10
Want of condition	5

100

A perfect bird to count 100 points.

DISQUALIFICATIONS.—COCK.

Trimming or dyeing of any kind; comb other than pea; deformity of any kind; twisted hackle; vulture hock accompanied with scanty foot feather; total absence of leg feather; twisted wing feathers; white legs; buff on any part of plumage; great want of size in adults; total want of condition; if shown with a hen, birds not matching fairly well.

NUMERICAL VALUE OF POINTS.—HEN.

Points to be deducted for defects.

Bad head	4
Bad comb	4
Scanty hackle	4
Want of cushion	6
Want of fluff	4
Defective leg feather	7
Bad shape or carriage of tail	3
Pale legs	2
Curved toes	3
Stain of white in deaf ear	2
Cloudy, pale, or streaky hackles	10
Black splashes	10
Impure white	10
Other faults of colour	6
Want of size	10
Defects of symmetry or carriage	10
Want of condition	5

100

A perfect bird to count 100 points.

DISQUALIFICATIONS.—HEN.

Trimming or dyeing of any kind; comb other than pea; twisted hackle; vulture hock accompanied with scanty foot feather; total absence of feather; deformity of any kind; twisted wing feathers; white legs; buff on any part of plumage; great want of size in adults; total want of condition; if shown together, birds not matching fairly well.

COCHINS.

GENERAL CHARACTERISTICS.—COCK.

Beak.—Short and stout at base, tapering to the point and slightly curved.

Comb.—Single, rather small, fine in texture, perfectly straight and upright, evenly serrated, free from side sprigs, and symmetrically curved from base of the beak to the back of the head.

Head.—Rather small, and neat in proportion to the size of the bird.

Eye.—Bright and expressive.

Deaf Ear.—Well developed, and fine in texture, hanging nearly as low as the wattles.

Wattles.—Rather long, fine in texture, and neatly rounded at the bottom.

Face.—Smooth and fine in texture.

Neck.—Short, well curved, carried rather forward, and abundantly covered with long hackle feathers, which should reach well on to the back.

Breast.—Very broad, deep, full and rounded in appearance.

Back.—Short and broad, rising towards the tail, and well furnished with saddle feathers, which should be soft and long.

Wings.—Small, the primaries tightly clipped up under the secondaries; the whole carried close to the body. The end hidden by the saddle.

Tail.—Small and full, rising slightly from the saddle; free from sickle feather.

Tail Coverts.—Soft and abundant, curving over and nearly covering tail.

Thighs.—Short, thick, and wide apart; abundantly covered with soft feathers.

Hocks.—Completely covered with soft feathers, which should curl round the joint and stand well out. Stiff feathers called "vulture hocks" objectionable, but not a disqualification.

Fluff.—Very full, abundant, and soft, standing out so as almost to hide the thighs.

Legs and Leg Feather.—Legs short, thick, and heavily feathered on the outside. The feathers should stand well out from the leg.

Toes.—Strong and straight; the middle and outer toe well feathered to the end.

General Shape and Carriage.—Broad, deep, massive, and rounded in appearance; the carriage bold, the head carried rather forward, and the forepart of the body rather low.

GENERAL CHARACTERISTICS.—HEN.

Beak.—Short and stout at base, tapering to the point, and slightly curved.

Comb.—Small, single, straight, evenly serrated, and fine in texture.

Head.—Small and neat.
Eye.—Bright and expressive.
Deaf Ear.—Rather large.
Wattles.—Small and neatly rounded.
Face.—Smooth and fine in texture.
Neck.—Short, carried rather forward, and abundantly covered with soft hackle feathers reaching well on to the back.
Breast.—Broad, deep, full, and rounded.
Back.—Short and broad, first rising into an abundant cushion, and then falling slightly to the tail.
Wings.—Small and tightly clipped up, the points buried in the cushion.
Tail.—Short and small, almost covered by the cushion.
Tail Coverts.—Very abundant and soft.
Thighs.—Short, strong, set wide apart, and abundantly covered with soft feathers.
Hocks.—Well covered with soft feathers curling round the joints. Stiff feathers called “vulture hocks” objectionable, but not a disqualification.
Fluff.—Very abundant and soft, and standing out well from the body and thighs.
Legs and Leg Feather.—Short, thick, and heavily feathered on the outside. The feathers should stand out well from the leg.
Toes.—Strong and straight; the middle and outer toe heavily feathered to the end.
General Shape and Carriage.—Broad, deep, massive, and well rounded; the head carried rather forward; the forepart of body slightly drooping; the cushion carried rather high.

POINTS OF COLOUR IN BUFF COCHINS.—COCK.

Comb, Face, and Wattles.—Bright red.
Deaf Ear.—Bright red, free from any tinge of white.
Beak.—Deep yellow.
Head.—Rich buff.
Eye.—Orange or pearl, the former preferred.
Hackle.—Rich golden buff, uniform in colour, and sound to the root of the feathers.
Back.—Same colour as hackle.
Wings.—Ditto, the flights buff and free from splashes of black or white.
Saddle.—Same colour as hackle.
Breast, Thighs, and Fluff.—Clear buff, perfectly even and free from all shading.
Tail.—Rich chestnut, shading to bronze, perfectly free from white, and with as little black as possible.
Legs.—Bright yellow, the feathers matching thighs and fluff.

HEN.

Comb, Face, and Wattles.—Bright red.
Deaf Ear.—Bright red, free from any shade of white.
Beak.—Yellow.
Eye.—Orange or pearl, the former preferred.
Plumage.—Clear rich buff throughout, perfectly free from all mottling, and hackle from any ticking.
Legs.—Bright yellow.

POINTS OF COLOUR IN LEMON COCHINS.—COCK.

Comb, Face, and Wattles.—Bright red.
Deaf Ear.—Bright red, free from any tinge of white.
Beak.—Yellow.
Head.—Bright lemon buff.
Eye.—Orange or pearl, the former preferred.
Hackle.—Bright lemon buff, even in colour, and sound to the root of the feathers.
Back.—Same as hackle.
Wings.—Ditto, the flight feathers buff, and as free as possible from any splashes of black or white.
Saddle.—Same as hackle.
Breast, Thighs, and Fluff.—Clear lemon buff, even in colour, and free from all shading.
Tail.—Rich chestnut buff, free from black or white, especially the latter.
Legs.—Bright yellow, the feathers lemon-buff, matching the body.

HEN.

Comb, Face, and Wattles.—Bright red.
Deaf Ear.—Bright red, free from any white.
Beak.—Yellow.
Eye.—Orange or pearl, the former preferred.
Plumage.—Uniform lemon-buff throughout, and perfectly free from all mottling.
Legs.—Yellow.

POINTS OF COLOUR IN CINNAMON COCHINS.—COCK.

Comb, Face, and Wattles.—Bright red.
Deaf Ear.—Bright red, free from any tinge of white.
Beak.—Yellow.
Head.—Rich cinnamon.
Eye.—Orange or pearl, the former preferred.
Hackle.—Rich cinnamon, perfectly even in colour.

Back.—Rich dark cinnamon.
Wings and Saddle.—Rich deep cinnamon, free from all markings.
Breast, Thighs, and Fluff.—Cinnamon, almost approaching chocolate, perfectly even in colour.
Tail.—Rich bronze.
Legs.—Yellow, feathers same colour as breast.

HEN.

Comb, Face, and Wattles.—Bright red.
Deaf Ear.—Bright red, free from any white tinge.
Eye.—Orange or pearl, the former preferred.
Beak.—Yellow.
Plumage.—Rich even cinnamon throughout, perfectly free from all markings.
Legs.—Yellow.

POINTS OF COLOUR IN PARTRIDGE COCHINS.—COCK.

Comb, Face, Deaf Ear, and Wattles.—Bright red.
Beak.—Yellow shading to horn colour.
Head.—Dark red or orange.
Eye.—Orange or pearl, the former preferred.
Hackle.—Orange or golden red, each feather having a glossy black stripe down the centre.
Back and Shoulder Coverts and Wing Bow.—Rich dark red. *Greater and Lesser Coverts.*—Metallic black. *Primary Quills.*—Bay on the outer web, black on the inner. *Secondary Quills.*—Bay on the outer web, metallic black on the inner.
Saddle.—From a bright golden colour to a rich orange red, each feather having a metallic black stripe down the centre.
Breast.—Rich black.
Underpart of Body and Thighs.—Black.
Tail.—Glossy metallic black.
Legs.—Yellow, feathers black.

HEN.

Comb, Face, Deaf Ear, and Wattles.—Bright red.
Beak.—Yellow shading to horn colour.
Head.—Light brown or yellow, finely pencilled.
Eye.—Orange or pearl, the former preferred.
Neck.—Golden yellow, each feather striped with greenish black down the middle.
Remainder of Plumage.—Light brown, every feather to be distinctly pencilled with a darker shade and uniform over the whole body, a light shaft objectionable.
Legs.—Dusky yellow.

POINTS OF COLOUR IN WHITE COCHINS.—COCK AND HEN.

Comb, Face, and Wattles.—Brilliant red.
Deaf Ear.—Brilliant red, free from any tinge of white.
Eye.—Orange or pearl, the former preferred.
Plumage.—Pure snowy white, glossy and free from all creamy or yellow tinge.
Legs.—Bright yellow, pale legs in old birds a fault, but not a disqualification.

POINTS OF COLOUR IN BLACK COCHINS.—COCK AND HEN.

Comb, Face, Deaf Ear, and Wattles.—Brilliant red.
Eye.—Red or black.
Plumage.—Rich glossy raven black, perfectly free from feathers of any other colour and sound to the roots, the more metallic sheen the better.
Legs.—Dusky yellow preferred, dusky legs without the yellow not a disqualification.

POINTS OF COLOUR IN CUCKOO OR CREOLE COCHINS.—COCK.

Comb, Face, Deaf Ear, and Wattles.—Red.
Beak.—Yellow, sometimes black markings.
Eye.—Red.
Plumage.—The ground colour nearly white, each feather barred across with dark blue grey.
Legs.—Pale yellow.

POINTS OF COLOUR IN CUCKOO COCHINS.—HEN.

Comb, Face, Deaf Ear, and Wattles.—Red.
Beak.—Yellow.
Eye.—Red.
Plumage.—The ground colour nearly white, each feather barred across with dark blue grey.
Legs.—Pale yellow.

BUFF, LEMON, OR CINNAMON COCHINS.

NUMERICAL VALUE OF POINTS.—COCK OR HEN.

Points to be deducted for defects.	
Defective colour	25
Want of size	15
Bad head and comb	10
Slip wings	5
Want of fluff	5
Want of cushion	5
Length of leg, and want of leg-feathering	10

Want of general shape	10
Want of condition	15
	100

A perfect bird to count 100 points.

DISQUALIFICATIONS.

Twisted or falling comb; plumage any other colour than shade of buff, lemon, or cinnamon respectively; legs any other colour than yellow; general want of Cochin points; crooked back, legs, or other deformity; total absence of feather.

PARTRIDGE COCHIN.

NUMERICAL VALUE OF POINTS.—COCK OR HEN.

Points to be deducted for defects.

Defective colour	20
Want of size	15
Bad head and comb	10
Slip wings	5
Want of fluff	5
Want of cushion	5
Length of legs and want of leg-feathering	20
Want of general shape	10
Want of condition	10
	100

A perfect bird to count 100 points.

DISQUALIFICATIONS.

Twisted or falling comb; general want of Cochin points; any deformity; total absence of feather.

WHITE COCHINS.

NUMERICAL VALUE OF POINTS.—COCK OR HEN.

Points to be deducted for defects.

Defective colour	25
Want of size	15
Bad head and comb	10
Slip wings	5
Want of fluff	5
Want of cushion	5
Length of legs and want of leg-feathering	10
Want of general shape	10
Want of condition	15
	100

A perfect bird to count 100 points.

DISQUALIFICATIONS.

Twisted or falling comb; plumage any other colour than pure white; legs any other colour than yellow; general want of Cochin points; any deformity; total absence of feather.

BLACK COCHINS.

NUMERICAL VALUE OF POINTS.—COCK OR HEN.

Points to be deducted for defects.

Defective colour	20
Want of size	15
Bad head and comb	10
Slip wings	5
Want of fluff	5
Want of cushion	5
Length of legs and want of leg-feathering	10
Want of general shape	15
Want of condition	15
	100

A perfect bird to count 100 points.

DISQUALIFICATIONS.

Twisted or falling comb; any mixture of red or white feathers; general want of Cochin points; crooked back or other deformity; total absence of feather.

CUCKOO COCHINS.

NUMERICAL VALUE OF POINTS.—COCK OR HEN.

Points to be deducted for defects.

Bad colour	25
Bad shaped comb	10
Want of hackle	8
Length of legs and want of leg-feathering	10
Want of size	15
Want of condition	12
Want of symmetry	20
	100

A perfect bird to count 100 points.

DISQUALIFICATIONS.

Numerous black, white, or red feathers; total absence of leg-feather; general want of Cochin points.

THE POULTRY CLUB.

A MEETING of the Committee of the Poultry Club was held at the Charing Cross Hotel on Wednesday, October 25th, at 2 P.M. There

were present—Messrs. T. W. Anns (in the chair), G. B. C. Breeze, A. Comyns, and C. F. Montresor.

ANNUAL REPORT.—The Annual Report to be presented at the General Meeting at the Crystal Palace was read by the Secretary and approved.

STANDARD OF EXCELLENCE.—Some details connected with the draft Standard of Excellence now in preparation were under consideration.

NEXT MEETING.—The next meeting was fixed to be held at the Charing Cross Hotel on Monday, November 13th, at 4.30 P.M.—ALEX. COMYNS, *Hon. Sec.*, 47, Chancery Lane, W.C. October 30th, 1882.

OUR LETTER BOX.

Testing Milk (Comber).—If you place the milk-tester bulb downwards in a vessel of milk, the depth to which it will sink will depend on the density of the milk, and its richness or otherwise will be indicated by the figures on the scale. You will easily understand its action if you first try the tester in pure milk, then in milk and water, and by similarly testing the products of different cows you will find which animal yields the richest milk.

Poultry Farming (E. B., Dublin).—The St. Leonards Poultry Farm, Ringwood, Hants, would probably be best. Unless you have had practical experience we would strongly urge you not to attempt the business, and even then only in a small way to begin with.

Feeding Cows in Winter (J. E.).—In keeping cows in the winter months on purchased food for the production of the richest milk and butter, we recommend that each cow should be allowed 56 lbs. to 64 lbs. of Mangolds daily, according to the size of the animal, 3 lbs. of Wheat crushed, and 3 lbs. of decorticated cotton cake, the usual quantity of good pasture hay and sweet oat straw cut into chaff per day. We do not approve of cooking food for ruminating animals; we prefer that the best yellow Mangold should be pulped, and the crushed Wheat and cotton cake, together with the straw and hay, be mixed together in the shape of pudding, this to be divided into three feeds per day. Wheat at 5s. per bushel, according to the weight and quality for butter-making purposes, is the cheapest food now to be purchased in comparison with other grain. Crushing also is better than meal, because of less waste. Mangold is the cheapest root adapted for milch cows, but Potatoes are the best root food if they can be bought cheap enough.

Cow-keeping and Mangers for Stables (A. L. L. W. and J. O.).—Your letter arriving as our pages were being prepared for press cannot be satisfactorily answered this week, and replies to them will be published in our next issue.

Turtle Doves (J. H.).—Turtle Doves in this country are birds of passage, coming in spring about the beginning of May, breeding here, and leaving again early in autumn. They are about the size of a Missel Thrush, measuring about 10 or 11 inches in length, and about 18 inches in breadth from tip to tip of the expanded wings. The Turtle Dove is exceedingly shy and wary in its wild state; they frequent the deep woods and thickets, preferring a Pine or Fir tree to build on. The nest is formed of twigs, and lined with finer twigs or roots, and but slightly depressed in the centre. It is often placed on a flat Fir bough covered by another. They lay two small white eggs, and sit about a fortnight; they feed on small grain and seeds. Although so shy in a state of nature, yet if the young are taken from the nest and reared by hand or mouth they become very tame, and will occasionally breed in confinement, and may be permitted to enjoy their liberty in summer; but care must be taken to confine them at the migratory season, or they will decamp without hope of returning the next spring. They breed freely with the Collared Turtle or common cage Dove. Dr. Bechstein remarks that the hybrid progenies are prolific, and the produce becomes larger each cross. Their coo is peculiar, and differs from either of the parents.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

22nd.—Dull and damp early; showery morning; fine bright afternoon; moonlight night.
 23rd.—Fine bright morning; heavy squall of rain and wind at 2.40 P.M.; fine evening.
 24th.—Very wet and wild early, with rapid fall of barometer and heavy gale, especially about noon; fine moonlight night.
 25th.—Fair but hazy morning; showery afternoon; fine evening.
 26th.—Foggy morning; afterwards fine and bright till 6 P.M.; heavy rain during evening.
 27th.—Damp and rainy all day.
 28th.—Wet all day; high gusty wind after 1 P.M.

Another very wet week, the rain having fallen every day for a fortnight, and to the aggregate depth of very nearly 4 inches. The temperature is near, but rather below, the average.—G. J. SYMONS.

9th	TU	Brixton Chrysanthemum Show (two days).
10th	F	
11th	S	
12th	SUN	23RD SUNDAY AFTER TRINITY.
13th	M	Stoke Newington (two days) and Lambeth (three days) Chrysanthemum Shows.
14th	TU	Royal Horticultural Society (Fruit and Floral Committees at 11 A.M.). Southampton (two days), Tooting, Putney, Twickenham, Walton, and Plymouth Shows.
15th	W	Bristol (two days) and Westminster Aquarium (two days) Shows.

THE CUCUMBER DISEASE.

BELIEVE there are at least two distinct forms of Cucumber disease, but I have only made the acquaintance of one, and I can assure your readers that this is quite sufficient. Where a daily supply of fruits has to be maintained throughout the year with limited convenience the task is not always an easy one, as accidents will sometimes happen. But, accidents and diseases excepted, it is quite possible to have an unbroken supply of Cucumbers for many years; and if my memory serves me right I had such an one for at least half a dozen years, then came a change. The nature of the disease which has been so troublesome I have not been able to ascertain satisfactorily, but I have discovered how it came and how it may be extirpated.

I had hitherto grown but one variety and saved the seed. This variety may not be the handsomest, and certainly the fruit from that is not the largest with which I am acquainted, but it bears freely in winter and the flavour is good. However, it was not good enough for an assistant who had charge of the Cucumber house, and a reputed better variety was introduced without my knowledge, "just one plant" among the rest to see the difference. Well, the difference was remarkable, for the new comer had no sooner commenced showing fruit than each of the said fruit, amongst other vagaries, attempted to describe a semi-circle, and, as I had not been accustomed to see my Cucumbers behave in this way before, the matter was inquired into and the truth revealed. It was just one of those cases in which gardeners may fervently pray to be "saved from their friends," especially such amongst the latter as would do them "good by stealth." It is unnecessary to say that the semicircular-fruited variety was quickly despatched, and I was in hopes I had finished growing Cucumbers of that shape. But "the evil men do lives after them," and so did that of my friend's Cucumber, for the whole stock somehow caught the bad habit, and semicircular Cucumbers were the rule. It was not, however, the shape only which was disappointing—that could be altered before they were sent to table—but there was a gummy substance exuded from the fruits, many of them were quite bitter, and there was a difficulty in growing a sufficient quantity, as only a few of the fruits would swell at all.

Various plans were tried to remedy the evil. Fresh seed was obtained from a source where the disease was unknown. It was raised in houses or frames some distance away from the

old plants, and fresh vigorous young plants were placed in dung beds or clean houses as the case might be, but with no better result. The disease seemed to be in the air, and do what we would it appeared as if we could not escape it.

But we will try again. It may be that the germs of the disease are capable of being carried by the attendants, or the implements which are used, and this theory at present has all the appearance of being the correct one.

Plants were raised and grown in an old house quite away from those in which the disease was rife; the attendant had his separate waterpots, &c.; he procured water from a different source, and had nothing to do with the houses where the diseased plants were. The latter were kept no longer than when the new plants commenced fruiting, and then, of course, they were carefully destroyed. Many readers will say, Why were they not destroyed at once? But gardeners who have to maintain a perpetual supply of everything will not ask that question. The first isolated stock of plants did very well, and we started another lot for the summer on a dung bed. This was also kept isolated from the Cucumber house proper with the same result. The house in which the diseased plants had been growing was fumigated with sulphur, every part that could be reached was scalded with boiling water, the walls were limewashed, the woodwork painted, and the house remained clear of Cucumbers for four or five months, during which time no disease was seen on the place. Now, I am happy to say, we have plants in the same house in full bearing in the most perfect condition—a sight such as has not gratified my eyes for several years.

It is plain, then, that nothing short of complete isolation and seed fresh from a healthy source will suffice. We had tried everything except isolating the attendant and his implements before and failed.—W. TAYLOR.

CEANOTHUSES FOR BEDDING.

CEANOTHUSES are generally regarded as wall-covering plants, and for this purpose most, if not all of them, are admirably adapted; but it may not be known to all men that some of the varieties at least are equally well suited for growing in the form of bushes in borders, or for filling large flower beds effectively. But such is undoubtedly the case, and thus grown they are at least as effective as when trained to walls, and, what is more, form masses of chaste blue flowers in the autumn, such as can be equalled by few, if any, other plants, hardy or tender, that are employed in gardens.

There is great diversity in the habits of the species and varieties of Ceanothuses, just as there is in the characters of Fuchsias. Some Fuchsias, as all know, are suitable for training up pillars, while others of more sturdy growth are equally well adapted for planting in borders and beds. For the latter purpose no one would think of growing such varieties as Lustre, Arabella, Champion of the World, and others of that type, but they would select such sturdy growers and free-bloomers as Rose of Castile, Erecta Von Novelty, and Lady Heytesbury, standards or bushes of which produce a charming effect when planted out in flower gardens in summer. It is precisely the same with Ceanothuses. For bedding such species as *C. azureus*, *C. divaricatus*, and *C. rigidus* must not be chosen, but a few others that will be named of sturdier growth, and which afford large lavender, pink, and white racemes in profusion. They require, too, precisely the same treatment as Fuchsias,

and this is easy enough, neither great cultural skill being needed, nor valuable space under glass occupied in wintering the plants. When old Fuchsias are planted out they simply need potting in the autumn, keeping moderately dry so that they will shed their leaves, then placing under the stage of a cool house or even in a shed where they will be safe from frost. In the spring they need pruning, just starting into growth gently, then planting out again at the beginning of summer, and they grow and flower until the approach of winter. Such is the simple routine of managing these popular plants for outdoor decoration, and it may be said that they grow far more healthily and flower more profusely than when allowed to be dried, parched, drawn, and insect-eaten under glass, which is the fate of thousands of plants every year.

Now Ceanothuses for beds require the precise treatment as above summarised for Fuchsias, and therefore their preservation and culture are within the means of the majority whose duty or pleasure it is to render flower gardens and pleasure grounds attractive during the summer and autumn months.

It was on the Continent where I first saw Ceanothuses grown as bushes both in pots and planted out, and their floriferous character rendered them far more effective than Veronicas. But it may be reasonably urged that, although they may succeed well there, it does not follow that they will be amenable to the same treatment in this country, and give equally satisfactory results. But experience has proved that they grow and flower quite as well in English as in Belgian and French gardens; at least I have never seen finer examples than those which many others have also seen this year growing in one of the large beds at Chiswick, and it follows that if they grow so well there and flower so profusely, that they will succeed just as well under the same treatment in a thousand other British gardens. A large bed of these plants, perhaps 15 feet long and 7 or 8 wide, was certainly the most distinct and attractive of all the beds in the garden during September and October. It was quite a mass—not a formal heavy mass of pale blue, but an elegant waving group of thousands of fine racemes.

In some of the London parks attempts are made every year to grow in bush form the good old greenhouse wall and pillar plant *Plumbago capensis*; but although it is amenable to this method of culture, as a rule the results are far from being satisfactory. If the same space were devoted to Ceanothuses treated as above indicated a far better display would be produced, and a distinct effect imparted to the groups of ornamental plants that are there so admirably represented.

While there are several varieties of Ceanothuses suitable for growing as bushes either in pots or planted out, many of them closely resemble each other, and therefore only four of the very best and most distinct that have come under my notice shall be named, as these will be quite sufficient to start with by those who may desire to try this method of culture. They are *Gloire de Versailles* for the centres of large beds, also equally suitable for low walls, for which purpose it is the finest variety; *Gloire de Vaite*, dwarfed, very free and fine. Both these are blue. The best pink variety is *Marie Simon*, and the best white *nivens*. I have seen these flowering freely in 5-inch pots.

Ceanothuses may be rapidly increased from cuttings, as the young shoots, not too soft, strike as freely as *Heliotropes* or *Verbenas*, and under the same treatment. It would be well to grow the plants in pots the first season in a light house at first, then in a cool frame, then plunging them in ashes in a sunny position out of doors; in fact, giving them the same general treatment as *Chrysanthemums*. They would thus ripen their growths, and afterwards the simple routine above sketched for Fuchsias would suffice for all further requirements.

Such plants as those blue varieties that have been flowering so profusely in the Royal Horticultural Society's garden would be most valuable for conservatory decoration in late autumn and early winter, and would contrast effectively both in habit and colour with *Chrysanthemums*.—J. W.

ANTS EATING GRAPES.—We have millions of small ants, which feed upon the late Grapes or any other ripe fruit. Can any of your readers state how to extirpate them? I have put treacle in jam pots and caught several, but there are so many that it seems like trying to

empty the Thames to get rid of them in that way. Is there any poison that would attract them that I could mix with treacle? Where I can apply it I have found paraffin and soapsuds effectual—in fact, it is a long time before they will attempt to go where paraffin has been applied; unfortunately that cannot be used in many places.—J. H. W.

APPLES, PEARS, AND STRAWBERRIES FOR THE NORTH.

PERHAPS it may be assumed that what is suitable for these northern parts will suit anywhere. I have long contended that the succeeding year is more depending on its predecessor for success than it is on either wind, rain, frost, or sunshine, and this year's experience has more than ever convinced me that the opinion I have formed thereon is correct. With suitable weather this year, and bearing trees not exhausted by overcropping, with wood ripened and fruit buds fully developed, it will be seen that troubles next year will be met with a robustness that will overcome the little difficulties that may occur. To be the more impressed with the necessity of a sufficiency of sun heat this year to secure success next, it may be well to remember that the fruits we love to cultivate most are imported from sunnier climes; or even if natives, by crossing may have been robbed of the hardy nature possessed when growing in natural wildness, and have so become unfitted for our clime.
