THE

JOURNAL OF HORTICULTURE,

COTTAGE GARDENER,

AND

HOME FARMER.

A CHRONICLE OF COUNTRY PURSUITS AND COUNTRY LIFE, INCLUDING POULTRY, PIGEON,
AND BEE-KEEPING.

CONDUCTED BY

ROBERT HOGG, LL.D., F.L.S.

Established

in 1848.

VOLUME V. THIRD SERIES.

JULY TO DECEMBER, 1882.

LONDON

PUBLISHED FOR THE PROPRIETOR 171, FLEET STREET.

1883.

LONDON:
PRINTED AT THE JOURNAL OF HORTICULTURE OFFICE,
171, FLEET STREET.

January 11, 1883.

TO OUR READERS.

HAVING "returned thanks" no less than seventy times on the completion of the half-yearly volumes of this Journal for the support that has been accorded us, the good wishes that have been expressed, and the lively interest that has been manifested in our work, what can we say more than that our acknowledgments to our friends old and young, writers and readers, deepen with increasing years?

That we have much to gladden us and encourage us to further effort, this our last completed volume affords ample evidence; for in not one of all that have preceded it is the work of so many pens and the reflex of so many minds recorded. This shows, if anything can show, that the interest in gardening and kindred home pursuits is at least as active as ever, and that this activity will continue we have had satisfactory assurance during the present week.

Our object is to be useful, to increase the trade in all gardening and home appliances, to improve the culture of everything that yields profit and affords pleasure, to provide a field for discussion and the interchange of ideas between those who are equally animated with ourselves in the desire to impart information and acquire knowledge; and especially our hope is to remove difficulties under which the young and inexperienced labour.

To this end we invite all those whose wants we do not anticipate to ask, without apology or hesitation, for such information as they may need; and if it is in our power to do so we will give it readily, not as a task but as a pleasure.

Correspondents, too, will in the future, as they have done in the past, submit their experience on any perplexing subject that is published in our columns. Thus those who seek instruction on special matters often become instructors by procuring information of the utmost value and importance.

All who can impart or elicit knowledge, and assist in making clear what was before obscure, will be welcomed as helpers in the work which on so many good grounds it is so desirable to foster—the advancement of horticulture.

INDEX.

—0—

- ADIES WEBBIANA, 33
 Abutilon Thompsoni, 210; culture of and varieties, 493; for winter, 531; new varieties of, 575
 Acacia Farnesiana, 151; three useful, 403
 Achillea Parmica flore pleno, 229
 Achimenes, selection of from Chiswick trials, 177
 Acrocliniams, double varieties certificated, 533
 Adiantum cydoniaefolia, 511
 Adiantum cucullatum, 501
 Adiantum punctatum, 345
 Agapanthus umbellatus, culture of, 403
 Ageratum Malvern Beauty, 177
 Allamandas, culture of, plagiarism, 99; 498 temperature for, 576
 Allium sacciferum, 175
 Alpine plants, selection of, 324
 Amateur's holiday in Scotland, 531
 American blight, the tar remedy 536
 Ampelopsis Veitchii, 242, 305; A. sempervirens, 243
 Anagallis tenella, 154
 Androsaces, notes on species of, 156
 Anemones, planting, 259, 465
 Anthurium Andreanum in Covent Garden, 343
 Antirrhinum Hendersoni, 39; versicolor, 259
 Ants, utilisation of in horticulture, 80; destroying, 450, 499
 Aphelexis, culture and varieties, 404
 Aphides, destroying black on Peach trees, 392
 Apples—D. T. Fish, syn. Warner's King, 151; The Cat's head, 157, 175; at Girtford, 300; crop in America, 249; the crop, 277; Pott's Seedling, 322; Reinette, Franche, and Pine Apple Russet, 343; Landsberger Reinette certificated, 346; Lady Heniker, 334; variations in, 376; effect of liquid manure on old trees, 386; for the north, 424, 474; Pott's Seedling, 425; The Domino, 428, 449; Cellini, 436; American importations, 448; Peasgood's Nonsuch, Ringer, and Tom Montgomery, 453; The Washington, 471; Lane's Prince Albert, 474; The Washington, 500; for market, 511; Ringer, Tom Montgomery and Early Julien, 519; Lane's Prince Albert, 520; Crab v. Paradise stocks for, 543; Hambleton Deux Ans, Hawthornden, history of, 601
 Aquatic plants, choice, 153, 154
 Aquilegia chrysantha, 151
 Arums, 306
 Arundo conspicua, 153
 Araucaria, improving, 352; notes on species, 436, 966; cone of A. excelsa, 457; Bidwilli, 532
 Asparagus and Globe Artichokes, 271; Asparagus in autumn and winter, 447; notes on culture, 477
 Asperula hirta, 6
 Asphalt walks, making, 188
 Asters, selection of perennial, 357
 Astrocarum mexicanum, 572
 Attacus Mylitta and cocoon of, 63; Atlas, 123; Polyphemus moth and caterpillar, 182; Yama Mai, moth of, 254; cocoon and caterpillar, 293; Yama Mai, 349
 Anchendrane, 574
 Auriculas, potting, autumn-flowering, 27; for borders, 34; Mrs. Douglas, 199
 Avocado Pear, 581
 Azaleas, watering, 67; destroying thrips on, 92; for forcing, 373; culture and varieties, 494; A. narsissiflora, 498; for forcing, varieties of, 597
 BANANAS—value of as food, 321
 Barbacenia purpurea, 386
 Barberry fungus, 361
 Barr & Son, partnership of, flowers exhibited by, 11
 Bass, death of Mr. Abram, 176
 Battersea Park, notes on, 315
 Bean, Bunyard's Broad-podded Kidney, 175; selection of, 255
 Beckett House, 521
 Bedding plants, propagating, 221
 BEES—
 Artificial swarming, Norfolk Show, a professor of bee-keeping, 20; unsettled points, eating pollen, Show at Reading, Cheshire and Lancashire Association, 44; not swarming, 46; prolonging lives of queens, bog heather for, 65; heather for on wet land, 90; standard frame, 92; driving stocks, prolonging life of queens, 113; Berks and Bucks Show, 114; autumn treatment of stocks, forecasts, 137; removing supers from hives, 139; autumn treatment of stocks, 161; glass v. tin for honey, equalising colonies, 162; cold and food consumption, comb foundation v. feeding, Bee-keepers' Association's Show, awards of, 185; critique of South Kensington Show, Neighbour's prize hive, 209; a retrospect of season, 232; the South Kensington Show, 233; driving and stupefying, Hertford Show, 234; Lancashire and Cheshire Bee-keepers' Exhibition, 256; swarming v. non-swarming, 257, 333; Sussex Bee-keepers' Association, 258; driving bees, 260; exhibition at Dundee, the black bee and red clover, Derbyshire Show, 282; honey crop of America, 283; notes for beginners, 333; in winter, plants for bees, 304; British Bee-keepers' Association's certificated teachers, 305; the Stewarton and bar-frame hives, 330, 394; the Stewarton hive, preparing for winter, 351; the Stewarton hive, thirty years' progress, Worcestershire Bee-keepers' Association, 374; frame hives, meeting of apiarians, 395; hives and how to make them, 413; the art of bee-keeping, 435; prize hives at the Dairy Show, 435; purchasing stocks, 437; art of keeping, natural history of and social instincts, 463; costly hives and results, 464; plants for, 486; hives, 488, saving bees, removing eggs, young and old queens, 509; art of bee-keeping, natural history, 510; profits of, 512; art of keeping queens, 534; antiquity of ringing swarms, superstitions, 557; hiving swarms, size of
 BEES—continued.
 hives, overstocking, under-feeding, 579; the art of bee-keeping, the drone, 599; the Stewarton hive, 600
 Beetles v. Strawberries, 61; eating Strawberries, 127, 217
 Begonias A. F. Barron, Mrs. Stevens, and Thomas Moore, 39; gogoensis, 82; Tuberosus, as border flowers, 120; notes on species of, 143; for bedding, 250; select ornamental-leaved, 222; large at Swanley, 223; at Forest Hill, 224; wintering tubers of, 425; semperflorens massiliensis, 429; at Swanley, 474; winter-flowering, 570
 Belgian horticulturists, visits to nurseries and gardens, 10; a week in—M. Pynaert's nursery, 223
 Benevolent (Gardeners') Institution, Mr. Perkins' appeal for, 99
 Berberidopsis corallina, 153
 Birch, origin of purple-leaved, 437
 Biron, presentation to Rev. H. B., 364
 Blackberries, American, 375; the Kittatiuy, 474, 519; Parsley leaved, 524
 Bog garden, 145
 Bomareas, notes on, 322
 Book, review of "Dictionary of Economic Plants," 178
 Borders, small v. large for fruit trees, 541
 Botanical phenomena, lecture on, 17
 Botanic (Royal) Society's report, 150
 Botany, "The New," 301
 Bougainvillea glabra, culture of, 599
 Bouquets, modern, 598
 Bouvardias, temperature for, 394; culture of, 450; Alfred Neuner, 545, 571; President Garfield, 570
 Bramble, the Parsley-leaved, 391
 Brick-kilns v. vegetation, Mr. Foster's trial, 176; trial on and verdict, 150
 British plants, two useful, 146
 Broccoli, Snow's Winter and Veitch's Autumn, 524
 Brussels Sprouts, Reading Exhibition, 542; the Aigburth, 568
 Budding and grafting, influence of stocks and scions, 173, 205; curious examples of, 296; fruit trees, 115
 CABBAGES—Wheeler's Imperial, 101; and how to grow them, 176; preparing for winter, 426
 Cactus Jenkinsonii, 578
 Calanthes at Marston, 571
 Calla aethiopia, 578
 Calceoliti, culture of, 601 [601
 Camellias, cutting blooms of, Campanula hederacea, 154, 176, 199; pyramidalis in borders, 223; C. pyramidalis, 276
 Canterbury Bells, 2
 Capsicum Little Gem, 476
 Carnations and Picotees, proposed show of at Oxford, 34; for towns, 55; Mary Morris, 104; certificated varieties, 105; raising from seed, 106; layering, 139; Gloire de Nancy, 150; Wakefield Show, 151; Mary Morris, 183; Duchess of Westminster, 198; Virgo, 273, 296; treatment of, 601
 Carrot difficulties, 523; failures and the tar remedy, 565
 Carters' Holborn Seed House, 294
 Cassia corymbosa culture, 415
 Caterpillars on Oaks, 187, 297; in 1882, 246; destroying Cabages, 352
 Cattleya Whitei, 82
 Ceanothuses for bedding, 423
 Celeriae, three-coloured, 476
 Celery, stimulants for, 45; in winter and spring, 553
 Charcoal as manure, 67
 Chenopodium atriplicis, 243
 Chermes abietis, 278
 Cherries, good varieties for succession, cheap houses for, 74; house and varieties for, 393; the Morello, 474
 Chlora grandiflora, 32; perfoliata grandiflora, 131
 Christmas and church decorations, 564
 Chrysanthemum La Petite Marie, 38; maximum, 251; coronarium, 348; in London, new varieties, 385; notes on annual, 393; fixtures of shows, Madame Desgranges, 428; La Nympe, Sœur Melanie, 429; in the London parks and gardens, 430; segetum, 452; Lord Wolseley, Crimson King, M. Desbreaux, and F. A. Davis, 454; Mr. Henslow's lecture on, 455; for decoration, 475; Sœur Melanie, 500; showing and dressing, 518; manure for, King of the Crimson, 549, 567; Duke of Albany and Ceres, 553; proposed election, late white, Rosa Bonheur, 570; Golden Circle, 571; Sœur Melanie, 575; growing specimens, 580; dressing and exhibiting, 588; white varieties, 591; a specimen, 595
 Chrysanthemum Shows—Bath, Birmingham, 502; Bristol, 484; Brighton, 501; Brixton, 458; Canterbury, 484; Chesterfield, 533; Dartford, 483; Kingston, 480; Lambeth, 459; Leicester, 500; Liverpool, 504; Manchester, 485; Northampton, 503; Plymouth, 484; Putney, 460; Southampton, 460; South Shields, 532; Staines, 504; Stoke Newington, 459; Tooting, 483; Tunbridge Wells, 481; Walton, 483; Wimbledon, 403; Westminster Aquarium, 482
 Cinerarias, stopping shoots of, 436
 Clarke, James, death of, 475
 Clay's fertiliser v. slugs, 57
 Clay, burnt for gardens, 187
 Clematises in pots, 139; coccinea, 273; propagating, 511
 Clerodendron fallax from seed, 208
 Climbers for conservatory, 21, 162, 436
 Coca, culture of, 200
 Cochlearia alpina, 52
 Cocoa-nut fibre for Peas, 320
 Coleogyne barbata, 592
 Coleuses from seed, 195
 Comet influences, 533
 Commelina caelestis, 243
 Compartmentia macroplectron, falcata vera, 82
 Conifers for hedges, 559
 Conservatories in summer, 336
 Corn mildew, 368, 369
 Cornus mascula variegata, 153
 Corydalis glauca, 250
 Cosmos bipinnatus, 265; diversifolius var. atro-sanguineus, 381; bipinnatus var. parviflorus, 553
 Cottagers' cropping, 53
 Cranberries, 178
 Crotons aureo-marginatus and Dayspring, 38; Thomsoni, 271; Eyrei, 347
 Cucumbers—pruning, temperatures for, 43; The Cardiff Castle, 64; culture of for winter, 192; disease, 284; in America, 408; disease, eradicating, 423, 470; curing disease of, 519; disease and high temperatures, 567
 Cucumbers and Melons failing, 381
 Cucurbits, ornamental, 139
 Culzean Castle, 389
 Cunninghamia sinensis, 553
 Cupressus Lawsoniana Silver Queen, 249
 Currant Black Champion, 202
 Cymbidium Mastersii, 388
 Cypripediums, notes on hardy, good species of, 194; Arthurianum, 347; reticulatum, 364; calcicola culture, 415; seligerium majus and other hybrids, 429
 DAHLIAS—Gem, 82; single, 104; edges, 199; National Show, 243; John Henshaw, Ruby King, and Christine, 255; White Juarez and Glare of the Garden, 295; Harrison Weir, John Henshaw, 319; single at Tottenham, select varieties, 337; new varieties certificated, 347; single varieties at Oxford, 344; viridiflora, 363; effective varieties, 387; notes on single, 427
 Daisies, single, quilled, 150
 Damsons, the Prune and Cluster, 474, 519
 Daphne Mezereum, propagating, 46
 Delphiniums, good double varieties, 78
 Dendrobium superbiens, 410
 Dew, formation of, 404, 447; in hothouses, 499, 522, 544, 564
 Digging and manuring, 566
 Draecenas, propagation and culture of, 577
 Ducks in garden, 46
 Dundee, proposed International Show at, 548
 Durdham Downs Nursery, 432
 EALING Nurseries, 225
 Earthworms in New Zealand, 519
 Earwigs v. Nectarines, 163
 Ecerriocarpus seaber, 331
 Echeveria Peacockii, 79; wintering, 199
 Echinum albicans, 29; E. rubrum, 77
 Edge Hall, 245
 Edinburgh and the Pilgrig Nurseries, 339
 Edinburgh nurseries, 365
 Elaterium, 138
 Electric light and vegetation, 235; for conservatories, 570
 Emigrants, a warning to, 224
 Epidendrum biornatum, 465
 Epping Forest Naturalists' Club, 249
 Ericas and Epacris for winter, 463; notes on, 545; Erica gracilis autumnalis, 581
 Erodiums, notes on species, 109
 Eryngiums, notes on, 115
 Erythroniums, 292

- Euonymuses, propagating 240; striking, 279, 290
 Eutoca viscida, 145
 Evergreens, transplanting, 397
 Exacum macranthum, 221
 Exhibiting—the good old times, 84; ethics of, purchasing flowers for, 219
- FARM—Short-horned cattle, history of, Booth's breed, 22; Short-horned cattle in Australia and America, high prices of, 47; maximum produce of crops, 68; weeds, eradication, 69; maximum produce of crops, 92; maximum produce of crops, 116; four-course system of cropping, 140; Norfolk system of cropping, harvesting, 163; breeding hunters and roadsters, 188, 212; Barley "Bigg," 190; sowing Trifolium, crops in Durham, the Scotch harvest, 213; Hereford cattle, 236, 262; Hop prospects, 237; prizes for crops, Rye Grass a second year, mites in hay, effects of salting, 238; scientific cheese-making, 262; influence of climate on cultivation, 284, 307; the seed harvest, Hop crop, 309; milking cows, 310; seed corn, notes on selecting, 332; agricultural distress, remedies for, Metropolitan Dairy Show, 333; seed corn for autumn sowing, 358; Beans for cows dangerous, 356; Devon cattle, 376; history of, 397; mules, usefulness of, feeding ewes, 399; neglected pastures and waste lands, 416, 437, 489, 512; dearth of sheep, 418; quantities and mixtures of seed for pastures, 438; cow-keeping, farm horse stables, 444; neglected pastures and park lands, renovating with manures, 466; Carrots for horses, Cabbages for cows, insurance of cattle, 492; manuring, 512; the Leicester breed of sheep, 537; ewes, feeding, cattle diseases, 538; improving pastures, 540; the Leicester breed of sheep, history of, 560; food for milch cows, tussock and moles in pastures, 561; maximum weight for age of cattle, 582; earth in stables, value of, 583; American yield of Maize, 583; weights of sheep, 602; earth floors for stables, 604
 Faulkner, death of Mr., 452
 Fencing, cost of split oak, 210
 Ferns for baskets, 86; Tree, notes on species, 230; raising from spores, 581
 Ficus elastica for rooms, propagating, 426
 Flgs—trees not bearing, root-pruning, 115; Negro Largo, 128; not swelling, 187; pruning, 465
 Fiji, forest ramble in, 319
 Filberts, pruning, 67
 Finsbury Park, notes on, 316
 Firs, decay of Spruce, 57
 Fittonias, culture of, 536
 Flies, destroying, 150
 Flower bed of hardy plants, 571; and lobster salad, 386; planting for winter and spring, 394
 Flowering plants, arranging, 129
 Flowers—changeability of colours of, 105; cheap, 126; notes on colours of, 171; in autumn, 317; simple mixtures of, 451; economy with, 470; recent autumn, 518; of the past season, 568; colours of, 591; selection of plants to afford a supply of, 602
 Forests, influence of on climate, 158
 Forget-me-nots, notes on, 172
 Foxglove, salmon sport from, 79, 91
 Frant Cottagers' Association, 127
 Frost, severe in Scotland, 571
 Fruit—modes of packing, 40; packing in moss, 213; notes on in Sussex, 221; pruning trees in autumn, 231; gathering and storing, 233; judging at Edinburgh, 289; trees, planting, 290; scraps about, 427, 453; pruning and dressing trees, 462; hardy, 474; pruning and training trees, 493; scraps about, 519; growing on chalk soils, 525; planting trees, 533; summer and winter pruning, 566, 578, 581; at Edinburgh, cards for judging, 569
- Fruit judging at Edinburgh, 318, 344, 368, 385; selections for amateurs, 358
 Fruit trees—pruning, 45, 91; good sorts for standard, 331; securing names of, 848; preparing ground for, 350; lifting and renovating, 352; importance of labelling, 380; pruning and training, palmette verriers, 542; growing for market, 559; borders for, 595
 Fuchsia Riccartoni, 315
 Fulham Nurseries, sale of, 343
 Funkia lancifolia albo-marginata, 45; spathulata alba, 57
- GAILLARDIA PICTA LORENZIANA, 568
 Gardeners' Royal Benevolent Institution, anniversary dinner, 10; fête for at Thornham, 295
 Gardeners changing situations, 263
 Gardenias, pruning, and destroying insects on, 90; improving unhealthy, 415; culture of, 446; potting and pruning, 495
 Gardening amongst cottagers, 11; learning, 22, 139; past, present, and future, 517, 567
 Garden refuse, charred, 259
 Gardens in North Durham, 201
 Gentianas, species of, 15
 Gesnerias for summer and winter, 336
 Ghent, proposed Horticultural Congress at, 344
 Girtford Experimental Garden, 88
 Gladioli, good early, 45; at Kensington, Bono, Jas. McIntosh, Ala. and A. F. Barron, 129; good white varieties, 249; Colvilli albus, 385; growing prematurely, 580
 Glass copings for walls, 119
 Glass-wall protectors, references to, 553
 Glazing, Rendle's Acme system, 405
 Gloxinias, large, 46
 Godetia Duchess of Albany, 38; Satin Rose, 129
 Gooseberries, value of crops of, 224; for profit, 558; culture of market, 596
 Gooseberry bushes, pruning neglected, 187, 477, 527
 Grammatophyllum multiflorum, 82
 Grapes, ripening late, 242, 294; Foster's Seedling, 271; Gros Maroc, 275; exhibiting, 316; Alnwick Seedling not setting, 353; Alnwick Seedling at Chiswick, 360, 446, 472, 493; not setting, 403; early white varieties of, 391; Buckland Sweetwater, 412, 430, 448, 470; bees attacking, 430; Golden Queen, 448; keeping, 462; notes on varieties, 469; Muscats at Knowsley, 494; estimate of white, 498; vagaries of, 512; low night temperatures for, 518; for September, 528; Early White, 530; over-cropping, 536; for September, 547; Muscat of Alexandria and sand, 549; Duke of Buccleuch, 586; notes on varieties, 593; description of Barbarossa, treatment of Gros Maroc, 601; selection of, 609
 Green & Sons, Messrs., annual meeting, 128
 Greenhouse, management of, 318; its inmates, 403, 580; heating, 477; temperature for, 580
 Guavas, 162
- HAILSTORM, DESTRUCTIVE, 104
 Hampton Court, 242
 Hardy plants, selection of, 144, 325; a garden of, 326
 Harefield Grove, Uxbridge, 320

 Harvest festival, church decoration for, 359
 Heaths for autumn and winter, 581
 Heating—Rippingille's stoves, 448
 Heckfield Place, 481
 Heliotropes, Bouquet Perfume and Madame P. Athles, 177; White Lady, 587
 Heraclium giganteum, 10
 Herbaceous plants, selection of, 124, 279; renewing and increasing, 401
 Herbarium of plants, an old, 321
 Hinds, Mr. W., death of, 593
- Hippophae rhamnoides, 353
 Hollyhock disease, 102
 Hong Kong, botany of, 154
 Hops, bad harvest of, 175
 Hop Plant, the, 488
 Horseradish, culture of, 544
 Horticultural (Royal) Society, arrangement with Commissioners, 33; Committees, 38, 81, 177, 188, 346, 453; Horticultural (Royal Caledonian) Society, results of International Show, 386; list of Committees, 574
 Hoya carnosa, 235
 Humus, 472, 497, 520, 546; its properties and action summarised, 569
 Hyacinthus candicans in pots, 99; culture of Roman, 353; for beds, 425
 Hybrids raised by Mr. J. Seden, 122
 Hyde Park, 202
 Hydrangeas with blue flowers, 243; Thomas Hogg, 476
 Hypericum undulatum, 127
- ICONOGRAPHY OF INDIAN
 Azaleas, 320
 Impatiens Sultani, 75
 Indian Figs, 178
 Indianrubber plants, new species, of, 54
 Ingestre Hall, 367
 Insecticides, notes on, 523, 596
 Insects, prevalence of, 56
 Ivy, planting, 235; and cattle, 580
- JACOBÆA LILY CULTURE, 559
 Jasminum gracillimum in winter, 591
 Judging at Edinburgh, 458
- KALOSANTHES, MANAGEMENT OF, 114
 Kangaroo Vine, 511
 Keir, notes on, 550
 Kidney Beans, preserving, 306
 Kinver seed farms, 252
 Kitchen garden, seasonable work in, 42
 Knowfield Nurseries, 528
- LABELS, LINCRUSTRA, 272; MR. Hibberd's, 347
 Laburnums, seeds poisoning swans, 570; planting in meadow, 591
 Lachenalias, 528
 Lacquer Tree of Japan, 316
 Ladybirds, migration of, 296
 Lælia harpophylla, 9; monophyllum, 295
 Lapagerias, propagating, 210; culture of, 494, 594
 Lastrea montana coronans, 129
 Lawn improving, 397; in winter, 591
 Leaves, skeletonising, 284
 Lettuces—Dick's Hardy Cos, 7; Green Unetuous and Paris Sugar, 39; Cooling's new Cos, 101; 249
 Libonia floribunda, 552; L. penrhosiensis, 594; culture of, 601
 Lilies, treatment after flowering, 148
 Lillium Thunbergianum cruentum, 38; L. pardalinum, 53; L. giganteum, raising from seed, 71; L. auratum virginale, 82; culture of, 128; L. speciosum var. Melpomene, 183; potting, 211; anatum in borders, 215; Parry's, 343
 Lime, quantity for light soil and Vine borders, 305
 Linaria cymbalaria, 243; vulgaris var. Peloria, 543; L. reticulata aurea purpurea, 568
 Linum triginum culture, 572
 Liverpool Show, 132
 Llewelyn, death of Mr., 199
 Lobelia cardinalis, 174, 207
 Locusts, and cost of destroying in Cyprus, 453
 Lonicea grata, 10; sempervirens minor, 147
 London parks and gardens, 152
 Lucas, death of Dr., 104
 Luculia gratissima, 475; at Knowsley, 549
 Luton Show, 77
 Lygodium scandens, 523
 Lythrum salicaria, 105
- MAGNESIA AS A MANURE, money value of, 225; phosphate of, manurial value of, 341
 Magnolia Campbelli, 454
 Malva moschata major alba, 11
 Mandevilla suaveolens, 131
 Manetti stocks, preventing suckers from, 45
 Manure, the best, earth closets, 171; used at Longleat, 205; from earth closets, value of, 218; for Vines, 230; earth-closet, 244, 276; trials of "Crown," 381; Standen's for Roses, 883
 Manures, chemistry of, 298, 325
 Manuring, spring v. autumn, 590
 Marguerites, propagating, 334
 Market gardening and fruit-growing, 178
 Masdevallias Shuttleworthii and triangularis, 31; M. tovarensis, 451
 Maxillaria picta, 531; M. nigrescens, 592
 Mealy bug, destroying, 46; destroying on Vines, 114
 Measuring conical heaps, 21
 Melons, supporting on trellises, 10; not setting, 21; setting and management of, 43, 45; setting, effects of bottom heat, 55; canker in, 250; Stamford Pet, certificated, 346; Sir Garnet Wolseley, 408
 Mentmore, 478
 Meteorological Society, 476
 Mezereon, berries poisonous, 80
 Michaelmas Daisies, notes on, 357; at Tottenham, 408
 Mignonette, new varieties certificated, 39; culture in pots, 49
 Mildew on Peas, 348
 Milton Abbey, 87
 Mitchellia alba, 387
 Monotropa uniflora, 501
 Mormodes unicolor, 347
 Moss, fertilised, for plants, 320
 Musas, culture of in Fiji, 320
 Mushrooms in cucumber beds, 31; destroyed by fungus, 375; preparing manure for, gathering, 580; growing in sphagnum, 596
 Mushrooms for the million—inserting spawn, 50; soil for, 51; casing the beds, temperature, 97; effects of frost on, 98; covering the beds, 168; watering, salt for, cutting v. pulling, 169; retaining the stems, different grades and relative value of, 216; packing, 312
 "Musk Tree," 396
 Myrica Gale, 428
 Myrtles, culture of, 124
- NARCISSUS ALBICANS, 501, 505
 Narcissuses for borders, 259
 Nectarines—good varieties, 278; Lord Napier, 291; Lord Napier for forcing, the good varieties, 327; estimate of varieties, 336; Lord Napier, failure of, 343; notes on varieties, 371
 Nepenthes Mastersiana, 274
 Nepenthes, culture of, cutting down, 303
 Nerium Sœur Agnes, Mons. Balaguier, and Madonni grandiflorum, 39
 Newcastle Horticultural Society's finances, 428
 Newington, death of Dr., 38
 Nitrate of soda, use of, 436
 Nitrates, production and loss of in soil, 41
 Nomenclature of garden plants, 477
 Norris Green, conservatory at, 475
 Nurseries, notes in London at Christmas, 592, 593
 Nymphaea candidissima, 32
- OAK, DWARF, 39
 Odontoglossums—O. Alexandra, 55; notes on, 58; O. Rossii majus, 59; Pescatorei Veitchii, Cervantesii decorum, and Halli nigrum, 107; notes on species, O. maculatum, 193; O. crispum vars. Dormannianum, and Wilsoni, Alexandra virginialis, 454; O. Halli, 546, 570
 Enocheras, notes on, 101, 150
 Omphalodes verna, 29; O. Lucilia, 52
 Oncidiums, notes on, 587; O. Rogersii, 375; O. stelligerum, 82
 Onions, 251; maggot, preventing, 21
- Oranges, culture of in Florida, 80; raising from seed, 574; grafting, 581
 Orchard house, planting, 187
 Orchids—in July, 35; hybrids flowering at Chelsea, 57; pruning, 104; in August, 134; in September, 248; peat for, 249; sale of Dr. Paterson's at Edinburgh, 272; liquid manure for, 321; in October, 341; at Kew, 344; notes on 509; Australian, 409; in America, 432, 407
 Origanum Siphyleum, 488
 Ornithogalum thyrsoides, 347
 Osmunda japonica corymbifera, 38
- PALMS—select and useful, 327; number of flowers on, 574
 Pansies, striking cuttings of, 91; Lord Waverley, 38
 Papaver umbrosum, 568
 Paraffin injurious in sewage, 383
 Parcels, revised rates by rail and post, 223
 Parsley difficulties, 525
 Peach Sea Eagle, 56; renovating trees, curing "yellows," 167; for succession, 210; trees, treatment of old, 240; Royal George, 259; lifting trees, 276, 319, 368; shallow v. deep borders for, 405; crop in Texas, 326; Hale's Early, 327; estimate of varieties, 335; The Dymond, 346, 428; for forcing and succession, 350; notes on varieties, 371; Dr. Hogg, 375; selection of, 602
 Peaches and Nectarines for succession, 65; notes on varieties, 384; cordon trees, 397
 Peach-wall protector, 495
 Pear-tree slug, 22; in New Zealand, 39
 Pears for walls and pyramids, stocks for, 337; heavy fruits of, 355; good late varieties, 396
 Peas, weights of large, notes on continental varieties, 428, Soldat Laboureur and Marie Guise, 453; selection of, 488; weight of Pitmaston Duchess, 500; weights of, 549; Josephine de Malines, 566; Pitmaston Duchesse, weights of, 588; Prince Napoleon, 597
 Peas—Lye's Favourite, Turner's Emerald, Statagem, and Alfred the Great, 39; Culverwell's Giant Marrow, 57; trials and suggestions for at Chiswick, 74; varieties for continuous supply, 101; selection of, 144; Pride of the Market, 153; a cottager's, new varieties, 170; Duke of Albany, 199; mildew on, 368, 406; General Garfield, 451; varieties of, 402
 Pelargoniums, cutting down, 92; essay on, 127; good double Zonals, 11; double Zonal, Charles Darwin, 175; Ivy-leaved, Rossini, 177; good new Zonals, 306; Albert Crousse (Ivy-leaved) and Aglaia (Zonal), 454; Madame Charles König, 547; double Zonals for winter, 571
 Pentstemons at Swanley, 127; P. virginale, 177; Mr. McFarlane, 347
 Perennials, hardy, for massing, nomenclature, 361
 Pereskias, culture and grafting, 536
 Pernettya mucronata, varieties, 347
 Perry Hill Nurseries, 392
 Pescatorea vervaetii, 533
 Petunias at Perry Hill, 127; Mrs. Dunnett, 129; Carter's Empress, 249
 Phacelia campanulata, 82
 Phalanopsis violacea Schröderi, 129; P. violacea, 154; Esmeralda, 347; at Wyncote, 548
 Phosphate of magnesia, 290; manurial value of, 317, 361, 388; value of, 406, 427
 Phylloxera, extent of damage of, 105
 Phylloxerated districts v. plant importation, 400
 Picotees Mrs. Rudd and Sarah Elizabeth, 343
 Pigeons, canker in and remedy for, 400
 Pines, temperature for, 462; culture of, 588
 Pinks, some species of, 62; a plea for, 318; proposed show of, 371; Show, postponement of, 451
 Pinus Lambertiana, 559
 Pit for Gardenias, 536
 Plagiarius, 99, 150

PLANTS CERTIFICATED—

Aecidium roseum and *Album flore pleno*, 553; *Begonia gogoensis*, 82; *B. tuberosa*, A. F. Barron, 39; *Carnation Mary Morris*, 183; *Cattleya Whitei*, 82; *Composita macroplectron*, 82; *C. falcata vera*, 82; *Chrysanthemum La Petite Marie*, 38; *Lord Wolseley*, *Crimson Klug*, M. Desbreaux, F. A. Davis, 454; *Duchess of Albany*, *Ceres*, 553; *Cosmos bipinnatus parviflorus*, 553; *Croton aureo-marginatus*, 38; *Dayspring*, 38; *Thomsoni*, 271; *Eyrei*, 347; *Cupressus Lawsoniana erecta alba*, 347; *Cypripedium Arthurianum*, 347; *Dahlia Gem*, 82; *Acquisition*, *Condor*, *Earl of Ravensworth*, *Evening Star*, *Gem Hope*, *Senator*, and *White Star*, 241; *John Henshaw*, *Christine*, *Ruby King*, 255; *Harrison Weir*, *Duchess of Albany*, *Nymph*, *Little Princess*, *Mabel*, *Little Duchess*, *White Star*, *Francis Fell*, *Cherry*, *Mrs. Burbidge*, *Mrs. Goldring*, *Pantaloons*, *Marguerite*, *Tyro*, *Yellow Gem*, and *Constance*, 347; *Davallia tenuifolia*, 38; *Gladiolus*, *Ala*, A. F. Barron, *Bono*, *James McIntosh*, 129; *Golefia Duchess of Albany*, 38; *G. Satin Rose*, 129; *Grammatophyllum multiflorum*, 82; *Laetrea montana coronans*, 129; *Lathyrus Bronze Prince*, 129; *Lilium Thunbergianum erulentum*, 38; *L. auratum virginale*, 82; *L. speciosum*, var. *Melpomene*, 183; *Morodes unicolor*, 347; *Odonoglossum Alexandra virginale*, 454; *O. crispum Dormannianum*, 454; *Oncidium stelligerum*, 82; *Ornithogalum thyrsoides*, 347; *Osmunda japonica corymbifera*, 38; *Pansy Lord Waverley*, 38; *Pelargonium Aglaia*, *Albert Crouse*, 454; *Pentstemon Mr. McFarlane*, 347; *Pernettya mucronata* varieties, 347; *Pescatorei Vervaei*, 553; *Petunia Mrs. Dummett*, 129; *Phacelia campanulata*, 82; *Phalaenopsis Esmeralda*, 347; *Pleopeltis fossa*, 38; *Renanthera matutina*, 82; *Rhododendron balsamiflorum album* and *nureum*, 38; *Sir Beauchamp Seymour*, 347; *Sir Garnet Wolseley*, 347; *Rose Duchess of Connaught*, 38; *Earl of Pembroke*, 347; *Salvia Hoveyi*, 454; *Scopolodrium vulgare crispum multifidum*, 129; *Tropaeolum Empress of India*, 82; *Tydaea Robert le Diable*, 38; *Vanda Hookeri*, 255

Plants, choice herbaceous, 14; selection of tall perennial, 148; good for borders, 162; hardy, flowering in August, 226; in rooms, 259; for winter flowering, 289; for moist positions, 311; acclimatizing in Sicily, 385; culture of hardy, 453; renewing, 455; nomenclature of, 493; in late vine-ries, 499; Mr. Garrett's paper on winter-flowering, 526, 545; notes on decorative, 542; notes on watering, liquid manure for, 576; selection of useful flowering, 602

Pleiones, notes on, 321

Pleopeltis fossa, 38

Plumbago capensis, 331

Plums drying, leaves silvery, 22; for exhibition, 306; culture of and varieties, 425; a double crop of, 427, 453; for market, 511; useful varieties of, 519

Polygala chamæbuxus, 49

Polypodium vulgare cornubi-cense *Fowleri*, *crispum multi-fidum*, 129

Pomegranates in London, 345

Poplars, Canadian, in Belgium, 222

Potatoes, late varieties of, 7; manuring, 12, 58; large crop of and manure used for, 77; cheap in London, *White Elephant*, 105; a good crop of, 125; early, 128; the *Manster* experiments with, 143; *Fox's Early*, 150; raising from seed, 193; culture of sound, 229; *White Elephant*, heavy crop of, 223; wintering, 259; *White Beauty of Hebron*, 274, 295; *International Show*, 289; exhibition of seedlings at Northampton, 292; early for market, 331; produce of *Magnum Bonum*, 334; twelve good varieties of, 381; notes on crops in Ireland, 407; productive, 499; sowing in autumn, 411; prolific, 423; forcing, 434; planting in autumn, 435; autumn v. spring planting, 497; American crop, 501

Potatoes and Peas, 234

Potato starch, American production of, 519

Potting plants, 339; soils and manure for, 545

Poultry—cross-bred for table, 48; in confinement profitable, unhealthy chickens, 94; early chicken shows, 113; fattening fowls, 141, 165; fraud at the *Warwick Show*, fowl coops, 142; crooked tails, *Hertford Show*, 161; notes, *White Leghorns*, 190; fattening for table, funnel-feeding, 214; late showing, 238, 242; *Carrier Pigeons*, 252; notes, crossing *Game fowls*, *Peacock moulting*, 283; judging at shows, 309; shows and entry fees, 334; at the *Dairy Show*, 355; the *Crystal Palace schedule*, *Poultry Club meeting*, 356; productiveness of hens, "Practical Poultry Breeder and Keeper," 373; *Bantam notes*, 399; at *Wolverhampton Show*, 400; spoiling the *Dorking*, 413, 438, 458; new *Standard of Excellence*, 418, 439; *White Dorkings*, 457; notes on varieties, 491; notes at the *Birmingham Show*, 514; *Club Annual Report*, 492; *Club Meeting at Birmingham*, disqualification case, chicken vaccination, 540; *Sunday shows*, 561; thermometric incubator, ovifer, egg-protector, sales at *Birmingham*, 562; choosing a *Dorking Cock*, 583; *Poultry Club Meeting*, withholding prizes at *Dorking*, *Watford Show*, 584; *Mr. Cook's poultry-yard*, 603

Precoat, Cucumber and plant-culture at, 147

Primulas, old plants, grubs attacking, 91; at *Swanley*, 47; at *Perry Hill* and *Reading*, 503

Pritchardia nobilis, 408

Progress, reporting, 585

Propagating bedding plants, 219

Pyrethrums, double, 264; *uliginosum*, 319

QUASSIA WATER, preparing, 45

Quinine, Columbian, 391

RABBIT WARREN, STOCKING, 23

Railway gardening, 452

Rainfall, extraordinary, 498

Ramondia pyrenæica, 13

Rasonowia ornata, 178

Raspberries, summer-thinning, 114; canes dying, 133; culture, 274, 333; autumn-bearing, 306; in America, 405

Rats, trap for, 437

Regent's Park, 228

Renanthera matutina, 82

Review of book, "Report on Experiments in the Cultivation of Potatoes," 135

Rhododendrons, *balsamiflorum nureum* and *rubrum*, 38; *balsamiflorum album*, 82; double hybrids, 102; *hirsutum*, 179; *Sir B. Seymour* and *Sir G. Wolseley*, 347

Rhubarb, *Stott's Monarch*, 42; forcing, 41; waste of, uses, 224

Rhynchospermum jasmimoides, culture of, 139

Ribes opulifolium, 123

Rice, paper, 179

Richardia æthiopia, forcing, 394

Ringloves, 23

Rippingill's stoves, 443

Rockery, making under glass, 415; in autumn, 471

Root-pruning, 278

Roses—prolificous, 5; among them at *South Kensington*, 25; *Maréchal Niel*, origin of, 32; *Brunonii*, 33; best in the Show, 35; *Duchess of Connaught*, 38; at *New Orleans*, 57; the "Queen of Flowers," origin of name, 67; conditions of proposed election, 73; at *Waltham Cross*, 81; at *Wirral*, 82; *Comtesse de Serenye* not expanding, 93; single for decoration, 104; notes on, 121; two-day shows, 123; a plea for standards, 170; the season of, a retrospect, 191; on own roots, striking cuttings, 197; standards, 202; best for forcing, 211; *Madame G. Luizet*, 217; remarkable tree at *Whitby*, 224; *National Rose Society's catalogue* of, 248; *Madame Gabriel Luizet*, 259; notes on, 255; climbing varieties, 283; for buttonholes, 284, 305; at *Canterbury*, 288; at *Cheshunt*, 291; for towns, preparing soil for, 331; election of H.P. exhibition varieties, 337; the poll, 338; at autumn shows, 344; *Earl of Pembroke*, 347; election, poll of *Teas*, 353; at *Great Doods* and *Holmfels*, 352; at *Woodhatch*, 363; *National Show fixtures* for 1883, 363; notes on new, 380; English and American elections, 382; *Rève d'Or*, 391; spring v. autumn planting, 402; *Rève d'Or*, 409; for arches, 415; spring and autumn planting, 423, 443, 494; *Hybrid Perpetuals* in pots, planting in spring or autumn, 473; planting in heavy wet soil, 517; for exhibition, 535; from cuttings, experiments with, 544; synonymous varieties, 548; *National Society's annual meeting* and report, 555; decline and cancer of *Maréchal Niel*, 565; spring and autumn planting, 572; oldest tree, 580; *Tea-scented varieties* for beds, 602

Rose shows—*Alexandra Palace*, 26; *Birmingham*, 73; *Brookham*, 40; *Canterbury*, 29; *Cardiff*, 54; *Christleton*, 56; *Crystal Palace*, 5; *Darlington*, 75; *Farningham*, 15; *Helenburgh*, 88; *Hereford*, 8; *Hitchin*, 17; *Leek*, 79; *Maidstone*, 16; *Manchester*, 52; *Mansion House*, 6; *National (Bath)*, 11; *National (London)*, 3; *Oxford*, 31; *Reigate*, 16; *Sutton*, 35; *Wirral*, 61

Roup, 284

Royal Horticultural Society, Committee Meeting, 254

Rudbeckias—*R. californica*, 390

SADLER, DEATH OF MR., 548

Salvia farinosa, 127; *S. tricolor*, 153 *S. Heeri*, 343; at *Kew*, 354

Sand for propagating, 411

Sanguinarin canadensis, 16

Savoy, *Sutton's Green-curl*, 525

Scabiosa caucasica, 241

Schizanthus, sowing, 272

Schizostylis eocinea, 385

Seakale-box, 511; forcing, 581

Seeds, collections and selections of, 173; price of selections and collections, 219; purchasers' and vendors' selections of, 535

Senecio japonicus, 37; *S. pulcher*, culture of, 133

Sericographis Ghiesbreghtiana in vinery, 543

Sewage, petroleum in—a caution, 383

Shallot, *Sutton's Giant*, 429

Shallots at *Chiswick*, 39

Shelter for Currants, 235

Showing, perplexities of, 223

Shrubs—*Agricultural Hall* *Imple-ment*, 43; *Aylesbury Vegeta-ble*, 391; *Barnard Castle*, 193; *Bath Floral Fête*, 423; *Botanical (Royal) Society's*, 18; *Bracebridge*, 199; *Brighton Autumn*, 275; *Croydon*, 14; *Crystal Palace Fruit*, 251; *Hindsworth*, 218; *Harpden*, 229; *Hawkhurst*, 69; *Manchester Gooseberry (National)*, 14; *National Carnation and Picotee*, 85; *Newcastle*, 107; *Newport*, 121; *Northampton*, 295; *Northenden Floral Society's*, 123; *Preston*, 241; *Reading*, 200; *Royal Caledonian Society's International* at *Edinburgh*, 236; *Sandy*, 294; *South Wales Horticultural*, 206; *Shrewsbury*, 189; *Sunderland*, 194; *Smithfield Club*, 539; *Taunton Deane*, 159; *Tooting Horticultural Society*, 34; *Tredegar*, 516; *Trowbridge*, 191; *Tun-bridge Wells*, 30; *West Kent*, 34; *West of Scotland Society's Pansy*, 93; *Wimbledon*, 33

Shrubbery, effective plants in, 17

Shrubs, comparative hardiness of, 81; choice flowering, 103; planting, 287, 523

Silkworms and silkworm rear-ing, 63, 123, 182, 233, 293, 343, 411, 499, 507; *Attacus Pernyi*, 461; *Emporer Moth*, 507

Snowdrops, culture of in *Lincolnshire*, 76; in pots, 601

Soil, mites in, 67; influence of on maturing crops, 103; for potting, 323; temperatures of *October to March*, 423

Sonerilas, new, 498

Soot, constituents of, 67

Soya hispida, 259

Spurmannia africana, standards of, 429

Special prizes for Cucumbers and Melons, 123

Spergula filifera aurea, 352

Spigelia marilandica, 8

Spiræa japonica, disqualifying, 21; *S. palmata*, hardy, 45; *S. Ulmaria flore-pleno*, 51; *S. japonica*, 74; *S. Lindleyana*, 80

Spray-diffuser, 559

Spruce Firs dying, 233

Spruce-gall aphid, 278

Stakes, wire, for flowers, 34

Standen's manure, 197, 349

Storm, effects of, 385; in *Ireland*, 319

Strawberries—methods of cul-ture, mistakes, 1; raising plants, 2, 6; modes of culture, mistakes, 28; *Forman's Ex-celsior*, 53; planting in various soils, 57; preventing beetles eating, 102; notes on, 126, 455; *Helena Gloede*, 138; culture of *Hautbois*, 183; and beetles, 217; in pots, autumn treat-ment, 314; notes on *Alpines*, 341; *Duke of Edinburgh*, 393, 424; wintering in pots, 428; *James Vick*, 452; the best variety, 455; in *December*, 549; relative value of, 590

St. Vincent's, *Grantham*, 157

Sunflower, the, 273; effective varieties of, 295; uses of, 483

Sussex manure and crop ex-periments, review of, 110

Sweet Pea *Bronze Prince*, 129

STRAWBERRIES—MODES OF CULTURE—MISTAKES.

MUCH has been written from time to time on the cultivation of this wholesome, delicious, and important fruit; and much more will have to be written before everybody is satisfied, and before each would-be cultivator knows the precise mode to adopt in planting and management for producing the finest possible crops. New cultivators are ever arising who have not of necessity the benefit of years of experience to guide them, and who are not infrequently bewildered rather than instructed by the differing practices that are detailed by a multitude of counsellors in the gardening press. Many cultivators have recommended the methods that have proved sound in their own practice, but have not been sufficiently explicit in describing the surrounding circumstances, simple, perhaps, yet all-important, that have contributed powerfully to the results that have been achieved; hence the methods, however good in themselves, may not be the best for all persons, soils, and districts.

There are few, if any, systems of Strawberry culture that have been recommended in the Journal during the past thirty years that I have not tried with the object of testing their merits, and most of them have been good, but not all good alike, as it is not possible they could be under the great influence that the soil and seasons exercise on this crop.

I have made mistakes in Strawberry culture, and seen mistakes made by others, and in all these instances it was thought the injunctions of authorities had been acted on; and so they had, but not intelligently. One instance will exemplify how necessary it is for writers to be explicit and readers attentive, so that they comprehend fully not only what a writer says in so many words, but what he intends to convey.

After spending twenty years "in the houses" it fell to my lot to have the charge of a garden where the cultivation of fruit and vegetables was of greater moment than growing plants. I was thus of necessity weak where I ought to have been strong, but trusted to industry and perseverance to carry me through. I found the Strawberry crop good without being great. It satisfied my employer, but did not satisfy me. In endeavouring to produce something startling in the way of Strawberries I worked as I never worked before nor since in preparing the grounds for a new plantation.

I read that strong and deep soil were necessary. Whatever differences were submitted as to the times and manner of planting, and also in respect of varieties, there was no difference on the question of soil. "Strawberries like heavy soil, and it should be trenched 2 feet deep," was the sum of what I read, search where I would for information. Now the soil of the

garden was neither strong nor deep. It had been tilled for half a century at least, but not deeper than a foot, and the surface soil was light. On digging deeper, however, it was found to almost approach to clay. What more natural than to conclude that nothing was needed but trenching? "Heavy soil trenched 2 feet deep" kept ringing in my ears, and strong arms and a will to work impelled me to improve on the 2-foot trenching by going down half a foot deeper. The ground, then, was trenched 2½ feet deep. I delved cheerfully, and my employer looked on admiringly. We both expected grand results, but both were bitterly disappointed. Only young men fresh from "the houses" will need to ask, "Why this failure?" Old hands have already anticipated it, yet for the sake of the young and inexperienced the nature of the error must be pointed out.

In all probability the ground had never been trenched before, and at least a foot of the soil brought to the surface had not been exposed to the air for a century—never since it was itself a portion of the surface, and had been covered deeper and deeper with increasing years. It was strong, adhesive, sterile, and in its sour inert state could neither grow Strawberries nor anything else. What ought to have been done as soon as the trenching was completed was to have trenched it over again; yet if any old garden labourer had suggested such a course no doubt he would in a moment of youthful ardour have been considered as belonging to the ancient order of antediluvians.

The Strawberries were planted, watered, mulched, but grow they would not, and did not; even weeds did not grow. Several of the plants died, others lingered, a few struggled as if determined to surmount the obstacles that ignorance had created. The result of three great efforts—the reading, and working, and tending—was a Strawberry bed patchy, miserable, and a disgrace to the garden. Yet it was produced in the orthodox style taught by books of "strong soil trenched 2 feet deep." This was dearly bought experience, but it proved most valuable in after years. Others can now have it cheaper, as this Journal only costs 3d., whereas spoiling that ground cost nearly £3.

I know well now what ought to have been done with that plot of ground, but there are others who do not know how to proceed in such a case. Instead of trenching 2½ feet deep and bringing the strong poor soil to the surface, it ought to have been dug about 15 inches deep, not more, mixing the 3 inches of heavy fresh soil with the foot that was light, and incorporating with the whole manure to improve its fertility. At the depth of 15 inches the soil—the subsoil, should have been well broken up and covered with a thick layer of manure or vegetable refuse, green or decayed, or both. Not half the time would have been spent that was wasted in trenching, while a ten times better crop of Strawberries would have followed. After the Strawberries the ground could have been turned over to a depth of say 20 inches, and the subsoil again broken; next another great crop of something taken; then, and not till then, could the trenching be safely done to the depth above indicated—2 feet. Heavy crops would have been had in the meantime that would have more than paid for the work of steady improvement, and in the end a splendid piece of land would have been produced. This narration of a serious error and how it might have been avoided may be useful to some who may be on the eve of a Strawberry career.

It is held strongly by some persons that Strawberries should never occupy ground for more than two years—that is to say,

that they should produce two crops and then be destroyed. Others say they may profitably remain on the ground for seven years, provided manure is added annually. Both systems may be right in certain soils and under judicious management, and it is a fact that both methods have been adopted with the best results. But it will never do to rely on the septennial system in light and rather dry soils, while it may be a costly mistake to rely on the biennial plan on cold strong lands. One such mistake may be mentioned. A garden which has been famed for its Strawberries for half a century, and the seven and even ten-year-old beds gave abundance for all comers, passed into the hands of a young gardener. Without thinking sufficiently he took runners after his first crop and destroyed most of the old beds. The result was, what was not known previously in the memory of man, a scarcity of Strawberries in that garden. By no attention that could be given could such bearing crops be produced the second as the third year, while the first year's crop was invariably poor. Let, therefore, there be no hasty judgment in determining the method to pursue, but consider well the nature of the soil and circumstances in each case, and act accordingly.

The lighter the soil is the deeper must it be for Strawberries, the firmer it must be made, and the less it must be dug between the plants. In some heavy soils Strawberries are much benefited by being forked amongst annually; in others that are very light, to dig amongst the plants at all is a mistake. The nature of the soil, therefore, must always be taken into account when preparing for the cultivation of the crop in question.

I have had to produce Strawberries in one of the driest localities in England, and in one of the wettest; in soil not far removed from a blowing sand, and in strong elays; and as a record of the systems pursued may be of some service I will endeavour to return to the subject in a future issue.—A NORTHERN GARDENER.

I NEVER experienced so much difficulty as last year in obtaining sufficient runners early in the season, and this was entirely due to drought. Had not the plantation been thoroughly soaked with water and at once mulched it would have been impossible to have obtained sufficient runners in time to make strong plants with bold well-ripened crowns, so desirable to yield a good crop of fruit in spring. Young plants planted especially for the purpose and the fruit kept off during the first season is by far the best way of securing abundance of clean early runners, and to rely for runners upon those plants that have to carry a crop of fruit is a great mistake. Some cultivators place out forced plants, and rely upon them for runners, and even assert the crop of fruit from them the following season is both heavier and finer in size than young plants will produce. They even go further, and contend the planting of those that have been forced saves a year. To accomplish this ground must be purposely reserved for them, and thus some other valuable crop be lost. My experience is that when forced plants have been exhausted by bearing, even if they have been kept free from red spider, they cannot compete with young vigorous plants.

When the system of making a plantation annually is practised there is no occasion for ground to be retained purposely for them, as any early or second-early crop can be cleared off before it is necessary to plant the Strawberries. I have taken from a plot of ground a crop of early Potatoes, planted 3 feet apart, and then a crop of Osborn's Broccoli planted between every two rows of Potatoes, the Strawberries being planted between the rows of Broccoli after the Potatoes were dug. The leaves of the Broccoli were shortened back slightly to prevent them injuring the Strawberries. Although the Broccoli crop was good and proved no detriment to the Strawberries, I shall not repeat the operation, because they grow rather too large. After the early crop, whether Potatoes or Peas, another crop may be taken from between the Strawberries of either dwarf Savoys, Coleworts, Lettuce, Endive, or Turnips for drawing late. Any of these can be planted when ready after the ground is clear, and the spaces left between them for the Strawberry plants. My practice is to make a new plantation every year, and to destroy one annually as soon as the fruit is gathered, relying for the following year's supply of fruit upon

those that have produced runners for pots. The ground from which the fruiting plants are cleared is afterwards planted with late Broccoli. The plants for this purpose are either pricked out in beds sufficiently far apart, or planted twice as thick as required between rows of Potatoes, lifting with a ball of earth every alternate plant.

The Strawberry ground is not dug, a hole merely being made with a spade and the Broccoli carefully placed in, a good supply of water being given if the weather be dry, the ground afterwards being loosened with a fork. These plants generally do not attain a large size, but are sturdy with hard stems, and in consequence resist severe weather much better than those of the same varieties planted earlier and on lighter ground. Early in spring the ground is manured and forked in amongst the plants, or failing this have one or two soakings of liquid manure. Such close cropping need not be followed where ground is plentiful, but no doubt many besides myself are compelled to make the most of the ground at their disposal.

As soon as the Strawberry runners are layered for the spring supply in the sized pots in which they are to fruit, those for planting should be commenced at once if any runners remain. They are layered in 5-inch pots, which we prefer to those of a smaller size. If the ground is not ready they do not dry so quickly, and are not so liable to become checked as those in small pots. The earlier they can be planted out the better, so that they become established before winter. When layered and planted out early they develop into strong fruiting plants, and are capable of carrying a heavy crop of fine fruit should it be desired.—W. BARDNEY.

TWO CROPS OF CANTERBURY BELLS.

ARE there any plants that produce a finer effect in borders during June and July than well-grown examples of Canterbury Bells? Are there any plants grown in pots more imposingly beautiful than these are for arranging in verandahs or in conservatories? If so, it would be interesting to know what they are. Canterbury Bells are no doubt beautiful enough, some may admit, but their attractiveness is of too short duration to give satisfaction. It is true that the plants, as they are generally grown, are transient, but nothing is more easy than to extend their beauty just as long again as is usual; or, in other words, to produce two crops of flowers instead of one. For the last three weeks Canterbury Bells have contributed more than any other flower to the attractiveness of my garden, and the blue, white, and pink pyramids have been greatly admired. The flowers have now faded, but in another week the plants will be more densely clothed than ever with their grand bell-shaped blooms.

It is not the mere flowering that exhausts the plants, but the formation and maturation of seeds. If the faded flowers are promptly removed and the formation of seed pods prevented flowers will immediately form in the axils of the leaves in far greater numbers than before, and the plants will once again render the borders gay. It will be of great assistance to give the plants a heavy watering with liquid manure, as this will accelerate the growth of the second crop of flowers and increase their size. In order to have the finest plants—pyramids 3 to 4 feet high and 2 feet in diameter at the base—they must be raised early. My seedlings are ready for transplanting; but good plants may be had by sowing now, at once, in pots or boxes covered with squares of glass to expedite germination and encourage early growth, subsequently transplanting in rich soil, or in pots to be plunged in ashes, and the plants to be treated as if they were Strawberries prepared for forcing.

All the varieties are beautiful, the calycanthena forms—those with coloured calyxes—being more lasting than the others, and generally preferable for cultivation in pots for the conservatory or verandahs. They may be flowered in pots varying in size from 7 to 12 inches in diameter according to the positions the plants are to occupy.

Every flower border should contain a number of these grand Campanulas. They are as easily raised as Cabbages, and decidedly amongst the most handsome of plants, hardy or tender, during their period of beauty—June and July.

Well-grown Canterbury Bells ought to be grown in hundreds in the London parks, and the public would have something to see that would command admiration. If planted thinly in beds intended for subtropical plants they would not materially interfere with the planting of the latter, while the beds would have a vastly different appearance from what they have now. In order to show

the effects of removing the faded flowers I send two sprays—one with the second crop of flowers advancing, the other with large seed pods and no flowers.—A SUBURBANIST.

[The sprays confirm all that our correspondent has stated. A spray that had a terminal flower removed is producing eight flowers from the axils of the leaves as a second crop, while where the seed pods are permitted there are no signs of further flowers. We have long adopted the practice described with the same results as recorded.]

THE NATIONAL ROSE SOCIETY. ROYAL HORTICULTURAL SOCIETY.—JULY 4TH.

At last the chief Exhibition of the above Society has been held at what may be termed the headquarters of national horticulture in this country, and it is not conceivable that a more appropriate place could have been found for the Exhibition. Neither would it be easy to find a more suitable position for showing the blooms to advantage than in the lengthy corridors that flank the conservatory, as the light is subdued just sufficiently to bring out the colours to advantage, and to maintain the freshness of the blooms. The corridors with the conservatory are probably nearly half a mile in length, and they were filled on both sides from end to end with Roses. Thus the Show was of great magnitude, and on the whole the blooms were of great excellence. Some were small, a few rough, and a few weather-worn, but bright, fresh, and beautiful examples preponderated, and the Show was a success. The great disposition to render it what it was is apparent by the great number of entries—nearly or quite five hundred; but although it was not possible for all to be represented, still the competition was good in most classes, and in some severe. Mr. B. R. Cant was the victor of the day, as he not only secured the challenge trophy with his grand premier collection of seventy-two blooms, but also the silver medal for the best Hybrid Perpetual Rose in the Show with Madame Gabriel Luizet, a fresh and beautiful bloom; and a similar award for the best Tea Rose with Souvenir d'Elise, the finest and most solid example that has perhaps ever been staged. The silver medal for the best Noisette Rose was awarded to Mr. J. Walker, with Triomphe de Rennes. Others, however, must criticise at a future time, as we can do little more at present than give characteristics of the stands, with the leading prizewinning varieties and the awards of the Judges.

NURSERYMEN'S CLASSES.

The principal class was that for seventy-two single trusses, in which some very handsome blooms were staged. Mr. B. R. Cant, Colchester, well won the chief honours (the Challenge Trophy and first prize) with fresh bright blooms of good substance. The varieties represented were the following:—Prince Arthur, John Hopper, Star of Waltham, La France, Sultan of Zanzibar, Emily Laxton, Victor Verdier, Mdlle. Bonnaire, Pierre Carot, Madame Eugénie Verdier, Madame Victor Verdier, Marquise de Castellane, Mrs. Baker, Moiré, Fisher Holmes, Mons. Noman, Penelope Mayo, Devoniensis, Louis Van Houtte, Marguerite de St. Amand, Sénateur Vaisse, Edouard Morren, Le Havre, Hippolyte Jamain, Camille Bernardin, Princess Beatrice, John S. Mill, Gloire de Vitry, A. K. Williams, Clotilde Rolland, Mons. E. Y. Teas, Madame Caroline Kuster, Ville de Lyon, General Jacqueminot, Madame F. Jamain, Souvenir de Mons. Boll, Ruhens, Marie Baumann, Madame Marie Finger, Marie Rady, Louise Peyronny, Antoine Ducher, Souvenir d'un Ami, Madame Charles Wood, Madame Hippolyte Jamain, Duchess de Caylus, Countess of Rosebery, Xavier Olibo, François Michelin, Duke of Edinburgh, Marquis de Mortemart, Madame Clemence Joigneaux, Marie Van Houtte, Comtesse d'Oxford, Madame Lacharme, Duke of Teck, Madame Lambard, Madame Ducher, Capitaine Christy, Duke of Wellington, Maréchal Niel, Charles Lefebvre, Innocente Pirola, Exposition de Brie, Madame Gabriel Luizet, Etienne Levet, Egeria, Alfred Colomb, Baronne de Rothschild, Duke of Connaught, and Souvenir d'Elise of extraordinary quality.

Messrs. Cranston & Co., Hereford, were second with a handsome

collection, including substantially the same varieties as those at the Hereford Show reported on another page. Messrs. Paul & Son, Chesnut, were third with fine blooms of similar varieties to those staged at the Crystal Palace. Messrs. Curtis, Sandford & Co., Torquay, were fourth with a strong collection.

For thirty-six trebles the competition was also good. Messrs. Paul and Son were easily first with very handsome blooms, the following varieties being grandly represented:—Marie Baumann, Etienne Levet, Prince Arthur, Duchesse de Morny, A. K. Williams, Star of Waltham, Alfred Colomb, Madame Gabriel Luizet, Marie Finger, Marie Rady, Mons. E. Y. Teas, Marquise de Gibot, and Dr. Andry. Mr. B. R. Cant was second with large and in some cases very handsome blooms, amongst the latter being Le Havre, Madame Gabriel Luizet, Etienne Levet, François Michelin, Alfred Colomb, and Souvenir d'Elise. Messrs. Cranston & Co. were third with blooms mostly of moderate size but superbly coloured, the finest being Le Havre, Beauty of Waltham, Marie Baumann, Sultan of Zanzibar, and Dr. Andry. Mr. C. Turner, Slough, was fourth with bright and neat blooms.

For twenty-four trebles Messrs. Curtis, Sandford & Co., won chief honours with a beautiful collection, the blooms being of good size, excellent colour, and regular in form. The varieties best represented were Général Jacqueminot, Duchesse de Vallombrosa, Camille Bernardin, Comtesse de Serenye, Sénateur Vaisse, Marie Baumann, Marie Rady, Lælia, Marie Verdier, A. K. Williams, Madame Gabriel Luizet, Magna Charta, Alfred Colomb, and Mons. E. Y. Teas. Mr. B. R. Cant was second with rather rougher blooms, La France, Ferdinand de Lesseps, Edouard Morren, Le Havre, and Marie Rady being the most notable. Messrs. Cranston & Co. were third, John Stuart Mill, Alfred Colomb, and A. K. Williams being the best blooms.

For eighteen Teas or Noisettes, distinct, the premier award was secured by Mr. G. Prince, Market Street, Oxford, with a magnificent collection, comprising handsome blooms of Alba Rosea, Amazone, Adam, Souvenir de Madame Pernet, Ruhens, Innocente Pirola, Anna Ollivier, Marcelin Rhoda, Mons. Furtado, Comtesse de Nadaillac, Maréchal Niel, Catherine Mermet, Jean Ducher, Souvenir d'un Ami, Devoniensis, Souvenir de Paul Neyron, Marie Van Houtte, and Souvenir d'Elise Vardon. The second place was secured by Messrs. James Mitchell & Sons, Uckfield, Sussex, with good blooms but mostly smaller than the other. Ruhens, Jean Ducher, Souvenir d'Elise Vardon, and Comtesse Nadaillac were very fine. Mr. B. R. Cant was a close third, his stand including some very good blooms. Messrs. Paul & Son were fourth with an even collection. Five entries.

For forty-eight single trusses Mr. Frank Cant, Colchester, was deservedly awarded chief honours for extremely handsome blooms, amongst the best of which were Marie Baumann, Pitford, Catherine Mermet, Fisher Holmes, Souvenir d'Elise, A. K. Williams, Duke of Wellington, and Madame Crapelet. Mr. James Walters, Exeter, was a close second with a bright collection, though the blooms were mostly small. Messrs. G. Bunyard & Co., Maidstone, and Messrs. Davison and Co., Hereford, followed as third and fourth respectively. Nine collections were staged.

For eighteen triplets Messrs. J. Walters, Frank Cant, Davison and Co., and G. Cooling & Son, Bath, won the awards, all staging well. For twelve Teas or Noisettes Mr. J. Matlock, New Headington, Oxford, gained the chief award with neat blooms of Souvenir d'Elise, Catherine Mermet, Devoniensis, Niphotos, Triomphe de Rennes, Marie Van Houtte, and others. Mr. W. Farren, How House, Cambridge, was a close second; Messrs. G. Bunyard & Co., third; and R. Veitch & Sons, Exeter, fourth, in a competition of six. In the class for twenty-four single trusses Messrs. J. Laing & Co., Forest Hill; Kinmont & Kidd, Canterbury; and Walker of Thame were the prizetakers in the order named, the first-prize stand containing clean, fresh, and bright blooms.

AMATEURS' CLASSES.

The blooms in most of these classes were of very good quality, and perhaps might be considered rather better than those in the nurserymen's classes considered generally. For thirty-six blooms, single trusses, the first prize and challenge trophy were awarded to E. R. Whitwell, Esq., Barton Hall, near Darlington, with a very evenly matched stand of blooms, the boxes being painted light green; and instead of the usual covering of moss, which is too frequently of a rusty green, these were covered with purple black velvet. Roses evidently show to a better advantage in this way. This collection consisted of La France, fine; May Quennell, Eugène Verdier, Marie Baumann, Monsieur Noman, good; Ahel Grand, excellent; Lord Macaulay, Madame Lacharme, Sir Garnet Wolseley, Marguerite de St. Amand, Baronne de Rothschild, Marquise de Castellane, Duke of Teck, small but bright; Marquise de Gihot, Madame Prosper Langier, Xavier Olibo, Duke of Edinburgh, Mons. Gabriel Luizet, A. K. Williams, Marie Rady, François Michelin, Duke of Wellington, Annie Laxton, Comtesse de Serenye, John Hopper, Fisher Holmes, Le Havre, Duchesse de Vallombrosa, Dupuy Jamain, Prince Camille de Rohan, Madame Hippolyte Jamain, Dr. Andry, and Princess Mary of Cambridge. Mr. J. Brain, gardener to A. J. Waterlow, Esq., Great Doods, Reigate, was second, his best blooms being A. K. Williams, Le Havre, Eugène Fürst, John Stuart Mill, Comtesse de Choiseuil, Charles Lefebvre, and a curious mottled sport, probably a sport from Comtesse d'Oxford. Mr. C. Davis, The Grammar School,

Aynhoe, near Banbury, was placed third, A. K. Williams being here very conspicuous for its perfect form and colour; Marquise de Castellane, Beauty of Waltham, and Capitaine Christy being especially good. Mr. W. Harrington, Corbets Tey, Romford, was fourth with a stand of well-built flowers. There were ten competitors in this class, and all of them very creditable.

For twenty-four single trusses there were twelve exhibitors, first honours falling to J. B. Haywood, Esq., with a grand box of flowers consisting of Madame Gabriel Luizet, very fine; Marie Rady, good; La France, Comtesse d'Oxford, Marie Baumann, exquisite; Baronne de Rothschild, Dupuy Jamain, and A. K. Williams, splendid; Alfred Colomb, Mons. E. Y. Teas, Mrs. Laxton, François Michelin, Annie Wood, John Stuart Mill, Madame Lacharme, Etienne Levet, Duke of Edinburgh, Duchess of Bedford, Capitaine Christy, Comtesse de Sereny, Louis Van Houtte, Cheshunt Hybrid, Beauty of Waltham, and Antoine Ducher. Second honours went to Miss Penrice, Wilton House, Norwich; third, Mr. C. Davis; and fourth to Mr. Joseph Davis, The Square, Wilton, Salisbury. Mr. E. R. Whitwell also exhibited a collection of twenty-four, which in our opinion ought to have been placed among the prizetakers in this class. All the other collections fell considerably below the standard of the first-prize collection, which was very fine.

For twelve distinct, three trusses of each, there were eight collections. Mr. G. P. Hawtrey, Aldin House, Surrey, was a good first with Mons. E. Y. Teas, good; Mad. Hippolyte Jamain, Mad. Lacharme, Thomas Mills, beautifully bright, and of splendid form; Marie Finger, Baronne de Rothschild, Avocat Duvier, François Michelin, Alfred Colomb, and Charles Lefebvre. Mr. C. Davis was second; and Mr. C. E. Cuthill, Chapel Croft, near Dorking, third.

Of twelve Teas or Noisettes, distinct, single trusses, there were nine collections. Mr. J. Brown received the premier award with Marie Van Houtte, Caroline Kuster, Innocente Pirola, Niphotos, Devoniensis, Jean Ducher, Madame Willermoz, Souvenir de Paul Neyron, Anna Ollivier, Madame Welch, Alba Rosea, and Caroline Kuster. Mr. C. E. Cuthill was a very close second, and Mr. J. B. Hall third. A fine bloom of Anna Ollivier was exhibited in Mr. G. Sharp's stand. Mr. W. Harrington was also awarded equal third.

For twenty-four distinct, single trusses, second division, Mr. G. Baker was well ahead of the other twelve competitors, and worthily deserved the first position awarded. Annie Wood, Marie Baumann, Countess of Oxford, Etienne Levet, and Charles Lefebvre were superb. His other blooms consisted of Alfred Colomb, Charles Darwin, Madame Lacharme, Dupuy Jamain, Capitaine Christy, Magna Charta, Fisher Holmes, Baronne de Rothschild, Mrs. Laxton, Marquise de Castellane, Comtesse de Choiseuil, Duchesse de Morny, Louis Van Houtte, Madame Gabriel Luizet, Boadicea, Camille Bernardin, John Stuart Mill, and Pride of Waltham. The Rev. H. A. Berners, Harkstead Rectory, Ipswich, was second; Mr. Alfred Evans, Marston, Oxford, third; and the Rev. J. H. Pemberton, Havering-atte-Bower, Romford, fourth.

Fifteen collections of eighteen varieties were staged in Class 14, the first prize being a piece of plate, valued four guineas, which was awarded to Mr. Alfred Slaughter, Jarvis Villa, Steyning. Alfred Colomb, Marie Baumann, A. K. Williams, Reynolds Hole, Madame Lambard, Mons. E. Y. Teas were magnificent blooms in this collection. The Rev. E. L. Fellowes was placed second, Mr. Alfred Evans third, and the Rev. J. H. Pemberton fourth.

Of nine Teas or Noisettes there were eleven collections. Mr. G. Baker, Holmfels, Reigate, first with Anna Ollivier, Jean Ducher, Perle des Jardins, Madame Lambard, Catherine Mermet, Alba Rosea, Souvenir d'un Ami, and Devoniensis. The Rev. H. B. Biron is a very neat second. A magnificent bloom of Jean Ducher is here exhibited. Mr. A. Slaughter third, and Mr. J. Wakeley, Rainham, fourth.

In division E. for twelve single trusses, Mr. H. Harris, gardener to E. M. Betham, Esq., Denne Park, Horsham, was first with excellent blooms, having Mons. E. Y. Teas, Alfred Colomb, Etienne Levet, and Baronne de Rothschild, very fine. Mr. Wakeley was a close second; Mr. J. Burton, Sawtry, Peterborough, third; and the Rev. F. P. Roberts, The Rectory, Scole, fourth. Eight entries. For nine single trusses Mr. G. Mount, Harbledon, Canterbury; Mr. E. Wilkins, Lyndhurst, Sutton, Surrey; Rev. A. Foster-Melliard, Tostock Rectory, Bury St. Edmunds; and the Rev. Alan Cheales, Brockham Vicarage, Surrey, were the prizetakers in that order; all showing moderately good examples. In the next class, for six single trusses, F. Burnside, Esq., Farningham, Kent; E. Mawley, Esq., Lucknow House, Croydon; Mr. J. Burrell, Heighington, Darlington; and Mr. W. Narroway, Headington Quarry, Oxford, secured the leading honours.

For six Teas or Noisettes Mr. G. Mount, Harbledon, Canterbury, was first with fine blooms of Souvenir de Paul Neyron, Jean Ducher, Marie Van Houtte, and Catherine Mermet. The Rev. F. Page Roberts, The Rectory, Scole, Norfolk, was second; Mr. W. H. Wakeley, third; and E. Mawley, Esq., fourth.

OPEN CLASSES.

For a collection of twelve new Roses not in commerce previous to 1879, Messrs. Paul & Son gained the leading prize with good blooms of George Moreau, Souvenir de Madame Alfred Vy, Edward André, R. N. G. Baker, Catherine Soupert, George Baker, Madame Isaac Pevière, Ferdinand Chaffolte, Jules Finger, Rosieriste Jacobs, Countess of Rosebery, and Madame Ducher. Messrs. Curtis, Sandford and Co. were second with Mrs. Jowitt, Mons. Alfred Leveau, Lady

Sheffield, Alfred Dumesnil, Madame Julie Weidman, Masterpiece, Souvenir de Mons. Drouche, Rosieriste Jacobs, Mons. Thouvenel, Duke of Teck, Marguerite Manoin, and Comtesse de Camonde. Messrs. Cranston were third with the following in addition to several of the same varieties shown in the preceding:—Madame Montet, François Levet, Comte Horace de Choiseuil, Crown Prince, Pride of Waltham, and Jules Jergenson. Four entries.

For twelve blooms of any yellow Rose, Mr. G. Prince won first honours with Jean Ducher, bright, fresh, and clean; Mr. B. R. Cant followed with Marie Van Houtte, and Messrs. Curtis, Sandford and Co. with Maréchal Niel. Seven entries.

For twelve blooms of any white Rose Messrs. Cranston were first with Madame Lacharme, very even and of good form. Mr. B. R. Cant took the second prize with Devoniensis, very handsome. Messrs. J. Jefferies & Co., Cirencester, were third with Madame Lacharme. Ten competitors.

For twelve blooms of any crimson Rose, Mr. James Walters, Mount Radford Nursery, Exeter, was first with fine substantial blooms of Marie Baumann; Mr. B. R. Cant taking the second place with bright examples of A. K. Williams; Mr. John Sargant third with Alfred Colomb, bright and fresh; and Messrs. Curtis, Sandford & Co. were fourth with Marie Baumann, very good. Thirteen competitors.

For twelve trusses of any Rose Messrs. Paul & Son took the first place with even blooms of Capitaine Christy; Mr. G. Prince followed closely with Catherine Mermet of excellent quality, even and of good form; Mr. B. R. Cant was third with La France; and Messrs. Cranston & Co. were fourth with A. K. Williams, very bright. Seventeen entries.

EXTRA CLASSES.

Several classes were provided in this section. For twenty-four bunches of Tea Roses, three trusses each, open to ladies only, Mrs. H. B. Biron, Harbledon, won the chief prize, a piece of plate offered by Mr. Prince, with beautiful blooms of good substance, comprising the following varieties:—Caroline Kuster, Madame Camille, Madame Hippolyte Jamain, Perle des Jardins, Rubens, Comtesse Riza du Parc, Catherine Mermet, Marquise de Sanima, Devoniensis, Souvenir de Paul Neyron, Marie Van Houtte, Madame Lambard, Homère, Madame Maurin, Jean Pernet, Madame Welch, Jean Ducher, and Souvenir d'un Ami. Mrs. Maria Slaughter, Steyning, secured the second prize with a collection little inferior to the preceding. Miss A. F. Pemberton, Havering-atte-Bower, Romford, was a good third. Four entries.

For six blooms of suburban-grown Roses Mr. J. E. Coleby, Rosenhams, Wimbledon, was first, securing the plate offered by Mr. Mawley with Mons. E. Y. Teas, Marquise de Castellane, Baronne de Rothschild, Alfred Colomb, Gloire de Dijon, and Paul Neyron, all of good substance. Mr. E. Berry, gardener to the Countess of Leven and Melville, was second with Marquise de Castellane, Capitaine Christy, Louis Van Houtte, François Michelin, Magna Charta, and Madame Lacharme even and fresh; J. P. Bookless, Esq., Wimbledon, being third with fair blooms.

For six Roses from amateurs who had not previously won any of the Society's prizes, the Rev. Canon H. Girdleston, Sunningdale, won the leading prize with large but rather old blooms of Alfred Colomb, Paul Jamain, Duchesse de Vallombrosa, Thomas Mills, Charles Lefebvre, and Madame Caroline Kuster. The Rev. A. Foster Melliard, Bury St. Edmunds, was second with fine blooms. Mr. W. Harris, gardener to E. M. Betham, Esq., Denne Park, Horsham, third with a very neat collection; and Mr. Ernest Milkins, Lyndhurst, Sutton, Surrey, was fourth in a class of twelve competitors.

For six blooms of suburban-grown Teas or Noisettes there was only one entry, Mr. J. Bateman, Highgate Road, N.W., being awarded the third prize for small and poor examples.

For six new Roses not in commerce previous to 1879 there were five competitors. Mr. J. B. Hall, Larch Wood, Rock Ferry, Cheshire, was first with Duke of Teck, William A. Richardson, Duchess of Bedford, Comtesse de Choiseuil, Harrison Weir, and Julius Finger. Mr. G. P. Hawtrey, Aldin House, Slough, was a close second, Comtesse de Choiseuil and Harrison Weir being good. The Rev. Alan Cheales, Brockham Vicarage, Surrey, was third. Five entries.

Miscellaneous exhibits were numerous and occupied considerable space in the conservatory. Very prominent was the handsome group from Messrs. Barr & Son, Covent Garden, which is described in another page. Mr. G. Prince of Oxford sent ten boxes of extremely fine Tea and Noisette Roses. Messrs. W. Paul & Son, Waltham Cross, also exhibited a large number of handsome Rose blooms. Mr. T. S. Ware, Tottenham, had a group of hardy plants, Lilliums being especially remarkable. Messrs. Lee & Son, Hammersmith, and Osborn and Son, Fulham, contributed collections of Roses. Mr. J. Walker of Thame had some fine trusses of Sweet Williams; Mr. B. Poster, Corse End, Maidstone, sent collections of Violas and Campanulas; Messrs. H. Cannell & Sons, Swanley, handsome Verbena blooms; Mrs. Pemberton, Romford, a collection of old Roses; and from Chiswick a large group of Mignonette was contributed, representing a number of different strains. Mr. John House of Peterborough exhibited a stand of that lovely Rose William Allen Richardson, which was the admiration of all who saw it.

CALTHA LEPTOSEPALA.—This is a very distinct species of the Marsh Marigold genus, of very dwarf habit, scarcely rising from 4 to 6 inches from the soil. Leaves shining green, roundish-cordate, with crenated edges, spreading; in the plants I have seen nearly flat

upon the surface of the ground. Flowers freely produced, nearly or quite 2 inches across; white, and veined externally with yellow. Superficially they much resemble miniature white Water Lilies, and are produced from May to July. It is a native of the western States of North America, where it favours marshy localities, and it thrives well under cultivation in very damp situations, and is on that account very acceptable owing to its very distinct appearance. It is increased by division of the root, but as my knowledge of it is but recent it is impossible to give any particulars in that respect.—N.

A PROLIFEROUS ROSE.

ONE of my Rose trees has indulged in the strange freak of producing blooms from blooms—that is to say, a shoot issues from the centre of a flower and produces another flower; but what is

Fig. 1.

even more singular, the small leaves that are produced under the second bloom are more or less tinted with pink like the petals. All the blooms were not thus proliferous, and the tree is very healthy. I am not sure what the name of the Rose is, as the variety is very old. I send you an example, and am curious to know if anything like it has ever been seen before. Our clergyman thinks he has read of something of the kind but cannot remember where, but thinks it must have been in the Journal. I do not think it can have been during the last six years, as I have read it carefully since 1876, and cannot recollect seeing any record of a similar case. It is very singular, and I cannot under-

stand how this second growth and bloom can be produced. Can you tell me anything about it?—JAMES HEBDEN.

[We cannot name the Rose, which was much withered. The example is almost exactly similar to the one submitted to us by Mr. Lee of Clevedon nine years ago. Usually, in fact nearly always, the growth terminates in the flower, but in this case there has been an abnormal prolongation of the growing axis for which we cannot account. The leaves just above the dark part of the stem were very small, pinnate, and two or three of the leaflets partly rose-coloured. The stem, Rose, and leaves represented in our engraving issued from the centre of another Rose, which was borne where the letter A is placed.]

CRYSTAL PALACE ROSE SHOW.

BRIGHTNESS of colour and good substance were prevailing characteristics of the Rose blooms which were abundantly staged at the Sydenham Exhibition on Saturday last. Of the twenty-one classes enumerated in the schedule only one, that for twelve trusses of *Maréchal Niel*, was unrepresented, and in some the competition was much keener than was expected considering the close approach of the National Rose Society's Show at Kensington. Two long tables were devoted to the stands, the few gaps which occurred through the non-appearance of exhibitors who had entered various classes being filled with small Palms, Ferns, and other suitable plants, others of which also formed a central line on the tables between the boxes of blooms.

Nurserymen's Classes.—In these some very handsome blooms were staged, particularly in the class for seventy-two distinct varieties, single trusses, six fine collections being contributed. In every respect the best was that from Mr. B. R. Cant of Colchester, who had an even beautiful stand of well-formed richly coloured blooms; indeed the first prize had been awarded for it, when it was observed that two blooms of *Madame Nachury* were included—an obvious mistake, but according to the terms of the schedule this collection had to be disqualified, though very regretfully on the part of the Judges, who indicated their appreciation of the exhibit by awarding it an extra prize. So many of the best varieties were admirably represented in this that the names of the majority may be given—*Baroness Rothschild*, *Marie Baumann*, *Madame Gabriel Luizet*, *Beauty of Waltham*, *Souvenir d'un Ami*, *A. K. Williams*, *Duchesse de Vallombrosa*, *Marguerite de St. Amand*, *Duke of Wellington*, *Duke of Edinburgh*, *Charles Lefebvre*, *Devoniensis*, *La France*, *Duchess of Bedford*, *Marie Van Houtte*, *Dupuy Jamain*, *Madame Willermoz*, *François Louvat*, *François Michelin*, *Reynolds Hole*, *Rubens*, *Mdlle. Marie Cointet*, *Capitaine Christy*, *Duke of Teck*, *Madame Charles Truffaut*, *Etienne Levet*, *Madame Ducher*, *Madame Nachury*, *Le Havre*, *Général Jacqueminot*, *Fisher Holmes*, *Marquise de Castellane*, *Madame Bravy*, *Triomphe de Rennes*, *Mrs. Baker*, *Madame Clemence Joigneaux*, *Comtesse de Serenye*, *John Hopper*, *Boule d'Or*, *Auguste Rigotard*, *Sénateur Vaisse*, *Jules Finger*, *Magna Charta*, *Abel Grand*, *Elie Morel*, *Comtesse d'Oxford*, *Madame Eugénie Verdier*, *Cheshunt Hybrid*, *Dr. Andry*, *Annie Laxton*, *Madame Charles Wood*, *Princess Mary of Cambridge*, *Ferdinand de Lesseps*, *Victor Verdier*, *Prince Arthur*, *Duchesse de Morny*, *Mr. Harry Turner*, and *Madame Marie Finger*. Messrs. Paul & Son, Cheshunt, were placed first, but though their blooms were large and in some cases of good form they were generally rougher than the preceding; the best blooms being *Etienne Levet*, *A. K. Williams*, *Countess of Rosebery*, *Alfred Colomb*, *Beauty of Waltham*, *Duchesse de Caylus*, *Penelope Mayo*, and *George Moreau*. Messrs. Cranston & Co., Hereford, were placed second with smaller but even and fresh blooms; Messrs. Curtis, Sandford & Co., Torquay, taking the third position with brightly coloured examples of leading varieties.

For forty-eight triplets Messrs. Paul & Son were deservedly accorded the first prize, their collection including some exceedingly handsome blooms, and it was evident the firm had concentrated their strength on this class. The most noteworthy varieties were *Capitaine Christy*, *A. K. Williams*, *Xavier Olibo*, *Duchesse de Morny*, *Ferdinand de Lesseps*, *Alfred Colomb*, *Exposition de Brie*, *Souvenir de la Malmaison*, *Sénateur Vaisse*, and *Abel Carrière*. Mr. C. Turner, Slough, was a close second with creditable blooms, fresh, bright, and neat; Messrs. Cranston & Co. taking the third place. For twenty-four triplets and the same number of single trusses Messrs. C. Turner, Frank Cant (Colchester), and Cranston were the prizetakers, all showing well. Mr. B. R. Cant had the best twelve Teas and Noisettes, comprising fine blooms of *Souvenir d'un Ami*, *Madame Caroline Kuster*, *Souvenir d'Elise*, *Madame Bravy*, *Rubens*, *Madame Ducher*, *President*, *Marie Van Houtte*, *Paul Neyron*, *Devoniensis*, *Innocente Pirola*, and *M. Jules Margottin*. Messrs. Mitchell & Sons, Uckfield, Sussex, followed very closely with good examples of *Rubens*, *Devoniensis*, *Comte de Paris*, *Catherine Mermet*, and *Belle Lyonnaise*. Messrs. Cranston were third, *Madame Bravy*, *Perle des Jardins*, *Jean Ducher*, and *Catherine Mermet* being noteworthy for their size and good form.

Amateurs' Classes.—The exhibits in these classes were not characterised by such general merit as in the preceding, and in the majority the blooms were rather small, though most of the collections included some fine blooms. The leading class was that for forty-eight distinct varieties, single trusses, and in this there were six

competitors; Mr. G. Rushmore, gardener to Sir C. R. Rowsley, Bart., Tendring Hall, Colchester, being awarded chief honours for substantial blooms, the following varieties being particularly well represented:—Jules Margottin, Duchesse de Caylus, François Michelin, Marguerite de St. Amand, Abel Carrière, Miss Hassard, Mons. E. Y. Teas, Thomas Mills, and Général Jacqueminot. G. P. Hawtrej, Esq., Aldin House, Slough, secured the second position with a collection nearly equal to the other in merit; Mr. J. Davis, Wilton, Salisbury, being third. In the class for thirty-six varieties the competition was also keen, eight collections being staged. Mr. W. Harrington, gardener to E. Mitchell, Esq., Corbet's Tey, Romford, gaining the chief honours with handsome blooms, closely followed by Mr. John Sargant of Reigate, and Mr. Rushmore. For twenty-four triplets and twenty-four single trusses Messrs. Hawtrej, J. Hollingworth, Turkey Court, Maidstone; T. Evans of Marston, Oxford; and the Rev. J. H. Pemberton, Havering-atte-Bower, Romford, were the prizetakers. For twelve Tea or Noisette varieties Mr. Harrington won leading honours with a praiseworthy collection, comprising fine blooms of Madame Lambard, Rubens, Perle des Jardins, Amazone, Madame Sertot, Marie Van Houtte, Madame Hippolyte Jamain, and Souvenir d'un Ami.

Open Classes.—The ten classes open to all exhibitors were very interesting, especially those provided for collections of white, yellow, pink, and crimson Roses, the others being chiefly for stands of one variety. A fine collection of Devoniensis from Mr. B. R. Cant was selected for first honours in the class for twelve trusses of any Tea or Noisette, Mr. J. Matlock, New Headington, Oxford, following with Souvenir d'un Ami. The best samples of Marie Baumann were staged by Messrs. Curtis, Sandford & Co.; Abel Carrière by Messrs. Paul & Son, Mr. C. Turner taking second with Charles Darwin very fine. Mr. W. Farren, How House, Cambridge, had the best twelve trusses of François Michelin, large handsome blooms; Mr. B. R. Cant taking first with a collection of Capitaine Christy, very large and full. The same exhibitor secured chief honours for a collection of yellow Roses, the following varieties being admirably represented—Marie Van Houtte, Madame Falcot, Isabella Sprunt, Rêve d'Or, Madame Welch, Gloire de Dijon, Jean Ducher, Caroline Kuster, Solfaterre, Marie Van Houtte, and Boule d'Or. He also took the lead in the class for white Roses, having Devoniensis, Innocente Pirola, Rubens, Niphotos, Madame Lacharme, Souvenir d'un Ami, Madame Willermoz, Souvenir de Paul Neyron, and Madame Bravy being the most notable varieties. Still continuing his success, Mr. Cant was first with crimson and velvety crimson Roses, his best blooms in the former class being Comtesse d'Oxford, Dupuy Jamain, Dr. Andry, Duchesse de Caylus, Duke of Teck, Alfred Colomb, Mrs. Baker, Sénateur Vaisse, A. K. Williams, and Marie Baumann; while in the latter class the finest were Duke of Wellington, Dr. Sewell, Duke of Edinburgh, Charles Lefebvre, Général Jacqueminot, Prince Camille de Rohan, Duchess of Bedford, and Fisher Holmes. The finest collection of pink Roses were also from Colchester; Marie Cointet, Madame Gabriel Luizet, Marguerite de St. Amand, Elie Morel, Marie Finger, and La France being the principal varieties staged.

Miscellaneous exhibits were not very numerous. Messrs. H. Cannell and Sons, Swanley, had a group of Gloxinias and Ferns, Messrs. Osborn & Sons a collection of Roses, and Mr. Wells of Red Hill samples of his spray-distributor.

A TRIAL OF EARLY TURNIPS.

SOME complaints of a scarcity of really good early Turnips last year induced the writer to inquire why it was so, and the answer was that the sorts grown ran to seed so quickly that very few Turnips of a useful size were to be had from the first sowings. It was, therefore, resolved this year to procure seed of as many sorts of early Turnips as possible, and to give them a fair trial side by side. Unfortunately all the seed had not arrived when the first sowing was made on March 4th of Early Strapleaf White Stone, Early Red American Strapleaf Stone, White Stone or Six Weeks, Extra Early Paris Market, Early White Flat Dutch, and Early Snowball. Seven days later close beside these sorts was sown Purpletop Munich, Silverball, Jersey Lily, and Teltow Early Yellow. By the second week in May these sowings were affording an excellent supply of small Turnips, many of which continued to improve, and were in use up to this time (June 24th), overlapping a sowing of all the sorts on April 14th, some of which are quite ready for use.

On May 30th Mr. Thomas of Maresfield Park happening to call, I requested him to examine the Turnips with me, and after a careful comparison it was decided that Purpletop Munich was best and Early Red American Strapleaf Stone second best, due attention being given to size, crispness, and flavour. Two or three other sorts were quite equal to Red American in size, but were decidedly inferior in the other more important points of excellence. Extra Early Paris Market all "bolted" without any perceptible root-swelling. Teltow Early Yellow also burst speedily into flower, more in the guise of a weakly dwarf weed than a cultivated Turnip. Early Snowball was the first to throw up its flower stems of those sorts which were really useful, and it was followed

by Red American, White Stone or Six-weeks, and Strapleaf White. Of the sowing on April 14th Purpletop Munich is again first and best, the next being Early Strapleaf White Stone, closely followed by Red American Strapleaf. Extra Early Paris Market has not run to seed, but its roots are unworthy of comparison with any of the others except Teltow Yellow, which appears worthless.—EDWARD LUCKHURST.

ASPERULA HIRTA.

THIS is, in my opinion, the most handsome species of Woodruff among those introduced from other countries. It is very dwarf in habit, growing from 3 to 4 inches high, with very slender suberect stems in close tufts. Leaves linear-oblong, whorled, 3 to 4 lines long. Flowers borne in terminal racemes, 3 to 4 lines across, cruciform, white shaded with pink, very freely produced, and they are very effective in contrast with the deep green elegant foliage, somewhat resembling miniature stars. It is a gem for the rockery, enjoying a sunny fissure, where it thrives rapidly, and it is readily increased by division of the roots or by the young cuttings, which will strike in a cold frame although they are rather slow. I have also raised it from seed. It is a native of the Pyrenees, and was first introduced in 1817, although we seldom meet with it even in the most complete collections; flowering from July to September. I obtained two plants from Froebel and Co. of Zurich, and last season it was greatly admired and freely distributed. The British *A. odorata* (Sweet Woodruff) is also a charming little plant for spring flowering, and I noticed a very happy arrangement during May in which it was fittingly employed. The groundwork of the bed was the common green Stonecrop (*S. acre*), in which were large patches alternately placed of this plant and blue Myosotis, surrounded with double red Daisies.—N.

ROSE SHOW AT THE MANSION HOUSE.

ON Friday last an Exhibition of Roses was held under the patronage of the Lord Mayor, the funds raised by the admission fees and the subsequent sale of the blooms shown being devoted to two charitable institutions. Ten classes were provided for amateurs only, two prizes being offered in each—namely, a silver and a bronze medal. In most of these classes very satisfactory blooms were staged, but by far the most extensive and beautiful portion of the display consisted of collections of Rose blooms and miscellaneous plants from nurserymen. These occupied the spacious and handsome apartment known as the Egyptian Hall, which presented a most brilliant and attractive scene when illuminated by the electric light. The blooms were arranged in banks on each side of the Hall, but though abundance of moss was employed it was observed that a few more Ferns suitably disposed would have considerably improved the effect, as there was rather too great a preponderance of bright colours. At each end of the Hall were pyramidal groups of Pelargoniums, Tuberos Begonias, and Fuchsias from Messrs. H. Cannell & Sons, Swanley, which were very striking. Around the columns and near the walls were also some tasteful decorations from the same firm, consisting chiefly of Delphiniums, *Spiræa Filipendula* fl.-pl., Roses, and Fern fronds, which formed graceful wreaths and banks, the Delphiniums being particularly effective. The chief exhibitors of Rose blooms in large numbers were Messrs. Paul & Son, Cheshunt; W. Paul & Son, Waltham Cross; G. Prince of Oxford; John House, Peterborough; Keynes & Co., Salisbury; Rivers & Son, Sawbridgeworth; Cooling and Son, Bath; Francis & Co., Hertford; Rumsey, Waltham Cross; and C. Turner of Slough.

The principal amateur exhibitors were Alfred James Waterlow, Esq., Great Doods, Reigate; Mr. G. Duffield, gardener to H. K. Mayor, Esq., Winchmore Hill, N.; Alfred Slaughter, Esq., Jarvis Villa, Steyning; E. Mawley, Esq., Addiscombe; C. E. Cuthell, Esq., W. H. Wakeley, Esq., and James P. Kitchin Esq., Hampton, who secured the leading prizes in all the classes with blooms of fair size and substance.

The general arrangements were satisfactorily conducted under the supervision of Mr. J. Forsyth Johnson, Horticultural Director of the Alexandra Palace.

CURRENT TOPICS.

THERE are several points of interest in the Journal of June 22nd which I would like to notice, and first as to layering Strawberries. The plan recommended by "SINGLE-HANDED" I can endorse as the best that can be tried, and superior to raising the plants in pots: in fact, anything which I want extra good and quick ready for use, and which may require preparation by a previous pricking-out in frames, are planted in half soil and half manure. Strawberries with a fortnight only in such a mixture will at this season obtain a valuable start. When time cannot be spared for preparing plants, quite as good results as can be obtained by layering in pots is obtainable by selecting the strongest

runners and planting them when rooted directly in their permanent quarters. We have about a thousand young plants which were thus planted last season, and which now average from 18 inches to 2 feet in diameter. These were planted after Peas, the ground being merely hoed and cleaned.

With regard to what Mr. Muir says about Lettuces, I may state that I find Hicks' Hardy Cos as procured from Messrs. Veitch of Chelsea the best summer sort I have been able to obtain, and it is also the best for winter use; in fact, we have it all the year round. However, the sort that may do well in one locality may be of little use in another; and, that aside altogether, it is found that tastes differ considerably in the matter of what is the best kind.

I imagine "W. J. M." will find Victoria the best late Potato he can grow, quality considered. Champion will soon be out of cultivation as a general field crop. Many are now growing Magnum Bonum extensively in this district; but, to give it as good a character as our experience warrants, it is very variable in quality. The other kinds named are all of inferior quality here. Grampian was good last year and might be worth a trial, bearing in mind this remark, which was made to me the other day by one of our estate mechanics—"The longer ye keep a new kind o' Tatie the mealier it gets, if it's wuth anything at a'."

As a cultivator of both Foxgloves and Hollyhocks let me remark on the singular mode of enhancing the value of a given flower at the expense of another which "SINGLE-HANDED" has taken. There is no basis for comparing the two on the ground taken. One might just as well object to employing half-hardy bedding plants for an autumn display on the ground that Primroses, Anemones, Wallflowers, &c., are as beautiful, or more so, and much more cheaply and easily cultivated. Because we have hundreds of Foxgloves flowering just now and during July, is that a valid reason for doing away with Hollyhocks, which are at their best from the middle of August to the end of October?—B.

RICHMOND HORTICULTURAL SHOW.

JUNE 29TH.

EIGHT years of steady progress have placed the Richmond Society at the head of those in the neighbourhood of the metropolis, and their shows have attained considerable fame both for extent and for the excellent quality of the productions there staged. The Exhibition held on Thursday last in the Old Deer Park was no exception to the rule, the same satisfactory advance being observable that has characterised each successive show. Indeed it may be safely asserted that it was the best the Society has yet held, and much credit is therefore due to Mr. G. Eyles, the new Secretary, for having in the first year of his management rendered such good service in forwarding the Society's interests. In nearly all the very numerous classes the competition was good, and in some cases it was more than ordinarily keen. Four marquees, two of moderate size and two very large, were filled with the exhibits, the former being chiefly devoted to vegetables and fruits and cottagers' productions, the others containing the groups, specimen plants, cut flowers, and table decorations.

Though the weather was dull and threatening, a large number of visitors assembled, amongst whom were the Duke and Duchess of Teck, the Lady Mayoress, and the Belgian horticulturists.

Stove and Greenhouse Plants.—For so late a period these were admirably represented by several collections, including well-grown fresh healthy specimens, and in some cases superbly flowered. Messrs. T. Jackson & Son, Kingston, were the most successful exhibitors in the open class for nine plants, having fine examples of *Lxora Williamsi*, flowering freely; *Allamanda cathartica*, vigorous; *Erica ventricosa Bothwelliana*, even and floriferous; *Rondeletia speciosa major*, with numerous large richly coloured flowers; and *Kalosanthes Dr. E. Regel*, a beautiful variety represented by a fine plant. Messrs. Peed & Son, Norbury Nurseries, Streatham, took the second position with specimens very little inferior to the preceding; *Pimelea spectabilis*, *Allamanda Hendersoni*, and *A. grandiflora*, with *Stephanotis floribunda* being the most noteworthy. Mr. H. James, Castle Nursery, Lower Norwood, followed, *Kalosanthes Phoenix* and *Bougainvillea glabra* being well shown. In the class for six plants from exhibitors in the Society's district, Mr. C. Attrill, Bank Grove, Ham, won chief honours, having *Kalosanthes coccinea*, *Allamanda Hendersoni*, and a *Bougainvillea* strong and freely flowered. Mr. Howell, gardener to Lady Parker, Stawell House, Richmond, was second with a plant of *Peristeria elata* bearing a spike 3 feet high with twenty flowers and buds. *Allamanda grandiflora* was also in satisfactory condition with several others.

Pelargoniums.—A bright display of these was contributed. For six Show varieties Mr. Wiggins, gardener to H. Little, Esq., Hillingdon Place, Uxbridge, gained the chief award with *Madame Thibaut*, *Setting Sun*, *Robina*, and *Prince Leopold* very well flowered. Mr. Croxford, gardener to Mrs. Dunnage, Albury House, Surbiton, and Mr. J. W. Wells, gardener to J. Rodgers, Esq., Selwyn Court, Richmond, were second and third respectively with much smaller plants. Mr. Wiggins also had the best six Fancy varieties, *Pilgrimage*, *Lady Harvey*, *Lucy*, and *Mrs. Graham* being in grand form. Mr. Croxford

again took the second position, but with healthy plants. Two collections in the class for six Zonal or bedding varieties were very noteworthy; these were from Mr. Bond, gardener to Mrs. Evans, Beech House, Teddington, and Mr. Croxford, who were first and second respectively. In the first-prize collection the plants were of even size, about 4 feet in diameter, and bearing fine trusses of flowers. The varieties, too, were well selected, comprising *Madame Thibaut*, *Master Christine*, *Nemesis*, and *Madame Baltet*. Mr. Croxford's best plants were *Mrs. Turner*, a fine rich rose-pink, and *Wonderful*, a deep glowing scarlet, both single varieties, and very effective.

Ferns.—Few of the extremely large specimens occasionally seen at the London shows were staged here, but all were distinguished by surprising health, and in one or two of the leading collections the plants were all that could be desired. For six exotic Ferns Mr. B. Morrell, gardener to J. S. Rutter, Esq., The Cedars, Richmond, was adjudged the principal position, his plants including excellent examples of *Davallia Mooreana*, *Gymnogramma Peruviana argyrophylla* very fine, *Dicksonia davallioides*, *Davallia pyxidata*, and *Gymnogramma chrysophylla*. Mr. G. Stevens, Putney, followed closely with *Dicksonia antarctica*, *Platycterium alcornu* large and fine, and *Adiantum concinnum*. Messrs. W. Fromow & Son, Turnbam Green, secured the third position, four really creditable collections being staged in this class. In the district class for six Ferns, Mr. D. East, gardener to F. Wigan, Esq., Clare Lawn, East Sheen, carried off the first prize for well-grown plants; Mr. Morrell being second also with specimens in very fine condition. Mr. C. Prickett, gardener to Dr. Francis, Manor House, Richmond, had the best twelve hardy Ferns, choice varieties and in good condition; Messrs. Wells and Morrell following with very similar plants.

Fuchsias.—In several classes these were admirably shown, although there was considerable difference in the style of training adopted. The finest specimens were shown in the open class for nine, and the Judges very properly selected a collection from Mr. Morrell for the chief honours. These plants were extremely even and graceful, of conical form, about 4 feet high, and flowering profusely; the lateral branches drooping slightly with their own weight, gave a very graceful appearance to the plants. The second prize was accorded to Mr. E. Beckett, gardener to J. P. Currie, Esq., Sandown, Esher, who had by far the largest plants grown, some exceeding 6 feet, all very healthy and well flowered. Mr. Bond followed with large conical-shaped plants in creditable condition, one example of *Earl Beaconsfield* being greatly admired.

Groups.—An important portion of the Exhibition was constituted by the entries in the open class for a group of plants arranged for effect in a space not exceeding 100 square feet. Six attractive and very diversely arranged groups were staged; but though there was considerable difference of opinion respecting the justness of the inferior awards, the one selected for the premier position was generally admired as both novel and tasteful. This was from Mr. H. James, who might with advantage show such groups more frequently, as they are instructive, and form a most agreeable break from the stereotyped even banks of plants too commonly staged. The second prize was secured by Messrs. Fromow and Sons, who had a graceful combination of fine-foliage and flowering plants, very bright and effective; but this, and the group from Mr. W. Brown, Richmond, placed fourth, were so similar in character and merit that they deserved equal awards. Mr. J. Bruckhaus, Hooper's Nursery, Twickenham, was third with a diversified arrangement of Palms, Ferns, *Dracenas*, and *Crotons*, with *Begonias*, *Campanulas*, and *Gloxinias*.

Amongst the numerous other plants shown the *Calceolarias* deserve especial notice, particularly the premier collection from Mr. East, which were in excellent health and the foliage finely coloured; the varieties *Madame Hunnibelle*, *Prince Albert Edward*, *Laingi*, *Chantini*, and *Cbelsoni* being beautifully represented. The other collections from Messrs. Sallows and Wigan were also good. Fine-foliage and *Tuberous Begonias*, *Orchids*, *Gloxinias* were all staged in satisfactory condition.

Cut Flowers.—Prominent amongst these were the *Roses*, which were extremely fresh and highly coloured. In the nurserymen's classes Messrs. G. Paul & Son, Cheshunt, secured the chief prizes with magnificent blooms of all the leading varieties. Mr. W. Rumsey, Waltham Cross, also contributed some handsome blooms. In the open class for twenty-four blooms Mr. C. Warwick, gardener to J. P. Kitchener, Esq., Manor House, Hampton, took the lead with fine fresh samples of excellent substance. Mr. Moorman, gardener to the Misses Christy, Coombe Bank, Kingston, also staged well in the same class. E. Mawley, Esq., Addiscombe, gained the chief award for twelve with beautiful blooms, and in other classes the following exhibitors gained well-deserved honours.—Mr. W. Croker, gardener to W. Register, Esq., Lawn Lodge, Isleworth; Mr. W. Bates, gardener to J. E. Meek, Esq., Poulett Lodge, Twickenham; Mr. E. Lake, gardener to E. Ascheron, Esq., Haversham Grange, Twickenham; and D. Roberts, Esq., Park Villa, Richmond. Several special prizes were offered for *Roses* and other cut blooms by C. Selwyn, Esq., Selwyn Court, Richmond; D. Roberts, Esq.; Messrs. J. & G. Peirce, H. Herbst, and others, and most were well competed for, Messrs. Moorman, Bates, Hinnell; Stephens, gardener to J. Bull, Esq., Redholm, Teddington; and Berry, gardener to the Countess of Leven, Roehampton House, being the most successful exhibitors.

Vases, bouquets, and table decorations were numerous shown, and some tasteful designs were submitted. Three stands from Mrs. Hol-

ford, The Cottage, Petersham, for which the silver medal given by the Duke of Teck was awarded, were very novel, the flowers consisting of white Water Lilies, *Gladiolus Colvillei albus*, with a few yellow Marguerites and *Spiræas*, leaves of the Copper Beech and *Adiantum* fronds being arranged with them. It was, however, observable that these were scarcely suitable for a table, as they were rather heavy, and further, only one side had been completely finished. Mr. W. Brown was the principal prizetaker for bouquets, and contributed some pretty arrangements; he was also successful in other classes for stands of flowers.

Fruit.—Numerous collections of fruit were staged in most of the classes, and the leading exhibits were of very good quality, though several others were characterised by a rather too noticeable deficiency in regard to ripeness, which was especially the case with the majority of white Grapes shown. For a collection of six dishes Mr. Wildsmith, gardener to Viscount Eversley, Heckfield Place, Hants, was placed first with finely coloured Black Hamburg Grapes, a good Queen Pine Apple, Brown Turkey Figs, Suttons' Heckfield Hybrid Melon, and Bellegarde Peaches. Mr. Hudson, gardener to H. J. Atkinson, Esq., Gunnersbury House, was a close second, his principal dishes being fine black Grapes, an even and well-ripened Queen Pine Apple, and good-sized Condor Peaches. Mr. Davis, gardener to the Rev. H. Morris, Roehampton Park, was third with smaller but creditable samples. The best three bunches of black Grapes were staged by Mr. P. Feist, gardener to R. J. Ashton, Esq., Bishopgate House, Staines, who well deserved the first prize awarded him for handsome bunches of Black Hamburg with large finely coloured berries. Mr. Davis and Mr. W. Fyfe, gardener to W. F. Dick, Esq., Thames Ditton House, were second and third respectively with less well-finished samples. Mr. Feist and Mr. J. Wagstaff, gardener to H. Elam, Esq., Firsleigh, Isleworth, were two of the chief exhibitors of white Grapes, Messrs. Attrill and Lake having good Peaches, and D. Heckle, gardener to W. Cunard Esq., Lebanon House, Twickenham, staged fine Strawberries.

Vegetables were largely and well shown, the leading prizes being secured by Messrs. E. Beckett, Wagstaff, and Morrell, who had some excellent collections. Messrs. Carter & Co.'s prizes for four dishes of Peas, of the varieties Telegraph, Telephone, Stratagem, and Pride of the Market, brought six competitors, the awards being granted to Mr. G. Williams, gardener to C. Liddell, Esq., Peasmarsh Place, Sussex; Mr. W. Chittleburgh, gardener to Col. Rous, Worsted House; and Mr. Phillips of Meopham, Kent. Messrs. Sutton & Sons' prizes for Cucumbers were also well competed for.

The Veitch Memorial Prizes.—This year the trustees of this fund decided to offer these prizes at Richmond—namely, £5 and a Veitch Memorial medal for the best stove or greenhouse plant in flower, and the same amount for the best two bunches of black Grapes. In the plant class there were six entries, the prizes being awarded to Mr. J. Hinnell, gardener to F. A. Davis, Esq., Anglesea House, Surbiton, for a specimen of *Erica tricolor dumosa* of globular form 5 feet in diameter, very evenly trained, and in good health, the flowers also being numerous but a little past their best. Mr. Bates had a well-flowered *Bougainvillea glabra* in the same class, and Messrs. Peed and Son a healthy *Allamanda grandiflora*. In the Grape class Mr. Hudson won amongst five competitors with two grand bunches of Madresfield Court, the berries of great size and superbly coloured.

Miscellaneous groups and exhibits were numerous and very attractive, the most noteworthy being the following:—Messrs. J. Veitch and Sons, Chelsea, had a beautiful group of Roses in pots, with Japanese Maples at the back and a margin of *Eurya latifolia variegata*. Six boxes of fine Rose blooms were also staged by the same firm. Messrs. C. Lee & Son, Hammersmith, contributed an attractive collection of ornamental shrubs and trees and Roses in pots, with boxes of Rose blooms. Messrs. Osborn & Sons, Fulham, had a pretty group of hardy plants; Mr. Wiggins a group of Pelargoniums; Mr. Kinghorn, Richmond, a group of miscellaneous plants tastefully arranged; and Mr. F. Pestrige, Brentford, had a collection of eighteen varieties of Tricolor Pelargoniums. All these were highly commended, as were also some particularly handsome Cherries from Messrs. Rivers & Son of Sawbridgeworth, and samples of a spray-distributor from Mr. Wells of Red Hill.

VINES AT LONGLEAT—MANURE.

EVERYONE interested in Grape-growing is deeply indebted to Mr. Taylor for his full and clear account of the system which has produced such splendid results at Longleat. In the cardinal question of manuring, however, which was treated of on page 485, there is an uncertainty which perhaps Mr. Taylor could in some degree clear up. Earth which has been used is necessarily of variable composition; but Dr. Voelcker, in the eighth volume of the second series of the Journal of the Royal Agricultural Society, states that in some specimens which he examined there was found to be about 0.07 per cent. of nitrogen added (equal to about 0.09 of ammonia), each time the same earth was used. In other experiments by Dr. Gilbert the addition of nitrogen was found to be more than double this amount. It obviously depends greatly on the quantity of earth used and the number of individuals using the dry earth; but in some places the earth after use is

dried and used twice, or three, four, or five times over, each time, of course, receiving an increment of strength. If used only once, and Dr. Voelcker's estimate is taken, the quantity employed by Mr. Taylor—half a bushel, or say 50 lbs. to the square yard—would be equivalent to a dressing at the rate of 12 tons of best rotten farmyard manure per acre, while at Dr. Gilbert's estimate it would be equal to as much as 20 tons dung per acre. If passed more than once through the closet the strength would be proportionately increased. Might I, therefore, ask Mr. Taylor kindly to say, as nearly as circumstances permit him, whether the earth he uses has been employed only once or more than once? and about what number of persons have on an average of the year used the earth, and what quantity has been so used?—J. B. K.

[In answer to "J. B. K.," I have to say that the earth is only used once. The closets, of which there are four, are fitted with a handle, which is pulled in the same way as when water is used. They are only in use about six months out of twelve, and then the number using them is on the average about fourteen. Only a small quantity of earth is used, but that is in the best possible condition; for falling naturally dried earth at any time there is always a heap of burned clay (of which I prepare a great quantity every winter) to fall back on. I was asked, when the buildings were erected, whether I thought it worth my while keeping them supplied with earth. My answer was that I should be very pleased to do the same for a whole town. There is no manure either natural or artificial so valuable as this, and yet in the majority of cases it is not only wasted, but is so managed as to bring on disease and premature death. It cannot be too often impressed on our readers that dry earth is a perfect deodoriser, and that water is not. I cannot obtain sufficient of this manure, and up to the present time half of the Muscat house has had none this season.—WM. TAYLOR.]

SPIGELIA MARYLANDICA.

THIS plant, which is commonly known as Worm Grass, from its medicinal qualities, is seldom alluded to in the press; yet it is worth growing. It is a showy little perennial with slender four-angled stems 9 to 15 inches high, varying considerably according to position as regards moisture. Leaves opposite, sessile, ovate-acuminate, acute, entire. Flowers four to eight at the top of the stems, with tubular corollas 1 to 1½ inch long; tubes rich crimson; limb with five ovate acute divisions, the upper surface yellow, which affords a striking contrast to the high-coloured tube. It is an extremely pretty plant for the border or rockery, enjoying a shady damp position in peat, loam, and sand, although a moist position is the chief thing to be considered in its successful cultivation, as I have grown it in soil entirely free from peat but damp, and it grew admirably; the position was withal most exposed, with the sun pouring upon it nearly all the day. Among others the Rev. Ewbank of Ryde expressed astonishment at the healthy condition of the plant in question. I mention this so that those who do not possess a shady place need not be without such a charming plant. It is a native of the United States, where it is very abundant, and from whence it was introduced as early as 1694, and a figure of it appears in the "Botanical Magazine," pl. 80. Its proper place is undoubtedly in association with other American damp-loving plants, such as Trilliums, Lilies, Gentians, &c. It is readily increased by division of the root, which is best accomplished early in spring just as growth commences.—N.

WEST OF ENGLAND ROSE SHOW.

HEREFORD.

THE sixteenth annual Exhibition of Roses in connection with the above Society was held on Thursday the 29th ult. in the Shire Hall, when, favoured with glorious weather, a numerous company of the Rose-loving and sight-seeing public were attracted to our ancient city. It need not be stated that, as an exhibition of Roses, the one just held did not come up to the average of former years. Nobody expected it would. At Bath last Wednesday both in quality and quantity the National Rose Society's Provincial Exhibition fell far short. But how could the issue be otherwise? The long-continued cold and sunless weather has for some weeks dangerously retarded vegetation, with its inevitable results of no blooms at all, or accompanied with the damaging faults of coarseness or want of symmetry. Strange to say, colour this year is all that can be desired (pink Roses of the old type of John Hopper and Clemence Joigneaux are quite red). This curious fact is worthy of comment, as light and sun are the main factors in the production of colour. The fixture for the day following Bath surely was most unwise, as it kept off several of the chief nurserymen, who always made a point of exhibiting at Hereford when they could. Nevertheless, in spite of all these drawbacks, and although a sad gap was left in the Hall by the absence of the Heavitree and Old Weir

exhibits (and will be in every exhibition throughout the season), a most enjoyable and excellent meeting was held, at which several new competitors meritoriously came to the front.

The following are the lists most likely to interest the general public:—Messrs. Cranston & Co. swept the board in the nurserymen's open division with seventy-two and thirty-six trebles, and twenty-four varieties. Their collection of seventy-two consisted of the following varieties—H.P.'s, Hippolyte Jamain, Jeanne Sury, grand in colour. Caroline Kuster, Pierre Notting, Marquise de Mortemart, Le Havre, fine; Etienne Levet, Marguerite Brassac, Duchesse de Morny, Madame C. Wood, Lælia, Exposition de Brie, Prince Arthur (Cant's), most useful; Marie Finger, Mrs. Baker, exquisite; Alba Rosea, Jean Liabaud, Victor Verdier, Sir Garnet Wolseley, Marie Cointet, J. S. Mill, Alice Durcau, Madame Victor Verdier, Caroline de Sansal, La France, everywhere gorgeous; A. K. Williams, the finest Rose in the Hall; Capitaine Christy, Charles Lefebvre, Baronne de Rothschild, Marguerite Manoin, L'Esperance, Louis Van Houtte, Monsieur Noman, Général Jacqueminot, Madame Nachury, Sénateur Vaisse, Madame Gabriel Luizet, Dingée Conard, Eugène Verdier, E. Y. Teas, Edouard Morren, Maurice Bernardin, Edouard Morren, Souvenir de la Malmaison. Messrs. Curtis & Co. took second prize with smaller, but fresh, smooth, and very well-coloured blooms. Especially noticeable were Pride of Waltham (a new and decided acquisition), Penelope Mayo, Camille Bernardin, and Paul Neyron, a Rose by no means to be despised when bright and symmetrical. This firm also took second prize for twenty-four varieties, and an extra prize, £5, for seventy-two varieties open to nurserymen not living in Herefordshire, this class not filling to entitle them to first prize. Messrs. Dawson & Whiting took third prize in seventy-two varieties, second prize in thirty-six trebles, and third prize in twenty-four varieties. In class, eighteen varieties, three trusses, there was no competition. In twenty-four single varieties the second prize was taken by Mr. Wm. Grove, Hereford, the only competitor.

In Class B, amateurs, open to the United Kingdom, thirty-six varieties, single trusses, first prize £5 (with National Rose Society's medal) was taken by Mr. W. J. Grant, Ledbury; second prize by Miss Bulmer, Broadlands, Hereford; third prize (not taken). Mr. Grant's collection, contained blooms small but fresh and good, with a fine sprinkling of Teas. Twenty-four varieties, single trusses.—First, Rev. C. H. Bulmer, Credenhill Rectory, Hereford; second, Miss Bulmer; third prize, Mr. Berrington. The special prize given by Cranston's Nursery and Seed Company, Limited, for a collection of twenty-four English-raised Roses not in commerce previous to 1878, had no entries. We may be allowed to say the wonder would be if it had. By the National Rose Society's useful catalogue of Exhibition Roses anyone can easily reckon that about thirteen varieties only could have been staged, and if the special had not been handicapped by any limit of time at all, even then only some twenty-seven varieties of exhibition Roses could have been staged.

In the amateur close division the competition was very keen, the more so doubtless from Miss Bulmer elevating herself this year to that position in the open amateur division, which the prize list shows she is so well capable of adorning. The blooms throughout this division, except those of Mr. C. Williams, Lower Eaton, were generally small or coarse, and evidently appealed for more persevering and intelligent treatment. Messrs. Cranston & Co. carried off first prize for twenty-four blooms of any one Rose, with faultless blooms (each) of La France, and Messrs. Dawson & Co. second prize with same varieties.

In Class D for new Roses Messrs. Curtis & Sandford took first prize with the following varieties as most noticeable—H.P. Mrs. Jowitt, very good; H.P. Pride of Waltham, also excellent; and H.P. Ferdinand Chaffotte, useful; and H.P. Madame Ducher, very promising. Messrs. Curtis & Sandford also carried off the prize for twelve blooms of any new Rose with H.P. Alfred Dumesnil, a new Rose of a most useful colour, fine form, and shown remarkably well. A fine collection from Mr. G. P. Hawtrey, Aldin House, Slough, arrived too late for competition. They were awarded on their extraordinary merits and misfortune a special prize.

The decorative department was unusually large, and carried out in the best possible taste and skill. Lord Bute's first prize was taken by Miss M. Berrows, and thoroughly deserved its premier position, especially as it was a first attempt in public. Miss Cypher of Cheltenham took the chief prizes in bouquets, for which she is so justly celebrated. Mr. J. H. Arkwright and Mrs. Arkwright of Hampton Court, Leominster, and Mrs. Harry Arkwright acted as Judges in this division. Rev. A. J. Williams, Alderminster Rectory, Stratford-on-Avon; Mr. Hall, Birkenhead; and Rev. C. H. Bulmer, Credenhill Rectory, Hereford, in the nurserymen's division; and Messrs. Cranston and Sandford in the amateurs' division.—HEREFORDSHIRE INCUMBENT.

LÆLIA HARPOPHYLLA.

THIS has now been in cultivation for about ten years, but until quite recently it was very expensive, and could only be ranked amongst the curios and rarities of Orchid collections; now, however, Mr. B. S. Williams of Upper Holloway has succeeded in obtaining a good stock, and in consequence plants are being offered at much more moderate prices that will place a really useful Orchid within the reach of scores who would have been

quite unable to obtain it at the previous high prices. It is one of the small-flowered species, but quite unlike any of the better known forms, such as *L. autumnalis*, *L. anceps*, and others. The flowers are star-shaped, with narrow spreading sepals and petals of a rich orange vermilion hue, a colour very rare amongst

Fig. 2.—*Lælia harpophylla*.

Orchids, and correspondingly striking. The neat little flowers if cut singly and wired would be admirably suited for bouquets or arranging with other flowers in vases for the table, and for choice and distinct buttonholes they would also be well adapted.

MUSHROOMS.—The idea of using virgin spawn for crops is new and interesting to me. There is force in the idea. I may mention that the heaviest crops and largest and finest Mushrooms I ever had were from beds in which the spawn was spontaneously developed—that is, without artificial spawn, the material of the bed consisting of stable

litter that had been laid in a pit for Melon culture for some time before, the spawn running in the soil bed after it was made up. I have many times gathered more than a pound weight to the foot from our beds, and received a higher price for all sold (many bushels) than that named in the Journal.—GROWER.

THE visit to this country of the BELGIAN HORTICULTURISTS may be said to have terminated last Saturday. After visiting Cliveden and Dropmore (on Wednesday the 28th ult.), with which and the surrounding scenery they were much impressed, and equally so with Frogmore, where a right royal repast was provided by command of Her Majesty, they inspected the excellently conducted nursery of Mr. Turner at Slough, and were hospitably entertained by the esteemed proprietor. On Thursday some of the market gardens in the Thames valley were inspected, and a visit was paid to the Richmond Show, which almost surprised them by its excellence, both as regards culture and variety of products, as a local exhibition. In the evening our friends attended the anniversary dinner of the Gardeners' Royal Benevolent Institution, at which the Lord Mayor presided, the company numbering 175 guests.

— ON Friday they visited Mr. WILLIAMS' ESTABLISHMENT AT HOLLOWAY. Passing through some forty houses and admiring the display of Orchids—Vandas, Cattleyas, and Odontoglossums being especially fine, also the great and healthy stocks of plants, such as Dipladenias, Allamandas, Ixoras, Crotons, Nepenthes, &c, occupied nearly three hours. One of the large cool houses was prepared for the luncheon, which by its excellence was in keeping with the nursery, and a most agreeable hour was spent amidst loyal toasts and complimentary greetings.

— A DRIVE of a few miles through a beautiful district was next enjoyed, and Mr. CUTBUSH'S NURSERIES at Barnet visited; one celebrated for the extensive collection of specimen variegated Hollies, the other for the propagation and culture of hardwooded plants—Heaths, Epacrises, Dracophyllums, Acacias, Hedaromas, Eriostemons, Pimeleas, &c., the stocks of which elicited expressions of approval. A return was then made to Highgate, and the nursery there passed through, and its great collection of Ivies, Sweet Bays, and choice evergreens inspected. A treat of a different character brought the day to a close.

— ADJOINING the above nursery is HOLLY LODGE, the residence of Baroness Burdett Coutts. This estimable lady not only readily afforded facilities for an inspection of the gardens and grounds, but provided elegant refreshments in the garden saloon and museum. Situated at the immediate verge of London, the pleasure grounds are almost startling by their rural beauty. The grounds, boldly undulated and richly wooded, walks enclosed in foliage, smooth lawns, and bright flower borders and beds, with the structures devoted to fruit and plant culture, afforded an opportunity of seeing gardening in its various aspects most ably conducted by Mr. Willard. The time, too short, was spent most enjoyably here. In the secluded grounds there is no suspicion of being near the busy haunts of men, yet pass through the thick belt of trees that fringe the hill and the largest city of the world is spread at our feet. Thus a busy day was brought to an agreeable termination, and all went home satisfied.

— ON Saturday the programme included CHISWICK, KEW, and SION HOUSE, with luncheon provided by Dr. Masters at the "Star and Garter," Richmond. Even a summary description of these establishments will not be attempted, and it must suffice to say that Chiswick is the embodiment of practical and experimental

horticulture; Kew unequalled for its rich stores of vegetable products; and Sion House is a fine type of a nobleman's residence and of general gardening as conducted by one of the most skilled practitioners, Mr. Woodbridge. The weather during the week has been fine, and all the arrangements have been carried out in a satisfactory manner.

— ALTHOUGH the majority of the visitors RETURNED TO BELGIUM on the close of the programme, yet a few remained and visited Mr. Rivers' great fruit-growing establishment at Sawbridge-worth on Monday, the National Rose Show on Tuesday, also Messrs. Veitch's nursery at Coombe Wood—one of the most picturesque, well-furnished, and admirably conducted establishments of its kind in the kingdom. Mr. Waterer's nursery, we believe, has also been visited by some individuals of the party. The visit of the guests has been a most welcome one to the representatives of horticulture in this country, remembering, as do the latter, the splendid receptions that have so many times been accorded them on their sojourns in Belgium.

— THE anniversary dinner of the GARDENERS' ROYAL BENEVOLENT INSTITUTION was held at the Albion Hotel, Aldersgate Street, on Thursday the 29th ult., when the chair was occupied by the Lord Mayor, supported on the right by Comte de Kerchove de Denterghem, Governor of the Province of Hainaut in Belgium, and on the left by Dr. Hogg. There was a very large attendance, which included the whole of our Belgian visitors, the Sheriffs of London and Middlesex, Dr. M. T. Masters, Mr. G. F. Wilson, a large number of amateurs, most of the leading nurserymen and seedsmen—in all a goodly company of 175 persons. The Lord Mayor strongly urged the importance of the Institution and necessity of having its claims pressed home upon the attention, not of gardeners only, but on that of the employers of gardeners. It was humiliating to think that out of the large number of people who are interested in gardening, and to whom its delights minister so largely, so few should be supporters of this admirable Institution. The subscriptions announced by the Secretary amounted to £600.

— A CORRESPONDENT writes:—"There are various methods of SUPPORTING MELONS WHEN GROWING ON A TRELLIS, including baskets, boards, and nets; but the most simple supports we have seen are employed by Mr. Wm. Taylor at Longleat. These consist of a piece of string tied in a circle, leaving one end out about a foot long. Two other pieces are fastened to the circle, so as to make three equal supports, and all is ready for fixing. This is done by slipping the circle on to the bottom of the fruit, and fastening the three supporting pieces to the trellis. After taking notice of some of the elaborate supports supposed to be necessary by some, the Longleat supports appear almost ridiculously simple, yet if the ties are properly fastened a casualty is out of the question, no matter how heavy the fruit may be."

— WE are informed that Her Royal Highness the Duchess of Teck visited MR. W. BULL'S EXHIBITION OF ORCHIDS last week, and expressed her appreciation of the many choice examples in the rich and varied display.

— ONE of the best of all Honeysuckles is LONICERA GRATA, and is particularly good in sbrubberies, as it does not climb, being itself of shrubby habit. For the purpose of garden decoration it should be extensively planted. The flowers are very showy, being red on the outside and yellow within. Flowers are always to be found except during winter. It is a sub-evergreen of vigorous growth. In appearance it resembles somewhat the common Honeysuckle. A native of North America.

— A CORRESPONDENT states that "the GIANT HERACLEUM is quite a striking feature in the Cambridge Botanic Garden. It reaches a height of 11 feet, and has leaves 6 feet long by 5 broad.

There is scarcely a finer hardy plant of tropical aspect, and now its immense umbels of white flowers make it extremely handsome. Before the seeds ripen the heads are cut off, as otherwise it would be a weed all over the garden, but in this way it is easily kept under control. The greatest luxuriance is attained where there is shade and moisture. It is commonly known as *Heracleum giganteum*."

— MR. W. IGGULDEN, writing from Marston House Gardens, Frome, observes:—"There is a remarkably fertile specimen of *ABIES (PICEA) NOBILIS* growing here. Several of the branches are carrying six or more handsome cones, but on one branch there is a cluster of ten large cones, and there are two more only slightly separated. They quite weigh down the branch, and I am afraid I shall have to remove them or lose the branch, which it is almost needless to say would much disfigure the tree. The fertile branch is about 30 feet from the ground."

— MR. PETER BARR writes us as follows:—"The partnership subsisting between myself (the managing partner) and Miss Fanny Pryor, under the style of Barr & Sugden, having ceased, I have commenced business under the style of BARR & SON at 34, King Street, Covent Garden, W.C." One of the most extensive and varied collections of hardy flowers we have ever seen was staged by this firm on the occasion of the Rose Show at South Kensington. The group occupied a length of tabling of upwards of 100 feet, and consisted of fine masses of Liliiums, Irises, Paris Daisies, *Chrysanthemum segetum*, *Rhodanthes*, *Hydrangea paniculata grandiflora*, with a choice assortment of Delphiniums, Iberises, Ixias, Orchises, Calochorti, Gladioli, Funkias, Cloves, Pinks, a new white variety Peter Barr raised by Mr. Howard being particularly attractive, and many other flowers too numerous to mention. The collection afforded an agreeable change from the Roses in the corridor, and was much admired by visitors to the Show.

—"W. J. M., *Clonmel*," writes:—"In your leading notes last issue you deservedly noticed some good things of recent introduction. Would you permit me to add *MALVA MOSCHATA ALBA MAJOR*, a new pure white Mallow, to those you name? The Journal, while in no hurry to write down bedding and half-hardy plants, has never closed its space against the merits of herbaceous and hardy ones. I welcome this introduction of last year on this latter ground, and desire to give Mr. Cannell, Swanley Nurseries, the credit he deserves for adding it to our border flowers. If I remember rightly it was certificated by the Royal Horticultural Society in the autumn of 1881. It is, therefore, not as plentiful as it will be by-and-by. I have grown my plants in a cold frame. This attention they seem to like, but when more plentiful I shall give them a separate bed, and would recommend your readers to do so too."

— RELATIVE to encouraging "ALL THE YEAR ROUND" GARDENING AMONGST COTTAGERS, Mr. W. H. Wharton, the Honorary Secretary of the Haslington Horticultural Society, writes:—"In several Shows I am acquainted with, I notice that many competitors for the flower garden prizes embellish their flower beds a few days only before the Judges inspect them, allowing just sufficient time to establish the plants. This practice is generally found to place at a great disadvantage other competitors whose gardens have been laid out and planted for a much longer period. The method we are now adopting will, we think, have a tendency to counteract this. The gardens are to be inspected during April, May, June, and July, and the period will probably be extended in next year's competition. I do not know whether this plan is adopted in other districts, but if you approve of the principle, and deem it worthy of consideration, perhaps you will kindly commend it to others." We

approve of the plan and commend it, but when the competition is great and the district extensive we have found difficulties not infrequently arrive on the question of judging.

NATIONAL ROSE SOCIETY.

BATH, JUNE 28TH.

THIS year's provincial Exhibition of the National Rose Society was held under extremely favourable conditions in the Sydney Gardens, Bath. Nothing was wanting to insure success, as the citizens of Bath fully appreciate the queen of flowers, and the efforts of those who are the means of bringing together such quantities of Roses, this being very evident from the support in the shape of subscriptions given, extra prizes offered, and the large and brilliant assemblage that congregated to inspect the Exhibition. As we have before mentioned, the Sydney Gardens are most convenient and admirably adapted for an exhibition. The weather generally of late has been most unfavourable for either exhibitions or the production of first-class Roses, and, indeed, of Roses of any description, owing to the prevalence and destructiveness of unusual numbers of insect pests. Hence the frequent remarks to be heard expressive of surprise at seeing so many excellent blooms staged. It is true, however, in nearly every case more or less the Roses staged gave signs of injury from excessive rains, this being more apparent in those of light shades. Many of these were faulty, and if staged as some exhibitions of the same magnitude would have spoilt the chances of the stands for the premier positions. A few of the well-known older varieties were conspicuously good throughout the display, and none more so than the *Marquise de Castellane*; while *Marie Baumann*, *Comtesse d'Oxford*, *A. K. Williams*, *Mons. E. Y. Teas*, *La France*, *Charles Lefebvre*, *Etienne Levet*, *Madame Gabriel Luizet*, *Horace Vernet*, *Alfred Colomb*, and the *Duchess of Edinburgh* were largely and well shown. Most of the leading professional rosarians were represented, including Messrs. Paul & Son, Cheshunt; C. Turner & Sons, Slough; Cranston and Co., Hereford; G. Prince, Oxford; Curtis, Sandford & Co.; R. Veitch & Co., Exeter; Cooling & Son, Bath, and others. While amateurs were well represented by Mr. Joseph Davis, Wilton, Salisbury; Mr. T. B. Hall, Rock Ferry, Cheshire; Mr. J. Scott, Warminster; Mr. G. P. Hawtrey, Slough; Rev. J. H. Pemberton, Havering-atte-Bower, Romford; Miss J. Watson Taylor; Mr. A. Evans, Marston, Oxford; the Rev. Alan Cheales, Brockham Vicarage, Surrey; Mr. C. Davies, Aynhoe, Banbury, and a few others.

Nurserymen's Classes.—Great interest was centred in the class for seventy-two single trusses, in which the premier prize was a silver cup value £10, presented by the Mayor of Bath, with £5 added by the National Rose Society. This was easily secured by Messrs. Paul and Son, Cheshunt, their most formidable opponents' Roses being scarcely up to their usual excellence. The Cheshunt Roses, though on the whole remarkably fine, still comprised several weak specimens, a difficulty evidently being experienced in staging so great a number of blooms, and this was still more apparent in the three other collections staged. The best in the premier stands were the blooms of *François Michelin*, *Etienne Levet*, *Madame Gabriel Luizet*, *Paul Neyron*, *Mrs. C. Wood*, *Charles Lefebvre*, *Guillaume Guillemot*, *Magna Charta*, *Catherine Mermet (Tea)*, *Comtesse de Choiseul*, *Marquise de Gibot*, *Marie Baumann*, *Marie Finger*, *A. K. Williams*, *Beauty of Waltham*, *Duchesse de Vallombrosa*, *Constantin Tretiakoff*, *Mons. E. Y. Teas*, *Comtesse de Nadaillac*, *Duke of Edinburgh*, *Ulrich Brummer*, *John Hopper*, *Ferdinand de Lesseps*, *La France*, *Xavier Olibo*, *Centifolia Rosea*, *Comtesse d'Oxford*, *Miss Poole*, *Alfred Colomb*, and *Prince Arthur*. The second prize was awarded to Messrs. Cranston & Co. The Hereford Roses were of good size and substance, but bore unmistakable signs of adverse influences. The best were the blooms of *Mdlle. Marguerite Mandin*, *Constantin Fretiakoff*, *Sir G. Wolseley*, *Marquise de Castellane*, *La France*, *A. K. Williams*, *Mons. E. Y. Teas*, *Comtesse d'Oxford*, *Beauty of Waltham*, and *Alfred Colomb*. Messrs. Curtis, Sandford & Co. followed with much fresher but smaller blooms. Messrs. Parker & Son of Bristol were awarded the fourth prize, but most of their blooms were too far advanced.

Messrs. Paul & Son were placed first in the next class, that for forty-eight distinct varieties, three blooms of each. Nearly the whole of the varieties mentioned as having formed part of their premier collection were again well represented. Messrs. Curtis, Sandford and Co. occupied second position with a collection inferior in size only, but at the time these notes were taken superior in freshness and colour, and less advanced than the Cheshunt Roses. The third prize was awarded to Messrs. Cranston & Co. for a creditable collection. With triplets of twenty-four distinct varieties Messrs. Paul & Son were again successful. Messrs. C. Turner & Sons secured the second prize in this class with generally good specimens. Messrs. Curtis, Sandford & Co. worthily occupied the third position.

There were only two exhibitors of eighteen Teas and Noisettes, distinct, and in single trusses. Mr. G. Prince easily secured the first prize with a good collection, in which the best represented were *Souvenir de Paul Neyron*, *Souvenir d'un Ami*, *Catherine Mermet*, *Francisca Kruger*, *Madame Lambard*, *Alba Rosea*, *Rubens*, *Amazon*, *Madame H. Jamain*, and *Moiré*. In Messrs. Paul & Son's second-prize stand were good examples of *Rubens*, *Comtesse de Nadaillac*, *Devoniensis*, *Souvenir d'un Ami*, and *Jean Ducher*. Exhibitors in the foregoing classes were excluded from the three following.

The best thirty-six distinct single trusses were staged by Mr. J. Walters, Mount Radford Nurseries, Exeter; this collection was generally fresh and good. Messrs. R. Veitch & Sons, Exeter, followed with a collection that comprised several damaged blooms. The third prize went to Mr. J. Jefferies, Cirencester, whose stands also included several blooms damaged by rain. Mr. J. Walters was also first with eighteen distinct varieties, three trusses of each. Messrs. Jefferies and Sons occupied the second position, being closely followed by Messrs. G. Cooling & Sons. Mr. J. Matlock, New Headington, Oxford, had the best stand of twelve distinct Teas or Noisettes, the most noteworthy being Rubens, Catherine Mermet, Maréchal Niel, Madame Bravy, Devoniensis, Marie Guillot, Marie Van Houtte, and Souvenir d'un Ami. In the second-prize stand of Mr. J. Walters, Narcisse, Perle des Jardins, and Madame Berard were good. Messrs. R. Veitch and Sons staged a fresh and good collection, and were awarded the third prize.

Amateurs' Classes.—A silver cup value ten guineas, with £5 added by the National Rose Society, was offered for the best thirty-six distinct single trusses, and for this there were but two competitors. Mr. J. Davies easily secured the valuable prize with a very creditable collection, in which were comprised excellent examples of Sultan of Zanzibar, Louis Van Houtte, Auguste Rigotard, Madame Gabriel Luizet, Duke of Edinburgh, Alfred Colomb, Mdle. Marie Rady, Marie Baumann, Mdle. D'Ombraïn, A. K. Williams, Mons. E. Y. Teas, and Miss Hassard. The second prize was adjudged to T. B. Hall, Esq. Mr. J. Davis also secured first position with twelve triplets, distinct, being closely followed in this instance by Mr. G. P. Hawtrey. The former had Beauty of Waltham, Madame Lacharme, Madame Montet, Marquise de Castellane, Marie Rady, and La France in good condition; while the latter staged good blooms, among others, of Mons. E. Y. Teas, Duke of Edinburgh, Clemence Joigneaux, Souvenir de la Malmaison, Thomas Mills, and Devoniensis. Mr. T. B. Hall staged the best twelve distinct Teas or Noisettes, his Madame Berard, Comtesse Riza du Parc, Comte de Paris, Souvenir d'un Ami, and Anna Ollivier being noteworthy. Mr. Hawtrey followed closely.

The exhibitors in the three foregoing classes were debarred from competition in the three following. For twenty-four distinct single trusses the first prize, a silver cup value five guineas, was presented by Mr. S. P. Rudd, and this attracted several very good collections, of which the best was staged by Mr. A. Evans. Mr. J. Scott followed with a creditable stand. Mr. T. Hobbs, Lower Easton, Bristol, was awarded the third prize, the fourth going to Miss J. Watson Taylor, both staging well. With eighteen distinct single trusses Mr. J. Scott occupied the first position, staging among others good examples of François Michelin, Cheshunt Hybrid, Triomphe de Rennes, Dr. Andre, and Marquise de Castellane. Mr. A. Evans and Miss Taylor were awarded the remaining prizes in the order named. Mr. C. Davies staged the best nine Tea or Noisette, single trusses, these consisting of Anna Ollivier, Marie Van Houtte, Triomphe de Rennes, Madame C. Kuster, Alba Rosea, Bouquet d'Or, and Catherine Mermet. The bloom of the latter was remarkably fine, and, in addition to materially influencing the Judges in favour of the stand, secured the exhibitor the Society's silver medal for the best Tea in the Show. Miss Watson Taylor followed closely, and Mr. A. Evans was a good third.

The next class in the schedule, not open to any exhibiting in the foregoing classes, was for twelve distinct, single trusses, and this attracted seven stands. The first prize was easily secured by the Rev. J. H. Pemberton. Mr. Julius Sladdon, Badsey, Evesham, and the Rev. C. Gardiner were worthily awarded the remaining prizes in the order named. In the class for six distinct trusses all exhibiting in the foregoing classes were excluded. Here the first prize was awarded to the Rev. Alan Cheales, his stand including beautiful blooms. Mr. W. Duck, Bath, followed; and to Mr. J. Stuckey, Bath, was awarded the third prize. The Rev. J. H. Pemberton had the best six distinct Tea or Noisettes, and was followed by Mr. G. Mount and Mr. E. Claxton, Allerton, Liverpool, in the order named.

Extra Class.—Messrs. Paul & Son, Cheshunt, presented as first prize for twenty-four Teas or Noisettes in bunches and distinct a piece of plate value five guineas, and this was secured by Miss J. Watson Taylor, a second prize being awarded to Mrs. Cater, both staging rather small but fresh blooms generally. The best six new Roses, distinct, and which were not in commerce previous to 1879, were staged by Mr. G. P. Hawtrey. Of these the most noteworthy were Mons. Alfred Dumesnil and Brightness of Cheshunt. The other varieties were Beauty of Stapleford, Charles Darwin, Harrison Weir, and Catherine Soupert. Mr. T. B. Hall was awarded the second prize, Paul Jamain being the best in this stand.

Open Classes.—In the class for twelve Teas or Noisettes Mr. W. Duck, Bath, presented for the first prize a piece of plate value five guineas, and this was well won by Mr. G. Prince, Messrs. Paul and Son taking the second, and Mr. J. Matlock the third prize, the exhibits being most creditable in each instance. The best twelve new Roses not in commerce previous to 1879 were staged by Messrs. Paul & Son, and consisted of fairly good examples of Madame Pevière, Guillaume Guillemot, Pride of Waltham, Ulrich Brummer, Edward André, Madame Montet, Rosieriste Jacobs, Comtesse de Ludrie, Francis Levet, Comtesse de Camando, and Ferdinande Chafolte. Messrs. Curtis, Sandford & Co. were awarded the second prize, who, in addition to several of the varieties in the premier stand, had good examples of Madame Ducher and Margaret Manoin. Messrs. Cranston & Co. followed with very similar varieties, Mary Pochin in

addition being most noteworthy. There were several excellent stands in the class for twelve trusses any dark Hybrid Perpetual, and remarkably fine were the first-prize examples of A. K. Williams staged by G. Paul & Son. Mr. C. Turner followed with brilliant examples of Marie Baumann; Curtis, Sandford & Co. taking the third prize with the same variety in excellent condition.

Stands of twelve light Hybrid Perpetual, any one kind, were not extensively shown, but the quality of the winning examples was high. It is very rare that La France is seen in such condition as those which secured the first prize for Messrs. Cranston & Co., and out of this remarkable stand was selected the premier Hybrid Perpetual in the Show, this being awarded the Society's silver medal. Mr. A. Evans also had La France in grand condition, and was awarded the second prize, Mr. G. Prince following with good examples of Baronne de Rothschild. The latter was the only exhibitor of twelve single trusses of any Tea or Noisette, and was worthily awarded the first prize for Catherine Mermet in good condition. The same exhibitor also staged very good blooms of Alba Rosea. Mr. Prince was first for twelve single trusses of any yellow Rose with Perle des Jardins, Messrs. Cranston & Co. and Mr. J. Walters being placed equal thirds, the former staging moderate examples of Maréchal Niel and the latter of Marie Van Houtte. No award was made in the class for any seedling Rose not yet in commerce or announced.

A handsome silver cup, value £10, called the "Bath City Cup," presented by Mr. S. Pavitt and others of Bath, was offered for a group of Roses arranged for effect in a space of 60 superficial feet. This was well won by Messrs. G. Cooling & Son, who arranged a fine bank in which were pyramids of good blooms of popular sorts, and innumerable vases of Roses and single specimens completed the effect. It must be admitted this firm had the best position, and it is equally certain their exhibit deserved it. The second prize went to Mr. G. Hawtrey for a Rose Temple in which was suspended a charming basket of Teas. The materials, however, were too meagre for a good effect, neither was the position suitable. Mr. J. Matlock followed with a very poor arrangement.

District-grown Roses.—Among these were numbered many excellent exhibits, which, if scarcely so fine as those from a distance, were unsurpassed for freshness and brilliancy of colour. Particularly good were the twenty-four distinct single trusses which gained Messrs. G. Cooling & Son the Bath Licensed Victuallers' cup, value five guineas. The second-prize stand was staged by Mr. S. J. Pavitt, nurseryman, Bathwick; and Mr. Henry Hooper was a good third. Messrs. G. Cooling & Son presented a silver cup for twelve distinct single trusses, open to amateurs, and this was well won by Mr. C. Catley, Mr. F. Clark and Mr. S. P. Budd taking the remaining prizes in the order named. Mr. S. Butler had the best six distinct single trusses, Mr. W. Duck being second, and Mrs. Pope third.

The best twelve bouquets of Roses staged by Mr. W. C. Drummond were particularly fresh and good. Messrs. G. Cooling & Son well won the second prize, and to Mr. W. Smith was awarded the third prize. Mr. H. Catley was the only exhibitor in the amateurs' class for six bouquets, and was deservedly awarded the first prize.

Mr. W. C. Drummond and Col. Landor kindly lent the Committee a number of fine-foilage plants and Ferns, and these were judiciously and effectively arranged at the back and between the stands of Roses, and added materially to the general effect. Messrs. Osborn & Sons, Fulham, sent several stands of very fine Roses, and Mr. Hooper arranged a fine lot of Carnations and Pansies. The weather experienced was all that could be desired, and as the attendance was large we may safely congratulate the respective Secretaries of the National Rose Society and the Sydney Gardens Floral Fête Committee, and all interested in those Societies, upon the undoubted success attending their labours.

MANURING POTATOES.

A FEW months ago there was a correspondence in the Journal about which was the best plan in manuring Potatoes, whether to put the manure over the set or under the set. I always had an objection to placing the manure over the set, but could not at that time say that my objection was the result of practical experience; but it so happened that I had tried the experiment in the spring, and was only waiting for digging-up time to be able to say what I thought of the result. I do not find much difference in the crop of Royal Ashleaf whether the manure was over the set or under; but I find that in the former case the manure is in much too close contact with the Potatoes, so that if the people who ate them saw them dug up they would not fancy them. For this reason, if no other, I cannot say I recommend the practice, and prefer the manure spread over the top of the ground and dug in, or else placed below the set.—AMATEUR, Cirencester.

QUEEN WASPS.

Is not the abundance or scarcity of wasps in autumn decided by the weather in July and August? Rain in those months drowns their nests, and our autumn fruits are saved from their depredations, but if those months are fine their numbers will be great in proportion. It must be a good thing to destroy the

queens in spring, but probably when we have done all we can in that respect enough nests will exist in June to admit of their becoming pests if circumstances are favourable. A very simple plan for destroying their nests is to pour coal tar in from an old watering pot, using a piece of turf to prevent the tar running out and being wasted. Many nests may thus be destroyed by one man in one evening at a nominal cost.—AN OLD SUBSCRIBER.

LIKE Mr. John Easter, I have no wish to enter into the wasp controversy, but the difficulty in my mind was how to keep out of it, so much interested have I been in the discussion. I have made at least half a dozen attempts to reply to the points raised, but the fact is the subject requires so much space and time that I have dropped it repeatedly, and a sense of duty only now compels me to give a few facts from my own observations.

I must say that when I read "DUCKWING'S" article on page 260 on the "Popular Fallacy" about wasps I remarked, "Then according to this theory, if our parents had never existed, we too should have been here, and more of us."

To my mind it was evident from "DUCKWING'S" first letter that he knew little about the subject, and every subsequent letter has proved it by the confusion of his reasoning, notwithstanding his reference to not "keeping our eyes open." For one thing, however, "DUCKWING" deserves the thanks of all readers of our Journal; he has been the means of bringing out some interesting letters from Mr. W. Taylor and "Y. B. A. Z."

Now for a few facts. In the spring of 1880 I ventured to call attention to the quantity of queen wasps I had killed, and advised others to do so if they wished to save their fruit crops. It is difficult to calculate the loss in money value of fruit destroyed annually by wasps, but it would in all probability amount to many thousands of pounds, which is a national loss; and every one of us knows of the individual losses, besides the vexatious disappointment, when we find our fruit, labours, and hopes destroyed by these pests. Therefore I hope the reminder before mentioned was not inopportune. I followed the wasps up so vigorously that very few escaped in this neighbourhood. Nearly every queen wasp, I believe, comes to my garden hedge in May for the same distance as the ordinary wasp would in case of the queens being left alone to breed, therefore I conclude that every queen destroyed in spring destroys a nest within a radius of a wasp's foraging flight. My plan of destroying them is to look out for them in the evening about sunset, when they appear to be most eager for their suppers, and consequently are easier of approach. They, apparently by smelling, find out where there is a particle of honeydew on the Hawthorn leaves. I have repeatedly seen them suck it off, and as they rise to fly away they are knocked down with a piece of wood shaped like a small cricket-bat for the purpose. On two occasions this spring I counted the proceeds of an hour's work, and destroyed over twenty each time, which at 2*d.* each would be good wages.

The result of killing the queens in the spring of 1880 before mentioned was that in the fruit season I never was so free from wasps. Two nests only in the district came under my notice, which were traced by the wasps' flight and destroyed, as every nest may be by people "keeping their eyes open" and noticing the direction they fly to their nests when they have had their fill from what they are feeding on.

What was the result of not killing the queens in other places? If my memory is correct one writer in the Journal wrote of the immense quantity in some place, stating he had a "million to spare." I well remember asking a nobleman's head gardener five or six miles away how he fared, and he said he never was plagued with so many wasps, adding, "I know of a score nests within a hundred yards of the lodge gates." I recollect being in a gentleman's gardens a few miles in another direction that year, and the gardens were alive with wasps, and I well remember seeing a Plum tree against a wall the fruit of which was being fast devoured.

To follow the correspondence with remarks would take too much space and time. My belief is, that every queen wasp seen in spring, if not destroyed in some way, will be the mother of a colony. I have killed hundreds and dissected many, examining them with magnifying glasses, and believe every one to be impregnated, and that the difference in size is chiefly in the different species of ordinary wasps. I enclose three specimens which are different in their markings, and which, I believe, are three different kinds, differing in size, and in some respects in their nature.

It is always a treat to me to dig out a wasp's nest intact, to mark their ingenuity in construction, even excelling our bees, in constructing their pillars and passages, and excavating large holes in the earth, carrying in their mouths particles of soil long distances before they are dropped. Last October I was aware of

four nests some distance away which I determined to destroy before the autumnal flight of the queens, and taking a man with me at night, I destroyed them all. One nest I dug out very carefully and put every wasp in a hucket, and counting them at my leisure I found 345 queens out of the combs, besides probably half as many more in partially developed stages, many of which would have come out if left alone. This, I believe, was the weakest nest of the four, and I have no doubt that 1500 queens were destroyed in those four nests. It is people's own fault if they are troubled with wasps if they have the chance to follow them and destroy the nests; too few take the trouble to look them up, and so they are allowed to spread.—J. HIAM.

[The three queens received differ in size and colour, and the characters of each would have been maintained in their progeny if our correspondent and the weather had been favourable for their increase.]

RAMONDIA PYRENAICA.

A VERY close-growing Pyrenean plant, with the leaves arranged in flattish rosettes. Leaves oblong ovate, coarsely bi-serrate, very hairy, with the surface deep green and much puckered. Racemes

Fig. 3.—*Ramondia pyrenaica*.

axillary, one-sided, 3 to 6 inches high, two to five-flowered. Flowers not more than an inch across; corolla rotate, with five lobes, violet purple; anthers yellow; there are also a few yellow spots at the throat of the corolla. This is a very attractive alpine and remarkably distinct, growing freely in pans or on the rockery, preferring a damp partially shaded position in rich light soil. It

should be so arranged that the rosettes are on the same plane as the soil. It commences to flower in May, and continues for two or three months. It is easily propagated by division or raised from seed, which it produces freely, especially in some counties. G. Loder, Esq., of Northampton, informed me that it ripened seed with him very freely. The side shoots taken off in a young state will root in sandy soil in a cold frame. It has been known and cultivated in this country for a very long period. Miller grew it at Chelsea in 1731 and much earlier. Parkinson describes it very minutely, having grown it in his garden, and he regarded it as an *Auricula*, for he calls it the "Blew beares cares with horage leaves" — (*Park. Parad.*, p. 237). Linnæus named it *Verbascum Myconi*, and it was figured under that name in the "Bot. Mag.," pl. 236. —X.

CROYDON HORTICULTURAL SHOW.

JUNE 28TH.

THE fifteenth Show of this Society was held in the grounds of Wellesley House, the residence of J. Spencer Balfour, Esq., M.P., an open and pleasant position for an exhibition of this character. Three marquees were devoted to the exhibits, one of considerable dimensions containing the groups and miscellaneous plants; the second, also very spacious, was devoted to the Roses and fruit, while in the third the cottagers' productions and vegetables were staged.

Groups.—One of the leading classes was that for a group of plants arranged for effect in a space of 100 square feet, the competition being confined to nurserymen. Mr. John H. Ley, Croydon, gained the first prize for a group consisting largely of fine-foliage plants, Dracenas, Aralias, and Palms predominating; amongst the latter was a fine *Stevensonia grandiflora*. Ixoras were the most noteworthy amongst the flowering plants, and the margin consisted of Golden Selaginella. Mr. R. W. Beedell, Wallington, was second with a larger number of flowering plants, and his group was consequently brighter if a little less graceful. The margin of blue and white Lobelias, with Selaginellas and *Isolepis*, was very effective. Mr. C. Chaff, Park Hill Nursery, was a good third, Palms, Ferns, and Pelargoniums being tastefully arranged with other plants. In the district class for gardeners and amateurs only Mr. Penfold, gardener to the Rev. Canon Bridges, Beddington, was adjudged the first prize for an extremely graceful arrangement of *Cordylines*, *Crotons*, *Cocos*, *Casuarinas*, with *Begonias* and other flowering plants, and an edge of *Caladium argyrites* and *Isolepis gracilis*. Mr. King, gardener to Phillip Crowley, Esq., Waddon House, was a very close second, a fine central plant of *Phyllanthus nivosus* being notable, Tuberoses, *Diplacus*, *Begonias*, and miscellaneous flowering and foliage plants being judiciously and tastefully employed; Mr. Fewell, gardener to J. C. Lanyon, Esq., Birdhurst, taking the third position with a group including some good plants, but rather too formal in design.

Fine-foliage Plants.—Some handsome specimens were staged in the classes for these and Ferns. For nine plants in the open class Mr. Penfold won easily with extremely fine examples of *Alocasia macrorrhiza variegata*, *Phyllanthus nivosus*, *Dracæna Lindenii*, *Anthurium crystallinum*, and *Martinezia Lindeniana* amongst others equally praiseworthy. Mr. King followed, his most noteworthy plant being a grandly coloured specimen of *Croton Johannis*, about 5 feet high, in splendid health, and with the colour better developed than we have seen before. Mr. Fewell took the third position, having large examples of *Areca lutescens*, *Stevensonia grandifolia*, and *Cycas revoluta*. In the district gardeners' class Mr. Penfold also won first with a most creditable collection, comprising grand specimens of *Latania borbonica*, *Aralia monstrosa*, *Areca lutescens*, *Carludovica Drudei*, and *Davidsonia pruriens*, the latter plant being extremely distinct and effective when shown in such fine condition. The same exhibitor had the best six exotic Ferns, *Adiantum cardiochloana*, *Woodwardia radicans cristata*, and *Adiantum peruvianum* being remarkably healthy and fresh. In the class for the same number of hardy Ferns Mr. G. W. Cummins, gardener to A. H. Smee, Esq., The Grange, Wallington, gained principal honours with a choice collection of *Athyriums* and *Lastreas*. Mr. Penfold followed with smaller but healthy plants.

Orchids were shown by Messrs. King and Penfold, who were awarded equal first prizes for two good collections of six plants in the open class. Mr. King's plants comprised *Aerides Lobbi* with three spikes, *Dendrobium thyrsoiflorum* with eleven spikes, *Lælia purpurata* and *Lycaste Deppei* both well flowered. Mr. Penfold's most striking plants were *Galeandra Devoniana* with twelve flowers, *Dendrobium Cambridgeanum*, and *Cypripedium Veitchii* in first-rate condition.

Roses.—These were largely represented, and the marquee devoted to them, the miscellaneous cut flowers, table decorations, and fruit was a highly attractive one. In the nurserymen's classes for Roses excellent collections were staged, especially by Messrs. B. R. Cant of Colchester, W. Rumsey of Waltham Cross, and Laing & Co., Forest Hill, who secured the leading prizes in the first two classes for forty-eight and twenty-four varieties. Messrs. Cant, G. W. Piper (Uckfield), and Coppin were the winners with stands of twelve Tea or Noisette Roses, the two first having very fair samples. In the amateurs' classes Mr. J. Ridout, gardener to J. B. Haywood, Esq.,

Woodhatch Lodge, Reigate; H. Slaughter, Esq., Jarvis Villa, Steyning; Mr. J. Bridges, gardener to G. Baker, Esq., Holmfels, Reigate; and the Rev. Alan Cheales, Brockham Vicarage, Reigate, were leading exhibitors, all having blooms of good quality, the Reigate specimens being remarkably good.

Table decorations, fruits, and vegetables were largely shown, and, like the other exhibits, were of admirable quality. The general arrangements were good; but although the weather was fine the attendance of visitors was not so large as might have been expected.

HERBACEOUS PLANTS.

THE *Aquilegias* have been very showy for some time. The great number of varieties of *A. vulgaris* and *A. glandulosa*, some of which are remarkably fine, have now become great favourites. *A. jucunda* is one of the most handsome of the genus, producing unusually large flowers, the calyx of which is bright blue, the corolla being blue and white with short curved spurs. I am afraid space will not permit much to be said regarding the *Delphiniums*, for they are too well known and appreciated, the Larkspurs being special favourites with most people. The same may be said respecting the *Pæonies*. They are found in nearly every cottage garden and well deserve the space allotted them. They have been exceptionally fine this season. *P. officinalis* is one of the most useful, and from this species the varieties with red, crimson, and white flowers have originated. The flowers last several weeks in perfection, and when the plants are not in bloom the foliage is very ornamental.

Violas are fine. There are so many varieties of these now used as hedges that they appear almost indispensable, and for the front of the herbaceous border associated with various other flowers of a dwarf character they are really valuable. There are also two or three species that deserve a word of praise. *V. gracilis*, a very dark blue, is flowering profusely, so also is *V. lutea* and *V. cornuta*. I lately saw a splendid tuft of *V. cornuta alba*. The flowers, as the name implies, are of the purest white and very freely produced. It is a good plant for edging some of the flower beds.

The *Dianthus* are aglow with their pleasing colours and sweetly scented flowers. What herbaceous border would be complete without a few plants of the favourite Pinks *P. plumarius* with its numerous varieties? *D. cæsius* is a very dwarf dense-growing species and well deserves a place; and *D. barbatus* (Sweet William) is so familiar to most people that little need be said regarding it. *Gypsophila acutifolia* is completely covered with its trusses of small pinkish white flowers; so also is *Silene colorata*, and *S. alpestris*, pure white, being dwarf and very free and admirably adapted for the front of the border. Several *Lychnises* are in flower, and amongst the most showy of the genus is *L. Flos-Jovis*, which has large dark pink flowers produced on footstalks a foot or 18 inches high, contrasting favourably with the soft silvery foliage. *Linums* and *Cerastiums* will remain in beauty for some time. *Geraniums* are both numerous and showy. *G. sanguineum* is a very handsome species and one of the best. *G. striatum* is a common species in cultivation, growing about a foot high in compact tufts, and flowers profusely throughout the summer. Other species that are well worth growing are *G. Endressii*, *G. macrorrhizum*, *G. eriostemon*, *G. gymnocaulon*, *G. ibericum*, *G. pratense*, and *G. tuberosum*. *Dictamnus giganteus* and *D. albus* with its numerous varieties having rose, bright red, and white flowers are very handsome and are well worth cultivating.

Some species of *Erigeron* are well worth a little attention. This is rather an extensive genus, nearly a hundred species being known to botanists: they come from temperate and cold regions. Amongst the most showy are *E. philadelphicum* with small pink Aster-like flowers, *E. glabellum* with blue flowers, and *E. speciosum* lilac blue. The *Pentstemons* are well known to most people. Their pleasing colours and showy flowers entitle them to a place in every garden. *P. confertus* and *P. speciosus* are now very showy. A good purple flower that is often met with in gardens is the Spiderwort, *Tradescantia virginica*. This is a very pretty and interesting plant, growing about 1½ foot high. There are several varieties in cultivation—one with white petals, another with rose-coloured petals, and a double-flowered variety. *Potentillas* are now in great variety, and are well suited for the borders or rockery. There are many shades of colour, of which crimson, yellow, and white predominate.

The *Lupins* have been very showy and useful for some time. Amongst the most noteworthy are *Lupinus polyphyllus*. There are several very distinct varieties of this species, which is the commonest and at the same time one of the best species in cultivation. *L. arboreus* is another good species. The foliage is very handsome, being deeply cut or divided. The young flowers are a fine sulphur yellow, changing to light purple with age. *L. nanus* is the dwarf annual Lupine. This may also be planted near the

front of the borders and is very useful for pot culture. It varies considerably in colour, including white, yellow, and various shades of violet and blue.

Spiræas should be extensively grown, for they are grand subjects for the borders; they are not only very showy when growing, but extremely useful for cutting purposes. *S. japonica* should have good prominent positions, and this season they are exceptionally fine. *S. Filipendula* and the var. *flore-pleno* should certainly find a place; it is a tuberous-rooted plant, and grows from 1 to 2 feet high. *S. Aruncus* is another species that should not be overlooked; it produces large spikes of feathery flowers which nod and bend in the breeze. *S. palmata* is one of the most striking and effective in cultivation; the flowers are brilliant crimson. It is a native of Japan, and of recent introduction. *S. digitata* and *S. fulvescens* are both worth growing. The Red Valerian (*Centranthus ruber*) cannot be over-estimated, the long spikes of dark pink flowers make it quite conspicuous. The above are amongst some of the most showy that are in flower at the present time.—C. W.

FARNINGHAM SHOW.

THE pretty village of Farningham, dear to all lovers of the gentle craft, was in a state of unusual bustle and excitement on Thursday last, on the occasion of the annual Exhibition of the Farningham Horticultural and Rose Society, and the collection of plants and cut flowers then brought together were of no ordinary interest; while to the lovers of the Rose especially, the excellent prizes offered and the cups and medals to be contended for made it one of those shows which all desire to bear something of, and it is therefore to those that I must first refer. The Kentish growers were undoubtedly strong, and the amateurs' classes were decidedly better than the nurserymen's; while the competition was very good, seven or eight boxes being staged in each class.

In the nurserymen's class for thirty-six blooms the first prize was awarded to Mr. Cant of Colchester, who had some excellent blooms, although on the whole they were not equal to his usual form. The following were good—Madame Ducher, A. K. Williams, a fine bloom; Comtesse d'Oxford, Dr. Andre, Hippolyte Jamain, La France, Capitaine Christy, R. Wallace, Marquise de Gibot, Devoniensis, a beautiful bloom; Mrs. Laxton, Baronne de Rothschild, and Ducbessc of Valombrosa. Messrs. George Bunyard & Sons of Maidstone were a good second, and Messrs. Kinmont & Kidd of Canterbury third. In the class for twelve Teas Mr. Cant was again first with a very pretty box of Devoniensis, Jean Ducher, Maréchal Niel, Souvenir d'un Ami, Catherine Mermet, Moiré, Madame Bravy, Jules Finger, Souvenir d'Elise, a lovely bloom; Marie Van Houtte, and Rubens. Messrs. Bunyard & Co. were again second. In the amateurs' class for twenty-four Mr. John Hollingworth of Turkey Court, Maidstone, was first with a good box containing amongst others good blooms of Marie Baumann, Mrs. Baker, Hippolyte Jamain, Star of Waltham, Mons. Noman, Marie Finger, Charles Lefebvre, and Duke of Edinburgh. In the class for twelve the Rev. H. B. Biron was first with a very beautiful box containing Marie Baumann, an exquisite bloom, which also obtained the silver-gilt medal of the National Rose Society for the best bloom in the Show; Eugène Fürst, Baronne de Rothschild, Etienne Levet, Madame Gabriel Luizet, La Rosière, John Bright, François Michelin, and Camille Bernardin. The Rev. V. M. Fuller was second with a very nearly equal stand. In the class for nine blooms Mr. George Mount of Harbledon was first with excellent blooms of Duke of Edinburgh, Marquise de Castellane, Baronne de Rothschild, Eugène Fürst, La France, Hippolyte Jamain, Madame Gabriel Luizet, Louis Van Houtte, and Marie Baumann. The Rev. H. B. Biron was second, and Mr. Wakeley third. In the class for six blooms Mr. Mount was first, Mr. John Wakeley second, and Mr. Burnside third. In the class for six varieties of Teas Mr. Mount was first with Homère, Souvenir d'un Ami, Marie Van Houtte, Catherine Mermet, Jean Ducher, a very fine bloom; and Souvenir de Paul Neyron. In Class 9, for six blooms of one variety, Mr. Biron was first with good blooms of Marie Baumann, and Mr. Mount second with Madame Gabriel Luizet. Class 10 was a silver cup value seven guineas, subscribed for by amateurs and to be competed for by them. It was won by Mr. Mount with an excellent box containing Baronne de Rothschild, Charles Lefebvre, A. K. Williams, Capitaine Christy, Duke of Edinburgh, François Michelin, Marie Baumann, Fisher Holmes, Abel Carrière, a most wonderful bloom, Madame Gabriel Luizet, Star of Waltham, and A. Colomb. The five-guinea cup for the best box in the Show, given by the Members for West Kent (the winner of the seven-guinea cup not being allowed to compete), was awarded to Mr. W. Wakeley for La France, François Michelin, Camille Bernardin, Capitaine Christy, Duke of Connaught, Marie Rady, Baroness Rothschild, Duke of Edinburgh, Marie Baumann, Madame Gabriel Luizet, and Alfred Colomb.

The dinner-table stands and decorations were unusually good, the stands by Miss Hasell, Miss Dalton, Miss Burnside, &c., being excellent, and I have seldom seen stands of wild flowers more gracefully or effectively arranged. The table arranged with flowers for dinner as exhibited by Mr. Spottiswoode was light and excellent, Mrs. Seale not being up to her usual form, exhibiting two large baskets at either end and a tall stand in the centre.

Coming now to the general exhibits, which at Farningham are

always good, as several large places are in the neighbourhood, the arrangements for decoration were exceedingly well managed. The plants were carefully chosen, were not overlarge, and bright in colour; there was no overcrowding, and yet the space was well filled up. In the stove and greenhouse plants Mr. Spottiswoode was first with a very excellent lot of six well-grown plants: Anthurium Schertzerianum, Statice profusa, Tabernæmontana coronaria fl.-pl. not enough in flower, Clerodendron fallax, Ixora Williamsi, and Clerodendron Balfourianum. Mr. J. F. Burnaby-Atkins was second with two good plants of Dipladenia Brearleyana and D. Regina, Clerodendron Balfourianum, Statice profusa small, Stephanotis floribunda well flowered, and an Ixora. In six foliage plants Mr. Mildmay was first with a beautiful plant of Anthurium crystallinum, Yucca variegata, Croton Weismanni, Dracæna Baptistii, and others. The Ferns were well shown, and there was the usual assortment of Fuchsias, Begonias, &c., and the cottagers' productions were very creditable. Amongst them, as a bee-master, I could not fail to notice the admirable lot of supers filled with pure comb exhibited by Mr. Skinner, a cottager at Eynsford. They were of first-rate quality, and showed that the exhibitor kept bees intelligently and well.

The whole arrangements of the Show were excellent; the day was fine; Mr. Burnside, the able and active Secretary, carried out the arrangements in perfect order; and I should hope, financially as in other respects, the Show was a success.—D., Deal.

GENTIANAS.

—(Continued from page 537, last volume.)

THE usual method of securing a stock is to raise seed, which is easily procured from Mr. William Thompson of Ipswich or from Frœbel & Co. of Zurich, who have perhaps a greater variety. Large quantities are also yearly collected and find their way to our nurserymen, and in commencing the wisest plan to adopt is to purchase well-established plants. In reference to seed, it is best when it can be obtained to sow it as soon as fully ripe, when it will readily germinate. If kept for any length of time it is slow in germination. As the seeds are very small it is prejudicial to cover them deeply. A little sand sprinkled upon it will be quite sufficient, and attention must be paid to the watering. I have been very successful in raising seeds in pots or pans by placing the seeds on the surface of the soil after giving the latter a good watering, and cover it lightly with sphagnum moss, which retains the moisture about the seed and lessens the necessity of watering, while it affords a shade. It is necessary to watch the seed in germinating and remove the moss before the young plantlets are drawn. If the seed pans are placed in a cold frame in a sunny position, shading when necessary, there is no doubt about the result. Seed may be sown at any time from March to August; the earlier the better, as the young plants will make good growth if proper attention is given in pricking-off and finally planting out or potting them.

Some kinds are, however, readily increased by division of the roots—such as the common *Gentianella* (*G. acaulis*) and others which produce numerous underground stems. This should be done soon after flowering, and when planting it is essential to press the soil very firmly about them, otherwise they will suffer considerably before the summer is past, especially if very dry weather ensues. Close and rather strong soils suit such kinds well. It is difficult to increase a large number by division, as they only produce one central axis, from the crown of which the flowering stems are periodically sent up, and if these are indiscriminately divided the plant sickens and dies. I have seen Gentians in good order at Mr. T. S. Ware's at Tottenham, and in a private collection it would have been difficult to find a better group than that existing at Oakfield, Wimbledon Park, the residence of the late J. G. Joad, Esq., whose enthusiastic love for hardy flowers caused his garden to become a home for all the rarest and best. In Mr. Whitehead's grand collection at Bickley they muster strongly, and I have a lively recollection of a fine clump of the charming little *G. bavarica* in a little bog bed, which would seem to be the proper place for it. The scarce and lovely *Polemonium confertum* from the Rocky Mountains in the same position was also healthy. Continuing the species from last week we note the following for completing a good collection:—

G. cruciata.—A vigorous-growing South European species, 6 to 9 inches high, with lance-shaped shining leaves, and terminal and axillary flower clusters. Flowers very numerous, 1 inch long, sub-campanulate, deep blue, appearing during the midsummer months. It is a very hardy and easily grown plant, thriving in almost any position.

G. decumbens.—A very scarce and elegant species from Asiatic Russia, re-introduced by Dr. Regel. It produces slender erect stems about a foot high, with narrow lanceolate leaves and terminal flower clusters. Flower globose, of a bright azure blue colour and very distinct. This lovely plant was for a long period

lost to cultivation, but can now be easily found. It grows freely in boggy places or in cool damp borders, flowering during June and July.

G. Kurroo.—This very beautiful species is a native of the Western Himalayas, growing at an altitude of from 8000 to 10,000 feet. It was first described by Dr. Royle, by whom many of the Himalayan plants were discovered. It has a woody rootstock crowned with tufts of linear acute leaves conspicuously veined. Flower stalks axillary, 4 inches or more high, supporting solitary flowers about 2 inches long, funnel-shaped, with a brownish white tube and a bright marine-blue limb, finely spotted with white, and white throat. It is a magnificent and free-flowering species, and may be regarded as quite hardy.

G. lutea.—A strong-growing species found in the Alps, Apennines, Pyrenees, and other mountain chains of Europe. Stem 2 to 4 feet high, erect, terminating with a whorled spike of flowers. Leaves large, ovate-oblong. Flowers 1 inch across, with 5 to 6-partite corollas of a bright yellow colour. It is a showy plant, succeeding in ordinary borders, and flowering in July and August. It is from this plant that the greater part of the medicinal Gentian root is obtained.

G. Newberryi.—A scarce Rocky Mountain species, occurring at very high elevations. Stem 4 to 6 inches high, slender, erect, arising from a rosette of obovate leaves of a light shining green colour. Stem leaves linear lanceolate. Flowers about an inch long, tubular, with a spreading corolla limb of a pale sky-blue colour, white internally, and spotted with green. A most handsome little species, requiring a damp position in peat and loam.

G. Pneumonanthe.—This is found in this country as well as in other parts of Europe. Stems numerous, erect, slender, 6 to 9 inches high, with lanceolate leaves. Flowers in terminal umbels, about 1½ inch long, bell-shaped, with a five-cleft corolla limb, deep blue. It is an elegant kind, occurring in marshy places, and it thrives well in the bog garden or in damp peaty borders. The white-flowered variety *alba* is very scarce. It is a native of Germany, but of unfrequent occurrence even in its native habitat. The flowers are white tinged with green.

G. septemfida.—This is said to be a native of the Levant. It is closely related to *G. gelida*, with the same habit. The flowers are rather larger and deeper in colour, and it is a very showy and hardy plant, easily grown, and flowering very freely when established during July and August.

G. umbellata.—A very pretty Caucasian species. Stem 9 to 12 inches high, four-angled, terminating with dense clusters of flowers. Leaves in a rosette, oblong, red-nerved. Flowers about half an inch across, open, of a light purple colour, very numerous. This is often quoted as a perennial, but it is really nothing more than a biennial, flowering and seeding very freely the second year, then dying away. It is, however, easily raised from seed, and is a very desirable plant, well worth the trouble of occasionally raising from seed.

G. verna.—This is found in a few British localities, and very plentiful in the Alps and other mountains of Europe. It forms dense dwarf tufts of evergreen glossy foliage. Leaves ovate-oblong, rather blunt and leathery. Flowers about an inch long, tubular, with a five-partite spreading corolla limb, of a brilliant blue colour with a white throat. This is a gem among alpine, the joy of all enthusiasts, especially when established on the rockery. It does well in rich loam, leaf soil, and sand, with a mixture of small cobbles of limestone, planted in a damp and partially shaded position.

G. Walujewi.—This is a grand species from Asiatic Russia, recently sent to this country by Dr. Regel, from whom I had the pleasure of receiving several good plants. Stems erect, a foot or more high, with lanceolate leaves and terminal flower clusters. Flowers large, erect, bell-shaped, bright yellow, spotted and marked with blue. A most distinct and scarce plant. It has a good constitution, and thrives well in ordinary soil and on the rockery, being remarkably showy when in flower.—N.

REIGATE ROSE SHOW.

ON July 1st the Reigate Association held their Rose Show under most favourable circumstances. Cloudy June was gone, and July opened with sunshine. That favoured locality had also had heavy thunder rain two days before—a most invaluable refresher to Rose bushes just now. The Show was held again, by invitation of Lady Henry Somerset, in the beautiful grounds of Reigate Priory. The exhibit was considered decidedly superior to last year. The Judges were the Rev. H. H. D'Ombraim and Messrs. George Paul and Francis. Mr. Paul brought a box of new Roses, with beautiful specimens of Duke of Teck and George Baker. Mr. Prince also contributed two boxes of the most exquisite Roses, Jean Ducher being a marvel and Madame Bravy fine. The Judges and Committee, with other friends, were as

usual most hospitably entertained at his residence by G. Baker, Esq., whose Rose garden of over a quarter of an acre presented a blaze of beauty and luxuriant growth very rarely indeed realised. Lady Henry Somerset received her friends and the members of the Association at a garden party during the afternoon, when the band of the Coldstream Guards discoursed at intervals very excellent music.

The winners, taken in order of the schedule, were as follows:—Twenty-four varieties.—Messrs. Wollarton, Cheales, and Cuthell, the box of the former containing fine specimens of Etienne Levet and Marie Baumann. Twelve varieties (seven entries).—Messrs. Haywood, Horne, and F. O. Paule. The winning box was of very high excellence, and contained splendid specimens of Duke of Teck, Louis Van Houtte, and Marquise de Castellane. It had also an Edouard Morren, a marvel of colour and symmetry, which obtained the National Rose Society's silver medal as the best Hybrid Perpetual bloom in the Show. The first prize carried with it the Ladies' Cup, which, having been obtained three successive years, becomes now the holder's property. Nine varieties.—Mr. G. Baker was first with a still more perfect box, containing magnificent blooms of La France, Marie Baumann, Baronne de Rothschild, Madame Gabriel Luizet (very largely shown this year), Hippolyte Jamain, and Annie Wood. Messrs. Wilkins and Warde won second and third. First prize, National Rose Society's gold medal. Six varieties (seven entries).—Messrs. Burnside, Mawley, and West were the prizetakers, Mr. Mawley showing a striking specimen of Lady Sheffield, of a pale, soft, cerise colour and excellent form. The prizes given by G. Baker, Esq., for four triplets, two dark and two light, were taken by Messrs. Waterlow and Cheales. In the twelve Tea class (three entries) Messrs. Baker and Waterlow were made an equal first, while Mr. Cuthell obtained a second. Mr. Baker's box contained an Anna Ollivier which obtained the silver medal as the best Tea in the Show. Mr. Waterlow's had an Innocente Pirola of great merit. Six Teas (five entries).—First Rev. A. Cheales, second E. Mawley, Esq. In the ladies' classes there was a very spirited competition for the President's prize. A single basket of Roses, all to use the same with Ferns or Grass (thirteen entries).—First Miss West, second Miss F. Thornton. Five competed for the wall basket prize, which was won by (first) Miss Smith and (second) Mrs. Ferrier. Hand bouquet.—First Mrs. Ferrier, second Miss Gosse. Buttonhole bouquet.—First Miss Cheales, second Mrs. E. Wilkins. Thirty-two shown. The first prize was taken by a bud of Narcissus surrounded with four little red Sweet Briar buds. There were other classes which were also well contested.

This increasingly large Association bids fair to hold its own in comparison with any other, and contains now, in the absence of Messrs. Baker and Jowitt, some of the most formidable of the principal all-England exhibitors.

SANGUINARIA CANADENSIS (BLOOD-ROOT).

THIS is a showy Ranunculaceous plant with a fleshy zizomatose rootstock abounding in a red juice, hence its common name. Leaves on short petioles, ovate-cordate, variously lobed and puckered, netted with reddish veins developed freely after flowering. Flowers solitary, on slender stalks about 6 inches high, 1 to 1½ inch across, with white oblong petals; very fugacious. Notwithstanding the short-lived character of the flowers this is a pretty little plant, flowering very early in the year (March to May), and succeeds best in a damp and partially shaded position in loam, peat, leaf soil, and sand, or in ordinary light border soil. It is well suited for the lower part of the rockery among shade-loving plants. It is found in the woods of Canada and other parts of North America, and according to Morrison was cultivated in this country as early as 1680. Dillenius figures three forms of it (*Dill. Elth.* t. 252), and a good figure of it appeared in the "Botanical Magazine," pl. 162. Parkinson regarded it as a Buttercup, in which of course he was wide of the mark—*Ranunculus virginensis albus* (*Park. Theat.*, 226). It is increased by division of the rootstock, which should be done in the autumn or very early in spring, or raised from seeds, which ripen freely under cultivation, and they should be sown so soon as they are ripe.—T.

MAIDSTONE ROSE SHOW.

AMONGST those places which do honour to the Rose, and in so doing do honour to themselves, the county town of Maidstone holds a foremost place. One of our veteran Rose-growers—if, indeed, he be not the oldest amateur we have—Mr. Hollingworth, who has been the hero and the victor of a hundred fights, lives in the neighbourhood, and ever ready as he is to foster every good work, the Maidstone Rose Club has prospered, and under the management of their able and courteous Secretary, who has about as wide a knowledge of Roses as anyone I know, and whose judgment in a case of mistaken identity I should be ever quite willing to take, is likely to continue. It has ever been a favourite place of meeting for our Kentish growers, and its contests are looked forward to with no little interest.

Suffice it, then, to say that the meeting on Tuesday last was quite equal to any of its predecessors. Its prizes are not such as to tempt the outside world, and therefore the Exhibition is small in extent, but

in quality it is always excellent. Growers put forth their best efforts, and there were some grand blooms displayed. Especially was this the case with Tea Roses. The boxes of blooms shown by Capt. Knight and Mr. Biron were grand specimens of this beautiful class; while the box which obtained the prize for the best box in the Show, exhibited by Mr. Biron, contained blooms which would have done credit to any grower. Where, however, all were so good it seems almost envious to particularise, and I therefore add the names of the winning flowers in the first prizes in each class, and can only express the hope that the Society may long flourish.

I would like to take the opportunity of saying that the name of the place where the first shot was fired was not Bibbing, but Bobbing.—D., Deal.

[Only the premier winners in the different classes have been forwarded to us, and are as follows:—In class 1, Mr. R. L. Knight. Class 2, Mr. H. H. Wakeley. Class 3, Rev. H. B. Biron. These classes are not designated. In the class for twelve Teas Rev. H. B. Biron and Mr. R. L. Knight were equal firsts. Mr. Wakeley was first with eight trebles, Mr. Mount with nine varieties, single trusses; Mrs. Heawood with six varieties, Rev. H. B. Biron with six Teas, and Mr. Knight secured the first position in the class for six blooms of one variety with La France.

The silver medal of the National Rose Society was awarded to the Rev. H. B. Biron for the best box of blooms in the Show, and the bronze medal to Mr. Knight for the best Rose in the Show—Marie Rady.

In consequence of the extreme pressure on our columns we are unable to publish the names of the varieties in the winning stands, which have been obligingly sent to us, but were not received until after the whole of our space was occupied or allocated.]

OBSCURE BOTANICAL PHENOMENA.

A LECTURE on this subject was delivered on the 22nd inst. by Rev. W. H. Dallinger, F.R.S., before the Sheffield Floral and Horticultural Society, the chair being taken by H. E. Watson, Esq., Shirecliffe Hall, President of the Society.

Mr. Dallinger, who was cheered on rising, said he did not propose to himself the formality of a lecture, but rather to lay before them a series of diagrams (which were illustrated by means of the oxy-hydrogen light) of some of the more obscure and rare phenomena of vegetable life. He first drew attention in a forcible and very lucid manner to the group of putrefactive organisms with which the scientific world is becoming more and more acquainted, and which could not yet be classed with any degree of certainty with either the animal or vegetable world, but which form a connecting link between the two. After pointing out how these putrefactive organisms set free at death the elements needful to living creatures, he proceeded to illustrate and describe the development of these organisms from the germs of oval form through the oblong to the globular and matured, and their methods of reproduction. Protoplasm and its continued activity after being set free from Algæ, and the method of reproduction of the Confervæ, Desmids, &c., were described; also of the fungoid growth which attacks flies in autumn, and of its identification with the salmon disease. The Peronospora infestans, or Potato disease, was well illustrated as to its method of fertilisation and reproduction. After giving descriptive illustrations of the organisms (Protococcus pluvialis) to be found in all rain water, particularly pools that have stood for some time, with their generation and development, an interesting and highly instructive lecture was brought to a close by the passing of hearty votes of thanks to the rev. lecturer and to the chairman.—J. U. S.

HITCHIN ROSE SHOW.

JUNE 28TH.

"WITHIN twenty miles of Hitchin," the limit according to the advertisement of the district covered by the Hitchin Rose Society, and in which is included a good deal of chalk, sand, and hungry clay country, several of the great growers also, although resident in the same county, being by the limit excluded, it will hardly be surmised that a large display would attend the zealous endeavours of the Hon. Sec., the Rev. F. H. Gall, especially as there was no open class and the time full early for the locality. Nevertheless, a fine Rose day, with occasional gleams of sunshine to light up the bright flowers and the equally bright faces and dresses of the goodly array of admirers who were present in remunerative numbers, rendered the Hitchin Show a fair success, and sufficiently so, I trust, to induce the genial Hon. Sec. to renew his efforts next year on a somewhat more extended scale, and perhaps to add an open class or two.

The flowers were, on the whole, hardly so good as those shown at Hitchin in 1881, and with the exception of the stands of Messrs. E. P. Francis & Co. of Hertford; the Rev. W. H. Jackson of Stagsden, Beds; and the Rev. E. Fellowes of Wimpole, Cambs, will not need much comment. In Class 1, open to nurserymen, Messrs. Francis were the only competitors, and were fairly awarded the first prize for a very good stand of twenty-four trusses of any variety, amongst their best blooms being A. K. Williams, Marquise de Castellane, Duke of Edinburgh, Antoine Mouton, François Michelin, a very bright and good

Baron Adolphe de Rothschild, and an unusually large Paul Neyron. In the amateurs' class for twenty-four trusses a good tryst came off between Mr. Jackson and Mr. Fellowes for first and second places, Mr. Jackson being ultimately placed first by the Judges with large, fully developed, and generally smooth blooms, including Etienne Levet, Gabriel Luizet, and Charles Darwin—all three model and perfect Roses. Mr. Fellowes had smaller and rather fresher blooms, his best being Madame Lacharme (pure white and exceptionally large), Le Havre, Madame Gabriel Luizet, Baroness Rothschild, and Louis Van Houtte. Mr. U. Heathcote of Sheephall was third. For the twelve varieties in the same division Mr. Jackson was easily judged first with large and well-formed blooms; Mr. Fellowes second; and the Rev. F. Jenyns, Knebworth, third.

In the open class for twelve Teas Mr. Fellowes was first with a fine stand, Bouquet d'Or, Anna Ollivier, Catherine Mermet, and Gloire de Dijon being well represented. Mr. Jackson was here second, having a very fine Catherine Mermet, Rubens and Innocente Pirola being also noticeable.

The silver medal of N. R. A. was secured by Dr. Swaine of Arlesey Asylum for nine trusses of any variety; and the Rev. F. Gall, who is an experimental farmer of Roses on the Hitchin Irrigation Farm, not by the acre nor the thousand trees, but by the yard and the dozen, was not disheartened with the baser metal for an approximately good stand of nine varieties. A few good Roses were shown in other stands, and a passable bloom of Duchess of Connaught, H.T.; but Alfred Colomb seems this year conspicuous by its absence.—T. LAXTON, Bedford.

OUR SHRUBBERY.

SINCE I wrote the first paper (page 320) many good varieties are over for this season, but at the present time there are several worth noting. Berberis canadensis has this season been loaded with its terminal drooping racemes of bright yellow flowers. There are several varieties of B. vulgaris, all of which are extremely pretty when in flower. B. vulgaris var. iberica is noteworthy, and B. vulgaris var. purpurea is certainly worth a place in every shrubbery border if only for the purple foliage; and when in flower is a very attractive shrub. Small plants from 2 to 3 feet high look remarkably well near the margin, the foliage contrasts well with shrubs of a lighter colour. B. chinensis is also good, the young foliage being remarkably handsome. B. aristata is a very distinct species on account of its upright growth, the majority being spreading or drooping; the flowers are like B. vulgaris.

The Calycanthuses are shrubs that are not often seen in private gardens; this is to be regretted, for when in flower they are very handsome, and should be planted in the fore part of the borders. The genus Calycanthus is but a small one, embracing only four species. C. floridus (or Carolina Allspice) is most commonly met with in gardens. There are several varieties in nurseries under the names inodorus, asplenifolius, with cut leaves; bullatus, with bladder leaves; pennsylvanicus, and nanus. It is a very compact-growing species, and the flowers are very agreeably scented.

Magnolia acuminata has been in flower for two or three weeks past. The flowers of this species are not so large and showy as many of the others, being of a greenish yellow and relatively small. It is commonly known as the Cucumber Tree, the young fruit somewhat resembling small Cucumbers. Small plants 12 or 15 feet high look very handsome amongst other commoner shrubs; the foliage is large, and of a soft green colour.

The Weigelas have been all aglow with their pink, rose, and white flowers. W. rosea is too well known and appreciated to need much comment; it was the first of the group that was introduced, and is certainly the most showy. There are, however, several others that are distinct and well worth growing. Amongst them are W. amabilis, W. Lowii, and W. multiflora, a Japanese species, very distinct in its narrow tubular purplish corollas, only slightly expanded towards the mouth.

I do not remember seeing the Viburnums flowered better than they have this season, for V. Opulus or the Snowball Tree has been weighed down with its snowball-like heads of flowers, especially in the morning when the dew is on them. This must be considered as the most useful for borders, and for single specimens it is well suited also. With a little pruning every year the single specimens can be kept well within bounds. V. prunifolium is a spreading shrub, and produces large clusters of pure white flowers. V. dentatum and V. plicatum tomentosum are amongst those that are now in flower.

The Lilacs have been glorious this season, and would have lasted much longer had it not been for the rough gale recently experienced. If Lilacs are judiciously planted throughout the shrubbery nothing could look better and more pleasing than they when in flower. There are many remarkable fine varieties of the common Syringa vulgaris; and amongst the many forms now

grown I may note the following:—Dr. Lindley, having extremely large clusters of reddish lilac flowers; alba, pure white; and violacea, rubra, insignis, and rosea grandiflora. Charles X. is perhaps the most handsome of this group, being remarkable for the immense size of its panicles and the beautiful colour of its flowers. S. Josikæa is very valuable, flowering later than the varieties of S. vulgaris, thus prolonging the season till June; it produces blooms of a bluish purple and quite scentless.

Cornus sericea has been very attractive for a long time; the yellowish white flowers show to advantage amongst the green foliage. The Halesias when in flower were very showy; they have been past now some time. There are only three or four species all limited to North America. H. tetraptera or Snowdrop Tree is the most common species, and the one generally cultivated. The flowers somewhat resemble in shape and size the common Snowdrop, and are produced in April and May before the leaves have attained their full size. They look extremely handsome dotted about amongst the evergreen shrubs. What looks better than the common Mountain Ash (Pyrus aucuparia) when in flower, and in autumn weighed down with its great clusters of scarlet berries? The foliage, too, is handsome. There are several other species that are worth noting, such as P. domestica, P. Aria, &c.

We must not pass the genus Cratægus without a word of praise. C. eoccinea and C. eoccinea var. maerantha is well known, and well deserves to be planted extensively. The foliage is large and cordate on rather long petioles. The flowers are large, pure white, and produced in lateral corymbs. Not only is it very showy when in flower, but in autumn also, particularly when carrying a good crop of large bright red fruit. Very handsome specimens can be formed by planting them singly in the open. C. Oxyacantha includes many varieties, for it is from this species that has given rise to the showy varieties that now adorn our gardens, such as the double white, single and double pink, single and double scarlet, also variegated and weeping forms. The double scarlet and double pink, especially Paul's double scarlet, cannot be over-estimated for shrubbery borders. They should be planted in prominent places, so that they may always be seen when in flower. For this last month they have been one mass of flowers and last long in perfection. The single flowers appear like miniature Roses.

The Laburnum also must not be forgotten. L. vulgare or Cytisus Laburnum is a general favourite. This very popular tree is probably more familiar to many people than many of our native trees. How cheerful and pretty two or three trees look in any establishment during May and early in June! Nothing certainly can excel the beauty of the pendulous racemes of bright yellow flowers which are produced in such profusion every year. There are several varieties of the common Laburnum in cultivation, differing from the type in having larger and different coloured flowers.

The common Elder (Sambucus nigra) is by no means to be despised, although so frequently seen; when in flower it is extremely showy and sweetly scented. There are several varieties in cultivation, and one, S. nigra var. laciniata, is very handsome, the leaves being deeply cut. Then the variegated forms are still more handsome, and through the summer months they assist in making the borders very cheerful. Cotoneasters judiciously planted are very useful, and for the front of borders C. microphylla is one of the best. Not only is it very pretty when in flower, but when in fruit also. C. bacillaris and C. buxifolia grow into bushes of great size, and now covered with their pure white flowers.

Two or three Spiræas are now flowering; their neat blossoms are always welcome. S. trilobata, S. chamædrifolia, S. callosa, and S. grandiflora, or, as it is now known, Exochorda grandiflora, are all in flower. The latter, by far the best, produces racemes of pure white flowers. Many of the species of Roses are well worth planting, for they flower much earlier than the choice kinds, and as single flowers are now becoming more and more fashionable they can safely be recommended. R. rugosa is perhaps one of the largest-flowered species; it produces flowers 4 or 5 inches across. R. microphylla is very free-flowering, but not so large as the latter.

We at length come to the Philadelphus or Mock Orange. P. grandiflorus cannot be over-estimated; for planting in a mixed border or as single specimens it is equally valuable. For cutting purposes it is indeed useful; the delicious perfume is readily detected where a small spray is employed for vase-filling. There are about twelve species known in gardens, one and all of which are worth growing. The latter species and P. tomentosus are now in full beauty; following on a little later is P. Gordonianus (one of the best), and P. latifolius. Many others might be mentioned that could be employed in shrubbery borders, but

some further notes must be deferred to another communication.—W. K.

ROYAL BOTANIC SOCIETY.

JULY 5TH.

THE second summer Show of the present year at Regent's Park was in every respect a most satisfactory one, the exhibits numerous, generally of high quality, and the arrangements excellent. The Show was one of the most extensive the Society has held, but the short time at our disposal will only permit a very brief record of the principal features and the leading prizewinners.

Orchids.—A beautiful bank of these was contributed by some of the leading amateurs and nurserymen. In the former class for twelve plants Mr. Spyers, Orchid grower to Sir Trevor Lawrence, Bart., Buiford Lodge, Dorking, carried off chief honours with a particularly handsome collection, which included *Cypripedium Stonei* with over two dozen flowers, the graceful *Epidendrum nemorale* with fifteen spikes, *Vanda teres* with fifteen flowers, and fine examples of *Cypripedium barbatum nigrum*, *C. niveum*, *Aerides affine*, *Masdevallia militaris*, and *Cattleya gigas*. Mr. H. G. Catt, gardener to W. Cobb, Esq., Silverdale Lodge, Sydenham, was a close second with well-flowered specimens of *Cœlogyne pandurata*, *Oncidium ampliatum*, *Epidendrum prismatocarpum*, *Odontoglossum caudatum*, *Oncidium macranthum*, and *Cypripedium Veitchii*. Mr. Spyers was also first with six plants, closely followed by Mr. J. Child, gardener to Mrs. Torr, Garbrand Hall, Ewell, who had a fine example of *Stanhopea tigrina superba*. In both collections the plants were very healthy. In the nurserymen's class for twelve plants Mr. H. James, Castle Nursery, Norwood, won chief honours with well-flowered specimens, *Masdevallia Harryana*, *Dendrobium Jamesianum*, and several *Cattleyas* being fine. Messrs. T. Jackson & Son, Kingston, and Mr. Cypher, Cheltenham, were second and third respectively with good collections.

Stove and Greenhouse Plants.—The principal class for these was that for twelve specimens, in which Mr. Cypher takes the lead with handsome examples of *Allamanda nobilis*, *Dracophyllum gracile*, *Erica Cavendishiana*, and *Azalea Souvenir de Prince Albert*. Messrs. Jackson & Son were second with neat even specimens, *Kalosanthes* Mr. Duphemis and *Rondeletia speciosa* major being the two most noteworthy in the group. Messrs. B. Peed & Son, Streatham, were third with well-flowered plants. In the class for six plants Messrs. Jackson and Son secured the first prize for vigorous well-flowered specimens; Messrs. B. Peed & Son were second, and Mr. H. James was third. In the amateurs' class for six plants Mr. J. Child won chief honours with praiseworthy specimens of *Stephanotis floribunda*, *Kalosanthes splendens*, and *Begonia Paul Masurel*, 5 feet high and 4 feet in diameter. Mr. G. Wheeler, gardener to Lady Louisa Goldsmid, St. John's Lodge, Regent's Park, was second, having very neat specimens.

Fine-foliage Plants.—The premier honours for six specimens were gained by Mr. C. Rann, gardener to J. Warren, Esq., Handcross Park, Crawley, who had *Croton undulatus*, *C. Andreanus* finely coloured, and *Latania borbonica* very large; with other handsome plants. Mr. R. Butler, gardener to H. H. Gibbs, Esq., St. Dunstan's Lodge, Regent's Park, was second with healthy plants; and Mr. G. Wheeler third. Mr. Cypher was the most successful exhibitor, taking first with handsome plants, *Croton Johannis* being very notable; Mr. B. S. Williams, Upper Holloway, was a close second; Messrs. Hooper & Co., Twickenham, were third, their *Anthurium cristatum* and *Phyllotænum Lindeni* being fine. An extra prize was awarded to Mr. James. For six Palms Mr. C. Rann secured the first position with grand specimens of *Pritchardia pacifica*, *Thrinax elegans*, *Chamaerops humilis*, *Livistonia altissima*, *Phœnicophorium seychellarum*, and *Phœnix tenuis*. Mr. R. Butler followed with smaller but vigorous specimens, and Messrs. Hooper & Co. were third. An extra prize was also awarded to Mr. James.

Ferns.—Mr. C. Rann won the premier award in the class for six plants, his *Gleichenias* being extremely fine in every respect. Mr. Child was a close second, his *Davallia Mooreana*, *Gleichenia dicarpa longipinnata*, and *G. semivestita* being in a beautiful condition. Mr. G. Wheeler was third with an even collection of small plants. In the nurserymen's class for the same number of specimens Mr. B. S. Williams took first with superb examples; Mr. Cypher was second, and Mr. James third.

Pelargoniums.—The collections of these staged in competition imparted a most agreeable brightness to the display. Mr. J. Wiggins, gardener to H. Little, Esq., Hillingdon Place, was the leading exhibitor with Show and Fancy varieties in the amateurs' classes, having admirably flowered specimens in both. Mr. C. Hammond, gardener to F. Hunt, Esq., York Lodge, Stamford Hill, who followed had smaller but healthy examples. Mr. C. Turner, Slough, secured the premier prizes in the nurserymen's corresponding classes with collections of Fancy and Show varieties, the plants being superbly flowered. Mr. Cypher also staged a fine collection of the latter. For Zonals Mr. J. Catlin, gardener to Mrs. Lermite, Finchley; Mr. W. Meadmore, Romford; and Mr. Wiggins were the prizetakers in that order, the first collection being by far the best.

Tuberous Begonias.—The first prize for a collection of these was gained by Messrs. J. Laing & Co., Forest Hill, who had fine plants of *Empress of India*, Hon. Mrs. Brassey, Annie Laing, General Roberts,

Exoniensis, Reine Blanche, Hon. and Rev. J. T. Boscawen, and Mrs. Dr. Duke, all superb varieties.

Heaths were shown by Messrs. Cypher and Jackson, who were first and second respectively with neat plants.

Cut flowers were largely represented, especially the Roses, very handsome collections being staged.

Fruit.—Numerous collections of these were staged, six competitors entering the chief class for six dishes, in which Mr. Coleman of Eastnor Castle, Ledbury, won the chief position; his Black Hamburg Grapes, Bellegarde Peaches, and Elruge Nectarines were very fine. Mr. Edmonds, gardener, Bestwood Lodge, Nottingham; Mr. T. Comber, gardener to J. H. Rolls, Esq., M.P., The Hendre, Monmouth; and Mr. Wildsmith, gardener to Viscount Eversley, Heckfield, Winchfield, also showed well in this class. Melons were well shown by Mr. J. Bolton, gardener to W. Spottiswoode, Esq., Coombe Bank, Sevenoaks; Mr. W. Nash, gardener to the Duke of Beaufort, Badminton; and Mr. W. Coleman.

Mr. Wildsmith had the best basket of Grapes, Black Hamburgs finely coloured. Mr. Edmonds and Mr. Woodbridge, gardener to the Duke of Northumberland, Syon House, followed closely. In the corresponding class for white Grapes Mr. J. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, Ilford, Essex, and Mr. P. Feist, gardener to R. J. Ashton, Esq., Bishopgate House, Staines, were the prizetakers, the former having Canon Hall Muscat very fine, and the latter Muscat of Alexandria in good condition. For three bunches of Black Hamburgs Mr. Wildsmith won with three fine examples. Mr. Molyneux, gardener to W. H. Myers, Esq., Swanmore Park, Bishops Waltham, and Mr. J. Hudson, gardener to H. J. Atkinson, Esq., Gunnersbury House, Acton, followed. For three bunches of any black Grapes Mr. Hudson led with three grand bunches of Madresfield Court; Mr. Wildsmith followed with Black Prince, and Mr. Woodbridge was third with Madresfield Court. White Grapes were finely shown by Messrs. Feist, Johnston, and Woodbridge; and Mr. E. Adams, gardener to W. H. Negro, Esq., who had grand examples of Buckland Sweetwater. Peaches, Nectarines, and Strawberries were also well shown. Pine Apples were well represented, the finest fruit being an excellent example of Charlotte Rothschild from Mr. Faulkner, gardener to F. R. Leyland, Esq., Woolton Hall, Liverpool, who was placed first.

Miscellaneous.—In addition to a large number of new plants handsome groups were contributed by the following:—Mr. C. Turner, Slough, had a large and tasteful group of Pelargoniums and Palms; Messrs. Laing & Co., Forest Hill, contributed a group of new Tuberosus Begonias, very handsome; Messrs. J. Veitch & Sons, Chelsea, staged a large group of new and choice plants; Mr. B. S. Williams, Upper Holloway, had a group of Orchids and miscellaneous novelties; Messrs. Hooper & Co., Covent Garden, a tasteful group of Ferns and Palms; Messrs. William Paul & Son (Waltham Cross) and the Cranston Nursery Company had fine collections of Rose blooms; Mr. G. Wheeler a group of flowering and fine-foliage plants; Messrs. Osborn and Sons, Fulham, sent a fine collection of hardy plants; and Messrs. Barr & Son, Covent Garden, had a similarly beautiful group in the corridor to that staged at Kensington on the previous day.

HARDY FRUIT GARDEN.

It is of the greatest importance to keep fruit trees free from insects, which during the recent unfavourable weather has not been an easy task. The removal of the foreright and other unnecessary shoots upon trained trees, as advised in former calendars, will have freed the trees to a great extent, as such shoots are generally most infested with aphides and caterpillars, and these should be collected and burned. The removal of the spray will permit the more ready application of an insecticide, and the thorough cleansing of the foliage with water from the garden engine. Cherry trees on walls are in too many instances much infested with the black aphides, which are difficult to destroy, as tobacco water or other liquid seems quite harmless to them. It is necessary to treat the shoots infested individually by rubbing them with the fingers frequently dipped in strong tobacco water or approved insecticide. This should be followed in the course of half an hour with a thorough application of an insecticide, which will in most instances effect a clearance, being followed the next day by a forcible syringing from a powerful engine. As soon as the trees are well cleansed the leading shoots and necessary young wood should be nailed, tied, or otherwise secured in position, to be followed by another washing with the garden

engine, and repeated as found needful. The long-continued dry weather and prevalence of east winds has been exceedingly favourable to the leaf-rolling caterpillars on Apple, Pear, and Nut bushes, and for these careful handpicking is the only effectual remedy.

Vines trained to walls in the open air should now be closely nailed or tied-in. Fig trees on walls must have similar attention, removing all superfluous shoots, pinching out the points of those retained at the fifth or sixth joint, except those of the leading shoots. Many outdoor fruits are now ripening, and should be protected by nets from the ravages of birds. Ground may be prepared for new plantations of Strawberries by being well manured and trenched, or at least as deeply dug as the soil admits. We have before alluded to the desirableness of layering a sufficient number of runners in small pots for the purpose, but where this is inconvenient the runners may be allowed to root into the soil, from which they should when well rooted be carefully raised with a trowel, and if planted and attended to until established they will afford a good crop another season.

FRUIT HOUSES.

Peaches and Nectarines.—The fruit being all gathered in the earliest house, attend still to syringing the trees forcibly in the afternoon, and the inside borders should not on any account be allowed to become dry, and in the case of weakly trees some liquid manure will greatly assist them. Still attend to pinching or removing the laterals and all superfluous growth in addition to the shoots that have borne fruit this season. When the fruit buds are fairly well plumped the roof lights can be removed, which, by exposing the trees and borders to the rain, will greatly benefit the trees and prevent over-development of the buds—a source of trouble in trees sometimes subjected to a course of early forcing; but where the roof lights are fixed ventilate to the fullest extent, and syringe occasionally, not allowing the trees to become dry at the roots. In the house started early in the year the fruit has been removed from some varieties, and syringing must be resorted to, a thorough watering being given at the roots, stopping the laterals, cutting out the wood that has borne fruit—not being extensions—and thinning out the growths for next season where too thickly placed. Any gross shoots may be stopped, and growths originated thereby pinched to one joint. In later houses where the fruit is swelling after stoning syringe vigorously to keep red spider under, and to secure the fruit swelling to a good size close early with plenty of sun heat, but ventilate early in the day to prevent scorching. Let there be no lack of moisture in the borders, and keep the shoots tied down as they advance, removing any that are superfluous, pinching-in to one joint the laterals on the strong shoots, and stopping any that are unduly vigorous. Feed those swelling off heavy crops of fruit with weak liquid manure, mulching the surface of the borders with short manure.

Figs.—The fruit from the planted-out trees in the earliest house will be all gathered, and the treatment as advised in our last calendar should now be continued, under which conditions the second crop will advance rapidly; and as there is sure to be a plentiful supply of fruit, it should be freely thinned, reserving those which are nearest the base of the shoots. Tie the growths to the trellis as they advance, stop those not required for extension. Syringe freely once or twice a day, as red spider is unusually prevalent this season, and will soon establish itself if syringing is neglected. Do not allow the trees to suffer for want of water; those in pots or planted out in borders of limited extent will require it frequently and copiously, and should on every occasion have a little guano mixed with it. In houses where crops are ripening maintain constantly a free circulation of warm dry air to ensure their ripening. Trees in pots required for early forcing must have their requirements in watering with weak liquid manure on every occasion regularly attended to, and be syringed occasionally.

FLOWER GARDEN.

Favoured by the recent rains bedding plants are at last making progress, and to aid them in filling the beds as quickly as possible all blooms should for the present be removed as they continue to appear. Verbenas, Petunias, &c., will require frequent attention in regulating and pegging. In dry seasons mulching flower beds is of great benefit, and is especially to be advised in light soils from lessening

the necessity for watering. Subtropical plants can scarcely have too much water if the weather be warm; they should be staked and tied as they advance in growth. Hollyhocks and Dahlias may be treated similarly. Carnations and Pinks must be neatly secured to stakes, and the propagation by layers and pipings can be pushed forward, making choice of an old spent hotbed on which to place the handlights, inserting the cuttings in sharp sandy loam, keeping them well shaded from the sun, and sprinkling them occasionally. Cuttings of Roses root freely at this season, provided they are taken from well-ripened wood, giving them the same treatment as advised for Carnations. Briars and other stocks will soon be sufficiently forward for budding, making choice of such buds as are on wood that has just borne flowers, as successful budding depends greatly on selecting sound mature buds; and in extracting the wood great care should be exercised, so that the bark is not bent too sharply or bruised. As Roses of the Hybrid Perpetual class cease blooming they should be shortened back, and every means taken to insure a free growth by mulching and watering. Climbing Roses must have the old flowering wood cut out, and the young growth laid in for next year's flowering.

PLANT HOUSES.

Greenhouses.—Usually these structures are kept much too dry during the summer months. In most cases no air moisture is provided but what results from the evaporation of the small quantity of water that escapes from the pots in watering, whereas the whole of the space inside the houses should be kept during the summer not merely sprinkled but wet, so that in sunny weather there is a continuous healthy moisture rising amongst the plants. Zonal Pelargoniums for winter flowering in a little heat should at once be prepared. Plants struck last autumn are most suitable, but early spring-struck cuttings are also useful. They should at once be placed in 6-inch pots in good loam, with a little sand and about a sixth of well decayed manure, potting as firmly as possible. Plunge, or at least stand, the pots on ashes in the full sun outdoors, stopping the plants so as to keep them in shape, and remove all flower buds, so that all the energies of the plants may be directed to making growth. Some of the best varieties for this purpose are Vesuvius, White Vesuvius, Tip Top, Eclipse, Commander-in-Chief, Beatrix, H. M. Pollett, Kleon, Mrs. Whiteley, Alonzo, Polyphemus, Miss Gladstone, Madonna, and Marguerite Ponton, which are all single. In doubles F. V. Raspail, Wonderful, Guillon Mangilli, Alba Perfecta, and Mrs. Chas. Pearce.

ARTIFICIAL SWARMING.

IN the Journal for June 15th, page 501, "CLIFTON" says he has lost confidence in Mr. Pettigrew's teachings on this subject, and further that he does not intend trying the plan again. I, like "CLIFTON," failed in my first attempt at artificial swarming; but with the use of a cool blast smoker with some dry decayed wood in it I lighted a few puffs from which quieted the bees, the practice was a perfect success. The same practice I have followed several times during the season with equal results. It has been said by some writers we should place the fresh skep where the old one stood after artificially swarming; but, like Mr. Pettigrew, I do not think that the best plan, as there is great danger of the whole of the bees leaving the old skep or hive and joining the new one. So much are they guided by familiar landmarks, that when those that were left in the hive fly into the air they will most likely settle on their old spot, and I have seen an instance where the whole of the bees have left their former abode, with its honey, comb, and young brood, and joined the other hive. Thus, as Mr. Pettigrew says, it is best to stand each lot right and left of where they formerly stood, if only a few feet.

I have some large bar-framed hives, and am anxious for the bees to fill the supers over them this season. When the swarms are not very strong when hived they seem to take nearly the whole of the season to fill the body of the hive. I have heard of people joining two or more swarms together, and once made an

attempt at the same; but it was evident from the dead which lay outside the hive in which they were put that it was not a profitable or desirable practice to be repeated. May I ask Mr. Pettigrew or any other of your able correspondents if they could give me the information sought for through the pages of this Journal—viz., making the bees smell alike, so that they may be successfully joined, so that by having them strong they would be more likely to fill my sections?—C. WARDEN, *Clarendon*.

THE NORFOLK BEE-KEEPERS' ASSOCIATION.

ON Thursday last this Association held its first annual Exhibition of bees, hives, and honey in the picturesque grounds of J. B. Coaks, Esq., at Thorpe Hamlet, a suburb of Norwich which may justly be termed the Richmond of Norfolk. A glorious June day, together with the attraction of the Norfolk and Norwich Horticultural Society's Show, drew together a large assembly, among whom were many of the *élite* of the county and city. Manipulations, the driving competition, and the short lectures delivered at intervals in the bee tent appeared to be the most popular of the day's proceedings, judging, at least, from the constant crowds pressing for admission. If we may indulge in vaticination we forecast for the Norfolk Bee-keepers' Association a bright future under the energetic guidance of its Secretary and local Committee, and expect before long to see it take rank amongst the foremost of our county associations.

The Rev. George Raynor, deputed by the British Association, assisted by the Rev. Blake Humfrey and three other members of Committee, awarded the prizes.

Amongst the foreign bees exhibited in uncomb and observatory hives we noticed a fine stock of Carniolian bees exhibited by Mr. Blow, which obtained the highest honours. In hives Mr. Blake of Dallinghoc, Suffolk, was placed first with a hive which we believe has frequently obtained similar notice at other shows, Mr. Blow taking second with one of similar construction. We observed, also, in this department several of the old straw skeps to which a most praiseworthy adaptation of the modern system of sectional supers had been made, thus instructing our cottage population in the more modern, humane, and lucrative system of securing the produce of their bees, and procuring honey in the purest and most saleable form. The three prizes offered by J. J. Colman, Esq., M.P., drew forth three competitors for the "best collection of hives, extractors, and other bee-keepers' appliances," whose select and extensive collections proved a great feature of the Show. Space would fail us to enter more fully into particulars; we therefore close our short summary by appending the prize list, merely remarking that the honey exhibited, both extracted and comb, although small in quantity—doubtless on account of the early season at which the Show was held—was fine in quality.

BEES.—The best stock of Ligurian or other foreign bees: 1, T. Blow, Herts; 2, S. Barge, Yarmouth; 3, T. Sells, Stamford. The best stock of English bees: 1, T. Blow; 2, T. Sells.

HIVES.—The best and most complete hive, on the moveable-comb principle, including covering, stand, floor-board, and facilities for storing surplus honey: 1, Andrew Blake, Wickham Market; 2, T. Blow; 3, Andrew Blake. The best and most complete hive, on the moveable comb principle, for cottagers' use, including covering, floor-board, and facilities for storing honey, price not to exceed 10s.: 1, T. Blow; 2, A. Blake; 3, Abbott Bros., Southall. The best straw hive, with facilities for storing comb honey in sections: 1, Rev. J. L. Sisson; 2, S. Barge; 3, T. Sells. The best frame hive for general use, the work of an amateur or cottager, being members of the Association: The Rev. A. J. Bellman and J. N. Eldridge, equal 2nd. The neatest and best supers, complete with racks and sections, for producing honey in the comb in the most saleable form: 1, T. Sells; 2, A. Blake; 3, T. Blow. The best and most complete collection of hives, extractors, smokers, feeders, and bee furniture, no two articles alike (prizes given by J. J. Colman, Esq., M.P.): 1, T. Blow; 2, S. Barge; 3, Abbott Bros. Any invention calculated, in the opinion of the Judges, to advance the culture of bees: T. Blow, for a feeder.

HONEY.—The best exhibition of super honey from one apiary: 2, T. Sells; 3, James Turner, Mulbarton. The best twelve 2-lb. sections of honey in the comb: 1, J. N. Eldridge; 2, J. Turner. The best twenty-four 1-lb. sections of honey in the comb: 1, Rev. J. Blake-Humfrey. The best twelve 2-lb. glass jars of extracted honey: 1, Rev. R. A. White, Ipswich; 2, F. T. Chevallier, Bungay. The best twelve 1-lb. glass jars of extracted honey: 1, R. Howes, Buckenham. The largest and best collection of extracted honey in glass jars: 1, T. Sells.

COTTAGERS' CLASS (for members of the Association residing in the county).—The best exhibition of honey in the comb, taken from one hive without destroying the bees (prizes given by the Very Rev. the Dean of Norwich): 1, and the silver medal of the British Bee-keepers' Association, Robert Moore, Norwich; 2, and bronze medal of the British Bee-keepers' Association, Robert Howes.

DRIVING COMPETITION.—The competitor who in the neatest, quickest, and most complete manner drove out the bees from a straw skep, captured and exhibited the queen: T. Blow.

Besides the above competitive classes there was an auxiliary department for the sale of honey, &c.

A PROFESSOR OF BEE-KEEPING.

IN a recent article in the Journal (page 522) Mr. Pettigrew urges the advisability of appointing two Professors of Apiculture (or bee-keeping, as some would say), one for England, one for Scotland, and suggests that Mr. Frank Cheshire would do well for the former, Mr. Raitt for the latter. Having brought a somewhat similar proposal before the Committee of the British Bee-

keepers' Association, and subsequently before the annual meeting of the members, I may perhaps be permitted to say that the importance of this matter has not been overlooked by the Association, and that as soon as an opportunity occurs another effort will be made to secure some such an appointment as Mr. Pettigrew desires. Both the Committee and the annual meeting gave their cordial support to the proposition when laid before them two years ago, but the Lord President of the Council of Education, although much interested in the facts that we placed before him, did not think that the time had arrived for an appointment to be made. The authorities at South Kensington invited Mr. Cheshire to lecture before some of their students, and I hope with Mr. Pettigrew that the time may soon come when still greater encouragement will be given us. He may rest assured that the British Bee-keepers' Association will do all they can to forward the object he has in view.—E. BARTRUM, *Berkhampstead, Herts.*

TRADE CATALOGUES RECEIVED.

E. H. Krelage & Son, Haarlem.—*Who'sale Catalogue of Plants.*
S. Bolton, Nelson, New Zealand.—*Catalogue of Trees and Shrubs.*

* * All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Sempervivums Decaying (C. A. J.).—The plants need a position where they can have more sun, as at present the leaves are unable to elaborate and assimilate the moisture that is supplied by the roots.

Vines Unfruitful (W. A. B.).—All you can do is to stop the growths and regulate the laterals so that the foliage is directly exposed to the light, admitting air freely yet judiciously, and employing fire heat in the autumn, if that is needed, for ripening the wood.

Orange Culture in the Tropics (E. Holland).—We know of no work which gives better information on Orange culture, "as practised on a large scale in those countries suitable for the growth of the trees" and ripening of the fruit than Simmonds' "Tropical Agriculture." Spon, Charing Cross, price 21s.

Climbers and Plants for Conservatory (Essex).—The climbers being required for pillars the following are advised:—*Rhynchospermum jasmynoides*, *Lapageria rosea*, *L. alba*, *Plumbago capensis*, *Clianthus magnificus*, *Proustia pyrifolia*, *Habrothamnus elegans*, *Sollya heterophylla*, *Jasminum de Poiteau*, and *Acacia Riceana*. These will take more time to cover the pillars and arches than rapid-growing climbers, such as *Passiflora Comte Nesselrode*, *P. Empress Eugénie*, *Tacsonia insignis*, *T. Van-Volxemi*, *Bignonia Chirere*, *B. jasmynoides*, *Clematis indivisa*, *C. indivisa lobata*, and such Roses as *Gloire de Dijon*, *Maréchal Niel*, &c. We give the two lists, but recommend the first. Of plants for the beds, in addition to two *Camellias* and the *Tree Fern*, we should have another *Fern* to match the one you have, few doing better than *Dicksonia antarctica*, with *Dracæna australis* and *D. indivisa*, *Chamærops Fortunei*, *Seafortia elegans*, *Phoenix reclinata*, *Corypha australis*, and two or more *Camellias*, or *Rhododendron Nuttali*, *R. Countess of Haddington*, and *R. formosum*.

Vines not Satisfactory (*Inquirer*).—The Grapes sent are not shanked but in a state of decay, induced unquestionably by the imperfect elaboration of the sap, consequent on the roots being in a wet and rich border, and the temperature of the house being kept too low, with a deficiency in the ventilation. Probably the heavy cold rains have increased the injury. For the present we advise a little ventilation night and day at the top of the house, to be increased when the weather is favourable early in the day, maintaining the temperature at 70° to 75° by artificial means, falling 5° at night, allowing an advance from sun heat to 85° or 90°, keeping the atmosphere dry and the laterals closely pinched. In the autumn examine the drainage, and if imperfect rectify it and give a good dressing of lime, and point in as deeply as the roots admit. If the roots are deep remove the surface soil, lift them, and lay them in fresh material nearer the surface.

London Market Gardens (C. B.).—You do not sufficiently explain your object. Mr. Warren of Isleworth, as has recently been published in the Journal, grows fruit and vegetables largely. Mr. Steel of Fulham is also a great vegetable grower. Mr. Ladds of Bexley Heath grows plants extensively; so do, amongst others, Messrs. Hayes of Edmonton, Reeves of Acton, and Hawkins and Bennett of Twickenham. We know of no method of gaining admittance to the experimental farm to which you allude otherwise than by writing to the manager.

Spiræa japonica (P. C.).—We are not surprised that you are disappointed by the disqualification of such an excellently cultivated and effective plant; and

in all probability had it been permitted to rank as a greenhouse plant, as it had been grown in a pot under glass, and the collection of which it formed a part had won a prize, the award would not have been seriously questioned. Still as the plant is as hardy as a *Delphinium* or a *Pyrethrum* the judges were justified in their decision, against which you raise no objection, but were simply taken by surprise. This *Spiræa* being perfectly hardy cannot be properly classed as either a stove or a greenhouse plant, although it does good service in a conservatory.

Melons not Setting (J. K. D.).—There is no doubt the soil has been too moist at the roots of the plants, and the atmosphere excessively moist and cold, with probably a too crowded condition of the growths. The remedy is to cease watering, or only give sufficient to prevent flagging, and be careful to wet the surface of the bed and the foliage of the plants as little as possible. If the growth is crowded thin it well. Keep the bottom heat at 80° to 85°, and the top heat 70° to 75° at night, with 10° to 15° rise in the daytime from sun heat. Allow a little ventilation constantly day and night, and ventilate freely when the weather is favourable. When half a dozen blossoms on a plant are fully expanded fertilise them, and continue daily to impregnate the fresh blossoms as they expand, stopping the shoots bearing the blossoms one joint above the fruit at the time of impregnation. When four to six fruit on a plant are set and swelling freely remove the others and earth-up the roots, supplying water copiously and as often as needed, creating a genial condition of the atmosphere by damping on warm afternoons, and close early.

Various (F. J.).—It is not easy to give a categorical reply to your first question. We can only say that for the majority of plants we should prefer slate to open latticework stages. The former are more durable than the latter, and the plants are less liable to suffer from over-dryness in summer than on dry open stages. In such matters, however, very much depends on management—that is to say, some cultivators grow plants much better on wood stages than others do on slate slabs, and if cost is no object you may safely adopt these. Loam may be stored in the open air, provided it is prevented being saturated by rain on the one hand or unduly dried by the sun on the other; but do not store it under trees, or it will be permeated with their roots and impoverished. *Bouvardias* are well adapted for a cool conservatory after they have been well grown in a light structure, having an intermediate temperature in winter and spring—viz., 50° to 55°. Cool frames are suitable in summer. The plants cannot be well grown in a house in which they are some distance from the glass or shaded by larger plants. A compost of two-thirds loam, the remaining third peat, leaf soil and wood ashes, with sand to keep the soil porous, will be suitable for most softwooded greenhouse plants; but for many, indeed we may say most, that are naturally of free growth, such as *Pelargoniums* and *Chrysanthemums*, peat is not needed.

Vine Leaves Scorched (*Lincoln*).—The foliage indicates that the house has been kept closed too long in the morning of a bright day, and then the ventilators opened too wide at once to lower the temperature. In such a case the evaporation from the foliage is always great, and tender leaves are browned at the edges—scorched or chilled. If sulphur has not been burnt in the house, the above is, we think, the cause of injury.

Determining the Solidity of Conical Heaps (*An Old Gardener*).—If the heap you wish to measure is a true cone, the following method will be applicable:—Multiply the area of the base by one-third part of the perpendicular height, and the product will be the solidity. But if, as your diagram seems to indicate, it is the frustum or basal portion of a cone, you can find the contents in this way: To the product of the diameters of the two ends add the sum of their squares; then this sum being multiplied by the height and again by 0.2618 will give the solidity. Another method to obtain the same result is the following—Multiply the areas of the two ends together, and to the square root of the product add the two areas; that sum multiplied by one-third of the perpendicular height will be the solidity of the frustum.

Nectarines Unsatisfactory (H. D. Hunt).—If the trees are in the open air we believe the fruit sustained injury by frost. The sap vessels and tissue were ruptured, and it is not unlikely they will commence growing as the fruit approaches maturity. The Shallots have been attacked with the maggot. There is no cure now. Next year you must plant on another site, dressing the ground liberally with soot and lime previously.

The Onion Maggot (J. Webster).—In our experience the Onion maggot may be to a great extent prevented, but when once the grubs have penetrated into the centres of the plants, they cannot be destroyed without destroying the crop also. Preventive measures are twofold—using soot, lime, and salt freely just before sowing the seed, and then sowing in drills which have been made 3 inches deep and nearly filled with wood ashes, covering the seed also with this material. In gardens where the Onion fly abounds it is wise to adopt the above precautions, and especially to have the Onion bed as far distant as possible from the site on where a previous crop has been injured. The next, and we consider the most effectual means of saving the crop, is when the plants are growing, and immediately they are attacked with the fly. Close observation and prompt action are requisite in this matter. Had you examined the plants closely during the morning of bright days in May and early June, you would have seen a number of white specks on them like particles of pollen, and if you had examined these through a good pocket magnifier you would have found they were clusters of eggs, which would, as seen, resemble ants' eggs, but more pointed. The Onion fly, *Anthomyia ceporum*, deposits these in thousands, and from these the maggots emerge that destroy the crop. As these eggs, as we have carefully observed, do not adhere to the leaves by any glutinous substance they are easily washed off. In fact they may be shaken off or blown off if needed, but the best plan is to dislodge them with the syringe and foreble applications of paraffin and soapsuds—a small wineglassful of the former well mixed in a gallon of the latter. One good syringing daily so long as the eggs are being deposited will, as we have proved to our own satisfaction, save a crop of Onions. If application of paraffin and soapsuds are not effectual in your case now, you may conclude you did not write to us soon enough for information. We know of no better remedy, but shall be glad to publish the experience of those who have been successful in extirpating the destructive pest in question.

Empress Eugénie Strawberry (J. S. G.).—The examples you have sent of trusses with fruit in various stages, also foliage, enable us to say that the above name is correct, and it follows that the variety which you grow under the same name, the fruit of which "differs materially" in character, is not *Empress Eugénie*. It is probably better, as we do not consider *Empress Eugénie* remarkable for good quality. If you compare fruit with the following description of this Strawberry in the "Fruit Manual" you will be satisfied the name is correct:—"Fruit very large, irregular, angular, furrowed, and uneven; skin of a deep red colour, becoming almost black when highly ripened; seeds small, not deeply embedded; flesh red throughout, hollow at the core, tender, very juicy, and briskly flavoured."

Plum Trees Dying (*H. Mount*).—We have many times, and in different places, observed the foliage of Plum trees assume a silvery appearance, and the branches afterwards die. We have also noticed that the occurrence has been most frequent when bright and dry days have followed a term of wet and dull weather. We have further found that the trees which have suffered the most were those with apparently fine healthy foliage, and that the leaves after the attack were harsh and dry like smooth paper. As we could not find any trace of insects and mildew to account for the condition of the leaves we attributed the cause of injury to sudden and extreme transpiration—a drying-up of the sap, and the consequent separation of the cuticle from the substance of the leaf, and the cuticle being transparent, must necessarily when raised impart to the leaf a silvery appearance. This is in substance what we have more than once stated; but with the object of gaining further information we submitted some of the leaves you sent to Mr. Worthington G. Smith, who is an adept in detecting under the microscope, and delineating things hidden from ordinary observers. His reply is in accordance with our own views on the subject. He found the cuticle raised from the leaves and much torn, only adhering to the veins. He attributes this to the substance of the leaf shrinking or drying up, which seems to show that at one period of growth there was a too rapid formation of leaves, and then the growth ceased, and the too much distended material shrank back and tore itself away from the cuticle, and at the same time made the wrinkles. This is all we are able to say at present on this serious change to which Plums, and occasionally Peaches and Laurels, are liable, as we regret to say we know of no practical remedy.

The Pear-tree Slug (*J. Adams*).—We know quite well what you mean, and you are acting wisely by endeavouring to prevent the increase of this destructive enemy of the Pear. You do not say that it has attacked your trees this year, but refer to its ravages during past seasons. We have never seen trees attacked until August. In reference to this insect Curtis, under the head

Fig. 4.—*Tenthredo adumbrata* (larva state).

of *Tenthredo adumbrata*, says—"Arbiculturists are familiar with a slimy black larva like a little leech, which appears as if glued to the leaves of Pear trees, and which is of very common occurrence in fruit gardens in September and October. From its form and appearance Réaumur called it the slug-worm. At the end of autumn, when it has attained its full size, it somewhat resembles a small tadpole. It has twenty feet, which, however, cannot be seen without dislodging it from the leaf. It does not begin at the edges of the Pear leaf, but gnaws away the parenchyma in the middle, leaving the smallest veins and the epidermis of the under side untouched, so that the leaves attacked are left like the finest lace (see fig. 4). After four times casting its skin it changes to an orange yellow colour, comes down from the tree, and forms a cocoon from particles of soil bound together by a few silken threads. The perfect insect (see fig. 5), according to Hartig, is $2\frac{1}{4}$ lines long, smooth, black, and shining

Fig. 5.—*Tenthredo adumbrata* (perfect insect).

with the horns almost as long as the abdomen; the legs are black, the joints and thighs reddish brown, the wings obscure." The grub is frequently very destructive to wall trees. It appears on Pear trees when the fruit are from one half to two-thirds of their full size, and by destroying the parenchyma of the leaves it prevents the elaboration of the sap, brings growth to a standstill, and the Pears, instead of swelling, drop. Some authors consider that the slug-worm of Réaumur produces the *Tenthredo Cerasi* of Linnaeus; others consider it to belong to the *Tenthredo Æthiops* of Fabricius. The investigations of Gorsky, Westwood, and M. De-

lacour have set the question at rest. They have shown that there are several slug-like grubs, which are developed into insects belonging to distinct species, and that the *T. Cerasi* of Linnaeus does not form its cocoon in the ground, but amongst the leaves of the Cherry. The best remedy is to dust the trees with quicklime as soon as the slimy grub is perceived, and to repeat the dusting as often as may be necessary.

Learning Gardening (*Wild Rose*).—We fear your aspirations are greater than your advantages. You cannot learn plant-growing for exhibition satisfactorily from any books, and we think you will experience great difficulty in gaining the information you need in nurseries. In fact, you would not find it easy to get an appointment in a good establishment. There are hundreds of

persons having far more experience than yourself and much better educated who are unable to get into a nursery and learn what you wish to learn there. A man cannot become competent in the various branches of gardening by working in a nursery for a year or two and reading books, especially if he, like yourself, "cannot lose much time to learn." So long as you entertain such an erroneous notion as losing time in learning you will certainly never succeed in your object. By learning you will be gaining, not losing, time; and it would have been a decided advantage to you had you not been afraid of losing time by learning to write. Such a badly written letter (bad alike in penmanship, spelling, and expression) as you have sent indicates that you have little aptitude for self-improvement. No gentleman would entertain an application from a gardener who wrote him such a letter as you have sent to us. Yet you are twenty-three years of age! If you have had good health during the past ten years you have wasted valuable time that you might have utilised. We cannot hold out any hope that you will obtain a good position as a gardener, since so many able and well-educated men fail to do so, and you might probably do better by seeking some other occupation for obtaining a livelihood. We should not have written so fully on your case for yourself alone, but there are other young men, far too many of them, who have been negligent in self-improvement, yet think they can easily "pick up gardening" and obtain good positions. We warn them against indulging in such visions, incurring disappointment and bringing discredit on a craft in which so many competent, intelligent, well-educated, and in all respects worthy men are struggling to live. To return to yourself, you ask if Thompson's "Gardeners' Assistant" is a good book. It is a very good and comprehensive work on gardening, and can be obtained through a bookseller, price 35s. If you want a less costly, yet very useful, work, the "Cottage Gardener's Dictionary" will be suitable, and can be had post free from this office for 8s. 3d. A book (or, as you write it, a "hok") still more cheap and very serviceable is our "Garden Manual," price 1s. 9d. post free.

Names of Plants (*R. B. T.*).—Both specimens arrived in a greatly withered condition. The one with white flowers is *Deutzia scabra*; the other is one of the dwarf Phloxes, but we cannot determine it without flowers. (*T. H.*)—1, *Achillea Millefolium*; 2, *Hoya bella*; 3, *Agapanthus umbellatus*; 4, *Euphorbia jacquiniædora*; 5, Insufficient. (*W. T.*)—1, *Deutzia scabra*, fl.-pl.; 2, *Calycanthus floridus*; 3, *Spiraea callosa*; 4, *Spiraea opulifolia*; 5, a *Ceanothus*, but we cannot determine it without flowers. (*W. Cranwick*).—1, *Cynosurus cristatus*; 2, *Poa trivialis*; 3, *Aira cœpitosa*; 4, *Dactylis glomerata*; 5, *Holcus lanatus*.

COVENT GARDEN MARKET.—JULY 5TH.

OUR market has been well supplied, and clearances made at last week's quotations. Soft fruit is reaching us in good condition and supply. Trade brisk.

POULTRY AND PIGEON CHRONICLE.

THE SHORTHORNED BREED OF CATTLE.

(Continued from page 547, last vol.)

OUR notes and references to the celebrated Shorthorn breeders of former times will not be complete without introducing the name of the Booth family, who began cattle-breeding at Studley about 1790 with Teeswaters, a breed of cattle of great substance. The fragments of history on which their origin rests are somewhat shadowy and uncertain. Some were found who contended they must have been of Dutch origin, or being only another type of the Holderness; be this as it may, the Teeswaters' capability

had suggested itself to the Brothers Colling. And with regard to their intelligence and fondness for the art of cattle-breeding, the Brothers Booth were, in a later period, what the Brothers Colling were in earlier days. It is likewise certain that no blood has been more widely spread than that of cattle bred by the Booths of Warlaby and Killiby, these being the names of the districts on which their herds of improved Shorthorns were reared respectively, and throughout the United Kingdom no blood commanded a finer bull-hiring trade; and it was from Buttercup, a daughter of Barmpton Rose, and crossed with Booth's Jeweller (10,354), that Butterfly sprang, the chief foundress, with Frederick (11,489) of the Towneley herd, whose victories in the store and fat shows combined are wholly without parallel.

For a period of more than twenty years previous to the year 1865 a large number of Shorthorn bulls were annually to be seen at the Dublin Easter Show. The far greater part of them were of Booth blood. France had been a customer for several years, and the Emperor had not only hired bulls from Warlaby, but purchased thirty females at upwards of a hundred guineas each. Bulls having been gradually distributed into many departments of France, the result of this was noticed in the Battersea meeting of the Royal Society in 1862, especially the effect of the Shorthorn blood upon the cattle from Poissy. Germany has not given such high prices, and has cared less for the best blood. The King of Wurtemberg's agents, however, were in the market as far back as 1824, and the Emperors of Russia and Austria in later years. Lately Sweden came out more spiritedly than she had ever done before, and Spain had bought some of the best Shorthorn bulls to put better points on the Andalusian cattle. The King of Sardinia had also been a purchaser, and so had the King of Holland, whose agents more especially obtained bulls from Yorkshire. These observations apply to the period before 1865. It was, however, to America that breeders had generally looked for their most spirited customers, and this was the case as far back as 1797, when a Favourite (252) cow was sent over, and, returning at the end of thirteen years, became the foundress of the Cambridge Roses. It is also recorded that the first and second Grand Dukes crossed the Atlantic with one thousand guineas on their heads, and it was the rivalry of American buyers which gave such a fillip to prices at the sale of Lord Ducie's cattle at Tortworth in 1853; for here the Americans threw all previous speculation into the shade by giving seven hundred guineas for Duchess 66th. Our own colonies had not been laggards. Van Dieman's Land was the first spot which gave Shorthorns a welcome at the antipodes when it imported bulls in the year 1831. The Boldens introduced them at Port Phillip nine years later.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—This is still divided between drawing the mowing machine, the tedding machine, horse rake, &c., also the carting of hay to the stack, and the odd horse or mule, as the case may be, will work the elevator at the rick. A capital implement is the elevator, which saves the men from the severest work they used to have to perform—viz., the unloading of hay from the waggons or carts on to the rick, especially when the stack was above half made. The other work, which will now be combined or alternated with machinery attendant upon hay-making, is the preparations for sowing the Turnip seeds or drilling the seed with manures; but on many farms we noticed that the land was very foul with couch in the early spring, therefore in various instances where the seeding for Turnips has not yet been done, much labour is still required before all the land can be seeded. Stetching and planting Cabbages and Kohl Rabi will still be continued, but should now be finished, the sooner the better. Upon the strong land farms much land is still foul, and requiring much severe labour by steam culture or otherwise before it can be called a clean fallow for Wheat; and when the horses cannot work on the Turnip land, or after the Turnip lain has been all seeded, the cross ploughings may be continued with advantage. Should the weather prove dry the land should be kept rough, and worked with Howard's self-

lifting drag harrow, so that in case the weather should continue dry enough the land may be thoroughly aerated, and the couch and weeds may die off without further trouble or labour, for we like the Wheat fallows to remain rough if possible until the season arrives for sowing. The old plan of working down the fallows at every ploughing in order to vegetate the weed seeds and then to destroy them is gone out of fashion or usage, as the best farmers prefer to keep the land rough, so that at the time of ridging for seeding it may be mellow and work kindly. With regard to the weeds in the strong soils, we are never safe from their damaging presence, especially where the land requires chalking or liming, unless the Wheat is drilled at 12 inches apart between the lines, in order that in the spring of the year the land may be deeply and effectually horse-hoed between the lines. Instead of using the horse-hoe adapted for working the same width as the drill, we much prefer an ordinary strong horse-hoe with three stout shares like the centre share in general use, as we find that the land can be moved deeper and the weeds cut up better than by the first-named plan of hoeing by the width of the drill. Strong land in the month of March or April after the winter's rains is usually settled down very close, and will not yield to the light implement hoes like it does in the hoeing of spring-sown corn; besides which we often find at the end of April or first week in May that the Wheat will turn off a yellow and sickly colour, which if left alone will only produce a small crop, but when the Wheat is drilled at 12 inches, and the three hoes are used deeply in the soil, the surface is broken sufficiently to give the Wheat plants a fresh start in life. We have always found this to alter the colour of the blade to a deeper green and a better crop. In all cases where the cultivation of the land is behind the proper season the home farmer should not depend upon horse labour only, but in those cases where steam power is not carried out by the necessary farm arrangements it should be hired, as it now can be done in almost every district throughout the country.

Hand Labour.—This is now required in connection with carting and stacking the hay. Men should also be employed, especially if the weather is showery and not fit for hoeing root crops, to use the scythe in the meadows and pastures where they have been fed off by cattle to mow down any rushes which were refused by the stock. This will weaken their future growth very much and allow the young grass to take their place. It is desirable also to cut off all the bunches of grass refused by the cattle, as these often encourage ergot, so injurious to dairy cows. What we call the bunch rushes, and tufts of coarse grass called hassocks, should not be cut off with the scythe, but be taken up with the turf-cutter or sharp-cutting spade and be burned into ashes; this if carefully done will weaken them much for a number of years and allow the better grasses to succeed. The droppings of fattening cattle and dairy cows should also be spread occasionally, or otherwise removed to a heap of earth, to be made into compost for dressing the pastures.

Live Stock.—This has been, and is now, a fine season for cattle fattening in the pastures, as well as the dairy cows. This, however, although abundance of grass is available, should not deter the home farmer from giving both kinds of cattle not less than 4 lbs. of cake per day, for the advantage will not only be found in the stock, but in benefit to the pastures as well. We prefer the best St. Petersburg oil cake for the fattening beasts, and decorticated cotton cake for the dairy cows. We have recently inspected a farm which we had seen three years previously, and we notice an extraordinary improvement in the pastures both as to herbage and bulk of the crop. This is owing to the dairy cows receiving cake daily throughout the year, and also to the application of 4 cwt. per acre of bone superphosphate. Sheep, either fattening sheep or ewes and lambs (if the lambs are weaned), whether feeding on the pastures and park lands or on green crops or grass on the arable land in very sunny weather, gather together under trees or hedges for shade, and there they leave their droppings both liquid and solid, which we contend are entirely lost. Our own plan was to fold the stock in a dead fold from ten o'clock in the morning until four o'clock in the afternoon, shifting the fold daily and giving them whatever trough food they were allowed in the fold; we thus saved the manure. But to protect the animals against the fly they are, of course, to be dipped and treated with fly powder and the usual composition for the purpose. In cloudy or showery weather when the animals do not congregate they may be allowed to roam on the pastures and fields in the day as well as at night.

POULTRY AND PIGEONS

RINGDOVES.

WITHOUT travelling beyond our province we think we may devote a column to these pretty pets. There is often a spare corner in the pigeonry which may be wired off for them, or they will even live in harmony with the Pigeons. Some little management is, however, necessary to make them do this, and we should

prefer to keep them apart, if in confinement, or to let them fly at large. As the term "Ringdove" has been variously applied, we may as well say at once that we do not mean the larger British ringed Turtle Dove, but the little pinkish grey Dove with a black ring round its neck, otherwise called the collared Turtle, well known in cage and aviary, but seldom seen at liberty in this country. So sweet and soothing is their note, and so elegant their flight, that any true lover of birds may well long to have them at liberty in a garden, which is by no means an impossibility.

Our fancy for them carries us back many years in recollection. We have at intervals kept them under various conditions, and will briefly give our reminiscences of them. We first recollect Ringdoves in the aviary of a rich and eccentric lady; her method of keeping them, however, we do not entirely recommend to our readers. Doubtless there had been small beginnings of her fancy, but in the days of our childhood it had somewhat outgrown the limits of reason, and we should think of pleasure too. Her flock then was supposed unvaryingly to consist of three hundred. In winter they lived luxuriously in rooms at a bailiff's house; towards summer they were removed to a gigantic aviary, the construction of which must have cost a perfect fortune. The interior of it was a substantial wooden house, fitted elaborately with perches and every convenience for nesting. The external wire enclosure was of immense size, not unlike several of the western aviaries of the Regent's Park Gardens thrown into one; it was partially roofed and partially covered with arched wire like a bird cage. Perfect groves of shrubs were planted in it, and a bird flying from end to end might well believe itself at complete liberty. The spring and autumn removals of the Doves were a great event in the establishment, for their summer and winter quarters were distant at least half a mile. They were carried in portable cages made on purpose, with handles at each end for the bearers, in palanquin fashion. Near at hand their cooing must have been somewhat overpowering; we can well remember that to us more than half a mile from their summer residence it sounded soft but somewhat melancholy. Of course when the flock had become so numerous eggs were destroyed in quantities to prevent its further increase.

The end of this dovecote was somewhat sad. A sportsman, but not a lover of birds, succeeded to the place and property. The aviary was required for laying Pheasants. The Doves were suddenly turned adrift. Had only a little kindness and care been bestowed on them we believe they might easily have been acclimated in the sheltered groves round their former abode, but they were left to chance. They flew into the surrounding gardens and thence dispersed about the park, not a small one, and filled with suitable shelter for them; thence they wandered in search of food into the cornfields and country beyond. Every idle urchin hunted them. They were caught in troops, in pairs, and singly, caged in thrush cages, and penned in rabbit hutches. For a few months they were to be seen hung out at many a cottage door, and were to be bought cheap of low bird-vendors in the neighbouring towns. In a year's time all were gone, and the country people only talked of the days of the Doves at Park. This complete dispersal was, of course, due to the utter neglect of them, or rather we believe to the fact that their new owner really wished to be rid of them entirely. Far kinder it would have been to give some away and kill the rest that were not required. On the other hand, we have often known them, as the author of the charming "Dovecote and Aviary" calls it, play at liberty in gardens. They are, we believe, natives of North Africa, Asia Minor, and the southernmost parts of Europe, and so prefer a warmer and drier climate than our own. We have seen them in perfect happiness flitting about among the exotics of the Borromean Islands in the Lago Maggiore, and in other of the famous Italian gardens. In those of the Vatican we fancy there were some at large. There certainly in the time of the late Pontiff was a large open aviary full of them at the entrance to the poultry yards. We have seen them, too, in English gardens, generally among Pine trees. Once during a visit near Bournemouth in frost and snow we used to watch them flying about in perfect health, sunning themselves in the morning and coming down for crumbs on to a terrace walk. Their only shelter was a pole house.

They must be gradually accustomed to this kind of life. We remember to have seen them breeding well in a Middlesex garden. They had been reared in a well-appointed aviary, the doors of which were thrown open in early summer. If this be done the risk of cats or other vermin getting in is very great. We should prefer the plan that we once adopted. The old favourites were not turned out, but some young birds through their first moult were hung up in a cage in a Pine grove. The top of the cage was covered with waterproof stuff, and there they lived till

quite accustomed to their surroundings. Then the door was thrown open, and they quietly flew out. The Pine grove was in an extensive poultry yard, enclosed with netting 6 feet high. This afforded some protection from prowling vermin. By degrees the Doves became very strong and fleet on the wing, and though they often flew far beyond their enclosure, they always returned at night to roost on one Pine branch.

There is little difficulty in rearing Doves. It should be remembered that if kept in cages they require some salt, grit, and mortar to help their digestion. So happy and contented are they that these little necessities are often forgotten, simply because they seem healthy without them, but they would not be long-lived. Dixon speaks of one as alive and well which had been caught eleven years before. We have one which was found exhausted in our garden eight years ago. The best food for them is wheat and millet; occasionally some maize and hemp may be given for a change, and in hot weather rice both raw and boiled. The cock and hen sit by turns on the nest, and their eggs hatch in fourteen days. The young ones grow very fast, and if their abode be tolerably dry are hardy enough. In a damp place, or in very bad weather, they sometimes fail at about a week old. Strangely enough the parents then often turn one out of the nest to die, and give their whole warmth of feather and affection to the remaining one. We have sometimes been in time to save the outcast by restoring it at a fire and then returning it to the nest. One caution may be given—Doves are peculiarly likely to be in-bred, they are not of sufficient value for people to take trouble about mating them. In the case of such semi-acclimated foreigners, in-breeding is specially detrimental to hardihood. The fancier who wishes to succeed in having Doves at liberty in his garden must from time to time make exchanges or purchases from another stock. They are the earliest of birds, and their sweet plaintive note is to be heard at dawn, or occasionally all night long when the moon is bright.

Nearly allied to them is a somewhat darker sub-variety, commonly called African, and a pure white one. They will interbreed, and their produce crossed is almost always of the commoner ringed type.—C.

OUR LETTER BOX.

Bird's Neck Featherless (C. A. J).—The cause is a defect of wholesome and green food. The remedy, good feeding and plenty of green food; at the same time rubbing the bald place with mercurial ointment, and giving a five-grain Plummer's pill every second day for a week. Separate the bird from the others, or they will probably aggravate the evil by pecking at the affected part. The Ducks referred to by our correspondent are not, we think, his own property, but we will endeavour to ascertain.

Rearing Guinea Fowl Chicks (T. S.).—Chicks of the Guinea Fowl require food soon after they are hatched. Their troughs should be constantly supplied, for they die if kept without food for three or four hours. Have the mother under a coop in a warm corner of the garden, and facing the south. Egg boiled hard, chopped very fine, and mixed with oatmeal is their best food. At the end of six weeks, if hatched under a Bantam or Game hen, they may be allowed to range with her, and be fed at the same time and on the same food as other chickens.

REMARKS.

25th.—Rain in early morning; fine, bright, and warm.

26th.—Rain at noon, with slight thunderstorm 0.20 to 0.25 P.M.; afternoon bright, evening overcast.

27th.—Fine, bright, and warm.

28th.—Fine and warm.

29th.—Overcast, storm-like, and close.

30th.—Cloudy and cool, latter part of day much brighter.

1st.—Very fine, calm, summer day; lunar halo after 11.15 P.M.

A generally fine week; temperature almost exactly the average.—G. J. SYMONS.

16th	SUN	6TH SUNDAY AFTER TRINITY.
17th	M	
18th	TU	Leek Rose Show.
19th	W	Luton Show.

ONCE MORE AMONG THE ROSES.

AFTER travelling all round the continent of Africa, after visiting the lovely island of Malta, passing through Egypt, and staying a month in the most beautiful island in the world, Ceylon; after visiting the Antipodes, and being very glad indeed to get away from them, I find myself in Old England just in time for the Palace Rose Show, amid my old favourites. Oh! what a lovely sight it was to see the well-known green boxes of Messrs. Cant, Cranston, and Paul, filled with the most glorious blooms, so fresh and so charming.

The Show itself has been reported, but let me here express my sympathy with my old friend Mr. B. R. Cant for having his fine collection of seventy-two blooms disqualified. It was a hard case to have a duplicate of such an inferior Rose as Madame Nachury, one bloom of which would mar any box, and for this Rose, accidentally placed, to disqualify such a seventy-two was indeed a misfortune. His Teas were most lovely, his dark Roses superb. Prince Arthur, Louis Van Houtte, Xavier Olibo—all the old favourites, were well to the front. His Marie Van Houtte has only once been equalled (never excelled) by my friend Mr. Baker at Exeter. And this reminds me to say how much I regretted the absence of the two great amateurs, Mr. Baker and Mr. Jowitt. The former has lately suffered the most severe domestic loss, which all rosarians will, I feel sure, deeply deplore. Mrs. Baker was such a good judge of a Rose, such an invaluable friend at staging, that I do not know when my old friend will have the heart to show again. Mr. Jowitt has lately changed his residence, and now lives by the sad sea waves in remote Tenby. A Rose show without these two great rosarians must suffer, and there can be no question that so far as the amateurs were concerned there was a great falling off. Mr. Cranston, though he was placed second in seventy-two's, yet showed the most even stand in the Show. It was a great pleasure to see him and Messrs. Paul and Cant having such a close fight. And now to the greater Show—the event of the season in the Rose world.

I think it will be granted that the metropolitan Exhibition of the National Rose Society was one of the largest and most comprehensive ever seen. I do not think I can add the “finest,” because I have been at shows where the Roses exhibited both by nurserymen and amateurs were superior to those at the Show in question; but still there were points of interest which were novel and exceedingly gratifying to rosarians.

I must say that the thanks and congratulations of all lovers of the Rose are due to the Committee of the National Rose Society. It seems to me that no class of Rose-growers has

been omitted. We find both the lordly seventy-two, distinct, of the great nurserymen and the humble six of the suburban rosarian. Very good indeed were these last-named Roses, as were also the, what I may call, “compensation classes,” because the Committee gave prizes in a class for those who had not previously won a prize, and judging by their exhibits I should imagine that the only reason why these amateurs have not won a prize before was because they had not previously shown Roses.

The sight of the Show was undoubtedly Mr. Cant's seventy-two, and the grandest bloom of the Show, of the year, and I should say also of the century, was his bloom of Souvenir d'Elise Vardon (Tea), which occupied the place of honour in his seventy-two, and gained the proud position of being the premier Tea in the Show. Mr. Cant's Roses were quite equal, and in Teas superior, to his beautiful stand at the Palace.

I think, perhaps the great feature of this Show was the display of my favourite Teas, and here I venture to think the amateurs bore off the palm. Miss Watson, the clever forewoman of Mr. Prince, when gloating over her own lovely box of Teas, would not agree with me. But after judging the seventy-two and forty-eight trebles I had nothing to do but examine the Roses, and I gave great attention to the Teas; and granting that Mr. Prince and Mr. Cant had magnificent stands, I still think they were equalled by some of the amateurs, while the rest of these amateurs' boxes were far superior in every way to the rank and file of the nurserymen's Teas. It really was quite sad to see so many beautiful stands passed over, which in any ordinary show would have been sure of a good prize.

In the amateurs' class for twelve Teas Mr. Cuthell, who was placed second, was in my opinion, and that of a great grower and still greater judge, indubitably first. I feel sorry for Mr. Cuthell, and only hope that he will continue to show such Roses as he did on Tuesday for many years, for he gave me and many others very great delight. His Marie Van Houtte, Jean Dueher, and other yellow Roses were superb. In one box a lovely bloom of Amazone was to be seen, also charming examples of Anna Ollivier, Comtesse de Nadaillac, and Mons. Furtado. These weak growers are rarely seen in perfection. Madame Lambard was represented in many boxes, and I am glad to see what an excellent place this charming Tea is taking. The gain to our Teas is very great, as Comtesse de Nadaillac, which approaches it most nearly in colour, is so difficult to grow, and still more difficult to purchase, that the advent of a Rose of similar features is to be gratefully welcomed.

The idea of giving a class to the ladies for an arrangement of Tea Roses was an excellent one, but how could they bear to cut all those lovely Teas for the bare chance of a prize? Mrs. Hawtrey, who was not placed, had some exquisite blooms, including the only examples I saw of Céline Forestier. Some ladies showed forty or fifty Teas, which must have been greatly missed at home. Among Hybrid Perpetuals the Rose that has advanced most in popular favour since last I had the pleasure of writing on Roses is the lovely soft satin pink Madame Gabriel Luizet. The bloom in Mr. Cant's seventy-two gained the prize for the premier Hybrid Perpetual of the Show. A. K. Williams was not shown quite so fine as last year.

Those great amateurs, Mr. Robert Baker and Mr. Thomas Jowitt, were unrepresented at head quarters, and their boxes were much missed by their sorrowing friends, but in their

absence many new comers have deserved well of their country. Mr. Whitwell, that plucky rosarian from Darlington, has come from the far north and defeated us all, carrying home in triumph the valuable epergne which formed the challenge trophy for thirty-six. "It will probably be seen no more," said, with a sigh, a well-known witty nurseryman; "it will most likely go down some coal pit and remain there." It strikes me that when we go over to Darlington we shall have to look out if we are to maintain in the absence of the two gentlemen before named the prestige of the south.

The writer of the article on the Show in the *Standard* seems to be under the impression that the "young Society," as he calls it, has always been connected with the Crystal Palace, and deplores the severance. Will he be surprised to hear that we are by no means so young, and that nearly a quarter of a century ago we held exhibitions at St. James's Hall, at South Kensington for many years, and only twice held our Show at the Crystal Palace? For a really good and accurate account of a Rose Show let me recommend your readers to peruse that paper. The reporter's opinion of Marie Baumann, and his description of Marie Van Houtte, are really so good, and will doubtless commend themselves so much to Mr. Hinton, that I trust that gentleman will at the next election of Roses send a polling paper to the reporter of the *Standard*.

Yes, I have seen *Allamanda Hendersoni*, *Ixoras*, *Dipladenias*, *Hibiscus*, growing like weeds in Ceylon; I have seen the most glorious tropical flowers and foliage, but sweetest of all and loveliest of all in my eyes are the Roses of Old England. Long may the queen of flowers flourish!—WYLD SAVAGE.

VINES AT LONGLEAT.

(Concluded from page 485, last volume.)

DISBUDDING AND STOPPING.

As soon as the Vines have fairly started into growth in the spring some of the shoots will require removal. This will cause them to bleed a little, and I used to wait till some of the leaves were full grown before commencing this operation, when some of the shoots could be removed without any bleeding taking place; but on the whole I find there is more lost than gained by deferring it, and I recommend it to be done as early as possible after growth has started. With vigorous Vines the shoots should be 15 to 18 inches apart on each side, and where more than one starts from the same spur the choice should be given to the one nearest the main rod if it is healthy.

The next operation is to remove some of the bunches as soon as they are visible. Two or three will generally show on each shoot by the time it is an inch or two in length, and one of these only should be left, preferably the one nearest the rod if it is a good one.

A few days later stopping the shoots becomes necessary, the strongest first, leaving the weak ones to grow unchecked for the present. But it must be the merest point that is taken out, altogether not larger than the smallest pea, and this requires considerable experience to do it nicely. The leaves, excepting those at the base, at this time are scarcely large enough to be called leaves, but the experienced eye can count their number, and they should be left according to the amount of space between the rods. Not less than two beyond the bunch is sufficient, and four is better if experience has taught there is room for that number to develop without any crowding. Small shoots (sub-laterals) will start from the axils of these bearing shoots, and they should be stopped and kept to one leaf; some of them indeed near the upper end of the shoot may be removed altogether if the foliage is likely to become too much crowded, but two or three nearest the main rod must be taken care of, or the eyes will

start which are required to remain dormant till another year.

The next thing to be decided is the number of bunches to be left on each rod. At present there is one on each bearing shoot or lateral, and if the Vines are in tolerably good health, and there is no prospect of the fruit reaching a large size, say not more than an average of three-quarters of a pound to the bunch, this number will not be too great; on the other hand, if there is a likelihood that the bunches may be made to average 2 lbs., one bunch to every other lateral will be sufficient, but a great deal depends on the quality of growth the Vines make, also on the space there is for the foliage to develop, and something too on the varieties. Mrs. Pince, which has comparatively thin foliage, requires a greater area of it in proportion to the fruit, while Alicante, which has leathery-like foliage, is the reverse of this. Most of the surplus bunches should be removed before the flowers commence to open.

THINNING THE FRUIT.

From ten days to a fortnight after the first flowers open on the Hamburgs thinning may be commenced. All the smaller berries and unfertilised flowers are removed first from a bunch; next the remaining berries, if they are so close that the thick end of a pencil cannot be pushed in between them, are thinned out sufficient for that, and the whole crop is examined in this way, by which time it can be seen which are likely to be the best berries, and the regular thinning is commenced in earnest. Preference is always given to the upper berries on a branchlet, and of those on the top of the bunch nearly all are left; others are thinned so that they average about half an inch from berry to berry. It is not a good plan, however, to insist on their being all at regular distances apart. The best berries should be chosen, and if sometimes there should be an inch of space and then two or three berries closer together, they will as they grow generally push one another into their proper places. I find that with young hands there is a great anxiety to have the berries regularly placed on every bunch, and to secure this many berries are left which are not likely to swell to the largest size. The bunches I thin myself often look very imperfect at first, but they alter before the season is over. The thinning of the late Grapes comes next to the Hamburgs, that of the Muscats being left to the last, and I do not think there is any advantage in thinning them till they reach the size of a pea. Large bunches of all varieties are tied out in preference to cutting them down to half their size.

After all have been gone over once they will require looking over again, and nothing but practice will teach exactly how much to thin them, as some Vines will make much longer berry-stalks or larger shoulders than others, and of course the longer the footstalks the less need of thinning. Late Grapes which have to be kept till the following spring are thinned considerably more than those which are to be used in autumn, but no bunch should ever be so much thinned that when it is cut and laid on one side the berries will roll out of their places.

SHANKING AND ITS PREVENTION.

Shanking is caused by an imperfect or insufficient assimilation of food by the leaves. It may happen

when the Vines are growing in the richest of borders, and it may be prevented when they are in the poorest. The leaves of a plant are not only its respiratory organs, they are also the organs by which digestion is mainly effected, and it is of no more use to apply rich manure to a plant, the foliage of which is unhealthy or insufficient, than it is to feed a bedridden and dyspeptic person with turtle soup. The way to prevent shanking, then, is to follow the instructions I have given for the production and sustenance of healthy foliage. If the foliage suffers from scorching or the ravages of insects, especially red spider, it cannot perform its work efficiently, and of course if the soil in which the roots are working becomes too dry at any time the effect will be similar. In mild cases of shanking the backwardest and most imperfect berries only suffer, but in severe cases whole bunches will go at once. There is no cure during the current season for this, but when it happens the cause should be sought out, and steps should be immediately taken to prevent its recurrence.

MILDEW AND ITS CURE.

As far as I know Vines are always liable to attacks of mildew. It is not, like shanking, a trouble which we create for ourselves; it is, however, most likely to come when the soil is dry and the atmosphere humid, and these conditions favour its rapid development. A constant look-out must be kept for it, and when it does appear an immediate check must be given. It generally comes first in the shape of small round mealy-looking spots little larger than the head of a pin, and scarcely visible to any but the most practised eye, but if left unchecked it will in a few days spread over a whole house. Sulphur is the most effectual remedy. The pipes are made hot while the ventilators are open; a wet rag is wiped along a couple of yards at a time, and sulphur is dusted on while the pipe is wet from a piece of muslin rag or hexagon netting doubled. In the evening, after the sun heat is mostly gone and the pipes have been made as hot as possible, the house is closed, when a bluish mist may be seen to rise from the heated sulphur, such as will make one's eyes smart, and will in the course of two hours kill all the spores of the mildew. It is scarcely safe to use such a severe measure before the Grapes have grown to the size of a pea, nor yet after they are ripe. In these cases sulphur can only be used locally by dusting it on to the parts affected; but sulphur tells tales, and although I am sometimes obliged to use it on the pipes, it never remains there more than forty-eight hours.

KEEPING THE FRUIT.

All fruit should be cleared off the Vines by the middle of January, and the Vines should be immediately pruned. The conditions for keeping it after cutting are the same as those named for keeping it on the Vines—viz., an even temperature with constant ventilation. About 45° is the temperature I generally aim at, but in a more northern latitude I should prefer 5°, or even 10°, lower. The best general advice is perhaps to have a little warmth and a current of air constantly. The stems should be inserted in the bottles or tubes containing water as quickly as possible after they are severed from the Vines, and they will do as well upside down as any way. No charcoal is needed, as the Vine stem itself, so long as it touches

the water, will keep it perfectly sweet; and it is unnecessary to close up the space in the neck, for the presence of water is not inimical to the keeping of the fruit here any more than in the vinery. A very dry atmosphere indeed should be avoided.—WM. TAYLOR.

NOTES ON THE AURICULA.

FROM all quarters we hear that the day of the Auricula has come, and that new growers are taking it on hand all over the kingdom. Much attention has always been given in this Journal to these lovely spring flowers, and now that they are more generally grown and better understood it is only fitting that notes should be increased on certain points in its cultivation. As one glad to pick up hints by the way, I am always pleased to see anything from experienced growers; and though I can claim only to be a young grower, yet the subjoined notes may be of interest to some who have been puzzled by conflicting teachings.

The operation of potting is of importance just now, as autumn flowering is held by some to be affected by potting early in the summer or later on. Practically I do not see that the time of potting has any appreciable effect on the plants throwing up flower trusses in autumn, and when I state the conditions of growth of the Auricula this point may be more clearly understood. With the lengthening of the day in earliest spring the Auricula commences growth—top growth first, and then activity at the roots commences. Up till the time the flowers are developed the root-action is merely an extension of the roots made the previous season; but about the time of flowering, there being a noticeable difference in different varieties, fresh roots are protruded from the neck of the plant, and these roots may be said to take on themselves the main burden of the maintenance of the plants. It is very plain that if the plant is to have the full benefit of the fresh soil the earlier it is potted the better, for by August root-action is virtually at a standstill, and plants left later than the beginning of June do not benefit by the repotting until the following spring.

Autumn-flowering, I am much afraid, is greatly dependant upon the weather, and to a great extent uncontrollable. What appears to me the best means of at least mitigating this evil would be to keep the plants as cool as possible during autumn the season they are so susceptible to a term of genial weather. If the winter is open, as last was for instance, the plants may be kept very dry at the roots without harm, and under such treatment the trusses do not come too early. From the time growth commences in spring until August, however, insufficient water is hurtful.

As compost I like a good loam, with some fresh but dry manure rubbed fine, in the proportion of one-third to one-fourth of the loam. I use cinders for drainage—a much better material than broken pots. The soil is pressed very firmly; in fact the firmer the soil the better the plants seem to thrive. The collar of the plant should be kept well down in the pot. Tap-roots I find are best dispensed with. The younger roots are the food-purveyors, and, believing that, we cut the "taps" pretty hard in, and use small pots, most of our flowering plants being in 3 and 4-inch pots, a very few extra strong well-rooted plants being in 5-inch pots. Offsets are best left on the parent plants until they are strong; small offsets are easily enough brought on with care, but I consider it is better to leave them as a rule until they are fit to bear the severance without hurt. I have just turned out some plants repotted four weeks from the time of writing, and I find them rapidly forming a ball of roots; had they been left till now how different the result would have been!

—A YOUNG GROWER.

THE ALEXANDRA PALACE ROSE SHOW.

THIS Show was held on Saturday last, and was far from being equal to former exhibitions held in the same building; indeed, in comparison with the National Rose Show at South Kensington it really was disappointing to see such vacant spaces and such relatively poor exhibits. There were, of course, exceptions, for such great growers as Cant, Cranston, Paul, and Turner were represented; while Mr. Whitwell from Darlington, Mr. John Wakeley, and Mr. Pemberton showed very fairly; but after all it can only be properly described as a ghost of a Rose show! Mr. Cant was again first in seventy-two, also in forty-eight trebles and twenty-four singles, followed by Messrs. Cranston & Co., and Paul & Son of Cheshunt. Mr. Cant's Roses showed signs of the inclement weather we have been lately having, but although they were inferior to those shown by him at the National yet his stands were very good. His best blooms were A. K. Williams, Baronne de Rothschild, Niphotos, Madame Gabriel

Luizet, and Marie Cointet. Duke of Edinburgh was shown exceedingly fine in colour in the amateurs' stands, being bright scarlet; Maréchal Niel small but very good in colour, and Général Jacqueminot. Mr. Cranston's Roses were inferior to those he showed at Kensington and Sydenham, bad weather having again been the cause of this falling-off. His best blooms were Baronne de Rothschild, A. K. Williams, Auguste Neumann, Louis Van Houtte, John Stuart Mill, and Charles Lefebvre. Messrs. Paul & Son's most noteworthy blooms were Duchesse de Morny, a most lovely treble; Duke of Edinburgh, A. K. Williams, Comte de Raimbaud, Marie Baumann, Prince Arthur, and Prince Camille de Rohan. Mr. Charles Turner also showed some fine trebles, including Sénateur Vaisse, Lord Macaulay, Abel Carrière, Alfred Colomb, Madame Lacharme, and that superb Rose A. K. Williams.

In the amateurs' class for thirty-six Roses Mr. Whitwell was the premier exhibitor, his fine blooms showing to advantage on black velvet stands. Mr. Davis was second, and Mr. Hollingworth third in this class. Mr. Whitwell was also in the premier position with twenty-four trebles. Mr. Pemberton was first in the classes for twenty-four single blooms and for twelve Teas, followed in the former class by Messrs. Mitchell and Wakeley, and in the latter by Mr. Harrington. Mr. Pemberton had a superb bloom of Belle de Bordeaux, which I suppose is hardly a Tea, also Perle de Lyon, Madame Lambard, and Madame Bravy. Mr. John Wakeley had a grand stand of twelve Roses; his Marquise de Castellane, Duke of Edinburgh, and La France did a great deal towards winning for him the first prize. Mr. Pemberton's excellent second-prize box included fine examples of Marquise de Castellane, Baronne de Rothschild, Alfred Colomb, Horace Vernet, and Fisher Holmes.

One of the features of the Show, and a very pretty one too, was the competition for bouquets. Prizes were given for white, dark red, yellow, mixed, and crimson Roses. Mr. George Paul had the best bouquets. His mixed one was so very lovely that the remembrance of it will linger with me for a long time. Messrs. Kinmont & Kidd were also prizewinners.

The classes for boxes of one colour were very fairly filled. Mr. Cant had a glorious box of dark Roses. The nurserymen's Teas were scarcely up to the mark. Mr. Prince and Mr. Mitchell did not exhibit, but Messrs. Paul, Cant, and Turner did. Mr. George Paul's Teas were small but very lovely; Mr. Cant's very good, but not equal to those previously shown by him this season. His Niphotos, however, was very fine, and his blooms of Maréchal Niel, Caroline Kuster, Madame Lambard, and Catherine Mermet good. Mr. Charles Turner showed a superb bud of Madame Lambard, which was quite different in colour to Mr. Cant's, being more like Comtesse de Nadaillac or Catherine Mermet. This Rose is evidently very uncertain as to colour, but is a most welcome addition to our Tea Rose lists. For thirty trusses of white Roses the prizes went to Messrs. Cant, Turner, and Paul.

There was only one entry for the modest class of one thousand Roses. Mr. George Paul did his best to fulfil a most absurd demand. Some stands and baskets were staged by Messrs. W. Paul & Sons and other exhibitors.

The weather was very bad, but perhaps it was a good thing that the rain descended and the sun kept in the background, as there was not the least shelter for the Roses except the glass roof. Confusion was everywhere. The clerk who had to write out the list of the prizetakers was new to the business, and made many mistakes. It was high noon before the Judges commenced their work. One or at most two policemen in vain tried to prevent the general public breaking in during the judging, and at one o'clock there was scarcely a prize card placed upon a winning box. I have endeavoured to give your readers as fair a description of the Show as I could under the most difficult circumstances; but at the time of my visit I was under the impression that a reporter from the Journal office was present, so that writing from memory I am unable to give a complete list of all the prizetakers.—WYLD SAVAGE.

STRAWBERRIES—MODES OF CULTURE—MISTAKES.

WHEN my notes, published on page 1 last week, were penned, the articles on page 506, June 22nd, had not appeared, or I should not perhaps have felt it necessary to write on the subject of Strawberry culture. Your correspondents, "SINGLE-HANDED" and Mr. Bardney have, however, saved me some trouble. I intended in effect saying much of what they said, and I have now only to comment on their remarks, and emphasise, under certain conditions, the value of the practices they have recommended for raising plants, referring also to some methods of culture that are adapted to special soils and districts.

Against layering runners in pots I have nothing to say, although I can grow Strawberries quite well by a simpler system. Layering in turves, as "SINGLE-HANDED" observes, has objections, but it also has advantages. When rightly managed turves do not dry to a serious extent. The pieces $3\frac{1}{2}$ inches square placed nearly close together, with leaf soil placed over them and worked between them, form splendid receptacles for young plants, and do not need half the watering that runners pegged in small pots do. Your correspondent, however, suggests the turf plan has

other faults. This is quite true, and one may be pointed out so that others may avoid a mistake that I once made in adopting this system. There were visible a few roots of couch grass, but it was thought all these had been drawn out of the square pieces of turf. The next season proved that this was not so, and the mixture of couch and Strawberries was not a result to be proud of. But worse than this, the turf contained Dandelion seed, which was good of its kind, for it germinated freely, producing thousands of plants. Turves then certainly have "faults," and it is easy to make a mistake in raising something else besides Strawberries in the fertile squares in question; but there is a remedy.

Without a charred heap of rubbish, prepared annually, it is certain that my failures in fruit and plant culture would have been more numerous than they are. It is the practice to collect rubbish of all kinds in the autumn—the refuse of the kitchen garden and pleasure grounds—leaves, weeds, hedge-trimmings, ditch-scourings, and clay. A huge fire is made that lasts for weeks; when in full glow it is cased every night with turves, which are thus completely scorched. These charred turves form the most valuable of all soil for general potting purposes. Nothing equals it, and nothing equals these now weedless turves for establishing Strawberries in, but to have them in the best possible condition they must be doctored. This is a very simple process. They are of course as dry as dust, and there is only one way of moistening them quickly and thoroughly, and that is to place them in a tub of water. And why not mix a spadeful or two of guano in the water—soak turves, in fact, in liquid manure? Let anyone try this method, and then say all they can against it. Let them insert Strawberry runners in such doctored turves, and they will have no weeds but splendid plants, sturdy in growth and of the deepest green. They will admit then that if the turf system has faults it also possesses advantages.

This is the best of all modes I have tried for raising Strawberries in a dry district. In a wet one the method of cutting off the runners as soon as they show rootlets and dibbing them in a rich bed of soil and manure, as if provided for pricking out Celery plants, is quicker, simpler, and good. If anyone asks why this latter plan is not equally good for dry localities, he will afford evidence that he has not experienced the anxiety of waiting for rain for weeks, even months together, watching plants of all kinds spoiling because they cannot be planted, while it would be almost certain death to them if disturbed. In districts where the soil is thin and light and periods of drought occur, these square turves are of enormous advantage in preparing Strawberries, as the plants can be kept growing in the most satisfactory manner for weeks if needed until the weather is favourable for planting, the turves being arranged in a convenient position, not packed closely together, but the spaces between filled with rich soil, and liquid manure will do the rest. My advice, then, founded on experience, is that those living in cool districts where summer showers are prevalent may adopt the plan advocated by "SINGLE-HANDED;" but in dry localities there is risk of the plants being injured, either by remaining in the nursery bed too long, or being removed in unsuitable weather for planting. It may be urged the turf system "takes time." Yes, it does; but is not the time of two days well spent when success follows? and is not the labour of less time wasted when failure ensues?

Mr. Bardney has advocated growing a few young, early, and healthy plants in a convenient position, specially for producing runners for propagation. Sounder advice than that was never penned. Obtaining runners in a haphazard manner from between the rows of bearing plants, which are more or less exhausted by the crop, is a bad beginning in Strawberry culture, and the initial cause of many failures. It is important that the plants for producing runners be obtained from a fruitful stock, as some plants are essentially unfruitful, and it is certain their nature is perpetuated by propagation. This I have proved by a careful experiment extending over a period of six years.

Another point of practical importance is to grow those varieties that are found to succeed best in your own garden. Strawberries are capricious, and this is the sequel of the widely different estimates that are given by different cultivators on the same varieties. A few years ago I had a remarkable crop of President. Runners were requested by visitors, and in due time supplied—strong, fine, early runners, but in two instances to my knowledge these gave no results, and after a full and disappointing trial the plants were destroyed. The soil was too good for them. They grew enormously, but produced little fruit, and the majority of this malformed. Similarly I have obtained from an undoubtedly fruitful stock plants of La Constante, Rivers' Eliza, Wonderful, Cockscomb, and Sir Charles Napier, but by no method of culture could good

crops be obtained from them, and during a three-years trial they proved to be cumberers of the ground, and were rooted out.

I would dissuade no one from trying new varieties, but it is necessary to urge upon young gardeners especially the desirability of having, in addition to the trials, a sufficient number of plants of proved kinds for meeting the full demand for fruit. Tempted by glowing eulogiums, and by, it may be, seeing a wonderful crop of a new variety, many cultivators have made mistakes by planting largely of the new, and limitedly of their own proved useful old sorts. I have been under the spell of the novelty fascination, and found myself a victim to its charms. If Vicomtesse Héricarte de Thury thrives with you, keep it; if President always bears, do not discard it; if Sir Joseph Paxton affords good crops, retain it; if Keens' Seedling bears abundantly, continue it—at least, until you have got the true Admiral Dundas, and it is found to be superior. Try also to make either British Queen or Dr. Hogg grow. The latter will often succeed where the former fails, and in such a case grow the best only. As late sorts Frogmore Late Pine is the best in quality—when it can be had. Where it fails the hardier varieties Eleanor or Elton usually succeed, and must be grown even if they are acid. Loxford Hall Seedling I have not tried. James Veitch is large, but too pale and sour. A new variety I have tried this year (Forman's Excelsior) is very promising. It is as early as the Vicomtesse, nearly as large again, and good in colour; yet some of the fruits are hollow, and the flavour is, well—"not bad." Sir Charles Napier is too tender for cold wet districts.

With the Vicomtesse (syn. Garibaldi), President, Sir Joseph Paxton, Admiral Dundas, Dr. Hogg, Eleanor, and Elton, and by planting the earliest in warm positions and the latest in cold situations, I can have an abundance of acceptable fruit over the longest period in a district where the soil is rather light, the summers often dry, and the winters usually severe. In fact, in my experience those varieties succeed almost anywhere, except, perhaps, President, which sometimes fails by growing too exuberantly in rich strong soil.

I have a little to add about planting, but must not add it now, or the Editor will do what he has sometimes done before—cut me down. I, therefore, profit by experience, although I confess I do not like stopping when the writing fit is on me, and I certainly object to start when it is not—*then* I much prefer digging.—
A NORTHERN GARDENER.

CANTERBURY ROSE SHOW.

ALTHOUGH one of the youngest of our Rose societies this is one of the most vigorous. Situated as the old city is in the midst of a district favourable for the growth of the Rose, and managed by two hardworking Secretaries backed by a good Committee, it has soon attained a position of importance, and is most ably supported by some of our first rosarians. When I say that Messrs. Mitchell, Cant, and Prince exhibited in force, as well as the Kentish nurserymen, and that Messrs. Haywood and Waterton, the well-known Reigate amateurs, and the well-known Kentish growers, the Messrs. Wakeley of Rainham, the Rev. H. B. Biron, Mr. Mount, and others in the neighbourhood entered, it may well be imagined that an exhibition of no ordinary excellence was made. Then, of all the rooms that I know there is none better adapted for a show than the Corn Exchange at Canterbury, while the quality of the blooms was quite equal to any that I have seen this season.

Taking the open classes first, the first prize for twenty-four was taken by Mr. Haywood of Woodhatch, Reigate, containing Comtesse d'Oxford, Mad. Gabriel Luizet, J. S. Mill, Baronne de Rothschild, Victor Verdier, Duke of Edinburgh, La France, Senateur Vaisse, Beauty of Waltham, Comtesse de Choiseul, Madame Iacharme, Louis Van Houtte, Etienne Levet, Mrs. Baker, Camille Bernardin, E. Y. Teas, Duchess of Bedford, and Eugène Fürst; Mr. Waterton was second with a very good box, amongst which was a very remarkable sport from Comtesse d'Oxford, splashed with white, very striking; and, as it is now I believe fixed, likely from its novelty to be a favourite. For the best thirty-six for nurserymen the first prize was won by Mr. Cant with some of his exquisitely finished blooms, Mad. Gabriel Luizet, Souvenir de M. Boll, Marguerite de St. Amand, Horace Vernet, La France, Duke of Edinburgh, Madame Charles Wood, Duke of Teck, Souvenir d'Elise, an exquisite bloom; Duke of Connaught, Baronne de Rothschild, Princess Mary of Cambridge, Capitaine Christy, Beauty of Waltham, Innocente Pirola, Duke of Edinburgh, a grand bloom; Etienne Dupuy, A. K. Williams, Anna de Diesbach, a fine bloom of an old Rose very rarely seen; Madame Eugénie Verdier, Annie Laxton, Souvenir de la Malmaison, Fisher Holmes, Devoniensis, &c. Two most exquisite boxes of twelve Teas were exhibited by Messrs. Mitchell and Cant, and there must have been considerable difficulty in deciding between them. Mr. Mitchell's contained Devoniensis, Catherine Mermet, Rubens, Souvenir d'Elise Vardon, a grand bloom; Madame Willermoz, Anna Ollivier, Duc de Magenta, Jean Pernet, Marie Van Houtte, Comtesse de Nadaillac, Maréchal Niel, and

Niphetos; in Mr. Cant's box were some lovely blooms, Souvenir d'Elise, Catherine Mermet, Innocente Pirola, very lovely, and others.

The amateurs' classes were well filled, and some thoroughly first-class flowers were exhibited. The cup presented by the President, Ashby Dodd, Esq., was won by a grand box of blooms exhibited by Mr. J. Wakeley of Rainham, containing La France, Etienne Levet, Belle Lyonnaise, Charles Lefebvre, J. S. Mill, Camille de Rohan, A. K. Williams, Capitaine Christy, François Michelin, Xavier Olibo, Marie Baumann, and Henry Bennett. This box also secured for the exhibitor the National Rose Society's silver medal as the best box in the Show. The same exhibitor obtained the first prize in the class for eighteen with Madame Victor Verdier, La France, A. K. Williams (this was a very grand bloom, and obtained the National Rose Society's bronze medal for the best Rose in the Show), Charles Lefebvre, Capitaine Christy, Etienne Levet, E. Y. Teas, Prince Arthur, Comtesse d'Oxford, Dr. Andry, Baronne de Rothschild, Marie Rady, Horace Vernet, Duc de Chalus, Eugène Fürst, and Prince Camille de Rohan. The first prize for twelve was taken by Mr. W. Wakeley with Baronne de Rothschild, Etienne Levet, Capitaine Christy, J. S. Mill, Le Havre, La France, Eugène Verdier, Mad. Gabriel Luizet, Camille Bernardin, John Bright, Ferdinand de Lesseps, and Fisher Holmes. In the class for twelve Teas Captain Knight was first with a good box, containing Catherine Mermet, Souvenir d'Elise, Madame Lambard, Laurette, Madame Hippolyte Jamain, Marie Van Houtte, Rubens, Mons. Furtado, Madame Bravy, Comtesse de Nadaillac, Souvenir d'un Ami, and Jean Ducher. In class 4, six varieties, three trusses of each, Mr. W. H. Wakeley was first with Henry Ledeehaux, Ferdinand de Lesseps, Baronne de Rothschild, Duke of Connaught, Capitaine Christy, and Alfred Colomb. In class 5, for twelve varieties, the first prize was won by Mr. G. Mount with a nice box containing Baronne de Rothschild, Marie Baumann, Capitaine Christy, Alfred Colomb, Victor Verdier, Mad. Gabriel Luizet, John S. Mill, Souvenir de la Malmaison, Jean Ducher, Louis Van Houtte, and Innocente Pirola. The same exhibitor also took first for the best six Teas—Catherine Mermet, Marie Van Houtte, Souvenir d'un Ami, Souvenir de Paul Neyron, Niphetos, and Anna Ollivier. Mr. J. Wakeley took the first prize for the best six of any one kind with a fine box of La France.

There were some excellent stands of flowers exhibited, the first prize going—as it almost always does—to Mrs. Biron, with a very prettily arranged stand in which wild Roses formed a very distinct feature, and for lightness and elegance left nothing to be desired. The smaller classes were also well contested, and there were really very few indifferent boxes. I have only enumerated the flowers in the first-prize stands, but on the trees exhibited by Captain Lambert, Mr. Buchanan, and others there were many excellent blooms; but it would serve no practical purpose to merely repeat the names. Unfortunately the day was not so propitious as might have been desired, otherwise the Show was a decided success, and I think all who have had to do with originating and sustaining the Canterbury Rose Show may well be proud of the results of their labours.—D., Deal.

ECHIUUM ALBICANS.

IN all respects this is a remarkable and showy plant. It is dwarf in habit, growing from 9 to 15 inches high. Leaves linear lanceolate, acute, very hairy, in dense spreading tufts. The flower stems have from six to ten thyrsoid racemose branches, carrying numerous flowers with hairy calyces; the corolla is funnel-shaped, about 1 inch long, less than half an inch across, light rose-coloured at first, afterwards changing to violet purple. It is a native of the mountains of Spain, occurring at elevations between 2000 and 5000 feet, but it is very scarce under cultivation in this country. I have seen in different collections more than one species under the same name, one of which was in the late Mr. Joad's garden at Wimbledon. It was a very large grower, for when I saw it, just previous to flowering, it was 5 feet high, with a coarse branching habit, totally distinct from this plant now described. It is more frequently met with on the continent, and I think it flowered outside last year with Mr. Max Leichtlin at Baden Baden. There is no doubt of its hardiness in this country, but excessive wet during the winter may cause it to decay, to prevent which it is advisable to afford it protection, as it is well worth it, for, as well as being extremely rare, it is very showy. It enjoys a well-drained sunny position on the rockery with a good depth of rich soil, and must be increased by seed, as the roots are not readily divided without injury to the plant.—N.

OMPHALODES VERNA.—A very useful old-fashioned flower, one of Mr. Fish's favourites, and nobody has, perhaps, grown it better. It is too well known to require description, except to say it is of dwarf habit, producing bright blue flowers about one-third of an inch across very early in the year—March to May. There is also a white-flowered variety known under the name of alba, which is a charming companion to the type. These are both plants well worth growing for the rockery or border, and they can also be well utilised for the spring garden decoration, as they are readily increased by division of the roots, which should be done soon after flowering; and for bedding

purposes the plants should be liberally treated and placed in a partially shady position in rich soil. It is a native of southern Europe, and was introduced as early as 1633.—R.

TUNBRIDGE WELLS SHOW.

JULY 7TH.

THE horticultural credit of one of the most beautiful districts of favoured Kent was admirably maintained at the Tunbridge Wells Show of last Friday; and though on some previous occasions the entries in a few of the classes have been more numerous, yet, taking the Exhibition as a whole, perhaps the general quality has never been surpassed. Plants, flowers, fruit, and vegetables were all well represented, the classes devoted to flowers being the weakest portion of the display, notwithstanding the fact that several satisfactory collections of Rose blooms were contributed. The handsome Public Hall opposite the South Eastern Company's railway station contained the fruit and flowers, three large marquees in the grounds attached to the Calverley Hotel being devoted to the other exhibits. These were arranged to the best advantage, and Mr. E. F. Loof, the Secretary, deserves much credit for his methodical system.

Stove and Greenhouse Plants.—Several collections of unusual merit were staged in the open classes, but that for which the first prize was deservedly awarded in the class for eight stove and greenhouse plants in flower is particularly worthy of note. These specimens were staged by Mr. J. Gilbert, Springfield Nursery, Hastings, and were much admired for their neatness, health, and beauty. The best were the following:—*Statice profusa*, about 4 feet in diameter, and bearing abundance of flowers, was very telling; *Allamanda cathartica* and *A. Hendersoni* were also in superb condition, though of moderate size, the blooms being very numerous and the foliage vigorous. That extremely showy plant *Kalosanthes coccinea superba* was admirably represented by a specimen of considerable size, bearing large trusses of brilliant flowers. The second position was secured by Mr. James Bolton, gardener to Wm. Spottiswoode, Esq., Coombe Bank, Sevenoaks, who also had specimens of considerable merit, amongst them being two that deserve particular notice—namely, *Tabernamontana coronaria fl.-pl.*, over 4 feet in height and most profusely flowered, and *Clerodendron fallax*, 6 feet high, with twenty grand trusses of rich scarlet flowers. Very rarely indeed is this attractive plant seen in such fine condition at exhibitions. Mr. Samuel Pope, gardener to F. F. Barrow, Esq., Holmwood, Tunbridge Wells, was third with smaller specimens but very neat, *Erica Bothwelliana* and *Kalosanthes coccinea* being the best. In the smaller class for four plants Mr. Gilbert was first with similarly creditable specimens to those in the other class, *Dipladenia amabilis* and *Allamanda Hendersoni* being in first-rate condition. Mr. Bolton followed closely, having a specimen of *Clerodendron fallax* nearly as fine as the one already noticed. Mr. G. Fennell, gardener to E. Cazalet, Esq., Fairlawn Park, was third, his best specimen being a well-grown *Stephanotis floribunda*. In the amateurs' and gardeners' class Mr. Pope was the most successful exhibitor, having *Bougainvillea glabra*, *Kalosanthes coccinea*, and *Statice profusa* in excellent form. Mr. Bolton was a good second, his leading plants being a large *Agapanthus umbellatus* and *Clerodendron Balfourianum*.

Fuchsias.—These were shown in most satisfactory condition, the plants being of pyramidal form, not too rigidly trained, very healthy, and extremely floriferous. Mr. F. Earley, gardener to G. H. Brittain, Esq., Ferndale House, Tunbridge Wells, won chief honours with six handsome grandly flowered plants, the varieties being *Rose of Castille*, *Sir Colin Campbell*, *La Crinoline*, *Mont Blanc*, *Peerless*, and *Arabella*. Mr. C. Shoebridge, gardener to W. Edwards, Esq., Fern Bank, Tunbridge Wells, was a close second, all his plants being good, but *Rose of Castille* especially so. Mr. N. Turner, gardener to F. R. La Lacheur, Esq., The Wilderness, Tunbridge Wells, took the third position, the most notable plant being *Arabella Improved*.

Achimenes.—For six specimens of these in 11-inch pots Mr. F. Allan, gardener to G. Hanbury Field, Esq., Ashurst Park, won the premier honours with beautiful examples, which were particularly noteworthy for the great size of the flowers. The specimens were 3 to 4 feet across, the foliage and growth healthy and vigorous, with most abundant blooms. The varieties were *A. longiflora* and *rosea*, Edmund Boissier, Margareta, Mauve Queen, and *Ambroise Verschaffelt*. In general good quality this was one of the best collections of *Achimenes* that has been shown this year. Mr. H. Scammell, gardener to C. Reilly, Esq., The Priory, Nevill Park, who took the second prize, also had well-grown examples of good varieties.

Pelargoniums were shown by Mr. J. Wilkins, gardener to Mrs. Williams, Shirley Hall, Langton, in satisfactory condition, especially in the classes for show and double Zonal varieties, the latter being represented by well-flowered specimens. Mr. Bolton's collection of Tuberous *Begonias* was also noteworthy for the good condition of the plants.

Fine-foliage Plants.—An important feature in the Exhibition were the entries in the classes for these plants, and, like all the other contributions, they were distinguished by their vigorous health. In the open class for eight specimens Mr. C. Rann, The Gardens, Handcross Park, Crawley, Sussex, took the lead with his large examples of *Areca sapida*, *Gleichenia Mendeli*, *Cycas revoluta*, *Croton undulatus*, and *Thrinax elegans*, amongst others nearly equally fine. Mr. Gilbert

was adjudged the second prize for well-grown specimens, his examples of *Dicksonia antarctica*, *Dasyllirion acrotrichum*, and *Phormium tenax variegatum* being large and healthy. Mr. Pope, who was placed third, had smaller but very neat plants, *Croton angustifolia* and *Beaucarnea longifolia* being the two finest specimens. In the amateurs' and gardeners' class the last-named exhibitor gained chief honours with excellently coloured *Crotons*, and a fine *Alocasia metallica*. Messrs. Johnston and Bolton followed in that order, both showing well.

For eight exotic Ferns in the open section Mr. C. Rann was again in the principal position with beautiful fresh healthy plants of *Dicksonia squarrosa*, *Gleichenia rupestris glaucescens*, *Cyathea Smithii*, and *Thamnopteris nidus*. Mr. Bolton had *Goniophlebium subauriculatum* and *Davallia Mooreana* in fine order in his second-prize collection; Mr. Pope being third with large *Agatheas* and *Dicksonias*. Mr. H. Scammell, who took the lead in the gardeners' class for six *Selaginellas* with beautiful examples in pans, the growths trailing freely over the sides. *S. caesia* was finely coloured, *S. Martensi variegata*, *S. Lobbi*, and *S. Willdenovii* being similarly good. Mr. Bashford followed with similar specimens of *S. stolonifera*, *S. caesia*, and *S. apus*, Mr. Earley being a good third.

Groups.—Eight pretty groups were staged in the gardeners' class for the most effectively arranged collection of plants in a space 9 feet by 6 feet, and all were distinguished by more than ordinary taste. Mr. Fennell won premier honours with a graceful and free but bright collection, which comprised a background of Japanese Maples, Roses and *Casuarinas*, *Cocos Weddelliana*, Ferns, *Aralias*, *Crotons*, and *Caladiums* forming the chief of the other fine-foliage plants employed; while abundant colour was supplied by *Tropæolums*, *Francisceas*, *Pelargoniums*, and *Gloxinias*, the margin consisting of *Panicum variegatum*. Mr. Bashford won the second prize, his group having a background of fine *Humeas*, and handsome plants of *Lilium auratum*, *Grevilleas*, *Petunias*, *Abutilons*, *Pelargoniums*, *Begonias*, *Coleruses*, and *Caladiums* were also freely employed, producing a very bright effect, but slightly more formal than the preceding. Mr. Bolton was a good third, also with a group abounding in bright colours, and perhaps this was its chief defect—i.e., too great a preponderance of such shades as those afforded by *Ixoras* and *Clerodendron fallax*, with scarcely sufficient foliage plants to subdue the brilliancy, though some neat little specimens of *Phyllanthus nivosus* were noteworthy. The margin of *Adiantums*, *Panicums*, and *Ficus Parcelli* was very pretty. Messrs. Turner, Pope, and Earley secured the other prizes in that order.

Cut Flowers.—As already noted the principal exhibits in this section were the Roses, several fine collections of which were staged. Amongst the nurserymen Messrs. James Mitchell & Son, Uckfield, showed particularly well, taking the leading position with forty-eight varieties, closely followed by Messrs. G. Bunyard & Co., Maidstone. For twenty-four varieties the positions of these two firms was, however, reversed, the Maidstone Roses in this case being decidedly superior to the others in form, substance, and colour. In the former class Mr. F. Woolard, Cooksbury, was third with fresh but small blooms, and in the latter Mr. G. W. Piper, Uckfield, obtained a similar position. The most successful amateurs and gardeners were A. Slaughter, Esq., Steyning, and R. Burton, Esq., Hurstleigh, Tunbridge Wells, who contributed blooms of considerable merit. One interesting class was that for a collection of wild flowers accurately named, in which Miss Ware of Frant won leading honours with 201 species and varieties mostly correctly and neatly labelled, but a few slips like *Sinapsis*, *Sonchus oloraceus*, *Solanum Dulcamaria*, and *Digitalis aurea* were notable. Bouquets, buttonholes, and table decorations were all well shown, several tasteful designs being staged, though the stands of flowers were in most cases rather heavy.

Fruit.—In the principal classes for fruits the competition was keen and the exhibits of very good quality. Particularly noteworthy were the collections of fruit, which not only included fine samples of culture, but were also remarkable for tasteful arrangement. Mr. A. Henderson, gardener to F. Deacon, Esq., Mabledon Park, deservedly won premier honours with a most excellent collection comprising fine bunches of Black Hamburg Grapes, Cherries, Strawberries, Raspberries, Gooseberries, Melons, Nectarines, Peaches, Red and White Currants, and a handsome Pine Apple. These were arranged in tin dishes covered with Vine leaves and placed in a square wooden tray also covered with leaves, the margin being a wreath of variegated Holly leaves. Mr. Fennell, who was placed second, had fine Black Hamburg and Buckland Sweetwater Grapes, with other fruits of good quality arranged in a square tray similar to the first. Mr. A. Waterman, gardener to H. A. Brassey, Esq., Preston Hall, Aylesford, was third with a tasteful arrangement of good fruits; and Mr. J. Hopgood, gardener to Sir J. Goldsmid, Somerhill, was a close fourth.

Black Grapes were well represented, ten competitors entering the class for three bunches. Mr. Henderson won with grand bunches of Black Hamburg, the berries large and finely coloured. Mr. Lewis Barnes, gardener to Lady Herschell, Hawkhurst, was second with Mrs. Pince's Muscat, well coloured; Messrs. T. Hopgood and G. Fennell were third and fourth, both showing Black Hamburg in fair condition. White Grapes, though equally numerous, were not so good as the preceding. Mr. W. Johnston, however, had moderate-sized bunches of Muscat of Alexandria fairly ripe; Mr. C. Adams, gardener to W. H. Trijo, Esq., Reigate Hill, being placed second

with three handsome bunches of Buckland Sweetwater beautifully coloured. For three bunches of distinct varieties Mr. Adams won chief honours with Buckland Sweetwater, Madresfield Court, and Foster's Seedling, all well ripened. Messrs. Johnston and Barnes followed, both showing fairly well.

Pine Apples, Peaches, Nectarines, and Melons were contributed by several exhibitors, the samples of the two first staged being especially good.

Vegetables and the cottagers' productions occupied a marquee of considerable size, and the majority of the exhibits were distinguished by their clean fresh appearance. The collections of vegetables were extremely fine, Messrs. Waterman, Barnes, Bolton, and Johnston being the prizewinners in the gardeners' class.

TWO MASDEVALLIAS.

FROM recent importations that pretty species of *Masdevallia* *M. Shuttleworthii* is now becoming much more abundant in gardens; and though it cannot be considered as a rival to such showy forms as *M. Lindenii* and *M. Veitchiana*, still it deserves to rank amongst the most interesting of the smaller-flowered species. It is a native of New Grenada, where it was found by Mr. Shuttleworth when travelling in search of plants, and it was first introduced to Mr. W. Bull's collection at Chelsea four or five years ago. It speedily attracted the attention of Orchid-growers, and now few collections of moderate size will be found without a few representatives. Like other species, this is found to vary in the size and colouring of the flowers, some being much finer than others. That shown in the woodcut, fig. 6, is from Mr. Dorman's garden at Sydenham, and is one of the best we have seen, though the woodcut fails to convey an accurate idea of its beauty. There is a peculiar delicate semi-transparency in the sepals which renders

Fig. 6.—*Masdevallia Shuttleworthii*.

the numerous rosy purple dots which are thickly strewn over the surface very noticeable. It is dwarf, of easy culture, and extremely floriferous.

M. triangularis (fig. 7) is another notable species with small flowers, these being yellowish dotted with purple—a rather striking contrast of colours. It is also a South American form from

Caracas, but it has been in cultivation much longer than the preceding. We believe that it first appeared in the Royal Gardens, Kew, but it has since passed into the hands of the nurserymen. The flower from which the woodcut was prepared was from one

Fig. 7.—*Masdevallia triangularis*.

of Mr. B. S. Williams' plants at Upper Holloway, where it thrives well with the numerous other species forming that collection.

MUSHROOMS IN THE OPEN AIR.

IT may be useful to state that the present is the time to get the manure together and commence turning for outdoor, autumn, and winter beds. I shall begin the latter end of the week to turn my heaps for the first beds. There is no better method of preparing the manure than that so fully detailed in the Journal of May 25th, and no one can err if they follow carefully the instructions there given. It may also be well to state if those having Cucumber, Melon, or Vegetable Marrow beds now were to insert a few pieces of spawn round the outsides they would probably find how easy it is to raise a good supply of Mushrooms.—J. F. BARTER, *Lancefield Street, Harrow Road*.

[We have grown excellent Mushrooms by the simple practice recommended, and had an abundant supply the whole of last winter from a spent hotbed on which a frame was placed. The Mushrooms were produced with great freedom both inside and outside the frame for months, but that, we apprehend, was in a great measure due to the mildness of the winter; still, our experience of many years warrants us in recommending a trial of the simple method of Mushroom-growing referred to.]

OXFORD ROSE SHOW.

JULY 6TH.

THE Oxford Rose Society was established in 1851, and has held an exhibition each year without interruption successfully, save in the matter of weather, as on several occasions it has been very rainy. Started as an "amateur" society it maintained its position as such for some sixteen or seventeen years, when it was felt desirable to throw open its show to all comers, and a very wise step it proved, for some of its shows since have compared favourably with many exhibitions of larger means.

At the time of year the Rose shows are usually held Oxford may be said to be empty. The University and many of the principal citizens get away to the sea or mountains so soon as the academical year closes. This fact renders it at all times a matter of anxiety to the executive as to what conditions of weather they may experience in holding their annual display with the view of making it a financial success. Happily for them the various College gardens are at their disposal, and on the 6th of July the thirty-first annual Show took place in the gardens of Trinity College, and it had been arranged to hold the Show under the leafy vault of the far-famed "Lime Tree Walk," an avenue of pollarded Limes some 110 yards long, whose branches have become interlaced as to form a Gothic-like groined roof. These trees are known to be three hundred years old. To the north of this avenue stood another avenue of Yews, some few of which are still standing. Beneath this shady retreat the tables were set and prepared to receive the boxes of Roses; when, alas! within one hour of commencing the duties of making the awards rain fell so heavily that nothing short of stout canvas could resist it, and a general "all hands to the pumps" being called, tables, tressles, baize, class cards, &c., had to be transferred to the shelter of a large marquee.

With regard to the Show, it can be maintained that high quality prevailed throughout, the whole of the boxes on view being filled with flowers of large size, good form, and of deep tone in colour. The entries justified the hope of a large exhibition, but the day previous telegram after telegram announced the fact that several large exhibitors had been prevented, owing to the storms then prevailing; consequently but few of the "open to all England" prizes were competed for. The only large trade grower who put in an appearance was Mr. Charles Turner, whose boxes were very bright and well up to the exhibition standard.

There was no competition in Class 1, for forty-eight triplets, but in forty-eight and thirty-six single trusses Mr. C. Turner gained the chief awards. His forty-eight box contained Dupuy Jamain, Capitaine Christy, Prince Camille de Rohan, Victor Verdier, Lord Macaulay, Malame H. Jamain, Alfred Colomb, François Michelin, Mdle. Thérèse Levet, A. K. Williams, Marie Van Houtte, Baronne de Rothschild, Sénateur Vaisse, François Louvat, La Duchesse de Morny, Cathérine Mermet, Marguerite Brassac, Marguerite de St. Amand, Camille Bernardin, Mons. Noman, Mons. E. Y. Teas, Elie Morel, Ville de Lyon, Mdle. E. Verdier, Général Jacqueminot, Paul Neyron, Souvenir d'un Ami, Auguste Rigotard, La France, Mons. Gabriel Tournier, Abel Grand, Marie Baumann, Madame Laurent, Constantin Tretiakoff, Avocat Duvivier, Comtesse d'Oxford, Devoniensis, Mrs. Harry Turner, Madame Lambert, Sir Garnet Wolseley, Edouard Morren, Beauty of Waltham, Louis Van Houtte, Countess of Rosebery, Abel Carrière, Madame Charles Crapelet, Madame Lacharme, and Duke of Edinburgh. The varieties in the thirty-six were similar, first prizes being awarded in each class.

For twenty-four Mr. John Walker, Thame, stood to the fore with fine clean blooms of Mdle. E. Verdier, Charles Lawson, Duke of Edinburgh, Duke of Wellington, Gloire de Dijon, Mabel Morrison, Lord Clyde, Charles Lefebvre, Marquise de Castellane, La France, Comtesse d'Oxford, Prince Camille de Rohan, Belle Lyonnaise, Duchesse de Caylus, Triomphe de Rennes, Lord Macaulay, Madame Charles Crapelet, Général Jacqueminot, Madame Victor Verdier, John Keynes, Mdle. Bonnaire, Marie Baumann, Jean Liabaud, and Madame Thérèse Levet. Mr. George Humphries, Kington Langley, Chippenham, proved a good second with fresh and bright examples of the leading varieties.

The class for twelve Hybrid Perpetuals, one variety, produced several fine sets of bloom. Dr. Bywater Ward, Warneford Asylum, Oxford, was first with grandly formed and pure Madame Lacharme; Miss Watson-Taylor, Manor House, Headington, Oxon, second with Marie Baumann; J. T. Strange, Esq., Aldermaston, Berks, third with Baronne de Rothschild. For twelve Teas several boxes were staged, and these of superior merit, Rev. E. L. Fellowes, Wimpole Rectory, Royston, Cambs, leading with splendid trusses of Anna Ollivier, Amazone, Souvenir de Paul Neyron, Madame Camille, Comtesse de Nadaillac, Catherine Mermet, Caroline Kuster, Madame Willermoz, Jean Ducher, Souvenir de Madame Pernet, Rubens, and Bouquet d'Or. Rev. E. P. Wellings, Stamford-in-Vale, was second with charming examples. The Judges pronounced this a splendid class.

In the second division, "not growers for sale," many good boxes were staged. The first prize in the class for thirty-six trusses fell to Miss Watson-Taylor for very even blooms, including A. K. Williams, Annie Wood, Auguste Rigotard, Beauty of Waltham, Capitaine Christy, Countess of Rosebery, Devienne Lamy, Dr. Andry, Duchesse de Caylus, Duchesse de Vallombrosa, Dupuy Jamain, Elie Morel, Ferdinand de Lesseps, François Michelin, Hippolyte Jamain, John Stuart Mill, Julius Finger, Madame Victor Verdier, Mdle. Marie Rady, Mdle. Marie Verdier, Marie Baumann, Marie Louise Pernet, Marquise de Castellane, Niphotos, Madame Gabriel Luizet, Mons. E. Y. Teas, Mons. Paul Neyron, Pierre Notting, Sénateur Vaisse, Sir Garnet Wolseley, and Star of Waltham. For twenty-four blooms Rev. E. L. Fellowes secured the chief prize with practically the same as in the preceding classes. Mr. A. Evans, Marston, Oxon, was second; and Mr. Jos. Freeman, Market Street, Oxford, third. For twelve blooms Dr. Bywater Ward was a good first with large well-formed examples; W. Wooten-Wooten, Esq., Headington House, Oxton, second; and Mr. John Allin, Sandford-on-Thames, third. In the division "ama-

teur members of the Society only" the classes were all closely contested. For twenty-four the card went to Rev. W. H. Jackson, Stagsden Vicarage, Bedford; and Rev. E. P. Wellings, Stanford Vicarage, Faringdon. For eighteen, Mr. A. Evans, Marston, first; Mr. J. Freeman, Oxford, second; Mr. C. Taylor, Headington, Oxon, third; and Mr. W. Narrowway, Headington Quarry, Oxon, fourth. For twelve, Mr. A. Evans again first; Mr. Narrowway second; and Rev. H. A. Pickard, Canterbury Road, Oxford, third. For nine, Mr. C. Colcutt, Holywell, Oxford, first; Mr. Thomas Wheeler, Kingston Road, Oxford, second; and Mr. T. Freeman third. For six, Mr. Walter Harris, 17, Kingston Road, Oxford, first; Mr. F. Harris, Walton Crescent, Oxford, second; Mr. E. Collins, 5, Grove Street, Oxford, third. For twelve triplets, Mr. Joseph Freeman and Rev. E. P. Wellings divided the honours; while for six triplets, Mr. C. Colcutt first, Mr. Thomas Wheeler second, and Rev. E. L. Fellowes third. For six trusses of one variety Mr. A. Evans took the card with Baronne de Rothschild, Rev. E. L. Fellowes second with Catherine Mermet, Mr. C. Taylor third with Marie Baumann, and Rev. W. H. Jackson fourth with Capitaine Christy. For one bloom, Mr. C. Colcutt was first with Marie Baumann, Mr. A. Evans second with Alfred Colomb, and Mr. F. Freeman third with Madame Willermoz.

AT a General Meeting of the ROYAL HORTICULTURAL SOCIETY held July 11th, 1882, George F. Wilson, Esq., F.R.S., in the chair, the following candidates were elected Fellows—viz., Henry John Blagrove, William Beriah Brook, Miss Agnes Grainger, Fred T. Mappin, M.P., James Pink (Director of the Botanic Gardens, Brisbane), and Lieut.-Col. R. F. Webb.

— WE are desired to state that the bloom of Edouard Morren, which won the National Rose Society's medal at the REIGATE SHOW, was not in Mr. Haywood's stand, but in Mr. Waterlow's second-prize box of nine blooms, which box was inadvertently credited in our report to Mr. Wilkins.

— A CORRESPONDENT writes:—"For several weeks CHLORA GRANDIFLORA has been one of the most striking plants in the ornamental house of the Cambridge Botanic Garden. Those who know our British *C. perfoliata* can imagine what this may be, as it is only a fine variety. The bright golden flowers are extremely showy among other decorative plants. It submits readily to pot culture, and, indeed, seems to be much finer under glass. Seeds should be sown early in the autumn, so as to produce stocky plants before winter. If sown too early it flowers weakly the same season."

— "UNDOUBTEDLY," observes the same writer, "the FINEST HARDY WATER LILY is NYMPHÆA CANDIDISSIMA. Its flowers measure 6 inches across, while those of the common *N. alba* growing close to it measure only 3 inches. The petals, too, are much broader, and the centre is of deeper yellow colour. It was contributed to the Cambridge Botanic Garden by Mr. Parker."

— RESPECTING the ORIGIN OF MARÉCHAL NIEL ROSE, Dr. Penjade writes in the *Revue Horticole* that it was raised by M. Pradel, a florist at Montauban in the South of France. M. Pradel states that he raised it from seed sown by himself, and that having grafted many stocks with it, he planted one of them in the garden of a M. Chateau, where it was observed by M. Rapin, Director of the Registry at Montauban. M. Rapin took it to an exhibition of the Horticultural Society which was being held at the time, and on the 3rd of May, 1862, the Jury, presided over by M. Helye of Paris, awarded a medal to M. Pradel, jeune, for the exhibit. The Rose received the name of Maréchal Niel in compliment to the Maréchal, who in the month of June previously had presided at the opening of the Garden of Horticulture and Acclimatisation of Tarn-et-Garonne at Montauban. The Rose was sent out by M. Pradel in 1863.

— SOME fine examples of CARTER'S LEVIATHAN BEAN have been sent to us. The shortest pod was 11 inches in length, and the longest exceeded a foot. This indicates that the variety is an excellent one for exhibition purposes. The beans were also of good size and quality.

— THE first attempt of the Royal Agricultural Society at an EXHIBITION OF MARKET-GARDEN PRODUCE was not encouraging if we may judge by what was shown at Reading on Monday last. In a tent set apart for the purpose, and which had a table round the two sides, we found as many vegetables as would have furnished a greengrocer's stall in any good market town in England. There were about a dozen half sieves of Potatoes and some Cabbages, a round basket full of Cauliflower, three baskets of Peas, a heap of young Onions, a few more Cabbage, and about a couple of dozen of Cabbage and Cos Lettuce. The fruit consisted of three boxes of Apples, two baskets of Cherries, one basket of Red Currants, two of Black, and one of Gooseberries. It was a relief to linger over the splendid exhibitions of seeds and roots that were made by Messrs. Sutton & Sons, Messrs. James Carter & Co., and Messrs. Webb of Wordsley.

— WE are gratified to hear that His Grace the Duke of Northumberland has promoted Mr. JOHN WOODBRIDGE, who has for so many years acted as gardener, to the office of Steward of the estate at Syon. This mark of confidence in one who has so well fulfilled his trust reflects great credit on His Grace, while he honours his faithful servant. Mr. Woodbridge still retains the superintendence of the gardens in connection with his new office, which we wish him long life to enjoy, for we do not wish to see for many years inscribed on his tombstone, as there is on that of Mr. Thomas Hoy, a former gardener at Syon, "Here lies an honest man."

— AN excellent sermon by the Rev. William Brown Keer of Heywood, Wilts, has been sent to us. The subject is "THE TILLAGE OF THE POOR." We can appropriately cite one passage.

"By the expression 'tillage of the poor,' we may understand those small holdings, or plots of ground, which in the East are cultivated as vineyards and Olive yards, or gardens of Maize or Cucumbers; and among ourselves as gardens or allotments for the growth of corn, fruits, roots, or vegetables. 'I cannot afford to grow weeds, I have too little land and too many mouths to feed,' said a labourer to me the other day, when I complimented him on the cleanliness of his allotment; and he added, 'I want all the corn, the roots, and the vegetables, and more than I can grow.' He was right. It is unprofitable, in more senses than one, to grow weeds; they exhaust the soil, choke the crop, and yield pernicious seed. Two or three, or even four crops a year, in well-chosen succession may be had in the same garden plot, while the large and wealthy farmer grows but one. What farm, indeed, on a large scale can be cared for half so diligently or effectually? And then, what of the result? A rod or perch of ground, commonly called here a 'lug,' or the 160th part of an acre, has, I am told, been known to produce a yield of nearly if not quite half a bushel of Wheat, or at the rate of very nearly twenty sacks an acre. Verily, 'Much food is in the tillage of the poor.' There is an old rhyme to this effect—

"Plow deep, while sluggards sleep,
And thou shalt have corn to sell and to keep."

Nothing is said to repay diligent labour so well as the soil. Here, if anywhere, the proverb is true, 'He becometh poor that dealeth with a slack hand; but the hand of the diligent maketh rich.'

— AT the NATIONAL ROSE SOCIETY'S SHOW held last week at South Kensington, Mr. T. Hobbs, Lower Easton, Bristol, was awarded an equal third prize with Mr. Evans in the amateurs' class for twenty-four blooms, this award not being included in our report of the Exhibition.

— MR. JAMES MCINTOSH has sent us from Duneevan flowering sprays of the charming ROSA BRUNONII. Now that single flowers are so popular for decorative purposes this Rose might with advantage be more freely grown. Its white flowers are produced in large bunches; and a plant, or tree as at Duneevan, when laden with flowers is very beautiful, and the perfume it

diffuses is delicious. It is classed as a climbing Rose, but it shows to greater advantage when grown as the wild Rose grows in the hedges, as severe pruning is not promotive of free blooming. We do not know whether this Rose is hardy in the north of England. It is a native of Nepal, whence it was introduced by Dr. Wallich in 1822.

— THE tenth annual Show of the WIMBLEDON HORTICULTURAL SOCIETY, held on the 5th inst., was, we are informed, an excellent one. Messrs. Veitch exhibited a hundred Roses in pots and splendid boxes of cut blooms, the chief prizes in the Rose classes being won by Mr. Wilkins of Sutton and Mr. Moorman of Coombe Bank, who were respectively placed first with twenty-four and twelve varieties. In the open class for miscellaneous groups of plants, open to all, Mr. Runnacles, gardener to Mrs. Schuster, was the premier winner, Mr. Bridger, gardener to L. Walker, Esq., being first in the members' class. Mr. Bentley, gardener to Sir T. Gabriel, was the most successful exhibitor in the specimen-plant classes; Messrs. Davis, Bentley, Dove, and Cole were among the chief prizewinners in the fruit classes; and Messrs. Star and Bentley were awarded first honours for collections of vegetables. Among the several donors of special prize were Lady Peek and Sir Trevor Lawrence, and thus under the encouragement that is given the excellent character of the horticulture of the district is likely to be maintained.

— A CONE-BEARING branchlet of ABIES WEBBIANA has been sent us, and it is so extremely beautiful that it is a pity this fine Silver Fir is so liable to injury by spring frosts. The cone is large, cylindrical, purplish black in colour, and contrasts effectively with the silver under surfaces of the foliage. An excellent and characteristic figure of a cone and spray of this Conifer is given on page 109 of Messrs. Veitch's valuable work on the Coniferæ, from which we cite the following:—"A. Webbiana is considered tender in many parts of England; it begins to grow early in spring, and this early growth is often cut off by frosts later in the season; but if young plants are protected by a slight covering at the time these frosts occur—and so small an amount of trouble is well worth taking to preserve so beautiful a tree—the injury may be prevented, and as the plants become established by age they also become more acclimatised. Many fine specimens growing in various parts of England attest this; the lower branches of the largest of these have attained lengths of from 15 to 18 feet, so that in selecting a situation for this tree a space having a radius greater than these dimensions should be allowed for it. The specific name was given by Dr. Wallich in compliment to Captain W. S. Webb, 'a distinguished traveller and zealous investigator of natural history,' who first discovered it in the Himalayas." A beautiful violet dye is said to be extracted from the cones.

— THE circular appended has been issued TO THE FELLOWS OF THE ROYAL HORTICULTURAL SOCIETY:—"In their circular to the Fellows of the 27th March last, the Council stated they were endeavouring to enter into negotiations with the Commissioners for the Exhibition of 1881, with the object of effecting an arrangement which would be in strict accordance with the trusts upon which the Commissioners hold their property, mutually advantageous to the Commissioners and the Society, and beneficial to the public. With this view the Council proposed that a joint committee of the two corporations should be formed to consider their future relations. This proposal was accepted by the Commissioners, but the Committee which has been appointed to give effect to it has not yet met, as it was found necessary, before such a meeting could be usefully held, to settle terms between the Society and the Executive Committee of the Great International Fisheries Exhibition, 1883, to whom the Commissioners had granted the use of part of the South Kensington

Gardens for the purposes of their Exhibition, reserving for themselves that portion known as the Ante-Garden, of which they intend to resume possession. The Council are happy to report that the friendly spirit in which the Executive Committee met them has enabled them to make a satisfactory working agreement with the Fisheries, which, whether the ulterior negotiations with the Commissioners are successful or not, secures to the Society, subject to the user required by the Fisheries, the ornamental part of the Gardens which lies to the north of the circular basins, until the end of the year 1883. The Council are not in a position to anticipate the result of these negotiations, but they believe the Commissioners wish to act liberally towards the Society, and they have no reason to anticipate that its connection with South Kensington will cease after 1883. As some further time must elapse before the negotiations with the Commissioners can be completed, the Council think it right to issue the foregoing statement for the information of the Fellows."

— MESSRS. BROOKES & Co. of Manchester, the makers of the tubular flower stakes referred to on page 425 of our last volume, send us the following note:—"We observe that a desire is expressed for LIGHT WIRE FLOWER STAKES of less than 2 feet in height. To meet this want we have designed a new wire stake with a foot and convenient top, and beg to send you a specimen for your examination and judgment. We have tested it practically, and think we find it strong, neat, stable, and certainly it will be very cheap." These stakes will be serviceable to many. The circular projection about 8 inches from the point will impart stability, but the loop at the top is much too large, if needed at all.

— WE are informed that Mr. Sydney Woods has succeeded Mr. Raffill as gardener to Lord Tredegar, Tredegar Park, Newport, Monmouthshire.

— THE following paragraph has been sent to us, which we readily publish:—"It has been proposed to hold a CARNATION AND PICOTEE SHOW AT OXFORD, in connection with the Exhibition of the Royal Oxfordshire Horticultural Society, on August 2nd, the Show to be regarded as supplementary to that of the National Carnation and Picotee Society, which takes place at South Kensington on July 25th. We understand that Mr. E. S. Dodwell has been requested to make the necessary arrangements for carrying out this proposal, which has our hearty concurrence, as it will provide, in consequence of the later date, a more favourable meeting ground for northern and southern growers than the meeting at Kensington will do. To provide the necessary prizes it is suggested that the two above-named Societies should each vote ten guineas towards a fund to be raised for that purpose, and that the remainder, about a similar sum, shall be raised by special subscription—say one-half from friends of the Oxford Society, and one-half from friends of the National Society. We cannot doubt the needful aid will be forthcoming, and we are heartily glad that Mr. Dodwell's health and strength has been so much recruited by his residence in the country that he is able to undertake the supervision of the arrangements. Several donations have been already promised, and a schedule of prizes has been issued."

— WRITING in reference to BORDER AURICULAS a correspondent of the "Gardener" observes:—"The border Auricula is not cultivated to the extent it should be. True there are not many herbaceous borders where samples of the 'Dusty Miller' are not to be found. But there is no comparison between the older and commoner kinds and the great, robust, rich-coloured kinds that are now to be had, and we doubt if there exists another perfectly hardy plant with so many claims. Less refined it may be than the edged show varieties, or even the hardier named Alpines, although it is itself included among the latter ;

but against that there is to be placed the fact that a good strain is more robust, more floriferous, and possessing colours as rich, as varied, and as effective. Then it requires neither frame nor pots, special situations, nor special soils. Moreover, a stock can be got up with greater speed, or indeed be created. A packet of seed if from a good strain will produce numbers of beautiful forms, and when once a stock is secured the road is open, for then one has only got to select what pleases, and seed from such, to get any number of plants in a year or two."

— A CORRESPONDENT writes us that "the July monthly meeting of the TOOTING HORTICULTURAL SOCIETY was a great success, the members well responding to Rule 1. Among the most noteworthy exhibits were some grand Gloxinias from Mr. Todman, measuring upwards of 2 feet diameter and carrying between eighty and ninety flowers: they received a cultural commendation. A fine Hydrangea from Mr. Eade was similarly noticed, as also was a very handsome Melon called Prizetaker. New plants were represented by a very fine and distinct dark Fuchsia from Mr. Bunby, the new curled Golden Feather sent by Mr. Gower, and a beautiful and most profusely flowered Pelargonium of the decorative type from Mr. Todman: these were granted certificates. Amongst cut flowers were good examples of seedlings and hybrids consisting of Gloxinias, Begonias, Fuchsias, Zonal Pelargoniums both single and double. Herbaceous plants were also well shown."

WEST KENT HORTICULTURAL SHOW.

JULY 8TH.

FOR some years the annual Exhibition of this Society, held either in Bickley or Chislehurst, has been especially distinguished by the number, extent, and choiceness of the groups contributed by metropolitan nurserymen, which have indeed formed one of the principal features of the Show. On this occasion, however, notwithstanding the fact that the pleasantly situated grounds of Camden House were selected for the site, there was a considerable falling-off in this respect, the marquees devoted to the exhibits having in consequence a rather bare appearance. Some compensation for this deficiency was, however, to be found in the excellence of the plants and other productions staged in competition, for the majority of the principal classes were very well represented. Four spacious marquees were devoted to the exhibits, one containing the table decorations—always abundant and good at this Show; in another the cut flowers, fruit, and vegetables were arranged; the third and fourth comprising the specimen plants and groups, which were all carefully and effectively disposed. Most unfortunately, the weather in the early part of the day was extremely unfavourable, heavy showers of rain occurring at short intervals.

Plants.—The principal class in this section was that for "a collection of stove and greenhouse plants to be staged with a frontage of 10 feet," as it is rather vaguely described in the schedule; a further clause, however, stating that the prizes will be awarded to those "which are staged with the greatest taste and symmetry, at the same time the quality of the exhibits will receive careful consideration." It was quite evident from the collections shown that the exhibitors had not all taken the same view of this stipulation, and in consequence the awards of the Judges would give dissatisfaction to some. If the Society really wishes for groups arranged for effect why is it not plainly stated? None of the groups staged could be considered as remarkable for the taste displayed in the arrangement, but at least two included some well-grown plants. The first-prize collection from Mr. Kent, gardener to F. Heritage, Esq., Orpington, was, it is true, distinguished by a little more freedom and taste in the disposition of the plants; but these were not very select, nor were they in first-rate condition generally. Another defect was the comparative scarcity of flowering plants, the preponderance of Palms and Ferns imparting a dull appearance to what might have been easily made an effective group. Mr. Gibson, gardener to J. F. Burnaby-Atkins, Esq., Halstead Place, was placed second, and it is an open question whether his collection was not entitled to a higher position; for though the plants were large for arranging to the best advantage, and rather too great a formality characterised the group, yet the plants were of such excellent quality, so healthy, neat, and well flowered, that many could not understand their secondary position. Mr. Mitchell, gardener to Mrs. Arbuthnot, Bridgend, Bexley, was placed third, also with healthy plants, but much too large for effective grouping.

Stove and greenhouse plants were represented by several collections of moderate-sized specimens, prominent amongst the best being the premier six from Mr. Gibson, which comprised Allamanda Hendersoni, Dipladenia Brearleyana in superb condition, the latter beautiful

plant being especially notable for the abundance of its large and richly coloured flowers. Mr. Mitchell followed closely with six good plants, *Dipladenia profusa* being very handsome, *Vinca alba* and *Allamanda grandiflora* also were fine. The last-named exhibitor was an excellent first with four handsome Fuchsias; Hugh Miller, Earl of Beaconsfield, and Display were particularly well flowered, though of moderate size. Mr. H. Cole, gardener to T. A. Mitchell, Esq., The Woodlands, Chislehurst, was a good second. *Achimenes* were well shown by J. Scott, Esq., Abbyfield, Bickley, who took the principal prize for six specimens; *coccinea*, Carl Woolfarth, and *longiflora alba* were admirably flowered. Messrs. Bridger and Kent were respectively second and third with collections of similar quality. Tuberous *Begonias* were chiefly staged by Mr. Bridger, who gained the leading position with six plants fairly well flowered, but the others were rather thin. Messrs. Scott and Bridger had the two best collections of *Gloxinias*—healthy plants flowering most freely. The second lot included several good unnamed seedlings.

Fine-foilage plants and Ferns, though not of unusual size, were generally of excellent quality, a most pleasing freshness distinguishing the majority of the exhibits in these classes. For six fine-foilage plants Mr. H. Turner, gardener to A. Phillips, Esq., Elmstead Lodge, won the first prize with vigorous even examples of *Maranta Lindeni* very fine, *Alocasia albo-violacea*, *Pandanus Veitchi*, *P. utilis* healthy and large, and *Colocasia antiquorum* in first-rate condition. Mr. Mitchell was a good second, his best plant being a fine *Maranta bella*; and Mr. Kent was third, *Stevensonia grandifolia* being highly effective in his collection. Messrs. Mitchell and Turner were also the prizetakers in the class for six exotic Ferns, the first-named having *Adiantum cuneatum*, *A. macrophyllum*, *A. gracillimum*, and *A. farleyense* very fine, with a good *Gymnogramma chrysophylla*. Mr. Turner had a neat specimen of *Lygodium scandens* and a large healthy example of *Platynerium alcinorne*. For a single specimen Fern Mr. Mitchell took the lead with one of the finest specimens of *Gymnogramma Wetenhalliana* we have seen; it was about 4 feet in diameter, and as healthy as could be wished. Mr. G. Grant, gardener to Mrs. R. Johnson, Kennel Manor, Chislehurst, was second with a similarly creditable *Adiantum farleyense*; and Mr. T. Spittle, gardener to W. A. Bradford, Esq., Elmhurst, was third with a fine *Adiantum cuneatum*. *Caladiums* were represented by plants of moderate size, but healthy and well coloured. Mr. Kent won the first prize with good examples of *Belleymei*, *Bicolor splendens*, *Chantinii*, *Max Kolb*, and *Houletii*. Mr. W. Gammon, gardener to C. Brosey, Esq., Bickley, was awarded an equal first for plants of similar quality.

Cut Flowers.—Roses were the most abundant amongst these, Messrs. B. R. Cant, Colchester; Paul & Son, Cheshunt; Rumsey, Waltham Cross; G. Bunyard & Co., Maidstone; and Laing & Co., Forest Hill, being the chief prizetakers in the nurserymen's classes, while in the amateurs' division Mr. G. Christy, Brookhurst Lodge, Westerham, and the Rev. J. M. Fuller, Bexley Vicarage, were the most successful. A class was provided for the best collection of hardy flowers, number unlimited, and two very interesting and beautiful stands were contributed. Mr. F. Maynard, gardener to J. Whitehead, Esq., Southwood, Bickley, was worthily adjudged chief honours for a collection of over sixty choice and beautiful species and varieties. Mr. Cole, gardener to T. A. Mitchell, Esq., Chislehurst, followed with a smaller but pretty collection of forty-eight distinct forms.

Fruit was well shown by Messrs. A. Waterman, G. Tucker, and Mitchell, who had the best collections. Grapes and Strawberries were of good quality generally. Vegetables were also represented by several collections of more than ordinary merit.

CARTER'S DEDHAM FAVOURITE AND VICK'S CRITERION TOMATOES.

I SEND you a sample dozen of Carter's Dedham Favourite Tomato. This is an undoubted acquisition, being good for cropping either in warm or cool houses, and is useful for pots. The dozen weigh $4\frac{1}{2}$ lbs., and as the fruits are not large you will see what a solid heavy variety it is. I am very pleased with it. The flavour is good, though not equal to that of Vick's Criterion, of which I send two fruits. Taste these two varieties in their raw state and you will at once perceive which is the best. The taste for Tomatoes, which is doubtless acquired, is fast increasing. I grow ten good varieties, but none equals Vick's. Speaking of new varieties, I wonder how many were "bit" over President Garfield. I, for one, consider it worthless and utterly unworthy of its name. Reverting again to Dedham Favourite, it is a very moderate grower compared with Vick's: this is worth knowing. With me the latter requires no feeding, and is benefited by cutting a good portion of the leaves away.—STEPHEN CASTLE, *West Lynn Vineyard*.

[The fruits of Dedham Favourite are remarkably fine. They are round, smooth, solid, of the same colour as Vick's Criterion, and by many persons would not be considered inferior in flavour to that variety. Tastes vary. Vick's is sprightly and sub-acid. The Dedham Favourite less acid, and possessing more of the true Tomato flavour; perhaps too much for some palates, but not for

all. The fruit of both are very firm and fleshy, and the plants have undoubtedly been well cultivated.]

SUTTON ROSE SHOW.

I HAVE to-day (July 7th) assisted at the inaugural Show of the youngest-born child of the National Rose Society, for I believe the parentage to be undoubted; and am glad to say that it is a most promising infant, showing considerable strength of limb, and if I mistake not likely to make itself soon heard in the rising suburb—for it is almost that of our huge city—Sutton, known to all frequenters of Epsom, and in their new and handsome Public Hall the first Exhibition was held. It had, of course, the deficiency of all first shows. Persons who do not know what exhibition Roses are, sent in boxes which only provoked a smile, but there were others there which would not disgrace any show, while I have certainly not seen this year anywhere such exceptionally good baskets and stands of Roses as were exhibited by the ladies of the neighbourhood, who may well be congratulated on the great taste displayed in their arrangements. The indefatigable Secretary of the Society, Mr. E. Wilkins, carried out all the management, assisted by a good working Committee, on the lines laid down by the National Rose Society, and everything went smoothly and well. The orchestra was most tastefully arranged by local nurserymen, and a most charming effect it had, and altogether the Show was a great success. I now give the names of the winning flowers. In Class 1, for eighteen varieties, Mr. E. Wilkins gained the first prize, given by Lady Lawrence, with good blooms of *Marie Finger*, *Comtesse d'Oxford*, *La France*, *Edouard Morren*, *Alice Dureau*, *Star of Waltham*, *Marquise de Castellane*, *Hippolyte Jamain*, *Dr. André*, *Gloire de Dijon*, *Duke of Edinburgh*, *Constantin Tretiakoff*, very good; *Marquise de Ligneris*, and *Marie Baumann*. In Class 2, for twelve varieties, the first prize was gained by Mrs. Thompson with *Jean Cherpin*, *Abel Grand*, *Annie Wood*, *Dr. André*, *Aurore Borealis* (a Rose I never heard of before), *Reine du Midi* (another Rose seldom seen), *La France*, *Abel Carrière*, &c. In Class 3, for nine blooms, Mr. E. Mawley took first prize with an excellent stand containing *Star of Waltham*, *Etienne Levet*, *Charles Lefebvre*, *Baronne de Rothschild*, *Pierre Notting*, *Madame Eugénie Verdier*, *Countess of Oxford*, *Dr. André*, and *Marie Baumann*. In Class 4, for six varieties, Mr. F. C. Poole was first with *Capitaine Christy*, *Dupuy Jamain*, *Duke of Edinburgh*, *Abel Grand*, *Le Havre*, and *Madame Gabriel Luizet*. In Class 5 Mr. H. Boulte was first. In Class 6, for six Teas or Noisettes, Mr. Cuthell was first with excellent blooms of *Catherine Mermet*, *Anna Ollivier*, *Marie Van Houtte*, *Madame Lambard*, *Perle des Jardins*, and *Souvenir d'un Ami*; he had also an extra box, in which was an excellent bloom of *M. Nabonnand*, very dark but rather thin. In Class 8, eight varieties, trebles, Mr. F. C. Pawle of Reigate was first with good blooms of *Cheshunt Hybrid*, *Marguerite de St. Amand*, *Marquise de Castellane*, *Victor Verdier*, *Prince Arthur*, *Beauty of Waltham*, *Alfred Colomb*, and *Marquise de Castellane*. In Class 9, four trebles, Mr. E. Wilkins was first with *Marie Finger*, *Paul Neyron*, *Etienne Levet*, and *La France*. In Class 10, for six trusses of any Rose, Mr. E. Mawley with *Baronne de Rothschild*, and Mr. Cuthell with *Alfred Colomb*, were equal firsts. In Class 11 a silver challenge cup, given by ladies, the prize was won by Mr. E. Wilkins with *Marie Baumann*, *Star of Waltham*, *Victor Verdier*, *Catherine Mermet*, *Prince Arthur*, and *Marie Finger*; this also obtained the silver medal of the National Rose Society for the best box in the Show, and to Mr. Wilkins was awarded also the bronze medal for the best bloom, a splendid bloom of *Marie Finger*.

As I have said, devices were exceedingly well shown. Miss Foulger obtained the first prize with fine baskets in ebonised stand, very tastefully arranged; and Mrs. Atkinson the second prize with a handsomely arranged basket, in which were Roses and *Adiantum gracillimum* gracefully arranged.

I am glad to hear that the Show was thoroughly appreciated, and that the room was crowded to a late hour, and all interested in it must be congratulated on a very successful first venture—the precursor, I hope, of many others.—D., Deal.

ORCHIDS IN JULY.

THE work of this month will be a continuation of that of last. The houses are very attractive with the many plants in bloom. *Aerides quinquevulnerum* is now bearing its compact pendent spikes of white and purple flowers, which last for about three weeks. *Aerides roseum* is a dwarf plant, and very pretty with its fine spikes of rose-coloured blooms. We find this does best in a basket hanging about a foot from the glass, and requiring less water than the other *Aerides*. *Aerides affine* is blooming well, and somewhat resembles *A. roseum*, but the flower spikes are longer and in many cases branching. It lasts in bloom for about a month.

Barkeria spectabilis is opening its lovely rosy lilac flowers, which will remain in perfection for nearly three weeks.

Cattleya gigas, without doubt the finest of all the known *Cattleyas*, is in good condition. It produces from two to five large handsome rose-coloured flowers with deep purple lip on a spike, five, however, being rather the exception than the rule. There is

an imported variety sold under the name of *C. gigas Sandersiana*, which, judging from the old flower seats, has borne as many as nine blooms on a spike. This will be anxiously looked for when established in this country. *C. Harrisoniana* is producing its beautiful rose-coloured blossoms, and is always a welcome addition to the *Cattleya* house when grown well. We find it succeeds best with a good drainage of charcoal and crocks, with good knobs of rough fibrous peat placed on the top, and grown in a light position at the warmest end of the house, with a moderate supply of water.

Lælia grandis, with its beautiful nankeen-coloured flowers lasting a long time in bloom, and *Lælia Schilleriana* bearing lovely flowers with rosy white sepals and petals and dark purple lip, are blooming freely. *L. crispa* is pushing its flowers up the sheaths, promising a rich display shortly of its large pure white crimson-lipped blossoms, which are doubly invaluable from their being deliciously scented.

Maxillaria grandiflora is nearly always in bloom. In cases where parties have a few specimens of this beautiful Orchid they are hardly ever without one of its large snow-white purple-lipped flowers. *M. luteo-alba* is now handsome with its large creamy white blossoms. *Mesospinidium vulcanicum* is producing its fine spikes of numerous pretty fiery red blooms, and makes a lovely basket plant.

The cool house is still rich with the pure white crispy flowers of *Odontoglossum Alexandræ*, the yellow purple-spotted blooms of *O. astranthum*, the curious green and brown blossoms of *O. bictoniense*, the citron-scented rosy-white blooms of *O. citrosum*, the chocolate-barred greenish-yellow of *O. cordatum*, the brown-spotted delicate white of *O. Ehrenbergii*, the sweet-scented greenish-yellow and purple flowers of *O. læve*, the crimson-sprinkled pure white of *O. nævium*, the snow white brown-clouded blooms of *O. nebulosum*, the delicate rosy white of *O. Pescatorei*, the white-lipped yellow-coloured blossoms of *O. radiatum*, the fragrant milky white purple-spotted flowers of *O. Roezlii*, the lovely lake-carmine of *O. roseum*, the reddish-coloured white-lipped blooms of *O. rubescens*, the straw-coloured *O. Schlieperianum*, and the large delicate-coloured flowers of *O. vexillarium*.

Promenæa stapelioides.—This curious little Orchid looks well now with its greenish-yellow purple-lipped flowers, and does well in pans with sphagnum and rough fibrous peat, and grown near the glass.

Thunia alba.—This free-flowering plant is attractive with its beautiful pure white blooms, as is also *Thunia Bensoniæ* with its large bright magenta blossoms. These do best in baskets with sphagnum, peat, and sand, and kept close to the glass, with a plentiful supply of water.—ORCHIDIST.

WEATHER FORECASTS.

I WAS pleased to see in the "Notes and Gleanings" column the quotation of Mr. Fawcett concerning the advisability of gratuitous weather forecasts by telegraph to agriculturists, because it offers an opening for a few remarks on the subject. As Mr. Fawcett evidently realises, the farmers are not alone interested in the possible state of the weather, but the followers of other professions, more especially that of gardening, would be equally glad of reliable information day by day. Unfortunately the weather forecasts as given in the daily papers are anything but reliable. Science is working wonders in all directions—more so, indeed, than many of us realise; but I am afraid it will never be sufficiently advanced to forecast the weather in any particular district. For that reason I advise all concerned to study the local signs and indicators, and to found their decisions on these rather than to rely upon those who can only give general information extending over a large area, such as the "south-western counties."

Thunderstorms at this time of the year we most dread, and what can our oracles tell us concerning these? Take for instance, out of the many I could adduce, the forecast for "England S.W. and South Wales," in which we are included, on Monday, June 26th. This was "Southerly to south-westerly winds, moderate; cloudy to fair." On that date we experienced three hours' heavy thunder rain, while within seven miles in one direction a cricket match was not hindered in the least, and the same phenomenon occurred in various parts of the country. The forecast in this instance was actually misleading, and I maintain they are generally vague and unreliable, comparing most unfavourably with a good barometer. One of these ought to be seen in every farmer's and gardener's house, and when thoroughly understood—I mean with regard to their indications—would prove invaluable. With its help the farmer would better know what to do with his hay and corn, and the gardener at this time of the year whether to be planting Celery, Broccoli, and other plants throughout the day, or

to prepare for fruit-picking, hoeing, and similar work necessarily or best performed on a dry day.

I possess a "wheel" barometer, and am also provided with a "cistern" barometer, and seldom decide upon any important work without consulting one or both of these. The former—which I consider the most serviceable, as by tapping its movements are anticipated—is hung on the outside wall of the living-room, and in this position it is more sensitive. No doubt this position causes a greater range, but this is immaterial, as I do not trouble to contrast the figures with those given by the qualified authorities. The cistern barometer is hung where barometers are generally disposed—viz., in the front hall; but I best understand the movements and indications of the dial-faced cistern, and generally depend upon that alone. Even in the case of a barometer it is difficult to formulate a general rule for the guidance of those interested, as so much depends upon the locality. I find a falling barometer does not always indicate wet, or the opposite movement fair weather, as we may experience heavy rains with the indicator or mercury, as the case may be, at 29.5 and much dull, if dry, weather at 30.4. Last winter the indications were remarkably abnormal; but, as a rule, by smartly tapping the barometer in the morning I can almost feel certain if the weather will be dull yet fine, showery, very wet, or clear and bright, and more than this I do not believe science will furnish. As a matter of fact, much has to be determined by the direction of the wind, and it must also be known from what quarter the most rain generally comes. Given a good barometer, and farmers and others need not solicit any aid from the Government. On July 1st the weather forecast reads "England S.W. and South Wales, north-westerly breezes, light; fine." This was right enough with regard to the direction of the wind, but two hours' thunder rain commencing about 1 P.M. was not agreeable to the haymakers or consistent with the forecast.—W. IGGULDEN, *Marston, Frome*.

THE BEST ROSE IN THE SHOW.

To look for this is now the concluding act at almost every Rose show, and it reaches its climax at the meetings of the National Rose Association. To find this on July 4th was no easy matter, as the Roses were a trifle past their best, and July 1st had perhaps seen that in southern England. There was no Rose of surpassing excellence like the A. K. Williams of 1880, which settled the matter at once. The Rev. H. H. D'Ombraïn, as usual, was equal to the occasion, and, assembling round him his array of Judges in the beautiful conservatory of the South Kensington Gardens, dispatched no less than four through the corridors on this special errand. We agreed to go two and two by different ways to note down what we found, and compare when we met, and this year the nurserymen quite beat the amateurs. The tables of the last three years were completely turned. The "great twin brothers" of former Rose shows were gone, and their places were still empty. One of them as a judge might still be seen flitting round the scene of his former triumphs, but too well-known circumstances prevented even the appearance of one other champion; nor had we even the genial presence and weighty battalion of our President, even though he was represented by his Vice, Mr. George Baker of Reigate.

When Mr. Mount and myself met Mr. Cuthell and Mr. Sladden both had found the best Tea in the Exhibition, and, as might be expected, it was *Souvenir d'Elise Vardon*. They were almost equal, but Mr. Cant's carried the day through a graceful bud and better foliage. The *Noisettes* were again, as usual, not satisfactory. No *Maréchal Niel* really worthy of its name was in the Exhibition. A wonderfully good *Narcisse* was found, but what is *Narcisse* even at its best? Then a singularly fine *Triomphe de Rennes* appeared in Mr. Walker of Thame's box, and gained the medal, though far inferior to many of the Teas. A *Catherine Mermet* in Mr. Cuthell's prize box of twelve Teas and a *Madame Lambard* elsewhere at one time were considered likely.

But now came the difficulty to find the best Hybrid Perpetual. Several *Gabriel Luizets* claimed our attention. A very fine *La France* was discovered in the "never won a prize before" class, where, I may remark, were several boxes that might have been expected to do battle in the open six, and were quite out of place amongst their feebler brethren. Then an *Annie Wood* in Mr. Baker's box, and especially an A. K. Williams in a grand box of twelve, which were shown in the open class. One of these and a magnificent *Alfred Colomb* were compared for five minutes without any decision. At last we gravitated irresistibly to the very eighteen box of Mr. Cant's, in which we had found *Souvenir d'Elise* (certainly the best eighteen Roses together in the Show), and there was the *Gabriel Luizet* we had admired, getting more beautiful every moment, and fairly taking the honours of the

premiership of 1882. It may be remembered that a bloom of this ran second in 1881.

The comfort with which the members obtained their view, the coolness and space of the arcades, and the excellent centre made by the conservatory with its many other floral exhibition excellencies, will have made this 1882 Show memorable, did nothing else do so, in the annals of the National Rose Society, and it is to be hoped will determine its future abode.—A. C.

SENECIO JAPONICUS, *Schultz, Bip.*

SUMMER and autumn bring a succession of the numerous members of the Composite order into notice, and many of them are

well-known ornamental and useful plants in gardens, but in so large a family it is not surprising that some possessing considerable attractions should be comparatively neglected. The plant represented in the woodcut (fig. 8) appears to be one of these, for when grown as it is at Mr. T. S. Ware's nursery, Tottenham, its effectiveness cannot fail to attract attention and admiration. Visitors to Kew must not, however, form an opinion of the plant's adaptability for garden culture from the specimen in the herbaceous grounds, as it is much inferior to that from which our engraving was taken, and it is evident that a shallow light soil is not the best fitted to ensure the vigorous growth which this *Senecio* makes under more favourable circumstances. At Tottenham it attains the height of 3 or 4 feet, its handsome pal-

Fig. 8.—SENECIO JAPONICUS.

mately divided leaves having a most distinct appearance; the large orange yellow flower-heads frequently exceeding 3 inches in diameter, being produced in a corymbose or raceme-like inflorescence, which rises a foot or more above the foliage. As a border plant in prominent positions it would be very useful, and though it flowers at a time when there are abundant attractions in the garden—namely, during the past and present months, still its bold habit and striking foliage will undoubtedly render it a favourite.

It can scarcely claim to be considered as a novelty, for tracing

it through its various synonyms of *Erythrochæte palmatifida*, *Sieb. et Zucc.*, and of Regel's "*Gartenflora*," tab. 492, to *Ligularia japonica*, *Less.*, we find, according to Decandolle's "*Prodromus*," pars. vi., p. 316, that it is synonymous with *Arnica japonica* of Thunberg and Linnaeus. Under the last generic name Thunberg mentions two species—viz., *A. japonica*, which he describes as having red flowers, and *A. palmata*, similar in most characters to the above, but with small yellow flowers. The *Senecio japonicus*, mentioned by the same author, is quite a different plant. In Martyn's edition of Miller's "*Gardeners' Dictionary*" *Arnica*

japonica is described, but it is not stated when it was introduced to cultivation, if it really was grown then. The same plant was subsequently mentioned by Loudon, who gives the close of the last century as the time of introduction; but the plant appears to have been lost, and again brought into notice within the past twenty years. Specimens have been in cultivation at Kew for some years, and now Mr. T. S. Ware has taken the plant in hand it will soon be obtainable by the general public.

DEATH OF DR. NEWINGTON.

It is with extreme regret that we have to record the death of Dr. Samuel Newington, M.A., Oxon. M.R.C.P. Lond., which occurred at his residence at Ridgeway, Ticehurst, on the 3rd inst. The disease to which he fell a victim was that of the heart, which he has been troubled with more or less for forty years, but not until three weeks from his death was he seriously affected and obliged to keep to his room; up to that date he was out daily wandering about his gardens, in which he took immense interest. Since October last he had given up professional duties, in which he had engaged over forty years, consequently of late had devoted most of his time to horticultural pursuits. Nor did he work in vain. Fertile in conception and prompt in action he devised and constructed amongst other things the ground or curates' vinery, which in various modifications has proved so useful for protective purposes; his last invention, which has proved of substantial value, being the tree-lifting implements figured on page 318, vol. iii., third series of the Journal. He also invented a dibber, which some years ago had a good reputation for planting Wheat, Beans, and other agricultural crops. The structures in his garden are all of his own design, and were home-made. The cylinder vineries are now occupied with Tea Roses. These are among the novelties of Ridgeway, but simplicity, durability, and utility characterise the ordinary structures. His "glass wall" for growing Peaches is figured in our nineteenth volume. It was erected at less cost than a wall could have been, and accommodates two rows of trees.

By his taste and labour the grounds and gardens were rendered highly picturesque. The rockery is a charming example of well-directed labour, and glades, dells, mounds, and fountains contribute to the attractiveness of the grounds, in which he employed some twenty-five men to assist him in his experiments and improvements that were constantly in progress. He was most liberal in disposition, and ever ready to impart information that might be useful. He was a frequent correspondent of the horticultural and agricultural papers under the signatures of "SIGMA" and "OBSERVER." For years past—we can scarcely say how long—he has contributed to our pages much sound matter and many suggestive hints, which have been turned to profitable account by many readers. With all his knowledge he was modest, kind in disposition, and affable, hence he was widely esteemed, as was shown by the numbers that attended his funeral on the 6th inst. He was sixty-eight years of age.

ROYAL HORTICULTURAL SOCIETY.

JULY 11TH.

THE exhibits were confined to the Council-room on Tuesday last, and principally comprised groups from Chiswick and Messrs. Ware and Howard, with new plants from Messrs. J. Veitch & Sons, Chelsea.

FRUIT COMMITTEE.—H. J. Veitch, Esq., in the chair. Mr. C. A. Pearse, gardener to Sir T. Stapleton, Henley-on-Thames, exhibited a Melon called Gray's Court; Mr. Allen, The Gardens, Ramsbury Manor, also exhibited a seedling Melon. Mr. Read, Moat Mount, Mili Hill, sent Read's New Life and Read's Hybrid Green-flesh Melon, all of which were inferior in quality. Mr. Osman, Metropolitan District Schools, Sutton, sent a dish of each Aquedolce and Seville Longpod Beans, which received a letter of thanks. Mr. Bonsall, Campsmount, Doncaster, exhibited a Pea called Bonsall's Curvilinear, and a Cauliflower similar to Erfurt. Messrs. Veitch & Sons exhibited a collection of thirty-nine dishes of Peas, all carefully named and marked with their height and date of coming into use. A cultural commendation was awarded.

FLORAL COMMITTEE.—G. F. Wilson, Esq., in the chair. Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, contributed a large and very beautiful collection of hardy flowers very tastefully arranged, neat little brown earthenware bottles being employed to hold them. Amongst the Lilies especially noteworthy were the following:—The deep rich red *L. Thunbergianum cruentum*, for which a first-class certificate was awarded; the bright orange red *L. croceum*, the neat shining yellow *L. Szovitzianum*, the peculiar creamy yellow *L. excelsum*, the small and pretty yellow red-spotted *L. canadense*, the dark purple small-flowered but striking *L. dalmaticum*, the showy yellow and crimson-spotted *L. Humboldtianum Bloomerianum*, with the old white *L. candidum*, and the handsome *L. longiflorum*, and

L. Browni. Of other notable plants represented were *Campanula alpina*, with small deep blue flowers; *Tritonia crocata*, orange red; *Papaver nudicaule*, bright yellow; *Gladiolus Colvilli The Bride*, white; *G. insignis*, salmon scarlet; *Adenophora coronata*, with small Campanula-like pale blue flowers; *Triteleia Murrayana atropurpurea*, with the umbels of deep purplish blue flowers; *Armeria plantaginea rosea*; *Liatris spicata*, and numerous fine Pinks, Carnations, Calochorti, and other flowers. A medal was awarded for this group.

Messrs. H. Cannell & Sons, Swanley, Kent, exhibited a large collection of Verbenas, comprising many handsome varieties. The best were Shakespeare, Fireball, and Lord Leigh, scarlet; Boule de Neige, white; Boy in Blue, deep purple, white centre; Lady Leigh, pale lavender purple; Mr. Gladstone, rose, large; Swanley Strip, scarlet and white; Stars and Stripes, pale rose and white; Blue Superb, purplish blue with white centre, large; and Queen of Verbenas, deep crimson with large white centre. Flowers of the large white *Oenothera speciosa*, *Malva moschata alba*, *Nicotiana affinis*, and the double white *Campanula persicifolia alba plena* were also shown in good condition, with a pretty selection of single Dahlias and a fine deep purple double Pansy named Lord Waverley, which was certificated. A medal was awarded to Mr. W. Howard, Southgate, for a fine group of Carnations, Balsams, Marguerites, Ferns, Rhodanthes, with Pink and Carnation blooms, some of the latter being extremely fine. Messrs. J. Carter & Co., High Holborn, sent specimens of two fine Lilies, *L. longiflorum Wilsoni* and *L. Thunbergianum atrosanguineum*; the former pure white, and the latter rich red.

A handsome group of well-grown Tuberous Begonias was sent from the Society's gardens at Chiswick, all the plants being extremely vigorous, but compact and well flowered. Several attractive seedlings were staged; three—namely, A. F. Barron, Mrs. Stevens, and Thomas Moore, being honoured with first-class certificates, and are described below. Of others not so noticed the best were the following:—Gippie, with bright rose flowers of excellent form, the petals broad, round, and even. The habit is very compact, and the flowers are produced with great freedom. James McIntosh was remarkable for the rich scarlet colour of the flowers; and several seedlings, only designated by numbers, were noteworthy also for the deep colours. A pretty group of Achimenes and Ferns was also staged, the former being mostly in small pots, but bearing large and richly coloured flowers. A collection of Neriums occupied one corner of the room, several of the varieties certificated recently being represented.

First-class certificates were awarded for the following plants:—

Tydeæ Robert le Diable (Veitch).—A most striking variety, with scarlet tube $1\frac{1}{4}$ inch long, limb $1\frac{3}{4}$ inch broad, similar ground colour to the tube, but densely spotted with maroon. Leaves elliptical, $1\frac{1}{2}$ inch long. The flowers are produced singly from the axils of the leaves on the upper part of the stem.

Osmunda japonica corymbifera (Veitch).—A dwarf Fern with bipinnate fronds, the pinnules being deeply and irregularly cut. The fronds are 1 foot or more in length.

Croton aureo-marginatus (Veitch).—A showy form from the South Sea Islands, with leaves 1 foot to 18 inches long and $2\frac{1}{2}$ broad, irregularly mottled with green and yellow, the latter predominating.

Rhododendron balsamiflorum aureum (Veitch).—One of the greenhouse hybrid section, similar in character to that recently certificated, but with bright yellow double flowers, though not so full as the rosy coloured form.

Rhododendron balsamiflorum album (Veitch).—Similar in general character to the above, but with larger pure white double flowers in fine heads of ten or more blooms.

Davallia tenuifolia Veitchiana (Veitch).—Very graceful, the finely divided fronds being 18 inches or more in length, of a plumose slightly drooping form. The reddish stipes also contrast agreeably with the pale green pinnules.

Croton Dayspring (Veitch).—A very distinct form, the lower leaves having three parts of the basal portion rosy red, the apex being deep green, the young leaves being bright yellow margined and tipped with green.

Pleopeltis fossa (Veitch).—A curious Fern, with shining green fronds, lanceolate in outline, 9 inches long, and cut at the margin into deep narrow segments of irregular size and form.

Pansy Lord Waverley (Cannell).—A remarkable variety, with double flowers 2 inches in diameter, of a deep purple nearly black shade. The blooms were of extremely neat form, somewhat suggestive of a double Ranunculus.

Lilium Thunbergianum cruentum (Ware).—One of the richest coloured Lilies in cultivation. The petals are oval in form, very deep red, the lower portion spotted with black, and the centre streaked with a darker shade. Very handsome.

Chrysanthemum La Petite Marie (Ware).—A diminutive Pompon variety, the specimens shown not exceeding 6 inches in height, with neat white flowers tinged with yellow. It will doubtless prove useful for decorative purposes. Second-class certificate.

Godetia Duchess of Albany (Daniels Bros.).—A handsome form, with large white *Oenothera*-like flowers, which are produced in great numbers near the points of the branches.

Rose Duchess of Connaught (Noble).—An excellent Hybrid Perpetual Rose, with dark scarlet blooms of good substance and very

full. The half-expanded buds were particularly beautiful both in form and colour.

Tuberous Begonia A. F. Barron (Royal Horticultural Society).—A handsome variety, with large bright scarlet flowers $3\frac{1}{2}$ inches in diameter, the petals very round, broad, and bright in colour. The foliage is very dark green, and the habit compact.

SCIENTIFIC COMMITTEE.—Dr. M. T. Masters in the chair.

Hollyhock Disease.—Mr. W. G. Smith exhibited specimens of fruits of the common Mallow with *Puccinia Malvacearum*. They were sent by Mr. Phillips, who gathered them near Shrewsbury. Their fruits confirmed the correctness of Mr. Smith's observation—that the fungus-infected fruits or seeds of the Malvaceæ fall to the ground, and are then capable of producing seedlings diseased with *Uredo* spores without an intervening *Æcidium* condition.

Hart's-tongue Fern Disease.—He also showed a specimen of this Fern attacked by *Didymium effusum*, Lk., new to Great Britain. It occurs on both sides of the frond, and grows over the ruptured masses of spore cases (sori), and even amongst the free spores.

Dwarf Oak.—Dr. Masters exhibited a spray of a dwarf Oak, *Quercus eucine* (humilis), from South Spain. It never attains a height over 2 feet. It was in full fruit.

Oat and Clematis roots attacked with vibrio were also shown by him. It appears to be one variety only of black Oat which is affected, and that to such an extent as to destroy whole crops year after year.

Gardenia and Petroleum.—He exhibited a spray of *Gardenia* treated with petroleum oil and water (a wineglass to a gallon) for killing mealy bug, showing the very healthy character of the plant.

Thuja japonica (Standishii).—Dr. Masters showed specimens in fruit.

Water Lily with Foliaceous Sepal.—He also showed a specimen in which a leaf blade had developed on the apex of a sepal, proving that the sepal, as is usually the case, is a petiole only.

Coloured Pea Pods.—Mr. Laxton sent pods of purple and white Peas, as well as pods of the former crossed by the latter, with purple and green intermixed. From examination it appears that the purple colour overlies the chlorophyll.

Antirrhinum Hendersoni.—Mr. Cannell exhibited flowers of this race, white with a narrow crimson border to the petals. It is an old form but rarely seen, as it will not set seed, this being apparently due to atrophy of the essential organs.

Aërial Tubers of Potato.—The Rev. G. Henslow exhibited tubers found in the axils of leaves.

Canker in Pears.—These were received from Daventry, where it appears very prevalent; the cause was unknown.

Plants Exhibited.—*Sedum Semluovii*, from the Caucasus, by Dr. Masters. *Hoya lasiantha* having hairy petals, from Borneo, by Messrs. Veitch, as well as *Impatiens Sultani*, with crimson flowers, from Zanzibar; as also a curious Aroid, *Lasia stipitata*, from Borneo. These three received botanical certificates. *Hesperaloe yuccæfolia*, from California, which had been flowering ever since June, 1881, was also sent by the same gentleman.

AT a meeting of the Fruit and Floral Committees at Chiswick on July the 7th certificates were awarded for the following vegetables and plants:—

FRUIT AND VEGETABLE COMMITTEE.—J. E. Lanc, Esq., in the chair. The collection of Peas was examined, and first-class certificates awarded to the following:—

Lye's Favourite (Lye).—A tall round white Marrow.

Gladiator (Veitch).—A dwarf round blue Marrow.

Turner's Emerald (Carter).—A dwarf white wrinkled Marrow.

Stratagem (Carter).—A dwarf green wrinkled Marrow.

Alfred the Great (Laxton).—A tall blue wrinkled Marrow.

Culverwell's Telegraph, Carter's Telephone, Culverwell's Giant Marrow, and Four-hundredfold (Bunyard), were highly recommended, the two former having been previously certificated.

Lettuces were next inspected—Green Unctuous (Benary), Paris Sugar (Benary), being commended.

Shallots were next examined, when it was found that only two truly distinct varieties existed under the names of No. 1, Small White, Silver Grey, Large Brown, Russian; No. 2, Large Red, Small Red, Large Russian, New Russian, Mammoth; the Exhibition Shallots of Stuart & Mein being a somewhat larger selection of No. 2; the Jersey Giant Red Shallots and the Jersey Silverskin Shallots of Pond proving to be some species of Onion to be subsequently determined.

FLORAL COMMITTEE.—Mr. B. S. Williams in the chair.

First-class certificates were awarded to the following:—

SINGLE ZONAL PELARGONIUMS.

Lumen (Pearson).—Plant of dwarf habit, the trusses very large; the individual flowers large, of fine rounded form, bright scarlet, with distinct white eye.

Eva (Pearson).—Plant of free growth; trusses large, borne well above the foliage; flowers of fine form, beautiful magenta scarlet.

Miss Hamilton (Pearson).—Plant of remarkably dwarf habit, the

trusses large; individual flowers large, of very fine form, beautiful blush white. Distinct and pretty.

Kléber (Lemoine).—Very free habit; trusses of medium size, somewhat loose; the flowers of a beautiful magenta-shaded scarlet, with bright scarlet blotch on lower petals. Very pretty colour.

Atala (Pearson).—Plant of dwarf habit, very free-flowering; the trusses large; the individual pips large, of a fine rounded form, bright orange scarlet.

Olive Carre (Pearson).—Plant of vigorous habit, free-flowering; the trusses very large; individual pips large, of very fine form, clear rosy pink with blotch of white on the under petals. Very fine variety for culture in pots.

DOUBLE ZONAL PELARGONIUMS.

M. Hardy (Lemoine).—Plant of dwarf habit, the trusses of medium size; flowers large, semi-double, delicate rose lilac.

Got (Lemoine).—Plant of very vigorous habit, the trusses very large and full; individual flowers of medium size, semi-double, bright scarlet. Very showy.

Aglaiä (Pearson).—Plant of very dwarf habit, very free-flowering; the trusses large, well displayed; individual pips large and double, purplish scarlet.

Candidissimum plenum (Pearson).—Plant of dwarf growth, very free-flowering; trusses of medium size; individual pips of large size, very double, of a pure white colour. The best white variety.

IVY-LEAVED PELARGONIUMS.

Comte Horace de Choiseul (Lemoine).—Plant of free trailing growth, very free-flowering, the trusses of medium size; individual flowers large and double, beautiful rosy pink with streaks of white along the petals. A very pretty variety.

Comtesse Horace de Choiseul (Lemoine).—Plant of trailing habit, free-flowering; the flowers very large, semi-double, beautiful rose centre shading to magenta towards the edge. Very distinct and showy.

DECORATIVE PELARGONIUMS.

Belle de Jour (Lemoine).—Plant of good compact habit, very free-flowering; flowers semi-double, pure white. Will be a good variety for market purposes.

Madame Harmant (Lemoine).—Plant of fine sturdy growth, very free-flowering; the trusses large; individual flowers large, of fine form, pure white slightly streaked with purple towards the eye.

Gloxinia Major Mason (Royal Horticultural Society).—A very fine erect-flowering variety; the flowers very large, with pure white throat, and clear purple margin shading to paler purple towards the edge.

Lantana Phosphoré (Lemoine).—Plant of very dwarf habit, remarkably free-flowering; the flowers clear golden yellow.

TUBEROUS BEGONIAS.

Mrs. Stevens (R. H. S.).—A beautiful free-flowering variety; flowers of fine substance and form, well displayed, beautiful flesh colour suffused with pink.

Thomas Moore (R. H. S.).—Plant of free growth, free-flowering; the flowers of medium size, of very fine rounded form, well displayed pale rosy scarlet. A very distinct and showy variety.

NERIUMS.

Sœur Agnes (Huber et Cie.).—Flowers single, large, pure white. Free-flowering and pretty.

Mons. Balaguer (Huber et Cie.).—Flowers single, well expanded, beautiful delicate pink shaded towards the edge with rose. A very fine variety.

Madonnæ grandiflorum (Huber et Cie.).—A very free-flowering variety; flowers with double corolla, creamy white. Very distinct.

Reseda odorata pyramidalis grandiflora (Vilmorin et Cie.).—Plant of fine dwarf stubby growth, very branching; heads of flowers very large, the flowers red. A fine variety for pot culture.

Reseda Golden Queen (Carter).—Dwarf habit; flower spikes large, of a fine golden yellow colour. This also is a fine variety for cultivation in pots.

THE PEAR TREE SLUG—FRUIT IN NEW ZEALAND.

I WAS much interested by your reply to a correspondent in reference to this insect. I do not recollect having ever noticed it in this country, but last January whilst in New Zealand I was quite astonished at the ravages wrought by it at Nelson. The Pear trees there suffered badly, but the Cherries far more so, and I do recollect seeing one Cherry tree that had not had its leaves almost entirely devoured by this insect, which they there call a leech, and which answers exactly the description you give. The quick hedges also suffered quite as much as the Cherry trees from this pest, though Apricots, Apples, Plums, &c., seemed unmolested.

While on the subject of Nelson fruit, it may interest some of your readers to know that I never before saw such crops of Green Gages, Plums, and Apricots. The last-named, as well as Peaches, are grown as orchard standards, and form fine trees. Mulberries also I never before saw so plentiful and of such a size, while the small fruits, more particularly Raspberries and Strawberries, thrive exceedingly well. Figs were good. I also noticed Lemons doing well. With regard to the prices realised, I am afraid the crops were not very remunerative. I saw Green Gages sold by auction in Auckland at $1\frac{1}{4}d.$ and $1\frac{1}{2}d.$ per lb., also Apricots at $2\frac{1}{4}d.$ and $2\frac{1}{2}d.$ per lb. Peaches are finer and grow better in Auckland. However, a better day is possibly commencing for the Nelson growers, as while I was there a jam factory had commenced operations, and was then daily taking some thousands of pounds of fruit.

Honey is everywhere plentiful, and the people are just beginning to give more serious attention to bee-keeping, especially in Canterbury.

You are at perfect liberty to make what use you please of these few remarks, and, if desirable, I may return to the subject on some future occasion.—W. H. MATTHEWS.

[We shall be very glad to hear from you.]

POLYGALA CHAMÆBUXUS.

THIS is a dwarf half-shrubby plant from 6 to 9 inches high, with creeping roots, with ovate or obovate leaves, rather leathery in texture. The flowers are solitary or in pairs, axillary, almost Pea-shaped; the standard and wings white, while the keel petal enclosing the stamens is white at the base, bright yellow at the apex, deepening in colour as the flowers get older. It is a very effective rockery or border plant, growing best in a damp shady place in peat, loam, and sand, in which it grows rapidly, forming dense bushes. It may be increased by divisions, cuttings, or seeds. The cuttings should be taken young after the plant had been gently forced. It is a native of southern Europe, and flowers here from May to June. Both Clusius and Jacquin make some observations respecting a purple-flowered variety, but which I think was unknown under cultivation in this country till within the last few years, when it was introduced and offered by Messrs. Backhouse of York, and which is named *purpurea*. The standard and wings are bright magenta purple and the keel yellow, hence it is a very attractive variety, and, according to the description given of it, it appears to be dwarfer than the typical form, as it is described as being from 4 to 6 inches high, but most likely it will attain the same proportions under cultivation.—T.

BROCKHAM ROSE SHOW.

THE village green of Brockham is perhaps one of the most lovely in Surrey, delightfully situated, encircled by picturesque dwellings, and overshadowed by its Ivy-covered memorial church. Brockham is not only happy in the possession of a perfect village church, but is fortunate in the vicar, who earnestly labours for the welfare of all entrusted to his ministrations and spiritual guidance. He is an ardent lover of Roses, and his zeal in the cause of these flowers is much appreciated by neighbouring friends, who from time to time have placed their grounds at the disposal of the Brockham Rose Society for their annual Show. This year, on July 6th, the Exhibition took place at Redlands, the seat of M. Rhode Hawkins, Esq.—a spot most admirably chosen; the grounds are laid out with great taste, and the surrounding district affords to the admirer of nature scope for many interesting researches. He can indulge any taste he may possess, whether as a poet, a painter, a botanist, or geologist—indeed, there is here every material that can be desired to excite the imagination or to stimulate a lingering fancy. It was near here that the good and great John Evelyn lived and died, and the spirit of the old philosopher and naturalist seems to hover round the scene.

There was a splendid show of Roses. The exhibits were well arranged under a large and convenient marquee, and too much praise cannot be given to Capt. Lang, the Rev. A. Cheales, and other members of the acting Committee for the excellence of all their arrangements to meet the requirements of the exhibitors. The attendance of visitors was smaller than on former occasions, and, unfortunately, the weather was most unpropitious, the rain ceasing but at short intervals during the whole of the afternoon.

The principal class was for twenty-four Roses, single trusses. Four collections were staged, the Rev. A. Cheales securing the first prize with beautiful blooms of great substance and good colour. Most of the varieties in this box were splendidly represented, especially Alfred Colomb, a perfect flower in every respect; Mons. E. Y. Teas, Capitaine Christy, Leopold I., and A. K. Williams were very fine. The second prize was awarded to C. E. Cuthell, Esq., for an excellent collection; Mons. E. Y. Teas, Marie Rady, Baronne de Rothschild, and Général Jacqueminot being almost faultless blooms. In the class for twelve, distinct, single trusses, which is one that generally excites

much interest and competition, G. G. Stone, Esq., was first with excellent blooms of good substance and evenness of form. Thomas Mills, Duke of Edinburgh, La Reine, and Annie Wood were especially fine. F. T. Wollaston, Esq., was second with a box scarcely inferior, and E. Horne, Esq., third with most creditable blooms.

Class 3, for six, distinct, single trusses, Captain Lang was first and Mr. Thompson second. Class 4, for four distinct varieties, three trusses each, G. G. Stone, Esq., again was first with even blooms of good substance, and Mr. F. T. Wollaston second with clean, bright, fresh blooms. An extra prize was given in this class by C. E. Cuthell, Esq., on the recommendation of the Judges, to E. Horne, Esq., for a very well-staged box of good quality. Class 5, for six single trusses, any kind, the competition was very great and interesting, two of the exhibits being so nearly equal in merit the Judges had some difficulty in awarding the gold medal of the National Rose Society; it was, however, deservedly given to C. E. Cuthell, Esq., for his box of remarkably fine blooms of Annie Wood. G. G. Stone, Esq., carried off the first prize for a box of Charles Lefebvre of extraordinary fine quality. Mrs. Mortimer secured the second prize, the Rev. A. Cheales by the rules of the Society not being able to take another prize with his box of *Marquise de Castellane*.

Class 6, twelve Teas or Noisettes, distinct, single trusses.—In this class there were six competitors. The first prize was given to E. Horne, Esq., for a box of very neat well-formed blooms, the Rev. A. Cheales taking second with blooms of nearly equal merit. C. E. Cuthell, Esq., exhibited in this class and staged a box of most charming blooms, Madame Lambard being remarkably fine in form, substance, and colour. Unfortunately he had placed a Hybrid Tea in his collection, which rendered the box disqualified according to the printed notice in the schedule of prizes. Class 7, six Tea or Noisette, distinct, single trusses.—Miss Barclay took first prize, and Mrs. Thompson second. The silver medal of the National Rose Society for the best bloom of any kind was awarded to Rev. A. Cheales for a magnificent example of Alfred Colomb, and the silver medal for the best Tea was taken by C. E. Cuthell, Esq., for his charming and perfect bloom of Madame Lambard.

Devices, in which ladies only competed.—The competition for the dinner-table decorations was great. Some beautiful arrangements of Roses with Ferns and other foliage were staged. Miss Fuller was deservedly awarded the first prize and Mrs. R. Hawkins the second, although all the four exhibits were good. Device for Drawing-room Table Decorations.—Here also the specimens exhibited displayed great artistic taste, and some really elegant exhibits were placed, so equal in refinement and charm of arrangement as to render it no easy task to determine which should take first prize. Eventually the Judges considered Miss Fuller first, Mrs. R. Hawkins second, and recommended an extra prize to Miss Heath. The somewhat novel decoration called the Brace Bouquet was introduced, and two very chaste and lovely specimens were exhibited. Miss Fuller had the first prize and Mrs. J. B. Nicholls second. Both were most gracefully and delicately arranged. In the class for button-hole bouquets, Rose buds combined with foliage of flowers and exhibited in groups of three, Miss Fuller was first, Mrs. Thompson second, Mrs. J. B. Nicholls third, and Miss Horne fourth.

Messrs. Paul & Sons of the Old Nurseries, Cheshunt, contributed a beautiful collection of Tea Roses, and also a second box of the new Hybrid Perpetual Roses, representing Ferdinande Chaffolte, Guillaume Guillemot, Rosieriste Jacobs, Lady Sheffield, R. N. G. Baker, White Baroness, George Baker, Edward Moreau, Duke of Teck, Charles Darwin, and a seedling of charming colour which promises to be a valuable and popular Rose for the future. Mr. Appleby of the Box-hill Nurseries staged a most attractive box of Teas and Noisettes, which gained much attention and were blooms of high merit. I have thus briefly noticed the chief stands in the Show; the fine character of the blooms and foliage clearly proved the great attention and care that had been given to the culture of the plants, and the skilful management bestowed upon them. In conclusion I cannot omit to mention the kind hospitality of Mr. and Mrs. Hawkins, who so graciously entertained the Committee and friends at luncheon. The Judges were Mr. George Paul, Mr. Appleby, and Mr. G. Baker.—G. B.

PACKING FRUIT.

IN commencing this subject I may warn my readers not to expect anything particularly novel. Originality, according to my experience, though commendable, is not always a proof of superiority, nevertheless I am always prepared to accept fresh ideas. When I hear of what presumably is a superior method or practice, I like to give that method a fair trial, and if its superiority is evident I adopt it, if otherwise we must fall back upon the old plans. As I have before pointed out (page 397) there are many methods of packing flowers for travelling, and it is equally certain there are as many methods of packing fruit.

A young man when learning the profession of gardening—that is to say, if he follows the orthodox rule of staying a limited time in each situation, has good opportunities of forming his opinion upon the merits of several methods. Even then there may be methods he has not seen in practice, and these he may learn from in the horticultural papers of the day. In some

instances the fruit has to be packed, not as the gardener would like, but as a certain set of boxes necessitate, these, perhaps, having been made at the instance of a predecessor; while in many cases the best has to be made of any boxes and packing material forthcoming. The latter happens, I should imagine, more often when packing fruit is only a casual occurrence. Probably the most expensive, and comparatively the least satisfactory, is the employment of tin boxes and trays. These are heavy, liable to rust, and, unless made very strong or with divisions, are more easily damaged than are ordinary deal boxes. Divisions for any kind of fruit, including Peaches, Nectarines, Plums, Apricots, Figs, Cherries, Strawberries, Gooseberries, and Raspberries, I thoroughly dislike, yet where tin is employed, and also often in the case of deal boxes, we find divisions the rule. Here we have a heap of such trays, these being made to fit into deep strong tin travelling boxes. Those for Peaches allow every fruit a space nearly 4 inches square and 4 inches in depth. As these divisions are much too large for any but the very largest varieties, they require a lot of packing material, and this so arranged to admit the fruit being drawn out by it, or they must be bruised. Besides, these heavy boxes with their comparatively few contents are heavily charged for by the railway companies.

I prefer lightly made deal boxes, and if these have tin corner plates, and the lids are lightly screwed down or tied instead of nailing, and thereby spoiling the lids, they will last several years. In a box 12 inches long, 9 inches wide, and 4 inches deep, we can, as a rule, properly pack twelve fruits. For Nectarines—these also answering for Apricots, Plums, and the smaller Figs—we have boxes of the same length and width, and 3 inches deep. At one time we lined the bottoms with cotton wool, then pulled some of the material into lengths about 12 inches by 6 inches, giving these a single fold lengthways, with the "skin" outward. Each fruit was placed in a half-grown Vine leaf, the base of the fruit near the base of the leaf; the cotton wool was wound tightly round the fruit, which was packed in the corner, others being closely added. In this manner the boxes were filled, one fruit assisting to fix others. More leaves were laid over the fruit, then a folded strip of cotton wool of the same size as the box, and on this the lid was tightly screwed. Thus packed the fruit may be roughly shaken and receive no harm. The Vine leaves being soft do not bruise, but serve to keep the fruit fresh, and besides contribute to the pleasing appearance of the fruit when uncovered—an advantage where the employer or recipient request to see it before it is unpacked, or, again, when sent to a market salesman. Vines on the open walls supply our principal wants in that respect.

Where, however, suitable moss is available this will be found the most economical. We collect it from walls and old tree stumps, and after slightly drying it beat out the dust and sift it to still further cleanse it. When packing, the boxes are lightly filled with the moss; the Peaches, Nectarines, Apricots, or Plums, as the case may be, are placed in a leaf, then wrapped in a piece of tissue paper and firmly bedded in and surrounded by the moss. The boxes hold the same quantity as in the preceding method, and the fruit is firmly but not roughly covered with moss, on which the lids fit tightly. Our Strawberry boxes are 12 inches long, 9 inches wide, and 2 inches deep, outside measurement, this including the lid as in other instances, and a single layer only is packed in each. Either a layer of moss or cotton wool is employed for the bottom, placing on the former a piece of tissue paper; and the Strawberries, each placed in a portion of a Strawberry leaf previously flagged and therefore softened, are packed flatly and closely together. On these tissue paper, more of the packing material, is placed in quantity sufficient to cause the lid to fit closely. The same boxes are available for Cherries, Gooseberries, and Raspberries; these, if very ripe or choice, going in single layers, but, if they will travel well, in double layers. Raspberries are usually packed separately in small softened leaves, but the Cherries and Gooseberries seldom require this. Figs are wrapped in tissue paper, then in cotton wool, and laid closely in a single layer in shallow boxes. These are bad travellers, and should be pulled before becoming dead ripe. It is also very important in each of the preceding cases that the fruit be picked before becoming full ripe, and they must also be sound if expected to travel well; this rule to be particularly observed when sending fruit to the markets.

It is a curious fact we invariably have the moss returned to us, but what becomes of much of the cotton wool gardeners are constantly sending to their employers' houses? I never yet saw it properly returned, and frequent outlay is consequently necessary. Unfortunately moss is not always available, neither is the best quality of paper shavings. The latter are particularly good for packing Melons, Pine Apples, and even Grapes. These shavings may sometimes be had of the printers, but as a rule they are sent

away to be worked up afresh. This, again, does not return as it should do, and I am now using moss for the Melons, these being first wrapped in paper and then firmly bedded in it with the stalks upwards, in order they may be preserved, a Melon in my estimation being incomplete without a footstalk. Pine Apples are not grown here. They are usually wrapped in paper, taking especial care of the crown, as this if bruised resembles imported fruit, while the fruit is well surrounded with cotton wool. In both instances they should be prevented from rolling about, as they will easily be damaged and also injure other occupants of the box.

It will be seen the practice I recommend with the Peaches and other small fruits is much the same as that for some time adopted by Mr. Coleman of Eastnor Castle, and which contributed to his success in the recent competition for special prizes offered for the best methods of packing fruit for long distances. It is only fair to state it was owing to his writings on the subject of fruit-packing that induced me to give moss a trial as a substitute for cotton wool. With regard to Grapes, unless they were for the market, I should not pack as he does, simply because the quantities to be sent are smaller. A basket or box for market Grapes in general use measures 18 inches in length, 12 inches wide, and 9 or 10 inches deep. The bottoms of these are covered and the sides lined with cotton wool, paper shavings, or—as practised by Mr. Coleman, and, if I remember rightly, a previous winner, Mr. Crump, late of Blenheim—with moss and tissue paper. The baskets are disposed in a sloping direction, and the bunches packed point downwards as closely as they can be worked in together. Nothing is placed between them, but a sheet of paper is placed over the whole, and the lid closing tightly on the stems effectually prevents oscillation and consequent injury from excessive friction. What I believe to be the next good method is to wrap each bunch in rather stout and very smooth white paper, and this is especially recommended when a few bunches only are packed in a box not made especially for Grapes. For a moderate-sized bunch I form a bag out of a piece of paper 18 inches by 12 inches by placing this lengthways on the bench, then taking hold of the middle of front edge with the thumb and forefinger, and the nearest right-hand corner with the left hand, bringing this over to the inside of the farthest left-hand corner, and finish off by twisting the point formed by the paper in the right hand. In shape it is similar to the old-fashioned sugar bags, and in this is disposed the bunch. They are packed in a sloping position on and surrounded by either moss, cotton wool, or paper shavings, and when unpacked do not appear so much rubbed as might be anticipated. By having all the boxes made of the same length and width they are easily tied together and dispatched, or, better still, may be packed evenly in the vegetable or other hampers being forwarded.—W. IGGULDEN.

THE PRODUCTION AND LOSS OF NITRATES IN THE SOIL.

MR. WARINGTON'S LECTURE.

(Continued from page 475, last volume.)

SPEAKING of the influence of a crop on nitrification, it was two-fold. First of all, they could not grow any crop on the land without diminishing the amount of drainage. The amount of evaporation from a field under crop is very much greater than from a field under fallow, and therefore the soil necessarily suffered less from drainage. The other effect was that the crop was eager to obtain nitrates, and therefore the nitrates were taken up by the roots and turned into insoluble organic matter. He would lay before them results of some determinations of the amount of nitrates present in cropped and fallow land. In 1878 they had at Rothamsted a field half in fallow and half in Beans. After the removal of the crop of Beans samples were taken from that land and also from the land under bare fallow. The first 18 inches of the soil that had been bare fallow contained 36 lbs. of nitrogen per acre, and that from which the Beans had been taken only contained 10.5 lbs. per acre. At the same time a similar experiment was tried with land under fallow and land under Wheat. The land under fallow yielded 33.7 lbs. of nitrogen per acre, and that on which Wheat had been grown only 2.6 lbs. per acre. That was a striking instance of the extremely perfect manner in which the removal of the nitrates from the soil was carried out by the Wheat crop. The drainage water from several plots of the experimental Wheat field contained in the summer time no nitric acid at all, as it was taken up so completely by the Wheat crop.

They had now arrived at three cardinal points as regarded nitrates—1, they were being continually produced; 2, they were very easily lost; and 3, that that loss can be prevented by a crop. This subject became one of very great agricultural importance when they saw the considerable money value of nitrates. Taking the present price of nitrates in the market, the loss by drainage of 44 lbs. of nitrates per acre represented a loss of 37s. per acre per annum. That was a

great loss, and it followed that economical farming depended very much indeed on the economising of the nitrates. Now, taking the various systems of cultivation, bare fallow involved the greatest risk of loss of nitrates, corn crops involved the next greatest, roots came next as causing a less loss, and lastly, pasture involved the least possible loss of nitrates. Why was this? They had seen that in bare fallow the loss was caused by the facility which the absence of crop gave for having the nitrates washed away. As to corn crops, their growing period was practically limited to three months—April, May, and June, but the process of nitrification in the soil would go on in July, August, and September with vigour, and the nitrates then produced were freely lost in winter when there was abundant drainage, and no crop to feed upon them. If Wheat was grown after Wheat there might be a considerable loss of nitrogen from the soil, from the fact that loss by drainage went on during a great part of the season when the production of nitrates was most active, and when there was no growing crop to retain them. When they came to the root crop they had growth going on in June, July, August, September, October, and up to November, during the very period of the year when they most wanted to save the nitrates.

Mr. (now Sir J. B.) Lawes deserved the credit of first pointing out that the roots in a rotation were a conservative crop—they saved the nitrates in the soil; when they were fed off on the land the roots returned to the soil the nitrogen they had saved. In pasture they had the best possible conditions for saving the nitrates, for there they had vegetation on the land all the year round—they had the largest amount of evaporation and the smallest amount of drainage. Was it, then, possible to do anything to diminish the loss of nitrates? He believed that a part of the present agricultural depression was owing to the extremely wet winters of the past few years, which had resulted in lowering the condition of the soil by washing out extraordinary amounts of nitrates. Could anything be done to alter this? He was not a practical farmer, and he wished them to take anything he said on that part of the matter as subject to a much better opinion than his own. But he would point out a few things that might possibly be a help. For instance, in the case of a bare fallow, the good work on the fallow was done in the summer time; that was when they got the advantage of the fallow, and the evil came in the winter. A gentleman had told him that he had found it a good plan to get the fallows clean in July, to then sow Mustard or Rape, and then before sowing the Wheat in the autumn, to plough the Mustard or Rape (which had grown vigorously) into the land, and then to sow the Wheat. Now that gentleman knew nothing at all about nitrates, but he had done just what he ought to have done if he desired to save them. The Mustard or Rape took up the nitrates, and turned them into insoluble organic matter, and when it was ploughed into the land it slowly resumed the forms of nitrates for the nourishment of the Wheat plant. But for that simple plan a great part of the nitrates produced in summer might have been lost by the drainage of the winter months. Again, he thought there was no doubt—though he was aware that there was a great practical difficulty about this point—that it was not advisable to plough light land in the autumn. By ploughing land in the autumn they did their best to give vigour to the production of nitrates. They were also destroying the weeds, and in the winter the weeds were the farmer's friends, for they prevented drainage to some extent; they also helped by taking up the nitrates, and thus if the farmer left the destruction of the weeds till spring, they were more or less equivalent to a green manuring. He would therefore recommend that no more ploughing be done in the autumn on light land than was absolutely necessary.

Having pointed out the value of long-rooted crops, such as Rape, Mangold, Clover, and Sainfoin, which helped to bring up again nitrates that had washed down to a considerable depth, and thus make them available for plant food, he passed on to say a few words on nitrification in relation to manures. Experiments had shown, from observations made on the drainage water from a field in which ammonium salts had been applied to the Wheat crop, that the ammonium salts in a very short time became nitrified, and in one case a distinct increase of nitric acid was traced in the drainage water within forty hours of their application. In fact, as far as could be judged, the whole of the ammonia applied might be completely nitrified in a month. Another set of experiments showed that the application of nitrate of soda resulted in a still more striking increase in the nitric acid draining from the land. Seeing that the nitrates found their way so quickly into the drainage water and were lost, it was of the highest importance to the farmer that he should not apply the costly manures which produce the nitrates before the crop was able to make use of them, and if they could only make sure of the seasons they would be able to arrange their dressings accordingly. If they could anticipate a dry season they would like to apply the manures in the autumn, while if the winter was wet of course a spring application of the manures would be preferable. In conclusion, the lecturer said a few words on the loss of nitrates occasioned by diffusion—viz., the passing of salts through wet soil without actual drainage taking place. [Applause.]

The Principal, in thanking Mr. Warrington on behalf of Professor Kinch, the staff, and the students, observed that the lecture had conferred a benefit not only on the College but on the agriculturists of the neighbourhood. He also impressed on Mr. Warrington that if he would go a little further than he had now gone, and give them a text book upon subjects such as that upon which he had lectured, he

would be doing them a very great benefit. [Applause.]—(*Gloucestershire Standard.*)

STOTT'S MONARCH RHUBARB.

THIS variety is not much known, but it is an excellent one, and in some respects distinct from and superior to any other. Eighteen months ago I had half a dozen small roots of it from Messrs. Dicksons & Co., Edinburgh, and these have now gained large proportions. Lately we have had stalks of it 10 inches in circumference and about 24 inches in length. The colour is a bright green, and the flavour good. Some of the leaves are 4½ feet across, and it has been suggested to me more than once that it would make a most effective foliage plant in pleasure grounds, and this it doubtlessly would, as there are few plants which produce such handsome leaves.—J. MUIR, *Margam.*

KITCHEN GARDEN.

MAKE a first sowing of White Naples and Tripoli Onions. If large bulbs are required the ground should be well manured, employing thoroughly decomposed manure; and a dressing of soot is useful in preventing the maggot. The first sowing of early kinds of Cabbage may now be made. Among other good varieties are Ellam's Early Dwarf, Denning's Early, and Hill's Incomparable; those preferring smaller kinds will find Atkins' Matchless and Little Pixie excellent. In warm localities the sowing should be deferred for a fortnight, as when sown too early there is danger of the plants running in spring instead of hearting.

The main crop of Endive should be sown without delay. Round-leaved Batavian and Picpus Green Curled are good sorts. Make a good sowing of Turnips; but small sowings of Spinach and Radishes at short intervals will for the present suffice. Lettuce in quantity to afford a late supply should now be sown, and from this sowing a sufficient number of plants should be transplanted in a position where protection can be given in severe weather, or they may be lifted and placed in pits or frames. Make a sowing of Chervil in a sheltered position for affording a supply the best part of the winter.

Parsley which has been transplanted withstands the frost better than if allowed to remain in the drills where sown; and where this is in great demand during winter a sufficient quantity of plants should be at once transplanted in pits, which can have lights placed over them and be otherwise protected in severe weather.

Rosette Coleworts will by this time be fit for pricking out from the seed bed preparatory to the final planting, and when the requisite number are withdrawn thin the remainder to 2 or 3 inches apart, and they will soon be ready for planting 12 inches apart as ground becomes vacant.

The present is a most suitable time for planting the main crops of Broccoli. Where kitchen gardens have been long established and high cultivation practised the soil becomes very rich, in which case it is best to plant Broccoli without digging the ground; this induces sturdy growth, rendering the plants more suitable for withstanding severe weather.

As ground becomes cleared of early Peas and Potatoes the space should be re-occupied without delay with Savoys, Borecole, and other description of winter greens. Plant out a good breadth of Cauliflowers from the late May sowing for autumn use and for lifting under some protection. Attend well to the requirements of Celery in watering, and plant out late crops in well-prepared trenches, also Leeks where these are required blanched. When fit take up and bunch Garlic, also Shallots. Tomatoes on walls or trained to stakes should be well attended to in stopping all lateral growths, and when a sufficiency of shoots is set stop the leading shoots so as to direct all the energies of the plant to the maturation of the fruit. Peg out the growth of ridge Cucumbers, keeping them moderately thin and stopped

as required, similar remarks applying to Vegetable Marrows, well attending to them with water in dry weather.

FRUIT HOUSES.

Vines.—Midseason or intermediate crops of Grapes now about colouring should have a temperature of 70° by artificial means night and day, and a little air given constantly and freely whenever the weather permits. If the borders are in the least dry give a thorough soaking with tepid water or weak liquid manure, and mulch with some short partially decayed manure; this watering will be sufficient to enable the Vines to ripen their crops. Moderate air-moisture is quite as essential to the Vines when finishing their crops as when the fruit is swelling; but, as before observed, the houses must be freely ventilated. Some kinds, such as the Duke of Buecleuch and Madresfield Court, are apt to crack when kept too moist at the roots, hence the preceding remarks must be modified in their case.

Late Grapes should have every encouragement in the shape of plentiful supplies of water or liquid manure to the borders in a tepid state, keeping a genial condition of the atmosphere by damping available surfaces as they become dry, more especially at closing time, which should be done early with a good sun heat at a temperature of 85°, admitting a little air in half an hour or so afterwards. Commence ventilating on fine mornings when the temperature reaches 75°; increase it gradually as the sun increases in power, and at 85° ventilate fully. Reduce the ventilation so as to keep it from falling below 80°, having the temperature through the day as near as may be at 80° to 85°, employing artificial heat to maintain a night temperature of 70° and 75° by day. Scalding should be guarded against by a warm condition of the atmosphere and abundant ventilation, especially in the early part of the day.

Late houses of Muscats require similar treatment to the thick-skinned black late Grapes; those ripening should have a little extra fire heat and a temperature from 85° to 90° as a maximum by day, with plenty of air. Late Hamburgs need not be pushed forward so rapidly as the kinds that are to keep over the winter, but they should nevertheless be assisted in dull cold weather with a little fire heat to maintain a night temperature of 60° to 65°, and 70° to 75° in the daytime; ventilate a little at 70° on fine mornings, and keep through the day at 80° to 85° from sun heat with free ventilation.

Laterals should be kept well in hand by frequently pinching them, only allowing extension where the Vines are weak or carrying heavy crops, and in no case tolerate them if they are likely to crowd or in any way interfere with the full exposure of the principal foliage to light and air.

Young Vines of this season's planting should be allowed to grow freely, they having to be cut down at the winter pruning to three or four eyes; but any supernumeraries intended for fruiting next season should have the laterals pinched at the first leaf, and subsequent growths as made to a length of 7 or 8 feet, above which the laterals may remain, as they will encourage root-action.

Vines in pots for early fruiting next season have completed their growth, and should have free exposure to light and air; they must not be allowed to become infested with red spider, but be syringed occasionally, and though they must not suffer by want of water, an overdose would be highly injurious.

Grapes thoroughly ripe should be shaded during prevalence of very bright sunshine to preserve their colour, bloom, and quality unimpaired.

Melons.—About this time, should the weather be warm and moist, the blossoms set very indifferently, especially in pits or frames where there is not the same means of expelling moisture as there is in houses heated with hot-water pipes. In cases of this description only apply sufficient water at the roots to prevent flagging, and avoid wetting the surface of the bed and foliage of the plants more than can be helped. Apply a good lining to the bed, and admit air constantly to allow the moisture to escape and so prevent its deposition, as would be the case on the foliage and flowers were the lights closed. Keep the growths thin, fertilising the flowers as they expand, and at the same time stopping the shoots one joint beyond the fruit. Similar precaution will need to be taken in dung-heated pits and frames

where the fruit is ripening, as in a close moist atmosphere it is liable to crack and be deteriorated in flavour. Admit a little air constantly, raising the fruit on inverted flower pots. Maintain a good bottom heat of 85° to 90° for young growing crops, and a moist atmosphere, syringing freely, except when the fruits are setting or ripening, stopping the laterals, and prevent crowding by cutting out superfluous growth. It is now important that the late plants should be planted without delay, therefore clear out as soon as possible those which are exhausted, and prepare for a fresh start at the earliest opportunity.

Cucumbers.—Fire heat will only be necessary in very dull cold weather to maintain a temperature artificially of 70° to 75°; but in the case of making new beds gentle bottom heat either by means of hot-water pipes, dung, or tan should be secured. If either of the latter is employed do not plant out until the heat, if it exceed 90°, is on the decline. Earth up from time to time those plants which have been in bearing some months, maintaining a firm condition about the roots. Apply liquid manure copiously once or twice a week, and maintain plenty of atmospheric moisture in hot weather. Syringe freely, and close the ventilators about 4 P.M. on fine days. Shade no more than necessary to prevent flagging. Fumigate if aphides appear, dusting with flowers of sulphur against mildew. Use the knife freely, cutting out exhausted growths and bad foliage frequently, stopping one or two joints beyond the fruit, avoiding overcrowding and overcropping as the greatest of evils. Now is a good time to sow a few seeds for autumn fruiting; and as it will take from three to four weeks to secure sturdy plants, make the necessary preparations in preparing the dung, if such be used for bottom heat, and soil, thoroughly cleansing the house in the meantime. Continue to train and earth up plants in pits and frames, and when warm rains prevail remove the lights for a few hours in the afternoon. Keep the growths well thinned out and stopped, damping the foliage at about 4 P.M., closing at the same time.

PLANT HOUSES.

Stove.—Assiduous attention must be given to cleansing plants from mealy bug and scale by the application of an insecticide with brush or sponge, taking care not to injure the young growths and flower buds. Red spider often seriously disfigures *Dracænas*. The best remedy is to sponge the leaves, especially on the under side, immediately the insects are detected, as if allowed to increase the plants will in a few days be spoiled in appearance. Thrips can be kept under by fumigation, but to be effectual it must be repeated on two or three consecutive evenings. Syringing should be practised on such plants as are liable to be attacked with insects, directing the water forcibly against the under side of the leaves, and a moist atmosphere should be secured by damping available surfaces frequently. Fire heat may be dispensed with provided the solar heat is sufficient to maintain by judicious closing a minimum temperature of 70° to 75°. Allamandas, *Dipladenias*, *Bougainvilleas*, and other free-growing plants soon exhaust the soil and fall off in their flowering towards autumn when most wanted, but when well managed they flower continuously all through the summer and autumn: in order to render them timely assistance surface-dress the soil with good manure, and apply liquid manure liberally.

Cuttings of most hardwooded plants are now in a half-ripened state and will root freely, and where there is not the convenience of affording a brisk heat early in the season it will be well to strike all that will be required now, and keep them slowly growing through the winter. It is best to insert the cuttings singly in small pots, as then there is no check consequent on potting off where several cuttings are inserted in a pot. Amongst flowering plants amenable for propagation now may be mentioned *Gardenias*, *Tabernæmontanas*, *Ixoras*, *Medinillas*, *Stephanotis*, *Dipladenias*, *Clerodendron* both the climbing and shrubby species, *Combretums*, *Thunbergias*, *Rondeletias*, *Bougainvilleas*, *Æschynanthuses*, and others of similar character.

Ferns.—Plants that did not require more root space at the time of the general potting in spring will now require it, and if not repotted they will get into a stunted state before spring. In potting use material of such a character that water can percolate freely by em-

plying a liberal admixture of charcoal or cinders in the soil and thorough drainage. Plants with creeping rhizomes, such as *Gleichenias*, should never be allowed to suffer from having the points of their creeping stems injured by want of room, as would be the case if they are allowed to extend over the rim of the pots. *Gleichenias* must never be allowed to suffer by want of water, for if the young fronds flag they never attain their proper development. Tree Ferns suffer similarly if insufficiently supplied with water, particularly *Alsophilas* and *Cyatheas*, any check to the development of the fronds causing their serious disfigurement. Thrips will now be making their appearance, and must be kept under by moderate fumigation on two or three consecutive evenings. Seale must be kept under, for if allowed to get ahead it is almost impossible to get the plants clean. Pot any seedlings of *Adiantums*, *Pterises*, in small pots, as they are useful in many ways for decorative purposes.

Roses in pots for winter flowering should be encouraged to make all the growth possible. They may be plunged in the full sun in ashes, not too close, and the surface of the soil mulched with decayed manure, affording liquid manure twice a week. Do not allow them to suffer from the ravages of aphides or red spider, and if such appear promptly take measures for their destruction, as Roses for forcing to insure their flowering well require every attention. Plants of *Echeveria fulgens* and *E. retusa* intended for winter flowering should be potted and be treated liberally for the next few weeks, as the stronger the plants the finer they will bloom. Attend well to *Salvias* for winter blooming, never allowing them to want water, or they will lose their lower leaves, and stop the shoots to keep them in shape. Encourage *Chrysanthemums* with liquid manure as soon as the roots have fairly taken to the soil.

THE BEE-KEEPER.

UNSETTLED POINTS.

THAT adult bees live on honey and do not eat pollen at all I stedfastly believed for more than forty years. Two or three years ago Mr. Raitt stated in a private letter to me that a highland lady fed her bees on barley bannocks, that he had found the husks of pollen grains in the excrements of his bees, and that such excrements changed their colour if the bees were fed on peameal. This statement was quoted into the pages of this Journal. This evidence appeared satisfactory and conclusive, and I said so at the time, though I was convinced that bees can live and be healthy for months on honey or syrup alone—or, in other words, without pollen or meal of any kind. Other writers have said that pollen contains the nitrogenous element necessary to maintain the muscular strength of bees. Much has been written and spoken on this point without giving facts to support it. Not so with Mr. Raitt, who gave substantial evidence for his statements. Many hundred stocks of bees have died of hunger with plenty of pollen around them, while they have been sitting on cells of pollen; but whoever heard of bees dying of hunger with honey beside them?

I will now quote a short letter on this subject from an American periodical: "The bees that I put into the cellar on the 21st day of November last had sugar syrup but no pollen, and, removed on the 19th of April, had but one opportunity of flying about. They had an airing on the 2nd of March. Now for the result of the experiment. They were all in splendid condition, except two hives that were overlooked and starved, and two that were queenless but strong in bees; this, however, I consider no fault in the manner of wintering, but my own fault in keeping such queens. I never before had bees winter without some of the colonies showing signs of dysentery. There was not a cell nor hardly an egg in the seventeen colonies left in the cellar. Their combs and bees were as clean and bright as they were last November. Now, if they wintered last winter for one hundred days and came out in good condition, why may they not winter another year?"

The editor appends to this letter a short note as follows: "Your experiment is a valuable one. If you had seventeen colonies that wintered without a particle of brood until new pollen came in, it is almost impossible to believe that the result was accidental, and that your depriving of pollen had nothing to do with it. We have for some years been under the impression that bees would

winter as well without pollen as with it. We should not be at all surprised if your treatment would do away with the possibility of dysentery." Bees use pollen in rearing their young, but this does not prove that adult bees eat it. This question, interesting to bee-keepers, is now open for examination and further experiment.—A. PETTIGREW.

BEES, HIVES, HONEY, &c., AT THE ROYAL AGRICULTURAL SHOW.

THE British Bee-Keepers' Association, under the auspices of the Royal Agricultural Society, have arranged an excellent display of bees, hives, and appliances used in the more advanced methods of bee-keeping. These annual apiarian exhibitions have formed part of the Royal Agricultural Society's programme since the Kilburn Show held in 1879, and have increased in popularity in each succeeding year. The present Exhibition of bee-keeping appliances at Reading far surpasses any of its predecessors. The present unsettled state of the weather has, however, greatly militated against the production of honey, and in consequence many of the entries in the honey classes did not appear at the Show.

Observatory hives stocked with bees and their queen are a great feature in the Show. The first, second, and third prizes in this class were all awarded to Mr. T. B. Blow of Welwyn, Herts. Mr. Blow also gained first prizes for the best collection of appliances adapted for modern bee-keeping and for comb foundation, the latter being prepared by a machine in the presence of the Judges. Messrs. Neighbour & Son of Regent Street, and Messrs. Abbott Brothers of Southall, have also an excellent display of goods in the several classes, the former taking second and the latter third prizes in the class for the best exhibition of hives and other appliances.

The classes for hives are well filled. Mr. Blake of Wickham Market, Suffolk, secures first prize in the class for the best frame hive, price not exceeding 15s.; Mr. T. B. Blow second, and the Rev. W. C. Burkitt third. In the class for cheap hives Mr. Blow takes first prize, Mr. Blake second, and Messrs. Abbott Brothers third.

The weather on the first day of the Show was most unfavourable for the manipulations and lectures in the bee tent. Weather permitting, displays of driving, transferring, &c., will take place every day during the continuance of the Show, which closes on Friday next. The Rev. E. Bartrum, Rev. S. R. Wilkinson, Mr. T. W. Cowan, Mr. G. H. Harris, and Mr. J. M. Hooker acted as Judges in this department.

LANCASHIRE AND CHESHIRE BEE-KEEPERS' ASSOCIATION.

THIS Association is now in course of formation, and I am hopeful that it will in time be one of the largest and best supported branches of the parent Association in London. I respectfully urge bee-keepers of every school in Lancashire and Cheshire to consider the desirability of joining this branch, and thus help to make it a success. Cheshire is an excellent district for bees, and bee-keepers are numerous. In the district of Bowdon alone there are some able bee-keepers, some of them having from eight to twelve stocks annually: altogether above a hundred stocks are kept. Some parts of Lancashire are not so good for honey, and some are equal to Cheshire. Lancashire is characterised by many large manufacturing towns, successful merchants, and plenty of means to support such associations. Mr. J. P. Jackson, 31, Jermyn Street, Prince's Road, Liverpool, is the Hon. Secretary, and he is anxious to assist the cottage bee-keepers in the two counties. I know Mr. Jackson very well, and believe that no effort on his part will be wanting to carry the movement on to a successful issue. The fee of membership is only 1s. per annum. The Association this year will have a bee and honey Show at Preston in the second week of September, offering £40 in prizes besides medals. Various processes of manipulation will be shown in the bee tent.—A. PETTIGREW.

TO CORRESPONDENTS.

** All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Measuring Gooseberries (L. T. T.).—A half sieve contains three and a half imperial gallons, or fourteen quarts, so you will perceive the Covent Garden prices and your own are as nearly as possible identical.

Brachycome iberidifolia (H. M.).—This is the plant to which you allude. It is figured on page 413 of our issue of November 3rd, 1881, and you can have the number if you desire it in return for 3½d. in stamps sent to the publisher. The plant is an annual, and seeds sown now would produce flowering plants late in the autumn. It is pretty grown in pots for greenhouse decoration, also for borders in the open air.

Early Gladioluses (A. M.).—The white Gladiolus which you have seen in the flower markets is *G. Colvilli albus*; The Bride is reputed to be a superior form of this, and is valuable for affording flowers for cutting. The scarlet and pink kinds are varieties of *G. ramosus*, of which there are several. Queen Victoria, Prince Albert, and formosissimus have scarlet flowers flaked with white; Lord Auckland and Ne plus Ultra have rose and white flowers, and Lavinia and insignis rosy purple and white. These are a few amongst others that are good. The very early dark purple kind sold cheaply in large bunches is *E. hyzantinus*.

Roses for House (Idem).—All the varieties you name will with good cultivation grow and flower freely under glass, but all of them will not cover a roof alike quickly. You do not, however, say you desire them all for that purpose. As dark Roses suitable for the roof, you will find Reine Marie Henriette and Cheshunt Hybrid excellent. Madame Lambard is a valuable variety either for the Rose house or open air.

Single Pyrethrums (Major).—Your small plants that produced one flower each, and "look as if they were going to die," will in all probability produce growths from the base, and form good plants next year. Remove the flowers, but do not cut the stems off close to the ground—that is to say, leave those portions having fresh healthy leaves. If the weather is dry water the plants freely, and if the ground is poor give liquid manure. In the course of a week or two fresh growths will appear close to the ground, and by the autumn will form fine healthy plants.

Second Growths on Pear Trees (J. Dawson).—Trees that are growing freely and have the shoots pinched or shortened early, say in June, always produce second growths, especially where there is no fruit to support. These growths should be promptly removed, as if left unchecked the trees will be more crowded than if they had not been pruned at all. Our practice is to remove these subsidiary growths as soon as they are 2 or 3 inches long, leaving one leaf at the base of each. When thus young and crisp they snap off easily, and a good-sized tree can be completed in a few minutes. Still further growths may issue, and they also must be removed.

Preparing Quassia Water (A Man of Kent).—Although it is usual to pour boiling water on quassia chips for producing a decoction for destroying insects it is not essential; the insecticide is more quickly made by that process—that is all. If you place quassia chips in a vessel and pour cold water on them, allowing them to remain for forty-eight hours or more, you will find the effect of the water as potent in destroying insects as if boiling water had been used. An ounce of chips to a gallon of water is the quantity to use, and no further dilution will be needed.

Suckers from Manetti Stocks (Eunice).—We can quite understand your disappointment, but as Roses thrive so well on this stock in your garden we certainly should not reject it entirely. The Manetti cuttings were roughly made, the eyes not having been removed from them before insertion, hence the annoyance to which you are subjected. We have grown hundreds of Roses on the Manetti, and seen thousands grown by others, and a sucker from the stock is a rare occurrence. In most nurseries where Roses are largely grown care is taken that the plants do not produce growths from the stock. You have been unfortunate.

Market Gardens (C. B.).—They are not public gardens, and it is not by any means easy to obtain access to all of them either with or without an introduction. Your only course is to write to such of the proprietors as you choose. Mr. Warreu, we feel sure, will permit you to inspect his grounds, and will probably be able to give you information that will be useful to you in your future movements.

Pansy (A. H.).—If you will state the name of the variety, if you are able to do so, or refer us to the description to which you allude, we shall be better able to reply to your letter. You simply say the flowers have "not answered to the description given," but do not indicate where that particular description is to be found, nor by whom it was given. If you will supply us with this information, or describe the variety more fully, we will do our best to aid you in procuring what you want.

Spruce Firs Unhealthy (G. S.).—It is not at all unusual for Spruces to lose their vigour in soil of your description after growing for twenty years. The growth is very weak, indicating exhaustion, and we know of no means for restoring the health of the trees, growing, as they are, in a shrubbery. In all probability they will get worse as they get older, as Spruce trees frequently do in such soil as you describe.

Pinching Dwarf Fruit Trees (An Amateur).—You ask if the trees "ought to have produced second growths" after the first growths had been pinched. Yes: unless trees are heavily cropped with fruit and do not produce second growths after the first were pinched in June we conclude they are not in a very healthy or satisfactory condition. See our reply to another correspondent, whose letter we had answered on the same subject before yours was received.

Spiræa palmata (P. C.).—Our remarks last week applied to this plant, and the name of *S. japonica* was the result of a clerical error. *S. palmata* is a hardy herbaceous plant—quite as hardy, so far as we know, as *S. japonica*. Deutzias are hardy shrubs, and not eligible for competition in classes for stove and greenhouse plants except under specified conditions. The same remarks apply to the Ghent and Mollis varieties of hardy or American Azaleas; but Azaleas of the indica type are greenhouse plants. The common Myrtle is also a greenhouse plant, and will not endure the severity of our winters in open positions without protection; but no protection whatever is needed by either *Spiræa palmata* or *S. japonica*, therefore they cannot strictly be regarded as greenhouse plants,

although they are often grown under glass, and are largely employed for the embellishment of conservatories.

Melons not Setting (R. C.).—You say nothing about the health or condition of the plants. Possibly they are too crowded, or the soil is too light and rich; if so, thin-out the growths, make the soil firm, and give less water. We should not shorten the leading growths so closely as you indicate, as if you stop them about a foot from the sides of the frame they will, we think, produce fruit-bearing laterals; and if the flowers are fertilised as they expand, and the temperature and ventilation are rightly managed, the fruit will swell and afford a succession to the plants that are now bearing. You will find further information relative to setting Melons in our "Work for the Week."

Growing Celery (F. Shaw).—The manure you have used is good, but that from the pigstye or cow byre is preferable to that from the horse stable for light sandy soil. Until the plants are earthed up—and we should not apply the earth too soon, but instead, tied them up loosely when they are large enough—you will find it of advantage to mulch the ground over the roots with rich manure. The water that is applied will wash its virtues to the roots, and the covering will prevent the evaporation of moisture. Soot water given occasionally, with an ounce of salt to a four-gallon pot or pail of water, will stimulate growth, so also will liquid manure made from cow and sheep dung. An ounce of superphosphate of lime dissolved in a gallon of water is good for Celery, but nothing that we know of makes it grow more rapidly than nitrate of soda used at the rate of half an ounce to the gallon of water. You will find it is good practice to vary the stimulants you employ, yet you must apply all of them judiciously, using liquid manure rather weak at first, increasing the strength as the plants become large. You must also remember that by forcing the growth unduly you may induce soft pithy stems, and large heads find no favour with judges unless the stems are very crisp and solid.

Funkias (E. Milton).—You ask, "What Funkias are like?" It is impossible to give you a reply that would be intelligible from any written descrip-

Fig. 9.—*Funkia lancifolia albo-marginata*.

tion alone, but the above figure will enable you to form an idea of the appearance of the plants. They are hardy herbaceous perennials; some have leaves 6 inches long and 2 inches wide, others having foliage twice that size, and the flower spikes range from 1 to 2 feet long. They are beautiful border plants that flower at this season of the year, and you cannot err by securing a collection for your garden. Some have rose-coloured flowers, and others lilac, more or less striped with white, and the foliage is very handsome. You will find them quite hardy in Yorkshire.

Caterpillars on Fruit Trees (D. D. L.).—We are sorry to learn that caterpillars are unusually abundant this year, and are doing great injury to fruit and forest trees in various districts. We doubt very much whether washing the stems of the trees with lime would prove a remedy for the present attack or act as a preventive against future attacks; but the application could not do harm and you need not hesitate to try it. In all probability if you were to syringe the trees with a solution of quassia chips and hellebore powder you would destroy many of the caterpillars. If you mix the hellebore powder with warm water so as to form a paste, then add a gallon of cold water to each ounce of hellebore, and with this mix water in which quassia chips have been immersed for twenty-four hours, at the rate of ounce to the gallon, and apply through a garden engine or hand pump, it will, we think, kill all the caterpillars it touches and do no harm to the foliage of the trees. You had better, however, gather the Cherries, if any, before washing the trees. Several fruit trees might be washed in a day, and the labour would doubtless be profitably invested, as if the caterpillars are not destroyed they may destroy the trees.

Neglected Plants (Gardener).—Plants of *Eucharis*, *Cypripedium*, and *Pancreatium* in the condition you describe could not have had better treatment

than what you appear to have given them. You had better grow them as generously as possible for some time to come so that they may gain strength. We think it would be decidedly a mistake to withhold water now or to check their growth in any way with the object of inducing flowers, as these if produced would be necessarily poor, and would most certainly be obtained at the sacrifice of the future well-being of the plants. You will do well if you succeed in producing a satisfactory display of Eucharises and Cypripediums in late autumn or early winter, and of Pancreatiums next year.

Large Gloxinias (*J. Gilbert*).—The flowers were much damaged in transit through not having been well packed. Not one arrived in a perfect state; but we can perceive they are of good substance, and some of them very large, one being 3 inches in diameter. The colours are not so bright and clear as is desirable, but by careful selection and crossing you will soon improve the strain in that respect. The leaf sent is wonderfully fine, measuring 11½ inches by 9½ inches exclusive of the footstalk; and as you say the plants have "not been fed up for the occasion, but grown in ordinary loam and leaf soil, each plant having from thirty to forty expanded flowers," you have been very successful in their production. You cannot do better than continue improving, especially as regards the colour of the flowers, and you will soon have a strain of considerable merit. At present your products are highly creditable to you both as a hybridiser and cultivator.

Mezereum (*Berry*).—This is the old and commonly employed name of *Daphne Mezereum*, a hardy deciduous shrub with fragrant flowers, followed by bright Red Currant-like fruits. It is admirably adapted for suburban gardens and good positions in the front of shrubberies everywhere. It has pink flowers that expand in February or March. There are also red and white varieties, the latter very attractive, which flower in spring, and a reddish-pink kind that flowers in autumn. They are increased from seed and layers, also by grafting on stocks of the Spurge Laurel (*Daphne Laureola*), also raised from seed. The seeds of *Daphnes* are usually two years in germinating, and those you have sown last year may afford you plants next if the seed bed has not been disturbed. It is a common practice to store them in sand until spring and then sow them. If you like to try this plan and have only a few seeds it would be well to mix them in damp sand in a flower pot and bury the pot. If your shrub has branches that can be conveniently bent down and pegged in moist soil they will in due time emit roots. Some shrubs planted rather deeply also produce rooted suckers. Grafting is done in the spring, the stocks being established in pots, and the scions attached and kept in a close warm case or frame until united with the stocks.

Mealy Bug in Peach House (*Kittie*).—We think you may check the increase of the insects, if not cleanse the trees, by forcible and frequent syringings of pure water. Mere sprinklings are of no use, but the water must be applied with as much force as possible short of injuring the foliage. If you can, and we think you can, wash the meal off the insects they will be at your mercy. If pure water will not effect your object mix half a wineglassful of paraffin in each gallon of soft water, agitating very violently. When using first eject several syringefuls into the vessel, then force one in the pail and apply one to the trees alternately. The two fluids will then be mixed, and if the work of syringing is thorough it will destroy the insects; but we should try the pure water remedy first, as we know from experience how effectual it is if effectively applied.

Forcing Rhubarb (*Novice*).—You do not advise us as to the means of affording artificial heat, but we presume there is means of doing so; if not, you will need to provide such either with hot-water pipes or fermenting materials, the latter being most suitable when available. We should arrange to have a pathway up the centre of the building 2 feet 6 inches wide, and should have beds on each side, the sides formed of boards so as to form bins 3 feet deep. These should be filled with fermenting materials, which are preferably composed of leaves—those of the Beech or Oak, to one part of fresh stable litter thrown into a heap and turned over a time or two, mixed, and watered if necessary so as to produce fermentation. Placed in the beds it will heat in a few days, but the roots must not be introduced until the heat has been tested and is on the wane, or declined to below 90°, then introduce the roots, making positions for them about half their depth into the fermenting materials, and filling up between them with rich compost and about a couple of inches above the crowns. The compost used should be moist, so as to lessen the necessity for water until the crowns have started into growth, and then water should be given as necessary in a tepid state to keep the soil thoroughly moist. With a top heat of 60° to 65° it will take three or four weeks to have stalks fit for gathering from the introduction of the roots. The best kind for early forcing is Johnstone's St. Martin's, which, however, is more costly than Victoria, an admirable kind for marketing purposes. Linnaeus is also good for early use. We cannot recommend dealers, but by consulting our advertising columns you will be able to obtain quotations by applying to those who have roots to sell.

Heating Greenhouse (*R. C. A.*).—The proposed number of 2-inch pipes will be sufficient to maintain in a greenhouse 40 feet by 10 feet a temperature of 45° to 50°, in fact two rows of 4-inch pipes would be ample; but there is this advantage in 4-inch pipes, that they do not cool so quickly as 2-inch from the greater quantity of water in the former, hence the necessity of having a proportionately larger extent of surface of 2-inch piping than would be needed of 4-inch. For instance, 1 foot run of flow and return 4-inch pipe will have 288 inches of heated surface, whilst four 2-inch pipes of the same length will have the same number of square inches of heated surface, but only contain half the quantity of water of the 4-inch pipes. This shows the necessity of using more piping with a small than large diameter of pipe. We should have the same number of return pipes as there are flows.

Ducks in the Garden (*C. A. J.*).—Mr. Iggulden can only oblige you by stating that the ducks alluded to on page 514 last volume were obtained by putting the eggs laid by wild ducks under a broody hen. When hatched the hen and ducklings were transferred to the garden, the former being kept confined under a coop, the bars of which are arranged so as to allow of the ducks going in and out till such times as they are independent of the hen mother. They are thus at liberty to roam about, and this they do surprisingly nearly all day long, but more especially when the slugs are generally out—viz., in the mornings and evenings. They are best without water to swim in, but are kept well supplied with water to drink in a shallow pan. They are not so heavy and work harder than the tame breeds, but when nearly full grown are rather destructive among Strawberries and Asparagus. They are now sent back to the lake where the eggs originally came from, but every evening they pay us a visit. It would be useless to get them full grown, unless their wings were clipped. Ducks are much the best workers and less destructive when in a young state; and next season Mr. Iggulden hopes to arrange for three successive broods.

Names of Plants (*R. B.*).—1, *Lonicera Ledebouri*; 2, a *Sisyrinchium*, but specimen insufficient for determining the species; 3, *Solidago Virgaurea*. We do not undertake to name varieties of Irises, Pelargoniums, Roses, nor similar garden or florists' flowers, but only species of plants. (*Jumbo*).—2, *A Francisca*, but no one could identify the species from such a fragment; 3, *Cyperus alternifolius*; 4, *Melilotus leucantha*; 5, *Centranthus ruber*; 7, *Polemonium caeruleum*. We cannot name the others; all the specimens were much withered. (*R. F. S.*).—1, *Jasminum Poiteau*; 2, *Passiflora caerulea*; 3, insufficient; 4, *Cobaea scandens*. (*No Name*).—1, *Maranta zebra*; 2, *Cissus discolor*; 3, *Hibiscus Cooperi*; 4, *Tradescantia zebrina*; 5, *Clerodendron Balfourianum*; 6, *Abutilon vexillarium*. You have sent us neither name nor initials to indicate your plants.

Bees not Swarming (*Clifton*).—The cause of your bees not swarming this year is not owing to bad management or an unfavourable neighbourhood or wrong position in your garden. The present season has been unfavourable for bees, honey-gathering, and swarming. The strongest hives have been late in swarming, and many hives have not yet swarmed. Your case is not singular or exceptional. The fact of your supering and nading one of your hives in May is the reason that the super is empty. Probably the nadir or bottom box is quite full of combs and bees. But be assured that up till the present date (July 7th) all bee-keepers in Great Britain regret the absence of honey weather. There have been plenty of flowers, but owing to the wind being often in the east and north there has been but little or no honey in them. We are now in the middle of the Clover season, and Lime trees are not yet generally in flower, and if we have a spell of fine weather this month we shall have plenty of honey after all. Then, after the Clover season ends, the Heather in moorland districts begins, and continues till about the 10th of September.

COVENT GARDEN MARKET.—JULY 12TH.

THE wet weather has seriously affected the quality of soft fruit the last few days, prices being somewhat lower in consequence, although supplies are heavy. Grapes are again lower, but good samples of Peaches and Nectarines are in demand.

POULTRY AND PIGEON CHRONICLE.

THE SHORTHORNED BREED OF CATTLE.

(Continued from page 23.)

WE now come to a period within our own recollection in speaking of Shorthorn cattle imported into Australia; and we have a vivid recollection of what was called the unbeaten bull, Master Butterfly, belonging to Colonel Townley, when he gained the first prize for Shorthorn bulls over two years old, at the meeting of the Royal Agricultural Society of England's Show at Chelmsford in 1856, which also took the first prize for bulls under two years old at the Carlisle Royal Society's Meeting in the previous year. On seeing this magnificent animal, which was of a bright roan colour, of enormous size and weight, and as near perfection in all his points as we have seen any Shorthorn, and after looking at him with wonder and admiration, and hand-

ling him with great care to ascertain by touch his quality and aptitude to fatten, we thought, as we still think, that his equal may never appear again. It is stated that this most remarkable animal was sold at this time to a Mr. Ward of Geelong, in Australia, for twelve hundred guineas. We were, however, very sorry to hear of this animal's death while travelling under the influence of a hot sun to a local cattle show in the Colony in the year 1858. Master Butterfly was the offspring of the cow Butterfly, of whom we have above related that her showyard winnings were without a parallel. The same cow subsequently produced, when mated with the same bull Frederick, another bull calf, Royal Butterfly, whom we saw as the winner of the yearling prize at the Royal Meeting at Warwick in 1859, and of the first prize for bulls above two years old at the Royal Meeting at Canterbury in 1860. For him also the large sum of twelve hundred guineas was not only offered but refused. Colonel Townley writes saying, "I refused at Warwick for my present bull, own brother to Master Butterfly, twelve hundred guineas." We will now make our last quotation from Mr. Dixon's prize essay: it states, "Prices may at times have been wild and fanciful, and 250 guineas may seem an extravagant bull-hire; but still there is some method in the madness which would give 125 guineas for Oxford 11th as a calf, 250 guineas for her as a three-years-old, and 500 guineas for her as a cow, on the only three occasions that this dam of Fifth Duke of Oxford—the first-prize aged bull at Chester, and a 300-guinea purchase at six months old—was brought into the sale-ring. When we look back to the calm foresight of the Brothers Colling, the courageous confidence of Mason, the Rev. Henry Berry, and Whitaker; Tommy Bates, and all his animated lectures on touch and form in his pastures, or on the showground; a quiet day at Wiseton; the dashing cow and heifer contests between Towneley, Booth, and Douglas; the victories of Duchess 77th, and the Twins; the dispersion of the late Jonas Webb's herd at the steady and paying average of £55 10s. for 145; the brilliant gathering which appraised the Butterflies; £8180 at Willis's Rooms for the seventeen grand Dukes and Duchesses, and then scan the result in so many fairs and pastures, we may well feel that Shorthorns have repaid all the money, thought, and labour which have been expended upon them."

Since the period to which the last observations refer there has been a continuous enlargement of the area to which Shorthorns have been located, and a still greater number of annual sales of the best herds in the kingdom, amongst whom we hope it will not be considered invidious to name Mr. Richard Stratton of Broad Hinton, whose genius and untiring efforts to maintain the value and utility of the Shorthorn breed of cattle has proved highly advantageous to posterity, because he persevered in rearing animals of full milking capacity, as well as perfection in type and style. He, however, died in 1871, leaving behind him a great reputation and a herd which were reared and obtained extensive showyard honours, without sacrificing its milking powers, which few have done in recent times with the same success. In fact, it is the only reproach against the Shorthorn breed, that during a considerable period milk has not been regarded so long as the stock obtained the highest prizes at the Royal and other Agricultural Societies.

We must now allude to the opening of the new departure or era in prices and values set upon the best animals, and this, like many other important epochs in agricultural matters, commenced in America, resulting from that which has not unreasonably been termed the sale of the century, but more especially as regards the extreme prices at which the most coveted animals were sold. Sale of the New York Mills herd, Oneida County, New York. Details of this extraordinary sale which have reached this country are too voluminous for us to give in their entirety as published

in the *New York Tribune*. The origin of the herd was the purchase made by Mr. S. Thorne of New York, of several animals of the Duchess tribe at the famous sale of the Earl of Ducie in 1853. After changing owners several times the entire herd came into the possession of Mr. Campbell, who disposed of them for reasons not made public, in 1873, just twenty years after Lord Ducie's sale. In the New York sale; summary—ninety-three cows, &c., sold for £70,045, averaged £757, equal sixteen bulls sold for £173, averaged £386. Of the thirteen Duchess females one was withdrawn, and one made only £90; the other eleven made £47,800, or £4363 each; the prices varying from £1140 for the twelfth Duchess of Thorndale to £8120 for the eighth Duchess of Geneva. Of these Lord Skelmersdale bought one for £6140; Mr. Pavin Davies one for £8120; Lord Bective three for £7000, £3060, and £2000 respectively; and Mr. Holford of Market Harborough, one for £3140. The others went to Kentucky, or were retained by buyers at New York. In analysing the sale it will be seen that the fifteen descendants of the three daughters (all full sisters) of Duchess sixty-sixth made altogether fifty thousand guineas. It is satisfactory to know that such valuable animals were bought and added to the herds of this country, for no doubt these animals have been carefully managed so as to preserve up to the present time stock of the same untainted pedigree as the originals. Since this sale the sales in this country have continued unceasingly of the very best stock, but prices have rather receded lately for well-bred stock, owing in some measure to the depression existing in agriculture; still, the best and full pedigree tribes make very large sums, and will without doubt continue to do so.

WORK ON THE HOME FARM.

Horse Labour.—This will still consist of preparations for seeding the land for root crops, but especially for common Turnips; and for the main produce we continue to advocate the Grey Stone variety, as they grow quickly, come a good size, keep well, and maintain their feeding value longer than any except the hybrid sorts. The fallows for Wheat will still require constant attention, chiefly by surface cultivation, by which any roots or bunches of couch, black bent, onion grass, and wild Oats will be kept at the top, and by the constant use of the scarifier and Howard's self-lifting drag harrow they will for the greater part be lifted to the surface by the first-named implement, and any roots not so lifted out of the land will be combed out and left on the surface to die. So much is this latter implement preferred at the present time that on most farms well cultivated the old-fashioned wooden-framed drags are not now to be seen. If any land in fallow for Wheat is clean we advise the sowing of White Mustard seed, not for the purpose of feeding off by sheep, but for ploughing down as manure. We have often seen this done with great care, and the Mustard so completely buried out of sight under furrow that it could not be discovered by viewing the work what crop had been buried. We were recently on a farm and viewed the result of this plan of manuring, one-half of the land being sown after Mustard ploughed in, the other half sown after bare fallow manured with farmyard manure, and we estimated the first-named half of the field at three sacks of Wheat per acre more than the bare fallow-prepared and dunged portion. It is the practice on many strong land farms to grow winter and summer vetches, the winter-sown to be fed off in early spring (or as soon as the crop of green fodder is full) by sheep folded upon the land; the spring-sown to follow these are being fed off at the present time. As fast as a portion of the early crop is fed off we like to plough the land carefully, burying under furrow all the unconsumed haulm, and seed the land with white Mustard. Now this plan will ensure a full crop of Wheat without any yard or town manure being required, and this is especially worth the home farmer's attention upon land lying wide from the farmyard and premises, for it thus saves long carriage of the manure. In case, however, of any of the outlying fields requiring manure, guano at seed time and nitrate of soda in the spring are the best substitutes for yard or town dung, for these also save the heavy expenses of cartage attached to the use of straw-made manures.

We notice the second cuttings of Red Clover are coming forward, and are promising a heavy crop either of seed or hay, as may be required on the farm, because under the system of artificial drying of hay, corn, and seed crops the risk of second growth of Clovers, which has hitherto been difficult, will now be not only a safer but an easier process. This is more especially the case in some of the northern and Scotch counties, for where Wheat does not come to perfection Oats are usually grown, but in five years out of six it is difficult to harvest the crop in good condition. Now in the mountainous and elevated districts this new system of harvesting will prove invaluable, not only for hay, but for the Oats, &c., also.

Hand Labour.—Hoeing Mangolds and Turnips will require constant attention, as also Carrots, Cabbage, &c., and any other vegetable crops which may be cultivated on the home farm, and in some cases the crops are varied in different ways, according to the soil, climate, and the requirements of the districts in which the home farmer may be placed.

Live Stock.—The purchase of ewe sheep for breeding lambs for the fat markets usually takes place to a considerable extent at the early fairs whether of Down sheep or Longwools. In the midland districts this matter may be deferred for a while, but in the southern or home counties the sooner the ewes are purchased the better. The next fair will take place at Overton, Hants, July 18th; then Alresford, Hants, July 27th; and Britford Fair, Wilts, August 12th. At all these, and various fairs in Dorsetshire and Sussex, the ewes can be bought soon enough to be mated with the best Down rams at their new home as soon as they arrive from the fairs. The dairy cows where they cannot have a change of fresh grass should now have a good bait of Clover in the racks at milking time night and morning, otherwise Italian Rye grass, water meadow grass, or other green fodder reserved on purpose for them. If they do not get something of this kind the flow of milk will diminish, and they will go dry at an early period, and thus prove out of profit; 4 lbs. of decorticated cotton cake, however, per day will go far to maintain the supply of milk, besides improving the pastures where the cows graze. Fattening bullocks on the pastures also will require some little assistance unless the pasturage is very forcing and plentiful, but especially if it is overstocked in numbers of cattle. But in this case some may now be sold with advantage, especially if drupe cows form part of the herd, for beef generally sells well through July and the early part of August. Cattle in the boxes will now be doing well with 4 lbs. of the best St. Petersburg oil cake allowed them per day added to a full quantity of green fodder, a succession of which should be considerably provided in order that there may be no deficiency in the supply at any time. Some arrangement, too, should be made so that the cake may be given them in the meal state, the best way being always to hold over a little Mangold for the purpose, or otherwise to provide some early Cabbages to be passed through Gardner's cutter twice; in this way the cake meal can be mixed with the root crops without waste. The breeding sows and also store pigs may be now doing well with some green fodder strewed over well-littered yards or large pens, receiving also a few cracked beans or peas twice a day in the troughs.

POULTRY AND PIGEONS

CROSS-BRED TABLE POULTRY.

THIS is no new subject; we have often given our opinion on particular crosses. Of late, however, many questions about table poultry have been put to us, and this is a time of year at which a beginner can obtain well-bred birds at moderate prices, so it seems a favourable opportunity for collecting a few experiences on crossing. At present we are only concerned with the production of table poultry, though of course if the pullets are also good layers so much the better.

At the outset we may be asked if we generally recommend pure-bred or cross-bred birds for eating. Our answer is that this must depend on circumstances. We are fully persuaded that no possible cross can be more excellent on the table than a pure-bred chicken of certain varieties; we should give the palm to Dorkings, Polands, La Flèche, Crève Cœurs, and Game. At the same time where the soil is not suitable to poultry, or where the chickens are likely to be too much left to chance, or where they are required to be reared in enormous numbers, we should without hesitation recommend first crosses. There is a robustness about birds of a first cross which can seldom be got even by constant introduction of fresh blood in a pure breed, and which seems to carry them through dangers of cold and damp and tainted ground in a wonderful manner. There is no risk, too, of interbreeding, for these crosses must be first crosses; all experience shows that to continue to breed from cross-bred birds leads to certain failure and degeneracy.

We do not pretend to have tried a great number of unions, the number which might be made between the now known varieties of fowls would be prodigious. It is simply a question of arithmetic; but the knowledge now possessed of the characteristics of most breeds is enough to show that the majority of the possible crosses would do far more harm than good. There are four crosses from which we have seen good results, and which we can safely recommend; many more may result in hardy palatable chickens, but we have little experience of them.

1, Brahma and Dorking. This is probably the commonest and best known of all poultry crosses. So useful has it been generally found that early Brahma-Dorking pullets often command prices almost of pure-bred stock. The Dorking has long been known

in England as the table fowl *par excellence*, but at the same time, as a delicate bird. We may observe, by the way, that whatever modern poultry fanciers have done for the form and size of the Dorking, they certainly have made it a far hardier bird than it was. The Brahma when first imported was found hardy and far less unsightly on the table than most of the Asiatic fowls. We fancy, nevertheless, that its strength of constitution was somewhat over-rated. What, however, more natural than that the old fowl of the country should be crossed with this new much-lauded importation? The result proved generally satisfactory. The chickens grew fast and were hardy; the cockerels became nice table birds at an early age; the pullets were precocious layers and good mothers. Thus the cross has acquired a reputation simply because it has been much tried and succeeded. We do not believe it to be superior to other crosses which have been less tried. It is often a question of which variety the male bird should be. We do not lay much stress upon the point, but are inclined to favour the union of a Dorking cock with Brahma hens, because the latter are more certain winter layers. On the other hand, a Brahma cock is more likely to be a certain father, and will generally last two or three years, while we should advise that only a young Dorking chancier should be kept, and a fresh one procured every year.

2, Crève Cœur and Brahma is a cross not much known, but a very good one all the same. We cannot say much of the beauty of its offspring, but their size is fine and their constitution strong. Their appearance is sometimes most peculiar. The beard of the Crève parent is not reproduced, but in lieu of it huge whiskers appear. The Crève, like the Dorking, is a full-breasted bird, and seems to impart this desirable property to its half-bred offspring. They are plump as well as large-framed, and the cockerels very early fit for the table. The pullets are capital layers. We know a yard in which they are generally kept for winter and spring laying, and are then killed off. By this time they make fine fowls, and must, of course, be hung accordingly, and not dressed like spring chickens two or three days after they are killed.—C.

(To be continued.)

OUR LETTER BOX.

Nitrate of Soda on Farms (A Fancy Farmer).—Your "fancy" for applying this powerful fertiliser to land in the autumn is one that we do not approve of. It is far better in our experience to apply it as a top-dressing to crops in spring, when they need some assistance to accelerate their growth.

Poultry for Table (J. Webbe).—As your Dorkings give you so much satisfaction, and thrive well in your district why do you want to change them for other breeds? Would not it be wiser to add than to substitute? You cannot do better than read the article in the present issue, and the notes we shall publish in continuation on the same subject.

Vermin on Canary (W. J.).—Mr. Brent says—"The red mites or cage bugs are a species of Acaris. They live in the cracks and joining of the cages, and at night sally forth to suck and annoy the birds; they multiply in great numbers about the cage and in the nests, tormenting the birds, causing the death of the young, and frequently of the old birds likewise. Some fanciers have recommended the use of the Persian insect-destroying powder; but I have not tried it, finding that by thoroughly cleaning the cages, saturating the cracks with linseed oil, and then filling them with flowers of sulphur, and dusting sulphur amongst the bird's feathers, also by cleaning the nest and sprinkling powdered sulphur in, that I can get rid of these pests."

MIGNONETTE AT CHISWICK.

HEW plants are greater favourites than the sweet and modest Mignonette, which is grown in vast quantities in the neighbourhood of London to supply the demand constantly existing for the flowers. Indeed the culture of Mignonette is a very important feature in many establishments where plants are largely grown for market, and hundreds of thousands of potfuls are collectively sent to Covent Garden in the course of the year. It is not, therefore, surprising that some attempts should have been made to improve so popular a favourite; and as this could only be done by careful and continued selection the progress which has been made is rather remarkable, for several distinct and handsome varieties are now in cultivation which greatly surpass the old and commoner form. This advance is admirably shown by the numerous races or varieties which have been tried at Chiswick this year, all of which possess some distinguishing characters of more or less merit, and several are marked by such excellence that they deserve particular notice. The forms may be conveniently ranked under three types—those in which the flowers have the petals pure white, larger, and more prominent than usual; secondly, those with the anthers large and red, the petals not being conspicuous; and thirdly, those with similar anthers but yellow. When a number of varieties are grown together these distinguishing characters are very noteworthy, the heads having respectively a white, red, or yellow appearance.

Taking the types in the order named above, a few of the leading varieties in each may be appropriately noticed, as the collection affords an excellent opportunity of judging their comparative merits. Foremost amongst the new forms of the first section is Hemsley's Giant White, a beautiful variety possessing several recommendations. In habit the plants are sturdy and compact, the spikes are large, full, and of great length, the flowers very white, the petals being large, and the fragrance is powerful and sweet. It partakes of the merits of Parson's White, a well-known variety, which attracted much attention when first sent out, and is, indeed, probably a selection from that form. The latter is also well represented, and with Garraway's White, a similar variety, bearing handsome spikes of white flowers, we have a trio of the best in the section; to which may be added the grand form, Miles's Hybrid Spiral, for though the flowers are scarcely so white as the others, it has spikes of great size and excellent form, which render it one of the noblest Mignonettes in cultivation when it is thoroughly well grown. These white-flowered varieties are particularly

useful for cutting, as the spikes have not such a dull appearance as some of the others when arranged in bouquets.

In the "red" section the forms are numerous, but several from different firms, though bearing diverse names, resemble each other closely. One of the most distinct and attractive is that recently exhibited and certificated as *pyramidalis grandiflora*, which was received from both M. Vilmorin et Cie. and Messrs. Barr & Son. As grown at Chiswick this surpasses all the others in the size of the spikes both in pots and borders, and in one bed some of the spikes are 6 inches or more in circumference at the widest portion. They are not of great length, but their surprising width, and fine, compact, conical form, render the variety most striking. It is extremely vigorous, with large leaves, but the plants are of medium height; the anthers are reddish, and the flowers very fragrant. Next in order of merit is *Victoria* (Benary), which is one of the most strongly marked red forms, the anthers being large and more deeply coloured than the majority of the type. The spikes are also of good size, very compact, and the habit sturdy. Dwarf Compact from Messrs. Veitch & Sons is the counterpart of the above, except that it is dwarfer and admirably fitted for culture in pots. Both these are first-rate varieties. *Pumila erecta* and *Diamond* (Benary), with *Giant Red Pyramidal* of Messrs. Veitch, Barr, and Henderson, are good forms, the first two being notable for their dwarf habit, and the last-named for the length of the spikes.

From a number of firms, such as Messrs. Veitch, Carter, Cannell, and Henderson, a remarkably distinct yellow-flowered variety was received as *Golden Queen*, and from the continent the same variety came as *ameliorata aurea*, all being precisely alike and equally good. The Floral Committee when recently visiting Chiswick signified their appreciation of this variety by awarding a first-class certificate for it, and this honour it well deserves, for without doubt it is one of the most distinct Mignonettes in culture. The habit is dwarf, sturdy, and compact, the spikes being of moderate size, but with flowers closely set to form a good head. The anthers are numerous and marked by a very notable yellow hue, which gives the spikes a tinge that is very observable when a number are grown together. Few of the varieties represented have attracted more attention from visitors than this one, chiefly owing to its distinct colour.

It should be added that all the Mignonette in pots has been admirably grown, and very rarely has a finer collection both as regards culture and varieties been shown than that exhibited at Kensington a few weeks since from the Chiswick Gardens. With some few exceptions the plants have not succeeded so well in beds, but *pyramidalis grandiflora* must be named as the most remarkable of the former, for in one bed it is much finer than in pots. Mignonette displays a strange partiality for particular localities in this respect; in one it may thrive as well as could be desired, and in another no attention seems successful. Too heavy soil, or one that quickly becomes parched, is unsuited for the plant, the delicate rootlets of which are soon injured either by excess or insufficiency of moisture, and a rather cool slightly shaded position is preferable to one that is fully exposed to the sun. When sown in a border amongst other plants Mignonette often does well, as the slight protection thus afforded seems to suit it, and in situations near much-frequented walks, or in borders under windows, the fragrance exhaled by the flowers is most pleasing, as all well know.

However, the culture of Mignonette in pots is perhaps the most important, and a few hints upon the subject may be acceptable, especially where it is desired to have a supply during winter or early spring, as preparations for sowing the seed should now be made. It is during the early months of the year that Mignonette is especially in demand, and very good prices are then obtained both for plants in pots and flowers. The latter are always valuable to the bouquetists, as they supply a fragrance that is not overpowering, and at the same time the colour is of a neutral tint that can be arranged with any other. All through the year, however, the demand is good, and fairly remunerative prices are obtained, even when it is most plentiful. In most of the large establishments near London, where growing for market is carried on to a great extent, a large proportion of the stock of Mignonette is ready for sale by March or a little later, and many thousands of pots are sent to Covent Garden and other metropolitan markets from then onwards through the summer months. Seed is sown towards the end of the present month or during August, and the plants are preferably grown in frames heated sufficiently to exclude frost and prevent an undue accumulation of damp, which causes the greatest injury to Mignonette in winter. But large quantities are grown in cold frames, covering being employed in severe weather, and, provided that excessive moisture can be guarded against, fine sturdy plants are obtained in this way with vigorous spikes of flowers. One great necessity is a free exposure of the plants at all times when there is not too much wet or frost, as if the frames are long closed the plants soon draw up, become weakly, and flower poorly.

The compost to be employed is an important consideration, and perhaps where failures with Mignonette occur they are chiefly due to mistakes in this direction. A heavy soil that would prove too retentive of moisture, or one that is so light that it dries very quickly, must be avoided; a rich friable loam with a good proportion of leaf soil and lime rubbish, say one-third, constitute a suitable compost, to which a little sand may be added if there is too great a tendency to heaviness. The lime rubbish is a highly necessary element, and though fairly satisfactory success may be occasionally obtained without it, in the majority of cases it is indispensable, and in its absence the best results cannot be ensured. A few of the rough siftings are employed for draining the pots, and they are then filled with the compost rather firmly, the surface being smoothed for the reception of the seeds, which are sown thinly but evenly, very lightly covered with a little finely sifted soil, and watered thoroughly with a fine-rose can. Some growers leave an inch or more of space from the surface of the soil to the rim of the pot to allow of a little rich compost being added as the plants are advancing; but this is by no means absolutely necessary, as, if any additional nutriment is needed beyond that afforded by the soil, supplies of weak liquid manure can be given, though some of the best Mignonette I have seen has been grown without any such assistance.

In sowing the seed, especially where large quantities of plants are grown, some judgment is needed to avoid wasting it, and at the same time to provide for a full pot. When the seedlings are well formed—less than an inch in height, thinning is necessary, retaining eight or ten in a 48 size pot, according to the strength of the plants. Early thinning is advisable, as the soil is then less disturbed in removing the superfluous plants, and the others are not so likely to become drawn. During winter water must be supplied very carefully, always choosing a fine day for the operation, and ventilating the frame as much as possible afterwards, removing the lights; indeed, these should be kept off as much as possible at all times. A cool moist base for the pots to stand upon is important, and perhaps nothing is better fitted for this than a layer of coal ashes or cinders an inch or two in thickness, moderately firm, and well levelled with a rake.

Though frames are preferable, of course Mignonette can be grown in any cool house if the plants be placed near the glass and freely exposed to air, as the great point is to obtain sturdy growth, and it cannot be insured without attention to these matters. As a rule it will be found that market Mignonette greatly surpasses that grown in gardens in this respect, and it

is entirely due to well hardening the plants, so that the slight supports supplied are scarcely needed, and an even potful of vigorous plants with fine healthy foliage and sturdy spikes of flowers are secured.—L. CASTLE.

MUSHROOMS FOR THE MILLION.

(Continued from page 530, last vol.)

INSERTING THE SPAWN.

It is worthy of special notice that those who are extensively and successfully engaged in growing Mushrooms for market, not only find it to their advantage to use spawn liberally but to insert it in large lumps. It is found the best practice to divide a brick into eight portions, and insert these about 9 inches apart, the smooth sides being placed outwards, and level or nearly so with the surface of the ridges. When the work is done those portions are plainly visible and are well represented in the engraving (page 463, last volume). No holes are made for receiving the lumps, but the manure is simply held up with the left hand, and they are forcibly pressed in with the right. There are then no interstices between the spawn and manure for the accumulation of steam, which if allowed destroys the mycelium. The reason why small portions of the spawn bricks are not deemed safe is this—if the bed should happen to be a little too hot or too wet it might injure if not kill the mycelium on the outside of the lumps, and if these were small the danger of the whole being destroyed would be great, but being large the risk of this occurring is reduced to a minimum, as if the outsides of the lumps were damaged, the mycelium in the interior might be as safe and good as ever. The wisdom and even economy of using large pieces will now be apparent. There is scarcely any doubt that numbers of Mushroom beds have been rendered effete by breaking up the bricks into too many and consequently too small portions when using them. It is far better to use large pieces, even if they are inserted at wider intervals, than to use small portions and insert them much nearer together. The somewhat fanciful practice of crushing the bricks almost to powder, and spreading the particles on the surface of a bed as if sowing seed before adding the soil, cannot be recommended. It is not adopted by growers of Mushrooms for market because considered wasteful, as if it results in anything at all it is a myriad of pea-like heads that are worse than useless, as they are not only worthless but arrest the growth of finer Mushrooms from the stronger mycelium in the interior of the bed.

The time for inserting the spawn is when the heat of the bed is decreasing, but has not fallen below 80° Fahr., an inch below the surface. This proper temperature can be ascertained by placing a thermometer in the bed, but it will not be necessary to use it many times. Growers of produce for market judge of the heat by the hand, and when the manure is a little warmer than the hand is when placed amongst it the spawn is inserted. It is never safe to do this when the heat is rising, as it may afterwards increase and kill the mycelium. If the spawn is good and the bed in the right condition the former will commence spreading or "running" in three days. Then, and not till then, the bed is cased with soil. Previously, if needed, it is covered with litter of the thickness requisite for maintaining the necessary heat. After being soiled it is again covered with the same object; and it may be observed that so long as the surface of the

bed under the litter is in the slightest degree warmer than the hand the temperature is right for Mushrooms.

SOIL FOR MUSHROOMS.

An opinion is somewhat widely entertained that it is of no great consequence what kind of soil is used for surfacing Mushroom beds. It is argued that the crop derives its support from the manure, not from the soil; indeed, a scientific writer has stated that soil is not necessary for Mushrooms, and he therefore did not place it on his beds from which he gathered what to him were satisfactory crops. Beyond doubt the material of which a Mushroom bed is made is of primary importance, and its character exerts a great influence on both the quantity of Mushrooms that are produced and their size. But the soil exercises an influence too, and, all other conditions being equal, the cultivator who has the command of strong turfy loam will obtain the greatest weight of produce from his beds. The material with which the Mushroom beds in the caves in France are covered is light and poor, and the Mushrooms are small. The soil which Mr. Barter uses is heavy and turfy, just such as a gardener would covet for growing Roses and Chrysanthemums, and the produce is large, Mushrooms often being cut weighing half a pound each. Thousands are gathered with stems varying from 1 to 2 inches in diameter, the pileus being an inch and upwards in thickness. "Too large," possibly some may say, especially those who only grow small ones; but those who grow Mushrooms for sale and can sell all they grow, are not afraid of growing them too large. For large Mushrooms, provided they are young, fresh, and only partially expanded, there is a great demand, especially in hotels that are patronised by foreign visitors to this country. The French may possibly prefer "buttons" at home; but it is certain they enjoy the large fat "broilers" here, and they seldom fail to ask for the fine rich juicy specimens that they can only find in England. Now to produce these, which are the most remunerative to the grower, strong and rich soil is essential—not soil recently enriched with manure, for the use of that is a mistake, but soil that is naturally fertile—such as the top spit from a pasture in which Buttercups are more plentiful than Daisies, the former indicating fertility, the latter sterility, when they are present in great numbers. There is no doubt whatever that Mushrooms derive a portion of their support from the soil with which the beds are cased. There is the same difference in the character of their roots as there is in those of other plants—in light, poor, and sandy soil they are small and numerous; in strong rich soil they are few and large, and the growth corresponds with the roots—strong when they are strong, weak when they are weak.

The fact that Mushrooms derive support from the soil, and in so doing deprive it of a portion of its constituents, is proved by the circumstance that if the soil is removed from a bed that has produced heavily, and is at once applied to a portion of a new bed, the remaining portion being cased with fresh soil, the difference in the weight of the produce from the two portions will be very apparent and overwhelmingly in favour of the fresh soil. Mr. Plant, a gardener near Manchester, has adduced conclusive evidence that Mushrooms are improved by the soil with which the beds are covered. He says (page 193, last volume), "During the long frost of 1879-80 we had not suffi-

cient material to soil a Mushroom bed, everything being frozen, so we turned a number of old Chrysanthemums out of their pots and used the soil, which had been very liberally mixed with ground bones—so much so that when spread on the bed and smoothed over it looked more like an asphalt walk than a Mushroom bed. The result was marvellous—such a crop of large fleshy Mushrooms as I never saw before." This experience is suggestive, and those who have only poor soil at their command for surfacing Mushroom beds would probably find it profitable to enrich it in the manner indicated, or add bonemeal at the rate of a quarter of a peck to a bushel of soil, and if light and sandy also a quarter of a pound of salt, the whole to be well mixed. But as above intimated, it must not be enriched with ordinary manure, or some unwelcome fungi might, and probably would, become established in the beds and do serious injury. Where soil is good for the purpose in question, yet scarce, it may be carefully removed from the beds, excluding all manurial particles, and mixed to the extent of one-half with fresh soil, turned over a few times during the season, then be used again for further crops. When ordinary garden soil is employed for Mushroom beds it is a safe practice to remove a few inches from the surface that may contain undecomposed manure, and select that immediately below it, always giving preference to strong overlight soil when there is any choice in the matter; but never under any circumstances permit any particles of manure to be mixed with the soil for surfacing Mushroom beds if troublesome, and it may be ruinous, crops of obnoxious fungi are to be averted.—J. WRIGHT.

(To be continued.)

A FEW USEFUL HARDY PLANTS.

SPIRÆA ULMARIA FLORE-PLENO.—This is the common Meadowsweet, with the flowers not unlike miniature white Bachelors' Buttons, in loose heads, on stems varying from 2½ to 3½ feet in height. It is a stately border plant, and it is somewhat surprising that it has not become a more general favourite. We rarely see it even in good collections of hardy plants. For gardens where the soil is cold and heavy this plant is invaluable. It succeeds best in good retentive soils, but will grow well in any ordinary border, and it looks well either associated with the shrubs or brought forward to the front of the border behind the lower growing kinds of herbaceous plants. In pots for a conservatory it is very useful. If for early forcing the plants should be taken from the reserve ground about January, potting them in any good compost, and placing them in a cool house to start them into gentle growth. They can afterwards be introduced into a higher temperature, where they can be brought into flower without being drawn. For blooming during the summer months the plants should be potted any time during early spring, and placed either in a greenhouse, cold frame, or plunged out of doors. Propagation can only be effected by division of the plants, as the flowers do not produce seeds. The best time for dividing the clumps is in spring just before the plants commence growth. A good piece of ground should be selected for the purpose, and if in partial shade so much the better. After planting out the divisions give the bed a good watering, which should be attended to occasionally afterwards if the weather be dry. No further attention is necessary except cutting off the flower stems that may appear, as this will cause the young plants to make stronger crowns. The variegated Meadowsweet is also a very ornamental plant, and deserves more attention both as a border plant or for conservatory purposes.

The double-flowered Dropwort, or *Spiræa Filipendula flore-pleno*, is a very old-fashioned garden plant, and may often be met with in old cottage gardens in its best condition. The value of this plant seems to be better known than that of *S. Ulmaria fl.-pl.*, for it is grown both in pots and borders, displaying its beautiful trusses of delicate bloom freely. It is much dwarfier than the Meadowsweet, attaining a height only of from 15 to 18 inches. The flowers, which are somewhat larger than those of

the preceding, are faintly tipped with red, a character more noticeable in plants that are grown out of doors. This is tubercous-rooted, and dividing the plant should be attended to in spring, when every tuber will grow and make a plant.

COCHLEARIA ALPINA.—A few years ago, when travelling in the hilly picturesque country north of Settle in Yorkshire, my attention was attracted by a very dwarf and small-leaved form of Cochlearia, which I at once lifted carefully to carry home. The plant in question is very dwarf, scarcely exceeding $2\frac{1}{2}$ inches in height. The leaves are very small, being under one-sixth the size of those of *C. officinalis*, varying in shape from orbicular to reniform. The lobate leaves are few, which adds more to its beauty. The flowers are very small and white, displayed in small erect racemes, only slightly exceeding the leaves in the early part of its flowering season. After a time, which is when the fruits have commenced forming, the stems elongate and become proliferous. After the seeds have ripened the flower stems can be cut away; there is then left an ever-beautiful cushion of dark shining green leaves until its flowering season again towards the end of March, when it becomes literally studded with racemes, which continue flowering for about three months. It is of perennial duration, which adds greatly to its value as a garden plant. Most of the forms of Scurvy-Grass are said to be annual or biennial, but this one clearly proves that there is at any rate one native form which is not so. The stems emit a number of fine roots, and it may either be propagated by division or by cuttings. I can class it as a gem amongst hardy alpines, and will doubtless make a good plant for capping the apices of rough bare stones on rockwork. I exhibited it in a pan at the late Manchester Show. It was in good condition then, but a month previous to that date it was much better-looking, being not much unlike a good mass of *Ionopsidium acaule*.—T. ENTWISTLE, *Didsbury*.

ROYAL MANCHESTER AND NORTHERN COUNTIES BOTANICAL AND HORTICULTURAL SOCIETY.

JULY 14TH TO 15TH.

THE Show of the above Society was held in the large exhibition house in the Botanic Gardens, Old Trafford, on the date named. The display of Roses, notwithstanding the inclemency of the weather, was a great success. Dark blooms, such as Prince Arthur, Horace Vernet, Alfred Colomb, A. K. Williams, Senateur Vaisse, and others of the same type and colours predominated, and on the whole were models of perfection. The light kinds showed the effects of the weather to a much greater extent; but that useful Rose La France, also Capitaine Christy, were really splendid in some of the boxes. The box of Tea Roses shown by Mr. Prince of Oxford were very fine, and staged in the best style.

In the class for seventy-two, distinct, single trusses, there were four collections staged. The premier award was deservedly given to Messrs. Paul & Son, Cheshunt, who were closely followed by Messrs. Cranston & Co., Hereford; Messrs. Davison & Co., Hereford, and James Dickson & Sons, Newton Nurseries, Chester, being third and fourth respectively. The first-prize collection contained good blooms of Senateur Vaisse, bright and full; Horace Vernet, Mrs. Jowitt, Ferdinand de Lesseps, Duke of Edinburgh, very large and bright; Charles Darwin, neat; Louis Van Houtte, Countess of Rosebery, remarkably fine; La Rosière, Comtesse d'Oxford, Comtesse de Serenye, Madame Alphonse Lavallée, R. N. G. Baker, Lady Sheffield, neat and of good form; Souvenir d'un Ami, Marie Van Houtte, Prince Arthur, Madame Marie Verdier, Madame Hippolyte Jamain, Duke of Teck, Comte Raimbaud, A. K. Williams, Beauty of Waltham, and Comtesse de Nadaillac. Messrs. Cranston & Co. staged excellent examples of Mdlle. Eugénie Verdier, grand in form and colour; Camille Bernardin, Star of Waltham, Mons. Etienne Levet, Duchesse de Vallombrosa, Duke of Teck, Royal Standard, Mrs. Jowitt, Sir G. Wolseley, La France, Capitaine Christy, Marguerite Brassac, Jean Ducher, and Madame Willermoz. The third and fourth collections also contained good blooms of many of the above-mentioned kinds.

Messrs. Cranston & Co. took the lead in the class for forty-eight triplets, followed closely by Messrs. Paul & Son, Cheshunt, and Messrs. Davison & Co. The first lot containing remarkable examples of Magna Charta, Exposition de Brie, A. K. Williams, Mrs. Jowitt, Constantin Tretiakoff, Marquise de Castellane, Madame Gabriel Luizet, Dupuy Jamain, La France, and Capitaine Christy. The second-prize collection included superior examples of Brightness of Cheshunt, Dr. Andry, Marie Baumann, Prince Arthur, Niphotos, Catherine Mermet, and Annie Wood. Messrs. Davison's had been injured by the weather, but Belle Lyonnaise and Comtesse de Serenye were extremely fine. Mr. G. Prince, Oxford, was first in the class for twenty-four triplets, and the blooms staged were unsurpassed in the Exhibition for size, substance, or colour. Messrs. Cooling & Sons, Bath, and Messrs. Cranston & Co. were the other successful exhibitors. Mr. Prince's best blooms were Madame Marie Verdier, Madame Marie Finger, highly coloured; Alfred Colomb, superb; Catherine Mermet, Madame Lambard, good; Marie Van Houtte, Senateur Vaisse, Duke

of Edinburgh, Perle des Jardins, Prince Arthur, Charles Lefebvre, and Souvenir de Madame Pernet.

For eighteen distinct Tea or Noisette Roses Mr. Prince was again well ahead, and staged in the best of condition Madame Lambard, Marie Van Houtte, Catherine Mermet large and full; Amazone, Rubens, grand; Anna Ollivier, Souvenir de Madame Pernet, Souvenir d'Elise Vardon, Souvenir de Paul Neyron, and President. Messrs. Paul & Son were second with smaller but very neat blooms, having good examples of Madame Lambard, La Boule d'Or, Jean Ducher, Souvenir d'un Ami, and Madame Willermoz.

In the class for twelve new Roses, single trusses, not in commerce previous to 1878, Messrs. J. Dickson & Sons, Chester, were distinctly first with fresh well-coloured flowers of Duke of Teck, Pride of Waltham, May Quennell, full; Duchess of Bedford, Julius Finger, Crown Prince, A. K. Williams, Countess of Rosebery, large and good form; Madame Ducher, Edward Dufour, and Brightness of Cheshunt. Messrs. Cranston & Co. were second with neat but smaller blooms of Masterpiece, Crown Prince, Pride of Waltham, Madame A. Dumesnil, Gloire de Bourg la Reine, Mdlle. Marguerite Manion, Comte Horace de Choiseul, and Barthelemy Joubert. Messrs. Paul & Son were third with good blooms of R. N. G. Baker, Mdlle. Marguerite Manion, and Pride of Waltham. There were five entries.

In the class for twelve single blooms any dark Hybrid Perpetual, Mr. Prince was first with grand blooms of A. K. Williams; Messrs. J. Dickson & Sons second with good Marie Baumann; and Messrs. Cranston & Co. third with smaller but good examples of Alfred Colomb, four collections being staged. In the corresponding class for twelve light Roses Mr. Prince was again first with La France, Messrs. Davison & Co. and J. Dickson & Sons taking the remaining prizes with the same variety.

Amateurs' Classes.—The Roses in the amateurs' classes, both open and local, were throughout good. Mr. John Burrell, Darlington, took the lead with thirty-six single trusses, followed closely by the Rev. Canon Hole with blooms equally good in size and form but scarcely so bright. In the first collection Countess of Oxford, François Michelin, Victor Verdier, Dupuy Jamain, Etienne Levet, Alfred Colomb, and Innocente Pirola were all good. Canon Hole staged fine blooms of Souvenir d'Elise, Marie Van Houtte, Duke of Wellington, Madame Hippolyte Jamain, and Madame Caroline Kuster. For eighteen triplets the last-named exhibitor was first, the most striking blooms being Capitaine Christy, Antoine Ducher, La France, Etienne Levet, Souvenir d'un Ami, and Madame Sophie Fropot. Mr. G. P. Hawtrey, Slough, was the only exhibitor in the class for twelve Teas or Noisettes, and staged very creditable blooms, for which the first prize was awarded, the best examples being Alba Rosea, Archimede, Niphotos, Madame Lambard, and Devoniensis.

In the local amateurs' class for twenty-four single trusses there was good competition, some even collections being staged. W. Brockbank, Esq., Didsbury, was first, having excellent blooms of the standard varieties before mentioned. W. L. Palfrey, Esq., Altrincham, was second; and Mr. Thomas Walkden, Wellington, third. For twelve blooms E. J. Thomson, Esq., Timperley, W. S. Palfrey, Esq., and Mr. J. R. Ward, Timperley, were the prizetakers as named, an extra prize being awarded to John Davenport, Esq., Altrincham. For six blooms Messrs. Palfrey, Thomson, and James Brown, Heaton Mersey, obtained the awards.

Bouquets.—In the class for three Mr. Mason, Victoria Street, Manchester, was deservedly placed first. One was entirely composed of a few dark buds and the rest Maréchal Niel with a tasteful intermixture of foliage; the next of a pink Tea and Niphotos, the third being divided into four quarters by dark Rose buds, each quarter being filled with various-coloured Teas with small buds of Niphotos standing well above the rest. Messrs. Cranston & Co. were second with neat examples, a good number of Moss buds being used. Messrs. Davison & Co. third. In the class for one bouquet the same exhibitors took the awards in the order as named for the three.

Miscellaneous Exhibits.—Messrs. Cole & Sons, Withington, contributed considerably to the effect of the Exhibition with a choice assortment of small stove and greenhouse plants, including Ericas, Crotons, Dracaenas, Palms, Ferns, Ixoras, Gloxinias, and others; also stove and greenhouse cut flowers in boxes. Messrs. F. W. & H. Stansfield, nurserymen, Sale, Cheshire, sent a collection of choice varieties of hardy Ferns; Messrs. Dickson, Brown & Tait boxes of cut Roses and herbaceous cut flowers; Messrs. Dickson & Robinson staged a similar but larger display; Messrs. Cooling & Sons, Bath, staged a large number of cut Roses in boxes and baskets. Mr. Samuel Barlow, Middleton, exhibited a very fine collection of Persian Ranunculus, which excited much attention and praise both from the Judges and public, and the Society's gold medal was awarded to Mr. Barlow for this unique contribution to an excellent Show.

OMPHALODES LUCILÆ.—This is a lovely alpine, native of Southern Europe, of very dwarf habit, a favourite with all connoisseurs in such plants. Leaves on short petioles, ovate-oblong, blunt, very glaucous. Flowers produced in lax panicles, about half an inch across, with saucer-shaped corollas of a porcelain blue colour tinged with pink. Most distinct and pretty, appearing throughout all the summer months. It was for a long time considered a very miffy plant, and is still treated as such by some growers. Such treatment ruins it, as it enjoys full exposure. Mr. Ewbank once remarked to the

writer respecting this plant, "It does like a weed in my garden;" and so it does, and in other places besides. The rockery is certainly its proper place, placed close to a ledge of stone so that the panicles can droop over; but it may also be planted in the border if the position is thoroughly drained and the plants supplied with very free soil, then it will flourish.—N.

FORMAN'S EXCELSIOR STRAWBERRY.

LAST year Mr. Laxton and other cultivators wrote approvingly of this variety, of which Mr. Gilbert has now sent us fruits. Two of these, showing the cockscomb (fig. 10) and conical form (fig. 11), are represented in the annexed engravings.

Mr. Gilbert writes in reference to this Strawberry:—"This being the first year of this variety fruiting here I cannot confidently speak of it as I believe it deserves; nevertheless, I may say it promises remarkably well. Forman's Excelsior has one really good property—it ripens the later fruit and swells them off in a remarkable manner. The flavour is all that can be wished; the size is also satisfactory, and the robustness of the plant is extraordinary. Small plants turned out of small 60-sized pots and planted on good land last August have now the appearance of

Fig. 10.

two-year-olds. I may add that too much manure would, in my opinion, grow the plants too strong."

From Mr. Henry Boothby of Louth, Lincolnshire, we have received the following account of Forman's Excelsior:—"This variety was raised by Mr. Forman of Louth about eight years ago. Its progenitor was James Veitch, and it partakes of the quality of its parent as to early productiveness. Its historical career commenced in July, 1875, at the Nottingham Arboretum Show, open to all England, when the Judges awarded it a first prize for the best new variety of Strawberry, a good judge remarking at the time, 'it certainly is the finest fruit yet raised for size, colour, and flavour combined.' A correspondent in last week's Journal says it is early like Garibaldi, and as large again in size, but some of the fruits are hollow. I have grown it for years, and must say I never saw any failing of this kind. One thing is to be avoided in its culture, and that is too rich soil. If this be given the plant makes growth to the detriment of the fruit. The weight of several fruits gathered this week was $1\frac{3}{4}$ oz., and the size $8\frac{3}{4}$ inches in circumference each."

We subjoin a description of the sample of Forman's Excelsior which Mr. Gilbert sent to us. Fruit large, varying from a symmetrical conical shape to a wide-spread cockscomb. Skin dark red, of uniform colour all over its surface, which is rather deeply pitted with moderately sized seeds. Flesh firm, tinged pale scarlet throughout, quite solid, juicy, rather briskly flavoured, and with a fine aroma. This is an early Strawberry, as large and as handsome as President, than which it is richer and rather more sprightly in flavour.

This appears to be a variety of considerable merit; and the hollowness of the fruit, which was referred to last week, was probably due to luxuriant growth of the plants and too generous culture, as we observe that both Mr. Gilbert and Mr. Boothby indicate that rich soil is undesirable for a variety of which the habit seems to be naturally robust. Now that Forman's Excelsior is

being distributed we shall probably hear more respecting its merits another year.

COTTAGERS' CROPPING.

NOTICING last year a successful example of cropping on a cottager's allotment I think it worth while to record it. It was adjoining a main road, and three good crops of vegetables were obtained with once digging and manuring. This piece of ground (about 12 perches) was manured and dug in February and the early part of March, and Myatt's Prolific Potato planted in rows 2 feet asunder before the last-named month was out. In the middle of June, the Potatoes having been hoed and earthed up, and the tops nearly meeting in the rows, Brussels Sprouts were planted between every alternate two rows, the haulm of the Potatoes being turned inwards into the furrow in which the Sprouts were not planted, thus giving them more light and air. Before the end of July the Potatoes were all forked out, thus leaving the rows of Brussels Sprouts 4 feet apart. The land when the Potatoes were cleared was levelled with a fork, the loose haulm removed, and white Turnip seed sown broadcast thinly in the 4-foot space, but not close to the Sprouts, and being showery weather at the time the Turnips made good progress, and were in use from the end of September till January. Many gardeners, and cottagers too, no doubt resort to the same practice, but to any who have not tried it these remarks may prove of some service. For the Brussels Sprouts to succeed it is essential that the Potato haulm be turned away from them with the hand into the space where none are planted. My coarse-growing Potatoes would not be good for this kind of cropping, but the early Ashleaf kinds are very suitable.—A. H.

LILIUM PARDALINUM.

MR. GEORGE WILSON of Heatherbank, near Weybridge, a most successful cultivator of Lilies, when visiting my garden last spring paid a great compliment to *Lilium pardalinum*, which were then in an early stage of growth. He said that they surpassed in size and vigour anything he had been able to produce in Surrey, and I must own that I have never seen them grow so fine anywhere else; I may venture, therefore, to give some account of their cultivation.

L. pardalinum has an extensive native range in the mountainous districts of the United States. Several local or accidental varieties have received distinct specific names, but intermediate forms of every gradation show them all to belong to one species. Mr. Elwes in his Monograph of Lilies gives it the name

Fig. 11.

of the Californian Lily. The name "californicum," however, is generally given to a very beautiful and distinct variety, of which the growth is less robust, but the flowers larger and deeper in colour, with the ground of the centre nearly white; they are also produced in smaller numbers—seldom more than three or four on a stalk—than in the type of the species.

The ordinary *L. pardalinum* grows to a height of from 7 to 9 feet, sometimes bearing as many as fifteen flowers on a stem, which is more or less branched above the lowest flowers. Another distinct form generally bears the name of *L. Michauxii*. In this

variety the whorls are more densely set with leaves, and the leaves more slender and pointed; the flowers are smaller, but abundantly produced; the general growth is less robust, but the increase very rapid. These three represent the most distinct forms, but there are many others possessing characters more or less marked, though perhaps all may be found amongst those imported and sold under the general name of pardalinum.

As regards cultivation, I believe that this Lily finds something especially congenial in the peat which I procure from the hills near me. The beds are dug out to a depth of 4 feet, thoroughly drained, and filled with a mixture consisting of two-thirds or three-fourths, or even more, chopped peat. The more peat the better this Lily seems to like the soil. As for situation, I have come to think that in the cloudy and rainy climate of Cheshire they cannot have too much sun. The surface of the bed is covered with *Ledums*, *Menziesias*, slow-growing *Ericas*, *Azalea mollis*, and similar shrubs. One I formerly recommended, *Pernettya mucronata*, grows too fast and roots too thickly on the surface, robbing the soil. Many of the *Epimediums* are good, but *E. pinnatum* I find liable to the same objection as the *Pernettya*—making too strong growth. The use of these plants is to keep the surface of the soil cool, and to protect the young growths in spring. I do not like the shrubs to be more than a foot high, or the growth of the Lilies is apt to be drawn too much. A late spring is to be desired for these as well as for other Lilies.

L. pardalinum has never been killed by frost in my garden, but when they have grown clear of the shrubs the point of the shoot is very sensitive and easily destroyed by frost. The more advanced it is the more tender it becomes, and every year I have several heads spoilt by late frosts: this year some were killed at the beginning of June. The capricious way in which the frost takes a head in the middle of a bunch, leaving those around it quite unhurt, is unaccountable. With the exception of *L. Hansoni*, which forms its buds so unfortunately early that I have never yet been able to make it flower out of doors, *L. pardalinum* is the worst sufferer from late frosts. Still 90 per cent. of the stalks generally escape unhurt, and make a grand forest of flowers about the middle of July. The beds, however, have to be filled with upright iron rods from 7 to 9 feet high, far more thickly, in proportion to their size, than the poles in a Hop yard. The stalk is so soft and brittle as to require to be tied against every wind, even in the most sheltered position I can give, but then my garden is a windy place. All the varieties of *L. pardalinum* increase fast, not less in my soil than threefold every year, and I have never left them for more than three years in the same spot. The bulbs soon grow in a cluster on the surface of the soil, and the heads become so crowded that the flowers cannot expand properly. I have now begun to plant them in my mixed flower beds, where they seem to be doing pretty well, but not so well as in the peat; but all my flower beds are artificially drained, and consist of made soil, or the stiff cold native clay would make all gardening hopeless.

Much has been written about the best time for transplanting Lilies. The question is an important one, for some Lilies seem to take three years to recover from transplanting, and we know that the roots of many kinds of Lily are in active growth when there is no indication of growth above ground. Mr. Wilson has told us that he has often found Lily bulbs grow and continue healthy for years without anything appearing on the surface. In all gardening operations, however, experience is better than theory, and in the case of *L. pardalinum* and most other Lilies I have found spring the worst and early autumn the best time for transplanting. When the tops begin to turn colour, but have still life in them, most Lilies are moved with least cost to their next year's growth.

L. pardalinum does not suffer much from the attacks of slugs or other ground vermin, and, though the stalks are often attacked with spot, that disease is not so destructive as it is to other Lilies. The flowering of many stalks not only of *L. auratum*, which, being latest, suffers worst, but of *L. Humboldti*, *L. canadense*, *L. superbum*, and others, is annually destroyed in my garden by this troublesome atmospheric blight. Happily, though it may be contagious, it is not hereditary or persistent, for I make a practice of marking by labels the worst cases, and not unfrequently find that those very bulbs which are worst affected one year are amongst the finest and most healthy the following year. *L. pardalinum* seldom shows signs of spot until the flowering is nearly over, and then not to such an extent as to kill the leaves and stalk prematurely. As far as my experience of Lilies extends this is far the best of all the American Lilies for general cultivation in gardens.—C. WOLLEY DOD.

INDIARUBBER PLANTS.—Mr. W. T. Thiselton Dyer recently brought before the Linnean Society an important communication on the

caoutchouc-yielding Apocynaceæ of Malaya and Tropical Africa. After giving a general sketch of the structural and physiological conditions of the occurrence of caoutchouc in plants, the author pointed out that the plants which appeared to yield it in commercial quantity in three widely separated regions all belonged to one tribe of Apocynaceæ, the *Carisseæ*. In the East Indies the "gutta singarip" of the Malay Peninsula, the "gutta soosoo" of Borneo, was the produce of a new species *Willughbeia*, *W. Burbidgei*. Many other species of this and allied genera also seemed to produce caoutchouc in quantity worth collection. In central Africa *Landolphia*, which was closely allied to *Willughbeia*, but differed in possessing terminal instead of axillary flowers, was the most important source. On the east coast caoutchouc was yielded by *L. owariensis* and *L. florida*, the latter a very ornamental plant. As the rubber exuded from the cut stems, it was plastered by the collectors on the breast and arms, and the thick layer when peeled off and cut up into squares was called "thimble rubber." On the west coast the most important species was *L. Kirkii*, the rubber of which could be wound off into balls or small rolls from the cut stems, like silk from a cocoon; this species was called "Materé." *L. florida* also occurred, and was called "m'bunga;" its rubber was worked up into balls, but was inferior in value. The rubber of *L. Petersiana* was of little importance. In South America *Hancoria speciosa* yielded what was called "mangabeira rubber."—(*Nature*.)

CARDIFF ROSE SHOW.

THE second Exhibition of this flourishing child of the National Rose Society was held in the Drill Hall, Cardiff, on Wednesday last, and notwithstanding the unfavourable "skye" influences, which have—by the constantly recurring showers—sadly militated against the freshness and brightness of the flowers, was greatly in advance of its predecessors. There were some excellent boxes of blooms and some very fine flowers shown, but there is still great need for improvement amongst the local growers, many of their exhibits being of an inferior quality, and manifesting a most heroic disregard of names. Still there was improvement. The absurdity of added foliage had been done away with; and although some still exhibited in the old slovenly style, yet I believe we shall see here, as we have seen elsewhere, that the presence of good exhibits showing the standard which is to be reached will have its effect. That the Society, under the able and genial secretaryship of Mr. Pettigrew, is a flourishing one may be gathered from the fact that two gold medals of the National Rose Society were given as prizes, and that a very liberal schedule inducing growers from a distance to compete was provided, in which, as in the parent Society's schedule, provision was made for all comers. Happily the day was fine, and a large number of the inhabitants of this busy place availed themselves of the opportunity of enjoying the feast of Roses and the performances of a very excellent band.

The following were the chief awards. Class 1, for forty-eight distinct varieties, the first prize was awarded, together with the National Society's gold medal, to the Cranston Nursery Co., Hereford, for a fine stand containing the following varieties:—*Capitaine Christy*, *Louis Van Houtte*, *Madame Vidot*, good and rarely seen now; *Charles Darwin*, *Marie Finger*, *Comtesse d'Oxford*, *Madame Gabriel Luizet*, *Mrs. Baker*, *La France*, *Reynolds Hole*, *Elie Morel*, *Duke of Teck*, *Comtesse de Serenye*, *Dingé Conard*, shown as we never see it by anyone else; *Royal Standard*, fine; *A. K. Williams*, *Madame Lacharme*, *Marie Raby*, *Jean Ducher*, *Fisher Holmes*, *Marquise de Castellane*, *Auguste Neumann*, *Catherine Mermet*, *Senateur Vaisse*, *Marquise de Mortemart*, *Marie Baumann*, *Lælia*, *Duke of Edinburgh*, *Madame Charles*, *Marguerite Mandin*, a Rose unknown to me—a large-petalled flower; *Général Jacqueminot*, *Baronne de Rothschild*, *Horace Vernet*, *Duchesse de Vallombrosa*, *Penelope Mayo*, *Souvenir d'un Ami*, *Alfred Colomb*, *Souvenir de la Malmaison*, *Mrs. Jowitt*, *Princess Mary of Cambridge*, *Jean Liabaud*, *Marie Van Houtte*, *John S. Mill*, *Bouquet d'Or*, *Pierre Notting*, *Marguerite de St. Amand*, and *Duke of Wellington*. In the class for twenty-four trebles the same firm was again first with the stands containing a selection from the above varieties. They were also first in the class for twenty-four singles, and still again first for twenty-four Teas—a fine box containing *Souvenir d'un Ami*, *Madame Emilie Dupuy*, a Rose I did not recollect to have seen before—a well-formed flower of the *Gloire de Dijon* type; *Madame Manin*, *Jean Ducher*, *Madame Willermoz*, *Marie Van Houtte*, *Catherine Mermet*, *Perle des Jardins*, *Anna Ollivier*, *Gloire de Dijon*, *Madame Bravy*, *Adam*, *Souvenir de Paul Neyron*, *Madame Lambard*, *Devoniensis*, *Madame Sertot*, *Madame Margottin*, *Triomphe de Luxembourg*, *Caroline Kuster*, *Madame Camille*, *Marie Guillot*, *Madame Furtado*, and *Madame Hippolyte Jamain*. In twenty-four of one variety they were equal first with Mr. Grant with Mrs. Jowitt, and first for the best twelve Teas of one kind with Niphetos, thus truly making a clean sweep of the first prizes. Messrs. Davison were good seconds in most of these classes.

Amongst amateurs Mr. G. P. Hawtrey of Slough and Mr. W. Grant of Ledbury were the chief exhibitors, showing excellent stands of slightly weathered flowers, although much less so than might have been expected. In the class for twenty-four Mr. Hawtrey won the first prize and the National Society's gold medal with *Charles Darwin*, *Souvenir d'un Ami*, *Hippolyte Jamain*, *Jules Finger*, *Jean Liabaud*, *Alfred Colomb*, *John Hopper*, *Capitaine Christy*, *Madame Boutin*, *Maurice Bernardin*, *Richard Laxton*, *Comtesse de Choiseul*, *La France*,

Madame Victor Verdier, Thomas Mills, Etienne Levet, Comtesse Riza du Parc, a good bloom of this capricious beauty; Mons. E. Y. Teas, Comtesse de Nadaillac, very lovely; Duke of Teck, Souvenir de Paul Neyron, Ferdinand de Lesseps. He also won the first prize for twelve Teas, amongst which Marie Van Houtte, Madame Hippolyte Jamain, Caroline Kuster, Alba Rosea, Niphotos, Souvenir d'un Ami, Souvenir de Paul Neyron, Catherine Mermet, and Madame Willermoz were very fine. Mr. Grant was first with eighteen trebles, and Mr. Barrington first with twelve of one sort with a good stand of La France, and Mr. Grant first with six Teas of one sort with Souvenir d'un Ami. Mr. A. Pettigrew was first for the Marquis of Bute's prize for the best box of York-and-Lancaster. These were the principal stands, and as space is limited I must not give the names of other winning flowers. The arrangements of the Show were excellent, and much praise is due to Mr. Pettigrew and Mr. Taylor, who, aided by a good working Committee, have managed to establish a flourishing Society, which as years go on will, I doubt not, be one of the largest of our provincial exhibitions.—D., Deal.

MELON SETTING—THE EFFECTS OF BOTTOM HEAT.

THE training, the soil, the variety, the treatment, generally have much to do with a good set of Melons or the reverse. When allowed to grow wildly instead of having the growths properly trained, regulated, stopped in order to concentrate growth, Melons often fail to set. When soil is too poor, too light, or too rich, the crop fails. Even when properly trained and properly fed a poor crop follows if the variety grown is a shy setter; while bad treatment generally, causing weakly health, will spoil everything, no matter how orthodox the training, how good the soil, or prolific the variety.

Independent of all these causes of failure there is another which may never have been suspected—we mean too high a temperature in the soil. That steady bottom heat is of much advantage nobody will deny, but when that is overdone the result is growth so wanting in strength as to be incapable of carrying a crop. I am not prepared to state what is a proper figure for bottom heat, but my experience is that 70° is better than 90°, for the latter, while it insures a rapid and even a vigorous growth, is against a free set. With the bottom heat at 70° the crop is larger. I am free to confess, however, that with the higher temperature superior fruit, more especially in flavour, is obtained.

In my case the heat cannot always be regulated, for three compartments are heated from one boiler. When the heat can be regulated care should be taken not to have a too high bottom heat till a full crop is set. In the case of dung beds they should be built as narrow as possible, and even have holes through them should the bottom heat exceed 80°. When the fruit is set linings can be applied to keep the heat from declining, or even to raise it, especially in case of crops ripening late in the season.—SINGLE-HANDED.

CARNATIONS FOR TOWNS.

IN the immediate neighbourhood of towns cultivators of outdoor flowers often experience considerable difficulty in obtaining their favourites in satisfactory condition, and many have to lament grievous failures in their attempts to add to the number of plants that can be grown in such situations. How many have endeavoured to acclimatise that popular favourite the Rose within the smoke radius of London, and how few can record even a moderate share of success! For the autumn we have the Chrysanthemum it is true, and that is a host in itself; but for the summer months the urban gardens are rendered bright usually by a few of the stereotyped bedding plants, amongst which scarlet Zonal Pelargoniums are frequently too prominent.

Perhaps there is no class of really hardy plants so well adapted to take the place of the Rose in city gardens as the Carnations and Picotees, which flower at the same period, and with little care give far more satisfaction. Mr. E. S. Dodwell's success with these plants, even from a florist's point of view, is well known, and yet the flowers which secured him such high honours were all grown under what might be considered very unfavourable circumstances—in a densely populated district, and in unpleasant proximity to a railway where hundreds of trains passed daily. It would, however, be difficult to find a better example of the excellent results that can be obtained in the culture of Carnations as hardy border plants in towns than that afforded by the collection in Messrs. J. Veitch & Sons' nursery at Chelsea, which is now in superb condition, and will doubtless yet improve for a week or more. Several thousands of plants, which had been grown in pots during winter, were placed out in beds in early spring, and with ordinary

careful attention to watering and other little requirements a display of flowers has been obtained that could not be excelled; in fact, one of the first points which strike a visitor is the astonishing floriferousness of the plants generally, and in some varieties particularly. Buds and flowers in all stages are most abundant, several of the more vigorous sorts having over five dozen on each plant. Neat and not too conspicuous stakes are employed, and as a result some of the beds present an even mass of flowers, the beauty of which either individually or collectively cannot be over-estimated. To further improve and prolong their attractions a light awning is placed over each bed at a convenient height, so that visitors can freely inspect the beds and yet injury from heavy rains or too powerful sun is obviated.

A large number of the best varieties in cultivation are represented, including several novelties, but it will be only necessary to point out a few of the best, preference being given to those which, from their vigorous habit, effective colours, and floriferousness, appear to be the best suited for general culture, though some of these would possibly be passed by rigid adherents to the florist's standard. The Carnations are the first deserving of notice; and it may be here observed that, beautiful and delicately coloured as the Picotees undoubtedly are, they cannot rank with their rivals in brilliance and effectiveness. The self Carnations in particular are extremely showy, especially in large beds, and the freedom with which they bloom is no mean recommendation

Fig. 12.—Olonglossum Alexandræ var. (See page 59.)

where flowers are largely in demand. Of the several fine varieties represented at Chelsea one that is likely to attract very general attention is W. P. Milner, a most promising novelty, with pure white blooms of good size, full and even, and produced in astonishing numbers—four, five, or even six dozens of blooms and buds by each plant. Such a variety would possess inestimable value to a gardener, yielding a rich supply of handsome white blooms, which are always in request. Virgo and The Bride are two other fine white-flowered varieties of great beauty, but not so remarkable as the preceding. Sulphur King, King of the Yellows, and Stanstead Yellow are three of the best yellow selfs, the first-named being dwarf and free. A new variety named Florence is, however, worthy of notice in this section; the blooms are bright yellow with an orange tinge, they are very large and full, and are produced in great numbers. Amongst the rose selfs Mrs. Teigner, with large handsome richly coloured blooms, was especially notable; Gertrude Teigner, though of paler colour, is also a pleasing variety, the blooms being of good size and freely produced; Lothair, also pale rose, with the preceding forms an excellent trio. Purple selfs are very handsome, the two finest being Auctioneer and Royal Purple; the former having blooms of medium size, of a rich purple tint, and produced in great numbers; the latter being similar in habit, but the flowers of a rather

brighter crimson purple hue. Scarlet selfs are very abundant, and all are more or less attractive. *Magnum Bonum* deserves the lead for its dark scarlet blooms are not only of great size and substance, but they are so abundant that the plants have an exceedingly showy appearance. *Crimson Pet* is distinguished by its peculiarly rich colour—dark scarlet maroon. *Coroner* is a brilliant scarlet self, with large well-formed blooms; *Fireman*, *Duke of Wellington*, *James Wilkins*, *Dan Godfrey*, and *Sportsman* being all scarlet selfs of considerable merit, varying slightly in the depth of shade, but similar in substance and quality of flowers.

In the other sections of Carnations the scarlet and purple flake varieties are most noteworthy at Chelsea; for though the bizarres are also admirably represented, they are scarcely so effective, and that is the point of view in which they are now being considered. Of the scarlet flakes *Candidate*, *Adrian*, *Lord Lyons*, and *William Mellor* have large handsome flowers, the last-named being particularly fine. The best purple flakes are *Earl of Stamford*, *Captain Jinks*, *Squire Meynell*, and *Bellerophon*, all richly coloured. The rose flakes are also very attractive, and they are all so good that it is difficult to make a selection; however, the following are noteworthy for their size, substance, and clear colours:—*Lord Chelmsford*, *Mrs. Anderson*, *Lord Beaconsfield*, and *Lady Mandeville*. Amongst the scarlet bizarres *Rembrandt*, *Douglas*, *Brilliant*, and *George Rudd*, the last being an extremely dark variety, are all meritorious; while the crimson bizarres *Rifeman*, *Isaac Wilkinson*, and *Albion's Pride* are the leading forms in that section.

Picotees are largely represented, but it is noteworthy that as border flowers the most suitable amongst these are the heavy-edged varieties, those with the fine margins being very beautiful when cut and staged, but their attractiveness is to a great extent lost when they are viewed at a distance. *Edith Dombrain*, a heavy rose-edged variety, is one of the most effective, and *Elise* is another good one of the same type. *Mrs. A. Chancellor*, a heavy purple-edged form, is very handsome. *Norfolk Beauty* is also a showy variety of that type. *Queen of Summer* is a new medium crimson-edged Picotee, with neat flowers, the margin very richly coloured. *Mrs. Brown* is a heavy-edge form, of similar colour to the above, and very striking. One other fine heavy crimson-edged variety need only be noticed—namely, *Coxswain*, which has large handsome flowers which are produced with great freedom. The best of the light-edged forms are the following:—*Rose and red*, *Bandmaster*, *Miss Skinner*, and *Miss Wood*. Purple, *Cynthia*, *Her Majesty*, and *Woodie*.

CHRISTLETON ROSE SHOW.

CHRISTLETON is situated two miles out of Chester. It has a Rose Show of growing pretensions, very well managed, easy of access, and worth attention on the part of exhibitors. The Show this year was held in the rectory grounds on July 11th; and though the afternoon turned out wet and diminished the number of visitors, those who braved the elements found a large tent full of beautiful Roses, superior both in quality and quantity to any seen in the neighbourhood.

In Section A, open to all (nurserymen included), the competition for thirty-six single blooms was reduced to a match between the two Chester firms, Messrs. James Dickson & Sons, and F. & A. Dickson and Sons; the former winning with a good box, the best blooms being *Xavier Olibo*, *Le Havre*, and *Eugénie Verdier*; the latter showed good blooms of *Marie Baumann*, *Madame C. Wood*, and *Madame Ducher*. In the same section (twelve blooms of any one light Rose) Messrs. James Dickson took first prize for a very fine box of *Capitaine Christy*, run very closely by the Rev. L. Garnett with beautiful blooms of *Baronne de Rothschild*. The same firm showed (not for competition) a grand box of twelve *Marie Baumann*.

There were two classes (twenty-four and eighteen single blooms) in Section B, open to all amateurs, and the competition in both was very close. In twenty-fours Mr. C. J. Day was first, closely pressed by Mr. T. B. Hall and the Rev. L. Garnett, while Miss Massey was highly commended. In eighteens the Rev. L. Garnett was first, Mr. T. B. Hall second, Mr. Day third, with Miss Massey placed as before. Mr. Day's best blooms were *La France*, *Louisa Wood*, *Victor Verdier*, *Dupuy Jamain*, *François Michelin*, and *Julia Touvais*. Mr. Hall showed good examples of *Marquise de Castellane*, *A. K. Williams*, *Louis Van Houtte*, *Marie Van Houtte*, *Général Jacqueminot*, and *Eugénie Verdier*. Mr. Garnett had *Baronne de Rothschild*, *Prince Camille de Rohan*, *Etienne Loret*, *Madame Willermoz*, *Annie Laxton*, and *Magna Charta*. Miss Massey showed a good bloom of *Marie Louise Pernet*. Section C, twelve and six single blooms, was intended for the smaller growers, exhibitors in Section B being excluded. The competition in this section was good, and the Roses shown very creditable, though of course inferior to those in Section B, which were indeed the best in the Show. For twelve single blooms Mr. W. E. Hall won the first prize; Miss Humberston the

second, and Canon Blomfield third. For six blooms the first prize went to Mr. F. N. Garnett, Mr. Hutchings being second, and Canon Blomfield third. Some very good blooms were shown by Mr. J. A. Hodgson in this section, which would undoubtedly have carried off the first prize, but owing to an informality of entry they were excluded from competition. Mr. Hodgson's Roses were as good as anything in the Show. There were several local classes, but the competition was disappointing and the Roses moderate. In Section E, for Tea Roses, Mr. T. B. Hall easily won first prize with twelve beautiful blooms, Mr. Day being second. The competitors in this class being excluded from the next (for six blooms), the Rev. L. Garnett here was successful, and Mr. W. E. Hall won the second prize.

Perhaps the most attractive feature in the Show was a class for hardy cut flowers, not more than twenty-four varieties. The Rev. L. Garnett won the first prize with a beautiful stand of twenty-four varieties, comprising *Spiræa palmata*, *Delphinium Cantab.*, and *Pompon Brilliant*, *Geranium pratense fl.-pl.*, *Phlox Lord Rosslyn*, *Lilium croceum*, *Campanula grandis* and *turbinata*, *Gladiolus Colvilli*, *The Bride*, *English Iris*, *Mimulus cupreus Brilliant*, *Corn Marigold*, *Lychnis chalcidonica*, &c. Mr. F. N. Garnett was a good second with *Phlox Mr. Hunter*, *Spiræa Aruncus*, *Alstromeria*, *Delphinium formosum Mr. Jas. Helme* and *ranunculoides*, *Centaurea montana*, *Lychnis Haageana*, &c. Mr. Townsend Ince was third with a neat collection, and Miss Currie highly commended. This part of the Show was judged by the Rev. C. Wolley Dod of Edge Hall, Malpas, who showed (not for competition) an extensive and most interesting collection of herbaceous flowers, chief among them being a most magnificent spike of *Lilium giganteum*, thicker than a man's wrist, bearing twenty-two fully developed flowers. This had been grown in the open ground, and judging from the stump which we saw two days later must have stood 9 feet high or more. Other showy flowers in his collection were *Cistus crispus*, *Oenothera Youngi*, *Geranium armenium*, *Silene armeria*, *Francoa rupestris*, *Centaurea macrocephala* (greatly admired), *Rudbeckia californica*, *Phlox Lady Napier* (a beautiful pure white with very large pips), *Armeria cephalotes*, *Cyananthus lobatus*, *Ononis rotundifolia*, *Orchis foliosa*, *Inula hirta* and *glandulosa*, *Lychnis dioica fl.-pl.*, *Lilium pardalinum*, &c. There is no doubt that these collections of hardy flowers, duly labelled and arranged for effect, were greatly admired by the visitors, and added much to the interest of the Show. Some very good Rose bouquets were exhibited, the prizes being adjudged first to Mr. G. O. Day and second to Mr. C. V. Lace, Miss Thompson's being highly commended. Special prizes also were offered for a vase or epergne dressed with flowers, the first prize being awarded to Miss Garnett, second to Mr. Lace, while Miss Yorke and Miss Theo. Lacc were highly commended. The general verdict upon the Roses was that they were superior to those shown last year, and considering the very unfavourable weather most creditable to the exhibitors. The arrangements made by the Secretaries, Messrs. C. J. Day and S. Earlam, were most complete, and we think that both exhibitors and visitors had reason to be well satisfied with their reception at Christleton, and are likely to come again.

We must not omit to notice a collection of decorative plants sent by the President of the Rose Society, Arthur Potts, Esq., of Hoole Hall. Chief among these were *Sarracenia Chelsonii* and *flava major*, *Dracæna Seaforthii*, *Croton Warreni* and *Queen Victoria*, *Nepenthes Hookerii*, *Begonias* in variety, with beautiful Peaches and Tomatoes.

A KENTISH correspondent writes as follows relative to RAIN AND INSECTS:—"The recent rains have not done so much good as I hoped they would in the way of diminishing the numbers of aphides and some other species that usually dislike rain. During the calm and peculiarly dull weather of last week there were some curious migrations of aphides, followed by a considerable deposition of honeydew. I do not see many ants this season."

— MR. RIVERS has sent us from Sawbridgeworth a splendid specimen of the SEA EAGLE PEACH, a variety which is not extensively known nor generally cultivated. The fruit is very large, 11 inches in circumference, and 3½ inches in diameter; round, with a wide suture, which extends all round the fruit, and terminated by a large prominent nipple; skin with a very delicate down, pale yellow, tinged and mottled and speckled more or less with rose colour, and with a mottled thin cheek on the side next the sun; stalk very short, embedded all its length in a deep cavity; flesh very delicate and juicy, deep red at the stone, the colour extending in rays well into the substance of

the flesh, which is quite melting, sweet, and with a rich flavour; leaves with round glands. The fruit sent to us weighed $11\frac{1}{2}$ ozs., and we presume it was grown on a tree in a pot. Grown outdoors it usually ripens in September.

— MAJOR-GENERAL MILMAN, in alluding to our reply to a correspondent last week on the DECAY OF SPRUCE FIRS, states that on his estate in Berkshire, and in the neighbourhood generally, there is scarcely a Spruce, either large or small, that is not afflicted with a sort of blight, which is getting worse daily. The vitality of the trees, with the exception of a green tip at the extremity of the branches, appears gone; the leaves turn brown and fall. Some very large trees here have hardly a leaf remaining. This occurs not only on the sandy and peaty soil of this place, but also on the clay at an estate some miles distant.

— RELATIVE to the new GOLDEN QUEEN MIGNONETTE that was recently certificated by the Floral Committee of the Royal Horticultural Society, we are requested to state that "it was sent by Messrs. Benary, Carter & Co., E. G. Henderson and Sons, and James Veitch & Sons." The official report that was sent to us last week contained none of these names, and Messrs. Carters' name was inserted because a certificate of the variety bearing their name alone came under our notice, hence we concluded the name had been accidentally omitted from the report.

— IN allusion to our reply to a correspondent last week, "S. W." highly recommends FUNKIA SPATHULATA ALBA, which he says is now producing freely spikes of small blush white flowers, which are of the greatest value for vase-decoration, and have also quite a pretty effect on the plants in the border. The plant was obtained from Mr. Ware of Tottenham, and its spikes of flowers are not unlike the white form of Dictamnus Fraxinella. Our correspondent thinks this Funkia should be more extensively grown, and says that the spikes which are a foot high require no sticks to support them.

— A CORRESPONDENT ("J. W. R.") writes to us as follows with reference to CLAY'S FERTILISER AND DAHLIAS:—"Having planted several single Dahlias in my garden where slugs abound, I spread around the plants a small portion of the above fertiliser. This has not only prevented the plants being eaten by the voracious nocturnal pests, but has had such a remarkable effect in accelerating the growth of the Dahlias that the circumstance should be known. It changed the foliage from a pale to a deep, almost black, green in a few days, and the growth has been so rapid that some of the plants are flowering freely. The powder is sprinkled round the plants so as to fairly cover the soil, and as long as it remains there it forms an effective barrier against slugs. When the rain washes it in more is spread round as often as is needed, and thus the slugs are completely baffled, while the plants are as signally benefited. I consider this manure a boon in my suburban garden, and it forms undoubtedly a valuable dressing for flower borders and vegetable ground where ordinary farm-yard manure is difficult to obtain."

— REFERRING to the PEAS CERTIFICATED AT CHISWICK on the 7th inst. and enumerated on page 39 last week, a correspondent writes to us complainingly in the following words:—"Were you not able to give a better description of them? You state nothing definite about their height, character, nor period of use. Surely the date of sowing and of gathering, with the height the varieties attained, might have been given, the same as Messrs. Veitch appear to have done with a collection that they exhibited on the 11th inst., and referred to in the same issue of your paper. It is very seldom I am disappointed with your descriptions of new things, but in this instance you can scarcely regard my complaint as ill-founded." The report of the Committee meetings that were

held at Chiswick on the 7th inst. was supplied to us and our contemporaries officially, and we did not curtail it in any way before publication.

— MR. MUIR has sent us from Margam a sample of CULVERWELL'S GIANT MARROW PEA, which he regards as the finest variety in cultivation. We have never seen finer Peas than those submitted to us. The pods are of great size, 7 inches long and $1\frac{1}{4}$ inch wide, curved, dark green in colour, and crowded with fine peas. Mr. Muir states the variety is a great cropper, and the produce is of the first quality when cooked. He thus esteems it as one of the most useful Peas in cultivation as well as one of the best for purposes of exhibition that can be grown.

— MR. THOMAS, late gardener to Sir Robert Peel, Bart., Drayton Manor, Tamworth, has been appointed gardener to John Corbett, Esq., M.P., Impney Hall, near Droitwich. Mr. Thomas enters on his duties on the 22nd inst.

— THE following HYBRID ORCHIDS are now flowering in Messrs. Veitch's collection at Chelsea—Cypripediums Morganæ, pyenoptrum, selligerum, ealanthum, porphyrospilum, superciliare, grande, euryandrum, Sedeni, marmorophyllum, œnanthum, albo-purpureum, and Dominii; Dendrobium rhodostoma; Lælias callistoglossa and Philbrickiana; Zygopetalum Sedeni, and Masdevallia Chelsoni.

— THE HORTICULTURAL EXHIBITION AND MARKET, which is to open in the Agricultural Hall, London, on the 24th inst. and closes on August 5th, promises to be both extensive and diversified. It is expected to comprise every requisite in connection with the garden, the following exhibits being enumerated in the prospectus before us:—Conservatories, greenhouses, frames, handlights, boilers, heating apparatus by water and otherwise, garden statuary and fountains, Fern cases, aquaria, window boxes, vases, flower pots, fancy tiles, rockeries, cascades and waterfalls; summer houses, garden seats and furniture of all kinds; lawn-mowers, verge-cutters, garden hose, engines, water barrows, watering cans, gardening tools, wire netting, guards, Rose stakes, dried flowers and grasses, artificial plants, flowers, fruit, seeds, bulbs, roots, plants, cut bloom, manures, insect-destroyers, &c. Thus an excellent opportunity will be afforded for visitors, and they will doubtless be numerous, of comparing the merits of the different articles exhibited, and selecting those best adapted to their purposes. The Exhibition, as may be seen by our advertising columns, will be held under very distinguished patronage.

— THE correspondent of an American paper writes in glowing terms on ROSES AT NEW ORLEANS. A Lamarque Rose is instanced as "growing 80 feet long. The stem is 8 inches through in the thickest part. It was planted seventeen or eighteen years ago. It is twined around a verandah, and its gorgeous clusters of cream-tinted Roses are splendid to behold. Maréchal Niel Roses run wild. The blossoms grow in gorgeous clusters of half a dozen or more, and the flowers are so large that they would more than cover the top of a large-sized coffee cup. The Rose the French inhabitants of New Orleans are fondest of for decoration is called the 'Gold of Ophir.' Northern florists have it, but it is not common. The bud is especially prized for its beauty. It is a smallish Rose, of a very pale pink, shading on towards the heart in a deep rich good colour. Faint streaks of crimson touch the outer petals. It is one of the loveliest Roses I ever saw."

STRAWBERRIES—MODES OF CULTURE—MISTAKES.

VERY light sandy soils, and especially if in a district where the annual rainfall does not exceed 24 inches, are perhaps the most difficult of all on which to grow Strawberries; and next to them, and almost as bad, are hungry clays where the rainfall averages 50 inches a year. An important matter in connection with soils of the former nature is to let them alone as much as

possible, and to apply all the manure near to and on the surface. To bury the manure deeply in sandy soils is to waste it; even when near the surface its virtues are washed away far too quickly, and to place all the dung a foot or more deep is practically manuring the drains, not the Strawberries. If plentiful a layer may be spread at that depth and be trodden firmly, but the bulk should be placed above the roots.

The less sandy land is worked the better, and it cannot well be too firm. Autumn and winter digging is a mistake, and late spring and summer digging when the weather is dry is a greater mistake still. Such soil should only be dug when it is moist, and it should be made as firm as possible as soon as it is dry enough to be trampled on, covering it immediately afterwards with manure if possible, or any other mulching, to prevent the sun parching the surface. Salt is a valuable application to soil of this nature, and may with great advantage be sprinkled on the surface at the rate of an ounce per square yard in the spring, repeating the dressing three or four times during the summer between the rows of Strawberries.

Close planting I have found of decided advantage on soils of the nature indicated, and it is doubtful if such good results can be had by any other method than inserting the plants a foot apart all ways. If strong plants are inserted in July their foliage will soon shade the ground, which is an important point, and a fine crop of fruit may be gathered within a year from planting. It is of the greatest possible advantage, too—how great no one knows who has not tried it—to place a handful or two of fresh soil round the roots when planting. Charred refuse of any kind, with decayed vegetable matter which has been saturated with liquid manure, and half a peck of bone meal mixed with each barrowful of compost, gives the plants an excellent start, and a good start is more than half the battle in growing Strawberries on poor or ungenial soil. It is very bad practice to plant with the dibber, crushing all the roots together; they should be spread out thinly their full length.

After the first gathering either every alternate row can be removed or every fourth row. By the latter plan a series of beds are formed in which the plants are allowed to grow in a mass, the runners not being removed from the plants. If the weather is very hot and dry in July I have found this plan the better of the two. It may be called a lazy method, perhaps, but a mere term of that kind can be endured if we have plenty of Strawberries.

When alternate rows are removed I have never seen the advantage of taking out alternate plants from the rows remaining in soil of the kind in question. In good Strawberry-growing land thinning-out becomes quite another matter where the plants have to continue bearing for four or five years, but in poor, light, or very sandy soil it is seldom profitable to allow the plants to remain a third year. Two good, sometimes heavy crops, can be had, but the third is almost invariably light and not infrequently worthless. The system above alluded to of occupying the whole surface of soils of a light and dry nature with Strawberries is, in my experience, and I have tried other methods carefully, decidedly preferable to planting in lines 2 or 3 feet apart, and occupying the space between the rows with Lettuces or other moisture-extracting crops.

It is scarcely necessary to dwell at any length on the cultivation of Strawberries in soils and districts naturally favourable to their growth. Those who cannot produce good crops in rather strong yet free-working fertile soil have missed their proper occupation. It may be stated, however, that in such soil it is a good plan to plant 18 inches apart in rows the same distance asunder, and after the fruit crop to remove every alternate row, and afterwards if needed every alternate plant in the rows. With good after culture plants thus having space to develop yield prodigious crops—sometimes for six years; in fact I have known highly productive Strawberry beds ten years old.

In a north-western county noted for heavy rainfall it was once my misfortune to be expected to grow Strawberries on a strong and almost unworkable soil. The garden men said it was no use trying as the plants always "went off," and judging by the miserable beds there was reason for that opinion. It was clear the orthodox method of planting was of no use here, and ridges were formed 2½ feet asunder, and a row planted on each ridge, soot being liberally mixed with the soil. The plants grew well, and a good crop was produced, yet the method was a mistake. By the continuous rains the soil was washed away, leaving the rhizomatous stems bare, and the roots which issue from those stems could not take possession of the soil; the plants consequently lost vigour, and a severe winter following killed half of them. But no one ought to fail without gaining valuable experience, and in this case the way to success was pretty clearly indicated.

The ground was next prepared as if preparing for Celery—that is to say, ridges were formed 3 feet wide with trenches between them. The ridges were dressed liberally with long manure, the straw not being half decayed, and soot in abundance. This is the best application that I am acquainted with for rendering strong soil friable. The manure was so littery, contained so much straw, that it was not easy to put out of sight, but it was of real benefit, as it always is in soils of a clayey nature. Two rows of Strawberries were planted zigzag fashion on each ridge, the roots being surrounded with light, rich, yet gritty compost. Better crops of Strawberries I seldom had than from those ridges, and the plants continued bearing well for four years.

I am not enamoured of the practice of planting Lettuces, Cabbages, &c., between rows of Strawberries. If a crop must be stolen I prefer such as winter Onions and Radishes. I once adopted a precisely opposite method with good results. Having observed how well winter Onions grew amongst Strawberries, it appeared self-evident that Strawberries would grow amongst spring Onions. Rooted runners were planted a foot asunder in rows 3 feet apart between the Onions in July and well watered. The Onions for a week or two appeared to provide agreeable shade to the young Strawberry plants, and as these required more light and air the Onions were just ready for having their growths bent down, these of course being laid from the Strawberries. In due time the Onions were cleared off the ground and spread on asphalt walk to dry; the ground between the Strawberries was hoed and then mulched with manure, and a very productive Strawberry bed was the result. The soil was light rather than strong, and the weather was showery when the Strawberries were planted. Those who have Strawberry runners ready for planting and no vacant ground at disposal might try the same method. There is not much to lose, and something useful might be gained by an experiment, which in the case mentioned was certainly *not* a "mistake."

I wish correspondents would state what they consider the best early Strawberry. I have not one that satisfies me. Black Prince is too small, and Vicomtesse Héricart de Thury is too late. Particulars relative to really early sorts would, I think, be acceptable to many readers of the Journal.—A NORTHERN GARDENER.

MANURING POTATOES.

WHETHER to put the manure over the Potatoes or the Potatoes over the manure seems to puzzle some of your correspondents. Generally speaking it is much better to do neither, but to surround the newly planted sets with clean wholesome soil, and to have the manure through the body of the soil. When this is done the crop turns out cleaner and often of better quality. In dry seasons the moist manure attracts the worms, the worms scarify the skins of the Potatoes, and scabbing results. No one wants scabbed Potatoes, because there is a loss in preparing such for table, and what should be the driest and mealiest part of the tuber—the outside, is rendered watery and waxy.

Even should worms not attack the tubers through the manure being applied in the drills, there is apt to be a rush into shaws, which exhaust the manure, leaving only the residue for swelling up the crops. When the manure is diffused through the soil the first growth may not be so strong, but when the tubers swell there is something to fall back on, and better crops of tubers, with less crops of shaws, are the result. This is not theory, it is experience.

There is no rule in gardening absolute, and neither is this. While the above truth may be generally adhered to with advantage, it may also be sometimes ignored. Very early crops come more quickly when from first to last their roots can run in manure not too rich. The same may be said of weakly varieties. In such cases it will be found advantageous to turn the sets upside down. By this means all the advantages of putting the manure over the sets, without the disadvantage of placing a body which is a non-conductor of heat between the sets and the sun, is gained. At present we are digging Potatoes, part of which were planted eyes up and part with eyes down, and the difference in the crop is considerable. The variety is Beauty of Hebron, which, being a weak grower but very early, requires treatment exactly opposite to what strong-growing late kinds require.—S.

ODONTOGLOSSUMS.

PERHAPS no genus of Orchids has so rapidly grown in public favour as those now to be considered, and judging by the large importations that are being continually announced the demand is still increasing. This is not surprising, for Orchids that will succeed in a cool temperature possess much to recommend them to notice, as they can be grown at so much less expense than their

relatives from warmer regions, and their beautiful flowers can be viewed without enduring the oppressively hot and moist atmosphere needed by natives of tropical climates. The majority, too, are of comparatively easy cultivation, flowering freely and regularly—recommendations of inestimable value. Amongst these cool-house Orchids *Odontoglossums* hold an important position numerically, and for the beauty distinguishing the flowers of many species, and in most establishments where Orchids are especially encouraged, the *Odontoglossum* house is by no means the least interesting or least attractive. Indeed, in many gardens where the tropical members of the family receive little attention it is becoming quite common to find a small and probably

unpretentious house devoted to the *Odontoglossums* and some of the other Orchids that thrive in their company. It is true we have not the brilliant colours that mark the occupants of the South American and East Indian houses, but it can safely be asserted that none of those excel their less gaudy relatives in delicacy of hues, semi-transparent or wax-like substance, or graceful forms. For bouquets or general decorative purposes the flowers of some of the *Odontoglossums* are unrivalled both in beauty and endurance, and foremost amongst these must be named that superb Orchid

O. Alexandræ, which well deserves first attention in noting the best forms of the genus. It may be remembered by some readers

Fig. 13.—ODONTOGLOSSUM ROSSI VAR.

that this is one of the Royal Horticultural Society's introductions through their collector Mr. Weir, who found it in the forests of Bogota at an elevation of about 9000 feet above sea level, and first sent plants to this country about 1864. In the following year at the November meeting of the Society specimens were shown and much admired, though plants of *O. Bluntii* shown at the same time were considered superior. It is rather interesting that Mr. Weir also claimed to have found the last-named, having supplied Mr. Blunt with plants from his collection. Unfortunately, although the name of *O. Alexandræ* is still the most generally accepted one in gardens, the species is considered to be the same as *O. crispum*, which was known some time previously. However, whatever name it bears, the plant is undoubtedly a beautiful one, especially some of the finer varieties that have been obtained in recent years. A flower of one of these from Mr. Warner's superb

collection at Chelmsford is shown in the woodcut (fig. 12, page 55), and well indicates the fine form, the breadth of sepals and petals, which render several varieties so remarkable. Some forms have the flowers pure white with very few spots, and others have the spots, blotches, and bars of reddish-brown or crimson very large and prominent. Several of the most distinct that have been imported have received names—as *Trianae*, one of the most beautiful; *guttatum*, *Warneri*, and others—all possessing considerable attractions, and some are much larger than the example figured.

O. Rossi.—Very different from the above, yet beautiful in no ordinary degree, is *O. Rossi*, a great favourite with all Orchid growers, and one of the most useful of the dwarf *Odontoglossums*. Grown upon blocks and suspended from the roof of the cool house it produces its flowers with great freedom, and renders the house gay for several weeks. Some growers, however, prefer

it in pots or pans, as it is found that plants upon blocks often become exhausted in a few years. The block system is much more pleasing in appearance than the other, but perhaps the best plan is to have some specimens grown in each way.

O. Rossi is a Mexican species of dwarf habit, and was introduced to England by Mr. Barker, who obtained it from his collector Mr. Ross, after whom it is named. The flowers are of moderate size, the sepals white or greenish with brown or purplish spots; the petals very much broader, frequently having the margin fringed, pure white with a few rich purple spots at the base. The lip is large, often beautifully fringed and pure white, contrasting very strikingly with the darker sepals. The flowers are borne singly or in pairs on short scapes which arise from the base of the small pseudobulbs. The variety *majus* greatly surpasses the old form in the size and rich colouring of the flowers, and is very similar to the variety represented in the engraving (fig. 13), which portrays one of those in the Trinity College Botanic Garden, Dublin. A very handsome unnamed variety is also grown in Mr. Dorman's collection at Sydenham, which is even superior to *majus* in the richness of the colouring. When well grown O. Rossi and its varieties are some of the most charming Orchids in cultivation, and they may be easily obtained in satisfactory condition under similar cool treatment to that afforded O. *Alexandrae* or other species, except as was previously mentioned, they should be suspended from the roof either in pans or on blocks.—L. C.

(To be continued.)

HAWKHURST HORTICULTURAL SOCIETY:

It is very pleasing to note the progress made in horticulture in the Hawkhurst district. Not only is this very apparent among gardeners and amateurs, but the cottagers, which the Society greatly encourage, are also giving abundant proofs of improvement. At the first few shows it was found necessary to induce well-known exhibitors to bring their specimen plants from a great distance. Now, however, the Committee is in a position to arrange one of the best exhibitions in Kent without any open classes. The leading inhabitants of the district and at Hawkhurst, where the Exhibition is invariably held, no difficulty is experienced in securing suitable and convenient grounds for the purpose. On this occasion the picturesque grounds of H. Maynard, Esq., Oakfield House, were chosen, and the selection was a wise one. The site being elevated dried rapidly, and to this and the almost unexpected fine day may be partly attributed the attendance of so many appreciative visitors.

There were six exhibitors of six flowering stove and greenhouse plants, all showing creditably. To Mr. F. Hodgkins, gardener to A. Oakes, Esq., Sandhurst, was awarded the first prize, his group comprising a beautifully flowered *Bougainvillea glabra*, a fine and brightly flowered *Kalosanthes coccinea*, creditable examples of *Allamanda Hendersoni* and *Statisia profusa*, and rather poor plants of *Rhynchospermum jasminoides* and *Imantophyllum miniatum*. Mr. F. Dean, gardener to W. F. Neve, Esq., Cranbrook, followed very closely with a more even group, among which were capitally flowered plants of *Vinca oculata* and *Clerodendron Balfourianum*. To Mr. C. Nicholls, gardener to C. A. Fisher, Esq., Hawkhurst, was awarded the third prize for an excellent group, which included a well-grown *Erica ampullacea Williamsi*. Mr. G. Rummery, gardener to Sir E. Hardinge, Bart., Hawkhurst, was worthily awarded the fourth prize. The best six fine-foliage plants were staged by Mr. H. Manktellow, gardener to Dr. Harris, Northiam, these consisting of a grand *Acalypha* highly coloured, a good *Phormium tenax variegata*, *Cycas revoluta*, *Maranta zebrina*, *Croton variegatus*, and *C. irregularis*. Mr. J. Gilmour, gardener to the Right Hon. G. J. Goschen, Seacox Heath, Hawkhurst, was a good second, his group including well-coloured examples of *Acalypha musaica*, *Aspidistra lurida variegata*, and a good specimen of *Seaforthia elegans*. Mr. G. Nicholls was placed third in this class.

Mr. F. Dean easily secured the first prize for six Ferns, these comprising well-grown specimens of *Gymnogramma chrysophylla*, *Adiantum farleyense*, *A. cuneatum*, *Pteris umbrosa*, *Phlebodium aurcum*, and *Platynerium alaicorne*. In Mr. Gilmour's praiseworthy second-prize group were good plants of *Davallia Mooreana*, *Adiantum gracillimum*, and *Lygodium scandens*. Mr. Hodgkins was awarded the third prize, his most noteworthy plant being *Davallia bullata*. Mr. W. Tanner, gardener to H. Maynard, Esq., staged the best four flowering plants, among these being good specimens of *Kalosanthes coccinea* and *Vinca rosca*. Mr. J. Vaughan, gardener to Mrs. Slaughter, Sandhurst, was a creditable second.

The Calceuses were quite a feature in the Show, and six beautiful even pyramids were staged by Mr. H. East, gardener to T. Moilliet, Esq., Hawkhurst. Among these the most conspicuous were Harry Veitch, Lovely, and Kentish Fire. Mr. C. Nicholls followed with larger but less symmetrical plants, and Mr. Manktellow was a good third. Mr. Gilmour easily secured the premier award for four *Caladiums*, these consisting of good examples of *Bicolor splendens*, *Chantini*, *Louis Duplessis*, and *Bellemeyi*. Messrs. Hodgkins and Nicholls took the remaining prizes in the order named.

The first-prize group of Fuchsias staged by Mr. Nicholls were

particularly fine. These included grand pyramids of Lucy Mills, Improvement, Lustre, Avalanche, and Wave of Life; Mr. Tanner and Mr. Rummery also staged good Fuchsias. Mr. Nicholls had the best Achimenes, these comprising fine pans of *Grandiflora*, Sir Treherne Thomas, Ambroise Verschaffelt, and *Longiflora major*; Mr. Tanner was a good second. The best Balsams were staged by Mr. East, Messrs. Gilmour and Barnes following in the order named. Mr. Tanner had good Gloxinias, and was awarded the first prize, being followed by Messrs. Rummery and Hodgkins; Messrs. Tanner and Hodgkins were also successful with Zonal Pelargoniums.

For a miscellaneous group of plants Mr. Hodgkins was awarded the first prize, principally on account of the Orchids included. Of these the best were the small pieces of *Cattleya Mossiae* and *Lælia purpurea*. It was, however, a moot point whether the group staged by Mr. Nicholls was not more deserving of the premier award, this including two good half specimen *Ericas* and other choice plants. The best single specimen plant, a well-flowered example of *Erica ferruginea major*, was staged by Mr. Gilmour.

Several good stands of cut flowers were staged, the prizes going in one class to Messrs. Gilmour, Nicholls, and Manktellow; and in another to Messrs. Vaughan and A. Butler, gardener to D. N. Olney, Esq., Robertsbridge, in the order named in each instance. Roses were staged creditably by Captain Swinney, Hawkhurst; and Messrs. Hodgkins, Barnes, and Butler. In the bouquet class the Judges preferred a closely packed specimen, exhibited by Mr. Dean, to one lighter and more elegant shown by Mr. Gilmour.

Mr. L. Barnes, gardener to Lady Herschell, Hawkhurst, easily secured the premier award for a collection of fruit, in which were good dishes of Golden Champion and Mrs. Pince's Muscat Grapes, the latter thoroughly ripe and well coloured, Melons, Apricots, and other good hardy fruits. Good collections were also well shown by Mr. Tanner and others, the hardy fruits in each instance being particularly good. Mr. Barnes' first-prize bunches of Buckland Sweet-water in the class for any white Grapes were most creditable, and the same may be said of the Black Hamburg in the corresponding class for black varieties, staged by Mr. Reeks, gardener to R. W. Smith, Esq., Wadhurst. Mr. Barnes was second in this class with well-coloured Mrs. Pince. Mr. Rummery was first in the class for scarlet-fleshed Melons with an excellent fruit of Blenheim Orange; Mr. Gilmour was a close second. Green-fleshed varieties were well shown. Mr. Barnes gained an extra prize for a well-fruited pot Vine, the variety being Duke of Buccleuch.

The collections of vegetables both by professional and amateur gardeners are always particularly good at Hawkhurst, and Mr. Gilmour in the professional class was awarded the first prize for clean well-selected specimens, among which were fine dishes of Glamorgan Tomatoes, Ashleaf Kidney Potatoes, Beetroot, and Telephone Peas. Mr. Barnes followed closely with fine White Tripoli Onions, Telegraph Peas, and Porter's Excelsior Potatoes among others; Mr. G. Rummery was worthily awarded the third prize. In the smaller class Messrs. A. Butler, R. Titley, gardener to J. Thompson, Esq., and J. Willard were the prizewinners.

The ladies' class for vases for table decoration was well filled, and there were several elegant and tasteful arrangements. The Judges, however, gave the preference to three very stiff and formal arrangements in which moss and scarlet Pelargoniums predominated. Mrs. Cook, Mrs. Pridgeon, Mrs. Cooper, and Mrs. Gilmour were also successful with their pleasing arrangements, those by the latter being preferred by many. Several very fine stands of Roses were presented by Messrs. G. Bunyard & Co. of Maidstone, these comprising among others excellent blooms of A. K. Williams, Horace Vernet, Dr. André, Sultan of Zanzibar, Madame Eugénie Verdier, A. Colomb, Etienne Levet, Hippolyte Jamain, Sir G. Wolseley, and Countess of Rosebery, Hybrid Perpetuals; and of Teas, Jean Ducher, Rubens, Souvenir d'un Ami, Madame Bravy, and Madame Lambard. Mr. Potten of the Camden Nursery, Sissinghurst, staged a well-selected group of tricolor, bronze, single and double flowering Pelargoniums, Coleuses and other plants. Mr. Martin, nurseryman, Hawkhurst, also staged a pretty group of serviceable plants.

The amateurs of Hawkhurst and district made a grand display of flowers, fruits, and vegetables, while the cottagers, from the various parishes comprised, brought an extraordinary large quantity of good vegetables and fruits in season. The whole system and arrangements reflect the greatest credit on the President Mr. Cook, the Treasurer Mr. Reeves, and the Committee generally, and judging from the support these receive from the leading inhabitants of the district, the Hawkhurst Society will long continue to carry out its good work.

EARLY TURNIPS.

THE thanks of your readers are due to Mr. Luekhurst for publishing the results of his experiments with early Turnips; but it may not be out of place to point out that Turnips run to seed much less readily when very liberally treated, especially with manures which are highly phosphatic. Let anyone mark the difference between Turnips sown on ground the surface of which has been forked full of manure, and those sown on ground dug in the ordinary way, and a very great difference will be seen. Vigorous growth from the first tends to retard the flowering season of every vegetable from Turnips to Celery, but perhaps

more in the case of these plants than any others. Certain it is that under the one system a fair crop of Turnips may be gathered before they "bolt," while, under the other, seed stems will often form before the roots are of any use.

Perhaps there is not any other manure better fitted for producing fine crops of very early Turnips than nightsoil, or rather ordinary manure saturated with nightsoil. Manure from the poultry yard is also very good, and so is guano. As has been said, the best way is to fork the manure into the surface; every drop of rain will cause it to go down. This way of applying manure is perhaps the best for everything, and few greater mistakes are made than digging manure deep into the earth and throwing poor soil to the surface; no pulverising with frost, fork, or hoe will turn such into a soil that will feed delicate seedlings abundantly. When plants are nursed into strength from the very first they are not much inclined to "run to seed" or succumb to insect attacks.

Later crops of Turnips grow finest on poor soil. On rich soil they grow coarse, with strong taproots and immense tops. On poor soil the taproots are like mouse tails, the leaves grow less coarse, and the "bulbs" are better shaped, finer, and firmer. When poor soil is recommended it is, of course, meant that the land shall be rich enough to maintain a steady growth. In most gardens the soil is rich enough to produce fine crops of late Turnips without manure. In the case of very early plants seed stems rather than bulbs are the result of sowing on poor soil, and a very rich soil is a cure for this. It is thus seen that for the very same crop conditions diametrically opposite have to be afforded at different seasons in order to secure the best results.—SINGLE-HANDED.

BETTER v. STRAWBERRIES.

OUR Strawberry beds were very fine and promising this spring, with abundance of flowers, which set well. Early in May, however, my gardener informed me that he had discovered in the beds some of the beetles which two years before had made such havoc among the Strawberries. We tried all means to arrest the plague, but nothing seemed of any avail. The creatures came out of the ground from the depth of sometimes 3 or 4 inches, swarmed in the roots of the plants, and soon increased by thousands. They only came out at night, like the blackbeetles that swarm in some kitchens. In vain my gardener and his men went out night after night slaughtering the insects by thousands; the conquering army could not be defeated. The Strawberries have been almost entirely devoured, and the fine crop that promised so well has entirely disappeared. I enclose some of the Strawberries that you may see the way in which the juices have been sucked out of the fruit. When I wrote to you on the subject two years ago your answer implied that you considered the beetles had only destroyed some other enemy of the Strawberry—the emmets or slugs. This, however, is certainly not the case. There is not the least doubt that the beetles attack only the Strawberries. Last season we had hardly any of them, owing, I suppose, to the severity of the previous winter, and the result was a fine crop of fruit. A curious fact is, that after devastating the Strawberries the beetles do not attack any other fruit or vegetables in the garden. They seem to subside; and though they are still found, the great army of them disappears. I do not find that any of our neighbours suffer from the attacks of these beetles. Our soil is light and gravelly, hot, dry, and flinty. We are on the edge of the chalk of the downs. The beetle is well known to the natives, and is called by them "the Black Bob." During the ten years that we have resided at this place this is the second outbreak we have had of this plague. I shall be greatly obliged if you can suggest a remedy. Would dressing the ground with seaweed be likely to have a good effect? I enclose some of the dead beetles for your inspection.—E. D.

[We publish the above letter as it refers to a circumstance which, so far as we know, is a very unusual occurrence. We have consulted a skilled entomologist on the subject, who states the insects belong to the tribe of ground beetles, sometimes called "Gardeners," from their utility in gardens, this particular species being one of the Carabi. There is every reason to suppose such a circumstance as their attacking fruit is of excessive rarity, and he fails to find any record of such a thing, their wonted food being other living creatures. Still there is no accounting for freaks amongst beings two, four, or six-legged, and possibly owing to their great numbers the beetles have been unable to obtain the requisite animal nutriment. These Carabi occasionally show themselves in swarms in marshes near the sea. What could have led to the establishment of this colony of them in a garden could only be conjectured by a study of the locality and its surroundings. We cannot conceive that a dressing of seaweed would be of any substantial benefit in eradicating the pests. It will be well to make

a plantation of Strawberries in another part of the garden, destroying the present bed and dressing the ground with gas lime. If any of our correspondents have had experience of the kind indicated, and can submit a method for extirpating the beetles, we shall be glad to hear from them on the subject.]

WIRRAL ROSE SOCIETY.

THIS Society's Exhibition was held on Saturday, the 15th inst., in the Archery Grounds, Birkenhead Park, and is the third that has taken place, each having been a great success as far as the exhibits have been concerned; but unfortunately the weather has been much against their financial success. The opening day has generally been wet, which was again the case on the present occasion, but fortunately the weather cleared, and the sun shone brightly before the Exhibition opened for the public. The blooms were more numerous than last year, and of good quality throughout, in fact slightly superior to those staged at Manchester on the previous day. The most marked improvement this year was observed amongst the open and local amateurs' classes. It is objectionable, as has been noticed on previous occasions, that none of the prize cards gave either gardeners' names or the addresses of the exhibitors.

In the open class for seventy-two blooms, distinct, Messrs. G. Paul and Son, Cheshunt, took the lead, followed by Messrs. Cranston and Co., Hereford. These two exhibits gave the Judges some trouble in deciding which was worthy of the premier award, but at last the matter was settled in favour of the Cheshunt collection. Messrs. James Dickson & Sons, Chester, were awarded the remaining prize for a very worthy collection. The Cheshunt boxes contained good flowers of Marie Baumann, Ferdinand de Lesseps, Marie Finger (very fine), Madame Ducher, Ferdinand Chaffolte, Senateur Vaisse, Mons. E. Y. Teas, Niphotos (large and good), Capitaine Christy, Beauty of Waltham, Penelope Mayo, Madame Vidot, Louis Doré (bright), Countess of Rosebery, and Marie Rady—all being bright and fresh. Messrs. Cranston & Co. had superior light flowers and Teas—Princess Beatrice, Baronne de Rothschild, Mdlle. Eugénie Verdier, La France, Capitaine Christy, Madame Gabriel Luizet, Duke of Edinburgh, and Pride of Waltham. The third collection showed very much the effects of the weather amongst the light flowers, but such blooms as John Hopper, Beauty of Waltham, Sir G. Wolseley, and Comtesse d'Oxford were superb. For thirty-six, three blooms of each, there were only two exhibitors, Messrs. Paul & Son and Cranston & Co. gaining each the same position as in the previous class. The former had good examples of Madame Lambard, Duchesse de Morny, Alfred Colomb, Marie Van Houtte, La France, Beauty of Waltham, and Marie Baumann (White Baroness was staged in this collection, but was thin and open in the centre); the latter having fine flowers of Prince Arthur, Baronne de Rothschild, Charles Lefevre, Marguerite Brassac, and Alfred Colomb. Mr. G. Prince, Oxford, was the only exhibitor in the class for thirty-six single trusses, his exhibit being worthy of the first prize awarded him. His box scarcely contained a faulty bloom, and the best were Prince Arthur, Madame Marie Verdier, Senateur Vaisse, Alfred Colomb, Beauty of Waltham, Constantin Tretiakoff, Duchesse de Morny, Xavier Olivo, A. K. Williams, Mdlle. Marie Finger, and Madame Georges Schwartz, Marie Van Houtte, Rubens, and Souvenir d'Elise. For eighteen triplets the same exhibitor was again first, having no opposition; his blooms were throughout of first-rate quality. In the class for twelve new Roses (single trusses) not in commerce before 1879, the lead was taken by Messrs. G. Paul and Son, who staged very creditable blooms of Countess of Rosebery, Mrs. Harry Turner (very bright in colour), Brightness of Cheshunt, Comtesse de Sudrie (a promising Rose, and good), Duchess of Bedford, Lady Sheffield, and Madame Montel (soft rosy pink in colour, distinct, but thin and loose). Messrs. Cranston & Co. obtained the second award. Mr. Prince was the only exhibitor in the class for eighteen Tea or Noisette Roses, and was awarded the first prize for fine blooms of Madame Lambard, Catherine Mermet, Rubens, Marie Sisley, President, Souvenir d'Elise Vardon, and Comtesse de Nadaillac.

The amateur classes were well represented. In the class for thirty-six varieties, single trusses, C. Davies, Esq., was first with a box of grand blooms, having good Marguerite Brassac, Capitaine Christy, Etienne Levet, and Le Havre. C. J. Day, Esq., was second, having good examples of John Hopper, Souvenir d'un Ami, and Lord Macaulay. Messrs. T. B. Hall and Wm. Stubbs were third and fourth respectively with fine collections, but scarcely so fresh as the preceding. In the class for twenty-four single trusses the competition was good. C. Davies, Esq., took the lead, followed closely by W. J. Grant, Esq., and the Rev. J. H. Pemberton; a special prize being given to the Rev. L. Garnett for a good box containing a wonderful bloom of Harrison Weir. The first two named exhibitors were again in similar positions for twelve triplets, the principal good blooms being such as are named in other collections. For twelve Tea or Noisette Roses T. B. Hall, Esq., was well first, followed by the Rev. J. H. Pemberton, whose blooms were rather too open. The first-prize collection was remarkably fine, and contained superb blooms of Madame Lambard, Madame Willermoz, Anna Ollivier, Madame Margottin, Perle de Lyon, Jean Ducher, Madame Hippolyte Jamain, Souvenir d'Elise, and Madame Caroline Kuster. For six triplets Mr. Hall was again first, having in his box handsome blooms of Madame

Maarin; Mr. C. Davies was second, having grand blooms of Catherine Mermet; and Mr. W. J. Grant third. The last-named exhibitor was first with six single blooms of Mrs. Jowitt. For twelve blooms of any dark Hybrid Perpetual C. Davies, Esq., first with Louis Van Houtte, a special prize being awarded Mr. Grant for a box of Alfred Colomb. In the corresponding class for twelve light Hybrid Perpetuals Messrs. T. Griffiths and L. Garnett were first and second, the former showing Capitaine Christy and the latter La France.

The remaining sections of the schedule were only open to amateurs within the Hundred of Wirral and ten miles round the Liverpool Exchange. A gold medal and plate was given as the first prize for twenty-four single blooms, T. B. Hall, Esq., being the most successful exhibitor, and staged grand blooms. A special prize was given for the best Hybrid Perpetual bloom in this and the following five classes, the same exhibitor being successful with a fine bloom of Annie Wood. Messrs. J. M. Hodgson and T. Griffiths were second and third for the twenty-four. For eighteen blooms the last-named exhibitor was first, followed by Mr. W. Mease, gardener to C. W. Newmann, Esq., Wynote Allerton; and Mr. T. B. Hall. In the class for eighteen single blooms, those competing in the above two classes being excluded, J. G. Churton, Esq., was successful, and was awarded the silver medal and plate. For twelve blooms the same exhibitor was again first. In the corresponding class for twelve blooms Mr. Waterman, gardener to A. Tate, Esq., was awarded the bronze medal. For twelve Tea or Noisette blooms Mr. T. B. Hall was again successful, but staged rather smaller blooms than in his above-mentioned exhibit. For nine blooms, E. Claxton, Esq., was first with really grand blooms, the best in the Exhibition of some kinds. A prize was also given for the collection having the best foliage, as well as for the best bloom, this exhibitor being successful in each case, therefore obtaining three first prizes for one box. The premier bloom was Alba Rosea, large, full, and good. For six blooms Mr. Waterman was first, staging grand examples of Madame Lambard and Madame Willermoz. Messrs. Mulleneaux, Mereer, Dod, and Edwards were the principal prizetakers in the remaining small classes. There were four classes devoted to cottagers, which were fairly well represented.

The miscellaneous exhibits were not numerous. Messrs. James Dickson & Sons, Newton Nurseries, Chester, staged a good assortment of cut Roses. Mr. G. Smith, Dell Nursery, Rock Ferry, had a neat collection of small decorative flowering and foliage plants; and Mr. S. Johnson, South Grove Nursery, Oxtou, staged a similar collection.

SOME SPECIES OF PINKS.

THE genus *Dianthus* includes some of our choicest Alpines, border, and florists' flowers. None need mistake their beautiful salver-shaped flowers, almost invariably grassy leaves, and jointed stems. Their flowers vary from white and yellow to the deepest crimson. For horticultural purposes Pinks may be divided into three sections: 1, the truly Alpine; 2, border kinds, being distinct species; 3, border kinds, being florists' flowers.

The first section contains some of our most lovely rock plants. *D. alpinus* is a diminutive species found naturally on limestone soils, upon which it retains its character and succeeds better, requiring a good peaty loam and a sunny position. It differs from the other dwarf kinds in its sturdy habit, half-woody stems, which become much developed in age, and obtuse, recurved, shining leathery leaves. It has rose-coloured flowers; the expanded portion of the petals are distinctly wedge-shaped, and have a dark blotch at their base.

D. glacialis may be regarded as the type of all that is lovely amongst Alpines. It enjoys a cool peaty loam entirely free from lime, and succeeds better, providing good drainage can be secured, on the general level than if elevated, because a more equable moist condition of the soil can be obtained. To give an idea of my meaning I would say the best plants I have seen of this species had a tiny moss growing amongst its stems; it also enjoys partial shade. The difference between this and the previous one is that there is scarcely any development of a woody stem, and the erect, pointed, membranous, dull green leaves always appear to rise directly from the ground. It has rose-coloured flowers almost circular in shape, supported on stems about 3 inches high. *D. Fischeri* is a close relative of the above and equally beautiful. It requires similar treatment.

D. neglectus amongst choice Alpine Pinks is the most likely to become popular, not being so fastidious as to soil, and is more robust. Like the Cheddar Pink (*D. cæsius*) it rapidly increases by its underground stems. In a sunny position in well-drained peaty loam it should give entire satisfaction. Its flowers are a most lovely rose, circular in shape, and although not less beautiful it is quite noble in comparison with the Glacial Pink. Its flowers are not borne singly, as is the case with the two preceding kinds. I have gathered seeds of *D. alpinus*, *D. glacialis*, and *D. neglectus*, but have never been able to rear plants from seed sown the following spring. Of *D. alpinus* I have gathered seedlings on dry limestone ledges, the seed having fallen from plants above. My impression consequently is that seed of these (and

perhaps many more Alpines) ought to be sown as soon as gathered.

D. arenarius is a very dwarf kind with pointed grass-like leaves. Its flowers, pale rose and much fimbriated, are borne on short wiry stems. It will grow in any free soil. As there are so many coarser and nearly allied kinds it is advisable to increase this by division, as seedlings do not come true.

D. petraeus is in appearance and habit generally intermediate between *D. neglectus* and *D. cæsius*. It has the beautiful, though not so deep, rosy flowers of the former, and the foliage, but not so glaucous, of the latter. It is easy to grow, but should be increased by division. Owing to its varying so much from seed I had considerable difficulty in obtaining the true species, and eventually procured it from the late Mr. J. C. Niven of Hull.

The Maiden Pink (*D. deltoides*) is scarcely choice enough for a good rock garden. It is certainly a very free bloomer, and its crowds of tiny crimson flowers (the petals of each flower have wedge-shaped dark blotches at their base) are very telling. There is, however, a very beautiful variety of this with glaucous foliage and neater habit, named *D. deltoides glaucus*. Its flowers are very pale rose, quite attractive, with a darker blotch, as in the case of the type. It increases freely from seed, but does not retain its character. Division is the better mode of propagation.

Section 2 includes kinds more adapted for a select herbaceous border occupying front rank. *D. collinus*, a very showy kind with deep rosy flowers, blooms late in the summer; the process of flowering so nearly exhausted it for two successive seasons, that only by cuttings, seeds being scarce, did I manage to keep up a stock. It is near the Sweet William (*Dianthus barbatus*), but has more grass-like foliage, much larger flowers, and cymes not so umbellate—what might be termed fasciated.

D. monspeliacus is a neat kind, with abundant rosy fimbriated flowers. There are many species nearly allied to this usually grown on rock gardens, which are equally adapted for the front rank of the border. *D. monspeliacus*, I think, is the best of the group, which includes what English nurserymen sell as *D. corsicus*, *D. fimbriatus*, *D. floribundus*, *D. fragrans*, *D. pini-folius*, *D. pungens*, *D. suavis*, and *D. Simsii*. None of the above can be relied upon to come true from seed, and should be increased by division.

D. plumarius var. *annulatus* is the parent, or at least one of the parents, of the double Pinks; the single form is very pretty and interesting.

D. tymphrestus seems to be a larger form of the old Maiden Pink (*D. deltoides*), and on that account will be more suitable for the border. It sows itself freely.

D. Seguieri is of recent introduction. It came to us from Dr. Regel and Messrs. Backhouse; but, like many other members of Caryophyllaceæ and Cruciferae, notably plants so long in transit from St. Petersburg, were dead when they arrived. It has a very neat appearance in summer, sitting upon the ground in grassy tufts, bearing very bright heads of comparatively large flowers, deep crimson in colour. In summer it might be taken for a large bright form of the Alpine *D. atrorubens*, but instead of one common swollen rootstock of the latter it has a ramifying underground growth, which is all, or nearly all, that remains of the plant in winter. *D. atrorubens* remains grassy above ground.

Section 3 includes what are known as florists' flowers, such as the Mule Pink, the various kinds of Carnations, Picotees, Indian Pinks, *D. superbus hybridus*, and Sweet Williams.—M. J. B.

FRUIT PROSPECTS—SLUGS.

THE fruit prospects in Gloucestershire are being very much marred by the continual downpour of rain. Early in the season the Strawberry crop was never more promising. There was plenty of bloom and plenty of fruit set, but in consequence of so much rain some of the fruit fell off the plants of the larger varieties, such as Sir J. Paxton, before they were ripe, and those which remained were not as good as usual. There was a good crop on the earlier varieties, such as Keens' Seedling and Vicomtesse Hericart de Thury, equal to that of last year, but many berries have become mouldy, and at one time the fruit was too soft to gather. We have had 5 inches of rain to the middle of July, and 2.20 inches in one day. The Raspberries are a good crop, but deficient in flavour, and we have to watch our opportunity to gather when dry. The Gooseberry crop will be seriously injured unless we have a change for the better in a few days.

Planting out small annuals has been rather heartless work this summer; the slugs abound, and seem to have most voracious appetites. We put out plants, and they are soon eaten off; we plant again with much the same result. We use lime, but the

effect is soon lost by its being washed away. Hand-picking every night was the only way to preserve the plants, and now they are not looking nearly as well as they ought to do at this advanced period of the year. The result of our labours this season have certainly not equalled the favourable expectations that were at one time entertained.—AMATEUR, *Cirencester*.

SILKWORMS AND SILKWORM REARING.—12.

(Continued from page 540, last volume.)

To what has been already stated concerning the methods of rearing the common silkworm (*Bombyx Mori*) I wish to add, by way of supplement, an extract from some observations upon the subject appearing in the "Entomologist" of June last. These interesting remarks are penned by Miss E. A. Ormerod, a lady who has distinguished herself in the direction of economic entomology especially, and who is now appointed honorary consulting entomologist to the Royal Agricultural Society. It seems that about ten years ago this lady made some experiments in rearing the Mulberry worm, a parcel of larvæ received at the beginning of June being divided into three companies or parties. All were fed similarly upon Mulberry sprays, in length from 12 to 18 inches or so, which were placed in pots and boxes of earth, and which were found generally to retain their freshness until the leaves were almost stripped. The surface earth of the pots, upon which the excretions of the silkworms fell, was occasionally removed. Little handling was requisite, and they had the advantage of plenty of air with natural exercise on the twigs. One of the parties was reared in a succession vinery, where the air was kept damp, and the temperature was genial but not high, varying somewhat when the heat of the sun was admitted. A second party was placed in a room of equable temperature (about 62°), cold air being excluded at night. To the third was given a home in a garden loft, the windows of which were open at all times, and where occasionally the thermometer fell below 50°. There was no great mortality amongst any group out of the three, but the worms kept in the vinery always appeared to be more active and flourishing than their brethren of the room or loft; also they made more rapid progress, and all their cocoons were spun before the tardy worms in the loft had completed their growth.

In estimating the value of this experiment, however, it must be remembered that these silkworms when so distributed were not newly hatched. As they are stated to have been from half to three-quarters of an inch in length they were probably a fortnight old. Had worms just out of the egg been placed in such a loft as is described it is likely many would have died. The vinery, again, during the very juvenile stage, might have had too forcing an effect, and obviously the feeding upon branches of Mulberry inserted in pots could only be carried out upon a small scale, whatever advantages it might have. These experiments quite confirm what has been previously advanced in reference to the need of scrupulous cleanliness and ventilation; it is evident, though, that silkworms will live and produce satisfactory cocoons in an atmosphere which varies greatly in temperature. Nearly allied to *Bombyx* or *Attacus Cynthia*, described in our last article, and a species having its habitat in several districts of Northern Asia, is the *A. Ricini*, an Indian species, rather less in size. Bengal is the province which has supplied most of the examples of this insect which have been sent to Europe. As the name implies, the food of the caterpillar or worm is the Castor-oil Plant—one or more species of *Ricinus*. We might infer, perhaps, from this fact that the leaves being somewhat unctuous, silk yielded by the cocoons of *A. Ricini* would be rich and glossy. It does not seem, however, to have any particular excellence, while the cocoons present some trouble in the winding. Since one Castor-oil Plant can be easily cultivated in such a climate as is that of Southern France, several attempts have been made to induce farmers there to grow crops of it, because the seeds would be marketable on account of their oil. But as this silkworm does not promise much the enterprise is unlikely to be followed up, and it is a serious drawback that the species of *Ricinus* in question is only annual in Europe.

A well-known article of Indian produce is the particular kind of silk called Tussur or Tussore silk, of somewhat coarse texture, yielded by the silkworm of an allied species, *Attacus Mylitta*, also named "Paphia" in some books, the latter being rather misleading. One or two of our British experimenters have been anxious to get this species encouraged in these islands, on the

supposition that by a little management the worms would thrive well enough without shelter from the effects of our changeable climate. The silk can be wound off, although it is more usually reeled, and the cocoons exhibit much variety in size and colour; though usually grey of some shade, they are also white or yellow in other examples. In Switzerland for fifteen or twenty years a succession of these worms were reared in the open air by M. de Chavannes, but subsequently the race died out through some accident. The moth is banded, and bears four eye-like spots, as may be seen in our figure (fig. 14); the caterpillar has the characteristic of *A. Cynthia*, shown in our preceding article, though superior in size.

Mr. Manuel, Manager of the Wild Silk Agency at Rangoon, has communicated several facts relating to the history of the Tussur silkworm, which is generally fed upon some species of Oak. He perceived, having had large numbers under observation, that they much preferred light to darkness, for when they were supplied with leaves in jars that were covered by thin white discs, the silkworms all endeavoured to reach a spot in or near these while they were reposing. Not uncommonly they devoured the cast-off skin after each moult, making also their first meal of the egg-shell that they had quitted. He suggests that these and other caterpillars may occasionally free themselves from the old skin by biting off portions. In their attitudes the Tussur worms vary, since part of them will moult with their heads stretched upwards, and part with it bent down; the latter, as a rule, were found to moult more readily. There has as yet been a difficulty in getting specimens of this insect, *A. Mylitta*, for British experiments, some further trials might advantageously be made. The remark applies to all the Oak-feeding species of silkworm, that if it is possible to

Fig. 14.—Moth of *Attacus Mylitta*.

place them upon trees or shrubs growing in the usual way, the worms do far better than when they are living upon the leaves of twigs cut off.

Attacus Roylei, the silkworm of the Himalayan Oak, has been tried both in Europe and America, some districts of Germany suiting it very well. In appearance this is more like the celebrated silkworm of Japan, called *B. Yama Mai* (to be hereafter noticed) than the others of its genus, and a crossing has been tried between this moth and *B. Pernyi*. The cocoon of the hybrid is excellent, superior to the natural cocoon of *A. Roylei*. The worm is also

Fig. 15.—Cocoon of *Attacus Mylitta*.

easier to rear; though M. Wailly of Clapham has fed with tolerable success the silkworm of the Himalayas in that London suburb, and obtained the above hybrid as well. During the winter the species is in the pupal state, moths emerge in May or June, and the silkworms feed through the summer. Upon the ordinary cocoon of *A. Roylei* there is a tough outer envelope which is of no value; the silk below it is therefore less in quantity,

and the moths, it is noticeable, fly about wildly, when confined acting quite differently to the placid B. Mori.—J. R. S. C.

NATIONAL ROSE, PANSY, AND PINK SHOW AT ROTHESAY.

A GRAND Exhibition of flowers was held on the 14th and 15th inst. at Rothesay (the Brighton of Scotland) within the new Public Halls. We give a list of the principal prizes.

Roses.—For twenty-four blooms the first prize (a gold medal) was awarded to Mr. H. Dickson, Belmont Nursery, Belfast, who staged splendid flowers of the following:—Duchess of Bedford, La France, Madame C. Wood, Julius Finger, Countess of Rosbery, Pride of Waltham, Madame Verdier, Duke of Teck, Madame Marie Verdier, Duke of Edinburgh, Lady Sheffield, A. K. Williams, Alfred Colomb, Horace Vernet, Auguste Buchner, Marquise de St. Amand, Roseriste Jacobs, Brightness of Cheshunt, Baronne de Rothschild, Mrs. Harry Turner, Capitaine Christy, Mrs. Jowett, Mons. E. Y. Teas, and Comtesse de Cammonda. Second prize: Mr. T. Smith, Stranraer, whose lot included fine flowers of La France, Capitaine Christy, Marquis of Salisbury, Marquise de Castellane, Harrison Weir, Alfred Colomb, Baronne de Rothschild, Charles Lefebvre, Duchess of Bedford, Madame Montet, Madame J. Periere, and Camille Bernardin. For twelve blooms the first prize (a silver medal) was won by Mr. Wm. Parlane, gardener, Roselea, Row, with excellent blooms; second prize, Mr. McIntyre, jun., gardener, Blairmore; third, Mr. J. Millar, Cardross.

Pansies.—In the class for twenty-four Show and twenty-four Fancy Pansies the first prize, a gold medal, was awarded to Messrs. William Paul & Son, Crossflat Nurseries, Paisley, whose flowers were of excellent quality, the Judges pronouncing the Show Pansies the finest staged for many years. The varieties were: Shows—Peter Lyle, A. Watt, J. P. Barbour, W. L. Thomson, dark self; Mrs. Galloway, white self; R. Pollock, Dr. Livingstone, Wm. Robin, Bailie Cochrane, D. Dalglish, A. Cameron, R. Williamson, yellow grounds; Mrs. Muir, Jeannie Grieve, Miss Meikle, Miss Baird, Jeannie Johnstone, white grounds; and seven seedlings unnamed. Fancies—James Lillie, Mrs. Scott Plummer, Mrs. Berkmyre, Jane Adair Martin, W. McIntosh, Thalia, A. Stephen, Jessie Budd, Sir P. K. Murray, Adonis, E. Caird, L. V. Heathcote, Catherine Agnes, Mrs. Russell, R. Cowan, Mrs. W. O. McCormick, Mrs. J. Watt, Mrs. Robinson, and six unnamed seedlings. Second prize Mr. John Sutherland, Victoria Nursery, Lenzie, whose Fancy varieties were much superior in merit to his show flowers, the following were the most noteworthy. Shows—Rev. J. Morrison, Mrs. Cadzon, Matthew Pollock, Wm. Robin, Manve Queen, R. Burns, Mrs. Arthur, Jessie Foote, Golden Circle, Mrs. Dobbie. Fancies—Catherine Agnes, Mrs. Jamieson, Livadia, Mrs. J. Stewart, Countess of Home, Robert Goodwin, Duchess of Edinburgh, Wm. Cuthbertson, Mrs. Findlay, Earl Beaconsfield, Mrs. Taylor, and L. V. Heathcote. Third prize Mr. W. Dickson, Ladyburn Nursery, Paisley, who had a very neat collection. For twelve Show and twelve Fancy Pansies the first prize, a silver medal, was won by Mr. Wm. Storrie, Lenzie, with fine blooms; second prize, Mr. R. Millar, Paisley; third, Mr. A. Irvin, Tighnabruich.

Pinks.—For twelve blooms, the first prize, a silver medal, was secured by Messrs. Wm. Paul & Son, who staged very large flowers, perfect in lacing, of the following—Wm. Paul, Modesty, Egeria, Adela, Wm. Watson, Wm. Bruce, Vanessa, Oimara, Dr. Masters, Mary Auberton, Lady Golightly, and Ada Louise. Second, Wm. Dickson, Paisley. Third, John Love, Rothesay.

Mr. Dickson, Belfast, and Mr. Smith, Stranraer, exhibited several stands of magnificent Roses; Messrs. Dobbie & Co., Rothesay, Phloxes, Pansies, &c. Among the prizetakers in other classes we observe the names of Messrs. J. Mackenzie, Lenzie; J. Stewart, Campsie; R. Stewart, Woodielea; J. Constable, Paisley; C. H. Johnstone, Bairhead; J. Douglas, Largs; J. McCrorie, Kilbarchan; J. Kidd, Rothesay; D. Wallace, Rothesay; D. Grant, Rothesay; J. Wilson, Largs; and G. L. Hunter, Row.

CARDIFF CASTLE CUCUMBER AND MUIR'S VEGETABLE MARROW.

SHOULD a Cucumber be prolific? Cardiff Castle is second to none. Should it be a free grower and hardy? This also excels in both points. And if quality and handsomeness, apart from mere bulkiness, be also wanted, this variety has these in an eminent degree. For amateurs, for professionals, for market growers, for exhibitors, it is alike suited, as whatever quality each of these may look for they will find it in Cardiff Castle Cucumber. Very high praise this, but not more than should be given. I have not had an opportunity of testing it as a winter Cucumber, but as a summer one I find it just such as I would recommend to any inquirer. Judging from its free and hardy habit, I imagine it must be good for winter work also.

Muir's Vegetable Marrow has given us the first Marrows this year, and capital little fruits they are. They are produced very

freely, and, although not large individually, the prolific crop makes up for that. In flavour and in tenderness it surpasses that standard old variety Moore's Cream. For private use it cannot be too highly recommended.—J. H.

STOPPING TOMATOES.

MR. MUIR and Mr. Iggulden have each had something to say on the setting of Tomatoes, the former considering a dry atmosphere important, the second placing his confidence in artificial fertilisation. Both are doubtless right so far as they go, but in a sunless climate I find that the method of training and stopping has much to do with securing a good set of fruit.

My system may be called the spur. A shoot is run up to whatever height may be desired, but the leader is always stopped just at the bunch, and the shoot which springs below trained as leader. This stopping insures the starting of shoots from the axils of the leaves, which soon show fruit. These shoots are stopped at the bunch and are not permitted to extend afterwards. These shoots I call spurs. This rigorous stopping causes a "set" that is never experienced when the shoots are allowed to grow long.—N. B.

[We presume our correspondent's remarks apply to plants grown under glass.]

HARDY FRUIT GARDEN.

EXAMINE the various kinds of fruit trees trained to walls, and secure the leading shoots, stopping those desired for forming spurs to about three leaves of growth, and remove those which are superfluous. See that fruit swelling off is not injured by nails or undue pressure in any respect, but is given room and properly disposed for receiving light and air for attaining proper development. Such fruit trees on walls as the Apricot, Peach, Nectarine, Plum, and Pear, which are swelling their fruit, should be assisted by liberal applications of liquid manure, and be afterwards mulched with short manure. Late Cherries should now be securely netted to preserve them from birds, the leading shoots being nailed or tied in, while the foreright shoots should be pinched. Morellos should have as much wood laid in as there is room for, and any not required for this purpose should be removed or pinched. Raspberries, to have them fine and prolong the season, should be well supplied with water if the weather be dry, and the young canes should be thinned out to four to six to each stool, reserving the strongest and best placed. The autumn-bearing varieties should now be encouraged by mulching and watering, and in exposed situations will need to be supported with stakes. Late kinds of Strawberries will need plentiful supplies of water if the weather be dry. Continue layering runners of Strawberries in pots as they can be procured for forming new plantations or for forcing.

FRUIT HOUSES.

Pines.—Plants started into fruit at an early period of the year will be ripened off as regards the early sorts, and those of the later varieties started at the same time will be sufficiently advanced to bear removal to a vinery or elsewhere to finish. Advantage should at once be taken of the additional space to give the successional stock more room. Avoid if possible making new beds now, but if it be necessary about 2 feet of new tan will be ample. Beds which had a liberal supply of new tan in spring will scarcely need any now, but will merely require to be turned over to a depth of 18 inches, while those not so renewed with fresh material at that time may, if it be necessary, have an addition of fresh tan about 1 foot deep, and mixed with the old material to a depth of about 18 inches. Suckers from the plants above alluded to will now be fit for potting. Rootless suckers at this season thrive best in a close moist pit, having a fermenting bed with a temperature of about 90°. In potting ram the fibrous loam firmly into the pots and around the base of the sucker, water at once, and plunge without delay, covering the surface of the pots so as to prevent the soil becoming dry at the surface. More

water will hardly be necessary until new roots are formed, as with effectual shading from powerful sun, and ventilating a little at about 85°, the suckers will root quickly. A slight syringing occasionally will be beneficial.

Peaches and Nectarines.—We have before urged the necessity of removing the roof lights off trees subjected to early forcing as soon as the buds are fairly advanced, as they will be by this time, and no further delay should be permitted in removing the lights. The night dews have a good effect upon the trees, and they are much refreshed by rains; but should these not fall sufficiently often to keep the soil in a moist condition artificial watering must be resorted to, for under no circumstances must the trees suffer by want of water at the roots, nor must red spider or other insects be allowed to obtain a footing on the foliage. Young trees that have stronger wood than older trees will require a longer time to mature the growth and buds than trees less vigorous, and the roof lights should not be removed so early in their case. In the case of young trees that grow too luxuriantly a trench may be taken out about one-third the distance from the stem the trees cover of trellis, and as deep as the roots, which should all be cut through at the distance indicated. The time to do this is as soon as the buds are formed and the foliage still upon the trees. The trench should be filled in again firmly, a good watering being given, and the trees syringed morning and afternoon for a few days, keeping the house rather close, and afterwards ventilating. This process seldom fails to overcome the difficulty sometimes experienced in securing a good set and the satisfactory stoning of the fruit.

Where it is contemplated to plant young trees, either in new structures or otherwise, the borders for their reception should now be prepared. They should be well drained with 3-inch pipes, both as regards the inside and outside borders, and have proper fall and outlet over the drains, and the bottom of the borders should be 9 inches to a foot depth of rubble—coarsest at the bottom and smallest on the top—and this should be covered with a layer of turves to prevent the drainage being stopped; 2 feet in depth of soil is sufficient. The top 3 or 4 inches of a pasture where the soil is a rather strong loam if overlying limestone it could not be better, and this being chopped up roughly should be put together firmly. If deficient in calcareous matter a tenth part of old mortar rubbish or chalk broken up from the size of an egg down to a hazel nut may be thoroughly incorporated with the soil. Failing the turfy loam any good loamy garden soil inclining to be stiff will answer, adding about a similar quantity of old mortar rubbish or chalk as advised for the turfy loam, and this should be put in firmly.

In planting young trees in houses it is advisable to choose such as have been grown upon the approved system of training two or three years, such being grown in pots under glass, trees of this description being prepared by the leading nurserymen, and coming into profit early. When trees of this kind are forthcoming no time should be lost in making preparation for and planting them. It is quite unnecessary to disentangle the roots, but loosen the sides of the ball carefully, make the soil around as hard as the original, giving a good watering, and mulch with manure so as to encourage feeders from the stem. If planted before the leaves have fallen the trees will become established in the borders, and may be forced the following season, the time of starting being regulated by the growth and its maturation in the previous season.

For early forcing Alexander, Hales' Early, Early Grosse Mignonne, A Bec, and Royal George Peaches will afford a succession of eight to ten or more weeks' duration. Suitable Nectarines for association with the above for early forcing are Lord Napier and Elrue. Of Peaches suitable for affording ripe fruit by forcing in June and onwards in addition to Royal George are Grosse Mignonne, Noblesse, Violette Hâtive, Bellegarde, Barrington, Stirling Castle, and Late Admirable. The last three along with Lord Palmerston, Sea Eagle, and Osprey, also Salwey, are suitable for late houses. Midseason Nectarines are besides Elrue, Violette Hâtive, Hardwicke Seedling, Pine Apple, Humboldt, and Victoria.

PLANT HOUSES.

Greenhouse.—Early-flowering Pelargoniums should be placed out-

doors in the full sun without delay, so as to thoroughly ripen their wood previous to cutting them down, just giving sufficient water to prevent flagging. Calceolaria seed should be sown if not already done, the pan being placed under a handlight in the shade, it being important that the soil be kept regularly moist to insure the germination of the seed, and the young plants require to be kept cool and moist.

The early-flowering varieties of Heaths that have since blooming made considerable growth should now be exposed to the open air to harden them and insure free flowering. In removing Heaths out of doors it is well to place them for a few days at the north side of a wall where they will not at first be fully exposed to the sun, as when powerful it sometimes turns the leaves brown. On the sun side of the pot place a piece of canvas or mat to prevent the sun heating the pots, or the roots will be destroyed. The plants will require more water than when under glass, and on no account must they suffer by want of it. Young Heaths potted in the early part of the season will be making free growth, and must have timely attention in stopping and training, keeping the strong shoots well tied down, and the weaker upright to induce equal vigour throughout the plants.

Orchids.—Many of the early-growing plants will now have completed their growth for the season: remove them to a cooler house with a temperature of 60° without sun heat. Many Dendrobiums, especially *D. Cambridgeanum*, *D. nobile*, &c., frequently make a second growth when kept in their growing quarters, in which case the new growths seldom become well matured; the plants, therefore, should be placed in a house less charged with heat and moisture, and a greater supply of air should be afforded them. Cattleyas in a growing state should be afforded plenty of moisture to enable them to make plump pseudo-bulbs. Afford *Calanthes* weak liquid manure, and sponge the leaves frequently to keep them free from scale, thrips, and red spider, using an insecticide, and afterwards wash it off with clean water. *Sobralias* being subject to red spider should have similar treatment. *Thunias alba* and *Bensoniæ* flowering at this season are valuable, and being of easy culture should have place in even small collections. They require similar treatment to *Calanthes* during the season of growth. Many *Odontoglossums* and *Masdevallias* will now require a shift, especially those that are growing strongly and have filled their pots with roots. Keep the *Odontoglossum* house as cool as possible, using the syringe freely, affording water plentifully to those growing rapidly. Fumigate frequently to keep down aphides and thrips.

THE BEE-KEEPER.

PROLONGING THE LIFE OF THE QUEEN BEE.

DR. DZIERZON'S letter on the above subject (page 500, last volume) contains some startling statements, which I shall briefly notice. As the Doctor's name is far-famed and stands high on the list of authorities on bee questions, I regret that he has written the letter I am now about to review. Most of his reasoning and assertions in this letter are based on assumption only. He says first, "That bees exhaust their strength and die in about six weeks during the busiest time in spring and summer, whereas those reared late in summer and in autumn look as strong and young on their first appearance in spring, after six months' rest during autumn and winter, as if they had only just left their cells." This is inaccurate, for bees generally do not exhaust their strength and die in six weeks after birth by reason of hard work. Every close-observing apiarian of experience knows that during the spring and summer months, when weather is favourable and honey abundant, bees work very hard—as hard as they can work—and yet the death-rate is far short of the birth-rate; for the increase of population in spring and summer is enormous, especially so when bees are working hard and getting much honey. If hard work exhaust and kill bees the population of hives would be much smaller in favourable seasons than in unfavourable ones. But this is not the case. In honey seasons numerous colonies are sent off, and colonies become strong in population, often become parent hives the same season.

Take a stock hive in April containing 20,000 bees. In May its population will increase to 40,000; it swarms twice or thrice, and after three months of hard work, the bees numbering 40,000 in each hive, weighing 8 lbs. per swarm, look as fresh and healthy as ever they did. Hard work, then, does not kill bees nor shorten the lives of queens. What, then, causes the loss of so many bees in spring and summer months? Some that are hatched do not live and labour long. Thousands and tens of thousands of bees die on the very threshold of existence. They are born with industrial instincts so strong that they commence working before they are fit for it; they go to the fields before they are well able to fly or bear cold or carry loads. Again, thousands and tens of thousands of adult bees inured to labour are overtaken on the wing by storms of wind and rain, driven to the ground and chilled into a helpless condition. In both cases the loss is caused by misfortune, not by continuous hard work. Hives are sometimes taken to the moors, and there in three weeks 40 lbs. or 50 lbs. of honey are gathered, the hives coming back as well filled with bees as they were when they went. But if storms visit the bees while they are at work on the Heather two-thirds of their number are lost. Hives containing 9 lbs. or 10 lbs. of bees have been known to lose 7 lbs. in three weeks. We thus learn that storms and weather are more destructive of bee life than hard work.

I now come to the notions of Dr. Dzierzon about prolonging the lives of queen bees, and I have no hesitation in saying that they are incorrect. He says, "The question as to whether and how the life of a queen may be prolonged was suggested to me by a dispute which had arisen between Miss Titz of Lasswitz, a great Silesian bee-keeper, and a bee-master of the name of St. Miss Titz, on the occasion of the Neissen Meeting, showed some friends who visited her apiary an Italian queen which she stated to be six years old, adding that she had succeeded in keeping this valuable queen alive so long by keeping her from excessive breeding. Mr. St was of a different opinion, maintaining that there was no doubt a young queen had been raised unnoticed, as, according to his long experience, the life of an Italian queen never exceeded three years. He further asserted that eggs became developed in the ovary of the queen and pass involuntarily, it being impossible for any influence to be exerted on the ovary. In my opinion Mr. St is wrong on both points." On both points I think he is right, and the Doctor wrong. A queen bee cannot alter the laws of Nature. She cannot determine the number or regulate the supply of eggs necessary for a hive. Among enlightened people arguments on this subject are unnecessary. When queen bees are a few days old they are fertilised for life, and are, according to Dr. Dzierzon, capable of laying and distributing in the cells 3000 eggs per day in breeding seasons—that is, 125 eggs every hour, or two every minute. An extensive experience and close observation have led me to conclusions very different from those of Dr. Dzierzon. I agree with Mr. St in stating that after impregnation queen bees have no power to limit or increase the number of eggs, neither have they power to retain them after they are formed. The evidence of a lady is not enough to convince us that she "prolonged the life of a queen bee by keeping her from excessive breeding." The word "natural breeding" should be here used instead of "excessive breeding," for nobody knows that the breeding of this queen was excessive. It is stated that the queen that lived six years "was kept from over-exerting herself." It is really not fair to use such words as over-exertion, for who knows what it is or how to prevent it? Queens that lay eggs enough for hives containing 4000 cubic inches of space are quite as healthy and live as long as those in hives containing 1000 inches of space only. The small space given to the one queen does not prolong her life, neither does the large space given to the other queen shorten her days. In my apiary I have had satisfactory proof that queens in small hives lay as many eggs as those in large hives, though three-fourths of those laid in small hives are not used. A queen bee is very productive. Dr. Dzierzon says, "An empty comb containing six thousand cells is often found full of eggs at the end of two days, which shows that a queen is capable of laying three thousand eggs a day." Something is said in the Doctor's letter about a queen being "able to keep back a mature egg in the ovary for some time without injury to herself or the egg." If she lays at the rate of 125 eggs per hour she cannot keep them back long. Often, very often, a queen lays two eggs in a cell, and sometimes three are dropped into one cell. In the act of swarming a queen has been seen to drop eggs on the flight board. Even if a pregnant queen is held captive in the bee-keeper's hand for a short time she lays eggs there. When more eggs are laid in a hive than are needed the bees remove them, and some cells are not visited by the queen, the bees carry eggs to them. As it is a very common occurrence for bees to set eggs and hatch young queens to take the place of old ones, I think that the queen said

to be six years old was younger, and had been hatched unseen and unknown by Miss Titz, and that the theory of prolonging the lives of queen bees is without foundation in fact, and will not be seriously considered by practical apiarians.—A. PETTIGREW, *Bowdon*.

BOG HEATHER.—In this district there are square miles of Heather growing on bog land, which is generally so wet that sphagnum grows plentifully among the Heather roots. Is this Heather likely to be good for bees? Those who live among it say no—that even in favourable seasons bees can hardly live on it, so little is the honey secreted by the flowers. Have any of your experts at bee-keeping any experience of such Heather? A few miles from here, in the land of the Macgregor, enormous honey harvests are secured by the railway officials and others; but then the Heather grows on dry land.—A NORTHERNER.

TRADE CATALOGUE RECEIVED.

Stephen Brown, Weston-super-Mare.—*List of Seeds.*

* * All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Late Cucumbers (*F. O.*).—Strong plants being provided, and planted now in good soil in a dung-heated frame, will, with good attention as regards watering, ventilation, and temperature, produce abundantly during the autumn months.

Caterpillars on Dahlias (*Alex.*).—You had better examine the plants carefully and pick off the depredators daily or nightly. Syringing the plants with quassia water might also render them distasteful to the caterpillars, and if you spread a ring of sharp sand saturated with paraffin round the stem of each plant and a short distance from it, it will doubtless form a good barrier against the manraders.

Andromeda (*Zenobia*) *speciosa* var. *pulverulenta* (*Olive*).—The plant, of which you send a small specimen, is an evergreen shrub bearing the above name, and was introduced from North Carolina at the beginning of the present century. It is hardy in the south of England, but requires a specially prepared border, as it prefers a compost of loam or peat, the latter forming a large proportion of the mixture.

Tomatoes (*J. Doyle*).—Secure the plants to the wall, the main or fruit-bearing stems not being closer than 2 feet. When these have produced four or five bunches of fruit stop the leading growths producing them and all other growths both above and below the fruit that may be produced. Only the principal foliage should be allowed to develop, and this be prevented shading the fruit densely. Supply the plants with liquid manure if they need it, as they require much support when bearing heavy crops.

Seedling Raspberry (*Amateur*).—The dates of the two next meetings of the Fruit Committee of the Royal Horticultural Society are July 25th and August 8th. If the fruit is carefully packed and addressed to Mr. A. F. Barron, Royal Horticultural Society's Gardens, South Kensington, and a letter is addressed to Mr. Barron by a previous post, giving particulars of the variety, the matter will be duly attended to. It will be well to send fruit-bearing sprays as well as a dish of ripe fruit of the Raspberry for examination of the Committee.

Exhibiting Plants (*Exhibitor*).—Unless there is any stipulation to the contrary the plants mentioned cannot be excluded from the classes quoted, as they are undoubtedly either stove or greenhouse plants. At some exhibitions Ferns are not admissible for competition except in specified classes, and in others they are allowed to form part of a collection of stove and greenhouse plants. If the condition of the class relative to hanging baskets is adhered to with the greatest strictness your Nepenthes would not be eligible. Everything in this matter depends on the object of the committee in providing the class. Nepenthes are really ornamental-foliaged plants, and most beautiful objects as basket plants. We should exhibit the plant.

Begonias Unhealthy (*M. D.*).—We do not think that either thrips or mildew are the cause of the discoloration and shrivelling at the edges of the leaves. The injury has been caused by a check which the plants have received in some way. An excess of water causing the roots to decay would be followed by the results before us, and precisely the same effects would be apparent if the soil had at any time been so dry as to cause the roots to shrivel. Further, the leaves of these plants almost inevitably shrivel if the plants have been for a time kept in a rather close frame or house, and then removed to a structure in which the atmosphere is much drier. Many plants are injured soon after their arrival from nurseries, because the conditions under which they had been grown were not known or followed as nearly as possible in their new quarters. You do not state in what condition the plants were when they arrived, nor the treatment

to which they have since been subjected; had you done so we should have no doubt been better able to have given a more explicit reply; but we repeat the injury is not caused by insects of any kind nor mildew. If the plants were healthy when you received them they have been subjected to some error in treatment.

Thuia aurea Dying (Castle Park).—We regret extremely the loss of such splendid specimens. Our opinion as to the "probable cause of death" is general debility consequent on the exhaustion of the soil, and the severe winters immediately following. We have known many specimens seriously injured and some killed during the past three years. This was undoubtedly due to extreme frost, which specimens deficient in strength and vigour were unable to resist—that is to say, old examples succumbed while some younger and stronger in the same collection survived. This Thuia produces a great mass of fibrous roots which do not extend to any great distance, and consequently after some years of growth the soil becomes quite exhausted. This is the reason why so many specimens become unhealthy and portions commence dying after a growth of twenty years, more or less, according to the nature of the soil. There is only one method of which we are aware of arresting the decay of such specimens, and that is to act promptly on the first signs of exhaustion by first removing the sterile soil as far as the roots extend; then if the soil is dry, as it generally is, saturate it with weak liquid manure, and next and last adding fresh compost, such as good loam and wood ashes with a slight admixture of bonemeal. This will incite vigorous root-action, the effects of which and the food appropriated will soon be visible in the renovated specimens. Occasionally healthy specimens succumb to intense and prolonged frost. In Col. Drummond Hay's pamphlet, published by the Dundee Horticultural Association, this Conifer is included in the list of those that sustained injury by frost in 1881.

Cropping Vines (A. J. L.).—It is next to impossible to say how many bunches of Grapes may safely be left on a Vine even if, as in your case, the length of the rod is stated. It ought to be obvious to all that one bunch weighing 3 lbs. requires more support than two bunches do that weigh 1 lb. each. Some Vines are more heavily cropped with a weight of a pound of fruit to every foot run of rod than others that have twice that weight. We never consider Vines too heavily cropped that continue producing strong sub-laterals freely beyond the bunches up to the time the fruit is ripe. When the production of such laterals ceases when the fruit is half grown it is an indication that the Vines are overweighted with fruit, however few bunches there are. This, we submit, is a simple test for determining what is a safe crop for established Vines to carry.

The "Queen of Flowers" (Mrs. Milner).—The following is perhaps the passage to which you allude relative to the origin of the above name "in connection with references to the Greeks and Hebrews." It was from the pen of Mr. G. W. Johnson, and first appeared in this Journal upwards of thirty years ago:—"The Rose delightful to everybody, so has it been in all ages and in all countries. It is the *Libetseleh* of the Hebrews, and among them was regarded as the most grateful of flowers. 'Come, let us fill ourselves with costly wines and perfumes—let no flower of the spring pass us by—let us crown ourselves with Rose buds before they are withered,' are the words attributed to the sensualist in the Wisdom of Solomon. It is the *Rodon* of the Greeks, and, like the Hebrews, they chose it for chaplets at their banquets, and as a gift most acceptable to those whom they loved. Anacreon only gave popular customs a poetic dress when he wrote—

"To make the beverage divine
Mingle sweet Roses with the wine;
Delicious will the liquor prove,
For Roses are the flowers of love;
And while with wreaths of Roses crown'd
Let laughter and the cup go round."

"Sappho joins in adulation of the flower, and our readers will see that the trite epithet of 'the Queen of Flowers,' was first bestowed upon the Rose by that 'Tenth Muse.'

"Would Jove appoint some flower to reign
In matchless beauty on the plain,
The Rose (mankind will all agree),
The Rose the queen of flowers should be;
The pride of plants, the grace of bowers,
The blush of meads, the eye of flowers;
Its beauties charm the gods above;
Its fragrance is the breath of love."

Large Palms and Ferns (R. S. L.).—The names of your plants are *Azophila australis*, *Dicksonia antarctica*, *Lantana borbonica*, and *Phoenix dactylifera*. We know of no other method of disposing of them than by advertising, stating particulars relative to their size and condition. There are many large plants for disposal now. If you prepare an advertisement and send it to the publisher he will inform you of the price for its insertion.

Watering Azaleas (Subscriber).—We have never yet seen pots so crowded with roots that we could not learn the condition of the soil as regards moisture by rapping them with the knuckles or a wooden mallet, and we have had plants 8 feet high and which had occupied the same pots for ten years. However, it appears you cannot determine the matter by this test, doubtless because you have not had many years of education in the work. There is one thing you must remember—namely, there is far greater danger in underwatering than overwatering such plants as you describe, especially during their growing season. We can ascertain whether the soil in a pot is dry or wet by rubbing the pot with great pressure with the finger. If the soil is wet moisture will in a moment or two follow the friction; if dry, it will not do so. It will probably not be safe for you to rely on this test at once, but you might nevertheless try it and note the results. The simplest method of determining when to apply water throughout the summer will be by rubbing your finger firmly on the surface of the soil. When the soil is not pasty—that is, if it crumbles even in the slightest degree, apply water at once in sufficient quantity to moisten every particle of soil in the pot. If once the soil becomes really dry such plants will sustain injury that may be very serious. Clear weak liquid manure given once a week would no doubt be of great benefit to the Azaleas, but not to the Epacris.

Yellow Sweet Sultan (M. L. G.).—This is the popular name of the plant of which you have enclosed a flower, its botanical name being *Centaurea suaveolens*. It is an annual, and grows freely in fertile garden soil. It is advisable to sow the seed thinly in pots or boxes towards the end of March or early April, raising the plants in a frame, and when large enough transplanting them in other boxes, and thus have them strong and early for planting out in May. They will grow equally well, however, but not flower so early, if the seed is sown in the open ground at the end of April or the beginning of May. We have plants thus raised just commencing flowering. The flowers are very popular for

floral decorations, and were largely employed last year, as they are this, in the arrangements of flowers for the furnishing of dinner tables and the adornment of rooms.

Charcoal as a Manure (H. J. G.).—You ask "if charcoal is of any good for flowers, and if so how?" As you do not say whether the "how" refers to its action or to the mode of using, we answer both questions by a citation from our manual "Manures for the Many." "Charcoal is a most efficient manure to all cultivated plants, especially to those under glass. Heaths, Rhododendrons, Cucumbers, Onions, Roses, Orchidaceous plants, Hydrangeas, Camellias, Melons, and Pine Apples have been the subjects of extensive and most successful experiments. We think no cultivated plant would be unbenefited by having charcoal applied to the soil in which it is rooted. It should be broken into small pieces, about the size of a nut, and, for potted plants, may be mixed in the proportions of one part charcoal to twenty parts earth. If applied to the open ground one-fourth of a bushel may be sown over a square rod or perch, and dug-in just before inserting the crop. The reason of charcoal being so useful as a manure is very apparent. MM. Sennebler, Saussure, and others have demonstrated that plants are rendered much more luxuriant and productive by having carbonic acid applied to their roots than other plants to whose roots no such application was made. Now, charcoal kept moist, as when buried in the soil, slowly combines with oxygen, and emits carbonic acid—in fact, it slowly dissolves. For drainage in flower pots none better can be employed than 2 inches in depth of pieces of charcoal about the size of a filbert."

Soot for Plants (Idem).—Your question on this fertiliser we also answer from the same work, which can be obtained post free for 4½d. "Soot is one of the most powerful and permanent of manures if dug into the soil. It is the volatilised unconsumed portion of common coal. It is thus constituted:—Charcoal, 371; salts of ammonia, 426; salts of potash and soda, 24; oxide of iron, 50; silica, 65; alumina, 31; sulphate of lime, 31; carbonate of magnesia, 2. It is an excellent manure for Peas, Onions, Carrots, and probably all garden crops. An excellent liquid manure is soot mixed with rain water, in the proportion of one tablespoonful of soot to a quart of water, for plants in pots; but for Asparagus, Peas, &c., six quarts of soot to hogshead of water. It must never be applied to plants in a state of rest. It suits bulbs admirably."

Mites in Soil (J. H.).—They are not the same as those referred to, nor nearly so injurious; in fact, unless in great numbers, they do not appear to do any appreciable injury to plants. They have been introduced with the soil, and may be extirpated by applications of clear lime water, or petroleum applied at the strength of half an ounce to a gallon of soft water, and well mixed by violent agitation. The condition of the *Stephanotis* will indicate whether it has sustained any injury or not. If the plant is healthy its non-flowering is not the result of either mites or maggots. The roots are healthy, and there are no nodosities on those before us. If there are nodosities on the Cucumber roots they are the result of *Vibrios*, which ruin the plants. You will find references to two forms of Cucumber disease on page 479 of our last volume, the issue of June 8th, 1882. The root disease is clearly illustrated in our issue of November 1st, 1877, and the number can be had in return for 3½d. in stamps. Numbers containing information relative to the disease that attacks the stems and fruit can also be had; they are enumerated on the page first quoted. The leaves you have sent appear to have been attacked by red spider, and are also more or less scorched. They are quite insufficient in themselves for anyone to determine the precise cause of their present condition. Cannot you make a fire and scorch the soil before using it? This would destroy all animal life, and greatly improve the fertility of the soil.

Pruning Filberts (S. M., Notts).—The fruit is produced principally on the former year's wood, and generally from compact side shoots, the produce of leaders of a short-jointed and mature appearance. Such lateral fruit-bearing branches may be induced in greater abundance by shortening back strong shoots of this character. Thinning-out, however, is one of the principal matters, for unless this be duly attended to the bush will become crowded with worse than useless spray; it will also obstruct the light from the bearing portions, as well as hinder the circulation of air. A great deal of small spray will be produced on the inner portions of the branches; and this, although of the character of bearing wood, is generally unfruitful, and must therefore be mostly pruned away. Anyone who observes the habit of the Nut closely will soon see that the shrubs are most disposed to bear at the extremities of the branches, thus evincing their partiality to plenty of light and air. These, then, are the portions of the tree where the eye must be directed as to fruit-bearing properties. The leaders, however, must not be encouraged so thickly as to cross each other, and in order to prevent the lower portion of the head from becoming naked a good, strong, well-placed shoot may be occasionally encouraged, heading it back in due time in order to keep it producing side branches. After duly thinning away superfluous shoots the principal leaders should be all shortened. As a general rule, we would say, Remove about a quarter of the length. This will cause the tree to produce abundance of side spray, from which in the future spring the fruiting shoots may be selected.

Names of Fruits (J. M. M.).—It is almost impossible to name Strawberries from one or two single fruits and a leaf, even if the fruits arrive sound and fresh; in this case they were almost shapeless, and we can only say the flavour resembles that of the variety Dr. Hogg.

Names of Plants (W. Cranwick).—1, *Lolium perenne* (common Rye Grass); 2, *Festuca duriuscula* (common Fescue Grass); 3, *Avena pratensis* (Meadow Oat Grass); 4, *Triticum flavescens* (Yellowish Oat Grass); 5, *Festuca gigantea* (Tall or Giant Fescue Grass); 6, *Festuca pratensis* var. *elatior* (Tall Meadow Fescue Grass). (W. Alison).—1, *Gymnogramma peruviana argyrophylla*; 2, *Achrophorus affinis*; 3, *Adiantum pubescens*; 5, *A. decorum*. The *Selaginellas* cannot be named except better specimens arrive in a fresh state, and particulars are supplied relative to the habits of the plants. (W. G.).—1, *Caladium esculentum*; 2, *Gymnogramma chrysophylla*; 3, *Caladium Chantini*; 4, *Ananassa sativa variegata*. (Keswick).—The specimen is quite insufficient for identification, as such a scrap must necessarily be by having been wrapped in dry cotton wool, and simply enclosed in a letter. We have many times stated that that is the worst of all methods of sending specimens, as the dry wadding invariably extracts all the moisture from small soft sprays. We shall require a larger specimen to arrive fresh to enable us to determine the name of the plant. (J. H.).—1, *Doronicum pardalianches*; 2, *Sisyrinchium alatum*; 3, *Phlomis fruticosa*; 4, *Erigeron glabellum*; 5, *Conium maculatum*. (R. A. P.).—The Buttercup-like flower is *Limnanthes Douglasii*. The small white flower we cannot determine, as it was much crushed in transit. (F. M.).—*Chrysanthemum segetum* (the Corn Marigold). (W. D.).—*Eryngium amethystinum*. (M. A.).—*Struthiopteris germanica*.

Dead Drone (Clifton).—The cause of the protrusion from the abdomen of the dead drone found in your garden cannot be traced or explained. A very

slight pressure on the sides of drones will often cause like protrusions and instant death. A sparrow or swallow may have caught the drone in its bill and dropped it. If you catch a drone between the finger and thumb and apply a little pressure a protrusion will instantly appear, killing the drone.

Uniting Bees (J. G.).—You ask if it “is advisable to unite the bees of one stock from which the honey has been taken to those of another stock for preservation, and what method should be followed in doing so?” The bees of a honey hive united to a stock for keeping make it very much stronger, and the practice of uniting swarms in autumn cannot be too strongly recommended. In uniting bees it is an advantage when both lots stand next to each other in the same garden. The bees of the honey hive are first driven into an empty hive, fed, and allowed to settle. About an hour before the union be attempted the stock hive should be fed by sprinkling a pint of syrup over the combs and bees of the stock hive. At the end of an hour both swarms are full of glee and indisposed for quarrelling, and thus they are put off their guard. In this state and at this time the hive to receive the bees should be inverted, and the bees of the empty hive cast into it by a violent shake or thump, all placed on one board, and the work will be done in most cases without the loss of a bee. The work is more easily done than described. In the hands of an expert bee-keeper this method seldom fails, but inexperienced men sometimes fail in their efforts to copy this plan, and fighting may result. In all cases it is well to be prepared with some rag or brown paper dipped in a weak solution of saltpetre and dried. A few puffs of smoke of such rag blown amongst the bees thus united so terrifies them that they cast away their fighting propensities and seek safety anywhere. Another mode is to drive the bees out of the stock into an empty one, and cast the bees of the honey hive amongst the combs and let them have full possession for about an hour; then cast the bees back to their own hive. By this method both swarms are placed at a disadvantage, find that they are not at home, and have nothing to defend. When both swarms are driven into empty hives the oldest queen should be destroyed before the swarms are cast together. Some bee-keepers in uniting swarms drive both into empty hives and cast them together on a sheet in front of the hive to receive them, and thus they unite in running into the hive. All the systems now mentioned will answer if the work is well done. Adopt that which you think you can best carry out.

COVENT GARDEN MARKET.—JULY 19TH.

THE continued wet weather has impaired the quality of soft fruit. Prices remain substantially the same as last week. Grapes remain as before, but good samples of Peaches and Nectarines are still in demand.

POULTRY AND PIGEON CHRONICLE.

MAXIMUM PRODUCE OF FARM CROPS.

WE hold the opinion that it is essential to the home farmer that he should understand the limits within which the production of agricultural crops are confined, or in other words how much it is possible to grow of the various crops under the most favourable circumstances of soil, climate, cultivation, and manuring. If this limit is undefined, the question of tillage and manuring must to a certain extent be also hazardous and uncertain; and although this is actually the result in various instances, it may be well, through the fact of certain crops having been extraordinary in those seasons when everything

has been favourable, to understand also as nearly as possible under what condition of the land and other circumstances such crops have been raised, such as the sort and quantity of seed sown. Unless we are assured of the various matters connected with our productions we cannot estimate how much of the success attending certain crops are the result of accidental circumstances over which we may have had little or no control, because, with all the experience which some of our oldest agriculturists possess, we cannot always accept their statements as satisfactory unless we get a full and fair description and detail connected with any unusual result in crops offered to our notice under the head of Agricultural Maxima. We therefore ask our readers to consider how far the greatest crops of any variety of farm produce which we may set forth for their consideration exceeds their own crops.

A comparison may be made of the circumstances attending both the produce offered for notice as a maximum, and the result of practice under somewhat similar conditions of soil, climate, tillage, manure, and variety of production in other respects; and we feel that under such circumstances benefit will arise in various ways which would never, or seldom, occur unless statements of unusual crops had riveted attention to the subject. We are ready to admit that various great products of the farm crops have been generally owing to the concurrence of extraordinary natural circumstances acting on good ordinary farming, rather than to any special effort on the part of the cultivator—that, in fact, they have happened rather than been sought; and we might suppose that these instances of maximum crops were of little or no interest to the home farmer. But we view this as an unwarrantable conclusion; for although they may frequently come unsought, yet they will be found sometimes to be the result of efforts of a new kind adopted by intelligent, practical, and persevering men, and it is only by examination of the circumstances out of which they have arisen that we are likely to find the causes of our ordinary as well as our extraordinary successes. Notwithstanding that some particular instances may at first sight seem of little lasting service, yet it is clearly on the multiplication of them that our expectations of increasing agricultural progress are most reasonably built. It is also plainly observable that it is the good cultivator only who gives full scope to the natural influences when they happen to be especially favourable.

On the ground, then, of the probability of their usefulness, we shall proceed with our instances of agricultural maxima. The following record we quote from an essay published in the Journal of the Royal Agricultural Society of England in 1859, and given by Mr. John C. Morton, the subject being “Agricultural Maxima.” The object of the writer has, it is stated, been simply to place on record a number of well-authenticated occurrences of the kind, whether explained or not by such history as is given of them. The first record is a most remarkable history, which has probably never been paralleled, and may therefore be accepted as a genuine agricultural maximum. It relates to the year 1844, and is authenticated by trustworthy eye-witnesses. Mr. William Cubitt of Bacton Abbey, North Walsham, well known in Norfolk as an energetic practical agriculturist, writes as follows:—“I now send you a short history of an extraordinary field of Wheat, and also a communication on the subject from the owner and occupier of the land, George Wilkinson, Esq., whose veracity may be relied on—‘This field, situated in the parish of Haisborough, about four furlongs from the sea, contains 5a. 1r. 38p., and is a good loamy soil resting upon a strong subsoil, but sufficiently porous not to require draining, and suitable to every kind of cropping.’ In 1843 it was sown with Peas, probably preceded by Wheat. In the autumn it was sown with Spalding Wheat, about 3 bushels per acre. It came up thickly, and in the following spring and during the summer it presented an unusually luxuriant appearance, particularly so when fully shot into ear, so much so that

many bets were made by practical men as to its probable yield, some estimating the produce at 9 quarters per acre. The field was harvested separately, and on threshing yielded 11 quarters 2 bushels per acre, imperial measure. In the same season and upon land almost adjoining, but occupied by another tenant, Mr. Howes, 10 quarters per acre were produced. This gentleman who had occupied land in the parish for a period of fifty years, affirmed that he never before grew anything approaching to such a crop, 7 quarters per acre being the largest crop ever produced previously to 1844." We have further notes from Mr. George Wilkinson, that although his crop of Wheat in 1844 gave 22 coombs 2 bushels per acre, that he attributes this abundant crop to the season, and not to any particular course of husbandry, which was the Norfolk or four-course system. He further sends the average of his growth of Wheat and Barley on his farm of 400 acres for the seven years commencing in 1844 to 1850 inclusive, the Wheat average being 10c. 1b. 3p. per acre, and the average growth of Barley for the same period being 11c. 3p. per acre. It is also stated that on some farms, instead of the strict four-course rotation of Wheat, roots, Lent corn, and Clover, the custom oftentimes was departed from by taking a crop of Peas or Beans after Wheat instead of roots, and then Wheat again, as was the case in the instance referred to.

Mr. John Wilson of Edington Mains, Berwickshire, author of the article "Agriculture" in the "Encyclopædia Britannica," and well known at the period to which we are referring (1824 and 1826) in the north as a most intelligent agriculturist, gives the following instances of agricultural maxima within his knowledge or experience. He states that "About this period, although I cannot exactly state the year, 5 acres were measured off in a field in this neighbourhood of Hunter's White Wheat; and these 5 acres being selected as the best portion of the field, were found to yield 66 bushels per acre—the highest yield that has come within my knowledge." We have to record an instance of a large Wheat crop of more recent growth—viz., in 1880, near to Southampton, produced upon a sharp gravelly soil on a field of 3 acres sown out of Clover lea once ploughed, and sown with 3 bushels of seed per acre, the sort of Wheat being the Club-head Rough Chaff or Velvet Hull variety; the produce was 66 bushels per acre, the grain being of the very best quality and sold at the highest market price. The land is in the occupation and belongs to the Bitterne Manor House estate, the property of Stewart Macnaghten, Esq. Another instance of large produce occurred in 1870 upon land in South Hants, the property of Mr. John Gater of Black House, West End, about five miles from Southampton, and in his own occupation, in which case the produce was 9 qrs. and 2 bushels per acre of a variety of Wheat called Morton's Red-strawed White. The land is a strong loam on clay but well-drained, and Wheat was drilled on small five-turn ridges after a summer fallow preparation.

We have to record one more full crop of Wheat, and said to have been the largest crop ever recorded in the district where it was grown, which contains some of the most fertile land to be found in the county—viz., the parish of Titchfield in South Hampshire near to the tidal rival Solent, the crop being grown on Fish House Farm, in the occupation of Mr. George Gray, one of the most practical and best farmers of the district. The soil on which the crop was grown is a hazel loam on gravel; and the Wheat, which was of the variety before named called Dwarf Club-head Rough Chaff, was sown $2\frac{1}{2}$ bushels per acre out of Clover lea, the result being a crop of 19 sacks and 2 bushels per acre. This, however, was in the splendid season of 1868, a year of the greatest general abundance we can recollect, for the quality of the Wheat and weight per acre places this crop in the first position in our estimation, because there is no variety of Wheat more esteemed by the miller for producing the highest class of flour than the

Rough Chaff White. We cannot help comparing this crop with that in the first case we have recorded grown by Mr. G. Wilkinson; for although his crop was 22 sacks and 2 bushels per acre of Red Spalding Wheat, that is a variety which we know perfectly well gives a large bulk of straw, but the grain is coarse and weighs light, and is considered by the millers quite a secondary class of grain. We have no desire, however, to detract from or depreciate any crop more than it deserves, but we are bound to state the practical truth in the interest of and for the information we wish to impart to the home farmer; and must conclude with the observation that in the markets which we usually attend the Spalding Wheat is not worth so much by 4s. per quarter as the Rough Chaff White.

[On page 47 last week, second column, eighth line, the word "equal" was inadvertently inserted; and in the following line the sum £173 should read £6173, the most important figure having been accidentally omitted.]

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—This has lately been attended with much disappointment, for no sooner has the land become dry enough for beneficial culture either with the plough or scarifier than the heavy storms which have prevailed in nearly every district of the kingdom have prevented sufficient work being continued on the fallows, whether in preparation for late root crops or for Wheat; and this is a very serious drawback in agricultural pursuits, as the fallow land generally was at the commencement of the spring foul and encumbered with couch and black grass. Harvest, too, is fast approaching, and the necessary work must be anticipated and provided for, such as having the reaping machines, horse rakes, and mowing machines examined and put into proper repair. All other implements, such as the elevator, waggons, and carts, must be examined and made fit and firm for the work which is now fast approaching, for in travelling in a southern county on the 8th ultimo we noticed winter Oats quite ripe enough for cutting, and Rye also not far behind in ripeness. The constant rains seem to have not only prevented effectual horse-hoeing, hand-hoeing, and singling of the Mangolds, Carrots, Cabbage, Swedes, and early Turnips, but has also wonderfully increased the growth of weeds; and on noticing this we were forcibly reminded of the difficulties we had to contend with in some very wet seasons when neither horse or hand-hoeing could destroy the weeds in extremely wet and sunless weather, especially in the years 1853 and 1860, in both of which we adopted the plan of women following the hand-hoers closely and picking up the weeds by hand and carrying them in spread aprons to heaps at certain distances, where they perished or were removed when the root crops were disposed of, either by carting off or feeding off by sheep. Having stated thus much we are bound to notice the result of this practice, for in fact the land was far cleaner after being once hoed and hand-picked than it was where it had been hand-hoed three times without hand-picking. In the ultimate result, where hand-picked the land was as nearly cleansed as possible, whereas that only hand-hoed was covered with weeds. If we recollect rightly two women followed each hoer, receiving 1s. per day as wages. There can in consequence be no question which work was done at the least cost. We also remember that the gentleman who wrote the essay in the Royal Society's Journal upon the farming of the county in which the farm was situated, stated that it was the most successful practice of destroying weeds and cleaning the root crops that he had witnessed during his travels. Unless the weather for the harvest should prove very bad the White Victoria Oats in the early districts will soon be ripe, so that the Turnip seed sown after them will be got in during the month of July with great advantage, if the seed is sown daily on two-thirds of the land, as fast as the crop is cut, tied, and set upon on the other third portion of the land. If, however, the Oats should have been seeded with Red Clover and grass in the spring, and the corn is cut a little higher than usual so as to leave the Clover and grass plants intact, a good crop for cutting as green fodder may be obtained in the autumn months, for we recollect perfectly well having cut up full crops of Clover for cattle and horses down to as late as the first week in November for five consecutive seasons.

Hand Labour.—There is much to be done by manual labour properly directed on the farm, although hindrance may have occurred through showery weather, especially when the ricks of hay, &c., are thatched by one of the farm labourers, as we venture to say that they ought to be. It was always our practice to retain a good thatcher amongst the staff of labourers usually employed on the farm, in order that as soon as thatching is required either of hay or corn ricks it may be done at once, instead of waiting the time and leisure of a journeyman or professed thatcher; and he fills up his time together with other men in drawing and piling straw in readiness for use when the weather may be showery and ill adapted for other farm work. This has always been our mode of management; we can recommend it to the home farmer with great confidence as being well worth his attention. All the pastures or park land upon which cattle

have been fed should have the tufts of old grass now mown down, which will greatly favour a regular growth of aftermath.

Live Stock.—All kinds of sheep and young cattle are extremely dear, and we must again call attention to the policy of rearing all the cattle we require in order that the home farmer may have the full advantage, not only of cattle grazing, but of breeding and rearing likewise. In most cases the same may be done with sheep stock. There are, however, some exceptions which require notice, for we think at the present moment in various midland districts, where a great scarcity of sheep exists in consequence of the losses by fluke rot during a few years past, it may be advisable, where the turf is good and where a bullock can graze till fit for slaughter without artificial food, it requires consideration as to the advantage of feeding sheep as well as cattle on the best pastures, for the sheep certainly will eat out the finest and choicest herbage, such as White Clover, leaving the longest and coarsest grasses only for the cattle, and, in our opinion, depreciating the value of the bullock food, and at the same time running the risk of rotting the sheep. Store cattle of the one year may graze on the poorest pastures and be growing into a condition for feeding off the best pastures for beef the succeeding year, and therefore dispense with the feeding of sheep altogether. Then if we take the marshland districts of certain eastern counties the question becomes almost reversed, for in these the sheep may be kept for grazing without any bullocks at all, and ten or twelve sheep per acre may be thus sold to the butcher every year, because the generality of the marshlands reclaimed from the sea originally do not endanger the health of the sheep by the fluke rot. Still, on those farms not well adapted for a breeding flock the best plan is to buy lambs in the autumn and put them out to winter feeding on roots, &c., in the arable districts, and on farms in certain districts this is done by a customary payment according to the season, and the lambs wintered on dry arable land at so much per head, returning to the occupier of the marshland at a stated time in April, or as soon as the grass on the marshes is equal to the maintenance of the stock in that condition, which, after being shorn, they may be sold in the markets for mutton, but only the long-woolled breeds of sheep are used in this way.

ROYAL AGRICULTURAL SOCIETY'S SHOW.—The awards for the best cultivated farms were announced at the General Meeting of members, when it was found that the first prize of £100 was awarded to Mr. J. J. Ratcliff, The Priory, Beech Hill, near Reading; and the second prize of £50 was awarded to Mr. Geo. Adams, Pidnall Farm, near Faringdon. The Judges recommend that an extra prize of £25 shall be awarded to Mr. Jenkin Davies of Wickerroft Farm, Englefield, Reading. We are informed that all the above competitors used Messrs. Suttons' seeds. The Prince of Wales visited Messrs. Suttons' trial grounds during the Show, and expressed the gratification that the inspection had afforded him.

POULTRY AND PIGEONS

CROSS-BRED TABLE POULTRY.

CONTINUING our remarks from page 48, we come to the third cross. The Dorking-Game cross has long been known. Before the days of Asiatic importations it was to be seen in many a farm-yard where a thrifty henwife had tried to improve her stock; the hens were known as excellent mothers, and generally layers of larger eggs than either of the parent races. The cross is still a common one, especially in the establishments of country gentlemen, where the poultry run in the park or the woodlands about the gamekeeper's cottage, and where the cuisine is good. Dorking-Game chickens are very plump, and their flavour gamy and excellent. We decidedly recommend that the male bird should be of the Game race; the Game cock is the traditional model lord of the yard, hardy and vigorous, and considerate for his wives; Game hens are quarrelsome and spiteful to each other's families, while Dorkings are generally peaceful. As to the kind of each breed to be crossed, much depends upon the fancy of the breeder. If he desires birds of rich red, yellow, and brown hues a Black Red or Brown Red cock may be crossed with Dark Dorking hens; if soft Silvery-Greys, a Duckwing cock should be procured and Silver-Grey Dorking hens; if pure white, a white Game cock and white Dorking hens, though curiously enough the chances are that their produce will not be pure white, but show dark feathers here and there, and yellow or red bands in the wing. One who likes peculiarity and distinctiveness in his poultry yard may gratify it by crossing a Red Game cock with Cuckoo-Dorking hens; the male produce are often very handsome, with a kind of golden cuckoo hackle. If white legs are specially desired it should not be forgotten that both White Game and Black Reds are procurable

with white legs. The latter are now somewhat rare; they are the old Knowsley strain, which still is prized by some amateurs, though the exhibitor would have little chance of winning with them. The cockerels of this cross should be killed early, for they naturally inherit some of the spirit of their paternal ancestors, and terrible frays may occasionally take place among a party of them. The pullets prove the best of mothers, but cannot always be trusted near the chickens of another hen.

The Dorking-Poland cross is another long known, but seldom tried in these days. Whether there once was a distinct lark-crested breed of fowls we have before discussed; however this may be, there certainly have long been seen in well-cared-for farmyards hens which show traces of Dorking blood in small fifth claws, and of Poland in small tufts. They are almost invariably good layers. Next to the Dorking we believe, possibly with the exception of La Flèche, Polands to be the best table fowls. Their bones are small, their breasts round and plump, and their flesh delicate; they are, too, always ready for killing. All these good qualities, combined with greater size and quicker growth, are to be found in their half-bred produce when the second parent is a Dorking. We remember in the class for table poultry at the Birmingham Dairy Show of last year to have seen a very pretty pen of chickens from the Patshull yards, a cross between Silver Polands and Cuckoo-Dorkings. They were short-legged, round-breasted, and small-boned, and just such as we should fancy for the table; they were very pretty too.

Any one of these four crosses will, we believe, be found a useful one. It must not be forgotten that for the production of strong and vigorous chickens robust and vigorous parents are necessary. They must not, too, be too numerous a troop. One cock and four or six hens on a free range will produce a stock large enough for most establishments. If the cock be Game, still more hens may be allotted to him. If, however, chickens for market or a very large household are required in numbers beyond the natural produce of one pen, two or more breeding pens should be made up separately. It is seldom advisable to let two cocks run with a double harem of hens.—C.

THE POULTRY CLUB.

A MEETING of the Committee of the Poultry Club was held on Wednesday, July 12th, at the Charing Cross Hotel. There were present Messrs. S. Lucas (in the chair), T. W. Anns, R. A. Boissier, A. Comyns, and C. F. Montresor.

The following new member was elected—Mrs. Herbert Philips, Oak House, Macclesfield.

SHOWS UNDER CLUB RULES.—The Secretary reported that Leek, Wolverhampton, Caistor, Hanley, and Lamberhurst Shows are to be held under Poultry Club Rules, and subscriptions were granted to the funds of the two first-named Shows.

The next meeting was fixed for August 4th at the Charing Cross Hotel at 2 P.M.—ALEX. COMYNS, *Hon. Sec., Poultry Club, 47, Chancery Lane, London, W.C. July 17th, 1882.*

REMARKS.

- 9th.—Heavy showers, with bright intervals.
 10th.—Fine bright morning, very heavy showers in afternoon.
 11th.—Rain during day, fine evening.
 12th.—Generally fine and bright, shower at 2.45 P.M.
 13th.—Showery at first and windy, afterwards fine and bright.
 14th.—Slight showers at first, afterwards fine and bright.
 15th.—Wet morning, fine afternoon and evening.
 Temperature again near the average, rainfall much in excess.—G. J. SYMONS.

LILIUM GIGANTEUM.

HE demand for this grand Lily continues so great that its price is still beyond the means of the more humble class of gardeners, otherwise it might be a common ornament of cottage gardens, as there is nothing in its requirements which makes its cultivation difficult. It is to be hoped that so many generations of seedlings are now in the course of development, that in a few years it will become common. Raising plants of it from seed to flowering size requires patience—more patience than the writer possesses, as about ten years is said to be required for the work. The process has often been described, and I believe requires but little skill. A plant which flowered and ripened seed out of doors last year in my garden, but which was grown in a pot, produced eleven flowers on a stem 9 feet high, and ripened eleven pods of seed. The seeds are so charmingly arranged in rows for counting that a very easy process of multiplication gives the total, and I distributed amongst friends who I thought would appreciate them between seven thousand and eight thousand seeds from this one plant. The bulb which has produced a flowering stem dies, as is well known, after flowering, but produces about five or six offsets, which are from three to four years, according to circumstances, before they flower. Early flowering—I mean as regards age, not season—is not to be desired in *L. giganteum*. The more that luxuriant growth is encouraged by rich deep soil and by spring watering, the longer deferred and the finer when it comes the flowering will be.

In the autumn of 1878 I bought what was sold as a "flowering bulb" of *L. giganteum*, then about as large as and not unlike a large-sized bulb of *Amaryllis Belladonna*. I planted it at once in a Lily bed made on a raised terrace, and backed by a wall at the north end, containing good peat 4 feet deep, and planted with *Ericas*, *Andromedas*, *Skimmias*, and such-like dwarf evergreens. I have dressed it annually with leaf soil, and perhaps a little very old decayed manure, and with soot to keep off the slugs. For three years the leaves grew larger, dying down late in summer, but this year a huge stalk appeared in April, being, I should say, more than 15 inches round at the base, and when it had grown upwards of 10 feet high it opened twenty-three flowers the first week in July, all equal in size. One of these was knocked off—my gardener suggested by a jackdaw settling on it, but more likely by a gust of wind. Five feet of the stalk with the other flowers (as I was only at home for one day) I cut off and took to a village flower show near Chester. The cutting was no easy matter; the stalk is hollow, but as tough as a green Bamboo, and I had to

notch it round with a large and sharp garden knife for some depth before it would break off. I had my keeper to carry it at arm's length in front of him, and luckily there was no wind, as it would not go inside a carriage, and of course it produced a sensation at the Show. The stalk is so strong and the rooting so firm, that though the westerly gales find out my Lily beds, and I am obliged to tie *L. pardalinum* from the time it is a foot high to the very top of the flowerstalk, I never thought of giving any support to *L. giganteum*. I have given the history of this specimen from first to last, because rules for the general treatment of the plant may be deduced from it.

I have often heard of two places in the kingdom where *L. giganteum* has been established in the shrubberies in quantity, and grows almost without cultivation. They are Merton Hall in Norfolk, belonging to Lord Walsingham, and Gordon Castle in Morayshire, the Duke of Norfolk's. On looking at the rain chart of Great Britain it will be seen that the rainfall of both these places, especially the former, is below the general average, and both have well-defined seasons and warm summers. Dry winters, late springs, and genial and even summers afford conditions favourable to the growth of most Lilies. These conditions, however, are not to be found in Cheshire, where the wet continues all the year round, and where a month of winter and of summer—last August and last January for instance—might often change places without anything very abnormal in the temperature or the rainfall. Hence the cultivation of Lilies in the open air in Cheshire meets with very partial success, and the frequent checks with which the plants meet in their growth encourage the disease called "spot." Still in the same bed in which the leaves and buds of *L. auratum* and *L. Humboldti* annually decay with spot before flowering, *L. giganteum* never showed the slightest indication of spot at any stage of its growth, and never took to any unkindly ways. I now have a good stock of offsets in different degrees of forwardness, but, as I said above, I am not anxious to hurry them into flower.

As far as I can judge no choice Lily seems to have a better constitution or to be more easily managed than *L. giganteum*, provided it has a rich, deep, but not too heavy soil, and a sheltered situation. Shelter it must have, or the large fleshy leaves would be torn to pieces, and the long petals of the flowers broken off by high winds. Still, I cannot see why the plant should not in time find its way into every cottage garden which supplies the mentioned conditions. Judging from what I see both in nurseries and in private gardens, I believe there are millions of home-grown seedlings scattered over the country in a more or less forward state, and are destined to produce a new feature in gardening.—C. WOLLEY DOD.

THE LONGLEAT VINES.

BUT for the fact that numbers of readers may be expecting me to say something now that Mr. Taylor has told us so much about his Vines I would not write a single word, for although the Editor left the question of whether it is better to restrict or give latitude to young Vines, the subject under Mr. Taylor's hand has broadened till it embraces everything in the cultivation of the Vine under glass. Under these altered conditions very little remains for me except to compliment Mr. Taylor on the able way he has acquitted himself of the self-imposed task, and to congratulate the readers of the Journal on the nature of the information which has been placed at their service

Not everyone would have so fearlessly laid themselves so open to attack from critics inclined to be adverse and unmerciful. It is very easy to prophesy after the event, and even the most ignorant could say, "I could have told you so;" but those who have struck out into "fresh fields and pastures new" know very well that events not calculated on or even dreamed of sometimes occur. Those who keep straight ahead in the beaten paths may keep pretty free from blundering, but they will hardly make discoveries or leave the world wiser than they found it. It is different with the seeker after better methods. He will make mistakes, even though endowed with more than average intelligence, and be laughed at by those who have less. To make no blunder proves nothing; to make many may prove, not that the perpetrator is incapable, but that he is not content, and is desirous of marching a step beyond the point reached by others. To be sure, blundering is not of itself a sign of incapacity, though incapables certainly blunder most, and are most ready to lay blame when only praise is deserved. This much we have said, not in defence of Mr. Taylor, who needs no such defence, but rather for the purpose of exploding an erroneous way some people have of judging others.

That Mr. Taylor did make one or two mistakes is, in fact, rather comforting to others, myself among the number, for really one is apt to feel incapacitated when mistakes occur in his own hands, and when he imagines nobody else would have been so stupid. Indeed, I am not sure if greater profit would not result if we were all to chronicle our mistakes and say less about our successes. Mr. Taylor has combined the good of both systems, for he has not only told us when and how he failed, but also by what means he secured success. The consequence of this is that a very large number of readers must have derived no small amount of benefit from what he has written.

Months ago, just at the outset of Mr. Taylor's description of the Vines at Longleat, the printer made one mistake by leaving out at the end of a paper "to be continued," and I made another by supposing Mr. Taylor had said all he intended to do, so a paper about my method of manuring Vines and the reason why was posted to the office as a finisher to what I had before written on the subject of Vine culture. I suppose that, now Mr. Taylor has really finished, it will see the light when the pressure becomes less severe on the space, and perhaps it will be found that, to some extent, I have supplemented what has appeared. I forget exactly what I wrote, but, if not mistaken, there are some analytical tables in it that will, perhaps, help even Mr. Taylor, for there cannot be any doubt but that when we know just what Vines take up we are guided in our efforts to supply those wants.

Pending the publication of that paper I will in the meantime confine myself to making a few remarks in a friendly way on what Mr. Taylor has written. To go over a tithe of the ground is more than I shall even attempt, but there are a few points that may be profitably noticed, and to these attention shall now be called.

The first is the matter of concrete bottoms. Like Mr. Taylor, I have come to the conclusion that these are really a mistake doubly, unless in such special cases as Longleat for instance. I also think with him, that first-rate Grapes could be grown on ordinary soil with very little preparation, and decidedly think it a mistake in nine cases out of ten to make artificial borders, as I believe these are often inferior to the natural soil. I am also unable to comprehend how it is impossible to give Vines all they need from the surface and to keep them in health indefinitely by such means. First-rate cultivators maintain the opposite, and their opinions must be listened to with respect, but we may be pardoned if we entertain doubts, of which the above is one.

Mr. Taylor's preference for applying water by cans in order to know exactly the quantity that is applied is scarcely justifiable, for it is surely an easy matter to calculate how much water will pass through any given pipe at any given pressure during any given time, and there is really a great difference between allowing water of itself to run where it is wanted, and paying gangs of men to apply it. It is to be hoped that those who contemplate erecting ranges of glass

will not be led into thinking that pumping water is better than allowing it to run of itself. As one whose arms have ached with water-carrying, I would urge upon proprietors to save much labour, and consequently money, by having pipes and hose and a proper supply of water from a high level if possible.

I cannot say I am enamoured of Mr. Taylor's waste of space by having his Vines so far from the glass. It is a mistake not to allow plenty of room between the glass and the trellis, but your correspondent has gone to the other extreme. As for the advantage of air-giving, the system of admitting air at the front only is, I hold, radically wrong; it is much better to admit it at as many small openings as possible. Neither do I think Mr. Taylor's elaborate system generally applicable. When it can be carried out as he advises nothing can be said against it, but doubtless hundreds of your readers are quite unable to adopt any such system of shutting and opening, and opening and shutting, to suit every passing cloud. Those who make compromises, and on blinking days have less ventilation than they would do were the sun to shine uninterruptedly, and more than if it were not to appear at all, find their system answer very well, and that a little air left on all night is a good plan, saving the Vines from being scorched if ventilation should be forgotten for an hour or two on a light summer morning. When at least one responsible person is within running distance of the vineries, closing when dull and opening when bright, is right enough, but another plan has to be adopted under different conditions.

I fear Mr. Taylor will look upon me as a "barbarous Turk" when I tell him that the last Vines I raised for planting had the points of the strong roots deliberately pinched off, and he who was so careful not to trim one will not agree with me when I say that such is of decided benefit by causing a multitude of fibrous roots to form instead of one long fleshy thong; but if he objects, I will question his consistency, for he, too, objects to fleshy roots, and he, too, prefers fibrous ones. If I err it is in good company, and more than one successful man has practised it.

The question of how far young Vines should be allowed to grow in their initial stages should, I think, be kept distinct from the one of how much young rod should be left at pruning time, although in the discussion which preceded Mr. Taylor's papers, and also in his papers, they were confounded. After reading what Mr. Taylor has said and thinking the matter over, I am inclined to think that cutting down young canes to within a few inches of the ground is a mistake—not for the same reasons urged by Mr. Taylor, however—but I am not at all convinced of the propriety of restricting their growth to about 10 feet. Mr. Taylor says, possibly with truth, that growth made late in the season or after July cannot be properly ripened. No matter what date we fix upon as the proper time for stopping—we would probably agree on that point—I submit it is only a question of dates and not of length of Vine rod at all. If I have 10 feet of Vine rod made and stopped by the 1st of July I am unable to see that it makes any difference whether there is another 10 feet below that of the same or the former year's growth, for each foot will depend on the conditions to which the whole is subjected, be the whole 10 or 20 feet. The difference consists in the time lost or saved. As for cutting down, perhaps the best rule would be to leave as much as could be induced to break into enough furnishing spurs; and, but for the supernumeraries in Mr. Taylor's way, I have read him wrongly if this, or something like it, is not what he would have practised.

I am quite at one with Mr. Taylor about the scraping, peeling, and painting with nasty mixtures to which Vines are so often subjected, because it has been the custom time out of mind to do so. There can be no doubt of his system of stopping and pinching being the right one. Rubbing off growths that are not wanted just as they appear, and stopping growths by merely picking out the smallest points, is very much to be preferred to allowing growths to utilise sap, to half smother permanent growths and leaves, and then to be broken off by the yard.

Perhaps the most valuable part of Mr. Taylor's experiments was his attempt to do without lime. Far too many try that.

True, they apply plenty to begin with, but the manure and water applied have the effect of making what is given very quickly disappear. If Mr. Taylor has impressed on every Vine-grower in the country that a little lime must be given periodically to Vine borders, or it will be useless to give anything else, then he has added tons of fruit to the future annual produce, and an incalculable sum of money from being spent on new borders, and saved many a heart from aching.

Your correspondent has applied the best manure without a doubt—a manure quite comparable to the generally employed guano; and if everybody can be made to understand that, money may be kept at home instead of being sent abroad. Money is draining away from the country in many directions that there is no necessity for. Mr. Taylor's example, and especially the result of the practice, will stop some of it. Until I see what is in the paper which is now in the Editor's hands I will say no more, but only point out that, as the main substances in bones are abundantly present in the manure used by Mr. Taylor, the bones may be saved. If anything be wanted I should say it was potash. Possibly the other paper will make that apparent.

In conclusion, let me hope Mr. Taylor will not be treated as he has treated other writers. He has, he says, never read an essay on Vine culture, and laid down the only book he ever took up on the subject whenever he found that he could not agree to all that was in it. Of all Mr. Taylor's mistakes this was the greatest, and it might be worth while for him to read some even yet, if for no other purpose than finding out that he is not so unorthodox as he imagines.—SINGLE-HANDED.

I HAVE read with great interest Mr. Taylor's history of the Vines at Longleat, and now he has finished it I desire to thank him most heartily for the valuable instruction I have gained by studying it from beginning to end. I think we ought to be very grateful to him for so much valuable information.—A YOUNG GARDENER.

THE ROSE ELECTION.

BOTH in print and to myself privately the electors of 1881 urged the propriety of separating the Teas and Noisettes from the Hybrid Perpetuals. I promised that the subject should be attended to; I therefore now put forward the plan for this year's election. As regards Teas and Noisettes, placing the lesser first, the question I ask is the following:—Name what you consider in your own experience of their growth the best twenty Teas and Noisettes for exhibition purposes. Distinguish by some mark the best ten.

As regards other Roses the question is—Name the best forty-eight varieties of Roses (excluding Teas and Noisettes) for exhibition purposes, as tested by your own experience. Distinguish by some mark the best and second best twelve.

This election will be of more importance than any of its predecessors, as it will proceed strictly on the lines of the catalogue of the National Rose Society. The following Roses will therefore be considered similar, or at any rate "too much alike." I, as returning officer, will permit the vote to be given to either variety, and will tabulate the results, but it must be distinctly understood that naming both will entail much extra trouble on myself, and perhaps disqualification on the voter.

It will also save trouble to all if intending voters, who must be prizetakers at National Rose Society exhibitions or frequent prize-winners at local meetings, would write to me for a form to fill up.

"TOO MUCH ALIKE" ROSES.

TEAS AND NOISETTES.

{ Adam	{ Madame Bravy
{ President	{ Alba Rosea

All lists of votes must be returned to me at latest by the last day in August, and the result of the poll will appear in the *Journal of Horticulture* in October.

It is also necessary to remind all electors that the Hybrid Tea Roses cannot be classed amongst the Teas and Noisettes.—JOSEPH HINTON, *Warminster*.

BIRMINGHAM ROSE SHOW.

THIS Show was held on Thursday the 13th of July in the Aston Lower Grounds, about two miles from the centre of Birmingham. The public expected to find a larger collection of Roses staged, but owing to the bad weather, which was very general throughout the south, west, east, and midlands, Messrs. B. R. Cant and F. Cant of Colchester; Messrs. Keynes, Salisbury; Messrs. Davison & Co., Hereford, telegraphed the previous afternoon to the effect that the rain, and in some of these districts the hail, prevented them from finishing the cutting of their blooms. Doubtless, too, Manchester Show on the following day, and Wirral on the Saturday, had something to do with the smallness of the Show. If, however, it was a somewhat poor Show as regards quantity, the public were rewarded by the excellent quality of the Roses. The colour was excellent, and in size, form, and substance both amateurs' and nurserymen's exhibits were good. It was most interesting to see Roses, many of which were fit for any stand, grown within two and three miles of the centre of Birmingham. We have been taught that it is useless trying to grow Roses in smoke, but it is not so. Mr. Griffiths and Mr. Rickards of Edgbaston staged blooms of most excellent quality; but I must now give the results.

Nurserymen.—For seventy-two single trusses Messrs. Paul & Son, Cheshunt, were first; Cranston's Company a very close second. In the first collection I noticed as very good, François Michelon, Marie Baumann, Duke of Edinburgh, Beauty of Waltham, Capitaine Christy, Horace Vernet, Madame Eugénie Verdier, A. K. Williams, Annie Wood, Le Havre, and a very excellent White Baroness. In Cranston's Company's collection there were superb blooms as follows:—Comtesse d'Oxford, Countess of Rosebery, Alfred Colomb, Mrs. H. Turner, glorious colour; Emilie Hausburg, and Royal Standard so called, but without a doubt another Emilie Hausburg; Lady Suffield exceeding pretty, and A. K. Williams. For thirty-six trebles Messrs. Paul & Son were again first, and Cranston's Company second. In Messrs. Paul's stand, Général Jacqueminot, A. K. Williams, H. Vernet, Duke of Teck, and Duc de Rohan were grand. While the second-prize stand had very well represented, Emilie Hausburg, Charles Darwin, Mrs. Jowitt, Abel Carrière, magnificent; Mons. Eugène Delaire, a very distinct new dark Rose, not large but colour very good; and Mons. Noman. Twenty-four trebles, Cranston's Company were first, there being no other entry in this class.

The classes open only to nurserymen residing in the three shires of Warwick, Worcester, and Stafford, Messrs. Perkins & Sons of Coventry staged some very good Roses. In the open classes they would have run the larger nurserymen closely. In the twenty-four single trusses this firm exhibited a truss of Abel Carrière consisting of a very large and perfect bloom surrounded by no less than six buds. In this class Mr. F. Perkins of Leamington was second, and Mr. Wm. Bryant, Rugby, third. In the twelve trebles and twelve singles the same order was observed.

Amateurs.—For thirty-six singles Mr. Whitwell of Darlington was first with a stand of very superior blooms to that which won the challenge trophy at South Kensington on the 4th inst. These thirty-six glorious blooms were in the opinion of the Judges quite equal to the stands staged in years past by Messrs. R. N. G. Baker and T. Jowitt, "the great twin brothers." Certainly Mr. Whitwell is to be congratulated upon his success; every bloom was large, not one coarse. If it rained and hailed elsewhere it could not have done so at Darlington, for Mr. Whitwell's Madame Lacharme was the finest I have seen for many years. Where all were so good it seems invidious to name the best, but these were Annie Wood, Alfred Colomb, Charles Lefebvre, Duke of Edinburgh, Capitaine Christy, and Paul Neyron, this last quite round and not coarse. Mr. Whitwell also showed very good treble blooms of this Rose. His advice is as follows with regard to this variety, "Cut young and only from cut-backs." Mr. J. Davis, Salisbury, was second in this class, and Mr. Parnell, Rugby, third.

In the class for twenty-four singles Mr. Whitwell was again first, Annie Wood Annie Laxton, Alfred Colomb, and Marquise de Castellan being his best blooms. He was followed as before by Mr. Davis and Mr. Parnell. Again in eighteen trebles the Darlington hero was to the front, but he had a close fight this time, Mr. Pemberton of Havering-atte-Bower, Romford, contesting point by point, and had it not been for a very bad treble indeed of Star of Waltham he would have been equal with Mr. Whitwell.

The local classes were very well represented, the prizes being generally divided between Mr. Griffiths and Mr. Rickards, though Mr. Griffiths had the largest share.

It seems a pity that such a central situation as Birmingham should not be the chosen spot for the National Rose Society's next provincial show; but a much wider extent of energy, liberality, and love for the Rose must exist there before any really successful show can be held. Birmingham used to have an excellent show, and, as

history repeats itself, so the time will come again.—J. A. W., *Alderminster*.

CHISWICK TRIAL PEAS.

IN examining the above many were noticed as being far behind the best kinds now in commerce; in fact, a Pea must be very good to gain a place in such company as Telephone, Pride of the Market, Stratagem, John Bull, or James' Prolific. There seems little opening for improvement either in dwarf or tall kinds; but this was said before the above were sent out, and in a few years these grand varieties may be, and we hope will be, eclipsed. From observation many of those on trial appeared to be more like selections from other kinds obtained by chance than the results of a carefully pursued course of crossing with the best types in commerce.

There is yet something to be gained that will combine the size of Stratagem with the rich flavour of that old gardeners' friend in need *Ne Plus Ultra*. Maclean's Premier is an excellent Pea, but the three consecutive bad harvest seasons have caused it to be scarce, or this would make a good parent. Again, white Peas have very little chance against blue or green-seeded Peas, and such must sooner or later go out of culture. Gardeners are rapidly advancing in knowledge and appreciation; the Knight's Marrows are already things of the past, and consumers are not, and cannot be expected to be, satisfied with Blue Scimetars.

There has been a great advance in early dwarf wrinkled Marrow Peas; but, except in favourable years and in suitable situations, they are not to be depended on for winter sowings. What with decaying in the ground, to which round Peas seem least liable, and the ravages of birds and slugs above and mice below ground—for they seem to prefer the sweeter foliage of the wrinkled kinds—the rows are frequently scanty; and this may account for the demand yet in vogue for Ringleader, Sangster's No. 1, and such small-shot Peas, which after all require less attention and do fill the basket and fill it early, though they ought to give place to Emerald Gem and William the First. The latter is not yet fixed in character, but is a very fine first early, and the true stock would be a good parent to work on to obtain a first early green round hardy Pea. Dean's Dwarf Marrow and Turner's Emerald are really good earlies; but American Wonder is so short in the haulm as to preclude its coming to the fore, although it looks well when cooked.

Veitch's Perfection is yet grand when well grown, and is desirable in point of flavour; but may yet be improved upon, for the fault is that this and Climax, Eugénie, Day's Sunrise, and other 3 to 4-foot Peas do not give pods full to the end, and do not give a fair return, except under favourable circumstances. Premier would make a good cross with this section.

I venture, therefore, to indicate a few different lines of work for hybridisers, and, as in breeding cattle or poultry it would be madness to start with an inferior stud, let raisers get the best to start with. Say try for

First, a round-seeded early green Pea with large pods—one that will withstand our winters, and be in advance of Dean's Dwarf and Blue Peter.

Second, a 3 4-foot Pea that shall combine the flavour and appearance of *Ne Plus Ultra* with the general habit and size of Stratagem.

Third, a Pea of the Veitch's Perfection style and flavour that shall fill out its pods thoroughly.

Fourth, a tall variety that shall give the enormous peas of Hays' Blue Mammoth, which rarely exceed five or six good peas in a pod, combined with the colour and full pod of the *Ne Plus Ultra* race, say, with the giant pod of Telephone.

All these should be blue or green Marrows and bear their pods in pairs. At the time the Committee viewed the trial Peas Culverwell's Autumn Giant was not ready, but it was the largest pod on the ground. In conclusion, all Pea-raisers are reminded that at Chiswick they can depend on a fair trial being made under Mr. Barron's capable management.—G. B.

AUSTRALIAN BIG TREES.—The Minneapolis *Lumberman* has an article on the gigantic trees of Australia, of which the following is an extract:—"The trackless forests in the west of Tasmania contain huge timber, and bushmen report that they have met with specimens of Eucalyptus measuring 200 feet from the ground to the first branch, and fully 350 feet in all. Until 1873 there was standing on the eastern slope of Mount Wellington, within four miles of Hobart Town, a Eucalyptus measured at 86 feet in girth and more than 300 feet in height, and its ruined bole still forms a grim chamber in which many a merry party have enjoyed a picnic. The famous tree of the Huon forest measures 70 feet in girth 6 feet from the ground, and is stated to be 240 feet high, but in the deep gorges of this grand forest the

writer has seen higher trees than this, though not of quite equal circumference. But Victoria now claims the glory of holding the biggest of all the living 'big trees' in the world, so far as height is concerned. In the Dandenong district at Fernshaw has recently been discovered a specimen of Eucalyptus amygdalina, or Almond-leaf Gum, which has been accurately measured as reaching the enormous height of 380 feet before throwing out a single branch, and 430 feet to the top, and having a girth of 60 feet at some distance above the ground. Some idea of what a height of 430 feet represents may be gained from the fact that this Gum Tree, if growing by the side of the Houses of Parliament at Westminster, would overtop the clock tower by exactly 100 feet."

SPIRÆA JAPONICA.

THERE are few plants better known, and none more useful, than this; but lately I have been thinking that many might have it much longer in bloom than is generally the case with very little extra labour and much advantage. With us the first flowers were cut last December, and the last at the end of June. During those seven months we had spikes more or less weekly. The plants which flowered first and on to the month of April were forced in pots. Then those in cool frames flowered, and were followed by some on south borders, and the last were a number of plants growing at the base of a north wall. Here they are never exposed to the sun, but they always grow and flower freely, and we have frequently cut flowers from them as late as the present time. The roots for forcing first are grown fully exposed to the sun, and are consequently matured early, and from Christmas onward are easily brought into flower. Later on they may be brought forward more easily, and others later still bloom naturally; but it is the plants near the north wall which keep up the supply so long, and it is to this plan of growing a few plants particular attention is called. For all kinds of winter floral decoration the flowers of this Spiræa are highly esteemed, but the spikes are never out of season, and are quite as much valued in July as January.—J. MUIR.

CHERRY HOUSES.

PERHAPS there is no hardy fruit crop grown in gardens that causes so much disappointment as Cherries, on account of the great difficulty that is experienced in protecting the fruit from birds. When trees are grown by the acre, as in Kent, there is sufficient both for birds and cultivators, but it is very different where only a few trees are grown. It is not too much to say that the supply of Cherries is not only insufficient in the majority of gardens, but the period during which fruit might be had is much too limited. It is somewhat surprising that the affluent should remain satisfied with this state of things, especially since a remedy can be so inexpensively provided. This consists in providing houses and growing trees in pots. The most economical and satisfactory example of growing Cherries in pots under glass that has come under my notice is in Messrs. Rivers' nurseries at Sawbridge-worth. The Cherry house is a simple span-roofed structure, inexpensively constructed, and not heated. The sides are formed of rough boards secured to stout posts that have been affixed at intervals along both sides of the structure, but the sides are not boarded up to the glass, as a space of about 18 inches above the boards is simply covered with fine-meshed wire netting. There may possibly be a lid in addition which may be opened or closed as needed, but from the interior of the house only the netting was visible. The roof is a fixture, and if there is any provision for ventilation there it will simply be at each end just over the ridge board.

The sides of the house do not exceed 5 feet in height, nor the height to the ridge in the centre 8 feet. The path runs under this ridge with borders about 4 feet wide on each side; on these four rows of trees are arranged, and they bear prodigious crops of splendid fruit. In glazing the roofs of his houses Mr. Rivers uses no top putty, which is considered worse than useless, but the glass is well bedded in putty, and made secure by two sprigs or brads driven into the sashbars near the bottom of each square, the laps keeping the top of the squares safe. The cost of such a house is trifling, while the fruit that is produced in it is of undoubted value.

From this plain yet essentially useful structure Cherries of the finest size and quality are gathered during a period of five months. So heavily do the trees in pots bear that the fruit can be gathered by handfuls, and a dish filled in two minutes. The fruit of some of the varieties hangs, like Grapes, for weeks after it is ripe, and develops a richness that is not attainable in the open air. Sound firm soil and attention in watering, with cleanliness, are the essentials for success in growing Cherries in pots, and just in proportion as these are provided so will the reward

be. In the north and cold districts generally it would be doubtless advisable to provide the means for affording a little artificial heat if it were needed; but it would be wise to use it cautiously, for there is danger of amateurs playing with fire when they have the opportunity of doing so, and it is not beyond the bounds of possibility that there may be gardeners addicted to the same practice. There is, however, no fire in connection with the Cherry house at Sawbridgeworth, but always ripe fruit in season—June to October, both months inclusive.

A few varieties of Cherries for affording a supply of fine fruit of the first quality over the longest period are the following:—Bigarreau Jabouley, the earliest of all, light red, a free bearer, and of superior quality. Early Rivers—this forms a fine succession; it is a splendid Cherry with large black fruit, juicy and rich. Governor Wood, an American Cherry, very productive, and of excellent quality; colour light red. Late Black Bigarreau, a variety of well-proved excellence. Monstreucuse de Mezel, the largest of all the Bigarreus, fleshy and rich; the two latest sorts

being Emperor Francis and Guigne de Winehal. Three or four good trees of each of the above, well grown and managed, will give an abundant and lengthy supply of this popular fruit.

IMPATIENS SULTANI.

AMONGST recently introduced flowering plants this Impatiens appears to be not only one of the most distinct, but also likely to be one of the most useful for stoves or similar warm structures. It is easily grown, is of surprisingly free habit, flowering continuously for several months, and the bright rosy-coloured blooms are so plentifully produced that a few specimens have a most showy appearance amongst foliage plants. It has been tried in cooler temperatures, and even out of doors in a sheltered position; but though it grows and continues healthy under such conditions, it does not flower so satisfactorily, and consequently is not so attractive as in a warm house. One great advantage it possesses is, that after flowering the plant can be cut back moderately and

Fig. 16.—IMPATIENS SULTANI.

fresh growth started, which will quickly refurnish the plant and produce flowers abundantly, thus yielding prolonged attractions.

Some particulars respecting the origin of this Impatiens were recently published in these pages, and may be advantageously repeated now. "Its appearance at Kew was due to a mere accident, and shows how many valuable plants may be lost by the want of a little thoughtful care. A case of plants had been received there from Zanzibar, and a portion of the soil in this was turned out under a stage in one of the propagating pits, where it was undisturbed for some time, when amongst the weeds, which generally appear plentifully in a short time, was noticed this Impatiens. It was carefully potted and grown, and when it flowered its full beauty was revealed. It was at first believed to be either Impatiens Walleriana or a near ally of that species, but Sir Joseph Hooker has now determined it to be an undescribed form, and has named it in honour of the Sultan of Zanzibar. It is of very compact bushy habit, with narrow, ovate, slightly tapering leaves, the flowers being about 1 or 1½ inch in diameter, and very bright rosy scarlet in colour, a peculiarly distinct but most effective hue. They are produced singly in the axils of the leaves, especially towards the summit of the stems, but so freely that a well-grown specimen appears to be quite a ball of flowers."

As regards the cultural requirements of the plant there is little to be said. Ordinary rich light loamy compost suits it well, with abundance of water during growth and occasional supplies of liquid manure. At present no plants have been raised from seeds, as these do not appear to ripen, but propagation can be readily effected by means of cuttings inserted in sandy soil in bottom heat, almost any portion of the growths striking readily. The Kew authorities have now distributed several plants to metropolitan nurserymen, so that a stock will soon be obtained. A botanical certificate was awarded to this plant by the Scientific Committee of the Royal Horticultural Society on the 11th inst.

NATIONAL ROSE SHOW AT DARLINGTON.

JULY 19TH.

DARLINGTON was *en fête* on Wednesday, thousands of visitors arriving by train from the surrounding district to witness the great Rose Show. The weather was most favourable—a warm genial sunshine with a gentle breeze prevailing all day. The Show was held in Southend Park, kindly granted for the occasion by the Misses Pease. The Park is easy of access and beautifully wooded. It is the first time the National Rose Show has been held so far north. This has

been mainly through the exertions of Mr. Whitwell, Barton Hall, along with a few influential gentlemen in Darlington to assist him. All may congratulate themselves on the result of their labours, and the success achieved may be attributed considerably to the influence of the promoters and the central position Darlington commands. We hope this may induce the inhabitants of the town to hold an exhibition yearly, as horticulture is well represented in the neighbourhood. Referring to the Exhibition, it was considered by gentlemen well fitted to form an opinion that it is the best that has been held this year, the only one approaching it being that held at Kensington on the 4th inst.

Nurserymen's Classes.—In Division A, for forty-eight Roses, single trusses, there were seven entries. The first forty-eight were far in advance of the others in size of flower, colour, and form, these being from Mr. B. R. Cant, Colechester, who had fine examples of Duke of Edinburgh, very large and rich in colour, nearly 6 inches in diameter; Marie Baumann, Elie Morel, Madame Charles Wood, Alfred Colomb, Madame Hippolyte Jamain, Etienne Levet, Triomphe de Lorraine, Madame Gabriel Luizet, Countess of Rosebery, A. K. Williams, Comtesse de Paris, and Mrs. Harry Turner. Messrs. Paul & Son, Old Nurseries, Cheshunt, were second with some fine blooms of Marie Baumann, Pride of Waltham, Madame Victor Verdier, Reynolds Hole, Exposition de Brie, La Duchesse de Morny, Duchess of Bedford, and Comtesse de Choiseul. The Cranston Nursery and Seed Company, Hereford, were third, their best flowers being Constantin Tretia-koff, A. K. Williams, Perle des Jardins, Countess of Rosebery, Pride of Waltham, Hippolyte Jamain, and Madame Hippolyte Jamain.

In the class for twenty-four flowers, three trusses, there were also seven competitors. Mr. George Prince, Oxford, Messrs. Cant and Cranston were the respective winners. The first stand contained good flowers of Baronne de Rothschild, La Duchesse de Morny, Annie Wood, La France, Duc de Rohan, Souvenir de Madame Pernet, Alfred Colomb, Duc de Rohan, Madame Marie Verdier, very fine; Mdlle. Marie Finger, Louis Van Houtte. The second lot contained Duke of Edinburgh, La France, Madame Eugénie Verdier, Madame Marie Finger, Countess of Rosebery, Dupuy Jamain, Horace Vernet, and Fisher Holmes.

In Division B, for thirty-six single trusses, Messrs. Davison & Co., Hereford, won chief honours with fine blooms of La France, Victor Verdier, Eugène Verdier, Mons. Etienne Levet, Mons. E. Y. Teas, Duchesse de Vallombrosa, Duke of Connaught, Belle Lyonnaise, Ferdinand de Lesseps, Mons. Noman, Mrs. Laxton, Senateur Vaisse, Madame Charles Wood, and Mdlle. Thérèse Levet. Mr. John House, Eastgate Nursery, Peterborough, was second; Mr. Thomas Horseman, Ilkley, third; and Mr. Frettingham, Beeston Nurseries, Nottingham, was awarded an extra prize in this class. For eighteen Roses, three trusses each, Messrs. Davison & Co., Hereford, were first, followed by Messrs. Frettingham and Harkness. The former had good blooms of Baronne de Rothschild, Marie Baumann, Alfred Colomb, Horace Vernet, La France, Peach Blossom, Louis Van Houtte, Ferdinand de Lesseps, Marquise de Castellane, and Mons. E. Y. Teas.

For twelve Teas or Noisettes, distinct, Mr. B. R. Cant and Mr. Prince were placed equal first. Mr. Cant had good blooms of Souvenir d'Elise, splendid; Gloire de Dijon, Madam Brown, President, Marie Van Houtte, Niphotos, and Anna Ollivier. Mr. Prince had Catherine Mermet, Comtesse de Nadailae, Souvenir d'un Ami, Rubens, Anna Ollivier, and Souvenir d'Elise, all good. No second prize was awarded, Messrs. Paul & Son being third. A plant of the new Noisette Rose William Allen Richardson was shown by Mr. John House, Peterborough. It is of an orange-yellow shaded saffron tint, and attracted much attention from the northern Rose-growers.

Amateurs' Classes.—In Division C Messrs. Whitwell and Burrell carried off the principal prizes. Both have been already very successful this year at all the leading exhibitions which have been held. For thirty-six single trusses Mr. E. R. Whitwell was deservedly first. He had large fresh blooms of La France, John Stuart Mill, Marie Rady, Alfred Colomb, Duc de Rohan, Dr. Andry, Marie Finger, Camille de Rohan, Mons. E. Y. Teas, Bouquet d'Or, Prince Arthur, Marie Baumann, and Général Jacqueminot. Mr. Thomas Hall, Chester, and Mr. G. Hawtrey, Slough, Bucks, took the second and third prizes, both stands being much inferior to the first collection. For eighteen single trusses Mr. Whitwell also secured the first award, followed by Mr. Grant, Ledbury, the first-named showing excellent flowers in this class.

In Division D Mr. Burrell of Heighington, near Darlington, was first for twenty-four single trusses, showing very fine flowers of John Stuart Mill, François Michelon, Emilie Hausburg, Marie Baumann, very fine; Exposition de Brie, Madame Hippolyte Jamain, A. K. Williams, and Marie Rady. No second prize was awarded. For eighteen single trusses Mr. Burrell was also first with very good flowers. In Division E Mr. Cuthbert Laws, Ponteland, took first honours for twelve single trusses; and for six Mr. Mawley, Addiscombe, Croydon was first. In the extra class for nine Teas or Noisettes Mr. Edward Mawley was first. His best blooms were Anna Ollivier, Marie Van Houtte, Comtesse de Nadailae, Mons. Furtado, Innocente Pirola, Madame Bravy, Souvenir d'un Ami. Mr. Thomas Hall was second. For twelve trusses of any kind Hybrid Perpetual (dark) Messrs. Paul & Son were first with fine large flowers, even and well coloured, of the charming Rose A. K. Williams, which were deservedly admired. Mr. Prince was second with Alfred Colomb, which were also superb in size. For twelve trusses Hybrid Perpetual (light)

Mr. B. R. Cant was first with Duchesse de Morny; Messrs. Cranston and Co. second with Capitaine Christy.

The marquee was decorated with plants for the occasion, which were kindly lent by Mr. J. Pease, Mr. A. Pease, M.P., Mr. H. J. Fry, M.P., Mr. J. Hodgkin, the Misses Pease, and Mr. E. B. Spence, nurseryman, Darlington. Mr. E. R. Whitwell; the local Secretaries—Messrs. Gibson and Byers—with Mr. Burrell, Alderman Shaw, Mr. George Page, Mr. Bousfield, and other gentlemen who rendered their assistance, are to be congratulated on the result of their labours. The Rev. H. Honeywood Dombain and Mr. Edward Mawley, the Hon. Secretaries of the National Rose Show, were also present, and rendered efficient service.

SNOWDROP CULTIVATION.

THE majority of readers are without doubt thoroughly conversant with the cultivation of this early-flowering bulb for decorative purposes in gardens; but many are not acquainted with its cultivation previous to passing into the hands of the trade. The object of these notes is to clear away, if possible, the vague notions now entertained by many that the bulbs ready for sale towards the end of August are of continental origin. I do not intend to assert that none are imported, but the majority are cultivated in this country, and are larger and better than any I have seen imported. I learn that the culture of these bulbs for sale is profitable, although the prices given to the grower per thousand appear small. In these days of depression the growth of Snowdrops might be extended with much advantage and profit, as thousands of these roots do not occupy much land. In fact, many are annually produced from land planted with standard fruit trees and hush fruit. All are not grown in such positions, for they do not develop quite so fast or make such fine bulbs as when more liberal cultivation is given them in an open space; but vast quantities are grown, and I am familiar with an orchard where thousands of roots have been grown and sold annually for the last twenty years or more. Perhaps my first occupation in gardening was to clean, lift, and select the saleable bulbs during my schoolboy days, and I have periodically visited the neighbourhood in which they are largely grown ever since.

Lifting is done during the month of July. The bulbs are sorted, the largest being selected for sale, and the others retained for planting again. When grown in the open an early or second early crop of vegetables is taken from the ground. After the bulbs are sorted at the first opportunity the ground is dug and manured, unless that operation has been well performed for the preceding crop. Manure is not really essential, as Snowdrops will grow almost anywhere, but where great success is anticipated manure is given, as they grow stronger, and in the end the bulbs are larger and more numerous. The small bulbs are not out of the ground long, but are planted at the first opportunity in rows 6 inches apart and about 1 inch between the bulbs as the digging of the ground proceeds. Others dig the ground first, and then draw out small drills, in which the bulbs are planted. Some plant closer than the distance I have given between the rows, but they cause more labour in keeping them clean when planted too thickly. All that is necessary for two years after planting is running the hoe amongst them occasionally to destroy the weeds; at the end of two years they are again lifted and sorted as before. Those who grow large quantities generally have two lots, so that they have bulbs for sale every year. The ground upon which they have been growing if out in an open space can be utilised for spring Cabbages, autumn-sown Onions, or any such crop that is serviceable to the grower. It will be at once seen that their cultivation for sale is simple, and quite as easy as growing them in our gardens for flowering during the spring.

Perhaps in no county are so many Snowdrops grown for sale as in Lincolnshire, and especially in that flat stretch of country known as the fens. The locality in which they are most largely grown is not so liable to be flooded as some other parts, but hundreds of thousands are grown within from one to four miles of land that was entirely under water two seasons ago and the Potatoes never dug. In this locality there certainly is a risk, as with all other crops, and in very wet seasons the bulbs are liable to decay. This happens occasionally, but not generally, and, on the whole, they are more certain than many crops. The ground generally is fertile if it could be drained, and will produce in good seasons as fine agricultural crops as any land in the country. When Snowdrops can be grown to be profitable in what would appear an uncertain locality, what might be expected in many other more favourable parts? There appears no difficulty in disposing of the bulbs, as the trade travellers visit the locality annually and buy up all they can obtain. It must be understood that many of the former grow them largely in spare corners of their little gardens and in positions where many other plants would not succeed. One cottager a short time ago remarked to

me "that lot grows where nothing else would grow, and the labour I consider nothing, and you see they pay the rent." Although the Snowdrop flourishes so well they do not cultivate the Crocus—at least very few—and the reason, I am told, is that the ground is too wet.

Those who only grow the Snowdrop on a limited scale for sale at present would do well to replant their whole stock for a few seasons instead of disposing of them. The demand for early flowers appears more general than ever, and I am of opinion that it will continue for some time to come, and this early-flowering bulb will be in greater request for planting in woods and other suitable positions in the future than it has been in the past.—W. BARDNEY.

A FINE CROP OF POTATOES.

SOME Myatt's Kidney Potatoes we lifted to-day were so fine, considering the conditions under which they were grown, that I was induced to ascertain the amount of crop and its present value per acre. I now send you the results arrived at. I may premise that we lifted a larger crop from a south border a fortnight ago, but these were grown under more favourable conditions. I am now sorry I did not make any note of the weight of that crop. Those now in question were grown on a border occupied permanently with large Apple trees, and between two main quarters in the vegetable ground. Turnips and such catch crops commonly occupied the ground, and it was kept in rather poor condition for vegetables; indeed it is several years since any manure was allowed it. Having more "sets" of Myatt's Kidney than were required I had them planted on this border, which had been dug in the early part of the preceding winter. The rows were 2 feet apart, and the "sets" 1 foot asunder, so that to the acre there would be 21,780 sets. Every set was furnished when planted with one strong bud half an inch in length. In planting, a line 4 inches deep was formed with a spade, the ground being pointed merely between the rows, and the succeeding row prepared for in the same manner as the first. Planting was performed in the end of March. A dressing at the rate of 6½ cwt. to an acre of chemical manure was applied along each drill before the sets were placed in, and, with the exception of having been once hoed, nothing has been done to them.

In stating the weight of the crop a gallon hamper was filled with the best Potatoes, commencing at one end of the row; then the seconds were gathered from the same space, and lastly the small unsaleable tubers. The number of best tubers to the gallon was eighty; these weighed 24 lbs., an average of 4¾ ozs. each. There were forty-one seconds, weighing 5¼ lbs., or 2 ozs. each; and nineteen small, slightly over 1 lb. The length of the row from which these were lifted when measured was exactly 18 feet, which gives a weight per acre of nearly 13 tons for the best, and of the seconds 2 tons 17 cwt. Rather more than three farthings per lb. in quantity is received for the best Potatoes on the ground, while the seconds sell at exactly a halfpenny per lb. Taking the price for the best at three farthings per lb. the return per acre would amount to £91 5s., while the seconds would be £13 5s. 6d., or a total of £104 10s. 6d. The earlier crop referred to was a larger crop than this, and from 50 to 100 per cent. more was received per gallon, but I hardly expect to find the crop in the main quarters any better, if so good, as this one when I test the weight and amount. The interesting point to me regarding these Potatoes is the fact that I have always distributed manures broadcast over the entire surface of ground, but in this case the manure was sown along the drills only. The manure used was composed of superphosphate from minerals, chloride of potash, and sulphate of ammonia, in the proportions of the first as sixteen, the second as twelve, and the third as nine. 1 lb. of this manure in a finely pulverised condition was put on 10 yards' run of the row.—B.

LUTON HORTICULTURAL SHOW.

JULY 19TH.

WHEN the Bedfordshire Agricultural Society visits the straw plait capital, which is about once in four years, the sister crafts, Agriculture and Horticulture, shake hands, and a good joint show is usually the result. The county town, Bedford, having been for some years quite disfranchised as regards horticultural exhibitions. The Show at Luton on Wednesday last was held in a ground adjoining and communicating with the County Agricultural Exhibition, and was contained in two large tents, but the canvas accommodation was much too limited, and dangerously so for the numerous fine plants which the liberal schedule brought together.

In the open class for twelve stove and greenhouse plants in or out of flower, no less than seven collections were staged. In this class Mr. Tudgey, gardener to J. F. G. Williams, Esq., Henwick Grange, Worcester, was awarded the first prize, his plants being all in flower,

Anthurium Schertzerianum having nearly seventy spathes of a rich colour; Dipladenia amabilis, Clerodendron Balfourianum, Allamanda Hendersoni, being also grand specimens. Mr. James Cypher, Cheltenham, was second with very fine plants, but all in flower. The best were of *Cycas revoluta*, Allamanda Hendersoni, Ixora Fraseri, and Erica Parmentieri. Mr. W. Parker, Rugby, was third, having Bougainvillea glabra very fine, Erica Parmentieri 4 feet in diameter and in full flower, and Kentia Fosteriana, a noble specimen. The fourth prize went to Mr. J. Freeman, gardener to W. B. Greenfield, Esq., Beechwood Park, Dunstable, for a very healthy collection of smaller plants. Mr. C. Butters, gardener to Mrs. Gerald Leigh, Luton Hoo, also staged some fine specimens, but mostly foliage plants. Good plants were also shown in the open class for six, as well as in the local class. Ferns were not correspondingly good, but Cibotium Schiedei and Davallia Mooreana were elegant examples.

In the open class for forty-eight Roses, single trusses, the only class in which Roses were efficiently represented, Mr. B. R. Cant of Colchester was first with fine blooms, his best being Hippolyte Jamain, Marie Finger, Countess of Rosebery, good; Duke of Edinburgh, Duchesse de Morny, Madame Nachury, Marie Baumann, A. K. Williams, Comtesse de Paris, Annie Wood, Prince Arthur, Penelope Mayo, Horace Vernet, Etienne Levet, Mons. E. Y. Teas, and Princess Beatrice. Mr. W. Rumsey of Waltham Cross was second, having fine flowers of J. S. Mill, Mdle. S. Fropot, a good cool season Rose; Mrs. Laxton, Star of Waltham, Duke of Edinburgh, Paul Jamain, Madame Chas. Wood, Marquise de Castellane, and Mdle. Camille in his stand. Messrs. G. Paul & Son, Cheshunt, who were also showing on the same day at the National Rose Society's Show at Darlington, were placed third; Madame Perreire, a promising Rose, in the way of Marie Verdier, but of greater substance; A. K. Williams, Chas. Lefebvre, A. Colomb, Comte de Raimbaud, Duke of Teck, Harrison Weir, and White Baronne being noticeable flowers. Several amateurs also entered the lists in this class, and the Rev. W. H. Jackson of Stagsden Vicarage, Bedford, with a few more blooms, equal to his best, would have been no despicable antagonist for a Colchester champion, his A. K. Williams, Chas. Lefebvre, Thos. Mills, and Emilie Hausburg (rarely better than from Stagsden) were all fine blooms.

Fruit was not largely shown, but a good collection of eight kinds for the first prize in the open class came from Mr. Freeman, who had richly coloured and finished Black Hamburg and Golden Champion Grapes, Royal Ascot Melon, Violette Hâtive Peaches, Pine Apple Nectarines, White Ischia Figs, Bigarreau Cherries, and Czar Plums. Mr. C. Pollard, gardener to J. B. Maple, Esq., Childwick Bury, Harpenden, took first for black Grapes with highly coloured Hamburgs, and Mr. Butters was first for white Grapes with good samples of Buckland Sweetwater. Fine Downton Nectarines came from Mr. Underwood, gardener to C. R. Fenwick, Esq., Harpenden, deservedly secured the first in this class. A good early red Gooseberry of the Champagne type, and above the ordinary size in earlies, called Glory of Oldport, was shown.

Vegetables were not so good as those usually shown in the northern side of the county, the chalky soil of the Luton district not favouring their development in exhibition form; and the best collection of twelve varieties came from Mr. G. Vines, gardener to H. Thornton, Esq., Kempston Grange, Bedford, whose large red Tomatoes, Telegraph Peas, and Pride of America Potatoes well indicated his skill as a successful cultivator of vegetables.

Dinner-table decorations were not remarkable, but the table of Mrs. Higgins of Upper George Street, Luton, who was awarded the second prize, was evidently more to the popular taste than that which was placed first. A combination of white Water Lilies and other white flowers interspersed with Adiantums and Grapes, and backed with leaves of the Purple Beech, produced a pretty and not inelegant effect. Miss M. A. Gardner, Luton, was awarded first for a commendable table, but of less pretentious appearance. Wild flowers formed a good feature of the Show, and Mr. J. Saunders of Luton showed a collection of two hundred specimens, 160 illustrative of the flora of South Bedfordshire and forty from the New Forest. The special point in this collection was the classification of the specimens. Each species was separately placed in a small vase, and to it was affixed a white card, on which were legibly written the number in H. C. Watson's London Catalogue, seventh edition, also the natural order, genus, and species, the nomenclature being that of Hooker's "Student's Flora." To the divisions conspicuous labels were placed, on which in larger characters the names Thalamifloræ, &c., were written. Commencing with the Ranunculaceæ, the whole of the two hundred species were arranged in their scientific succession, the lowest natural order being the Gramineæ, as the exhibit was limited to the Phænogams. Under these circumstances the affinities of the various groups could be traced, and the whole served as an illustration of the principles on which British classification is based. The New Forest specimens included some of our rarest British species, as, for examples, *Spiranthes æstivalis*, from the locality given in the guide books as near the old Lyndhurst gate; *Gladiolus illyricus*, *Cicendia filiformis*, *Radiola millegrana*, *Pinguicula lusitanica*, *Utricularia minor*; the three *Droseras*—*rotundifolia*, *intermedia*, *anglica*; and *Carex pulicaria*. The general effect was improved by the specimens being placed in dark glass vases, which were stood on white paper.

ECHIU RUBRUM.—This is a pretty hardy plant well worth notice. The flowers have hairy calyces; the corolla is about an inch long,

more open and deeper cleft than *E. albicans*, deep red at first, changing to purplish crimson, presenting a very attractive appearance, and lasting a long time in beauty—June to September—and last year it ripened seeds freely, especially those flowers which expanded first. I notice different authorities quote this as a biennial, but my experience is to the contrary, as after flowering the plant was more vigorous, forming fresh tufts of foliage, and showed no signs of decay, and it passed the severe winter of 1880-81 without any protection. I received seed from Dr. Regel of Petersburg, from which the plants were raised in a cold frame treated as ordinary hardy-plant seeds generally are, and this appears to be the only method of securing stock of it. It requires a well-drained position with a good depth of soil, the rockery being the proper home for it, and the effect it gives is very striking and novel.—T. R.

DOUBLE-FLOWERED DELPHINIUMS.

THE Delphinium has maintained its position in our gardens after being cultivated for a very long period as a perfectly-hardy plant, especially *D. formosum* and its varieties and congeners. Later on there have been introduced several other species, very variable, from the tall deep blue-flowered kinds, which, however, are not so showy, nevertheless they are equally desirable in our gardens, such as the scarlet *D. cardinale*, which is a strange divergence in coloration from those we have been accustomed to see, and *D. nudicaule* of the same colour, but not such a good plant. It would be grand if we could get scarlet-flowered varieties with the robust and hardy characteristics of the *D. formosum* series. At present we see no chance of expecting such, therefore so far we must remain content with our sturdy blue-flowered kinds, which, however, very materially vary in point of colour. There are not wanting indications in many of the varieties of a disposition to break out into crimson.

The double-flowered varieties of Delphiniums are especially worthy the attention of floriculturists, however humble their pretensions; these should be well cultivated. It is insufficient to give them such illiberal treatment as is frequently afforded the single varieties. A good rich soil is necessary—not very stiff, for as a rule they prefer a free soil. Deep digging is essential. In planting these and double Pyrethrum I have the ground thoroughly dug two spits deep—*i.e.*, when cultivating them in beds, and a liberal supply of manure is well worked in the soil, and the plants are arranged about 3 feet apart each way; or for the first year they may be planted 18 inches apart, and when necessary every alternate plant can be removed to make room for the proper development of the rest. Before the stems are very high it is advisable to stake them, as strong winds are apt to break them down, for the heads of bloom are very heavy. They may be increased soon after flowering by dividing the roots, which usually bud out freely at the crown of the rootstock at that time. The stools should be raised and carefully cut, leaving each division with as good a supply of roots as possible; or they may be split up in the same way in early spring, transplanting the newly made plants as speedily as possible after the operation, well pressing the soil about them. If the roots are split up into very small portions they should be placed into 60 or 48-sized pots, and be transferred to a cold frame until root-action is resumed, and thus re-establish them, when they may without fear of loss be planted out again in beds or borders. With border cultivation there is not the convenience for deep digging as in the case of a bed, as many other plants might be unfairly disturbed; but at the same time the soil where the plant is to be placed can be deeply broken up and well enriched with manure, and if a little trouble is incurred it is more than likely a good reward will be obtained. Double and semi-double-flowered varieties may also be raised from seed, as that is the means by which all the beautiful kinds at present known to us have been obtained. It is advisable, where good double forms exist, to keep them well separated from the other varieties if the seed is required true; and although it is probable that only semi-double flowers may be obtained from the seedlings, yet they may be novel, or at least well worth growing, as they are frequently very showy, producing large and variously coloured flowers. Seed may be sown in the open border after it is ripe, where it speedily germinates, and the young plants may in due course be transplanted where they will bloom the ensuing season. Or it may be raised in pans in a cold frame, the seedlings being pricked out when large enough.

To those unacquainted with these flowers the following selection of varieties may be serviceable. I have grown besides them many others perhaps equally desirable; in fact there are a very great number of first-class kinds, and that number is constantly increasing, and, speaking generally, they are all good. *Amedée Hans*, 2½ feet high; spike very full, with large flowers bright sky blue with white centres. *Barlowi*, a very old semi-double kind, little

more than 2 feet high, with flowers of a deep blue colour shaded with bronzy red. *Barlowi perfectum* is an improved form of the last, with dense spikes of rich indigo blue flowers shaded with crimson; a very effective and dwarf kind, not more than 2 feet high, but one mass of bloom. *Caire Courant*, 4 feet; flowers very large and double in dense spikes, bright sky blue throughout; very free and fine. *Grandiflorum plenum* is a scarce plant, 2 feet high, with immense branching spikes of large double flowers, dark shining blue shaded with bronzy red; a most distinct and conspicuous variety, and when once established it is a most magnificent plant. *Exquisite*, 4 feet; flowers semi-double, in great spikes of a rich cobalt blue suffused with rosy lilac; very large and showy. *Globe*, 2 feet; a very effective kind, with dense spikes of very double flowers of a rich lavender tint, with paler centres. *Hermann Stenger*, a favourite, 4 feet, with very long branching spikes of large very double flowers; outer petals bright purplish blue, centre ones rosy purple; a most showy variety and very free. *Eugène Verdier*, 3 to 4 feet, with dense spikes of very double flowers like a *Ranunculus*; outer petals violet blue, inner ones blue, with white star-like centres; a most distinct and novel form. *Keteleeri*, 3 feet, with dense spikes, freely branched, of flowers of a rich lavender blue tint with white centres; a much-esteemed and free-growing variety. *M. Le Bihan*, 3 to 4 feet, with a large central spike half as long as the whole stem, densely set with large semi-double flowers; outer petals bright glistening blue, inner ones rosy purple; most conspicuous. *Pompon Brilliant*, 2 feet, very robust, with long spikes densely packed with large very double flowers, rich violet-blue outside, with the centres reddish-purple. *Ranunculiflorum*, 3 to 4 feet; spikes very freely branching, and crowded with double rosette-like flowers, with the outer petals rosy-purple edged with light blue, and the inner ones paler in colour; very effective. *Star*, 3 feet, with long pyramidal spikes of full double flowers, pale azure blue, with white star-like centres; a most persistent bloomer. *Triomphe de Poissy*, 3 feet, with medium-sized flowers on very full spikes, semi-double, shining sky blue, tinted with pink; very free. *Robert Parker*, 3 to 4 feet, with dense spikes of large very full flowers of a clear violet blue colour; a most distinct variety. *Victor Lemoine*, 3 to 4 feet; spikes very large, filled with large perfectly shaped flowers, very double, clear sky-blue outside, with white centres.—N.

LATE VEGETABLE CROPS.

THE present is a good time to see to these. Many varieties of vegetables may be sown now to give supplies in late autumn and throughout the winter. At these seasons abundance of good vegetables are just as much valued as any during the early part of the season, and it should be remembered that variety is very desirable in most cases, and as this is more difficult to secure in winter than summer timely provision should be made for it.

Colerworts.—Seed of these which come in throughout the winter in a form resembling young Cabbage may yet be sown, and the seedlings planted out when large enough in rich ground. They do not grow very large, and may stand 18 inches apart each way.

Winter Spinach.—This comes best from the prickly variety, and should be sown now and again in another month. Nothing is more useful in the kitchen in winter than this, and a good supply of it will compensate for many deficiencies. Those who think it is a worthless vegetable to grow and valueless at the table are mistaken. If it is not grown so extensively as it should be it must be because its merits are not known. South borders and open sunny quarters are good positions for present and subsequent sowings. The drills for the seed should be 18 inches apart and 2 inches deep. Soil from which Potatoes or any other crop has been recently taken will be found to suit Spinach. Moderately rich ground suits it well; when too rich it is liable to grow soft and not stand cold weather uninjured, and when too poor the leaves are not so succulent as they should be. A good breadth of it may be sown at once. When the plants are 2 or 3 inches high some should be drawn out, and this may be done again until the plants for the permanent crop are 8 or 10 inches apart. After this the leaves will expand freely, and they should be gathered before they become too old, only the centre ones being left to yield fresh supplies, which they will continue to do until very severe weather stops their progress. Autumn-sown Spinach plants do not generally flower until spring, and until then gathering may be done as sufficient growth is made.

Carrots.—Varieties of the Early Horn section, if sown on a south border now, will give some useful little roots late in autumn, and these are much valued. Large old Carrots are useful in many ways in winter, but they cannot take the place of small delicate young roots, and those may be secured by attending to these notes. In our district the spring-sown Carrots have been

much attacked by the grub. If this is the case in many parts winter Carrots may be scarce, but the deficiency may still be made good by sowing at present. The seed should be put in rows about 1 foot apart; sowing Carrot seed thickly at any time is not a good plan. In August and September they do not grow so fast as in May and June, but as soon as they become close together the smallest should be drawn out to give room to the best. At the first thinning few may be large enough for use, but when they are thinned a second time the roots may be turned to account.

Turnips.—Seed of these may be sown at the same time as the preceding. They should be sown in rows 18 inches apart; Chirk Castle is our favourite kind for present sowing. It is excellent in winter, being both most hardy and high-flavoured. Yellow Turnips are very hardy too, but they do not meet with the same favour as the white-fleshed kinds. Were it not for this yellow Turnips might be grown with profit, as they are not so likely to flower as the white. Their culture for winter is easy if the seed be sown now. They must be thinned out early, as crowding at first is against their free development. The more hardy they can be grown the better will they bear the severe weather. If sufficient seed is sown now fine useful roots may be had daily from October until April.

Late Kidney Beans are worth growing, as numerous dishes may be had from a small space, and when they can be sown in such a way that frames can be placed over them in autumn they will give a supply long after those in the open air are over. Osborns' Forcing is the best kind to sow now, to be treated in the manner we have indicated.

In many instances Globe Artichokes have now supplied all the heads formed this spring, and if left uncared for they may not produce more this season; but by giving them copious supplies of liquid manure now they will be induced to throw up many fresh stems and form heads so late as November. It is now too late to plant Brussels Sprouts to do any good this autumn, but Cauliflower, Broccoli, Savoys, and Celery may still be placed out. Salading may also be placed out in quantity, and the seed of winter Lettuce, Endive, and Radish should be sown. Most of the vegetables here mentioned have been noted in these pages before, but it is so important to have them sown at the right time that I have been induced to call attention to them now.—
A KITCHEN GARDENER.

LEEK ROSE SHOW.

I KNOW few lovers of the Rose who are more to be commended than those of Leek—not for the excellence of their culture so much as for the manner in which, under adverse circumstances, they maintain their exhibitions; for I have never been there yet that there has not been wet weather, if not on the day of the show, at any rate—what to a Rose-grower is nearly as bad—on the day before, and we all know how to small growers this is a great calamity. But they have one thing in their favour; they have one or two excellent growers of plants in their neighbourhood, and to Mr. E. Glover of Highfield they are much indebted for the liberal manner in which he supports the Show, and for the encouragement given by the exhibition of his beautiful and admirably grown plants, which are so well managed by his able gardener Mr. Roberts. I had the pleasure of being his guest, and had the opportunity of going through his garden, and it would be impossible to excel even at our metropolitan shows some of his stove and greenhouse plants, while fruit is grown in a thoroughly excellent manner. Sometimes we hear people say that they have left their best things at home, or they would have occupied a very different position; but I am bound to say this is true of Mr. Glover, for the simple reason that the door of the room where the Show took place was not large enough to admit them!

We know how much the growers for sale contribute to the beauty of a Rose show by their exhibits, but although liberal prizes were offered only one firm responded to the invitation. It may be that the National Rose Society's Show at Darlington taking place on the following day, or the exceeding awkwardness of the railway accommodation, may have been the reason. Only one stand, that of Messrs. Jas. Dickson & Sons of Chester, was exhibited. It was a good stand, containing the following varieties:—A. K. Williams, Marie Baumann, Elie Morel, Marie Rady, Baronne de Rothschild Exposition de Brie, Marquise de Castellane, Cheshunt Hybrid, Charles Darwin, Madame Ferdinand Jamain, Horace Vernet, Comtesse d'Oxford, Gabriel Tournier, John Hopper, Sir Garnet Wolseley, Comtesse de Serenye, Miss Hassard, Oxonian, a good bloom; Richard Laxton, Sultan of Zanzibar, Dr. Andry, François Michelon, Senateur Vaisse, Marie Verdier, Paul Neyron, a really good not over-large bloom; Souvenir de Victor Verdier, very good; Duke of Edinburgh, Etienne Levet, Captain Lemaire, very good; Beauty of Waltham, Pride of Waltham, Madame Victor Verdier, Madame Hunnebelle, Pierre Notting, La France, Constantin Tretiakoff, very good; Princess Mary of Cambridge, Comtesse de Paris, Princess Beatrice, and John Stuart Mill. Mr. Eyre took the first prize amongst amateurs, and also the National Society's silver medal, while the bronze medal for

the best Rose in the Show was given to a fine bloom of Louis Van Houtte, an Alfred Colomb in another stand gaining another, as there was not half a point even between them. Mr. Eyre had good blooms of Louis Van Houtte, Marquise de Castellane, Marie Baumann, Madame Victor Verdier, Etienne Levet, Madame Gabriel Luizet, Princess Beatrice, Constantin Tretiakoff, which seems a favourite flower in the north; Duchesse de Vallombrosa. The other exhibits do not call for any particular remark. There is certainly still much room for improvement, and I hope the amateur growers of Leek will take a friendly word from one who wishes them well, that they would rise to the occasion and endeavour to raise the standard of their exhibits.

The stove and greenhouse plants of Mr. Glover and others made a fine show in the room, and contained good plants of Clerodendron Balfourianum, Cocos Weddelliana, Crotons, Vinca rosea and alba, Kalosantes, &c. Some fine Ferns were shown by Mr. Holden and Mr. Kemp, comprising Dieksonia antarctica, Adiantum farleyense, Davallia Mooreana, and other well-known varieties.

The Society has had many changes in its secretariat, which is always a disadvantage. Mr. A. Johnson, who is now fulfilling the duties of the office, is most thoroughly in earnest, and the arrangements of the Show were well carried out, and, strange to relate, everything was ready for the Judges at the appointed time—a most unusual circumstance. I hope that despite all adverse circumstances (it was a pouring wet day) the Society may continue and prosper. Difficulties have not deterred, nor do I think they will in the future.—
—D., Deal.

AT a general meeting of the ROYAL HORTICULTURAL SOCIETY, held on Tuesday last (Jas. McIntosh, Esq., in the chair), the following candidates were elected Fellows:—viz., John H. Raffety, James Steains, and W. Terriss.

— DR. C. STUART of Chirnside, N.B., sends us a spike of a FOXGLOVE with the following observations:—"When with the Scottish Alpine Botanical Club in Glen Lochsie, near the Spittal of Glenshee, two years ago, I cut a spike of a salmon-coloured sport from the centre of a plant of the common purple variety. I brought it to the south, put it in a bottle of water, and ripened several of the seed capsules. The plants from this seed were put out in the open border a year past in spring, and have only flowered during the last month. To prove that the colour was merely a sport several purple specimens have flowered from the same seed pod. I have, however, succeeded in perpetuating the variety, which is very distinct and handsome." The colour of the flowers is a peculiarly distinct rosy salmon tint, the inner portion of the corolla being dotted with rose.

— A VISITOR to Hampton Court observes that the flower and carpet beds will, weather proving favourable, shortly be in fine condition and worthy of inspection. In the carpet beds ECHEVERIA PEACOCKII is employed with great effect, and imparts a colour that is not found in any other plant. This is by far the most attractive of all the succulents for lines and panels, and it is likely to be increased as rapidly as possible by those who indulge in this style of garden decoration.

— IN the same grounds the HAMPTON COURT CRIMSON VERBENA arrests attention by its free growth, floriferous nature, fine trusses, and rich colour. Although the soil is light and dry this Verbena grows as freely as any other kind of plant in the garden, and reminds us of the gorgeous masses of Verbenas that were seen a quarter of a century ago. In general appearance the Hampton Court Crimson resembles that fine old bedding variety Crimson King, but is much larger and a better grower. This is a strong recommendation, but not too strong, as those will find who plant healthy and clean plants in ordinarily fertile soil. This variety is now in commerce, the stock having passed into the hands of Messrs. Cannell & Son of Swanley.

— IN one of the shrubby borders the most conspicuous object is SPIRÆA LINDLEYANA. There are several specimens from 6 to 8 feet high, which, with the large pinnate leaves and terminal plumes of white inflorescence have a remarkable effect. The specimens are not crowded by other shrubs, to which circumstance their present floriferousness is doubtless to be attributed.

— DURING the past week—namely, from the 18th to the 25th inst., Messrs. Cranston & Co. of Hereford have had an EXHIBITION OF ROSE BLOOMS in the Royal Botanic Society's Gardens, Regent's Park, which has attracted many visitors. About forty boxes were staged in the corridor, the majority containing thirty-six blooms each, and thus there were collectively over one thousand blooms, representing a large number of the best varieties in commerce. Fresh blooms were supplied every morning from the Hereford nurseries, and thus a fine display was maintained throughout the week. Such well-known and much-appreciated varieties as *Senateur Vaisse*, *A. K. Williams*, and *Alfred Colomb* were especially fine, the last-named being represented by particularly handsome blooms. *Duchesse de Morny*, *Charles Darwin*, *Lady Sheffield*, *Princess Beatrice*, *Mrs. Baker*, *Xavier Olibo*, *Comtesse d'Oxford*, and *Marquise de Castellane* were similarly good. But perhaps there was not a more attractive box in the whole Show than that filled with blooms of *Crimson Bedder*. These, though not large, were remarkable for their neatness of form and rich scarlet crimson hue, the half-opened buds being admirably suited for bouquets or button-holes. Some large trusses of buds and flowers well indicated the astonishing floriferousness of this useful variety.

— A CORRESPONDENT writes as follows:—"POISON BERRIES—MEZEREON.—A child in Maidstone has been seriously poisoned by eating the berries of *Daphne Mezereum*, possibly mistaking them for Red Currants. It may be as well to caution those who have these pretty spring-flowering shrubs in their gardens." The *Daphnes* are distinguished by possessing rather strongly marked acrid, caustic, or purgative qualities, which are especially developed in the fruits and bark. Some preparations have been used in medicine, but in large quantities they are injurious. *Daphne Mezereum*, *D. Gnidium*, *D. Cneorum*, *D. Laureola*, and several others possess similar properties.

— GARDENING APPOINTMENTS.—Mr. E. Butts, foreman at the Royal Gardens, Kew, has been appointed head gardener to Mrs. Tredwell, Leigham Court, Streatham; and Mr. John Woolford succeeds Mr. D. Greig as head gardener to the Right Hon. Earl of Bandon, Castle Bernard, Bandon, Cork, Ireland.

— OUR correspondent "SINGLE-HANDED" sends the following note relative to ROOTING STRAWBERRY RUNNERS:—"NORTHERN GARDENER," in noticing my method of securing early-rooted plants of Strawberries, says it is not suited for a very dry district. Now it is just such a district where it is superior if, as I recommended, the young runners are dibbled into frames kept close, shaded, and moist. If anyone with a spare frame will try that plan they will go on repeating it annually. During dry hot weather when no frames are to be had this plan might not be so successful, but even then much might be done by shading and watering."

— A SCOTTISH correspondent writes:—"Partly owing to the very mild winter and spring, partly to the 'growing' weather experienced during summer here 'in the north country,' a SECOND SPRING is being experienced, and bouquets may be had of *Roses* and other July flowers mingled with *Alpine Auriculas*, *Primroses*, and other *Primulas*. [Some people profess to be frightened at these things, but it is doubtful if any real harm can come to the plants thus growing again. The summer's rest which many things take is often forced on them by a heat and drought that

paralyzes them into inactivity; but, as 'only the flying cloud changes and lightens—only the waving wing changes and brightens,' so only the growing plant spreads and gains strength for showing off its beauty in all its fulness. Instead, therefore, of moaning over untimely growth a rare opportunity should now be seized for dividing many such plants as we have named, for the warmth and moisture are just suited for making them strike root and become established."

— MR. C. V. RILEY, writing in "Nature," has the following respecting the UTILISATION OF ANTS IN HORTICULTURE:—"Dr. C. J. Macgowan has sent me from Han Chow, Province of Hainan, China, a little paper on the 'Utilisation of Ants as Insect-destroyers in China.' It seems that in many parts of the province of Canton the Orange trees are injured by certain worms, and to rid themselves from these pests the inhabitants import ants from the neighbouring hills. The hill-people throughout the summer and winter find the nests of two species of ants, red and yellow, suspended from the branches of various trees. The 'Orange ant-breeders' are provided with pig or goat bladders, baited inside with lard. The orifices of these they apply to the entrance of the bag-like nests, when the ants enter the bladders, and, as Dr. Macgowan expresses it, 'become a marketable commodity at the orangeries.' The trees are colonised by placing the ants on their upper branches and bamboo rods are stretched between the different trees, so as to give the ants easy access to the whole orchard. This remedy has been in constant use at least since 1640, and probably dates from a much earlier period. This is certainly a new way of utilising ants, which as a rule are deservedly considered a nuisance by the horticulturist. I should like to learn whether the facts communicated have before been known in Europe, and, if so, whether the species of ant has been determined."

— RELATIVE TO CARTER'S NEW FAIRY QUEEN VIRGINIAN STOCK a correspondent writes:—"This is an acquisition among early-flowering dwarf annuals, its compact growth and numerous richly coloured flowers completely putting the typical form of the old favourite in the shade. The flowers are variable, but the majority are rosy crimson, and large flowering masses are sparkling cushions of brightness, there being at the present time nothing prettier in my garden."

— A DAILY paper says:—"Not a few capitalists in the United States are investing large sums of money in what promises to be a very profitable and lasting industry—namely, the cultivation of ORANGES IN FLORIDA. It will scarcely have escaped the attention of any middle-aged man that we in England seem now-a-days to have Oranges nearly all the year round, whereas twenty or thirty years ago they had their season, like Gooseberries. The reason is that we are no longer dependant on Spain or a few tropical islands for our supply, but we receive Oranges from many parts of the world, and when one crop is exhausted another arrives. Not many years ago Oranges at a halfpenny each in the middle of July would have been deemed curiosities; but so much as a matter of course is their appearance now considered that it is doubtful whether even those who sell them can explain how the change has been brought about. The beginnings of several large fortunes have been made by speculators who have taken up land in Florida and planted it with Orange groves. Not many years ago that State was regarded as an unhealthy swamp; but as a proof of how little was known of the capabilities of the practically uninhabited parts of North America, Florida now produces fifty millions of Oranges per annum, and will yield a great many more millions when the estates now undergoing cultivation are brought into full bearing condition."

— IN the paper discussing the COMPARATIVE HARDINESS OF HARDWOODED PLANTS by Col. H. M. Drummond Hay, which

we recently noticed, occurs the following interesting passage on the variability of hardiness:—

“To show the uncertainty of plants; some which have been looked upon as hardy, in having previously passed through many a severe winter, yet succumb to the effects of some one in particular, where another species not usually considered so hardy survives, but ultimately itself falls a victim to some succeeding winter, both having been grown under precisely similar conditions. I may instance the Rosemary and Gum Cistus (*Cistus ladanum*). Every plant of the former—of which there were several, some of them old and long-established plants, one of them having stood with impunity the severe winter of 1860-61—was utterly destroyed in 1878-79, while the Gum Cistus was scarcely touched, but every plant was finally killed in 1880-81. This latter I very much attribute to the wet summer of 1880 and the snowstorm of March 1881, and I merely mention this to show, as I have before said, how much the hardihood or non-hardihood of plants in our climate depends on circumstances, and those mostly local, certainly not from the degree of latitude, as many plants which flourish in Devonshire and the southern counties of England may be found growing in Scotland and standing the winters without injury, while in intervening counties in England they perish. This is particularly to be noted on our west coast, where even such a plant as *Eucalyptus globulus* attains a considerable size, and where the *Fuchsia* as I have seen in the Island of Arran—which with us in the neighbourhood of Perth when grown in the open air and not on a wall, requires to be treated like an herbaceous plant, and cut down every season—grows as a tree, with stems as thick as a man's thigh, to all appearance at least fifty years old—thanks to the influence of the Gulf stream. Then, again, on our own east coast, and especially in the vicinity of the estuary of the Tay—at Dundee, Broughty Ferry, Newport, &c.—many plants will flourish and safely pass through our severest winters, which a few miles further inland will succumb. Thus, the *Laurustinus*, magnificent bushes of which I observed in fine health and vigour at Scotsraig towards the end of the winter of 1880-81, Admiral Maitland Dougal assures me have never suffered in the least; while at Seggieden, not more than seventeen or eighteen miles further up the river, as a crow flies, every plant was cut down by the frost, and some of them old bushes of twenty years' standing, were entirely killed, roots and all. This difference, I think, may in some measure be attributed to the brackish water in the estuary, which does not reach so far as Seggieden. The influence on plants, especially evergreens, owing to the presence of brackish water at the mouth of our larger rivers, I believe to be much greater than is generally supposed, from the fact that such water is of a higher temperature than either pure fresh water or the sea, it being a well-known law in chemistry that when two fluids of different densities come in contact, the temperature of the mixture is elevated for a time in proportion to the difference in density between the two fluids, from mutual penetration and condensation. Such a mixture is constantly taking place at the mouths of rivers that run into the sea, and the mixed water maintains a temperature two degrees warmer than that of the river or the sea—thus, no doubt, in some respect softening the temperature of the air with which it comes in contact, and so have a beneficial effect on vegetation.”

A SATURDAY AFTERNOON AT WALTHAM.

I SHOULD like to be able to grow Roses of all varieties, and thousands of each; but this being impossible, the next best thing is to be able to see them in all their beauty under these conditions, and having had this privilege lately I want to try to tell your readers a little of what I saw in a few hours in Messrs. Paul and Son's old-established home of the Rose at Waltham Cross.

Arrived at the nursery and having found Mr. A. Paul, our first start was to the quarters devoted to new Roses and seedlings, and as we see the magnificent flowers that are ever and again sent out, we do not wonder that varieties which our forefathers esteemed so highly disappear from the catalogues and the exhibition stands. To begin with Waltham Roses, the first to attract attention was this year's novelty, Duke of Albany. At first sight this looks like Duchess of Bedford, but upon closer inspection it is seen to be quite distinct from that fine variety. The shape is different, and the whole flower darker, each petal being shaded with a beautiful velvety black—a splendid acquisition in all points, and I learn a free autumnal bloomer. Next came Pride of Waltham, a beauty of quite another stamp, being an addition to our light Roses. It is something like *La France* in colour, but a larger flower, of better form, and a stronger grower. *Lady Sheffield* is of a bright rosy colour, shaded lighter, with fine glossy foliage. *Red Gauntlet*, a free-blooming bright crimson rose, is sure to be much in request for beds while *Queen of Queens*, reserved for another year, will be bought by all who remember and love the true old *Maiden's Blush*, for it is simply an improved version of this old favourite, having the same perfume, the same continuity of blooming, with a stronger growth, finer foliage, and blooms often up to exhibition standard. Two very promising seedlings not yet sent

out are *Lord Bacon*, a fine dark, and *Charles Lamb*, a good light Rose.

Passing to the more general stock we come to a fine batch of *Manetti* maidens, very healthy; though not yet in full beauty, still there are plenty of blooms of *A. K. Williams*, and they are magnificent; surely this is the finest of all recent introductions. *Constantin Tretiakoff*, very fine indeed; *Maurice Bernardin* is still holding its own; *Senateur Vaisse* is also very fine. *Capitaine Christy* and *Baronne de Rothschild* seem as good as ever, while of the firm's splendid 1879 introductions, *Duchess of Bedford* and *Countess of Rosebery*, the display quite bears out the statement that they never have enough plants to meet all demands; and the three *Maries*—*Baumann*, *Rady*, and *Finger*—show that they well deserve the large space allotted to them. *Appropos* of the last-named and *Eugénie Verdier*, disciples of the “synonymous” theory will be likely to have their confidence shaken if they pay a visit to this establishment. First comes Mr. Paul, jun., with a strong negative to the statement of the two being alike, and an account of a visit last year to a Liverpool rosarian who had planted a bed with one hundred plants of each variety, the distinction being as plain as if the bed were divided by a path; and really as seen growing side by side here they are evidently quite distinct, and in point of depth of colour, freedom of bloom, and vigour of growth *Mlle. Finger* has the best of the contest.

Quitting this quarter we next visited the Teas on the *De la Grifferaie*, which, judged by the appearance of these plants, seems to be one of the best of all stocks for this class. There was a good number each of all the best varieties, all growing like Vines, and I was assured many of the plants would be over 6 feet high before the end of the season. Indeed, the shoots of that king of yellows, *Maréchal Niel* (which appears to do better on this stock than any other), had reached and exceeded that height already. In very fine condition also were *Catherine Mermet*, *Niphotos*, *Innocente Pirola*, and *Madame Lambard*, a grand addition, in colour particularly, to our Teas.

Some idea of the extent of the Rose business (which, be it remembered, is but one of many branches) of this firm may be gathered from the fact that all the plants seen at this nursery are but a very small selection, there being several acres devoted to them at Loughton, and a yet larger area of land at Framfield in Sussex.

From the outdoor quarters we adjourned to the houses, passing on our way thereto a splendid collection of *Camellias* ranging from magnificent specimens down to small plants in 32's, all in perfect health, maturing their wood and setting their flower buds. The first house visited had the roof covered with *Maréchal Niel* Rose, which, having flowered when cut back, was making fine growth for the production of blooms next year, the lower part of the house being filled with smaller plants of Teas in pots. The next house was filled with *Tree Carnations* to provide cut blooms all the year round. Another house was covered with *Rêve d'Or*, *Cheshunt Hybrid*, and other ramblers, and yet other houses for own-root Roses, grafted plants, &c.

In concluding these brief notes I must say one word as to the extreme courtesy and kindness both of Mr. W. Paul and his son. I had never met either of these gentlemen, and I did not go to the nurseries with a thousand-pound order in my hand. I simply went to look at their Roses, and yet no one could have been more warmly welcomed.

The object of my visit having been accomplished, I had the privilege of inspecting the fine horticultural library, and a walk round the garden attached to Mr. Paul's residence, which contains some grand old Elms, with bushes of *York-and-Lancaster*, *Maiden's Blush*, and other really old Roses. Altogether this garden is most enjoyable; my Saturday afternoon at Waltham was one of the pleasantest holidays I ever spent and one that will remain long in my memory.—A VISITOR.

ROYAL HORTICULTURAL SOCIETY.

JULY 25TH.

NEW plants were well represented at this meeting, but general exhibits were not abundant in the Council-room, though several interesting groups were staged in the conservatory.

FRUIT COMMITTEE.—H. J. Veitch, Esq., in the chair. One of the most remarkable exhibits was a grand collection of fourteen *Pine Apples* from Mr. D. Wilson, gardener to Earl Fortescue, Castle Hill, North Devon. They were all *Smooth Cayennes*, varying in weight from 7 to 9 lbs., the total weight being 104 lbs. 8 ozs. They were of great size, even, and in beautiful condition. A silver gilt *Flora* medal was recommended. Mr. R. Phillips, gardener to Captain Jackson, The Deodars, Mcopham, Kent, sent samples of *Tomato Perfection*, said to be a cross between *Acme* and *Trophy*. They were very even, and of good size

and colour. The Committee considered it very promising, and desired it to be sent to Chiswick for trial. Mr. C. Turner, Slough, sent six dwarf standard Red Currant trees, bearing an abundant crop of large bunches of fine fruits. Mr. J. Clarke, gardener to Lord Trevor, Brynkynalt, Chirk, Wales, sent a Cucumber, said to be the result of a cross between Blue Gown and Telegraph. The fruits were of moderate size and very even. Mr. G. Weedon, Ealing, also sent six fine fruits of Cucumber Best of All, which were considered promising, and the Committee asked that it should be exhibited again. Mr. Eckford, The Gardens, Sandywell Park, Cheltenham, exhibited several seedling Peas, which are to be tried at Chiswick. Mr. D. Brown, Linthorpe, Middlesborough, sent fruits of a seedling Strawberry named Duchess of Edinburgh, of conical form and large size. Mr. S. Castle, The Vineyard, West Lynn, King's Lynn, sent some bunches of Gros Maroc Grapes well coloured. Messrs. W. Paul and Son, Waltham Cross, were awarded a letter of thanks for a fine collection of Gooseberries, comprising over one hundred varieties. Mr. R. Laing, East Grinstead, sent a fruit of Green Gage Melon. Mr. C. A. Pearse, gardener to Sir F. Stapleton, Bart., Grey's Court, Henley-on-Thames, sent a Melon named Alexandra, a cross between William Tillery and Victory of Bath. Mr. T. Laxton, Bedford, sent samples of Richard I. Pea, John Harrison Long-pod Bean, Sir Beauchamp Seymour Strawberry, and Early Orange Vegetable Marrow, and Messrs. J. Hamlin & Co., Wood Green, had examples of good Mushroom spawn.

Messrs. Hooper & Co. offered prizes for the best dish of Abundance Tomato, which were secured by Mr. Phillips of Meopham, Kent, and Mr. S. Castle, King's Lynn, Norfolk, in that order, the first-named having neat even fruits of excellent colour.

FLORAL COMMITTEE.—G. F. Wilson, Esq., in the chair. Messrs. J. Veitch & Sons, Chelsea, exhibited several new plants, amongst which were the two hybrid Orchids *Lælia callistoglossa* and *Cattleya Chamberlainiana*, the former obtained by crossing *Lælia purpurata* with *Cattleya gigas*, and the latter a very attractive form with bright rosy crimson flowers, a cross between *Cattleya Leopoldi* and *C. Dowiana*, the first-named parent's characteristics predominating. *Lilium auratum platyphyllum*, a very large-flowered variety of this well-known Lily, was also well shown with the red-spotted *L. gloriosoides*, the yellow and maroon-spotted *L. Leichtlinii*, and *L. auratum virginale*, which was certificated. *Dendrobium bigibbum album* has long spikes of small white flowers; *Lastrea prolifera*, a Japanese Fern, has bipinnate dark shining green fronds 6 to 8 inches long; and *Begonia gogoensis*, a new species from Sumatra, was shown and certificated. Mr. J. C. Spyers, gardener to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, exhibited a collection of choice Orchids, several of which were certificated, and are described below. One, however, is especially deserving of notice—namely, *Mormodes luxatum eburneum*, which has creamy white fragrant flowers in a dense spike, the lip being hooded, with a central purple band. The column is also purple and strangely twisted sideways under the hood of the lip. Mr. H. Heims, gardener to F. A. Philbrick, Esq., Q.C., Oldfield, Bickley, was awarded a vote of thanks for a handsome basket of *Aerides affine superbum*, the plants bearing nine long spikes of rosy flowers.

Mr. C. Bennett, Kilmiston House, Shepperton, was awarded a cultural commendation for a fine specimen of *Olianthus Dampieri*, the growths bearing four or six trusses of flowers each. The plant was in excellent condition, the growths vigorous, and the foliage healthy. Mr. W. Williams, Signell Hall, Eccles, showed a variety of *Cattleya Eldorado*, having white fragrant flowers and an orange-stained lip. Mr. G. Weedon, St. John's Nursery, Ealing, exhibited several seedling *Lobelias* with very dark blue flowers and white centres. Messrs. W. Paul & Son, Waltham Cross, sent blooms of their new Hybrid Perpetual Rose Queen of Queens, of good size, excellent form, and clear pale rose tint. G. F. Wilson, Esq., Weybridge, was accorded a vote of thanks for large flowers of *Iris Kæmpferi*, white and purple and very full. A vote of thanks was also accorded to Mr. R. Dean, Ealing, for a collection of *Antirrhinum* flowers of various colours.

In the conservatory several fine groups and collections were staged. Messrs. J. Veitch & Sons, Chelsea, exhibited a magnificent collection of border Carnations and Picotees, comprising about three hundred blooms, and representing a large number of handsome varieties in all sections. Messrs. W. Paul & Son, Waltham Cross, had ten boxes of Rose blooms representing some handsome varieties; Lady Sheffield, Marie Baumann, and others being fine. Two boxes of twenty varieties sent out from Waltham Cross were very interesting. One box of white Roses was also attractive, the varieties *Boule de Neige*, *Baronne de Maynard*, *Madame Lacharme*, *Madame Noman*, and *Olga Marix* were especially noteworthy. Messrs. H. Cannell and Sons, Swanley, Kent, exhibited an attractive collection of *Verbena* blooms, comprising many fine varieties. Mr. W. Howard, Southgate, sent a collection of *Carnation* and *Picotee* blooms. Mr. H. Hooper had two stands of handsome *Pansy* blooms. Mr. C. Turner contributing forty-eight grand *Dahlia* blooms, representing many of the best Show and Fancy varieties. Handsome groups of *Ivy-leaved Pelargoniums*, *Tuberous Begonias*, *Mignonette*, and *Achimenes* were contributed from the Society's Gardens at Chiswick.

First-class certificates were awarded for the following plants:—

Begonia gogoensis (Veitch).—A distinct species from Sumatra, with large peltate leaves 9 inches in diameter, of a peculiar metallic green colour on the upper surface, the veins being of a lighter shade

and the under surface bright red. The flowers are small and white or pinkish, the peduncles and pedicels being red.

Lilium auratum virginale (Veitch).—A beautiful variety, with large white flowers, streaked with yellow in the centre of the perianth divisions.

Comparettia macroplectron (Heims).—A pretty dwarf Orchid, with elliptical leaves 6 inches long and 2½ broad. The flowers are borne in short drooping racemes, three to five blooms in each. The sepals and petals are small, ovate, pale pink dotted with bright rose. The lip is 1½ inch in diameter, nearly circular in outline, but deeply cut at the apex, pale pink veined with a darker tint.

Renanthera matutina (Sir Trevor Lawrence).—A species of slender habit, with panicles of scarlet and orange flowers in panicles 2 feet or more long, each bearing two or three dozen blooms. The sepals and petals are narrow, orange spotted with scarlet or crimson.

Grammatophyllum multiflorum (Sir Trevor Lawrence).—A peculiar Orchid, with long lanceolate leathery leaves a foot long and 3 inches broad. The flowers are pale green heavily blotched with brown, and are arranged in racemes 2 to 3 feet long.

Comparettia falcata vera (Sir Trevor Lawrence).—Very striking and different from many varieties in cultivation, the lip being very large and bright orange-coloured.

Cattleya Whitei (Low).—This was stated to have been obtained from Brazil, and was provisionally shown under the above name. The sepals and petals are about an inch broad, of a dull purplish colour; the lip being rich crimson, slightly fringed, and bright yellow in the throat.

Phacelia campanulata (Mr. W. Thompson, Ipswich).—A charming dwarf herbaceous plant, 6 inches high, with heart-shaped dentate leaves 1½ inch broad, and racemes of deep blue bell-shaped flowers having a white centre.

Oncidium stelligerum (Sir Trevor Lawrence).—A distinct species, with inflorescence 3 to 4 feet long, having short lateral branches, each bearing three to four flowers. The petals are pale yellow blotched with brown, the lip being white, and the base a dull purple at the upper part.

Tropæolum Empress of India (Messrs. J. Carter & Co.).—A very dwarf and useful variety, with small dark green leaves and rich scarlet flowers produced very freely.

Dahlia Gem (Turner).—One of the Pompon section, with neat rich scarlet flowers.

ROSES AT WIRRAL.

IF ever Judges had their work cut out it was at Wirral on the 15th of July in the amateur classes. It is not often that when five boxes of twenty-four single trusses are staged the Judges are obliged to count the points of each box before deciding which two are to be set aside, and yet this was the case at Wirral. The Rev. Lionel Garnett had a grand twenty-four and still he was thrown out, but he had the reward of a special extra prize. His Harrison Weir alone was worth it. In the thirty-six singles the Judges had hard work. Again in the local classes the competition was very severe indeed, so much so that the Judges were obliged to call in the aid of the President and Chief Secretary of the National Rose Society in order that the judging might be finished before the public were admitted. This was my first visit to Wirral; may it not be my last. Certainly they are very enthusiastic in that quarter. It is all the Rose, the Rose, the Rose, and nothing but the Rose with them. I ventured to mention that my *Oenotheras Youngii*, *macrocarpa*, and *fruticosa* were in good bloom; but I was sent to Coventry at once for my presumption. If only the Wirral Society would adopt the National Rose Society's method with regard to exhibitors' numbers and cards, and if also the Society would "just for a change" invite exhibitors when their weather is somewhat fair, I think that "à Birkenhead" would be a very general cry on the part of all amateur and professional rosarian prizefighters.—J. A. W.

RHODODENDRON BALSAMÆFLORUM.

WHEN a cross was effected many years ago between the white Malaccan *Rhododendron jasminiflorum* and the buff Javan species *R. javanicum*, it was not anticipated that such remarkable results would follow, and that a race of plants so valuable would be established. Many of these beautiful "greenhouse Rhododendrons" are in commerce, and are deservedly popular, while others more beautiful still have been exhibited and honoured, but not yet distributed. We allude now to the single varieties, a typical example of which is *R. Taylori*, figured on page 349, vol. xxxii., of this Journal, the issue of May 10th, 1877.

During the present season a most distinct and remarkable advance has been made in these plants, for already three varieties with double flowers have been certificated, these having deep rose, rich yellow, and pure white flowers respectively, and two others quite distinct from them have expanded. It is natural to ask how such a result could have been effected, and by what

parentage such massive flowers and distinct colours could have been produced? The answer must be of a nature that could scarcely be anticipated, for all these varieties, each so double and so distinct in colour, were not only obtained from one pod of seed, but the flower that produced the seed was fertilised with its own pollen. Whence, then, have come the colours? This opens an interesting question—namely, the transmission of properties by some mysterious process that now and then asserts its existence in a striking and unexpected manner. For example, the colour of the flower of the yellow variety above referred to (*R. balsamiflorum aureum*) can only be accounted for by the employment of

a Bornean species, *R. Brookeanum gracile*, in hybridising some twenty years ago. The potency of that cross has been seen repeatedly in the buffs, orange reds, bronzy yellows, and other tints that have been produced in several single forms; but now for the first time it is reproduced in its integrity after a lapse of years, and in a double flower, the parent of which was an unnamed pink seedling, fertilised, as above observed, with its own pollen! Surely this is a strange result, and as Mr. Taylor, the originator of this race of Rhododendrons, remarks, "there is much to be learned and much to be done yet in hybridising."

It was a little peculiarity in the flower that has been so singu-

Fig. 17.—RHODOLENDRON BALSAMIFLORUM ALBUM.

larly productive that caused it to be selected for self-fertilisation, and thus a circumstance which the majority would probably have passed as trivial has, by being promptly and intelligently turned to account, produced what may be termed a new race of flowers, of which the specimen figured, *R. balsamiflorum album*, is a fair typical example. The individual flowers range from 2 to 3 inches in diameter, and closely resemble well-formed Gardenias, while the trusses are very large and appear to be freely produced. Well-grown plants of these double Rhododendrons must be very imposing, and will some day be seen contributing with great effect to the embellishment of conservatories.

To Mr. Heale, one of Messrs. Veitch's competent foremen, the

credit is due of raising the double forms in question, and also the fine single varieties that have been lately certified.

UNMANURED ROSES.—If those who did not agree with what I wrote advocating a more sparing use of manure for Roses were to see those here unmanured for years, and could just now compare them with others under precisely similar circumstances only very liberally manured, they would be compelled to own that for such a climate as has to be endured here heavy manuring is a real and a very apparent mistake. It is true the season has been very favourable for a vigorous growth, and spring found the plants well furnished with sound wood and plenty of prominent and unstarted buds.

All these things have been favourable, and the result is the best display of Roses ever seen here. So long as such results are attained it would be folly to go back to the old plan of heavy manurings, unripened wood, and killed or crippled bushes in consequence.—SINGLE-HANDED.

HORTICULTURAL EXHIBITION AT THE AGRICULTURAL HALL.—JULY 24TH TO AUGUST 5TH.

ON Monday last an Exhibition of a novel character was commenced at the Agricultural Hall, Islington. It is devoted to all kinds of appliances, implements, erections, heating apparatus, &c., not in competition, for no prizes, medals, or other awards were offered, as it was the object of the promoters to avoid giving distinctions confessedly difficult to determine that would render a few exhibits unduly prominent. Several trade exhibitors entered into the spirit of the venture, but some large firms are not represented. Heating apparatus, including boilers of innumerable forms, pipes, and valves are largely represented; ornamental, terra cotta, composition, and cast iron vases, fountains, and statues constitute another feature of interest, while garden chairs, tables, and summer houses, either of plain or rustic designs, have also considerable space devoted to them. Wire arches, temples, and flower stands, houses illustrating various modes of glazing, implements, a few groups of plants, and miscellaneous sundries make a diversified exhibition.

It is impossible to give a detailed report of all the exhibits, and we can only refer briefly to a few of the most prominent, at the same time recommending all who are interested in it to pay the Hall a visit before the Show terminates. As already stated, the vases and similar articles formed an important feature; but the collection from Mr. J. Matthews, Weston-super-Mare, is especially fine, including a very large and choice assortment of terra cotta vases, flower pots, window boxes, baskets, &c., of rustic and most ornamental designs. The admirable taste and finish distinguishing all these attracted much attention to the exhibit. Messrs. F. Rosher & Co., King's Road, Chelsea, also have a large collection of vases, statues, and edging tiles, the former being composed of a material similar in appearance to Portland stone, but really a composition said to be very durable. Some of the vases are of very graceful designs. Messrs. Pullham and Son, Broxbourne, have a rockery very tastefully arranged and planted. Real stone and tufa are employed, the construction being characterised by the picturesqueness for which the firm is noted. Mr. B. W. Warhurst, 33, Highgate Road, has a varied display and one of the most extensive. Several samples of patent boilers are staged, some of which, such as "Ben's Boiler" and the Paxton Independent, have been previously noted at Kensington and elsewhere. Another patent boiler termed the Monarch is a combination of an upright tubular with a conical, the tubes being surrounded by an outer iron casing. Samples of the Syphon Hygieic gas or oil stoves are shown, and are much recommended for heating small greenhouses or halls. Valves of various approved designs are also staged with two small houses, one illustrating the Eclipse system of glazing with lead bars without putty, and the other showing a mode of glazing without top putty.

Messrs. J. J. Thomas & Co., 87, Queen Victoria Street, have a large collection of wire stands, baskets, arches, &c., of most graceful and diversified designs. A number of neat and well-constructed garden seats are also staged by the same firm. Messrs. W. Richardson & Co., Darlington, have some small models of their wall-protectors, specimens of hooded tubular boilers, portable frames, and wooden Parisian greenhouse blinds, which consist of thin laths arranged on metal bands, and serving to effectually break the force of the sun's rays without rendering the interior of the house dark. The Thames Bank Iron Company, Upper Ground Street, S.E., have the largest exhibit of boilers and hot-water-heating apparatus, including valves, pipes, and other fittings. Messrs. Deane & Co., 46, King William Street, E.C., have considerable space devoted to vases, metal tables, garden chairs, metal barrows, water barrows, and various other appliances, all remarkable for their lightness and strength.

Messrs. Messenger & Co., Loughborough, have a large exhibit of boilers of various approved patterns, new valves, small frames or "plant protectors" as they are termed, a sample of the "amateurs' portable greenhouse," a neat span-roofed structure well-built and admirably adapted for a small establishment, with many other useful articles. The Pall Mall Lawn-edger Co., 15, Pall Mall, had specimens of Adie's Patent Lawn-edging Machines, which attracted much attention from the visitors. Messrs. F. Brangwin & Co., Hackney, contributed a large collection of well-constructed park and garden seats, ornamental tables, and numerous other exhibits.

Many firms besides those mentioned above also exhibited largely, but we cannot refer to their contributions at length, though the following list will give an idea of the principal features:—Mr. J. Trotman, Holloway, rustic houses, tables, and chairs. Mr. J. Keith, Edinburgh and Arbroath, hydraulic rams and patent boilers. Messrs. Bailey, Pegg, & Co., Bankside, and Brierley, Staffordshire. Messrs. Appleby & Co., Chesterfield, pumps, boilers, and pipes. Messrs. Grover & Co., London, house showing the simplex glazing system, with strips of lead in the place of putty. Mr. J. T. Anderson, Shore-ditch, seed bags, cordage, netting, &c. Mr. Conway Warne, Weston-super-Mare, terra cotta vases, pots, and baskets. Messrs. Smith and

Williams, 23, Farringdon Road, E.C., teak Orchid baskets of various forms and sizes. Messrs. Andrew Handyside & Co., London and Derby, a large collection of ornamental cast iron vases and fountains. Messrs. Jeffrey & Co., samples of ornamental ironwork, Rose temples, and flower stands. Coalbrookdale Iron Company, ornamental cast iron vases and flower stands of pretty designs. Mr. J. Lewis, Stamford Hill, examples of patent methods of glazing without putty. Messrs. T. H. P. Dennis & Co., Chelmsford, picturesque summer houses and glass houses. Mr. W. H. Lascelles, 121, Bunhill Row, London, a large span-roofed house glazed without putty, and a new material for rockeries. Messrs. Ewart & Son, 346, Euston Road, ornamental tiles for flower boxes. Messrs. Silig, Sonenthal, & Co., Queen Victoria Street, London, "The Easy" lawn mower, chiefly notable for having open rollers of metal bars. Mr. W. Wells, Redhill, samples of his patent spray-diffuser. Mr. W. P. G. Phillips, Oxford Street, a handsome collection of glass and china vases and stands for the table. Messrs. Tracey & Sons, Ilford, a house showing their patent system of metal glazing. Messrs. R. Jenkins & Co., Rotherham, the "Duplex Cylinder," "the Victor," and other boilers. Messrs. John Crowley & Co., Sheffield, samples of "the Invincible Lawn Mower." Messrs. W. T. Allen & Co., Upper Thames Street, ornamental iron ware. Messrs. W. Edgcombe, Rendle, & Co., Victoria Street, London, houses, showing their patent method of glazing without putty; and Mr. Deverill, Slough, exhibits his patent irrigator. Messrs. G. Neighbour & Son, 127, High Holborn and Regent Street, have a most extensive and interesting collection of hives, sections, honey-extractors, foundations, bee-feeders, honey, and various appliances useful to bee-keepers.

The two principal exhibitors of plants were Messrs. Cutbush and Son of Highgate, and Laing & Co. of Forest Hill. The former have a very large group of Laurels, Palms, variegated Maples, and small Conifers margined with grass, and small specimens of Retinosporas, variegated Euonymus, and Thuias; a collection of Rose blooms is also staged by the same firm. Messrs. Laing & Co. have a smaller collection, in which the Tuberous Begonias, Rose blooms, and black Grapes are the most notable.

Under the superintendence of Messrs. John H. Raffety, Shirley Hibberd, and W. H. Holmes the Show has been most satisfactorily arranged, and the very complete catalogue issued will be found useful to visitors.

EXHIBITING—THE GOOD OLD TIMES.

"OH for the palmy days of Chiswick! We shall never see the like again. There is no spirit now. The best growers will not exhibit if they cannot do so for prizes, and unless these are large showing docs not pay." Who says this? Well, it is said and repeated almost wherever there is a gathering together of old and young exhibitors, and it is rather singular to observe how much the latter know of the "palmy days" in question.

Would those who are yearning after the impossible—the return of past days, be surprised to learn that the prizes offered at the fine old shows in question were less in value than are now provided either in London or at some provincial exhibitions? If my memory is not at fault such was and is the case. It is a long time, however, since I stood by the side of my exhibits when Prince Albert led his little boy, the Prince of Wales, by the hand, and the Queen was pointing out the beauties of the Show to the Princess Royal of Prussia, who was not then in her teens; and I cannot, therefore, remember the exact amounts that were provided in the classes, but I feel sure those amounts are exceeded now to a very considerable extent.

I have a recollection, too, that the prizes in those good old times were much less in the nurserymen's than in the amateurs' or gardeners' classes. It is impressed on my mind, for instance, that Messrs. Veitch on one occasion, and possibly on more, won the first prize for fifteen Orchids, which was £7, the second prize in the class being £4. In the amateurs' class the prizes were larger, but the aggregate amount was not equal to that apportioned in similar classes now, yet eleven collections and nearly 150 plants were staged at the Show in question. In one of the amateur classes Mr. Williams, then gardener to C. B. Warner, Esq., of Hoddesden, and now the esteemed head of the Holloway Nurseries, won a prize of £7 with twenty plants; and Mr. Kinghorn, then gardener to the Earl of Kilmorey, now the genial proprietor of the Richmond Nursery, secured a first prize of £4, the lowest prize in the same class being £1 15s. I am sorry to say I have not an old schedule of the Chiswick shows, but I feel certain my memory is accurate as regards what I have written, as, being interested in the classes in question, several things were rather deeply graven on my memory.

My showing days are over, but I often think of past times and compare them with the present. My views are old-fashioned perhaps, but I sometimes fancy there was not such a race for wealth then as now. I mean much was done for love then, that will only be done for money now. Exhibitors certainly cannot justly be blamed for this, for what may be termed the "paying"

aspect of exhibiting has not been brought about by themselves, but by the rivalry that has existed among societies. In London and the provinces a sort of auctioneering policy has been steadily pursued of late years, each making an attempt to overbid the other, until they have almost brought themselves into a state of bankruptcy. Not a few practically live on sufferance. Some are unable to pay the prize money at all, while others appear to find it necessary to postpone payment for a year, trusting, it would seem, to the "takings" of next year, with all their uncertainty, for paying the debts of this or last year that have been but too certainly incurred. I fail to see the wisdom of pledging the future in this manner, or pursuing a policy which seems in principle essentially unsound.

On what do the managers of societies thus conducted base their foundation? Theoretically, on the subscriptions of members no doubt; and if this principle were adopted in its integrity all would be well, but practically they leave this solid foundation to one weaker than sand—water, for they rely on the weather, and the consequence is that there have been some narrow escapes of drowning. It is to be feared that not a few societies, and some of high standing, are in the condition of a man living above his income, trusting to the charity of friends to extricate him from his difficulties that are sooner or later certain to overtake him; and what is the opinion of the prudence of a man like that?

There appears to be too clear evidence that societies have, in endeavouring to over-reach each other, during the past twenty years over-reached themselves; and what is the result? They have established a trade in exhibiting in which the chief object of the workers is to make money. These have a right to earn all they can, and wages have been kindly forced up for them. Accustomed to reap what has been so generously sown they are ever looking for still higher remuneration; and if, by whatever cause, it is found necessary to retrench and propose a reduction, those engaged in this trade, workmen-like, refuse to work, and fall in with the fashion of the times—strike.

I sometimes ask myself if the inevitable result of this high-pressure policy will not soon come to pass, for it is inevitable in all the affairs of life—a strong and united effort for self-preservation. At present societies are living an artificial life; the pace is too fast. Already a slackening is perceptible, and a reaction occurring. For a time the trade was stimulated by this strongly advanced, go-a-head, and showy policy—a policy of big posters and sensational programmes. Not satisfied with steady progress founded on an adherence to sound business principles, they have hurried onwards until it is a question if in the race for gain, and fame, and prestige they have not at least injured the goose that lays the golden eggs. And where is the gain from this neck-and-neck race? The committees of the several societies secure no advantage; they work hard, incur anxiety, and at times run the risk of loss, and for all their labours, given gratuitously, they are rewarded too often with a measure more or less large of abuse, as if committees were made to be grumbled at. It is quite certain, too, that the owners of hundreds of private gardens do not feel they are benefited by those great efforts that are made in exhibiting, and it is a question if the numbers of these are not increasing.

Not a few are beginning to observe that better all-round horticultural work is often to be seen in establishments unconnected with shows and showing than in many others where exhibiting would appear to be the chief object. The exhibitors themselves benefit, if they are successful, as they have a right to do, especially when they grow their own "stuff," instead of borrowing or buying it. Nurserymen have doubtless benefited immensely by exhibitions, not by the value of the prizes they have won—as these are and ought to be considered by them a small matter—but by bringing their products before the public who visit the shows, and to the notice of the thousands who do not visit them through the press. Perhaps it was this consideration that weighed with the committees of shows in the good old times—the palmy days, when allocating the prizes and devoting the lion's share to amateurs. In fact I think, but am not quite certain on this point, that no money prizes at all were given when the Chiswick Shows were about the zenith of their splendour. This was before I was an exhibitor, but I have a recollection of having heard that such was really the case.

I have alluded to the existence of a practice, that is with pretty good reason supposed to exist, of exhibitors obtaining prizes for products which they never grew. It is to be hoped that such a mode of gaining honour is not very prevalent; but whether it is so or not, far greater blame attaches to the societies than to the men who exhibit under their rules. Let us take the schedules of the Royal Horticultural and Royal Botanic Societies. If I interpret the rules and regulations correctly there is nothing to prevent me going to any of the nurseries and purchasing collec-

tions of plants, or to Covent Garden and obtaining as many dishes of fruit and vegetables as I like, and winning prizes with them if my exhibits are the best in competition. I may not have grown one plant, nor dish of fruit, nor plate of vegetables; yet if the products staged were better than those of an exhibitor who had grown his own "stuff," and he was awarded the prize while I was disqualified, the decision, strange as it may seem, would be illegal, and I believe that the production of a receipt in a court of law showing that I had paid for my goods would establish the perfect legitimacy of my purchased materials for competition in the show.

Is this as it should be? Is it encouraging horticulture in its best and truest sense and inciting to superior cultivation? Is it not rather sporting with the products of gardens, with the object of what?—making a show; and for what?—of getting money for paying the prizes that were perhaps won a year or more previously. Is not this system of management unsound? It appears like trading in bills of acceptance, as is practised by men of straw, who yet contrive to make a great display of wealth previous to the coming collapse. Are important horticultural societies setting a worthy example by opening their doors to such sporting practices as above referred to? By the present system is there not a danger of flower shows becoming so frequent, so common, and consequently so little appreciated, as to meet sooner or later the fate of spelling bees and skating rinks—namely, going out of fashion?

Yes, it would be well if the "palmy days of Chiswick" could return again. We want more showing for honour and less for mere gain. Estimating the value of garden products by the amount of money they bring in prizes is a practice of either sporting or trading which not a few societies are encouraging, and crippling themselves in the process. The result of this is that people are getting tired of shows and of showing, and if a reaction once sets in and becomes established it will not be good for horticulture either as a pleasurable and salutary home pursuit or as an important industry of the country.—A VETERAN.

NATIONAL CARNATION AND PICOTEE SHOW.

THE annual southern Exhibition of this Society was held in the conservatory at the Royal Horticultural Society's Gardens on Tuesday last, and though in some classes the competition was not so keen as it has been at some previous shows, yet the general quality was extremely good. Indeed, some of the veteran growers considered that the blooms were much above the average of exhibition quality. This certainly applied to a large proportion of those staged by Messrs. Dodwell, Douglas, and Turner, who shared the chief honours between them in all the chief classes. The first-named of the trio was particularly successful, the aggregate number of prizes won by him much exceeding the others. In many cases, however, where the Oxford, Slough, and Ilford blooms were staged together their merits were so nearly equal that much difficulty was experienced in determining their relative positions. There was considerable falling-off in most of the other collections which took fourth, fifth, or sixth-rate places, but all were distinguished by a clear bright appearance.

CARNATIONS.

For twenty-four blooms, not less than twelve distinct varieties, Mr. C. Turner, Slough, gained chief honours with a handsome collection of blooms, even, fresh, and bright, the following being especially noteworthy:—Wm. Laing, Rifleman, Lord Lewisham, Florence Nightingale, James Macintosh, John Keets, Jupiter, Squire Dodwell, Admiral Curzon, Sporting Lass, Jessica, Thomas Moore, Matador, John Hines, John Ball, Mrs. Matthews, Master Fred, and Rev. F. Tymons. Mr. J. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, Ilford, was a very close second, though some of his blooms were a little rougher than the preceding. The best were Robert Lord, a beautiful even bloom of good substance, which was selected as the premier Carnation; James Taylor, Apollo, James Douglas, Rob Roy, William Skirving, and Sarah Payne. E. S. Dodwell, Esq., Stanley Road, Oxford, was third with a fresh collection of good varieties; Mr. J. Hines, 81, Bramford Road, Ipswich, was fourth; and Mr. H. Hooper, Bath, fifth.

Mr. Douglas carried off chief honours with twelve varieties, having fine blooms of William Skirving, Florence Nightingale, Dreadnought, Earl of Stamford, Sarah Payne, Sportsman, Admiral Curzon, John Keets, J. D. Hextall, Annihilator, a sport, and a seedling. Mr. Dodwell followed closely with handsome examples of J. Douglas, Ben Simonite, Rifleman, Henry Cannell, Tim Bobbin, Master Fred, Florence Nightingale, and Harry Matthews. Mr. Hines was third; Dr. Abercrombie, 13, Suffolk Square, Cheltenham, was fourth; Mr. J. Buxton, 27, Manor Street, Clapham, fifth; and Mr. F. Cattley, Bath, sixth.

For six blooms Mr. J. P. Sharp, Perry Bar near Birmingham, was first; Master Stanley Dodwell second; and Mr. W. Slack, Queen Street, Chesterfield, third, all showing well.

SINGLE BLOOMS.—These were largely and well shown, about 150 blooms being entered in all the classes. *Scarlet Bizarres*—Mr. J.

Douglas first and second with Admiral Curzon, and third with Edward Adams; Mr. C. Turner fourth with Admiral Curzon, and fifth with Robert Lord. *Crimson Bizarres*.—Mr. J. Douglas first and second with Rifleman; Mr. C. Turner third with the same variety; and Mr. E. S. Dodwell fourth and fifth with H. K. Mayer. *Pink Bizarres*.—Mr. J. Douglas first and second with Sarah Payne; Mr. C. Turner third and fifth; and Mr. J. Hines fourth with the same variety. *Purple Flakes*.—Mr. J. Douglas first and third with Earl of Stamford, second with James Douglas, fourth and fifth with Florence Nightingale. *Scarlet Flakes*.—Mr. J. Douglas first, third, and fifth with Sportsman; Mr. C. Turner second with Matador, and Mr. E. S. Dodwell fourth with Scarlet Keet. *Rose Flakes*.—Mr. C. Turner first with Jessie; Mr. E. S. Dodwell second with Tim Bobbins; Mr. J. Douglas third and fifth with Rob Roy; and Mr. Gorton fourth with the same variety.

PICOTEES.

For twenty-four blooms, not less than twelve varieties, Mr. C. Turner well won chief honours with large blooms of good form. The leading varieties were Mrs. Chancellor, J. B. Bryant, Madame Corbin, Baroness Burdett Coutts, Louisa, John Smith, Constance Heron, Princess Dagmar, Mrs. Payne, Her Majesty, Queen of Summer, Muriel, Evelyn, Mrs. Gibbons, Mrs. Bower, Royal Visit, Imogene, and Portia. Mr. E. S. Dodwell took the second position with very creditable blooms, a few being a little weak. The best were Mrs. Wilson, Dr. Epps, Medina, Tinnie, Lady Louise, John Smith, Ethel, and Mrs. Chancellor. Mr. Douglas was third, also staging handsome blooms, amongst which was the premier bloom Mrs. Payne, very neat and even. Other good blooms in the same collection were Her Majesty, Brunette, Mrs. Gorton, Jessie, and Norfolk Beauty. Messrs. Hines and Hooper were fourth and fifth.

For twelve varieties Mr. E. S. Dodwell gained the chief award with large blooms of Tinnie, Mrs. Payne, Mrs. Chancellor, Clara Penson, Zerlina, Edith Dombrain, Ethel, Mary, Medina, Dr. Epps, Esther Minnie, and Master Norman. Mr. Douglas followed closely with a very even collection, Mr. J. Buxton being third, Mr. Hines fourth, Dr. Abercrombie fifth, and Mr. G. Duffield, Bramford Cottage, Winchmore Hill, N., sixth. There were seven entries.

For six varieties Master Stanley Dodwell; Mr. W. Slack, Queen Street, Chesterfield; and Mr. Sharpe were the prizetakers in that order with neat blooms.

SINGLE BLOOMS.—Like the single specimen class for Carnations, these were well represented. *Red, Heavy Edged*, 130 blooms being staged.—Mr. C. Turner first with Henry, Mr. J. Douglas second and fifth with Princess of Wales, third and fourth with Brunette. *Red, Light-Edged*.—Mr. C. Turner first and fifth with Thomas Williams, Mr. J. Douglas second with Mrs. Gorton, and third with Violet Douglas; and Mr. E. S. Dodwell fourth with Thomas Williams. *Purple, Heavy-Edged*.—Mr. C. Turner first with Muriel, third with Mrs. Chancellor, and fifth with Zerlina; Mr. J. Douglas second with Mrs. Chancellor and fourth with Alliance. *Purple, Light-Edged*.—Mr. E. S. Dodwell first, fourth and fifth with Mary; Mr. C. Turner second and third with Clara Penson and William Fulton. *Rose or Scarlet, Heavy-Edged*.—Mr. J. Douglas first and second with Mrs. Payne, Mr. C. Turner third and fourth, and Dr. Abercrombie fifth with the same variety. *Rose or Scarlet, Light-Edged*.—Mr. C. Turner first and second with Evelyn, and fifth with Lady Carrington; Mr. J. Douglas third with Miss Lee and fourth with Mrs. Allcroft. *Yellow Ground*.—Mr. J. Douglas first, second, third, and fourth with Ne Plus Ultra; Mr. H. Hooper fifth with Sir F. Roberts.

SELFS, FANCIES, OR YELLOW GROUNDS.—For twenty-four blooms of not less than twelve varieties Mr. C. Turner won chief honours with superb blooms of Jessica, Etna, W. P. Milner, Unexpected, Sybil, Elegante, Robert Scott, Lady Rosebery, Géant des Batailles, Constance, Albert, Duchess of Connaught, Lord Lewisham, Fred, Rosa Bonheur, Lady Stamford, Matador, and Harry Bertram. Mr. J. Douglas was a close second with brilliant blooms, and Mr. H. Hooper was third.

For twelve blooms, distinct varieties, Mr. E. S. Dodwell won the chief position with fine examples of Sarah Payne, Mercury, Dr. Hogg, John Soper, and Purple King. Master Stanley Dodwell was second, Mr. G. Duffield third, Dr. Abercrombie fourth, Mr. H. Cattley fifth.

For twelve yellow-ground Picotees Mr. J. Douglas was placed first with fine blooms of Mr. Colman, Ne Plus Ultra, Lightning, Alice, Princess Beatrice, Prince of Orange, and Eleanor. Mr. H. Hooper was second, the best in his stand being Crown Prince, Mrs. Moore, Harry, and Glow-worm. Mr. H. Cattley was third with similar blooms.

Plants in Pots.—For twelve specimens in 8-inch pots Mr. C. Turner took the lead with well-grown plants bearing three to six flowers each. The best Picotees were Her Majesty, Miss Small, Lady Boston, Constance Heron, Louisa, Queen of Summer, Mrs. A. Chancellor, and Mrs. Payne. The best Carnations were John Ball, Admiral Curzon, and Jupiter. Mr. J. Douglas was second, his plants bearing more flowers but rather smaller than the preceding. Carnations Rose of Stapleford, Joseph Crossland, H. K. Mayer, and Mayor of Nottingham were the best, the finest Picotees being Mrs. Bonar, Zerlina, and Brunette.

New Varieties.—There was good competition with seedling Carnations and Picotees, Messrs. Dodwell and Douglas taking each two first and two second prizes in the former, and one first and a certificate

in the latter. First-class certificates were awarded to the following varieties:—

Carnation Tim Bobbin (Dodwell).—A bright rose flake of good form and substance, heavily coloured.

Carnation Florence.—Twelve blooms of this were shown by J. A. Wallington, Esq., Manor House, Trowbridge. It was stated to be a good bedding variety. It is a buff yellow self, the blooms large, full, and slightly fringed.

Carnation Mrs. Page (Duffield).—A pretty self variety, with fringed petals of a delicate pale pink, nearly white hue. Very full and of good form.

Picotee Mrs. Gorton (Douglas).—A light red-edged variety, bloom even and full.

Picotee Esther Minnie (Dodwell).—A light rose-edged variety of similar substance and merit to the preceding.

FERNS FOR BASKETS.

OF late years much attention has been paid to Ferns and their allies by plant-collectors, and their exertions have enabled lovers of this class of plants to form extensive collections. According to Mr. John Smith, ex-curator of the Royal Gardens, Kew, the Ferns grown at Kew in 1823 numbered about forty hardy species and about the same number of tender exotics. Mr. Smith states that in 1825 he arranged the tender Ferns at the end of a lean-to house, the space they occupied being 12 feet by 6 feet. Since that time the collection has undergone great changes, for now they occupy two houses. For the tropical species a house of no small dimensions is set apart for them, and one of much less size is devoted to the cooler-growing kinds. No doubt in 1825 the Kew collection was as rich in species as any in the country, and by the aid of different expeditions and plant-collectors despatched from Kew the number has steadily increased since that time. That we are greatly indebted to the noted pteridologist, Mr. John Smith, none will deny for the introduction of many new species of Ferns, for when he was in office as curator he worked long and hard at the science, and was successful in raising many new species from spores that he collected from dried specimens sent home by different collectors from various countries.

Everyone is well aware of the usefulness of many of the more common species of Ferns. In fact, Ferns are indispensable. As a proof of this, how few establishments in this country do we find that have not at least a small collection of the most useful and ornamental kinds. For furnishing purposes they are extensively used. In fact, they are indispensable, and some market growers make them a speciality. I would now like to draw attention to a few species that are most suitable for hanging-baskets. I will name a few that I have grown for some time with good effect. Some of the species mentioned will be suitable for large baskets and thrive in a comparatively cool house, whilst some of the more tender kinds are well adapted for smaller baskets and warmer quarters.

I have tried several *Adiantums*, and amongst those I like best is *Adiantum concinnum* var. *latum*, a variety that Messrs. Veitch sent out some years ago. It is, however, a semi-deciduous Fern, losing a quantity of fronds through the winter season. It is very useful either for pots or baskets. The graceful manner in which the fronds hang over the sides of the baskets renders it a desirable acquisition for either the warm or cool stove. *A. concinnum latum* is a more robust plant than the type. The stipes are about 12 inches long, shining and black. The entire fronds are between 2 and 3 feet long and from 12 to 15 inches broad. It grows much better in a compost of sandy fibry loam with a little leaf soil than it does in the soil generally used for Ferns. By using a stronger soil for *Adiantums* the pinnæ come much finer. The typical form is rather widely distributed, and found growing in tropical America from Mexico to the West Indies southward to Peru and Brazil.

A. Williamsii is better suited for baskets than pots on account of the rather slender arching stipes, and somewhat resembles *A. chilense*. The caudex is creeping, and soon travels to the side of the pots. In the event of its habit being the same in baskets, which in all probability it will, this will make one of the best of *Adiantums* for baskets. As soon as the rhizomes travel to the sides of the basket they should emit young fronds, and no doubt grow through the sides and bottom of the basket. The young fronds as they appear, and until they are fully developed, are covered with a yellow sulphur-like dust; as the fronds get matured they lose this character. This is its first season in a basket, and so far it has more than realised my expectation. It thrives well in a cool stove temperature, although it is a native of Peru, and found growing on mountains at an elevation of 12,000 feet.

A. peruvianum is a noble Fern, and well adapted for baskets; it is compact in habit, a very fine and well-marked species. It is by no means common in collections, and richly deserves to be

more extensively grown. As the specific name implies it is a native of Peru. I find it succeeds remarkably well in a cool stove temperature. *Asplenium cicutarium* is an extremely handsome Fern either for pots or baskets, and in the opinion of many is the most handsome of the genus. In a well-grown plant the fronds attain the length of about 15 inches, and from 4 to 6 inches broad, with from ten to fifteen horizontal pinnæ on each side; the texture is rather thin, and a very pleasing bright green colour. The fronds arch gracefully over the sides of the basket, and is a great acquisition to the warm fernery. It is a native of Tropical America, and delights in a warm humid atmosphere.

Asplenium longissimum is a very useful Fern for baskets, in fact that is the only way in which it can be satisfactorily grown. For lofty situations this is one of the few Ferns that is really suitable. The fronds droop immediately over the sides of the basket, and hang down to a length of 6 or 7 feet. This is one of the prolific species, forming young plants at the end of each frond. After the young plants are formed the stock can readily be increased by taking the young plants off with a small portion of the frond, and pegging them down on a pot filled with sandy soil. It is a native of Java, Borneo, Malacca, and Mauritius, and grows best in a cool stove temperature, although I have a plant in the greenhouse doing fairly well, but not so free-growing as the plants in a higher temperature.

A. furcatum answers well for a large basket. This is a well-known species, and common in collections; it is a rather strong-growing species. The fronds grow to a length of between 18 inches and 2 feet long, and from 4 to 6 inches broad. It is a very accommodating Fern, and answers well either in a cool stove or greenhouse temperature. *A. flaccidum* is another well-known species, and a very useful Fern; for basket work it is amongst the best natives of Australia and New Zealand, and seems quite at home in a cool temperature. In a well-grown plant the fronds grow to a length of between 2 and 3 feet, and from 4 to 8 inches broad.

Davallias are numerous, many of which answer better in baskets than pots. Amongst the number I have grown and which do remarkably well are the following:—First, which is a great favourite with most people, and what is commonly known as the Hare's-foot Fern, *D. canariensis*, is too well known to need much said in its favour. The stout creeping rhizomes, which are densely covered with pale brown linear scales, are very suggestive of a hare's foot, from which character it has its local name. The rhizomes creep over the surface, sides, and bottom of the basket, sending out at intervals its quadripinnatifid fronds, which are nearly 18 inches long and a foot broad. It is a native of the Canary Islands, N. Africa, and Madeira, and always thrives in a rather cool temperature.

D. eiliata is a most valuable plant for baskets, and should find a place in every collection. The rhizomes are much the same as *D. canariensis* but not so thick, and densely covered with sharp-pointed ferruginous scales. The deeply cut lanceolate fronds grow nearly 2 feet long, and from 6 to 8 inches broad. The rhizome travels over the surface, bottom, and sides of the basket; as they extend they should be pegged in close to the basket; at intervals they send out fronds which look exceedingly pretty growing in different directions. Being a native of the Philippine Islands it requires a stove temperature.

D. immersa is a handsome Fern for a basket or pot work. Before the young fronds are perfectly developed they have a peculiar brown tint, and to a stranger look as though they have suffered some injury. The tripinnate fronds measure from 12 to 18 inches long and 6 to 9 inches broad, and are very useful for cutting purposes. The rhizome is wide, creeping, and peculiar in developing underneath the surface of the soil. There are several other *Davallias* that are well adapted for basket work, such as *D. chærophylla*, *D. dissecta elegans*, *D. hirta cristata*, *D. Mooreana*, and *D. repens*.

For large mixed baskets the *Nephrolepis* are exceedingly useful, *N. exaltata*, *N. acuta*, *N. cordifolia*, and *N. davallioides* are all worth growing. *N. davallioides* var. *furcans* is a valuable Fern, and well deserves to be grown in a basket; the large drooping fronds furnished with pinnæ of great size and substance renders it a desirable plant in any collection.

Polypodium pectinatum var. *Paradisæ* makes a splendid basket Fern, and well suited for a position where a spreading plant is required. In pots it appears out of its element, for the fronds with me grow about 4 feet long, slender, and gracefully arched; the frond is cut down to the rachis into close blunt horizontal pinnæ. This variety is a much more handsome Fern than the type; it is a native of the West Indies and Mexico, and grows well in a stove temperature.

Polypodium (Goniophlebium) subauriculatum is amongst the most suitable of all Ferns for baskets. It requires to be suspended

in a rather lofty position on account of the long pendulous fronds, which attain the length of nearly 8 feet in a well-established plant. It is a rapid-growing Fern, and when once thoroughly established soon makes a handsome specimen. It has a wide creeping rhizome covered with dull brown scales. The rhizomes often grow through the sides of the basket, in time sending out fronds. The pinnæ are about 4 inches long and three-quarters of an inch broad. It is a native of the East Indies, and widely distributed, therefore enjoys a warm stove temperature.

Woodwardia radicans is a well-known species, and well suited for pots or baskets. It is a strong-growing Fern, and when growing likes copious supplies of water. For the conservatory or greenhouse it is invaluable. The fronds grow from 4 to 6 feet long and from 12 to 18 inches broad. The old fronds are prolific, producing young plants at the points. If grown in a basket it should not be crippled for root room, using good rich soil for the occasion.—AQUILINA.

MILTON ABBEY, DORSET.

THE seat of Charles J. S. Hambro, Esq., D.L., is about seven miles south-east of Blandford, and eleven miles north-east from Dorchester, delightfully situated in one of the most picturesque spots surrounded by hill and dale. The road leading to Milton is for the most part up hill, so that before reaching our destination we had risen to a considerable height. Turning which way you might every yard of the road seemed to present a fresh picture, and from the top of one of the heights called Houghton Hill the sea is visible. After leaving this we pass along an almost level road to the Abbey through the village. Turning sharp to the right down a steep declivity we are at once attracted by the beautiful picture. The trees in the background to this beautiful picture might be said to resemble a horseshoe, we entering at the heel end, with the lofty trees surmounting the hills right and left, and in the distance beyond the village in front.

As we pass the village we come more closely to what has been the foreground to our picture, at the base of which there is a considerable piece of water which we leave to the right, passing through the lodge along the other side of the lake a considerable height above it, along the carriage drive into the open park, and enter the garden. There we were met by the gardener, Mr. Goodall, and conducted into one of the houses which form a group; two span-roofed houses extending north to south forming the outer boundary to the heated pits, span-roofed Cucumber and Melon houses, and span-roofed stove, which stands between them, facing the south.

Passing through a Peach house containing large well-furnished and well-fruited trees, we entered a greenhouse filled with Camellias, Orange trees, Ericas, Epacrises, and other hardwooded plants, also some healthy well-grown plants of Show Pelargoniums, which were bright with bloom. Turning to the heated pits, four ranges in all, in which were growing some suitable plants for winter flowering, such as *Begonia nitida alba* and *rubra*, *B. fuchsoides*, *Poinsettias*, and that new favourite *Nicotiana affinis*, of which there was a good batch. Cucumber and Melon plants were the principal occupants of the remaining. A small span-roofed house in two divisions next received attention; the first division containing the second batch of Melons for this season, the other was devoted to *Stephanotis* trained to the roof, *Gardenias* in variety, *Tabernæmontana coronaria*, and others. A span-roofed stove contains a number of healthy plants. Covering part of the roof is a very large plant of *Passiflora quadrangularis* bearing a number of fruits as large as full-grown fruits of Queen Anne's Pocket Melon. There were also many other kinds of climbing plants, including *Jasminum Sambac*, which is a great favourite there, and *Allamanda Hendersoni* grandly flowered. Noticeable among the other plants were some large highly coloured specimens of *Croton variegatus*, and also a number of smaller specimens suitable for decoration, all equally well coloured, and including many of the newest kinds; there were also a number of healthy *Dracænas*.

A range of span-roofed vineries on the opposite flank to the Peach house and greenhouse is in three compartments, the first containing several kinds, including Muscat of Alexandria, Madresfield Court, Duke of Buccleuch, well set; and Waltham Cross, also well set and bearing some enormous berries. The next division contains Black Hamburgh, and the third has Lady Downe's, Trebbiano, Gros Colman, and Black Alicante, all bearing large bunches and in excellent health. The other glass structures consist of three lean-to houses, two of which are occupied with Black Hamburgh Grapes, and the third with Figs; the varieties are Brown Turkey and Negro Largo, the latter a great favourite. At the back of this house Tomatoes were bearing an excellent crop of fruits. The kitchen garden, which is about four acres in extent, is in two divisions, and subdivided by Hornbeam hedges, which form a background to a spacious herbaceous border very rich in rare and choice plants.

Returning from the kitchen garden we cross the park to the mansion, a massive square building of Portland stone, with a courtyard in the centre. On one side of this mansion, and between it and the Abbey church, is a very large conservatory, the roof of which was covered with *Tacsonia Van-Volxemi* and other climbing plants, and

beneath were some healthy well-grown Palms. The beautiful marble statuary, the fountains, and the beautiful inlaid stone floor, are quite in keeping with the general style. Passing on to the flower garden, where there are some very prettily filled beds, part of which were in the carpet style, others prettily filled with old proved favourites that are indispensable in every garden; one bed of Tuberos-rooted Begonias was particularly attractive. The walks around the different parterres are composed of Derbyshire spar, broken slate, and ballast, which has a very pretty effect. Standing at this point and looking upon the abrupt rising ground, before us is a very noticeable border of a rectangular shape, the outer band of which is composed of Box bushes, then a band of Aucuba japonica, and the central portion is filled up with Mahonia japonica; the whole, being cut even with the knife, always looks well both winter and summer.

There is a walk along the top of this, approached by means of steps at one end, and hidden from view by the overhanging branches of a tree, under which were growing luxuriantly the common Vinca and Scolopendrium vulgare, forming a carpet. At the top of this elevated ground a commanding view of the flower garden is obtained. Following this walk it eventually leads us into the wild garden. Romantic as such places usually appear, it is in this case greatly improved by being close by the remains of a Benedictine monastery. Standing on this commanding ground fine views of the magnificent hills clothed with beautiful woods are obtained, with glimpses of some curious old ruins in the distance, almost hidden by the growth of Ivy.—A TOURIST.

WEST OF SCOTLAND ROSE SHOW.

JUST on the eve of going to press we have received a report of the Show held at Helensburgh on the 20th inst., which for the reason indicated we can only publish in an abridged form. A novelty in this year's Exhibition was the introduction of Pansies and Pinks, those shown by Messrs. W. Paul & Son, Paisley, eliciting great admiration. The display of Roses was magnificent, Messrs. Alex. Dickson & Sons, Newtonards, Ireland, securing the gold medal for forty-eight distinct varieties; while Mr. Hugh Dickson, Belfast, carried off the premier prize for thirty-six distinct sorts. The number of Rose blooms in competition was 1408, and of Pansies and Pinks 468. For twelve blooms of Tea or Noisette Roses, distinct sorts, Mr. A. H. Gray, Dunkeld, was first; and G. P. Hawtrey, Esq., Aldin House, Slough, second. For thirty-six blooms of Roses, distinct varieties, open to Scotch growers only, Mr. Wm. Parlane, Row, secured the first prize, a silver medal and £3, with grand flowers. The same exhibitor was the most successful with twenty-four blooms.

Pansies.—These, as already stated, were largely shown. For twenty-four Fancy Pansies, distinct varieties, Messrs. William Paul & Son, Crossflat Nurseries, Paisley, were first, staging large brilliant flowers of excellent varieties. Mr. D. Findlay, Lennoxton, was second, also with good blooms; Mr. James Barr, Paisley, being third. For twenty-four Show Pansies, distinct sorts, Mr. James Barr was first with smaller blooms than those in the second-prize stand, but of fine quality. Messrs. William Paul & Son followed closely. For twenty-four Show and Fancy Pansies, distinct (open to gardeners and amateurs), Mr. D. Findlay was first with fine flowers; Mr. R. Millar, Paisley, second; and Mr. D. Malcolm, Kirkintilloch, third.

For twelve Pinks, distinct varieties, Messrs. W. Paul & Son and W. Parlane were the prizetakers.

THE EXPERIMENTAL GARDEN AT GIRTFORD.

A FEW days ago we were much interested in visiting Mr. Laxton's Experimental Garden at Girtford, between Sandy and Blunham. The principal work carried on there is the raising of new vegetables, fruits, and hardy flowers, the staple in each department consisting of Peas, Strawberries, and Roses, to the cross-breeding of which Mr. Laxton has for many years given special attention. As the raiser of the Peas William I., Supreme, Omega, Fillbasket, Marvel, and other varieties now largely grown for market, Mr. Laxton's name is best known. This class of vegetable is still under his care with a view to improving the quality and appearance, as well as increasing the hardiness and fertility of sorts suitable for market. The strains selected for working upon are William I., Dr. Hogg, Telephone, Marvel, John Bull, British Queen, and Ne Plus Ultra, which have all been intercrossed and also crossed with various hardy and fertile varieties. The results are some new sorts of very handsome appearance, the pods being large, well filled, and of an attractive deep green colour. A new dwarf Pea named William Hurst, although not much exceeding a foot in height, is very early, and the fine long pods almost conceal the rest of the plant. This is considered a great improvement upon Little Gem. Altogether there appear to be many hundreds of varieties to select from, the very best only being retained. Agricultural Peas have also been worked upon, and a new early Maple or Partridge Pea, three weeks at least in advance of the old Maple variety, has been obtained. There are also Peas with black, white, and striped pods, and Crown or Mummy Peas with almost all coloured flowers.

In Broad Beans some fine long-podded varieties, with the pods well filled and produced in abundance, have been secured by crossing the hardy Mazagan Bean with a long-podded but somewhat tender sort of Mexican origin; and handsome dwarf sorts have been obtained

by breeding between the latter variety and Beck's Dwarf Gem. Runner Beans have also been taken in hand, and a very fertile and large-podded variety obtained by crossing the Champion Scarlet Runner with a large White Russian variety.

The Potato is now also an object of Mr. Laxton's attention, with a view to raising varieties of higher quality and early maturity, and with stronger powers of resisting the attacks of the Peronospora, so destructive of late years to the Potato crop. For this purpose the Victoria, Myatt's Prolific Ashleaf, the Jersey Fluke, and most of the useful market sorts, have been crossed with the Scotch Champion, Magnum Bonum, and other woody-stemmed sorts, generally more capable of withstanding the disease. A cross between the Victoria and the Champion is especially noticeable, as bearing out the hoped-for results. The early-ripening English market sorts have also been intercrossed with the best of the American varieties, with a view to obtaining increased fertility combined with the better quality of the English sorts.

A new early Vegetable Marrow, of the bush type, called Early Orange, has been raised by crossing the Custard with Hibberd's Prolific. Rhubarb is being advanced by crossing the Monarch, Victoria, and other large late sorts with the small but very early crimson sorts, so as to get more size combined with colour in the very early Rhubarb. Asparagus of the large French type, and of course, in Bedfordshire, the Onion, are not neglected by Mr. Laxton, who has some very fine strains of both these vegetables. Large numbers of seedling Strawberries attest what Mr. Laxton is doing in the department of hardy fruits. These are mostly the offspring of crosses between Black Prince, Vicomtesse Hericart de Thury, President, Sir Jos. Paxton, Sir Charles Napier, and British Queen, some of them being also from crosses between these varieties and the best of the American and continental sorts. Several seedlings, combining earliness with increased size, quality, and fertility, are shortly to be offered to the public. A variety called Pioneer, raised by Mr. Laxton, is now becoming much appreciated as a market Strawberry.

The hardy American Vines are also being crossed with the best-enduring English sorts and continental vineyard Grapes, with the object in view of obtaining new varieties which it may be possible to ripen in the open air in higher latitudes and in colder seasons than has been attained of late years in England. Mr. Laxton, although somewhat disheartened by the recent cool and sunless seasons, is not altogether discouraged in the hope of yet being able to provide a Grape which may again give us vineyards in England. A very handsome and free-bearing new Apple, named Schoolmaster, and which recently received a first-class certificate from the Fruit Committee of the Royal Horticultural Society, will shortly be issued from the Girtford Garden, and several distinct seedlings are being worked.

As a raiser of new Roses the name of Mr. Laxton has long been familiar to Rose-growers. The varieties Annie Laxton, Charles Darwin, Mrs. Laxton, Empress of India, Emily Laxton, Marchioness of Exeter, Mrs. Harry Turner, and many others of his raising are much appreciated both as garden Roses and on the exhibition stands. Mr. H. B. Ellwanger of Rochester, New York, in his recent carefully written work on the Rose, says that the Roses of this raiser are best adapted of all the English sorts to the American climate. All Mr. Laxton's Roses are bred in the open air, and consequently he has been able only to grow from the hardiest varieties. Although otherwise under a great disadvantage, especially during the many cold and wet summers we have recently passed through, rendering a good deal of labour in attempting to ripen seed futile, some fine seedlings containing the blood of that hardy variety Gloire de Dijon intercrossed with Roses of the dark Hybrid Perpetual race, will shortly be forthcoming. Many minor matters in flowers have not escaped Mr. Laxton's attention. Formerly the double Zonal Pelargonium was within the scope of his labours, the well-known Dwarf Jewel having, with many others, been raised by him. But latterly Mr. Laxton's object has been to condense his work, and to endeavour only to improve such horticultural plants as are of general and increasing utility, and such as are likely to make experimental gardening remunerative as well as interesting. In appreciation of Mr. Laxton's labours in cross-breeding, the late Mr. Charles Darwin was a contributor towards the establishment of the garden at Girtford.—(*Bedfordshire Times.*)

KITCHEN GARDEN.

WHERE it is desired to have a supply of Lettuces in winter after that outdoors is stopped by frost, a sowing should now be made in frames or in a sheltered position, so that a frame and lights when necessary can be placed over the plants, and such protective material afforded as may be deemed expedient to exclude frost; but where it is imperative to have a supply of Lettuce in winter for salad a heated pit is necessary. The seed should be sown where the plants are to

remain. The rows may be 9 inches apart for the Cabbage varieties, of which the best are All the Year Round and Stanstead Park. Of the dwarf Cabbage or Tom Thumb class Commodore Nutt is an excellent sort, and may be sown in rows 6 inches apart, the plants being thinned to that distance asunder. Of the Cos varieties Bath or Brown Sugarloaf and Hick's Hardy White stand well. These should be sown in rows 1 foot apart, and thinned to 9 inches asunder. The soil should be rich and firm, so as to secure a sturdy habit. Keep the surface stirred, and dust well about the plants with charcoal broken up small, ventilating whenever the temperature outdoors is over 35°.

In order to obtain a supply of French Beans when those in the open ground are cut off by cold a sowing should now be made in a pit having hot-water pipes, so as to maintain when necessary a temperature artificially of 55° to 65°. The soil for these should be rich and light, but made tolerably firm, so as to induce a sturdy habit and free bearing. The rows should be 18 inches apart, and the plants thinned to 9 inches apart, which answers for such kinds as Osborn's Forcing and Sir Joseph Paxton, but Negro Long-podded and Canadian Wonder should be given 6 inches more distance between the rows. The lights will not be needed until the close of September, perhaps not then; but when the plants flower protection must be given from heavy rains and frosts. Free ventilation is essential.

Although there are serious complaints about the Potatoes being infested with disease in many localities, so far as we have seen it is that form of the disease known as "the curl." Any early kinds that have the skins set should, when the disease manifests itself in the foliage, be at once lifted, sorted, and those required for use kept in a cool dark place, those for seed having a cool but light position. If there be any disease in the tubers it will develop rapidly under exposure. The haulm should at once be burned. Ground thereby set at liberty should without delay be planted with late Broccoli, Coleworts, Borecole, Savoys, or what may be considered necessary to assure a good supply for winter; also late crops of Celery. Of the latter we find none to stand the winter so well and late in spring as Sandringham White and Williams' Matchless Red. Place out in a sheltered border a good breadth of Cauliflower from the late sowing, which, if the early winter be favourable, will afford useful heads, but be chiefly valuable from affording heads of the size of a small teacup for lifting and placing in pits or elsewhere to continue the succession through the winter.

Notwithstanding that all available space should be occupied with Brassicas as above indicated, also with Lettuces, Endive, &c., yet ground must be reserved for Winter Spinach and Tripoli Onions. This should be prepared by manuring and digging, and where the soil is rich and light it should be made moderately firm. Periodical sowings will still be needed of Mustard and Cress, also Radishes at intervals, according to the demand.

Celery can hardly have too much water or too much liquid manure, only it must not be given too strong. Early crops will need to be earthed as the plants advance, always doing so when they are dry, keeping the soil from the centres of the plants, and giving, if needed, a thorough watering before earthing. If there is any appearance of Celery fly remove the worst infested leaves, burning them, and whilst the foliage is wet dust freely with soot. Lettuces will need plentiful supplies of water, and to ensure well-blanching heads tie up the Cos varieties at intervals and when dry. Asparagus, Seakale, and Rhubarb can be freely supplied with liquid manure now, which will enable them to develop good crowns. All decayed leaves and spent flower stalks of Globe Artichokes should be removed, and the spring-planted to afford a late summer and autumn supply of heads be well mulched and supplied with moisture. Where it is contemplated to form new plantations of Asparagus, seedlings of this or last year may now be planted. It prefers a deep rich sandy soil, or one that will allow of the water percolating through it freely. For ordinary purposes 4 feet beds, with three rows of plants in each and 2 feet alleys between the beds, answer well. Supply water if the soil is dry, and the plants will be well established before winter. They succeed better than plants of the same age put out next spring. Indeed, spring planting, unless it be deferred until the "grass" is grown about an inch, is the worst of all times next to winter to move Asparagus.

FRUIT HOUSES.

Vines.—Early houses from which the Grapes have been cleared should be kept cool and well ventilated, the border fairly moist, not saturated, nor on the other hand allowed to become parchingly dry. An occasional syringing will be useful in clearing the foliage of red spider and dust. With a view to the preservation of the foliage and prevent undue development of the fruit buds for next year's bearing shoots a moderate lateral growth may be allowed, otherwise if the foliage be healthy keep them closely pinched. It is wonderful to see the effects of a year's rest on Vines that have been forced for say ten years to afford ripe fruit in May, but it is more marked when young canes are trained to displace the old, which is seen in the season of growth on the crop of the season, and more decidedly in the next by the larger bunches, finer and better finished berries. This should not be done more distantly than every ten years, but of course where the extension system can be practised it is not necessary; indeed by cutting away long bare spurs and laying in young wood much may be done to keep the Vines in a satisfactory condition over a lengthened period, although the growth is made when climatic conditions are most unfavourable, or from December to May inclusive. Generous treatment is essential. A top-dressing should annually be given, the old soil or mulching being removed down to and picked out carefully from amongst the roots. Fresh turfy loam where it can be obtained should be supplied in place of that removed, to which about a fortieth part of bone meal has been added. It should be made firm, and a good watering given with tepid liquid manure. The best time to do this is whilst the leaves are quite green, yet the buds must be plump and the wood ripe, keeping the house rather close, shaded if necessary (for the foliage must not flag), and the Vines damped occasionally. Where the roots are poor and bare lifting must be resorted to, and this likewise should be done whilst the foliage is green.

The following is the best mode of performing the operation:—Shade the roof with mats after closing the house, and during the lifting syringe the Vines occasionally through the day. Commence removing the soil of the border at the point most distant from the stems, and remove the whole of the surface soil down to the roots, and cover with mats to keep them from the air. Now, again, start at the most distant point from the Vines, and carefully remove the soil from amongst the roots, which should be laid aside and covered. In this manner proceed to the stem of the Vines, where great care must be taken not to injure the roots. See that the drainage is perfect. Place in a foot depth of compost rather firm, which will be suitable for the lowest tier of roots, spread out the roots carefully over it, and these should be covered with about 6 inches of compost also made firm. Another tier of roots should then be introduced and covered with a layer of soil 6 inches thick. Above this there will be no roots but those of a small fibry character, and these should be spread out carefully, and have some compost worked amongst them with the hand, covering them with about 4 inches depth of compost, and as they will be shorter than the other roots the soil should not be taken out more than a foot beyond their extension, which will give the border a slight incline from the Vines. The operation completed, give a thorough supply of water at 100°, and mulch the whole of the surface with short stable manure 3 inches thick. Syringe the Vines two or three times a day, continuing the shading, and ventilate only to prevent the temperature rising above 90°. In the course of ten days or a fortnight fresh rootlets will be emitted, which will be evidenced by the foliage not flagging when air is given or the shading withdrawn, and this being the case ventilation should be resorted to gradually, and the shading withdrawn by degrees. Vines may be so treated without prejudice to their fruiting satisfactorily next season. Turfy loam, light rather than heavy, is most suitable, adding a tenth of old mortar rubbish, a twentieth of charcoal, and a fortieth of half-inch bones or calcined oyster shells, the whole thoroughly incorporated. If turfy loam be not obtainable garden soil of a light loamy nature with the ingredients above indicated to keep it open answers well, manure being best given at the surface. Laterals may be encouraged as an aid to root-action for a short time, but they should not be given too much freedom, or it will impede the ripening of the foliage and delay pruning operations.

If late Grapes are at all backward a little assistance may be given by fire heat, and will be of greater benefit than at a later period, as for the well-keeping of Grapes it is indispensable that they be early and thoroughly ripened. Any not yet commencing colouring should have a night temperature of 70°, and 75° to 80° in the daytime artificially, advancing with ventilation from 75° to 85° or 90°, or even 95° from sun heat. Ventilate houses freely which contain Vines of Lady Downe's with a night temperature of 70° to prevent scalding, from which the berries are not safe till colouring is commenced. Inside borders must not lack moisture, giving when needed a thorough soaking of tepid weak liquid manure in the early part of the day, so that superfluous air moisture will pass off before closing time. Do not allow the laterals to become crowded.

Melons.—The latest batch of plants must be placed in the Melon house. Plant on hillocks or ridges about 1 foot deep, making the soil firm, maintaining the bottom heat at from 80° to 85°, top heat 70° to 75° artificially, and 80° to 90° from sun heat. Secure to the plants a genial condition of the atmosphere by damping available surfaces two or three times a day, and close at about 3.30 P.M.; syringing the plants moderately at the same time. Attend to former instructions as regards plants swelling their crops, also in maintaining a dry condition of the atmosphere and at the roots to plants setting or ripening their fruits. In pits and frames the last batch will soon be setting their fruits, at which time be very sparing in the use of water at the roots and on the foliage, and keep the foliage fairly thin by the removal of superfluous growths. Fertilise the flowers daily when three or four female flowers are expanded on a plant, at the same time stopping the shoots one joint beyond the fruit. Syringe freely, and afford a plentiful supply of water to the roots of those with fruits swelling, earthing up those plants that have just set their fruits. Keep a sharp look-out for cracked fruits, and if any appear cut the stems about half way through about 6 inches below the fruit as a preventive in the others, keeping the soil and atmosphere dry. Upon the first appearance of canker rub quicklime into the affected parts.

Cucumbers.—To insure a free and fruitful growth pay close attention to stopping and well thinning the growths, giving regular attention to watering, shading, and ventilating. Water copiously and syringe freely between 3 and 4 P.M. Complete the preparations for the autumn fruiters, as advised in our last calendar. Plants growing in pits or frames must be regularly watered and syringed and the lights closed about 4 P.M.

PLANT HOUSES.

Stove.—Gardenias that flowered late may be cut back if too large; they should be thoroughly cleansed of scale and mealy bug, the plants bearing when cut back a much stronger application of an insecticide than when in tender growth. We use nicotine soap at the rate of 6 ozs. to the gallon of water at 120°, dipping such as are not too large, and syringing others, repeating it in half an hour, as to be effectual the work must be thoroughly done. When the solution becomes dry syringe the plants thoroughly with clear water at 140°. Stephanotis, Ixoras, Dipladenias, and similar plants liable to be attacked with scale and mealy bug, should be treated similarly after they have flowered. Young stocks of any of the above that it is desirable to increase in size should be moved into larger pots placed at the warmest end of the stove, where they can be syringed every afternoon, and encouraged to make growth.

Euphorbia jacquiniæflora being of straggling growth should have the shoots stopped, but not later than the beginning of August, after which to encourage them to make all the strong growth possible keep them near the glass, syringing every evening. All winter-flowering plants, such as Aphelandras, Poinsettias, Plumbagos, Centropogons, Eranthemums, Sericographis, and Luculias, should be exposed to all the sun and light they will bear without scorching, and be otherwise encouraged to make firm sturdy growth.

During the next two months is a good time to repot Anthuriums that have flowered early in the season. Use light open material, the best fibrous peat in lumps the size of an egg, removing the finer particles by sifting, adding an equal proportion of sphagnum and charcoal or crocks broken small, with about a sixth of sand. Remove

all the old potting material, work the soil well amongst the roots, and surface with live sphagnum. As the plants require abundant supplies of water when growing the drainage must be efficient. Stove climbers planted out should have abundant supplies of liquid manure, and the free-growing Passifloras must have their growths frequently regulated and thinned.

A first batch of Roman Hyacinths, Double Roman and Paper White Narcissus should be potted without delay for early flowering. Employ rich light soil, and plunge the pots or pans 6 inches deep—i.e., over the pots in ashes in a cold frame, in which they should remain until the pots are filled with roots and growth is being made, when they may be removed to a house with a temperature of 50°, placing them in a light position to keep them sturdy. The plants when withdrawn from the ashes should be gradually inured to light. When the spikes are showing they may be forwarded in a higher temperature.

HEATHER ON WET LAND.

A CORRESPONDENT asks for the statement of experience on the question of Heather growing on wet land being less productive of honey than Heather growing on dry land. The question is important for beginners, for though practical and experienced bee-keepers have no doubt on the matter, young apiarians should know what others have proved satisfactorily. In my native parish bees are extensively kept by working men for profit. Heather is abundant on high-lying parts of the parish, and in adjoining parishes to the north. The ground on which the Heather grows is wet, but not marshy. Almost all the bees of the parish were removed to these home moors in my younger days. Even then bees did fairly well, and it was well known that bees placed among Heather hills did better. About thirty years ago the late Mr. Robert Read of Carluke took some of his hives to Abington, twenty-four miles distant by the Caledonian railway, and there on the Heather his bees gathered far more honey than those of equal strength did on the Carluke moors. For many years afterwards many hives were annually sent to Abington, to the moors near Tinto (the highest hill in the Lowlands of Scotland), and to the moors of Carwath, and in all these places the bees do better than on the moors in and near Carluke parish. Here the practical bee-keepers found it to their advantage to remove the bees to distances ranging between twelve and twenty-four miles, though they have Heather within the easy distance of three miles, at most four miles, in their own parish. Carrington Moss in this county, three miles from Sale, is a great swamp or wet bog with Heather on it, which yields but little honey to bees. Though so near my apiary at Sale, Carrington Moss was disregarded, my bees being annually sent to the hills of Derbyshire above twenty miles distant. For bees we like the pasture of rich warm land well exposed to sunlight. Clover as well as Heather yields large crops of honey from such land.—A. PETTIGREW.

BRITISH BEE-KEEPERS' ASSOCIATION.

THE ninth great annual Exhibition of bees and their produce with hives and other bee-keeping appliances will be held at the Royal Horticultural Gardens, South Kensington, on August 3rd, 4th, 5th, 7th, and 8th. The Exhibition this year promises to be of a highly interesting character. The entries for appliances are more numerous than in any previous year, including a grand display of observatory hives stocked with bees of various races.

Various meetings will be held during the Show week. On Thursday, August 3rd, representatives from county associations will consult with the Central Committee upon topics relating to the development of county associations. A general meeting of the members will be held on Friday the 4th, under the presidency of the Baroness Burdett Coutts.

On Monday, August 7th, an examination of candidates desirous of obtaining certificates of proficiency in bee management, qualifying them to act as experts for county associations, will be held under competent examiners appointed by the Association. The rapid growth of county bee-keepers' associations throughout England has created a large demand for the services of competent experts to attend horticultural and other local shows for the purpose of giving practical demonstration of the more advanced methods of bee culture. Their services are also in much request in the visiting of apiaries and

diffusing knowledge of the art in various ways. The Central Committee have wisely determined that such experts should hold certificates, and have made arrangements for annual examinations. The prizes gained by the several competitors at the South Kensington Show will be distributed in the large conservatory by H.S.H. The Duke of Teck on Saturday, August 5th.

TRADE CATALOGUE RECEIVED.

Ant. Roozen & Son, Overveen, near Haarlem, Holland.—*Catalogue of Bulbs.*

* * All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Fumigating Grapes (*Anxious*).—We advise you to proceed cautiously in fumigating a vine in which the Grapes are "ripe and ripening." A far safer and more effectual method of destroying the thrips will be to apply an insecticide with a sponge or spray-distributor.

Large Foxgloves (*Foxglove*).—We have never seen a Foxglove 13 feet high, and we consider your plant, which you say is 8 feet high by 3 feet 9 inches in diameter, and producing nearly five hundred flowers, a very satisfactory example of culture. Such well-grown plants of good varieties have a grand effect in those shrubby borders where space is afforded for their development.

Orange Fungus on Rose (*G. O. L.*).—The leaves you have sent are seriously attacked with this fungus. We know of no better remedy than sponging them with a solution of sulphate of copper prepared by dissolving 2 ozs. of blue vitriol in a little hot water, and then adding two or three gallons of cold water. If any of our readers can inform us of a better mode of destroying the fungus we will readily make it known.

The Swan River Daisy (*H. M.*).—We can scarcely plead guilty of causing you disappointment, since your question was answered on page 45 of our issue of the 13th inst.; it is the second reply on the first column of the page quoted. We are glad to learn we have been of service to you in the management of bees; it is not all apirians who have the satisfaction of recording the taking of "lots of honey this year."

Melons—Old v. New Seed (*F. C.*).—As a rule Melon plants raised from seed many years old grow less vigorously than those raised from new seed, yet after all the question of vigour is very much a question of seed and treatment. If you pursue the method that has previously given you satisfaction you will doubtless succeed again. Many more Melons are grown every year from new than from old seed, and over-luxuriance can be checked by making the soil very firm, and not having it very rich. Pure, fresh, and rather strong loam is suitable, and if the plants do not grow freely enough they can be stimulated with liquid manure.

Striking Pansy Cuttings (*Idem*).—They may be inserted now, choosing the young growths that have not produced flowers, and which are not hollow. Rather rich yet light gritty soil surfaced with sea sand will be suitable, the sand having been for some time exposed and washed by the rain or artificially. We should not use any fertiliser, as it might be injurious where there are no roots to absorb its virtues. Slugs may be kept in check by dustings of fresh lime or soot applied at night when they are moving and feeding, not in the day when they are lurking in their haunts. Insert the cuttings in a shaded position, but not under trees.

Old Primulas (*Idem*).—We have occasionally seen old Primula plants flower excellently a second season, and many times seen them fail. Everything depends on the condition of the plants and the treatment to which they are subjected. If the plants are healthy you may try them by removing all discoloured foliage and premature flowers, removing also a portion of the old soil and adding fresh, rich, and gritty compost. There is great danger in over-potting old Primulas, and possibly the pots your plants are in will be large enough, but you afford us no data for expressing a definite opinion. Other questions will be answered in a future issue.

Pananas (*C. S.*).—In your search for information you have evidently overlooked an article on page 417 of our last volume, the issue of May 25th of the present year. Several species of Musas are there referred to, and the cardinal points of culture pointed out. If you require further information, and will specify your wants and state your conveniences for growing Bauanas, we shall be glad if we can aid you in accomplishing your object.

Striped Pelargoniums (*E. M.*).—All varieties having striped flowers are of a sportive nature, and liable to revert to the normal form, especially when too generously cultivated. If the Zonal variety, New Life, is planted out in rich soil it grows strongly and often produces scarlet flowers, but if grown in a pot and partially starved the flowers generally retain their peculiarity. It is undoubtedly advisable to select growths for propagating that produce striped flowers, and the plants should not be grown in large pots nor rich soil. The same remarks apply to the other variety of which you have sent a specimen. That is all the "secret" there is about the matter that we are aware of.

Onions versus Beetroot (*Ignoramus*).—In a collection of ten sorts of vegetables shown in July we should prefer the white winter Onions, which you state measured 15 inches round and were "very handsome," to "coarse Pine Apple Beet." You will find by reference to previous issues of this Journal that the former are invariably included in the premier prize collections staged at the London shows, and the judges are generally disposed to favour Onions rather than Beet. Both, however, may well be included in a collection of ten sorts.

Mulching Rose Beds (*A. M. B.*).—In very dry seasons and districts the method you propose might with advantage be adopted, but it will scarcely be necessary to mulch the beds now, as the earth is moist, and Roses generally have made good growths, heat being now needed for their maturation. There is one contingency that should not be overlooked in mulching beds with grass from an orchard—namely, the liability of filling the ground with weeds, some of which may be very difficult to extirpate.

Exhibiting Pelargoniums (*S. J.*).—Both the classes to which you direct our attention appear clear enough. The first stipulates for twelve distinct single trusses, and more cannot be staged. In the second the term "bunches" has no doubt been inserted studiously, not accidentally, and means that several individual trusses may be grouped together to form the requisite number of bunches, and you cannot be disqualified by so exhibiting them, as you would be in exact conformity with the schedule. Size of trusses is an important property in a Zonal, but much less so in a Show and Fancy Pelargonium; hence, no doubt, the distinction that has been made, and which is not unusual.

Insects on Plum Trees—a Dilemma (*C. A. J.*).—We fear we cannot tell you what to do under the circumstances, but will give the purport of your letter in case any of our correspondents may be able to suggest a remedy. "The under sides of nearly every leaf of a standard Plum tree are thickly covered with aphides. From its position the tree cannot be syringed, nor can anything be burned under it; what can I do?" We repeat, we have no clear idea of what you can do in such a case; nor can we tell you how to banish house flies from your room, much as we desire to aid you in obtaining what you long for—"a few moments' peace."

Roses Unhealthy (*W. Waterfield*).—The leaves you have sent indicate that your plants are in a debilitated condition, the consequence of sterile soil. In such a case they are peculiarly liable to be attacked by the black fungus. We advise you to give very copious supplies of liquid manure at once, and also at a convenient time to remove the soil from over the roots, and as far as they extend, and apply a heavy dressing of rich manure. This will stimulate the production of stronger growths and larger and stouter foliage, which will probably not be attacked by the fungus. At the same time dissolve 3 ozs. of soft soap in a gallon of water, and with this syringe or sponge the plants, dusting the leaves when they are wet with flowers of sulphur. The stamens in the flowers of cultivated plants vary considerably, often exceeding the normal number, especially when they are very vigorous. Six stamens is the usual number in the Ixolirions and other allied plants, and the exception you have noticed was due to the cause named above.

Tomatoes (*Hortus*).—The proper mode of training Tomatoes can only be determined by circumstances. Grown outdoors we do not stop our plants until they have produced four or five trusses of flowers. The plants are then topped, all the axillary growths pinched out, and all subsequent growths pinched as fast as they appear. The whole strength of the plant is then directed to the support of the fruit and the principal foliage, and some of this also is removed to prevent the fruit being too much shaded. The same system may be adopted under glass, but training another growth that issues after topping as a leader if the space to be occupied is not covered. See also the plan recommended on page 64 of our last week's issue. You would find Mr. Iggulden's manual on the Tomato useful; it can be had from this office post free for 1s. 1d.

Planting Bulbs in Turf (*Narcissus*).—All the free-growing Narcissuses will grow well in your churchyard if the soil is moderately fertile, together with the other bulbs you name. Any time from now to the end of September is a good time for planting; but it is not sufficient to make holes with the dibber and drop the bulbs in them, as the surroundings are then often so hard that the roots cannot readily take possession of the soil. The proper plan is to take up a square of turf with the spade and dig up the soil to the depth of a foot, and place the bulbs so that when the turf is replaced they are 3 inches below the surface. Thus treated they root freely into the loosened soil. When the turves are placed on again they will be slightly above the general level, but will not remain so for long. If you object to this a little of the soil can be spread on the grass, which it will benefit. Snowflakes and Snowdrops may be planted 2 inches deep.

Vegetable Marrows not Thriving (*Sherbrook*).—The recent very cold nights have seriously checked the growth of Vegetable Marrows, especially where they have no artificial heat to the roots by fermenting materials. In all probability your plants are suffering also by the want of support. We should give them warm liquid manure, soot water being good for them, and not permit them in their present weak state to mature their fruit. If you cut the fruits when they are 4 or 5 inches long they may be 18 inches apart, but if you suffer them to grow large you must not allow them to be half so numerous. There is nothing unusual in Lilies of the Valley producing seeds, but if these are allowed to mature they exhaust the plants and prevent the formation of strong crowns for producing future flowers.

Grubs on Primulas (*F., Ashbourne Hall*).—These are the larvæ of one of the Weevils (*Otiobrychus sulcatus*), insects very injurious in gardens both as larvæ and beetles. Usually they enter the pupal stage before this time, appearing as beetles in August. These attack the Vine and various fruit trees, particularly at night, afterwards resorting to succulent plants to deposit their eggs just below the surface of the earth. They may be searched for with a lantern, and to keep them off plants in pots it has been recommended to water with a clear solution of lime or with soot water. We have recently heard that a very diluted solution of carbolic acid, a few drops only in a quart of water, proves particularly distasteful to them. If eggs are deposited, the larvæ hatch in September, hibernate, and feed up in the spring and summer, when they do the most damage.

Pruning Espalier Fruit Trees (*F. R.*).—The best method to pursue can only be properly determined by the condition of each tree. Assuming your trees are established and in a bearing state, at the same time healthy, we may say generally that the plan followed by your gardener appears to be right in principle, and that suggested by yourself in a certain sense right too. If, instead of the shoots not wanted being cut out entirely now, they had been prevented forming by disbudding in April, those selected to remain would have had a better chance of assuming a fruitful habit. Still, it would not be wise to do as you suggest—namely, permit these to grow unrestrictedly. They should be shortened in June or July to within four or five leaves of the base, the axil-

lary growths following being pinched as fast as they appear. The principal leaves at the base of the shoots are then exposed to the full action of the sun and air, and the formation of fruit buds on the spurs below or amongst them usually follows. Shoots required for extension or for occupying vacant space, as replacing branches that are not satisfactory, must not of course be shortened, but all the others should be; and as a rule this shortening is too long deferred, especially when the trees are disposed to grow vigorously, as an extension of luxuriant shoots incites root-action, and if this is too powerful fruit spurs are not readily formed.

Insects on Azaleas (C. D.).—Your plants appear to be infested with thrips. These insects have a great partiality for Azaleas, and seriously injure the plants. Dissolve 2 ozs. of soft soap in a gallon of water, and pour half a gallon of boiling water on an ounce of strong tobacco. Mix the two solutions thoroughly, and then syringe the plants heavily. The best mode of doing this is to lay the plants on their sides on a mat or other clean surface, and by turning them round the insecticide can be directed to the under sides of every leaf, while at the same time the soil is not saturated. This should be repeated at intervals of ten days throughout this and the ensuing month, and the plants will be cleansed. Dipping small plants is even more effectual than syringing. It is not necessary to place Azaleas in the open air, provided they are properly attended to in a suitable house. It is, however, better to place them outside for a few weeks than to keep them heavily shaded under Vines. When placed in the open air it is important to shade the pots from the sun, as the roots will be injured, and means must be adopted to prevent worms entering the pots.

Show Pelargoniums after Flowering (H. C.).—As they have been outdoors some time, cut down each shoot at two or at most three eyes of the base of the last season's growth; and when they have broken and have shoots barely an inch long turn them out of the pots and remove all the old soil, trimming in the roots, and repot in a size less pot than those they were flowered in, and place them in a cold pit or frame, keeping rather close until fresh roots are formed, then admit air abundantly, protecting from heavy rains. At the close of September or early in October remove them to shelves or stages in a light airy position. In November they may be stopped, and in December have them in their blooming pots. Three parts turfy loam, one part old cow dung, one part leaf soil, and half a part of silver sand, forms a good compost. Zonals which have done flowering may be treated in the same way.

Names of Plants (W. G.).—Every effort has been made to obtain the name of your plant, but without avail, and all that can be determined is that it is an Anthericum. Had it been packed so as to have arrived here with fresh flowers its specific name could doubtless have been ascertained. (*W. W. Myers*).—5, *Festuca ovina*, Sheep Fescue Grass; 19, *Bromus Asper*, Rough Brome Grass; 20, *Bromus sterilis*, Barren Brome Grass; 21, *Millium effusum*, Wood Millet (birds are fond of the seeds of this Grass); 23, *Brachypodium sylvaticum*, Wood Brome Grass; 26, *Poa trivialis*, Rough Meadow Grass. (*M. McK.*)—The specimens were much withered, but the following were recognisable—5, *Rhus typhina*; 7, *Ornithogalum exsepium* (*G. S.*);—1, *Agrostis vulgaris*; 2, *Epilobium hirsutum*; 3, *Ononis reclinata*; 5, *Hieracium aurantiacum*; 6, *Vicia gracilis*. (*P. A.*)—1, Insufficient; 2, *Pteris cretica albo-lineata*; 3, *Pteris serrulata cristata*; 4, *Nephrodium setigerum*; 5, *Blechnum occidentale*; 6, A variety of *Pteris tremula*. (*W. T.*)—See our remarks on the subject of naming Roses, which are a repetition of what we have many times stated in previous issues. (*Irish Correspondent*).—We have not received your Roses, nor do we undertake to name varieties of Roses or other florists' flowers, but only species of plants. (*R. A. P.*)—*Omphalodes luteifolia*.

Standard Frame (T. E. L.).—At a meeting of the Special Committee of the British Bee-Keepers' Association which had been appointed to consider the subject, held on March 16th of the present year, it was unanimously resolved that the outside dimensions of the standard frame should be 14 inches long, 8½ inches deep; the top bar to be three-eighths of an inch thick, bottom bar one-eighth of an inch thick; side bars a quarter of an inch thick. These dimensions do not refer to anything outside of the rectangle. It was also resolved that standard frames duly stamped should be provided at 1s. each. It is better and more economical to feed bees with syrup than with dry sugar. Please address your letters correctly; it was only by chance that yours reached us after having been refused in the Strand.

COVENT GARDEN MARKET.—JULY 26TH.

OUR market has been light this week, and with buyers for soft fruit off prices have been lower.

POULTRY AND PIGEON CHRONICLE.

MAXIMUM PRODUCE OF FARM CROPS.

(Continued from page 69.)

IN the essay previously alluded to Mr. J. C. Morton says:—"No list of Agricultural Maxima is complete which omits the experience of the Rev. S. Smith of Lois Weedon, Northamptonshire. His land in one field is a clay loam, and in another a clayed gravelly soil. It has borne successive Wheat crops, in the one case for thirteen years, and in the other for eight years. The crop in the former case has averaged upwards of 35 bushels per acre, and has gradually increased, so that latterly it has been more nearly 5 quarters." What especially distinguishes this from ordinary agricultural experience is, that these crops are obtained without the addition of manure. The Lois Weedon mode of growing Wheat consists simply in the deep and thorough cultivation of wide fallowed intervals between adjacent triplet rows a foot apart from one another. These wide intervals, a yard in breadth, are at once the feeding ground of this year's crop and the seed bed of the next. This cultivation as conducted by Mr. Smith costs £7 3s. 9d. per acre, including rent and taxes (£2 4s. 3d.), and it results in obtaining from what is really half the land a crop which would generally be considered a good one though taken from the whole of it, and this it yields annually and constantly. At the time this experimental practice was carried out previous to 1859 it attracted some attention, but principally on account of no manure being used, trusting to cultivation to bring into operation the elements of production contained in the soil. As, however, we have no analysis of this soil we must suppose that it was rich in potash chiefly, such as we have known to exist in land in a certain district as having produced full crops of every kind under ordinary cultivation without manure for upwards of fifty years. The Lois Weedon system has since been overshadowed by the system of continuous cropping and corn-growing introduced to notice by Sir J. B. Lawes' experiments, and put into practice with more or less success by Messrs. Prout and Middleditch, a full account of whose practice, with our own comments thereon, was given in this Journal under the heading of "Continuous Corn-Growing and Clay Farming" from the 22nd of September to the 13th of October, 1881.

We wish now to call attention to another mode which has had a powerful influence towards producing maximum crops where tillage and manure has been applied with judgment and experience. We allude to the effects of selection called "pedigree in cereals," and as this matter was introduced first by Major Hallett about twenty years ago there is no doubt but his efforts have been attended with success, and that the agriculturists of this country have now a much better class of cereals for seed purposes in consequence. We shall only shortly allude here to Major Hallett's mode of selection, but for further information refer the home farmer to an article in this Journal upon the subject entitled "Pedigree in Cereals," dated June 24th, 1880. The question involves three points. First, that no two grains of any cereal will produce plants precisely equal, and that, therefore, in any given quantity of any cereal, whether a dozen grains, a pint, or a quarter, there is one grain superior in producing power to any of the others; second, that this superiority is inheritable; third, that it may, by repeated selection year after year of the best descendant grain, be greatly increased, and become practically a fixed characteristic

of the plant. "To support this theory we grow a crop of Wheat, say of 40 bushels per acre. We wish for more. How is more to be obtained? Can we grow more ears in number? and if so, by what method? Can we sow more seed per acre? No; for if we do we shall obtain green fodder only, not corn. If we drill 1 bushel of seed, or broadcast 2 bushels, per acre we can only obtain about one million of ears per acre. The only means of increase then is by increasing the size of the ear and its contents, and this I have effected by my system of selection." These observations of Major Hallett's clearly show that the character of the grain will influence the maximum produce under any system of cropping, of soil, or manuring.

We will now refer to maximum crops of Oats. We have obtained a statement through a medium which may be relied upon as truthful. It is, however, desired by the grower that his name should not be mentioned, although the information is freely given. A field on chalk soil in a well-cultivated district near to Andover, a town in North Hants, was sown, after a crop of roots fed off by sheep, with black French Oats in the spring of 1869, and the produce realised was 16 quarters per acre over the whole field. Although these French Oats are generally rather light weighers, and probably not weighing over 34 lbs. per bushel, still this must be considered a crop of sufficient value to be recorded by us. We, however, pass on to furnish a record of a large crop of Oats, and which our informant had an opportunity of viewing before they were cut whilst almost ready for harvest. This occurred in the year 1828 on a farm called Hook Grange, occupied by Mr. J. Wilkinson, in the parish of Titchfield in South Hants, and near the seashore. The land, which was sown with white Tartarian Oats after Swedish Turnips fed off by sheep, was about 7 acres, the soil being a deep hazel loam upon gravel. The produce was 17½ quarters per acre, with an enormous crop of straw, which it would be difficult to exceed in quantity. The drawback to this crop was in consequence of the light weight of the grain, which did not exceed 33 lbs. per bushel, owing to this sort of Oat growing with very much awn or beard at that time. They have, however, been much improved latterly by selection, but the straw for feeding value is excelled by none.

A remarkable valuable crop of what is called drege, being a mixture of winter Oats and winter Vetches grown together, next deserves notice. This occurred in a good agricultural district in Wiltshire. We are, however, not authorised to give the grower's name, although we rely upon it as truthful that the produce per acre reached the large quantity of thirty-two sacks per acre, the grain and pulse being of heavy weight, and the produce being of about equal quantities both of Oats and Vetches.

We now proceed to record crops of Barley. We first must name a full crop of American Barley grown in a good district in North Hants, being on the chalk formation, and although the grower is a most enterprising agriculturist, we are not at liberty to furnish his name in connection with this statement, but it can be confidently relied on as being correct. This crop was grown after Turnips fed off in the year 1874; the produce, 9 quarters and 2 bushels per acre, of high quality and heavy weight. This crop has, however, been exceeded by a home farmer who is an excellent manager, Mr. Burnett, on the estate of the Misses Taunton at Ashley, near Stockbridge, Hants. The land is on the chalk formation, and on a field of 3 acres. In the year 1860, after feeding off a crop of roots, the land was sown with what Mr. Burnett calls the Giant Barley, which we suppose is neither more or less than the long-eared American variety. The crop obtained, however, was extraordinary, being sixty-one sacks, the produce off 3 acres of land, and the grain of good malting quality, and it is the more remarkable in consequence of the land being on a hill farm of thin chalk soil. We must not, however, omit to notice the record of crops of Barley alluded to by Mr. Wm. Cubitt of North Waltham in Norfolk, who states in the Journal of the Royal Agricultural Society in his letter to Mr. J. C. Morton, that in the year 1844 the quantity grown on farms in that district varied from 7½ to 9 quarters per acre. We have various cases which may be recorded of the growth of 8 quarters of Barley per acre of fine quality in years long gone by, but we do not deem it worth stating here, as they have been entirely eclipsed by several well-authenticated records as above stated.

The next cereal crop to be named is Rye. The value of straw of this cereal is increasing year by year, and is higher in price than that of any other crop. We have one record to make of a very large crop of Rye, and that was grown on a chalk soil in a well-farmed district of Wiltshire; it was thirty sacks per acre, and the statement may be fully relied on.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—Preparation will now be needed for late sowing of Turnip seed after green crops or early cereal crops such as Rye, Winter Oats, White Canadian, and other early sorts of Oats; and when the heavy rain storms which have prevailed of late occur the horses may be employed in cross-ploughing the fallows on strong land in preparation for Wheat-seeding; also where it is intended to lay out farmyard or town dung for Wheat, the sooner it is done the better. It is, however, bad policy to draw bulky manures to distant fields, for it is now so well understood that artificial or portable manures are equally adapted for Wheat crops as ordinary yard dung, and it is only to refer to these columns in past seasons to ascertain the sorts and quantity of manures which we have so often advocated in years gone by as well adapted for the sort of Wheat and the nature of the soil. At every dry interval horse-hoeing and hand-hoeing amongst the various root crops should be continued; but we notice daily instances in different parts of the country that this work has been sadly neglected, and where it has been done in time it does not destroy the weeds, the weather continuing very showery. It will be recollected that last week we referred to women picking-up weeds after the hoers as having been a successful practice by one farmer in 1860 and other wet seasons. It is, however, now very difficult to obtain female field labour; still some substitute may be found by men's labour, that as fast as the weeds are cut up with the hoe they may be collected with the light iron garden rakes in small heaps between the lines of roots, and then removed at leisure to larger heaps at certain distances with the light five-grained iron forks. Some may think that this would not pay for doing, but it is just a question of the loss of crop or saving it, for continual hoeing will not kill the weeds, although done at greater cost than collecting them. The only difficulty we foresee is in those outlying districts where a sufficiency of hand labour either by women, lads, or men could not be obtained.

Harvest has commenced in many of the early districts by cutting early Peas, winter Oats, Rye, &c., and this should call the attention of the home farmer to the reality of his position, and therefore anticipate the arrival of the general harvest of cereal crops, and so be prepared for the work of using the mower, also the reaping and binding machine, in the various kinds of works for which each are best adapted; and likewise to make full provision for all eventualities in connection with harvest work, but especially the hiring of those excellent implements which he may not possess. We must also remind him that the harvest month and following few weeks is the best period for cleansing foul land in ordinary seasons, and that the ordinary work on the farm usually done by horses cannot be made available to do sufficient work where there is much cleansing of stubbles to be done, and that steam power alone can be depended upon to do the needful work, but be supplemented by the work of horses in finishing off; and that whatever the expense and cost may be, it will not only prove the best policy but the cheapest, because it is done at the right time and without any delay or hindrance to other valuable farm labour peculiar to the autumn period of the year, such as seeding of Trifolium, Vetches, winter Oats, and Rye.

Hand Labour.—This is the busy period of the home farmer's year, and all possible diligence and forethought will be required of him, as just on the verge of harvest numerous requirements crowd upon his mind, all of which must be considered in relation to each other, and also that which may be the most important and requiring his first attention. There is yet some hay ungathered in most districts, for in the early districts of gravel, sand, or chalk soil the first growth of Clovers may have been stacked and the meadows and parklands also; yet the second growth of Clovers and other Grasses will in a few days be ready for cutting if more hay is required, and unless it is upon some stock and breeding farms for sheep the Clovers should be cut for hay the second time, or otherwise for seed, as these furnish items of sale so much required when corn is low in price; besides which the Clover roots will furnish a much better preparation for the Wheat crop than when they have been fed close by sheep. The sowing of Turnip seed after the early Peas or Rye, &c., has been cut should all be done before the crops are harvested, as there will not be time when stacking the crops has commenced. Our plan is therefore to sow the seeds every day as fast as the crop is cut between the stooks or pooks, after which these can be removed on to the sceded land, and the seeding be finished entirely before the crop is carted to the stack. Where the harvest is late in some of the western, north-western, and north midland districts there will still be some work of haying in hand, and this fact leads up to the question of making the hay upon the new system, and to which we have previously given some instructions as to the working of it in this Journal of the 22nd of June last. The generality of farmers have had no chance of having satisfactory proofs of its success, for the meeting of Royal Agricultural Society at Reading where the trials of the exhausting-of-heat system were to have been carried out, and was looked forward to by many, expecting the matter would be decided upon the occasion as to the value of the system by the exhibition of practical illustrations of the work in all its detail. This may be done in about two months' time, when the ricks connected with the trials may be cut and the question of the condition of the hay be decided; for although the heat may have been exhausted out of the ricks the condition in which they were put together will have its influence, for the weather was wet and unsettled during the early

period of the trials at Reading and interfered very much with the trials as contemplated. Let these trials turn out as they may, we are not to be discouraged in this matter, and we advise the home farmer to make his own trials upon corn ricks, as well as hay ricks, under the best directions which are given by the makers of the fans for exhausting heat and water from the stacks. In making some observations upon the subject we advise that hay should be what is called half made before stacking, in order when the heating takes place that the atmospheric air may pass into and through the rick and dry it as fast as the heat is withdrawn by the fan; for at half made the hay may be put together, although it may have received a shower and is not quite dry; but if the grass is green it will settle so closely that although the heat may be drawn out the air cannot follow to dry or cool the hay.

POULTRY AND PIGEONS

PROFITABLE POULTRY IN CONFINEMENT.

ENCOURAGED by "RETIRED OLD FARMER'S" remarks on the above subject in the Journal of a few months ago, I decided to try what I could do in the same way myself. I have now pleasure in giving my experience, and hope it may be of use to some of your readers.

Having a small lean-to shed which could be spared I soon had it converted into a good roosting place, in connection with which I manufactured a run, 8 yards long by 2 yards wide, with some rough slabs of timber and galvanised wire which I had by me. On the 18th of March last I bought twelve hens and a cock, two of the hens being pure Grey Dorkings, the others mixed common barndoor fowls, for which I paid £1 10s. 10½d. From the 18th of March to July 15th they have laid 612 eggs. Most of them were sold in the local market (those used at home were priced the same), and realised £2 1s. 8d., being at the rate of 10d. per dozen as nearly as possible. I also sold a broody hen for 3s., set two, and have now twenty chickens, which I value at about 14s. Sold a couple of the oldest fowl for killing for 4s. 9d., being the price I gave for them at first. The result is that I find I have made a profit in the four months of 18s. 1½d., besides having the ten remaining fowls for nothing. The account stands as follows:

RETURNS FROM FOWLS.			
	£	s.	d.
612 eggs	2	1	8
Broody hen sold	0	3	0
20 chickens	0	14	0
One couple sold	0	4	9
	£3	3	5
		3	3
		5	
COST OF FOWLS AND KEEP OF DITTO.			
	£	s.	d.
13 fowls	1	10	10½
Light corn and maize, &c.	0	14	5
	£2	5	3½
		2	5
		3½	
	£0	18	1½

I may say that I had no previous experience whatever in the management of fowls, but followed the advice given in your paper as regards feeding, cleanliness, &c. Having removed my abode the fowls have had their liberty and the run of a grass field during the past month, with the result that they lay larger eggs, and that it does not cost half as much to keep them.

I find that the Dorking does not stand confinement well. The sort that did the best are here called Cuckoo, and Cuckoo and Brahma crossed.—T. O.

POULTRY AND PIGEON NOTES.

THE season which opened so prosperously for the poultry yard has sadly changed for the worse. The warmth of the winter and early spring was most favourable to the fertility of eggs and to incubation. We began with splendid broods, but, as we subsequently stated, as the season advanced it seemed as if the parent birds were exhausted. From all directions we received bad reports of hatching both of Ducks and chickens, though we must say that we had little to complain of in our own yards. During the last few weeks, however, dismal accounts of mysterious maladies and high mortality are almost universal from our fancier correspondents. Even the most hardy kinds of fowls seem to have suffered severely, and we have heard of many deaths in the yard of a great Game-breeder, whose chickens lead the most natural and hardy lives. It seems as if the air was at times pervaded with influences hostile to feathered life, as epidemics sometimes prevail among the human race. Unfortunately we are quite unable to prescribe any specific for the pre-

sent want of condition in chickens, for in our own broods illness has appeared in many forms—coughs, colds, rheumatism, and diarrhoea. The latter malady has been very destructive, doubtless from the excessive growth of rank vegetation. We have fed our younger broods almost entirely on rice, both boiled and raw, and since this régime was started the chickens have picked up wonderfully. The half-grown birds have suffered from a kind of influenza in whole flocks; not violent cold or roup, but a constant coughing and thickness in the throat. Of course, it is impossible to administer medicine to each bird individually where the stock is large, so they must be treated collectively. The tonic mixture which we have often prescribed should be given in the water, and Walton's tonic paste dissolved in hot water and mixed with the soft food is a gentle and excellent stimulant. As long as fowls are well and thriving we dislike all stimulants, but this is just the time for them, and their judicious use may change a limp and dejected lot of young birds into bright and vigorous specimens. When froth collects in the throat we have found perchloride of iron (single strength) very useful. We paint the throat lightly with it with a camel's-hair pencil, and the growth of any canker is at once checked, otherwise a frequent sequel to a cold becomes chronic.

WITH us the course of the Pigeon season has been the converse of that of the poultry. It opened badly; the hens seemed exhausted with the warm winter and in many cases constant laying during the months of their separation; they laid irregularly, and the young ones hatched were weakly and poor. Since the wet weather began our own birds have improved marvellously and are breeding rapidly, while hardly a squab has flagged or died. We have always found hot seasons unfavourable to a large increase of our Pigeons; they dislike thundery and airless weather, which seems to predispose them to many complaints. The rains we have had have doubtless cleared the atmosphere, which invigorates the birds. It must not be forgotten that high-class Pigeons likely to be required in autumn for the show pen must be parted early in August. We have often let our own continue to breed into the autumn and have always regretted it. The feeding of successive pairs much exhausts the parents, especially the cocks, and the later young ones generally succumb to a cold autumn. Those who have a stock of feeders must look out for a pair nesting at the same time as each valuable pair of breeders to transfer the last pair of eggs to them. These are then saved, the parent cocks can be left with any squeakers they are still feeding for a few days, and the hens at once put into the separate loft or apiary they are to occupy for the winter. All nests and all boxes suitable to nesting should be removed, otherwise encouragement is given to the hens to keep on laying. By this time the sexes of early-hatched young Pigeons can generally be distinguished. They should be separated from the general flock and put respectively with the old cocks and hens.

SOME extra classes and cups have been added to the schedule of the Hertfordshire Show. Entries are to be kept open till Saturday, 29th inst.—C.

REMARKS.

- 16th.—Fine, bright, and warm.
- 17th.—Fine and breezy till 6 P.M., then rain.
- 18th.—Fine, bright, and breezy.
- 19th.—Fine, warm, windy.
- 20th.—Very fine throughout.
- 21st.—Fine and bright; much wind, overcast afterwards.
- 22nd.—Fine but overcast, with showers.

The temperature continues very near the average, but more equable than usual, the nights being warmer and the days cooler than is generally the case, and owing to the amount of wind and to showers high maximum temperatures are altogether absent.—G. J. SYMONS.

7th	M	Manchester Gooseberry and Table-decoration Show.
8th	TU	Royal Horticultural Society, Fruit and Floral Committees at
9th	W	[11 A.M.]

WHY, WHEN, AND HOW WE MANURE OUR VINES.
THE CAPACITY OF SOILS FOR SALTS AND GASES.

IN order to be fairly understood upon this important subject it will be necessary to go into details, but at the same time I hope to be at once clear and concise enough to enable your readers to follow me without effort and without weariness. To begin with, something must be said on the capacity of soils for salts and gases, for different soils need different treatment in order to secure approximate results with a minimum of expense and of loss. All soils are not equal either in their natural fertility or in their capacity for retaining plant food. Some soils, sands for instance, instead of retaining the salts and gases supplied in the form of manures, and instead of only parting with them to cultivated crops, part with them to the rains when these come in sufficient quantities to pass in bulk through the soil. Others, again, although they are admirably fitted to retain salts and gases, are so very close and adhesive that they are not suited for arable culture, and peculiarly unsuited to the cultivation of fruit trees, and especially the Vine. Both kinds of soils are therefore avoided as far as possible, or the one is corrected by being duly mixed with the other. This, in many cases, might be done with great advantage, and might, in some instances, be even preferable to carting medium loam from a long distance, as when one description of soil is at hand only a half, more or less, of the opposite description will be needed. At all events it is necessary, or at the very least wise, to have a certain proportion of clay in every cultivated soil, and much more especially in a Vine border, for according to the proportion of clay in the soil will be the capacity for retaining manures, whether applied as liquid manure to pass through, or as top-dressings to be washed in. At the same time it is also necessary that enough opening material be either naturally in the soil or artificially mixed with it, for unless this is the case water will not readily pass away, and so will become stagnant and destructive. Neither will the roots ramify freely, and unless the soil be gritty enough and firm enough to cause the roots to multiply and break up into numberless fibres the results will not be first-class.

The above remarks are only general, but sufficient to convey my meaning. In the case of Vine borders I put more value upon having the soil mechanically right than chemically so, always providing, of course, that it contains nothing deleterious. As regards Vines we trust much more to what food is furnished artificially than to what the soil will yield of itself, for that in the richest natural soil would not produce results to satisfy any of us. With orchards it is somewhat different, for we expect

orchard trees to find much, if not most, of their food in the soil, and this they do on favourable orchard soils.

As we think it necessary to furnish most, if not all, the food needed by Vines artificially without altering the mechanical nature of the soil, we first of all inquire what food (and in what proportions) a Vine needs, and in what form it may be best applied. The first thing we turn to is the composition of what the Vine takes out of the soil to manufacture stems, shoots, and fruits. To those who have not tables of analysis ready to turn to it may not be out of place to say here that

THE ASH OF VINE WOOD IS COMPOSED OF

	1st var.	2nd var.
Potash	34.13	to 37.48
Soda	7.59	1.33
Magnesia... ..	6.55	1.05
Lime... ..	30.28	43.88
Phosphoric acid	16.35	9.20
Sulphuric acid	2.66	3.61
Silica	1.45	0.72
Peroxide of iron	0.16	1.08
Chloride of sodium	0.83	1.61
Total	100.00	99.96

These tables approximate to all others that I have seen, although some show slight differences; still the above are sufficient as a guide. The wood, it ought to be remembered, consists chiefly of water, and even after the water is by evaporation driven off, what remains is chiefly organic substances, which, when burned, leaves a small percentage of ash. This ash is all that is taken out of the border, if we except a little ammonia or nitric acid, which is very easily returned, and is generally, in fact, applied in very much greater quantity than is necessary. This needs to be borne in mind. Of course there is the annual crop of fruit (as well as shoots) which is annually taken from the Vines; but if green Vine wood consists chiefly of water, what shall we say of Grapes, and especially of those not very well cultivated? The truth is the total amount taken out of the border by the annual crops is very small. Nevertheless, it is none the worse to know exactly what is taken out, so we, as in the case of the wood, may just as well state here that

THE ASH OF GRAPES CONTAINS OF

	Must.	Skins.	Stones.	Juice.
Potash	62.74	46.89	29.45	46.89
Soda... ..	2.66	1.62	—	1.62
Lime	5.11	21.73	35.57	21.73
Magnesia	3.95	4.45	8.51	4.45
Phosphoric acid	17.04	15.66	21.05	15.66
Sulphuric acid	4.89	3.88	2.61	3.88
Oxide of Manganese	0.30	0.51	0.45	0.51
Iron	0.40	1.97	0.65	1.97
Chlorine	0.70	0.71	0.35	0.71
Silica	2.18	2.71	1.27	2.57
	99.97	93.24	99.91	99.99

We have collected a great number of analytical tables, but the above are the only ones to hand which give the analysis of the mineral matters found in Grapes; and although it might have been better to have given one table only, showing the exact percentage of each component of the whole fruit taken together, still some advantage may follow from having them separate, for possibly such facts as the one that Grape stones have a greater percentage of phosphoric acid than not only any other part of the fruit but of the Vine, may throw some light on the conditions necessary to secure a free set or to do away with stones altogether. One fact stands out above all

others, and that is that foremost among the substances required by Vines, whether to supply the wants of the fruit or of the Vines, is potash, and next to potash lime, then phosphoric acid.

MANURES.

Having found what Vines require as food from the soil, and what kind of soil at once promotes the formation of proper roots and retains best the salts and gases of the manures we apply, we will next inquire what is usually applied as manures.

Lime.—We notice lime first because it is most easily disposed of. Lime is universally applied to soils, and Vine borders generally have their full share—at least when these are first made. Nevertheless, it is quite probable, and even tolerably certain, that not enough is given afterwards. Repeated and effectual waterings of the borders tend to carry the lime in the borders out of the soil and into the drains, and so in time the soil, even soils naturally limy, becomes deficient in this essential plant food. Lime, again, is particularly valuable in keeping soil sweet, or even in purifying it when sourness already exists, and there need be no fear of excessive liming, for even when present in large quantities, comparatively speaking, it will not hurt Vines, but the reverse. Bearing this fact in mind I give lime to the soil when making up the borders, and occasionally afterwards in winter time sprinkle a dusting over the borders inside and out to keep the soil sweet, and that the Vines may not lack lime in their food.

Phosphoric Acid.—After lime we place phosphoric acid, not because that Vines require it in greater quantity than anything else, or in even so great an abundance, but because the majority treat their Vines as if they did.

After lime bones are generally applied in rather large quantities for the reason often given, that bones are a lasting manure, and the fact of their being lasting leads not a few to make bones the only manurial substance applied when the borders are made—a practice we are very far from condemning, although their application may altogether be dispensed with without the border being thereby any less fit to produce full crops of Grapes. Whether bones should be applied either when the borders are made, or afterwards as top-dressings of bonemeal annually, as some do, or not at all, wholly depends on the means to be afterwards adopted to keep a proper supply of phosphoric acid within reach of the roots. As we are going into details somewhat it may be as well, for the sake of your younger readers, to say that bones in a fresh state are made up of phosphate of lime or bone earth and organic matter, which is rich in nitrogen, and which when decaying in the soil form ammonia, to the action of which the first effect of bonemeal, when applied to grass land or vegetable crops, is due. The bone earth (it differs in different animals) contains about 40 per cent. of phosphoric acid, generally 55 per cent. of lime with traces of magnesia.

After Vine borders are made up and the Vines growing and bearing they are generally "helped" with top-dressings, but more especially with liquid manure. It may be fairly stated that 90 per cent. use guano alone in making liquid manure, while not a few use sheep and deer droppings. These waters applied to plants that are growing in exhausted soil, but otherwise healthy, produce an instantaneous and wonderful increase of vigour, which has led many to use such when better material was running to waste at their hand. The value of such liquid manures depends very largely, their immediate effect almost wholly, on the nitrogen they contain, and after the nitrogen as it exists in ammonia or nitrates to phosphoric acid, although potash is also present. Still guanos (they differ largely), generally speaking, owe their value chiefly to the bone-earth and nitrogen they contain, so that the use of bones and guanos chiefly, or even largely, does not meet the demand of the Vines for potash. It is true very fine Grapes have been grown by the use of these alone, but not economically, for when potash is supplied in sufficient quantities by the use of guano there must be a very great waste of valuable and costly phosphates and nitrogen.

With the idea of furnishing potash to the Vines wood ashes have been very much recommended of late years, and will no doubt be largely used by many. Potash as it exists in wood ashes is easily soluble, and even in good holding loam dis-

appears rather quickly when only supplied in this form when the borders are made. Used in moderation as top-dressing either annually or biennially they are more likely to do good; but I would here remark that not only is potash thus applied liable to disappear quickly, but it is a popular fallacy to suppose that wood ashes—unless, indeed, it be Vine wood—are particularly rich in potash. Doubtless a few woods leave ashes rich in potash, but a very much greater number furnish lime chiefly. When we have to apply 100 lbs. of ashes in order to furnish 5 lbs., 10 lbs., or even 15 lbs. of potash, there is, I apprehend, no small danger of overloading the soil with matters not wanted. At the same time, while uttering this warning note, I do not condemn their use, for lime and other matters may be thus furnished economically, and it is certainly better to use the refuse of a burning heap to furnish this than to spend money buying it elsewhere and allowing that at the door to waste. Economically and safely it can only be applied in small quantities. When applied for the sake of the potash they contain only, it is better to wash the soluble matter out and apply the water, or to sprinkle the ashes on the border and allow the salts to be bleached in with the rains or watered-in, afterwards removing the refuse.

Top-dressings generally consist of animal droppings or merely ordinary stableyard manure half decayed. Such will yield all the different compounds the Vines require, including potash; but as a matter of fact most of the mineral matter is in the straw and is removed with it, for it is only when the whole becomes altogether decayed that the mineral matter is available for food, and this is the reason why in farming one manuring is found sufficient for a four or a six-course rotation. Top-dressings, as we have said, are generally removed before they become so decayed as to form part of the soil, and I think this is well, for nothing so speedily makes a healthy loam inert as large quantities of decayed manure mixed with it. This evil I believe exists in nine out of every ten cases of old Vine borders, and when it happens the surface ought to be bodily removed and replaced with healthy material. Top-dressings are in our opinion more valuable as conservers of moisture and for encouraging roots upwards than for the actual food they supply.

We use urine with a view to maintaining an abundant supply of potash. That from the stables and cow houses supplies us with an inexhaustible store. Rich in potash, it is also rich in many other foods, and chief among these we may mention nitrogen compounds. It is this chiefly which makes guano valuable. Of course urine contains no phosphoric acid, but in borders containing the usual amount of bones a further supply of phosphoric acid is hardly needed. I used bones rather sparingly for two good reasons, one being that we have a tank filled always with sewage water, and that everybody knows is peculiarly rich in phosphoric acid. This sewage water is very weak, and I consider it to be of just about the same value of equally weak guano water. In times of drought we have often no other water, and I never hesitate to use it freely and with first-rate results. This is used in summer, the urine is used in winter. One thousand pounds of cow's urine contain somewhere about 40 lbs. of potash salts, say 20 lbs. of potash. Twenty pounds of potash is more than an ordinary houseful of Vines will use in a long time. This quantity is contained in half a ton of pure urine, or from four to five times as much as is contained in half a ton of ordinary stableyard manure. The reason it is used in winter is that it may be applied pure when the roots are resting without injuring them. This I have proved beyond the possibility of a doubt. The application of half a ton of liquid manure to a border is a small task compared with applying 3 tons, and when applied in summer it is not even safe when diluted to that extent. Moreover, as we have already said, it occasionally happens that the only water available here in summer is liquid manure. But above all, urine is not fit for plant food in a fresh state. The potash is bound up chemically with lactic, hippuric, and sulphuric acids, and these salts are better when allowed to soak into lumps of loam or clay, and become changed into the carbonate, in which state the roots readily and with benefit use it. Again, the urea which is in the urine also changes for the better, first to ammonia and then to nitric acid, in which states

it is readily used. By applying it in winter, then, it gets prepared to do its work just when it is required. Last, but by no means least, often urine cannot be had except during winter.

Among plant foods water occupies the chief place, just as water is the chief item in every bill of fare for animals. That is pretty well understood, and it would have been hardly worth while repeating it here. Many Vines are allowed to suffer by want of a proper supply. The amount of water that a healthy Vine will evaporate is very great, especially in hot weather, and no matter what other food is provided, unless water is used very freely first-rate results need not be expected. Those who have been most successful have all used water freely. In many cases as much as 70 or 80 inches are given in the course of a summer with advantage.

On this point I will not further enlarge, but feel constrained to point out that water is Nature's great cleanser, and that soils, more especially those heavily manured, such as Vine borders, will not long remain sweet and healthy unless water passes through them freely. When manure is always being washed into borders and none ever washed out it must remain there, and even the best composed border will become surecharged in time, and that time not a distant one, when food much in excess of what the roots remove is continually applied. The case is very simple. No one need fear the impoverishment of a properly made border by passing water through it. Only that which the clay cannot hold will pass away, while the clay will continue to hold an ample abundance. No border need ever become sour if enough lime and sufficient water be applied—that is, if it is well drained and properly constructed of suitable materials.

Such is an outline of my practice and the reasons for it, so far as the application of food to Vines is concerned. The results of this I have previously given, and they speak for themselves. At the same time the use of proper materials for forming borders and for maintaining them in a state of full and healthy fertility is only one phase, although an important one, of successful Grape culture. The management of the tops was recently discussed, no doubt with profit to all, and I then gave my practice, holding nothing back. I have done the same in this case, and in whatever discussion may follow I expect equal frankness.—SINGLE-HANDED.

MUSHROOMS FOR THE MILLION.

(Continued from page 51.)

CASING THE BEDS.

A SECTION of the casing is shown in the figure previously referred to (page 463, last volume). The thickness of the soil on Mushroom beds must be governed by its nature. If very heavy it will only need to be an inch thick when beaten as firmly as possible; if of medium texture it may be $1\frac{1}{2}$ inch thick; if light or of a sandy nature 2 inches. When the work of casing is well done it seals up the heat in the bed to a surprising extent; but it will not do this effectually if the orthodox plan is followed of dipping the spade in water, and plastering the soil, making it smooth as a cement floor. It should be made firm and also smooth, but the soil must be sufficiently moist for the necessary compression, and should be watered to make it so, if needed, before being placed on the beds. There is a very good reason for this which all who are engaged in growing Mushrooms, or trying to grow them, do not fully comprehend. When the surface is plastered like mortar it shrinks sooner or later and forms fissures. If these are produced quickly the heat and virtues of the bed escape through them; if they do not form for some weeks and the soil has become permeated with the mycelium the delicate threads are broken, and when this is the case we have no more right to expect an abundance of fine Mushrooms than we have to expect that a telegraphic

message will be transmitted when the wires are cut. It is this cutting off the lines of supply from the interior to the surface of the beds that is the primary cause of Mushrooms ceasing to grow after they have formed, turning brown, and withering. The shrinkage of the soil breaks these slender lines of communication, and they are not unfrequently severed by the weight of a man being suddenly thrown on the bed, that weight, as is common, resting on one hand for the purpose of some portion of the bed being more easily reached with the other. It is not the mere weight that does the injury, but the jerking manner in which it is applied. This may appear a small matter to dwell on, but like a number of other small matters it is of more importance than is apparent at the first glance. The withering of thousands of Mushrooms have perplexed many cultivators. The beds and house have neither been too wet nor too dry, too hot nor too cold, yet the pea-like Mushrooms have refused to move, except backwards. The snapping of the extremely brittle and cobweb-like mycelium is with much confidence submitted as the chief cause of the evil, and it is a little surprising it has not been submitted before.

TEMPERATURE FOR MUSHROOMS.

September being the month in which Mushrooms are produced the most bountifully in pastures, the temperature of that month will indicate their requirements under cultivation. It is certain that not a few failures occur in Mushroom houses by too much heat accompanied by an unduly dry atmosphere, such as is produced by hot-water pipes and a deficient supply of moisture. As a rule those houses in which Mushrooms succeed the best are kept at a temperature ranging from 55° to 60° , a genial atmosphere being at the same time maintained. Now, what do we find in the open air during the Mushroom-growing month—September? Those who will take the trouble to examine the daily September (London) temperatures for the past ten years and will take the means for the whole period will find the maximum to be 67.7° and the minimum 48.8° , or a general mean of 58.2° . How far is this from the temperature of a well-managed Mushroom house? "Rather too high," perhaps some may say. Possibly it is. Neither is the average quite fair as applied to Mushrooms, as the figures represent the temperature at 4 feet from the ground, and Mushrooms do not grow there, at any rate in the open air. On the contrary, they nestle among the much colder dew-bespangled grass, where the mean minimum radiation temperature of the past decade averaged only 47.1° . Now if we take the average between this, the lowest point, with the above-mentioned highest, we reduce the average by 1° —viz., 57.2° . This temperature is thus ample for Mushrooms; indeed, it is practically too high, as they grow much quicker during the colder air and moister surroundings of night than under the increased heat and drier air of the day. Still, were it not for the comparatively high day temperature of nearly 70° , the earth's heat would not be retained at the requisite degree for the crop; and what is this? The average for the period named is at a foot below the surface 58.1° ; or, what is a little curious, almost identical with the average mean of the air, 58.2° . As near, then, as can be ascertained from the book of Nature from 55° to 58° Fahr. may be stated as the proper temperature for Mushrooms. That they will endure more heat than

represented is unquestionable, and that they will grow freely under a lower temperature is undeniable, for this the minimum grass radiation figures demonstrate. And what do these September temperatures suggest? First, that there is a danger of keeping Mushroom houses too warm; and secondly, what is more important for our purpose, that the heat indicated can easily be maintained with a body of fermenting materials in the open air, and straw to cover the beds and arrest radiation. On a mild day in January of the present year the radiation temperature of a bed that was just commencing bearing heavily in the open air was 60° under a layer of 9 inches of straw. This was a little too high, as the Mushrooms were rather drawn. On a colder day it would have been 5° lower, and if it had been 15° colder no harm would have been done, only the growth of the Mushrooms would have been slower, or much about that of those in pastures when the radiation temperature on grass is equally low as it often is in September.

MUSHROOMS VERSUS FROST.

Cold does no real injury to Mushroom beds, it only arrests the growth of the mycelium—does not destroy it. During the severe weather of December, 1880, some outdoor ridges were frozen quite through, and were like a mass of stone, yet on the return of genial weather the same beds produced abundant crops. This is a very important fact, and shows that the Mushroom is not such a tender plant as is generally imagined, and that a failure is not likely to follow if the heat cannot be maintained at some fancy figure. But it must be stated that Mushrooms already formed are liable to injury by extreme frost. It is only the mycelium that can endure it with impunity; but this circumstance alone is gratifying, and the experience proves that Mushroom-growing on outdoor beds in winter is perfectly safe. Since these notes were written (in January) a correspondent of the *Journal of Horticulture* communicated an article containing the following evidence bearing on this subject:—"Two years ago last autumn I made two beds in a cold shed with a north aspect. They were spawned and soiled in the usual way, and then left all that severe winter. I looked at them sometimes in passing, and found them frozen as hard as a brick wall. I never expected to have a Mushroom from either of them, for I had always been taught that if a bed became frozen it would never bear any Mushrooms. In the spring I told the men to wheel both beds into the garden for manure, I happened to be present when the men started, and the first spadeful that was taken up showed that spawn had worked all over the bed like a network. I immediately stopped all operations and had the beds covered with litter, and they turned out two of the best beds of Mushrooms I ever saw."

That a low temperature is not fatal to the growth of Mushrooms is apparent from the fact of their presence at the base of hotbeds late in the autumn; indeed, fine examples have been gathered which were pushing their way through a covering of snow. This no doubt was exceptional, and was without question the effect of very strong mycelium produced direct from the spores, as previously alluded to. While such low temperatures must not be sought for, it may still be asserted with much confidence that a high temperature and dry atmosphere are inimical to Mushrooms, and the

cause of many failures and unsatisfactory beds.—
J. WRIGHT.

(To be continued.)

COMTESSE DE SERENYE ROSE.

I SHOULD be glad to have information on the following questions:—Does Comtesse de Serenye open best on the seedling Briar or the Manetti? I only have one plant, which is very vigorous, but it has not opened a flower during the last three years; it is on the Manetti. Soil, well-manured good clay. It is now covered with fine buds, but none are opening. Other Roses do well in the same place.

Which stock, the seedling Briar or Manetti, is considered the best for bad-opening Roses?

I should like to have the names of about a dozen of the very darkest and the same number of the very lightest coloured Roses that are allowed to be the best?

My small stock consists principally of such coloured varieties as Marie Baumann and Alfred Colomb. I have the catalogues of all the principal nurserymen, but it is difficult for a person like myself who has seen no large exhibition of them to select from them, as they are all described either as superb, magnificent, grand, splendid, or similar superlative terms.—NOVICE.

WEST OF SCOTLAND PANSY SOCIETY.

THE third annual Exhibition of this Society was held in the City Hall, Glasgow, on the 26th ult., and was a decided success. There was a splendid display of Roses, Pinks, and Pansies, the latter forming the major portion of the Show. The competition for Show and Fancy Pansies in the nurserymen's class was very strongly contested, the first prizes being secured by Messrs. Wm. Paul & Son, Paisley, with large well-defined blooms of splendid quality. The same firm won the first prize in the nurserymen's competition for twenty-four Pinks with large double flowers perfectly laced. In the nurserymen's class for Roses Mr. Hugh Dickson, Belfast, and Messrs. A. Dickson and Sons, Newtownards, divided the honours with well-formed blooms in splendid condition. The competition for twelve hardy herbaceous blooms brought a good number forward, Mr. Peter Sinclair of Campsie gaining the silver medal with beautiful specimens. We give the principal awards.

PANSIES.

Nurserymen's Classes.—Twenty-four Show Pansies, distinct varieties. First (timepiece) Messrs. Wm. Paul & Son, Crossflat Nurseries, Paisley, with D. Malcolm, Artemis, Peter Lyle (seedling), Jas. Clelland (seedling), W. Shearer, dark self; Mr. Galloway (seedling), Mrs. Dobbie, white self; Golden Queen, yellow self; R. Pollock, D. Robertson, Bailie Cochran, R. Donaldson, Try Me Oh (seedling), yellow grounds; Fair Maid, Mrs. D. Wallace, Mrs. Muir, Mrs. J. G. Paul (seedling), Tickler, Jeannie Grieve, Sweetness (seedling), white grounds, and several seedlings. Second Mr. John Sutherland, nurseryman, Lenzie. Third Mr. Wm. Dickson, Ladyburn Nursery, Paisley. Twenty-four Fancy Pansies, distinct varieties. First (silver medal) Messrs. Wm. Paul & Son with large gorgeous-coloured blooms of H. L. Blacklaw, Mrs. H. Hunter, James Gardner, Catherine Agnes, Thalia, Livadia, Wm. Windle, Sir P. K. Murray, R. Goodwin, Tom McComb, Mrs. Jamieson, John Taylor, Mrs. Russell, Earl Beaconsfield, Schoolmaster, Hecla, Sultana, R. K. Mitchell, Wm. Stewart, and seedlings. Second Mr. W. Dickson; third Mr. J. Sutherland.

Gardeners' Classes.—Twenty-four Show Pansies, distinct varieties. First (silver medal) Mr. Hugh Stewart, Ayr, with well-grown flowers of J. P. Barbour, Robert Black, Rev. J. Morrison, Golden Circle, Mrs. Dobbie, Silverlight, Miss Baird, Miss Ritchie, Fair Maid, W. Robin, A. Cameron, Bailie Cochran, D. McHutchison, and seedlings. Second Mr. D. Findlay, Campsie. Third Mr. R. Stewart, Lenzie. Twenty-four Fancy Pansies, distinct varieties. First (silver medal) Mr. R. Stewart with large blooms of Mrs. E. H. Wood, Mrs. Findlay, Mrs. Jamieson, Hecla, Countess of Home, Mrs. Scott Plummer, W. McIntosh, Mrs. Russell, W. Windle, Ringleader, Jane Adair Martin, Catherine Agnes, G. Nettleship, Earl Beaconsfield, Mrs. J. Watt, Hugh Paton, Mrs. Taylor, and seedlings. Second Mr. D. Findlay; third Mr. A. Duncan, Paisley.

Amateurs' Classes.—Eighteen Show Pansies, distinct varieties. First (silver medal) Mr. D. Malcolm, Kirkintilloch, with lovely blooms of Alex. Watt, Rev. J. Morrison, Crosshill Gem, Mrs. Cadzow, Gomer, Mrs. Dobbie, Mrs. Muir, Mrs. Ritchie, Mrs. Arthur, Miss Ritchie, R. Burns, J. B. Robertson, and seedlings. Second Mr. John Stewart, Campsie. Third Mr. J. S. Ritchie, Denny. Eighteen Fancy Pansies, distinct varieties. First (silver medal) Mr. D. Malcolm with grand blooms of Mrs. Forrester, Catherine Agnes, Mrs. Jamieson, Alex. Stephen, Master Dan, R. Goodwin, Mrs. Russell, Earl Beaconsfield, Sir P. K. Murray, Ringleader, Mrs. J. Stewart, Perfection, Mrs. E. H. Wood, Lady Falmouth, D. Wallace, and seedlings. Second Mr. J. Stewart; third Mr. Jas. Black, East Calder.

Open Classes.—Twenty-four Show Pansies, distinct varieties. First

(silver medal) Mr. William Storrie, Lenzie Junction, the most noteworthy blooms being J. P. Barbour, J. Dalziel, Alexander Watt, D. Malcolm, G. McMillan, W. Crockhart, Snowball, Mrs. Cadzow, Mrs. Ritchie, Mrs. D. Wallace, Miss Ritchie, Captain Speirs, Jeannie Grieve, R. Pollock, Mary M'Comb. Second Messrs. William Paul & Son. Twenty-four Fancy Pansies, distinct varieties. First (silver medal) Mr. William Storrie with magnificent flowers of W. McIntosh, James Reid, Catherine Agnes, A. Stephen, Mrs. Scott Plummer, Mrs. Barrie, Mrs. Kidd, R. Goodwin, Mrs. Taylor, Earl Beaconsfield, Mrs. McTaggart, Luck's All, Mrs. Jamieson, J. C. Murray, L. V. Heathcote, G. H. Gill, Mrs. Main (seedling), Bob Montgomery (seedling), Mrs. Storrie (seedling), R. Cowan, Perfection, Mrs. E. H. Wood, W. Cuthbertson, and W. Dickson. Second Mr. John Stewart, third Mr. A. Duncan.

PINKS.

Nurserymen's Classes.—Twenty-four blooms, distinct varieties. First Messrs. William Paul & Son with Wm. Paul, W. Murray, D. Saunders, Premier, W. Bruce, Dr. Masters, Henry Cannell, Col. Holms, Emmeline, Bertram, Egeria, Nelly, Modesty, Emily, Captivation, William Kilgour (seedling), and eight seedlings. Second Mr. W. Dickson, third Messrs. Dicksons & Co., Edinburgh.

Gardeners' Classes.—Twelve blooms, distinct varieties. First Mr. A. Duncan with Wm. Paul, W. Murray, Bertram, Tottie, Modesty, Enid, Mrs. G. Dickson, Dr. McLean, Ada Louise, W. Bruce, Egeria, Teaser. Second Mr. J. Stewart, third Mr. J. T. M'Corrie, Kilbarchan.

Amateurs' Classes.—Twelve blooms, distinct varieties. First Mr. W. McIntosh, Glasgow, with Wm. Paul, Oimara, Adela, Ada Louise, Wm. Edmiston, J. Carswell, Kittiwake, John Facer, Fircman, Mary Auberton, John Ball, Bertram. Second Mr. A. Borrowman, Glasgow; third Mr. D. Dalglish, Glasgow.

ROSES.—As before mentioned, Mr. Hugh Dickson and Messrs. A. Dickson & Sons secured the chief honours in the nurserymen's class, the former being placed first in the class for forty-eight blooms, the latter having the premier position with twenty-four blooms. In the gardeners' classes the prizes were secured by Messrs. Wm. Parlane, Row; John M'Coll, Row; and John Stewart, Campsie. In the amateurs' classes the successful competitors were Messrs. D. Wallace, Rothesay; D. Black, Blairmore; and John Kidd, Rothesay. In the class for twelve blooms Tea or Noisette Roses, distinct varieties, Mr. A. H. Gray, Dunkeld, was first with beautiful flowers; and Mr. Wm. Parlane second.

HARDY HERBACEOUS FLOWERS.—For twelve distinct, first (silver medal) Mr. Peter Sinclair, Campsie, with large spikes and trusses of *Linaria purpurea*, *Actæa spicata*, *Stenactis speciosa*, *Achillea serrata*, *Alstromeria aurea*, *Potentilla* Wm. Rollisson, *Coreopsis lanceolata*, *Lychnis chalcidonica fl.-pl.*, *Gaillardia Admiration*, *Mimulus cardinalis*, and *Lychnis dioica alba fl.-pl.* Second Mr. D. Findlay, third Mr. J. Stewart.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION—A GARDENER'S APPEAL.

THE Committee of the Gardeners' Royal Benevolent Institution have made another praiseworthy effort to augment the pension fund, and it is hoped the money required will be secured. There are many gardeners not in a position to do much. Several have large families, some with a heavy doctor's bill, almost yearly; others assist in maintaining an aged father or mother, perhaps both; some have an invalid brother or sister; education for the children and periodicals for himself that he may know what is going on in the gardening world have to be provided, all of which prevent a man from doing what he would in other matters.

Whether in spring, summer, autumn, or winter a gardener's work is never done. He must face all weathers—hail, rain, storm, and tempest, heats and cold: no wonder so many of the craft suffer so much with rheumatism, &c.

There are many pleasures in gardening and many disappointments, great responsibility, and many enemies to contend with. No one but the gardener himself knows the hundreds of jobs which are daily staring him in the face, many of which he knows can never be done, and others are hurried over too quickly to his liking. As gardeners have contributed much pleasure and information to the masses, I think it would be a good thing if all the gardeners in the United Kingdom were to ask their employers to allow their gardens to be open to the public for one half day. I believe most if not all would agree to the same if it was put fairly before them.

There are upwards of 2300 noblemen's and gentlemen's seats in this country, and the sums obtained by admission fees would be from £1 to £50 according to the size of the grounds. Supposing it averaged the low sum of £5 all round, it would come to the handsome amount of £11,500; or should it reach £10 on the average, it would be £23,000 (I hope I am not building castles in the air). This would, as all will agree, put the institution on a good sound footing, and would make the pensions £25 for old gardeners and £20 for their widows.

I would suggest that as many gardens as possible should be open on bank holidays; if not convenient to the proprietor on those days, then any time in May, June, July, August, or September. No two gardens within ten miles of each other should be open on the same day.

There are plenty of people who would gladly pay their shilling to look round a large garden, many for the sake of information, which would, therefore, pay in a twofold way.

I would propose the admission fees to be 1s. from 1 to 4 P.M., and 6d. from 4 to 8 P.M.; children under twelve half price, and the village school children free. Non-alcoholic drinks (tea, coffee, &c.) should be provided at cost price, gardeners to get all tickets and bills printed, the latter to be well posted two or three weeks before the event, and well advertised in the local papers. Music I think will be indispensable, as flowers and music always blend well. Flags can often be borrowed or hired for a trifle. Lawn tennis, cricket, and summer games for the youngsters would make up a good afternoon's amusement. In agricultural districts it will be advisable to have what I will call "the grand fête" either before or after harvest.

All gardeners who will be able to send up to headquarters the sum of £10 10s. and upwards to be qualified for such sum as a life subscriber with all its privileges from the date on which the above sum was paid.

And now, as a start, I have asked my noble employers Lord and Lady Henniker to comply with this project, and their answer was, "Yes, with very great pleasure."

We hope to have our half-day the early part of September, or as soon after harvest as possible.

I feel sure my brother gardeners will do their best for a good cause, and I hope by the end of September, 1883, the worthy secretary, Mr. Cutler, will be able to give a very satisfactory report.—JOHN PERKINS, *The Gardens, Thornham Hall, Eye, Suffolk.*

[We commend this excellent suggestion to all owners of gardens and their gardeners. The object for which support is needed is so worthy and the method of increasing the funds so appropriate, and further the pleasure that thousands would derive by a visit to the best gardens in their districts would be so great, that on every good ground the project is deserving of encouragement. In the meantime Lord and Lady Henniker with their excellent gardener Mr. Perkins deserve a hearty vote of thanks from the entire gardening community for their willingness to inaugurate a scheme which, if it can be well and systematically carried out, will be fraught with pleasure to the healthy and substantial benefit to the afflicted and infirm who have been prevented making provision for their needs when their strength fails them. We shall await with interest the results of the experiment at Thornham Hall.]

LILIUMS AND HYACINTHUS CANDICANS IN POTS.

I DESIRE the advice of some of your contributors as to what is best to be done with Lilies, such as the *L. lancifolium*, *L. umbellatum* and others, when they have been forced in pots so as to make them available for another year.

Hyacinthus candicans *alias*, I believe, *Galtonia*, is well worth pot culture, three bulbs in a 7 or 8-inch pot. I have never grown it before this year, but it has done very well with me, and produced tall free-flowering spikes from 3 to 4 feet high, which do well as a centre to other plants. I wish to know whether the same bulbs are of any use for blooming another year, or whether it is better, as with other Hyacinths, Narcissuses, &c., to plant them out in a perennial border to make fresh bulbs to bloom in another two years or so.—C. P. P.

PLAGIARISM.

I BEG to direct your attention to an article on page 69 of the *Garden* of the 22nd ult. on the Culture of *Allamandas*, written by some needy individual signing himself "D. D., *Nash Court, Faversham, Kent.*" Almost the whole of this article has been stolen from my article under the same heading that appeared in the *Journal of Horticulture*, August 7th, 1879, page 101. This certainly is one of the most glaring examples of plagiarising I have seen for some time. You will observe that "D. D." has altered a word or two here and there, shortened a few sentences, and transposed others; but no one can doubt that he has substantially copied my article, and palmed it on the public as his own. For my own justification in preferring a charge so discreditable as this is I must request that you publish the two articles in parallel columns. I question if a more flagrant example of literary pilfering or a more clumsy attempt at altering has ever been seen. It would be interesting to know if this is the first attempt of "D. D."

in work of this nature; but be that as it may, it is to be hoped it will be the last.—WM. BARDNEY.

CULTURE OF ALLAMANDAS.

Journal of Horticulture, August 7th, 1879:—"Allamandas are not only ornamental but useful for a variety of purposes, either grown as climbers up the roof of a stove, or for the decoration of the conservatory during the latter part of the summer. For the purposes named the plants produce a fine effect when well grown, and to accomplish this end they should be treated liberally. Allamandas are capable of producing flowers for eight months out of the twelve; they are easy to grow, and do not require so long a season of rest as many people suppose. Seven or eight weeks' rest is sufficient. Neither is bottom heat necessary in any stage. They succeed well either in pots or planted out. We would recommend large pots in preference to planting-out, as water can then be given and withheld at will, and the soil partially removed and renewed at the proper season.

"Propagation is effected by means of cuttings from the young shoots taken off close to the wood of the previous year; they should be inserted in small pots singly and placed in a Melon house, and must be shaded from the sun. They are not particular as to soil in this early stage. We employ light turfy loam with a dash of sand in the centre of the pot for the base of the cuttings to rest on. We may here say that the lovely species *A. grandiflora* is best managed by being grafted on any of the stronger species, such as *Schottii* or *Wardleyana*. In grafting it is important that the wood be ripe, both of the stock and the spray that is to be employed for the scion. They can be inured similarly to Vines. Supposing the stock is in a 3 or 4-inch pot it should be shortened well back to within 3 or 4 inches of the soil; any of the ordinary modes of grafting employed for Roses, young fruit trees, &c., will answer well. The piece employed for the scion should contain two or three buds, and after carefully fitting the two together they must be made secure with worsted where the union is to take place, and be then well rubbed over with clay or grafting wax. This being done they must be placed in the propagating frame, where they can be carefully attended to until growth has commenced and the union is complete. When root-action is becoming vigorous they should be transferred into larger pots. This species grows much slower than any of the others, but its flowers are produced very freely.

"*Allamanda nobilis*, *A. Schottii*, and the old *A. cathartica* are all worth growing where a collection is the object. *A. grandiflora* and *A. Wardleyana* are the two most worthy of a place. We recommend Mr. Wardley's, which is named after him, and very frequently seen under the name of 'Heudersonii.' It will produce nearly double the number of flowers that *A. Schottii* will; the flowers are as large or larger in size with as much substance, and the brown markings are more prominent in the throat or tube than in its parent *Schottii*, while it possesses the light markings of its other parent *cathartica*. The young plants must be grown on rapidly. We might here say that the *Allamanda* can be grown too strongly and robustly the first or second season. To guard against this the wood must have light, sunshine, and air when developing its growth rapidly to solidify the wood. Another important item is that very firm potting is required. The plant will then rest, and when cut back and again started in January or February it will grow freely. On the other hand, if not firm and ripe when pruned it often dies back.

"The young plants when well rooted in 3-inch pots must be transferred into 6-inch pots, using this time loam, sand, a seventh of manure, and a little leaf soil, which will assist them to start freely into growth. After this potting the compost we find most suitable is rich fibry loam, a seventh of manure,

CULTURE OF ALLAMANDAS.

The Garden, July 22nd, 1882:—"Allamandas are, as is well known, useful both in pots and as roof climbers in conservatories during the latter part of the summer. Thus used, if well grown, they produce a fine effect. For this purpose they should be treated liberally, and if healthy and vigorous will keep in flower at least eight months out of the twelve; they are easy to grow and do not require so long a season of rest as many people suppose; eight or nine weeks' rest will be quite sufficient. They will succeed without bottom heat, but are much benefited by it when making their growth. I like large pots better than planting out, as in that case water can be given and withheld at any time, and the soil can be partially removed and renewed when required.

"In propagating use cuttings made of the young shoots taken off close to the wood of the previous year. They should be inserted in small pots singly, and placed in the propagating house or pit, and shaded from bright sunshine. In their early stage Allamandas are not particular as to soil. We employ light turfy loam, with a small portion of sand in the centre of the pot for the base of the cuttings to rest on, and then place them in a bottom heat from 80° to 85° with bellglasses over them. I should add that *A. grandiflora* does best grafted on some of the stronger species, such as *A. Schottii* or *A. Wardleyana*. In grafting it is important that the wood be ripe enough both as regards stock and scion. Allamandas may also be inured similar to Vines. Let us suppose that the stock, in the case of plants to be grafted, is in a 4-in. or 5-in. pot: it should be shortened back to within 3 in. or 4 in. of the soil. The scion should contain three or four buds, and after carefully fitting the two together, as in Rose or fruit-tree grafting, they must be made secure with matting where the union is to take place, and be then well rubbed over with grafting wax. This done they must be placed in a propagating pit, where they can be carefully attended to until growth has commenced and the union has become completed. When root-action is getting vigorous they should be shifted into large pots. *A. grandiflora* grows much weaker than any of the others, but its flowers are produced very freely. *A. nobilis* and *A. Schottii* are both worth growing where a collection is the object, but *A. grandiflora* and *A. Wardleyana* are the two best. The latter will produce double the amount of flowers that *Schottii* will, and the flowers are equally large, and even larger in size, equally good in substance, and with more prominent markings in the throat or tube. The treatment that applies to the one will also suit the other, but *grandiflora* requires more careful cultivation. *A. Wardleyana* should be propagated early, and the young plants must be grown on rapidly, but not so rapidly as to cause weak growth. To guard against this the wood must have light, sunshine, and air to ripen it. Another important point is firm potting; the plants will then rest, and when cut back and again started in January or February will grow freely, while, on the other hand, if not potted firmly and the wood is not ripe, the shoots often die back when pruned. On plants in 16-in. pots, and treated as has just been recommended, we have had thousands of fully expanded blossoms and buds.

"Young plants when well rooted in 3-in. pots should be transferred to 7-in. ones, using this time loam, sand, and a sixth part of sheep manure which will assist them to start freely into growth. After this the compost which we find most suitable is rich fibry loam and one-third sheep manure. In this the young plants grow rapidly, and should be moved into 12-in. pots the first season. The leading shoots when about 1 ft.

From the *Journal of Horticulture*—continued—

and sufficient coarse sand to make the whole porous. The young plants will extend rapidly, and can be shifted into 12-inch pots the first season. The leading shoot when about 1 foot in length should have the point taken out and two shoots allowed to grow instead of one. No better place to train them can be found than under the roof of a stove, in an upright position. By the end of the season the two shoots will be strong; they should be well ripened and receive a good rest. Our mode of resting is to withhold water when the wood is ripe until the foliage flags. Very little water is given afterwards, only sufficient to keep the wood plump.

"The cultivator in pruning must be guided by the condition of the wood and the distance the shoots can be laid to the right and left of the pot. If thoroughly matured a yard on each side can be left. The ball of the plant if very dry should be partially shaken out and steeped in tepid water. After being thoroughly soaked and the water well drained from the soil the plant can be placed in a pot either the same size or larger, the latter will be the best, using the compost recommended, and the soil must be rammed firmly into the pot.

"Allamandas can be potted as soon as pruned back, but we prefer leaving them a time to rest after the final pruning. No attempt is made to wait until the plant breaks into growth before the operation is carried out. Very little water is needed at the root until root-action and leaf-growth have well commenced. If the wood at the pruning time was well ripened bloom will be produced when the young shoots are about 18 inches in length. The second season a good quantity of bloom will be produced. The plants will continue branching and flowering until late in the season, when rest to a large extent has to be forced on them. With two batches of plants, one started early and the other late, *Allamanda* blooms may be had all the year.

"If desirable to extend the plant two shoots, one on either side, should again be left at pruning time a yard or more long and trained horizontally as before; the other shoots should be pruned back to one or two eyes like Vines on the spur system. Plants can in this way be extended until they fill the whole side of a house. The syringe is sometimes necessary if the small yellow thrips makes its appearance in the points of the shoots, which if allowed to remain soon does much damage. Nothing is better than the syringe to keep down this insect, it does not like water. With plenty of moisture in the atmosphere and the plants growing rapidly there is little fear of its attacks. In our mode of treatment the syringe is seldom used—never after the first flowers make their appearance.

"The *Allamanda* while growing requires liberal applications of water, and is much benefited with liquid manure when the pots are full of roots. It is something wonderful what a large amount of growth the plants can support with limited root room, provided they are liberally supplied with water and their wants attended to in other respects.—WM. BARDNEY."

[We cannot properly refuse to comply with Mr. Bardney's request, and we have the less hesitation in reprinting the article since it is a record of sound and successful practice that will be useful to new readers. The article was originally written by our special desire after having seen the admirable manner in which Allamandas were grown by Mr. Bardney, and possibly our commendatory note at the foot of the paper influenced "*D. D., Nash Court, Faversham*," in the selection of a subject for pilfering purposes. We may add that this is by no means the first instance that has been brought to our notice of the alleged concoction of articles from our pages. Unscrupulous writers who impose on editors in this manner can only be characterised as literary parasites, and when discovered should no longer be permitted to "adorn" the pages of public journals. We have ourselves been victimised once, and the writer was informed that no further com-

From the *Garden*—continued—

in length should have their points nipped out, and two shoots should be allowed to grow instead of one. No better place to train them can be found than under the roof of a stove in an upright position. By the end of the season the two shoots will be well ripened and should receive a good rest. Our mode of resting is to withhold water when the wood is ripe until the foliage flags, and very little is given afterwards—only just sufficient to keep the wood plump. The pruning before starting into growth must be in accordance with the condition of the wood and the distance the shoots can be laid to the right and left of the pot; if thoroughly matured, a yard on each side may be left. The ball of earth, if very dry, should be partly shaken out and steeped in tepid water. After being thoroughly soaked and the water well drained from the soil, the plant can be placed in a pot the same size or a little larger than that it was in, using the compost recommended, which must be rammed firmly into the pots. As soon as pruned back the plants may be potted, but I prefer leaving them for a time for rest after the final pruning, but the plants should not be allowed to break into growth before they are potted. Very little water is needed at the roots until root-action and leaf-growth have well commenced. If at the pruning time the wood was well ripened, blooms will be produced when the young shoots are about 18 in. in length.

"The second season a good quantity of blooms will be secured, and the plants will continue branching and flowering until late in the season, when they should be allowed to rest. With two batches of plants, one started early and the other later, *Allamanda* blooms may be had all the year round. If it is desired to extend the plants, two shoots, one on each side, should again be left at pruning time a yard or more long, and trained horizontally as before; the other shoots should be pruned back to one or two eyes like Vines on the spur system. Plants thus managed may be extended until they fill the whole side of a house. Syringing will be necessary if the small yellow thrips makes its appearance on the points of the shoots, for, if allowed to remain, it soon does much damage; nothing is better than syringing to keep down this insect. It dislikes water. However, with plenty of moisture in the atmosphere and the plants growing rapidly, little fear need be entertained of its attack. Under our mode of treatment the syringe is seldom used—never after the first flowers make their appearance. Allamandas while growing rapidly require liberal applications of water three or four times daily, and are much benefited by applications of liquid manure when the pots are full of roots. It is wonderful what a large amount of growth these plants can support with but limited root room, provided they are liberally supplied with water, and their wants in other respects are attended to.—D. D., *Nash Court, Faversham, Kent.*"

munications could be accepted from him under any circumstances. Had we acted otherwise we should have become parties to a practice that cannot be too strongly condemned. We should like to know who the present plagiarist is. Unless there has been any change since the "Directory" was published he is not the gardener at Nash Court, but this is a matter that can be explained; at any rate "D. D." has made himself notorious as a mere scribbler and copyist, and we must express our conviction that such individuals should not be encouraged to act as "instructors" (?) to the gardeners of this country. We have taken a few introductory lines from both the articles, and a few sentences from Mr. Bardney's, but have not altered those remaining, nor have we expunged a word from or altered a sentence in the citation from our contemporary. Impartial readers can now form an opinion on the whole matter.]

VINE CULTURE AT LONGLEAT.

AS Mr. Taylor has now finished his articles on this subject, perhaps you will allow me to make the following observations on some of his statements thereto. As Mr. Taylor's success as a Grape grower has been brought about by a system of culture which others, including myself, have advocated in the case of both the Vine and the Peach and other fruits before Mr. Taylor had a word to say on the subject (I mean "extension" v. temperatures, the main features of his essay), it can afford them nothing but gratification to hear of that success; but when he tells your readers that he had "*never yet read an essay on Vine culture,*" that his system of culture is "*the plan we should probably follow if we had never heard of any other,*" and that "*that will probably account for his following it,*" I think he is taxing the credulity of his readers a little too far. To speak plainly, had he not made these declarations I should have concluded that he was perfectly familiar with every essay that had been previously written on the Vine, for his articles contain what to anyone would appear conclusive evidence of the fact; and when I came on the following passage of his I think I might well have been excused for thinking that he had read a certain essay of my own, published in a contemporary about two years ago. I put the passages in opposite columns.

Mr. Taylor's version.

"Cutting down the stem of a Vine does not add to the vigour of the growth produced in the same way or in the same proportion as cutting back does in the case of the Apple, Peach, or other fruit tree. The superiority of the shoot made when a young Vine is cut down which has ample roots to sustain a large amount of stem and foliage is more apparent than real, as may be seen afterwards when it comes to ripen. . . . The growth at the end of a young healthy Vine left 12 feet long will not compare unfavourably even at starting time with that of a similar Vine which is cut down to the ground."

I think the similarity of these two passages and the order of the words and ideas would strike an expert in such matters, as to my knowledge they have struck others of your readers besides myself as exceedingly singular coming from one who has never read any essay but his own. In the same chapter from which these remarks of mine are taken I also discuss the merits of young Vine rods 12 feet and 60 feet long, and in his chapter Mr. Taylor does the same, reasoning to the same effect upon them; while, according to his own statements, it does not appear that he ever had young Vines either 12 feet or 60 feet long, while I have had both, and have described them accurately more than once. That portion of his remarks cannot apply to his Vines at Longleat, but must have been taken for granted, I imagine, from the experience of others.—J. S. W.

As a reader of the Journal I have been very much interested in the papers contributed by Mr. Taylor on the culture of Vines at Longleat. Permit me, therefore, to ask if the papers will be published in book form, and if so when, also where it may be obtained and at what cost. If you would kindly impart this knowledge through the Journal I doubt not it will be serviceable to others, and it will oblige—C. K.

[It is the intention of Mr. Taylor to have his articles published in the form of a cheap manual. This is now being prepared, and the particulars requested will shortly be announced.]

My version.

The Garden, August 14, 1880: "Neither do I believe that the mere cutting back of a Vine induces a permanently stronger growth, or adds in any way to the vigour of the Vine. How can it? The rebound that a cut-back Vine rod makes when it begins to grow again is more apparent than real, but it is certain that the Vine which is allowed to make the most growth and pruned the least lays on timber fastest and thickest. For example, a Vine that makes 20 feet of cane the first year, if left that length at pruning time, will, provided it breaks all its buds regularly, make just as good a Vine in the end as one which is cut back annually."

At page 32, in my notes on the Longleat Vines, there occurs an error that may have puzzled not a few, and I hasten to put it right. I am made to say: "As for the advantage of air-giving, the system of giving air at the front only is, I hold, radically wrong." Instead of "the front" it should have been "two points"—namely, top and bottom.—SINGLE-HANDED.

NOTES ON VEGETABLES.

WHEELER'S IMPERIAL CABBAGE.

ALTHOUGH this has been in commerce some years, it does not as yet appear to be so well known as it deserves to be, and for what reasons I am unable to say. This much, however, I can freely assert—viz., as an early spring and summer Cabbage I know of none to equal it, and on this account I would strongly commend it to the notice of those with whom it is a stranger. Its character may briefly be described thus—Medium size, conical in shape, wonderfully crisp and of excellent flavour, with heads at this time of the year as hard as a bullet. It may be as well to state that it was raised and sent out by that veteran florist, the late Mr. George Wheeler of Warminster; and to make sure of obtaining the true variety I would recommend those who wish to grow it to procure a packet of seed from the present representative of the firm, Mr. James Wheeler.

LETTUCE.

By what particular name a variety which was sent me for trial some time ago is going to be sent out under, I know not. Still, I think it will not be any breach of confidence to state, for the information of your readers, that a packet of seed was sent me by Messrs. Cooling of Bath, with a request that I should give it a fair trial and report to them accordingly in due course, it being at the time stated to be a selected variety from that general favourite Bath Cos, and of which, it may be added, there are so many types. Respecting the particular variety under notice, I can honestly say that it is a decided improvement on the original Bath Cos, being much broader in the leaf, more crisp, and of larger size, and last, though not least, of sufficient hardness to stand through the winter. That it will be extensively grown when its merits are well known and when it is distributed there cannot be a doubt, but as to when it will find its way into commerce I am not in a position to state. Of novelties which are of sterling merit, enormous quantities of seeds or plants, as the case may be, are required to meet the trade and retail demand, and under these circumstances the public may have to wait some time before they will have an opportunity of verifying for themselves what is stated above.

PEAS.

Of these there are so many varieties, that to those who are not perfectly acquainted with each it becomes a somewhat difficult task to make their selections when scanning through the catalogues of some of our leading firms. The following varieties may be depended upon, and, I might almost say, would give satisfaction to the most fastidious of critics—viz., William I. for very early supplies, Telegraph, Stratagem, Veitch's Perfection, Marvel, and Ne Plus Ultra. Given these six sorts, a continuous supply of finest flavoured Peas may be had from the end of May to October.

TURNIPS.

Early Munich is an acquisition and a valuable friend early in the spring. It has quite superseded our old favourite Early Stone and other well-known varieties. Where Turnips are in demand every day in the year, as they are here, the above and Chirk Castle are the only sorts I find it necessary to grow.—ET CÆTERA.

ŒNOTHERAS.

AMONGST Œnotheras, which are generally hardy in the unkindly climate of Cheshire, perhaps the most useful for mixed border decoration is Œ. fruticosa or Œ. Fraseri, for I am unable to make any constant or well-defined difference between the two. In spite of its name it seldom assumes a shrubby habit, being generally truly herbaceous, and certainly doing best when starting fresh from the ground in spring. It has a very long flowering period, lasting for two or three months from early summer. It does not spread much in breadth, but the shoots soon become so densely crowded on the crown that they cannot be properly developed, and the plants ought to be pulled to pieces and replanted every third year. It grows from 2 to 3 feet high, but needs supports.

Œ. Youngi has decidedly larger and handsomer flowers, but is more straggling and less upright in growth, though it comes very

near the last species. If carefully tied and well managed it is superior to *Œ. fruticosa*, having nearly the same flowering period. It does not increase nearly so fast at the root and grows best from cuttings, which strike readily at any time. It seems by nature to be a prostrate plant.

Œ. marginata has the most beautiful flowers of any of the genus, but they last a very short time. It is a dwarf rapidly spreading kind with very large fragrant white flowers, which turn pink before they fade. It requires a rich open soil, and produces flowers in rapid succession from the middle of June till August. I find it best to confine it in an earthenware hoop 12 inches in diameter sunk to the upper rim in the soil. This keeps it in a compact mass, so that the flowers produce a better effect.

Œ. taraxacifolia is often treated as a biennial, being liable to die in severe winters after flowering. It is easily preserved by cuttings kept in a cold frame during winter. It does not run, but its prostrate branches cover a good deal of ground. The flowers are large, white, and handsome, though smaller than those of the last species, with which it vies in showiness.

Œ. macrocarpa or *missouriensis* is a well-known old favourite, easily raised from seed, and having a similar habit to the preceding species. Like that kind it does not spread its rootstock, but is perfectly hardy and lasts for many years. It is useful for growing with tall plants, at the base of which it trails, seeming to delight in the shelter they give.

Œ. speciosa hardly deserves its name. It has an upright growth of about 2 feet. The flowers are moderate in size and of a dull white, and the general appearance of the plant is rather shabby and common. It is a most tiresome runner, and if not confined to one spot will come up everywhere but where it is wanted. Still, it is very distinct from all other *Œnotheras* and should be tried.

Œ. riparia is a prostrate and very floriferous plant, increased easily by cuttings, but sometimes killed by severe winters. The flowers are small and the leaves slender, but it is one of the neatest of the *Œnotheras* for positions near the edge of a border or for a rockery. I always keep a panful in a cold frame through winter to avoid losing it.

Œ. pumila is a neat dwarf plant, with small yellow flowers about the size of those of the common Willowherb.—C. W. DOD.

ROYAL HORTICULTURAL SOCIETY.

THE following reports of exhibits at South Kensington on the 25th ult. did not reach us in time for insertion last week:—Late in the afternoon, after the meeting had dispersed, a very interesting consignment was received from M. Girardin-Collas, Horticulteur, Argenteuil, comprising two baskets of very fine fruits of the Figs Blanches d'Argenteuil, which seems to be the same as what is known in this country as White Marseilles, also bearing shoots of the same variety, and Violette Dauphin clustered with large and fine fruits; a basket of Apricots Plein-Vent d'Argenteuil, very large and fine, with a deep rosy red hue, almost unknown in this country, remarkably beautiful; a basket of roots of the Cerfeuil Bulbeux (Tuberous Chervil), about the size of Early Horn Carrots; and several examples of the one-year-old Asparagus plants, particularly strong, Asparagus culture being a great speciality of M. Girardin-Collas.

SCIENTIFIC COMMITTEE.—Sir J. D. Hooker in the chair.

Ræstetia lacerata.—Dr. M. T. Masters showed specimens of the common Hawthorn badly attacked by this fungus.

Hybrid Tacsonia.—He also showed a blossom of a plant, the result of crossing *T. exoniensis*, itself a hybrid, with *T. Van Volxemi*. He will report further upon it.

Rhododendron camelliaeflorum.—Mr. Mangles exhibited a spray of this late-flowering species, having but one flower instead of two as described by Hooker. It is a native of Sikkim, growing in a pendulous way from trees and rocks. The foliage agrees with the so-called *R. Maddeni*. Mr. Mangles thought it might be identical with *R. sparsiflorum*, Booth, of Bhootan.

Diseased Rhododendron Leaf.—He also brought a leaf spotted with black as if by a fungus. It was referred to Mr. Smith for examination and report.

Hollyhock Disease.—Mr. W. G. Smith gave an account of his planting healthy seeds of Hollyhock and others affected by Puccinia. He sowed twenty tainted seeds. One survived of two only which germinated. This one appears to be unaffected. Of fifty healthy seeds all germinated. After the third week leaves of common Mallow affected with Puccinia were scattered amongst them; in less than a week forty-six of the seedlings died of the same disease. M. Du Port of Mattishall writes to say he has also found the leaves of seedlings of Hollyhock to be covered with the disease.

Rhododendron Hybrids.—Mr. Veitch sent cut flowers illustrating his seedling hybrids just raised. A flower of a hybrid of unknown parentages, showing a slight tendency to be double, was artificially self-fertilised. Of this several seedlings were obtained, five having lately flowered—a deep rose (*balsamæflorum*), a double white, a semi-double yellow, a salmon, and a semi-double rose. A remarkable

feature in these seedlings is that crossing white with orange a pink is the result, and that a calyx is begun to be developed, that organ being wanting in *R. jasminiflorum* from which they are descended. Mr. Henslow remarked on the general tendency to suppress the calyx in flowers which are small and massed together as in Rubiaceæ, Caprifoliaceæ, Umbelliferae, &c., and suggested that its return was due to those seedlings acquiring a larger size of flower, and there being fewer in the truss than in *R. jasminiflorum*.

STRAWBERRIES EATEN BY BEETLES.

WE are apt to imagine that our experience is that of others, and it was therefore with some surprise that I read the editorial comment on "E. D.'s" communication at page 61 of the Journal, but I could certainly not call to mind a recorded instance of damage inflicted on Strawberries by black beetles. For years we have had to contend against the attacks of these insects; and though I cannot boast of much success in reducing their numbers, I do not now fear them, and if my experience is of any use to your correspondent I willingly place it at his service. It appears that only one species of beetle troubles "E. D.," but here we have several, all, I believe, closely allied, one of which is very small, but is destructive out of all proportion to its size. Our knowledge of the love of beetles for Strawberries was dearly bought, for it was on the foreed fruit that they commenced their attacks, and I well remember how mystified we were at finding every morning a number of fine berries spoilt and could not discover an enemy. The Strawberries in question were planted out in a bed of soil, and for some time the only discoverable living creatures were some frogs which were, I am now ashamed to say, accused and convicted on no greater evidence than their presence in considerable numbers. But the banishment and execution of these inoffensive creatures did not stay the mischief, and then we took to bribing the nocturnal enemy with breadcrumbs strewed thickly over the bed, all of which disappeared; but no matter whether in the daytime or evening, the consumers of this wholesome repast were never visible, but the fruit did not suffer so much—in fact by the aid of many quatern loaves the crop was saved. Little by little, however, the truth dawned upon us, and after many trials we defeated the thieves by simply propping up the fruit on twiggy birch, and have never since suffered when we have adopted timely precautions. We grow here a considerable quantity of Strawberries for market, but we could not do so did we not set every fruit up from the ground, for I really believe that a place more infested with beetles does not exist in the whole world; and I am certain that if the berries laid on the soil, quite 90 per cent. of them would be eaten or so disfigured as to be rendered unsaleable.

What is curious about these insects is, that although they climb up walls when confined in a dwelling or in frames they scarcely ever attack a fruit if it simply rests on a piece of tile or on a brick; indeed we found that even placing them on so thin a material as glass sufficed to preserve them. From what I have observed these beetles love concealment, and endeavour to burrow in the soil underneath the Strawberry before attacking it, so that in a general way the under portion of the berry suffers. My advice would be to make a practice of raising the fruit off the ground as soon as it is formed, using some of the manufactured Strawberry supports, tiles, or twiggy birch, in the forks of which the berries will rest quite safely. There is no need to tie the flower stalks, and if the birch is used green it is easily cut up—an employment for wet winter days; and if drawn out as soon as the crop is over and stored away in a dry place will last several years.

As the outcome of experience, I will give "E. D." a hint which may prove useful to him. We have found that when the plants are thickly set together the foliage, intercrossing as it grows, in a great measure supports the fruit, so that but little of it touches the soil; and we do not then find the beetles do much damage, especially if the surface is made firm and kept free from littery material, for the more moleh the more beetles. A top-dressing with Clay's manure when the plants start into growth will give all the nourishment they need; and as the sun cannot penetrate the thick screen of foliage to parch the roots beneath it, the necessity for mulching is done away with.—J. CORNHILL, *Byfleet*.

I CAN assure your correspondent "E. D.," in the Journal of July the 20th, that his is no solitary case, for I have been troubled with the beetles for several years past, and some of my brother gardeners have suffered in the same way. At first I thought it was mice that caused the mischief, for the beetles nibble the seeds of the Strawberry the same as mice. I do not think anything in the way of dressing will destroy them; I make a point of killing every one I see. Toads will eat them, and so will

young chickens. I may say that I have been but little troubled with them this season. My soil is light and stony.—J. P., *Erith*.

FLOWERING SHRUBS.

SPRING is the flowering season of most of our best shrubs, and it is then that our gardens assume their gayest, brightest aspect; and when "Rhododendron time" is over and summer comes swiftly onwards, its lengthening days and increasing heat bring with them very few flowers besides Roses among the shrubs, and a comparative dullness prevails where but a short time before all was brightness and beauty. All summer-flowering shrubs and plants suitable to associate with them are welcomed and cherished with loving care; but after all has been done we have no substitute for our best spring beauties, and where space can be had it is a good plan to plant bold masses of bedding plants in front of the shrubs, which then receive and impart beauty to the flowers by the force of contrast and the relief and softness which the varied shades of green foliage impart to the bright colours.

Not unfrequently a fringe of hardy perennials is found in shrubberies, especially in old ones where Laurel, Box, Yew, and Holly predominate; but I do not like an unbroken flower border in such a position, for although we have nothing approaching the peerless beauty of the Rhododendron among late-flowering shrubs, yet

Fig. 13.—*Odontoglossum Pescatorei Veitchii*. (See page 107.)

there are many possessing attractive features—so attractive that by the exercise of skill and good taste shrub groups may be pleasant throughout the year, offering us some special attraction peculiar to each season, and thus adding that charm of variety which every feature of a garden should possess in addition to intrinsic worth and beauty. Let it not, however, be supposed that the writer would rigorously exclude perennials from shrubberies, for there are a select few quite equal in effect to many of our choicest shrubs. Take for example *Spiræa palmata*, which in good soil so quickly makes large clumps, with an annual growth 4 to 5 feet high and quite as much in diameter; what shrub can surpass it when its lovely pink flowers are at their best? Or the earlier-flowering *Dielytra spectabilis*, which assumes even larger dimensions under favourable conditions? Then, too, there are hardy *Fuchsias*, objects of exceeding beauty, sometimes to be seen in specially favoured gardens from 6 to 10 feet high; *Pæonias*, *Phloxes*, the tall *Œnocheras*, many *Lilies*, the white Japanese *Anemone*, and such favourites as the stately *Bocconia cordata*, the *Acanthuses*, *Centaurea aurea*, *Delphinium cardinale*, *Dietamnus Fraxinella*, the curious *Eremurus robustus*, *Ferula communis*, *Melanthus major*, the Himalayan Poppy (*Meeonopsis nepalensis*), and *Papaver orientalis*, which is so striking that I have often known much admiration called forth at the sight of one of its huge scarlet flowers, with a couple of its curious flower buds cut off and put in a vase. Planted at intervals singly in nooks reserved for them along the margin of the shrubs, such stately plants are far more ornamental than they ever can be in a crowded perennial border, standing alone as they then do, distinct from and yet in perfect harmony with their surroundings.

Returning now to the shrubs, let us see what comparison seasonable sections bear to each other, marking the best as we go along. Spring.—Here of course Rhododendrons take precedence of all

others. In making selections care should be taken not only to secure favourite colours and fine flowers, but also good successional flowers in order to prolong the season. Thus every garden should possess at least one specimen of such early-flowering varieties as *Broughtonianum*, all the varieties of *Nobleanum*, *Cunningham's White*, sometimes called *caucasicum album*, *altaclerense*, and *Victoria*. Of intermediate sorts to be regarded as indispensable there are *Mrs. John Clutton*, *Lady Eleanor Cathcart*, *Barelayanum*, *Alarm*, *Brayanum*, *Lady Lopes*, *geranioides*, *atro-sanguineum*, *William Downing*; and of later kinds *Star of Ascot*, *John Spencer*, and *John Waterer*, the opening flowers of which afford a sure indication that the end of "Rhododendron time" is drawing nigh. Upon the lovely *Azaleas* I need not dwell further than to plead for space for a group of *A. pontica*, so deliciously fragrant as it is; to claim a sheltered nook for a few varieties of the early-flowering *mollis*; to once more note the singular beauty of *A. amœna* as single specimens in rock beds, and that mixed groups are here found to alternate admirably with others consisting entirely of *Kalmia latifolia*, the evergreen habit of the *Kalmia* atoning somewhat for the bareness of the deciduous *Azaleas* in winter. All the other *Kalmias* are found to answer best mixed with *Andromedas*, *Gaultherias*, *Menziesias*, and other dwarf shrubs. Next among our best spring shrubs come *Berberis Darwinii*, *B. duleis*, *B. stenophylla*, *B. japonica*, and *Mahonia aquifolia*; *Escallonia macrantha* more beautiful this year than I have ever before seen it; *Garrya elliptica*; double *Gorse*, good only for five or six years; white and yellow *Broom*, *Cratægus pink* and white, *Laburnum*, which, with *Lilac*, *Guelder Rose*, *Weigela*, and *Syringa*, link together spring and early summer. Let me here note the great beauty of the large-flowered *Syringa* (*Philadelphus grandiflorus*), which answers well both in sunshine and partial shade, and is planted in both positions to prolong its flowering season; *Forsythia viridissima*, a mass of golden flowers this year; *Buddlea globosa*, *Magnolia stellata*, *Ribes*, *Deutzia gracilis*, *Xanthoceras sorbifolium*, *Siberian Crab*, and *Tree Pæonias*.

Summer.—*Roses* trained to pillars, especially *Gloire de Dijon*, tell well among shrubs, and the single Japanese *Rose* takes high rank among shrubs of handsome bushy growth. *Deutzia crenata flore-pleno* is one of our best early summer beauties. The shrubby *Spiræas*, too, are more valuable from the succession of bloom which one variety after another affords. Two or three fine specimens of *S. callosa alba* are now very full of bloom; but the most beautiful white-flowered variety is undoubtedly *S. ariæfolia*, just now passing out of bloom. When thoroughly established it throws up sturdy shoots 7 or 8 feet high, upon which its large soft white feathery plumes show to great advantage. The pink-spiked species *S. Lindleyana* and *S. Nobleana* have still many unopened flowers; so, too, has the lovely *S. Douglasii*. Then there are the varieties of *Hibiscus syriacus*; the yellow Spanish *Broom*; *Ligustrum japonicum*, queen of all the *Privets*; *Desfontainia spinosa*, a veritable gem; *Gum Cistus*, with its chaste yet fleeting beauty; *Veronica salicifolia*, with lovely pink flower spikes; *Œsulus laciniatus*, not half so much grown as it deserves to be; *Desmodium penduliflorum*, which, like all Japanese shrubs, has peculiar and distinct characters as well as much beauty. *Hydrangea hortensis* and *H. paniculata grandiflora*, which, although highly valued for its handsome clusters of white flowers, has not answered my expectations, for the first flowers that I saw of it were grown in Cornwall, and all of them had red blotches; but I have not seen it so clearly marked since. *Rubus fruticosus albopleno*, *R. fruticosus roseo-pleno*, and *R. laciniatus*, the first two for their charming double flowers, and the last for both flowers and fruit. *Kerria japonica*, *Lycæsteria formosa*, *Potentilla fruticosa*, *Diplopappus chrysophyllus*, somewhat dull-looking now it is in bloom, but valuable for its yellow stems and leaves; nor must I omit the wild *Olive* (*Rhus Cotinus*), that is so beautiful with its soft purple flower plumes. It will thus be seen that we have a considerable number of really good summer-flowering shrubs, which are turned to good account and form an admirable fringe to bold masses of Rhododendrons.

Autumn and winter derive brightness, the one from changing foliage such as we have in the *Liquidamber* and *Ampelopsis japonica* and the silvery plumes of *Pampas Grass*; and the other from the bright-hued berries of the *Holly*, *Arbutus*, *Skimmia*, and *Benthamia*, where it is found to answer. Our only good winter-flowering shrub is *Laurustinus*, but this will not answer in low-lying damp situations.—EDWARD LUCKHURST.

WEST OF SCOTLAND ROSARIAN SOCIETY.

THERE is no place, even in more southern counties, where there is greater favour shown in the culture and exhibition of the *Rose*, or more thoroughly carried out, than in Helensburgh, a favourite bath-

ing place on the Clyde. It has always a great interest for me, not only because of the hearty and cordial welcome which always greets me, but also because it does my judging credit, of which I shall have as usual more to say by-and-by. The Exhibition was held, as it has been of late years, in a tent in Westwood Park, but here as elsewhere the cry is for some covered hall, where neither the Roses nor the company are exposed to the vicissitudes of our varying climate. The flowers were arranged on the long stages provided by the Society, and each exhibitor has to take his Roses out of their own stand and place them on these stages. All thus are doubtless on the same level; and although the appearance is certainly marred by the yellow character of the moss, there has been a very considerable advance amongst the local exhibitors; and although some stands of inferior quality were shown there was a very decided general advance, while the Messrs. Dickson of Belfast and Newtownards showed such admirable stands that we regret very much they cannot enter into competition with some of our noted English growers, for I am quite sure that they would be victorious in many a contest if they did so; but it is a "far cry" to Belfast, and it would hardly be possible to get the Roses sufficiently fresh to enable them fairly to compete. Pansies were well shown also, but of course the great interest was centred in the Roses. I was much amused at the rapid manner in which the Roses were sold by auction after the Show was over. It was not only the proverbial "saxpence" that disappeared, but half-crowns for bouquets, and altogether a sum of upwards of £5 was added to the funds by this novel method. I was amused at the wit and humour shown by the auctioneer and appreciated by the crowd, evidently disproving Sydney Smith's disparaging remarks on the difficulty of getting a Scotchman to understand a joke.—D., Deal.

WE are requested to state that the PELARGONIUM SOCIETY'S ANNUAL MEETING will be held in the autumn, and the members will have timely notice of the date.

— AN EXHIBITION OF PINKS, we are informed, is in process of organisation for next season. Persons who are willing to subscribe 5s. each to form a prize fund are desired to communicate with Mr. Shirley Hibberd, who has taken charge of the matter for the present.

— A BRISTOL correspondent sends us the following note relative to a GREAT HAILSTORM NEAR BRISTOL:—"On the evening of the 25th ult. this neighbourhood was visited by one of the most extraordinary hailstorms ever witnessed, the ground being covered with hail, which remained in many places the whole of the night, for on Wednesday morning we measured some where it had rolled into a heap 5½ inches deep at seven o'clock. We have not a flower left outside, and I fear tender plants such as Alternantheras and Coleus are permanently injured, as they were covered up for some time in hailstones, and now they have the appearance of having been frozen. Everything is more or less damaged, Beet especially so."

— MR. J. SMYTHE, the well-known horticultural sundriesman of Drury Lane, has sent us blooms of his new SEEDLING CARNATION MARY MORRIS, grown in his garden at Forst Hill. Mary Morris is a self of a rich glowing rose colour faintly suffused with salmon, the flowers being large and full. As the variety is a good grower and free bloomer—Mr. Smythe having cut sixty-eight blooms from one plant—it will prove valuable for garden decoration and for affording a supply of cut flowers of a colour that few can fail to appreciate. Mary Morris was commended by the Judges at the National Carnation Show last week, presumably as a decorative variety, and beyond doubt large masses of it would have an excellent effect in gardens.

— RELATIVE to the note on page 80 on raising STRAWBERRIES IN FRAMES, our correspondent, "A NORTHERN GARDENER," writes:—"If 'SINGLE-HANDED' would read more attentively his criticism would be more effectual. When the

plants are raised in frames I said, 'In dry localities there is risk of the plants being injured by remaining crowded in the nursery beds too long, or removing them in unsuitable weather.' I never suggested they could not be established in frames; the question was one of removal. I have been in a dilemma more than once—the plants spoiled if they remained, and were injured if removed, when the sky was cloudless for weeks and the soil like a bed of hot ashes. I wrote from experience, which it is quite evident your correspondent lacks under the same conditions. The plan he advocates is an excellent one when planting can be done at the proper time, but it has failed with me, as it must fail, during a hot and dry season."

— A CORRESPONDENT writes as follows respecting SINGLE DAHLIAS—"Lovers of elegant flowers who have commenced the cultivation of single Dahlias will not regret the step. Plentiful as flowers are just now, there is not another that could be named as a substitute for these, and those who have not yet indulged in single Dahlias have still an untasted pleasure in store. Ours were raised from seed sown in February in heat, and the seedlings afterwards nursed on in pots, and finally planted out at the end of May, and now, July 21st, they are in full bloom. It will thus be seen that they may be very easily obtained. Those who have no means for forwarding seedlings in spring can buy half a dozen, or as many more as they have room for, and if planted on fairly good soil and treated like other Dahlias a rich reward will be reaped."

— THE same writer also sends the following upon WILD ROSES—"Some of our wild flowers are unsurpassed for beauty and elegance, and first among them are wild Roses. They are just as worthy of cultivation as are single Dahlias, and for home decoration there is hardly anything to equal them. All round my district there are wild Roses in plenty, yet in half a dozen odd nooks and corners I have planted wild Roses, and I use their blooms when they are in flower for dinner-table decoration, and find employers and visitors equally delighted. They would pass these very blooms on the roadside; but whenever, instead of the ordinary garden flowers, wild Roses are used everybody is delighted beyond measure. Just let those who have hitherto despised such do so no longer, but put in a plant or two and see if the labour is misspent."

— WE have received an intimation of the death of DR. CARL EDUARD LUCAS, Royal Garden Inspector, Proprietor, and Director of the Pomological Institute of Reutlingen in Bavaria. He died on the morning of the 24th July, between nine and ten o'clock. Dr. Lucas has been long known throughout Germany as an accomplished pomologist and an indefatigable worker in the pursuit of pomology. His labours have been incessant, and are fully recorded in the eight volumes of the *Illustriertes Handbuch der Obstkunde*, to which he was a contributor under the editorship of Oberdieck. In conjunction with the same author he produced the *Pomologische Monatshefte*, which appeared for twelve years. Of his independent works the most important are *Auswahlverthroller Obstsorten*, *Pomologische Tafeln zum Bestimmen der Obstsorten*. Besides these there are a score of smaller treatises on various pomological subjects, and his last work was *Enleitung in das Studium der Pomologie*.

— GARDENING APPOINTMENT.—Mr. Robert Parker, late gardener to Mrs. Bertwhistle, Rockwood, Skipton, succeeds Mr. Brown as head gardener to C. F. Taylor, Esq., Winsley, Ripley.

— "F. W. B." observes in the last issue of the "Gardener" that "the question of PRUNING ORCHIDS is as yet far from settled, and much depends on the way in which it is performed. We often differ in opinion from each other simply because our local surroundings are different, and not so much because we really think

a certain practice to be right or wrong in a general way. I knew an old exhibitor of stove and greenhouse plants in Yorkshire who grew *Dendrobium nobile* better than I ever saw it elsewhere, and he always cut away the old pseudo-bulbs—*i.e.*, some of the three and all the four-year-old ones—when he dressed up his plants for the shows. We have all been brought up to the dogma that the old pseudo-bulbs of Orchids are reservoirs of nutriment—savings-banks, as it were, of superfluous sap. This may be true, wholly or in part, as the case may be. In a state of nature every provision is no doubt the actual outcome of absolute necessity, but what is necessary to a plant growing fully exposed to all the vicissitudes of nature may be very unnecessary when the plant is placed in artificial circumstances, and receives regular cultural attention so far as heat and moisture are concerned. If it be true that the young growths of Orchids draw on the old pseudo-bulbs during the early and rootless stages of their existence, as seems probable, it is also equally true that the shrivelled and rootless old bulbs plump themselves up only at the expense of the young growth, and mainly just at the time that it attains its full development. It must be self-evident that rootless old pseudo-bulbs have no power of acquiring anything from the compost."

— AT the Notts Agricultural Show we are informed that the MEADOW FOUNDRY COMPANY had a splendid collection of designs in double, ornamental, and single coil pipes and cases for heating halls, public rooms, &c., while the garden vases and pedestals were above the average in workmanship and design. The large fountain placed in the centre of the open square was much admired. A Portland tubular hot-water boiler capable of heating a mile of 4-inch piping, for heating public buildings, conservatories, &c., was inspected by many with curiosity, being the second boiler of its kind manufactured.

— FIRST-CLASS certificates were awarded for the following new varieties at the NATIONAL CARNATION AND PICOTEE SOCIETY'S SOUTHERN SHOW held at Kensington on the 25th ult., in addition to those noted in our report:—Carnations, Alfred Hudson, a scarlet bizarre of good form and rich colour; W. H. Hewitt (Douglas), a crimson bizarre sport from the rose-flake James Merryweather, a beautiful and finely coloured variety William Skirving (Gorton), a handsome pink and purple bizarre staged by Mr. Douglas, the blooms large and even.

— UNDER the heading of "Great Companies and Trading Firms," the nurseries of MESSRS. WILLIAM PAUL & SON of Waltham Cross are described in an entertainingly written article in Colburn's new monthly magazine for July (E. W. Allen, 4, Ave Maria Lane, London). The cross of Waltham which marks the spot where the body of Queen Eleanor rested is thus referred to—"Time, that insidious iconoclast, has dealt gently with this beautiful memorial of marital affection, for the regular features of the Queen are still distinct, and the tracery has suffered but slightly from six hundred years' ceaseless wooing of wind and rough weather." It is not necessary to cite anything about the nurseries, as they were described by a correspondent in our columns last week.

— A "CITY MAN," referring to the FINE CROP OF POTATOES mentioned on page 77 last week, observes:—"While the results achieved by 'B.' are excellent and his experience valuable, his prices for Potatoes are too high, as any quantity of Potatoes of undeniable quality can be purchased from costermongers' barrows in London and in greengrocers' shops for a halfpenny a pound. There must have been two profits at least obtained, and possibly three, before the last-named vendors made their trifle. First the grower's profit, next the salesman's (commission), then the merchant (purchasing by the ton from salesmen), and lastly the small retailers who purchase from the merchants. What in

such a case, when the latter can sell at the low price mentioned, could have been the original price that the cultivator obtained? Certainly not three farthings a pound."

— THE following is submitted as a characteristic example of American satirical humour:—"Those who have been pestered to death by the irrepressible DANDELION on their lawns may now take heart. The pest will pester them no more. Eastern markets have begun to utilise them for greens, so that gardeners cultivate them for sale. The plant having thus become useful the bugs will eat it off above ground, the grub will saw its roots in two, the sun will parch it to death, the rains will drown it out, the rain will thrash it to strips, and the boys will dig it out and steal it. Thus the Dandelion, which has been among the first of the weeds to coax its way into human favour in the spring by throwing out its golden blossom, will retire from the field and the lawn to the seclusion of the guarded greenhouse."

— MR. CLARK, The Gardens, Tedfold Lodge, Sussex, states that he obtained 1 lb. of WHITE ELEPHANT POTATOES from Messrs. Carter & Co. of High Holborn, and planted them in the spring, and although he had to lift the crop some time before growth ceased, as he wanted the ground urgently, yet the produce was 174 lbs. of very large tubers. White Elephant is a new American variety, and has the reputation of being highly productive, a great disease-resister, and a good keeper. Mr. Clark will in due time be able to speak of the quality of this variety, which he does not appear to have tested.

— "X." writes:—"Very showy just now in some herbaceous borders are the forms of LYTHRUM SALICARIA, especially roseum and grandiflorum, which are not unlike another common plant—the Narrow-leaved Willowherb (*Epilobium angustifolium*), and are equally free in flowering. The two varieties of Loosestrife named above have larger and more brightly coloured flowers than the type, and with me they are rather dwarfer than it. They succeed well in any moist situation, and their stems thickly clothed with rosy flowers have a very pleasing appearance. The *Epilobium*, also mentioned above, should not be despised because it is common, for a patch of it in a corner of the garden that would perhaps be otherwise unoccupied is very welcome."

— IN his report upon the trade and commerce of La Rochelle for the past year Mr. Vice-Consul Sadler draws attention to the havoc of the PHYLLOXERA in French vineyards. The phylloxera commenced its ravages in the Department of the Gard in 1863, and is believed to have been introduced into Europe by Vines imported from America. In 1881, 104,536 hectares of Vines, or 258,395 acres, were destroyed in France, against 37,000 hectares, or 91,450 acres, in 1880, and the malady has since made its appearance in five fresh arrondissements. The State is doing what it can to check the disease, and the proprietors are joining associations of mutual defence, but not much headway has been made as yet. Nothing can make up to the cultivators of the Vine for its loss. The land where Vines are destroyed is scarcely worth one-third of its former value, and could not easily be disposed of at any price. The depreciation in landed property due to the ravages of the phylloxera is already estimated at £12,000,000 in a single department.

— IN an interesting article by Mr. Grant Allen in *Nature* upon the COLOURS OF FLOWERS, many curious facts in regard to the changeability of colour are noticed. He says—

"All flowers, it would seem, were in their earliest form yellow, then some of them became white; after that a few of them grew to be red or purple; and, finally, a comparatively small number acquired various shades of lilac, mauve, violet, or blue. Some hints of a progressive law in the direction of a colour-change from yellow to blue are sometimes afforded us even by the successive stages of a single flower. For example, one of our common little English Forget-me-

nots, *Myosotis versicolor*, is pale yellow when it first opens, but as it grows older it becomes faintly pinkish, and ends by being blue like the others of its race. Now, this sort of colour-change is by no means uncommon, and in almost all known cases it is always in the same direction, from yellow or white, through pink, orange, or red, to purple or blue. The common Virginia Stock of our gardens (*Malcolmia*) often opens of a pale yellowish green, then becomes faintly pink; afterwards deepens into bright red, and fades away at last into mauve or blue. Fritz Müller noticed in South America a *Lantana*, which is yellow on its first day, orange on the second, and purple on the third. The whole family of *Boraginaceæ* begin by being pink, and end by being blue. In all these and many other cases the general direction of the changes is the same. They are usually set down as due to varying degrees of oxidation in the pigmentary matter."

SEEDLING CARNATIONS AND PICOTEEES.

THE above are indispensable in all gardens where quantities of flowers are in daily request for cutting. No matter at what season of the year their blooms are produced, they are always welcome and more eagerly sought after than those of any other hardy plants, the Rose excepted. This is the case whether the plants are grown in pots and forced into bloom during winter and spring, or when flowering outside naturally. Beds filled with Carnations, either of one colour or a number of varieties together, are useful and attractive, and these plants when in flower have a gay appearance that would, independently of their fragrance, commend them to all. When planting them in beds or borders no better position can be chosen than amongst dwarf Roses. The latter should be planted sufficiently far apart that the Carnations or Picotees can be planted alternately with them. For example, a bed of Roses in three rows can have a row of Carnations planted on each side of the centre line of Roses. A bed of *La France* Roses with any dark-flowered Carnation will be charming through the whole season.

I do not think it is generally known that these plants thrive admirably in the smoky neighbourhood of towns. Here they grow luxuriantly, especially seedlings, although the air is contaminated with chemical vapours. Whatever florists may urge in favour of named varieties, they are not so useful as seedlings. The beauty of form and markings of many of the flowers of the named kinds are all that can be desired, but many of them are bad growers and only produce a few flowers, which are soon over. Many named kinds do not produce more than a dozen flowers from a single plant, which are all past in a few weeks, especially if the weather is hot and dry. Such Carnations and Picotees are but little use for the gardeners who require a continuous supply either for packing or filling vases at home. Perpetual seedlings of both Carnations and Picotees should be grown for this purpose; they are robust in habit, and profuse and continuous flowerers; in fact many of them commence flowering before the named kinds, and produce abundance until stopped by frost. I have at the present time plants with over two hundred flowers and buds upon them, and these from single plants layered in August last. These seedlings do not only produce a few flowering stems from the centre early in the season, but continue to produce in rapid succession flowering shoots from the base. Some of these attain a height of 3 feet 6 inches to 4 feet in length, and form strong lateral shoots nearly the whole of that length.

Last August I had layered a number of late-flowering shoots into 6-inch pots, the pots being plunged into the soil until the plants were well rooted, which were severed from the parents just before the approach of frost and placed under cover. Quantities of blooms were produced from these plants during the winter, and I intend to adopt this practice on a much larger scale, and do not doubt a succession of flowers will be produced through the whole winter and spring.

The present is a good time to sow seed for obtaining a stock, but the sooner it is done the better. If sowing is delayed until spring many of the plants raised will not flower the same season. This entails labour in carrying out the operation of layering before there is any chance of determining whether the plants will have single or double flowers; but when sown now, or better still if sown about the month of June, and established and wintered in 3-inch pots, and then the whole planted out in nursery beds in early spring, they will flower towards the end of July, the best can then be layered and the worthless ones thrown away. If the seedling plants are moderately strong from seed sown during the month of June I do not hesitate to plant them out in early autumn, as these are perfectly hardy, and satisfactory results may be relied upon; but when sown late the young plants during winter should have the protection of a cold frame, or better still if they can have a position where they can grow slowly during the winter, for the greater progress they make the earlier they

will flower the following season. Some of the seedlings may have single flowers. The showiest of these make grand border plants; but I have always been fortunate, and always had a greater percentage of double than single flowers, and many of them of superior quality.

The seed should be sown in pans, using a light compost of loam, leaf soil, and sand. The seed must only be lightly covered and then well watered with a fine-rose can. The pan may be placed in heat and covered with glass until the seed germinates. It is a good plan to cover the glass with moss until the seedlings appear, when it must at once be removed and light and air gradually admitted to the young plants. The only object in raising them under glass or placing the seed in heat is to bring on the plants more rapidly than if the pans or boxes in which the seed is sown was placed in a shady place outside. Amateurs having neither greenhouses or frames may be very successful in adopting the latter method. If the glass is kept close over the plants after the seedlings appear they are liable to suffer from damp. When large enough the young plants should be potted singly in the sized pots already named, which is preferable to pricking them off into other pans or boxes. After potting, and as soon as root-action has fairly commenced, they should have a cooler position, where more ventilation can be given, which will prevent them drawing up weakly. When well hardened the young plants can be plunged outside or planted out, but if small at the approach of cold weather it is best to keep them in frames.

Those that have not raised seedling Carnations and Picotees for purposes of cutting, as well as the embellishment of beds and borders, and have hitherto relied upon named varieties, would not be disappointed with the result for the time and labour required in raising a stock of these useful plants from seed.—
W. BARDNEY.

THE INFLUENCE OF SOIL IN MATURING CROPS.

It will be found that an abundance of manure will bring forward young Turnips, Carrots, Radishes, Cabbages, and weakly-growing but very early Potatoes, and many other vegetables; but (and this is especially true in cold, wet, dull seasons) it has exactly the opposite effect on Peas, Cauliflowers, Strawberries, &c. Here the season has been such as is favourable to a great development of leaf, and the consequence is that Strawberries in thoroughly good soil have made such growth as has had the effect of hiding the enormous crops of fruit under a leafy screen, where the slugs can hide and feast unseen, and where the shade is such as causes the fruit to ripen very slowly indeed. None of our Strawberry plots are in really poor condition, but the poorest and oldest, though once far less promising, are much more satisfactory than are those younger and on better soil. Had the season been hot and dry the opposite would have been the case; but as it is, our earliest and best fruit have come from the plots where the soil is thinnest and the plants weakest.

A fortnight before we had any Strawberries a market grower in the neighbourhood had plenty, and the variety was the same as our own earliest—namely, *Vicomtesse Hericart de Thury*; but his were in poor soil, and the plants were making little growth—the fruit was being forwarded by starvation.

It is the same with Peas. The earliest Peas here were from a row sown on rather poor soil. From this row two or three dishes were obtained before as many pods were filled on the bulk of the other batch, although the later ones were in a more favourable situation than the others. The only difference that could cause such a result was the extra manuring the later rows received, for they were sown in land liberally manured and trenched for Strawberries, which we expect to plant immediately.

With our Cauliflowers it is the same. Even yet the Dwarf Erfurts that were kept over winter are hardly exhausted, but they are on the same soil as the Peas. Even now spring-sown *Eclipse* is plentiful, but the heads are only turning in from plants that from some cause or another have not grown very well. The stronger the plants the later is the produce, but in all cases is finer. The late heads of the Erfurt Cauliflower are quite out of character, they are so large. In the case of the Peas the later crops are also very heavy.

Onions on moderately rich soil are growing fairly and promise a return of useful bulbs; those on very rich soil are growing fast, but should the weather not become brighter, warmer, and drier, they will be so late as to be useless. It really is a question of earliness *v.* lateness, for a quantity that were pushed forward in spring and transplanted in May, although growing strongly, are for the most part bulbing satisfactorily, some being now (July 21st) 4 inches in diameter. But for the artificial forwarding it is doubtful if, in such a season, they would have bulbed at all; as

it is it will take them some time to mature. The others not so forwarded will be too late; those forwarded by starvation will also be in time.

To some extent a knowledge of these facts may help us, still it is so much a question of climate we hardly know when preparing the soil what to do. I prepared for a hot dry summer, for till now such, in my experience, has always followed a mild winter. The consequence is most of my crops, Peas especially, are so strong that though I grow only medium sorts I can hardly keep them up. Outdoor Tomatoes are just the same; they grow strongly but the produce is very late. I suppose everyone knows that poverty causes precocity in Tomatoes.

Now, if someone could tell me a year before the event what the weather was to be I would know how to act. Even as it is the knowledge gained will not be lost, and these remarks are penned in the hope of setting your readers thinking, and may be they will profit too. Neither mulching nor liquid manure is needed this year, except in a few instances, such as for giving Cauliflowers a start before they take on a stunted habit and "button." In ordinary years these practices will make amends for soil not very rich to commence with, and help to maintain a growth that threatens to be too precocious.—N. B.

ODONTOGLOSSUMS.

(Continued from page 60.)

IN so large a genus as that now under consideration it would be unnecessary to give descriptive notes of all the species in cultivation, though the majority possess attractions that well entitle them to notice. In few, however, besides the collections at very large private establishments, at nurseries where Orchids constitute a speciality, and in some botanic gardens, will a large number of species be found, and there is an increasing tendency to grow a number of plants each of a few really useful and beautiful species in preference to one or two specimens of a great many distinct forms. In a strictly practical point of view—that is to say, where a really imposing display is required at one time, and where Orchid flowers are in demand for decorative purposes, this plan is an excellent one, particularly if the accommodation for such as need different treatment is much limited.

Resuming the review of the chief species, one that now deserves notice is

O. Pescatorei.—A charming New Grenadan Orchid, which when in good condition is surpassed by few members of the genus. This is especially the case with some of the best varieties now in cultivation, which are greatly superior to the older type in the form, size, and colour of the flowers. Undoubtedly, however, that of which a flower is represented in fig. 18, p. 103—viz., *O. Pescatorei*

Fig. 19.—*Odontoglossum Cervantesi decorum*.

Veitchii, is the finest that has yet been introduced, and the fact that certificates have been awarded for it by the Royal Horticultural and Botanic Societies during the present year is a good indication of its distinctness and merits. In the ordinary forms the sepals and petals are white with a tinge of rose, the lip being white with rose and yellow, but in the one now being noticed the flowers are of beautiful form, the sepals and petals broad and heavily barred with rich purple, presenting quite a unique appearance in comparison with the other forms of this species. It was

introduced by Messrs. J. Veitch & Sons of Chelsea, who first exhibited it at Kensington on March 28th of the present year.

O. Cervantesi.—A Mexican species of dwarf habit that thrives admirably in small pans or shallow pots suspended from the roof of the cool house, where it blooms freely in spring and early summer. Like so many other Orchids several varieties have now been obtained that greatly surpass the old forms, and in a gardener's view the difference between a poor form and such a superb variety as *O. Cervantesi decorum* is greater than exists between many species as far as external form is concerned. The last-named is a very handsome variety, and as the accompanying woodcut (fig. 19) shows it is most peculiarly but prettily marked. The sepals and petals are white, of semi-transparent substance,

Fig. 20.—*Odontoglossum Halli nigrum*.

upon which the concentric lines and bars of rosy purple or deep crimson stand out most distinctly. The margins of the petals are usually slightly waved, and this adds rather to the pleasing appearance of the flowers. The bloom represented was obtained from Mr. R. Warner's collection at Chelmsford, and though not so large as some others it was specially remarkable for the rich colouring at the lower part of the floral divisions.

O. Halli.—Quite different from the last is *O. Halli*, which forms with a few others, such as *O. luteo-purpureum*, a distinct section of the genus in a horticultural point of view. Its long racemes of large flowers render it very prominent in a mixed collection, and the dark-coloured varieties are especially remarkable when arranged with the lighter-tinted *Odontoglossums*. Early in the present summer, when Mr. W. Bull's collection of cool Orchids at Chelsea was in good condition, the *Odontoglossums*, and particularly some very dark forms of *O. Halli*, were very noticeable. Of the latter the darkest by far was that appropriately named *O. Halli nigrum*, of which a flower is represented in fig. 20. This is an extremely handsome Orchid of bold appearance, the racemes long and the flowers large. The petals have a buff yellow ground being heavily spotted with dark reddish brown almost black, the sepals are brownish towards the upper half, and marked similarly to the petals at the base. The lip has somewhat of purple in the spots, the ground being yellowish, inclining to white at the base; it is deeply but neatly fringed, and the waved margins of the sepals and petals are also very pleasing.—L. C.

NEWCASTLE FLOWER SHOW.

THE Durham, Northumberland, and Newcastle-upon-Tyne Incorporated Botanical and Horticultural Society held their annual Exhibition on Wednesday, Thursday, and Friday the 26th, 27th, and 28th of July, in the Leazes Park, Newcastle-on-Tyne. This is one of the oldest societies in England, and in the last few years has been im-

proved so as to rank among one of the best also. It is unnecessary to mention the suitability of Leazes Park for an exhibition of this kind, its commanding view of the Tyne and the vale of the Derwent. The exhibits were staged in a series of tents arranged ridge-and-furrow fashion, with one central division, and covered an area of 24,700 square feet. The entries in some classes were not as numerous as in former years, but the exhibits were generally superior. Many of the prizes went to local exhibitors, Mr. Watson, Tanfield, gaining first for six stove and greenhouse plants. The Darlington contingent of exhibitors was strong, showed well, and generally victoriously. The first day was excellent for weather, the second bad, and the third good; but the receipts are reported to be good, which we hope will help the Society to hold their autumnal exhibition another year.

Referring now to the classes, we will give the results of the competition. In the Division A, open to all, the Society offered £26, apportioned in prizes of £12, £8, £4, and £2, in the class for eight plants in bloom; only three competitors staged. Mr. Letts, gardener to the Earl of Zetland, Marske-by-the-Sea, was easily first; his plants were fresh, well flowered. He had an *Anthurium Schertzerianum* over 5 feet in diameter with one hundred flowers, the spathe of which were 5 inches long; *Phœnocomma prolifera* was over 5 feet through, fine in shape, and profusely flowered; *Erica ampullacea*, *Statice profusa*, *Erica oblata*, *Ixora Williamsii*, and *Dipladenia amabilis*. All possessed more than average merit. Mr. Adams, Swalwell, was second with much smaller plants, his best being *Phœnocomma prolifera* Barnesi, a good *Erica Bothwelliana*, and a *Dracophyllum gracile*. Mr. Noble, gardener to Theo. Fry, Esq., Woodburn, Darlington, was third.

For eight foliage plants in this section the Society offered £18. Mr. Hammond, gardener to Sir Wilfrid Lawson, Brayton Hall, Carlisle, was first with a fine collection, including *Latania borbonica* 10 feet high, *Croton pictus* 9 feet high, *Phoenix rupicola*, *Encephalartos villosus*, *Dasyliirion glaucum*, and others. Mr. Noble was second with good examples of *Stevensonia grandifolia*, *Kentia Fosteriana*, *Cycas revoluta*, and *Dasyliirion serratifolia*.

The Society offered £20 for groups of miscellaneous plants 20 feet by 10 feet, arranged for effect. This brought four competitors. It was one of the most striking and important features of the Show, and helped to make up for the deficiency of the table decorations. Mr. McIntyre gardener to Mrs. Gurney Pease, Woodside, Darlington, was first with a well-arranged group, comprising new *Anthuriums*, *Crotons*, and *Begonias*, a background of tall plants, all freely and tastefully arranged, being suitably toned with *Ferns* and *Lycopods*. Mr. Hammond was second also with a tasteful group, in which *Acalyphas* were artistically encircled with *Ferns*. This was a really superb arrangement, and close in merit to the preceding. Messrs. Clark Brothers, Carlisle, were third; and Mr. Noble fourth, both arrangements being good.

For six *Ferns* Mr. Noble was first with a good *Davallia Mooreana*, *Gleichenia Mendeli*, *G. Speluncea*, and *Asplenium Belangeri*. Mr. Hammond was second, and Mr. Methven third. In the corresponding B Division, for gentlemen's gardeners only, Mr. Noble was also first with a corresponding lot of *Ferns*; Mr. Bullock, gardener to Charles Wilson, Esq., Shotley Bridge, being second, and Mr. Watson, Tanfield Hall, third. For twelve hardy *Ferns* in the A division Mr. Bullock was first, followed by Mr. Saunders. The former had fine examples of *Athyrium Filix-fœmina*, *Hymenophyllum unilaterale*, *Scolopendrium bimarginatum cordatum*, and *Athyrium Filix-fœmina crispum*.

For three *Crotons* Mr. McIntyre was first with fine coloured examples of *Majesticus*, *Queen Victoria*, and *Andreanus*, all well coloured. For four *Ericas* Mr. Letts was first with good plants of *Erica æmula*, *coronata*, *tricolor* *Wilsoni*, and *tricolor elegans*; Mr. Methven being second. In the division B for six foliage plants Mr. Letts was deservedly first with a fine *Chamerops humilis*, *Dasyliirion acrotrichum*, *Dion edule*, and *Croton Johannis* well coloured; Mr. Hammond was second with a good *Croton Disraeli*, *Macrozamia Fraseri*, *Bonaparte juncea*, and *Yucca filamentosa*. In this division the entries in the class for six plants in bloom were excellent. Mr. Watson, Tanfield Hall, was awarded the first prize for a handsome *Stephanotis floribunda*, *Allamanda Wardleyana*, and *A. nobilis*, very fine; *Clerodendron Balfourianum*, and *Ixora Williamsii*. Mr. Adams was second with fresh examples of *Bougainvillea glabra*, *Allamanda Wardleyana*, *Statice profusa*, and *Clerodendron Balfourianum*. Mr. Methven was third with fine plants in very satisfactory condition. These formed one of the most important features of the Show.

Cut Flowers.—The epergnes, hand and bridal bouquets, and button-holes were not so numerous as in previous years. The table decorations were greatly missed in this department. In the open class for an epergne of cut flowers Mr. T. Rutherford, Durham, was first with a neatly arranged Marsh glass, the top containing Everlasting Flowers, *Oncidium flexuosum*, *Gloxinias*, *Oleanders*, *Stephanotis*, and *Eucharis*. The base contained *Anthuriums*, *Allamandas*, and *Ixoras* fringed with *Davallia Mooreana*. In the corresponding class for gardeners Mr. Baynes, Sunderland, was first. The same exhibitor also took first for bridal and hand bouquets. Mr. Whiting, gardener to E. Walker, Esq., Shot Tower, Newcastle, was first with table plants. For stove and greenhouse cut flowers Mr. McIndoe showed a very fine collection, including spikes of *Cypripedium Lowii*, *Allamanda Hendersonii*, *Anthurium Andreanum*, *Stephanotis floribunda*, *Odontoglossum Roezlii*, and several *Ericas*. Mr. Black, gardener to Misses Pease, Southend,

Darlington, was second with beautiful examples of *Vanda suavis*, *Pancreatium fragrans*, *Swainsonia grandiflora*, and *Dendrobium densiflorum*. In the B division Mr. Black also gained the chief prize with *Vanda suavis*, *Allamanda Hendersonii*, *Lapageria rosea*, *Ixora javanica*, and *Erica jubata rubra*. Herbaceous flowers were very good; Mr. Battersby, Hagg Hill, Blaydon, taking first with a good collection.

In the Division B, for twelve pots of alpine or rock plants, Mr. Larke, gardener to the Rev. W. Wheeler, Whitby, was the principal exhibitor, winning chief honours with *Armeria Pink Beauty*, *Achillea ageratoides*, *Geranium argenteum*, *C. turbinata pelviformis*, *Linaria pallida*, *Erigeron mucronatum*, and other plants. The same exhibitor was also first with bedding plants, which were very good. For twelve pots of hardy succulents Messrs. Clark Bros. were first with a good collection, including *Sempervivum Lagerrii*, *S. hirtum*, and *S. arboreum variegatum*. For four Orchids Mr. George Hankin, Haviston, Stockton, was first, staging *Epidendrum nemorale*, *Dendrobium formosum*, *Cypripedium Parishii*, and *Odontoglossum Alexandræ* in fair condition. Mr. Noble was first in the corresponding class of Division B. For six Tubercous *Begonias* Mr. Noble was first with well-flowered plants, Mr. McIntyre second, and Mr. Garret, Newcastle, third.

The Society offer special prizes for window plants, which were well competed, *Fuchsias* being strongly represented. In the division C, which is open to amateurs only, some excellent plants were staged.

Roses.—These were extensively and well shown. For forty-eight *Roses*, twenty-four varieties, there were seven stands, Mr. B. R. Cant, Colchester, being first; Messrs. Mack & Son, Catterick Nurseries, York, were good seconds. The former had fine blooms of *Alfred Colomb*, *Duc d'Edinburgh*, *Souvenir d'Elise*, *Annie Wood*, *Marie Baumann*, *A. K. Williams*, *Countess of Rosebery*, *Innocente Pirola*, *Fisher Holmes*, *Comtesse de Paris*, *Baron Gonella*, *Exposition de Brie*. The best of Messrs. Mack's blooms were *Marie Baumann*, *Paul Neyron*, *Constantin Tretiakoff*, and the *Duke of Edinburgh*. Messrs. Paul and Son, Cheshunt, were third. For thirty-six blooms, not less than eighteen varieties, Mr. Whitwell, Barton Hall, Darlington, was first with fresh bright blooms of *Beauty of Waltham*, *Alfred Colomb*, *Comtesse de Serenye*, *Duchesse de Morny*, *Marie Baumann*, *Alfred Colomb*, *Thomas Mills*, *Dupuy Jamain*, *Elie Morel*, *John Stuart Mill*. These were very fine and attracted much admiration. Mr. B. R. Cant was second, and Messrs. Paul & Son third. Mr. Cant's stand contained excellent blooms of *Eugène Verdier*, *Duke of Teck*, *Madame Marie Finger*, and *Alfred K. Williams*. For twelve Tea *Roses* Mr. B. R. Cant took the first place with splendid blooms, including *Madame Hippolyte Jamain*, *Niphotos*, *Souvenir d'un Ami*, and *Souvenir d'Elise*. Mr. B. R. Cant also took first for twelve blooms of any variety with *Marie Baumann*. For twelve yellow *Roses* Messrs. Paul & Son were first with *Bouquet d'Or*. This *Rose* was much admired, it has the habit of *Gloire de Dijon* with the colour of *Maréchal Neil*. In the other classes, Messrs. Burrell, Heighington, and Laws, Ponteland, were the principal prizetakers.

Fruit.—The excellence of the fruit has been at all times remarkable at the Newcastle Show, and the last Exhibition was no exception to the rule, indeed many well-known exhibitors were not discontent with being placed third. For a collection of eight dishes £8 and the Royal Horticultural Society's bronze Knightian medal were offered. There were four competitors. Mr. Edmonds, gardener to His Grace the Duke of St. Albans, gained first prize with good bunches of *Muscat of Alexandria* and *Black Hamburg*. An excellent *Queen Pine* was shown nearly 4 lbs. in weight. *Royal George Peaches* and *Elruge Nectarines* were good, and a dish of *May Duke Cherries* was also noteworthy. Mr. McIndoe was second with *Duchess of Buccleuch* and *Madresfield Court Grapes*, *Pitmaston Orange Nectarines*, *Barrington Peaches*, *James Veitch Strawberries*, and *McIndoe's Scarlet-flesh Melon*. Mr. H. A. Mann, Grantham, was third; his best dishes were *Brown Turkey Figs*, *Muscat of Alexandria* and *Black Hamburg Grapes*. Mr. Jowsey, The Gardens, Ledbury Park, was fourth with even specimens. For four dishes of fruit, *Pines* excluded, Mr. Edmonds again secured the first prize with similar samples to those in the first-named collection. Mr. H. Johnson, gardener to H. Mumis, Esq., Castle Eden, was second with good *Black Hamburg Grapes*, *Melon*, and *Royal George Peaches*; Mr. A. Mackie being third. The best *Pine* was also shown by Mr. Edmonds, who had a good *Queen* 4 lbs. in weight. For bunches of *Grapes* Mr. Hammond was first with *Black Hamburg* and *Buckland Sweetwater Grapes*, the former very fine. Mr. E. Douglass followed with *Black Hamburgs* and *Muscat of Alexandria*, both very good; Mr. Larke, Whitby Park, being third. For two bunches of *Muscat* four lots were staged. Mr. Douglass was first with *Muscat of Alexandria*, well coloured and large in berry. For two bunches of white *Grapes* Mr. Hammond was first with *Buckland Sweetwater*, very large in berry; Mr. Black was second. There were five entries in this class. For two bunches of *Black Hamburg* Mr. Hammond was also first. For two bunches of *Black Grapes* Mr. Matthew Larke, gardener to Rev. M. Wheeler, Whitby Park, was first with *Madresfield Court*, Mr. Westcott following.

For green-fleshed and scarlet *Melons* Mr. Jenkins and Mr. Larke were first respectively with *William Tillery* and *Benheim Orange*. Mr. Mackie had the best dish of *Peaches* (fine examples of *Noblesse*), Mr. Edmonds being second with *Chancellor*. Mr. McIntyre was third with *Exquisite*, which were also good. For the best *Nectarines*

Mr. W. Jenkins, gardener to W. Brodie Cochrane, Esq., Durham, was first with superior fruit unnamed; Mr. Black second with Elruge. Figs, Cherries, Strawberries, and Tomatoes were also well shown.

Miscellaneous.—Amongst the exhibits not in competition were a stand of Gladiolus and Dahlias, both of which were good, exhibited by Messrs. Harkness & Sons, Bedale, Yorkshire. These were generally admired, as in the north such fine blooms are rarely seen so early. Messrs. Thompson & Son, Newcastle, showed a fine stand of named Phloxes. Messrs. Stuart & Mein exhibited some fine Petunias. Messrs. Little & Ballantyne, Carlisle, contributed Roses. Mr. Sibbald, nurseryman, Bishop Auckland, had a fine stand of cut blooms of seedling Begonias. Mr. William Joseph Watson had a fine collection of Conifere and alpine plants. Messrs. Fell & Co., Hexham, Wentworth Nurseries, contributed a similar collection. The centre of attraction, however, was the group from Mr. B. S. Williams, Upper Holloway, London, which comprised a superb collection of new plants that were much admired by the visitors each day.

The Committee, along with the Secretary, were indefatigable in securing the comfort of visitors and exhibitors.

ERODIUMS (HERON'S BILLS).

THIS interesting group of plants belongs to the family Geraniaceae, and the common appellation of Heron's Bill is a precise rendering of the scientific name, which is not so frequently the case as one would wish. *Erodium* is taken from *erodios*, a heron, on account of the carpels when united to the column resembling the head and beak of that creature. Superficially there is much similarity between them and the Geraniums; they are rather different in the mode of growth in most instances, but still there is a great family likeness, and structurally there is much resemblance between the two genera. The distinctive characteristics of the *Erodiums* are the sterility of five out of the ten stamens, the hairiness of the inside of the carpel tails, and the spiral manner in which the latter coil up when separated from the column—a characteristic which is very striking in *E. romanum*. In Geraniums the carpel tails merely recurve when split away. They are numerous and very widely distributed, consisting of annual and perennial species, the majority of them perennial. Southern Europe and the countries bordering on each side of the Mediterranean are their headquarters. Three species are British, all of annual duration, while about the same number are found in Asiatic Russia, and one or two occur at the Cape which are not hardy in this country. They are mostly mountain plants, found at moderate elevations, and for the majority of them the rock garden is the only place to cultivate them successfully, about which, however, there is no difficulty. They are dwarf and compact growers, and by no means disposed to require a large amount of space until they are thoroughly established and two or three years old, by which time they will prove themselves worthy of it. *E. Manescavi* is an exception, as it is a much stronger grower than any of the others, but it is a plant worthy of a position of any extent, as it is very showy and perfectly hardy. They possess the advantage of not overrunning all their neighbours, as many alpinists are wont to do; but they are neat in appearance, evergreen, with elegant foliage and pretty flowers, enjoying a sunny and dry position but plenty of moisture during the growing season, although they do not suffer so quickly from drought as some plants. They are not particular as to soil, thriving in ordinary garden soil, a rich loamy sandy compost suiting them well. For the choicer kinds I have employed a mixture of loam, leaf soil, sand, and pieces of brick or limestone broken up finely, and found them do remarkably well in it, and any little trouble taken in this way with plants deserving it is not lost, but amply rewarded in the extra progress they make and their greater floriferousness.

They are increased in various ways. Some of them will divide, but this is not a very quick method of securing stock, as in the case of one group the rootstock is large and fleshy, and in the other there are woody stems or branches. To successfully divide the latter they should be planted deeply, so that the branches may root, when it can be accomplished without any fear of loss. Well-ripened cuttings inserted in pots placed in a cold frame, adding a liberal amount of coarse sand with the soil, will nearly all root, although they are rather slow. They are also easily raised from seed, which most of them produce in the southern counties, also in the neighbourhood of London. The seed may either be sown as soon as it ripens or be kept until the following spring, April being a good month to sow in pots, which may be placed in a cold frame or a cool greenhouse, keeping the soil fairly moist and have the pots well drained, and in three or four weeks the young plants will appear, which should be potted singly into small pots, when they can be handled and kept in them until they are well established, when they should be planted out, with the exception

of two or three plants, which should be kept in reserve in the event of loss from any cause. Especially is this commendable in the case of the rarer kinds. I should imagine they would readily increase by means of root-cuttings made from the principal roots, cut into lengths about an inch long; and although I have not tried this method, most likely the end of summer would be the best time to make the experiment, and those interested might try it in a small way. The cuttings should be dibbled in pots of sandy soil and placed in a cold frame.

The species enumerated below are all hardy, and there are other very pretty kinds in cultivation, which, however, will not endure our winters outside. I well remember seeing one such in the collection of the late Mr. Joad of Wimbledon Park under the name of *E. pelargonifolium*, which was very showy, flowering all the summer in one of his alpine houses, which had not any artificial heat. *E. mauritanicum*, which I have lost in ordinary winters, flourished remarkably in the same house. It has occurred to me that some of the brilliant colours of the Geraniums might be infused into some of the species by cross-breeding without the issue being too tender to withstand our winters, and I made a limited number of experiments in this direction, but through unfortunate circumstances they were not carried through. Perhaps some of our enthusiastic amateur cultivators will think the matter worthy of consideration.

E. absinthoides.—A very dwarf close-growing species, not more than 4 inches high, with very finely divided light green foliage, oblong in outline. Flowers in umbels on stalks raised slightly above the foliage, half to three-quarters of an inch across; the two upper petals rosy purple with blackish blotches, the lower ones rather light rosy purple distinctly veined. It flowers very freely through all the summer months from May. It is a native of Spain, and is apparently very scarce in cultivation. I have noticed it at Kew and one or two other places.

E. cheilanthifolium.—A recently introduced species from the mountains of Spain, with silvery grey foliage, very finely divided and Fern-like; taller-growing than the last. Flowers in umbels most freely produced, nearly an inch across, rather deeper in colour than those of the last, and but slightly blotched. This is a very rare and lovely species sent out by Fröbel & Co. of Zurich, and it requires a dry position in light sandy soil. It is very free-flowering, continuing from June through all the summer months.

E. chrysanthum.—This is also an extremely scarce species, native of the mountains of Greece, and sent out about three years since by Fröbel & Co. It grows about 6 inches high, with finely divided foliage of a silvery grey colour, the blade portion shorter and narrower than that of the last. Flowers in umbels borne on erect stalks just above the foliage, about 1 inch across, of a soft yellow colour; most distinct and charming. It requires the same treatment as the last, and to insure against the loss of such a gem it would be commendable to afford it some protection during the winter until a sufficient stock is secured, so that one or more plants might be risked. This applies to our colder counties. In the south it is quite hardy, and I have kept it near London. In flower from June to August.

E. hymenodes.—Quite distinct from all the species here described. It has a short gouty stem. Leaves simple, roundish-cordate, conspicuously lobed or serrated. Flowers in three to six-flowered umbels; the two upper petals light rose marked with crimson blotches, the lower ones lighter in colour, pale rose. The flowers measure half an inch or rather more across. It is a pretty little plant, resembling a miniature Pelargonium in appearance, and it thrives well in a sunny dry situation, flowering in July and August. It is a native of Northern Africa, and the same precaution is necessary as advised for the last.

E. Manescavi.—A much more robust-grown species, forming large tufts of pleasing green foliage a foot or more high. Leaves 9 to 12 inches long, alternately pinnate the greater portion of their length; leaflets deeply cut. Flowers numerous, in large umbels borne well above the foliage, 1 to 1½ inch across, of a bright purplish red colour freely veined with crimson. It is a most conspicuous plant when in flower, which is during the greater part of the summer—from June to October—very free, and is suited either for the embellishment of the rockery or the border. Plenty of space is necessary for it, but on the rockery it is a very telling plant, and in the border it makes a grand show. It produces seeds freely.

E. macrodenium (*E. glandulosum*).—A dwarf species, forming tufts of elegant finely divided foliage, similar to *E. absinthoides*, but the leaves are longer and not so freely divided as those of that species. Flower stems about 6 inches high, umbellate. Flowers three-quarters of an inch across; upper petals pale rose with black blotches, lower ones flesh-coloured and conspicuously

veined with purple. It flowers very freely during the summer months, forming a very pretty plant. Native of Spain.

B. romanum.—A pretty little species, resembling a miniature *E. Manescavi*. It grows in tufts. Leaves alternately pinnate; leaflets ovate-oblong, serrated, hairy. Peduncle 6 inches high, umbellate. Flowers half an inch or rather more in diameter, bright pink. This is a biennial species, rarely lasting more than two seasons; but it is easily raised from seed, and it readily establishes itself where introduced. It is a native of Italy, and Linnæus, who first described it under the name of *Geranium romanum*, states that it was frequently found in the streets of Rome.

E. Reichardi (*E. chamædryoides*).—This is the dwarfest of all the species here enumerated—not more than 2 to 3 inches high. Leaves roundish-cordate, variously lobed, half to three-quarters of an inch across, on very slender petioles. Flowers solitary, on slender stalks, very freely produced, half an inch across, white with radiating pink lines, with regular ovate petals. It thrives well on the rockery, forming compact tufts clinging close to the soil, flowering from June through the summer months. It is a native of the island of Minorea, from whence it was introduced into France by a gentleman named Reichard, in honour of whom Professor Murray named it. It is still a scarce plant, although it was cultivated by nurserymen in the neighbourhood of London a century back under the name of *Geranium acaule*, and a figure of it appears in the "Botanical Magazine," plate 18, under the name of *G. Reichardi*.—N.

REVIEW OF BOOK.

Report of the Proceedings of the Sussex Association for the Improvement of Agriculture. Season, 1881.

DOGMATISM in things scientific is not worth indulging in, for what is accepted as fact to-day is to-morrow shown to be fallacious. A year or two ago phosphates in manures were reckoned as of little or no value, and only acid-treated phosphates considered of use for plants. The Aberdeenshire experiments, conducted by an able and original chemist, Mr. Thomas Jamieson, dealt the first blow to the old theory—for it never was more than a theory, though universally accepted as proved fact, and acted on as such. The most recent work on the use and manufacture of artificial manures places dissolved phosphate at 4s. 6d., and undissolved mineral phosphate at 1s. Space will not permit us, in the present instance, to give even a short *résumé* of the Aberdeenshire experiments, but the one thing they proved above everything else was that undissolved phosphate is, for the crop to which it is applied, very nearly equal to dissolved, and in certain circumstances even quite equal, and not a whit behind over a rotation; while the continual use of phosphates treated with sulphuric acid had a tendency to produce disease, so that on the whole undissolved phosphate is preferable to dissolved, independent of its greater cheapness.

The report before us bears out in a wonderful manner the Aberdeenshire experiments. Some doubted, many denied that the Aberdeen experiments were conclusive; but here in Sussex, in a different climate, in different soils, the self-same answers are given to the same questions. Here, too, the manufacturing chemists have been shown to be in error and it has been shown that much money is being annually thrown away.

From the animated discussion lately conducted in these columns on the subject of artificial manures, we feel assured that our readers will be interested in a few of the main facts brought to the surface by the Sussex investigations. Indeed the matter is of national importance, as is shown by the following quotation:—"Of roots only, not taking into account the Wheat crop, there were about 71,000 acres in Sussex, and assuming that out of 30s. an acre one-third, or 10s. an acre, could be saved" (that is by the use of the cheaper or undissolved phosphate), "the saving to Sussex would be £35,000 annually." If this sum be multiplied by every such county in the kingdom the importance of the subject becomes evident at once.

One of the ascertained benefits resulting from the use of dissolved phosphate over undissolved is that it gives the plants the advantage of a quicker start where only chemical manures are used. Although this is the case it is shown in the report before us that dissolved phosphate has a tendency to fail towards the close of the season, while the undissolved holds on, and in the end gives equal and in some instances even superior results. For Turnips it was found that the manure that gave the best results was steamed bone powder and ground coprolite. At Preston the unmanured portion gave a crop of 9 tons 14 cwts. With pure dissolved bones costing 63s. 9d., 11 tons 4 cwts. resulted. Dissolved coprolite of equal value gave 9 tons 19 cwts.; undissolved

coprolite costing 33s. 9d. gave very nearly equal results, while a mixture of undissolved coprolite mixed with sulphate of lime gave 12 tons 8 cwts. The only two of these that can be compared are the first and the last, and under the old system of valuing the last would be considered next to useless, yet it proved superior.

In some instances the manures were tested along with a precautionary mixture. In such cases—and these give the most reliable results—the economy of using undissolved phosphates is brought out. To produce 14 tons 7 cwts. 100s. 1d. worth of manure was needed when dissolved coprolite was used, but when undissolved coprolite and bone flour was substituted—the mixture costing 57s. 9d.—the result was 14 tons 2 cwts., or very nearly the same.

The experiments show that artificial manures alone do not prove so suitable as when coupled with farmyard manure; that, valuable as they undoubtedly are, they are more to be relied on as auxiliaries than when employed by themselves, especially in seasons of drought. At Preston 25 tons of farmyard manure gave 15 tons 5 cwts. of Swedish Turnips, while 12½ gave 13 tons 17 cwts. Four portions were partially dressed with farmyard manure at the rate of 12½ tons, each further fertilised with different artificials. One plot, in addition to the farmyard manure, was treated with commercial dissolved bones, costing 45s., and the result was 14 tons 2 cwts. With ground coprolites, bone flour, and sulphate of lime, costing 28s. 8d., the result was 17 tons 5 cwts.—a very great difference in cost and in results. When to this latter mixture was added potash and magnesia 19 tons 16 cwts. was the result, proving that it is not always safe to assume that there is enough of these substances in even fertile soils; yet this is just what is almost always done. At the same time only a moderate allowance should be made to begin with, and cautiously increased, for too much may do mischief, as is proved by the fact that when more potash and magnesia was added to the above the produce was reduced 1 ton 10 cwts.—not a paying experiment.

All the soils operated on were poor, but that at Hassock's Gate was a sheer sand containing hardly any traces of any plant food after the black surface had been removed. On this startling and exceedingly instructive results were obtained—results at once proving the necessity of everything being added to some soils, and that phosphates by no means require to be rendered soluble. When no manure was applied the seeds germinated but made no progress whatever. When everything except phosphorus was given the result was hardly different, the produce hardly amounting to half a ton per acre. When phosphate—even as ground coprolite—was added the produce at once went up to 20 tons an acre: truly a wonderful result, and such as must convince everyone of the value of undissolved mineral phosphate. As Mr. Jamieson remarks, anyone who still persists in doubting, "the doubt must be an integral and inseparable part of his constitution. If those who have little or no difficulty in accepting the fact nevertheless lean to soluble phosphate as a superior form, they will be confirmed in their belief by these experiments, but they will see that the superiority is not one to lay much store by. If we were to venture on prediction, based on former experiments, we should say that as time passes the superiority will decrease and disappear, and that the flush at the outset will give place to disease in the end."

Some interesting facts are brought out by the experiments with potash salts, and one discovery has been made. With everything applied except potash the average weight from each plot was 38.59 lbs.; when the carbonate was applied only 36.50 was the result, thus confirming the former experiments of several chemists, and once more proving that the value put upon the carbonate of potash (as found in wood ashes) by gardeners to be not well founded. When potassic phosphate was added the result was 40.52 lbs.; potassic sulphate gave 40.69 lbs., or a little more than the phosphate; potassic nitrate gave 72.94 lbs., a great increase due to the presence of the nitric acid doubtless, but once more confirming the value of potassic nitrate (nitre). With potassic chloride the produce was nil—it killed the plants. The results of this particular set of experiments go to prove that Turnips on fertile soil do not want potash, for even when its presence could hardly be detected a good crop resulted even when it was withheld. As its addition on other plots gave an increase we may suppose that its use on particularly barren sands might be repaid.

The destructive effect of potassic chloride when applied to land deficient in organic remains was well illustrated on all the plots to which it was applied at Hassock's Gate. We will give the result in Mr. Jamieson's own words. "There is something wrong with No. 9," said the superintendent. "Is it not No. 12?" "No." "Nor No. 8?" "No, it's No. 9." I had expected No. 12 (no potash) to be backward; No. 8 (sulphate) turning out ill would not have surprised me. I had doubts about No. 6 (carbonate),

but that No. 9 should be so very backward—the chloride so generally favoured—myself no exception in the belief, was unaccountable.

“On arriving at the station the four chloride plots were visible at a distance; the plants were not only small and sickly but almost blanched or chlorinated, if I may use the term, for the well-known bleaching action of chlorine appeared evident. The two plots of Peas and two of Turnips were all suffering similarly, while the neighbouring plots were all healthy. . . . Talking the matter over while on a visit to Hassock's Gate with a member of the Aberdeenshire Association, Mr. Maedonald, factor on the Cluny estates, he suggested our repeating the experiment on the adjoining black sandy soil overlying the white sand in which the injurious action was experienced. Although the season was far advanced I carried this out. Six plots were opened up.” It may be explained here that this black sand was the surface mould which had been removed in the case of the other experiments—black because of the decayed vegetable matter contained in it. For comparison some were treated with sulphate, others with chloride, others had no potash. The result at the end of the season was 4 tons 4 cwts. where no potash was applied, 5 tons 16 cwts. where the chloride was given, and 6 tons 5 cwts. where sulphate was given.

“To what was this difference due? The surface sand was derived from the sand below; the one was black the other white—in other words, the one contained decaying organic matter, the other none or only traces. Chemical analysis revealed no other difference, except that the food ingredients were rather less scarce.”

From this Mr. Jamieson concludes that the chloride of potash may be used with safety on land rich in organic remains. He also considers that the ill effects may be neutralised by the employment of nitrate of soda. He says—“But we had heavy crops of healthy Turnips in the phosphate series on the white sand. What form of potash was used? It may be difficult to realise that it was the chloride.” The nitrogen in this case was supplied by nitrate of soda, in the other by bone. Mr. Jamieson considers that in this case the soda seized the chlorine, forming common salt. We have seen Mr. Jamieson's conclusions termed hypothesis, but the facts are these:—When chloride of potash was applied to soil containing no organic matters the effect was disastrous; when organic matter was present it proved harmless. The same happened when along with the potassic chloride sodic nitrate was given.

The effect of potash on Peas was more marked than on Turnips. The plots treated with carbonate produced nearly one-third more of total produce, and fully a third more of Peas than the no-potash plots. The sulphate gave much more straw than the carbonate, but the yield in Peas was a fourth less; in this it was equal to the nitrate, but the latter produced still more straw. The phosphate gave about the same amount of straw as the sulphate, but the yield of Peas was actually less than when no potash salt at all was given, while, as before stated, the chloride gave nothing except instruction. It ought to be stated, however, that rooks spoil a portion of the Peas, so that the experiments can hardly be considered reliable.

The space at our disposal will hardly allow of our culling more; but before closing the report we would like to call attention to the experiments with Oats. As in the case with certain of the Turnip plots, plots were dressed with a mixture containing every essential; while others, for comparison, had one kept out from each plot. The result proves so far that no one ingredient can be withheld without the plant thereby suffering. When all was withheld the produce over the series was 92 lbs., when nothing was withheld it amounted to 118 lbs. Curiously enough, when no phosphate was given the gross weight was 119 lbs., a fact hardly according with the ideas held of phosphates for cereals. The produce of the grain was rather less, however, confirming the opinion that phosphates fill the ear. The withholding, however, of potash, magnesia, and nitrogen seemed to be more felt by the plants than the withholding of phosphate. It would thus seem that nitrogen alone for cereals and phosphates alone for Turnips is a mistake.

The per-centage of water in Turnips is often greatly altered by the kind of manure applied. Dissolved phosphates and nitrogen tend greatly to increase it, and it has been found that the increase caused by the employment of the latter is only water, the dry produce remaining the same. As solid Turnips keep much better than watery ones the use of nitrogen may thus prove a double loss, first the money spent, secondly the Turnips lost.

It has been asserted that chloride salts, magnesia especially, possess the power of producing watery Potatoes. Possibly they may have similar effects on Turnips. Mr. Jamieson seems just

the right man in the right place for ascertaining whether there be any truth in such an assertion, and of showing whether part of the effect attributed to dissolved phosphate and nitrogen may not be due to the chloride of potash. We would suggest the desirability of clearing up this point; for, having shown that we may now employ chloride of potash freely in rich garden soils without fear of mischief, it would be of much value to know what form of potash is most favourable not only for producing large crops of Potatoes but good tubers.

The main facts worth remembering are that 1 ton of ground eoprolite and bone flour, which cost about the same as a ton of superphosphate, is yet worth twice as much ultimately, though hardly so effective at the first growth. That superphosphate tends to produce disease. That chloride of potash is not quite safe on land very deficient in organic matter, but when that is present, or when used along with nitrate of soda, it may be used without fear (some say newly slaked lime makes it safe). That artificial manures may take the place of farmyard manure, but are better when used along with it. That on very poor soils all the essentials had better be supplied, thus confirming the opinions of the older chemists. That the best way to analyse soil is to experiment with manures (properly compounded) containing every essential, and to compare the results with other manures from which each one in turn is excluded. By this means we may soon find out whether we can dispense with phosphates, or potash, nitrogen, sulphur, magnesia, &c., in our own particular case, or whether we can dispense with any. In this way we may all become chemists and arrive at results not attainable in the laboratory. What we want now is not so much experiments there, but experiments in the field and the garden. We need hardly recommend agricultural experiments. The country is getting alive to their importance. What man, or body of men, with means sufficient will do for horticulture what our Jamiesons are doing for agriculture?

KITCHEN GARDEN.

Sow Cabbage seed for the main crop about the 6th to the 8th of August, suitable kinds being Ellam's Early Dwarf, Hill's Incomparable, and Nonpareil Improved, which are sufficiently large for private gardens; but if larger varieties are required for market Enfield Market and Battersea or Fulham are suitable. See that the earlier-sown Cabbage do not lack the needful attention in thinning and pricking-out as soon as they are fit, the time occupied in that operation being compensated for by the sturdier condition of the plants. Sowing Tripoli Onions should be attended to about the 10th of August, giving them rich soil well firmed in an open situation. Winter or Prickly Spinach should be attended to in sowing at the same date, giving this esteemed winter vegetable a distance of 18 inches between the rows, so that it can develop and be cleaned and gathered without injury.

Where Carrots are grown outside for use in spring now is the time to sow the seed, the Horn or Intermediate section being the best for this purpose, sowing in drills about 9 inches apart in a sheltered position where the soil is of a friable character, giving a good dressing of soot.

A breadth of Turnip seed should now be sown for winter and spring use, choosing an open situation and rich firm soil, suitable sorts being Veitch's Red Globe, Orange Jelly, and Chirk Castle Black Stone.

HARDY FRUIT GARDEN.

Apricots will in most localities be ripening, and will need to be protected against predatory vermin. Ants are generally the most troublesome, the remedy for which is drawing a line of gas tar at the base of the wall and renewing it when it becomes dry. Guano sprinkled over their nests and haunts will cause them to migrate. Wasps should be trapped in soda-water bottles about a third filled with sweetened beer, or hexagon netting may be suspended in front of the trees so as to exclude them. Plums of the early varieties, such as Early Prolific, Czar, July Green Gage, and Sultan, are ripening, and must also be protected from insects and small birds. The early

varieties of Peaches are advanced (Early Beatrice being ripe), and will need daily attention in gathering the ripening fruit, which should always be done before it falls from the trees, as they are benefited rather than otherwise by being allowed to lie for a day or two in the fruit room. In gathering the Apricots and Peaches great care should be exercised, as the slightest undue pressure is sufficient to injure the tender tissue, decay commencing and spreading rapidly. Gooseberries, Cherries, Raspberries, and all soft fruits should not be gathered until they are required. Morello Cherries must be protected from birds, and after hanging a time these Cherries form excellent table fruit, esteemed highly by some persons. In order to the preservation of the fruit to a late period a few bushes of Red Warrington or other late sorts of Gooseberry, together with Red and White Currants, should be covered with nets to preserve the fruit to a late period. Hexagon netting should be used in preference to mats. The latter ought never to be used, as they exclude air and light, engendering damp, which altogether very soon deteriorate the flavour of the fruit.

Mildew sometimes appears on the foliage of the Apricot, especially Royal, Blenheim, or Shipley, and should be combatted by thoroughly dusting the trees with flowers of sulphur. Grape Vines on walls will need similar attention, likewise Peaches and Nectarines. Continue to regulate the shoots of Vines, removing all superfluous growths, keeping them as close to the wall as possible without touching, and the berries on each bunch should be carefully thinned. Keep the leading shoots of wall-trained trees of all sorts carefully and closely nailed or tied in, and continue to remove or stop superfluous or foreright shoots, in order that the young wood retained may become thoroughly ripened.

FRUIT HOUSES.

Figs.—The fruit on the earliest-forced Fig trees in pots, if a second crop was taken, will be ripe; and as soon as the fruit is gathered the foliage should be thoroughly cleansed, dressing the trees if red spider be present with a solution of 4 ozs. of soft soap to a gallon of water. A free circulation of dry warm air will need to be maintained in the house until the wood is thoroughly ripened and the leaves give indications of maturity, when the trees may be placed outdoors in a warm situation and be plunged in ashes to the rim of the pots, which will induce their resting quickly; but when there is any doubt about the maturity of the wood they should be kept under glass and the house freely ventilated, lessening the supply of water, only giving a little to prevent the foliage becoming limp and falling prematurely. The second crop on early-forced planted-out trees will be ripening fast, and syringing must cease, and a circulation of dry warm air should be maintained constantly to secure well-coloured highly flavoured fruit. After the fruit is all gathered an occasional syringing may be given to cleanse the foliage of red spider and dust. Trees that ripened their first crop in June will now have a second crop swelling, and must be liberally supplied with liquid manure at the roots and have the mulching kept wet to encourage surface-rooting, syringing them daily to keep red spider in check.

Cherry House.—The roof-lights can now be removed to give the trees the benefit of full exposure, which is essential to arrest premature growth, to which Cherry trees, with other stone fruit subjected to early forcing year after year successively, are peculiarly liable. Although the leaves are not now particularly inviting to red spider its progress must be checked by a good washing occasionally, and if there be any black aphides destroy them by the prompt application of tobacco water or other insecticide. See that the border is sufficiently moist, for it must not be allowed to become dry, supplying liquid manure if the trees are not too vigorous. Trees in pots should be regularly attended to, and the foliage maintained in a healthy condition as long as possible.

Peaches and Nectarines.—The trees in the late succession houses should receive every attention as regards syringing to keep red spider in check, and watering the inside borders whenever they become dry. To assist the swelling of the fruit to a good size close the house early in the afternoon, with plenty of atmospheric moisture, and allow the temperature to rise to 85°, admitting a little air before nightfall, and ventilate early in the day to prevent the foliage being scorched. To assist in the perfect colouring and ripening of the fruit it should be

exposed as much as possible to the influence of the sun and air by removing some of the foliage; and where the fruit is on the under side of the trellis the shoots should be untied, and the fruit brought up to the light, being kept in position by laths placed across the wires. Tie and regulate the shoots, keeping the laterals closely pinched to one joint of growth.

FLOWER GARDEN.

Flower beds now require frequent attention to remove dead or decayed leaves and flowers. Seed pods of Pelargoniums, Verbenas, and indeed all kinds of bedding plants, should be removed immediately the petals fall, as the production of seed, besides giving the beds a shabby appearance, tends greatly to the exhaustion of the plant. Verbenas should be frequently examined and kept well thinned, so as to bring up fresh shoots and insure continuity of flowering. Calceolarias, Violas, Lobelias, Verbenas, and similar plants must have an abundant supply of water in dry weather, but the first-named should not be watered overhead or the flowers will be filled with water and fall off. Free-growing plants, such as *Mesembryanthemum cordifolium variegatum*, *Stellaria graminea aurea*, and others employed for carpet bedding, soon encroach on others of less growth if not frequently trimmed. The marginal and other lines forming the different patterns should be kept clear and distinct, or the effect is greatly marred.

Continue the sowing and pricking-out of hardy perennials, such as Carnations, Picotees, Wallflowers, and Brompton Stocks, as soon as large enough to handle. Stocks, Asters, Marigolds, and Zinnias should be well supplied with water or plentiful supplies of liquid manure. Dahlias and Hollyhocks will need to be securely staked and be well supplied with liquid manure. Continue to stake and tie the various border flowers as they advance in growth, and remove dead flowers and seed pods from such as are going out of bloom. Pippings of Pinks may still be inserted, and any that are rooted should now be planted out where they are intended to bloom. Carnations and Picotees if not yet layered should at once be attended to. The summer bloom of Roses is now nearly over, and all straggling shoots should at once be cut in, and every encouragement given the plants to make young wood for autumn blooming.

PLANT HOUSES.

Greenhouse.—The removal of the specimen hardwooded plants outdoors will allow more room to the young growing stock, which are usually kept during the early part of the season in pits with brick sides, which does not allow of sufficient light reaching the lower branches; hence they should now be removed to the more open situation occupied by the larger plants previous to the latter being placed outside. They should be raised near to the glass and be placed thinly so as to be exposed to all the air and light necessary to mature their growth, ventilating freely both day and night.

Camellias.—The general stock of plants are now setting their flower buds, and this is unquestionably the best time for repotting, as there is not the danger of giving a check, as is the case in spring, by disturbing the roots when they are starting into growth; but in carrying out the repotting now—*i.e.*, after the buds are set, it is imperative that it be done before these are larger than a small pea, for if deferred longer it is likely the buds will drop from the effects of moving. As to soil, we prefer turfy loam taken off a couple of inches thick where the soil is inclined to be light and full of fibre, but where this cannot be had fibrous peat should be used. It should not be stacked longer than to destroy the grass, or it may be employed fresh, as when much decomposed it is no better than ordinary soil, and certainly not equal to leaf soil. Do not break the turf very fine, and do not interfere with the roots more than is necessary in removing the crocks and any portions of the ball not occupied with roots, making the new soil as firm as the existing ball. Good drainage is essential, with sufficient sand to keep the soil open. Avoid overpotting.

Primulas from seed sown in spring should now be sufficiently advanced for moving into larger pots. Good fibrous loam three parts, and a part each leaf soil and well-decayed manure with a sprinkling of sand, will suit them well. A light pit, where abundance of air can be given and a thin shade afforded from powerful sun, is the

most suitable place for them. For general purposes 6-inch pots are quite large enough.

Cinerarias for winter and early spring-flowering, seed of which was sown early, should be shifted into 6-inch pots for general purposes, and 7 or 8-inch pots when large plants are required. The soil advised for Primulas suits them. They should be stood on a bed of ashes in a pit or frame, as they do not thrive in a dry medium, and should be near the glass. It is important that they be kept free from aphides by moderate fumigation or dipping in or syringing with tobacco water. Shade should be given them from powerful sun.

Fuchsias that flowered early and been rested may now have the shoots shortened back a little, have the surface soil removed to the depth of an inch or two, supplying fresh, cleansing the foliage with an insecticide, and afterwards remove them to a house or pit where they can be kept a little close and moist by syringing overhead morning and evening. They will break freely and come into flower in about six weeks, and, being assisted with weak liquid manure, will continue to do so until autumn is far advanced. Young Fuchsias are much to be preferred to old plants. Cuttings of free growth should be inserted now and kept close and moist until rooted, afterwards as soon as rooted shifting them into 3-inch or 4-inch pots.

THE BEE-KEEPER.

DRIVING STOCKS.

PLEASE to inform me through the Journal when will be the best time to drive stocks of bees. I artificially swarmed them during the latter part of May and the early part of June. My intention was to drive them on the twenty-first day after swarming, but they were so dreadfully light at that time they were not worth the trouble. I am afraid the honey harvest will soon be over here, the Limes and white Clover are the chief pasture now. What I want to know is when I may expect to find the least unhatched brood.—DERBY.

P.S.—We have only had eight days without rain, more or less, since the 3rd of June.

[If your hives are full of bees and brood now we would advise you to drive three-fourths of the bees into empty hives and vigorously feed them as swarms; the other fourth of the bees should be left to hatch the brood, and at the end of three weeks give all the bees to the swarms. Thus hives extra strong would be obtained. The feeding of the swarms would enable them to build combs rapidly and fill them with brood. This plan is, we think, the best to get strong stocks for winter and next year. If the hives are not strong enough to stand this treatment the bees should be encouraged to breed by feeding for a fortnight or three weeks, and thus made strong enough. Another plan is to let them go on as they are doing till September or till all the brood is hatched, and then drive all the bees at once into empty hives and feed them into stocks. This plan is more extensively practised than the other, but we prefer the former for creating good stocks, the latter for a chance of a late harvest of honey. In September queens naturally cease laying, and artificial feeding then does not cause so large hatches of brood as it does in July and August. This advice is given on the assumption that the honey season is nearly over this year.—A. P.]

PROLONGING THE LIFE OF THE QUEEN BEE.

I CANNOT help protesting against the assumptions of Mr. Pettigrew (page 65) in regard to the duration of life of the queen and worker bee. Not a jot of the evidence he adduces meets the case. Had he worked with bar-frame hives and Ligurian bees he must long ago have given up his theories as untenable. The now common operation of introducing a yellow queen into a black stock proves to a certainty that the whole population of a hive is changed in from four to six weeks in summer, and from six to eight months in the resting season. If the proper deduction from this fact is not that work exhausts bees I cannot conceive any other. There is a difference, however, between outdoor and indoor work, my experience being that the latter—viz., comb-building and brood-rearing, are by far more exhaustive than outdoor labour. The extended existence of a queenless stock proves this.

There are, however, other elements at work in reducing the

population of hives even at midsummer. I have reports from several districts in Scotland before me to the effect that during May and June of this year strong hives lost so many thousands of bees (mostly young bees too) that they dwindled rapidly, and were rendered useless as super-producing stocks for the present season. In these cases the symptoms were exactly such as I have formerly described as the result of feeding on honeydew off certain trees. The bees young and old were found running helplessly about in front of the hives. They could not fly, and though lifted on to the floorboard refused to re-enter their hives. On being dissected their honey bags were found full of a sticky substance like glue, probably honeydew. But these are exceptional causes of depopulation, the main fact standing much as Dr. Dzierzon expresses it. The practical value of the facts lead all advanced bee-keepers to guard against any cessation of breeding in the early autumn months. We do not double stocks to ensure strong populations as the disciples of Mr. Pettigrew wastefully do. We only stimulate by gentle feeding during the early months of autumn and spring, and thus get at little expense a fresh hatch of young bees, 1 lb. of which in August are worth 5 lbs. of driven bees at a later date.

As to queens, I am also constrained to differ from our venerable friend of skeps. Mr. Pettigrew seems to teach that nothing the bee-keeper can do has any effect on the number of eggs laid by a queen; that, in fact, there is no such thing possible as stimulation, and that consequently every queen bee should live out her full term of four years or more. Now, it is somewhat extraordinary that though I never kill a queen that is doing well, especially if she is an Italian, I have not in an apiary of nearly forty hives one queen over two years old. Careful observation leads me to conclude that the bees quietly supersede queens that are failing far oftener than we generally suppose. Only three weeks ago I found the last of my three-year-old queens laying on a comb alongside of a princess a few days old; in a few days more I found the dead body of my old favourite in front of the hive, and I have every reason to believe that other four or five of my oldest queens were thus superseded during this summer. Bee-keepers generally do not take means of identifying their queens, all are alike to them, consequently an old queen may be superseded and the young one get the credit of all her years added to its own. Thus we hear of queens seven years old, the proof being that the stock never swarmed all that time!

Others, however, like myself, know almost every queen by sight. We see them frequently and note their differences in shape, size, or colour. Mixed apiaries of black and Italian bees soon come to have queens with different characteristics; and this is useful, especially at swarming time, for we can separate a mass of bees composed of two or three swarms and return each queen to her own hive if desired. One is pure black, another is a dark Italian, a third is yellow to the tip, the fourth has a very yellow body with a black tip, and so on. Thus we are able to some extent to follow out the history of our queens and to certify their age; others, not content with natural marks, dye or punch the queen's wings, or clip off certain portions of them each year in order to be able at a glance to tell her age. I have all valuable queens clipped, not only to mark their age but to prevent loss of swarms. I mention these things to show that we do not speak without book when we mention the ages of our queens.

Now, I may state it as a fact that before the advent of comb foundation it was the rule rather than the exception for my queens to live from three to four years. Now, however, they are so frequently superseded by the bees, or fail otherwise before they are three years old, that I never judge it safe to keep one over two years. Comb foundation, combined with stimulative feeding perhaps, has shortened the life of queens by a year. And this is how it happens. Instead of wintering a stock on all its combs we remove all that are not crowded with bees. In spring we insert, as fast as the bees get crowded, sheets of foundation in the centre of the brood nest. We use these rather than the old combs, because we get nearly twice as many eggs laid in them. The bees, seconded by the queen, use every endeavour to occupy the hiatus, and often in twenty-four hours there are from three thousand to four thousand eggs laid in these sheets. We know this is hard on the queen, and only by great care do we prevent a permanent separation of the brood nest into two. Now if the queen has no power over the production of eggs it seems strange that a good queen so nearly lays in proportion to the number of bees. Doubtless, occasionally she will lay three or more eggs in a cell, but not if she have room otherwise within the cluster. This does not prove any inability on the part of the queen, but only her uncommon prolificness, and the necessity for supplying her either with more bees or with empty cells.

Leaving facts and venturing on theory, I should say that it seems

to me that a queen bee can only lay a limited number of fertile eggs during life. The number may be millions, but it has a limit, and that limit is generally reached when the contents of her spermatheca are exhausted. So far as I can learn spermatozoa are not reproductive in the spermatheca of the queen. Their number is being reduced with every egg that is laid, and an end of them comes at last. The queen may still be capable of laying thousands of eggs, though, as we know, these being unfertilised, produce drones only. She herself does not realise this, for she lays them still in worker cells. The wonderful instincts of the bees lead them generally to anticipate this failure and to raise a successor. But the fact remains that the queen, apparently perfectly healthy, has laid her last fertile egg. We cannot say she herself is exhausted, for it is rarely that the queen dies of old age; she is superseded and killed because her spermatheca is empty.

Dzierzon's theory of the fertilisation of queens has withstood all opposition for years. The views he now endorses regarding the possibility of prolonging their life are in perfect accordance with his former abundantly proved theories. They only need the experience of advanced bee-keepers to verify or refute them, and I must say that I, for one, not only endorse them but have acted according to them for years.—WILLIAM RAITT, *Blairgowrie*.

BERKS AND BUCKS BEE-KEEPERS' ASSOCIATION'S SHOW.

THIS Association held its third annual Exhibition of hives, honey, &c., at Buckingham, on Tuesday, the 25th of July, in connection with the Show of the Horticultural Society. A remarkably fine day, together with the numerous attractions of the flowers, vegetables, dead poultry, eggs, fruit, hives, honey, bee-driving, &c., drew together a large concourse, not only of the middle and lower classes, but of the nobility and gentry of the town and county, the clergy being especially conspicuous by their numbers. This is as it should be, and some other counties may well take a lesson from the Bucks and Berks Association in this respect, and by patronising similar associations help forward a work pregnant with untold benefits to their poorer neighbours and dependants. To say that the Rev. H. R. Peel, the indefatigable Secretary of the British Bee-keepers' Association, was the manager of the apiarian department and the giver of various prizes, is simply to announce its success. Wherever this gentleman goes he appears to galvanise life into bee-keeping, and we trust that Buckinghamshire may carry on into remote years the impetus already given. The county, physically speaking, is indeed worthy of the effort, for its rural scenery, varied by wood and dale, and its rich pasture land, covered at the present time by the most luxuriant crops of white Clover, cannot fail to render it one of the most prolific honey-producing counties in the land.

The exhibits and the successful exhibitors we cannot find space to particularise. In addition to the prize list, which we give below, suffice it to say that the well-known names of Messrs. Abbott Brothers of Southall and Mr. Blow of Welwyn, Herts, were conspicuous on the prize list and for the variety and quality of the specimens displayed. The Rev. George Raynor of Hazeleigh Rectory, Essex, performed the office of Judge. We give the list of the prizetakers:—

For the best observatory hive stocked with bees and their queen, the bees to be in confinement.—First, £1, T. B. Blow, Welwyn; second, 10s., R. H. Stouhill, Stewkley.

For the best moveable comb hive for general use, price to be taken into consideration.—First, £1, T. B. Blow; second, 10s., Abbott Bros., Southall.

For the best moveable comb hive for a cottager's use, price not to exceed 10s.—First, 10s., Abbott Bros., Southall.

For the best straw hive adapted to modern bee-keeping, price not to exceed 5s.—First, 7s. 6d., W. Martin, High Wycombe; extra, 5s., Abbott Bros.

For the best and most complete collection of bee furniture.—First, £1 10s., T. B. Blow; second, £1, Abbott Bros.

Special class, open to the members of the Berks and Bucks Bee-keepers' Association only. For the best twenty-one 1-lb. sections of comb honey.—First prize (silver medal given by the British Bee-keepers' Association) W. Carter, Clewer, Windsor.

For the best display of comb honey in sections, no section to be more than 2 lbs. in weight (prizes given by the Rev. H. R. Peel).—First, 15s., M. Hunt, Addington; second, 10s., J. K. Filbee, Nap Hill, High Wycombe; third, 5s., G. B. Lacey, High Wycombe.

For the best super of honey, not sectional.—First (a special prize given by Mr. Welham Clarke, a bar-frame hive value 12s.) G. B. Lacey; second, 7s. 6d., W. Martin; third, 7s. 6d., J. K. Filbee.

For the largest and best exhibition of run or extracted honey in glass jars or bottles, quality chiefly considered.—First, 10s., W. Martin; second, 7s. 6d., J. K. Filbee.

For the best sample of pure beeswax not less than 2 lbs. in weight obtained from combs made by the exhibitor's own bees.—First, 7s. 6d., Abbott Bros.; second, 5s., W. Martin; third, 2s. 6d., J. K. Filbee.

Driving competition.—For the competitor who shall in the neatest, quickest, and most complete manner drive out the bees from a straw skep, capture and exhibit the queen.—First, £1, R. Stouhill (4 min. 30 sec.); second, 10s., J. K. Filbee (8 min. 30 sec.); third, 5s., W. Martin (8 min. 35 sec.).

BRITISH BEE-KEEPERS' ASSOCIATION.—The annual great metropolitan Show of bees, hives, honey, &c., opens this day (Thursday). Upwards of three hundred entries have been made. The Exhibition promises to be a most successful and memorable one, inasmuch as the

Committee have arranged to conduct an examination of candidates who are desirous of gaining certificates of proficiency in the art of bee-keeping. Eighteen candidates have entered for such an examination, amongst the number being several schoolmasters.

TRADE CATALOGUES RECEIVED.

T. H. P. Dennis & Co., Mansion House Buildings, London, E.C.—*List of Greenhouses, Frames, &c. (illustrated).*
L. Späth, Berlin.—*List of Bulbs.*

* * All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Budding Briars (*Robin*).—It is certainly not too late to insert buds provided the bark separates from the wood of the stocks freely. We consider therefore that you have been misinformed on that point. Nor do we consider you have been well advised to shorten the Briar shoots nearly close to the buds, when the latter are inserted. We do not shorten them at all at that time, and it is very rarely indeed that we have inserted a bud that has failed to grow.

Chrysanthemums and Grapes (*Dr. Muckenzie*).—The flowers are forms of *Chrysanthemum carinatum* and are very good indeed, the colours being very bright and rich. Varietal names are given to some of the most distinct by seedsmen; the darkest flower you have sent resembling a variety named Lord Beaconsfield. The seed that has produced your plants has evidently been obtained from a good strain or collection. It is by no means easy to determine the name of a Grape from half a dozen imperfect berries, and we can only say that we think your variety is Royal Muscadine; it is certainly not Buckland Sweetwater.

Raspberries (*D. Lake*).—We have never transplanted Raspberry canes at this season of the year, nor do we suppose we shall, for the sufficient reason that we can attain our object without trying such an experiment. We have planted young suckers in showery weather in the spring when they were from 6 to 9 inches high, as when of that size many of them have produced roots. The suckers so transplanted made excellent canes the same season. By all means remove the old canes now, or as soon as you have gathered all the fruit, and you may with advantage remove some of the young growths also if they are crowded, but do not injure the foliage of those remaining. The best canes thus thinly disposed will mature and assume a very fruitful character. Your fruit being dry and small is due either to poverty of soil, overcrowded and consequently weak and immature canes, or an inferior variety.

Mealy Bug on Vines (*Inquirer*).—As the Grapes are cut you will be able to keep the insects in check by violent syringings or an occasional washing with a garden engine. Merely wetting the foliage is of no use, as the meal of the insect is impervious to water thus applied; but forcible and continuous syringings are useful. If immediately after a washing of this kind you syringe the Vines with a solution of paraffin and soft soap at the rate of half a wineglassful of the former to 3 ozs. of the latter to each gallon of water, applying at a temperature of 120°, you will not injure the Vines, while it will destroy many insects if the work is well done. A correspondent, "A. C.," published a useful hint in our columns in 1880. He did not permit the leaves to fall, but as soon as they turned yellow removed and burned them. On placing the leaves and prunings on a sheet he found hundreds of insects that would otherwise have found shelter in the house. The Vines sustained no injury by the early removal of the foliage, as the Grapes were better in the following year. You will find the article referred to on page 163, August 19th, 1880. You had better also read an article on page 63, July 22nd, 1880. If you do not possess these numbers they can be had in return for 7d. in stamps sent to the publisher with the request that he send you Nos. 4 and 8, Third Series.

Kalosanthes (*B. D., York*).—The shoots that have flowered this year will not flower next season, but the young growths if sufficiently strong and are matured under full exposure to the sun will form flower heads. You had better cut down the shoots that have flowered and encourage the others. If the latter are not numerous or not sufficient for producing a satisfactory display it will be well to cut down the plants entirely. You will then ensure numerous and regularly disposed growths, and with good culture fine flowering plants in 1884. Some cultivators have two sets of plants, which they flower and cut down alternately, and by no other method can such satisfactory results be secured. The plants should be kept rather dry in the winter, but not dust dry by any means, or their vigour will be impaired.

Balsams (*Hender & Sons*).—Although the blooms were much bruised and shaken on account of the box not having been quite filled, we are able to say they are excellent. They are very double, some of them being quite filled to the centre like a Camellia; and the colours represented are pure white, blush, rosy lilac, scarlet and purple, some of the petals being marbled. There must, we imagine, be some difficulty in obtaining seed from such flowers as those before us; in fact some of them could not produce seeds, as all the stamens, &c., have been transformed into petals.

Fig Tree not Bearing (*Old Subscriber*).—Your tree has no doubt been permitted to grow too luxuriantly, and the wood has consequently not been matured. You say you cut the roots once with no effect. Cutting the roots is a very relative term, and we suspect the work was imperfectly done. We should dig a trench round the tree at one-third the distance from the stem that the tree is in height. This trench should be 2 feet wide and be dug quite below the roots. The semicircular mass of soil thus formed should also be undermined, severing all the roots that penetrate the subsoil. Fill this trench with hard poor material, lime rubbish being excellent, and ram it down as hard as a floor. This will check root-action, and the growths will be more firm and short-jointed. Remove also all sappy and luxuriant growths at once, exposing those that are shorter and weaker to the full action of the sun. The leaves of these must not be shaded at all, and any shoots that are afterwards produced promptly removed. When once the tree produces short-jointed growths but little pruning will be needed beyond removing entirely any superfluous growths which otherwise would shade the foliage of those intended for producing fruit. Overcrowding the foliage of Fig trees and undue root-extension, which is incited by a multitude of shoots, are quite sufficient to prevent the trees bearing fruit. If you carry out the advice we have given thoroughly and thoughtfully, and the trees still remain barren, you may dig them up.

Pruning Morello Cherries and Gooseberries (*Idem*).—Secure as much of the young wood to the wall without shortening the shoots as can be done without unduly crowding the trees, removing at the same time those shoots that are not required for retention, remembering that as a rule the most luxuriant growths are not the most fruitful; these therefore should be cut out, preserving those that are moderately strong for fruiting. Gooseberry bushes if crowded may be partially pruned now by shortening the side shoots on the main branches to within 2 or 3 inches of the base of each, allowing the terminals to extend unless they are growing beyond the allotted bounds. The pruning can be completed in the winter or early spring. See our remarks to another correspondent on pruning Raspberries.

Eryngiums (*J. W. L.*).—The plants of which you desire some particulars are members of the natural order Umbelliferae, but very distinct in general appearance from the commonest types of that family. The leaves in several species are long, narrow, and spiny, something like the leaves of a Pine Apple plant. The flowers individually are not conspicuous, but the tall inflorescence is striking. In some forms, as *E. amethystinum*, *E. maritimum*, *E. Bourgati*, and *E. caeruleum*, have a bluish hue that is very pleasing; and *E. eburneum*, of which a plant is shown in fig. 21, is a handsome species from Brazil, but hardy in the south of England. All the Eryngiums succeed best in rather light sandy soil, but in other respects they are not at all particular. *Eryngium campestre*, or common Eryngo, is a native of the whole continent of Europe, and is found in some places

Fig. 21.—*Eryngium eburneum*.

in Britain. The root has a slightly bitter and aromatic taste, which it almost entirely loses by boiling in water, and in this last state the country people on the continent use it as an aliment. The Sea Holly, Sea Holver, or Sea Holme (*E. maritimum*), grows on the seashore in many parts of Britain. According to Linnæus the young flowering shoots of this plant, eaten like Asparagus, are very nourishing. The leaves are sweetish, with a slight aromatic warm pungency. The roots are supposed to have the same virtues as the Orchis tribe. They are kept in shops caudied, and have the reputation of being stimulating and restorative. They were first caudied at Colchester in Essex about the beginning of the seventeenth century by an apothecary named Robert Buxton, and the same business is still continued in that town. *E. aquaticum* is a native of low wet places in the United States, where it is called Button Snake-root. The root has a bitter, pungent, aromatic taste, causing, when chewed, a flow of saliva.

Begonia Flowers Falling (*L. W. S.*).—When the plants are flowering profusely it is not unusual for a few flowers to fall prematurely, and the beauty

of the plants is not seriously impaired. This, so far as we understand your letter, is the case with your plants. If the pots are filled with active and healthy roots a little weak clear liquid manure applied twice a week will have a beneficial effect. Soot water is safe and good, and should be given of the same colour as pale ale.

Cinerarias Unhealthy (*Idem*).—A leaf-mining insect sometimes attacks Cinerarias, doing them much injury. We know of no remedy, nor any better course to adopt than to remove those leaves that are much mutilated, and by generous culture encourage the production of new and better foliage. Remove the healthy plants from the others, and they will with good attention probably remain healthy. We presume the plants are in frames. A greenhouse is unsuitable for them in summer, and a too dry atmosphere is the cause of many plants being "stunted." If we had manure such as you describe, decayed so as to crumble to mould, we should prefer it to leaf soil for all free-growing soft-wooded plants. Your last question relative to the addition of a fertiliser is unanswerable, as you do not intimate what the plants are that you desire to cultivate.

Heating a Conservatory (*Novice*).—There is no method of heating a building of the kind you mention at all comparable with a small boiler and 4-inch pipes. In all probability if you could invite an intelligent gardener or local nurseryman to inspect the house he would be able to devise a plan for attaining your object; or an ironmonger having experience in heating would point out to you an arrangement that would answer. The smoke flues from the furnace of many conservatories are connected with a chimney of the house near which the structures are erected, and possibly a similar arrangement can be made in your case.

Reporting (*Anonymous*).—We agree with you that it is of the greatest importance that shows be correctly reported. Every endeavour is made to accomplish this, and if an error occurs we most readily publish a correction when it is brought to our notice in a proper manner and duly authenticated. While we agree with you on that point we hope you will agree with us on another—namely, the extreme desirability of first ascertaining the truth of a matter before a grave charge of inaccuracy is preferred. Mr. Douglas, one of the Secretaries of the National Carnation Society, is not of the same opinion as you are, or were, and possibly he may have told you so. In a letter before us he says—"I do not see the errors in the Journal, and think the report is a very good one; but as it was late before the new flowers were examined, and as they were scattered about in the various stands, it was easy enough to make mistakes in reporting, and I trust your reporter was not put to any inconvenience; as it is *he did his part as well as it was possible to do it.*" This is a very different letter from yours both in matter and tone, and if you cannot substantiate the charges you have made, and your sense of justice should impel you to offer an apology to our reporter, it will not be less frank and graceful if you do not do it anonymously.

Heating Arrangement in Pinery (*F. C.*).—You do not give the size of the pit, but we presume there is a path along the house, which will take up at least 2 feet of the width, and the flue also will occupy another foot, which will leave some 4 to 5 feet as the width of the pit or bed. Two rows of 4-inch pipes in a chamber beneath a bed of the width above indicated will be sufficient to afford a bottom heat of 90°, provided the pipes are disposed about a foot from the sides of the pit all round and immediately under the covers or flags forming the bottom of the plunging bed, the space of the heated chamber not being deeper than will admit of the pipes being clear of the ground or floor of the chamber. It is no deterrent to the heating of the bed for the covers of the chamber to rest or lie on the pipes, and the joints of the covers should be open, only being sufficiently close to prevent the plunging material from passing through the interstices. Sand is a bad conductor of heat; a more open material should be used, such as tan, sawdust, or cocoa fibre refuse, or even ashes. The sand will account in a great measure for the difficulty in maintaining the bottom heat at 90°, but we think, from the section, that the heating chamber is too deep, the pipes being arranged one over the other instead of on the flat or same level, with a slight incline to the boiler in both from the highest point, or that most distant from the boiler. It will be necessary to have fire day and night more or less as the weather determine to maintain the requisite bottom and top heat. For so small a boiler a ton of fuel (coal or coke) would serve about ten weeks. We do not think the consumption of fuel excessive.

Budding Fruit Trees (*Idem*).—The proper time to bud the Apricot and Cherry is from the beginning of July to the early part of August, according to the locality and the earliness or lateness of the season. Peaches and Nectarines are usually not ready for budding until after the middle of July, and sometimes not until the middle of August, it being important that the wood become rather firm and the buds developed before operating. The condition of the wood and buds is of far greater importance than any mere date for performing the operation. Procure more buds and insert them now, and if these and the stocks are in a proper state you will probably succeed in your object. We cannot undertake to interpret the passages to which you refer, nor is it necessary, after the author has stated truly that "the only rule that can be laid down in the case is that the buds should appear plump, fully and perfectly formed in the axils of the leaves, and the bark rising freely in the shoot into which the bud is to be inserted."

Fragaria indica (*X.*).—The plant concerning which you desire some information bears the above name, being a species of Strawberry that is very useful for decorative purposes. When a number of plants are grown in small pots they form a most pleasing edge for shelves in greenhouses or conservatories, the slender trailing growths then forming a fringe of green, in which the bright red fruits are very conspicuous.

Names of Plants (*C. H. Stephens*).—We have stated repeatedly, and even as late as last week, that we do not undertake to name varieties of florists' flowers. The petals had fallen from the single varieties: the semi-double form is probably Wonderful, a sport from Vesuvius. (*K. L., Cheshire*).—*Sedum Sieboldi variegatum*. (*H. J. G.*).—1, *Aspidium aculeatum*; 2, *Asplenium marinum*; 3, *Doodia media*; 4, *Pteris serrulata*; 5, a *Selaginella*, specific name not determinable from such a fragment. (*J. W.*).—A very richly coloured variety of *Scabiosa succisa*. (*G. S.*).—*Veratrum nigrum*. (*R. C. F. G.*).—The Fern is *Woodsia obtusa*. The blue flower is *Centaurea montana*. (*A. G.*).—1, *Adiantum Capillus-Veneris*; 2, *Gymnadenia conopsea*; 3, *Polypodium rhæticum*. (*Keswick*).—*Tecoma stans*. (*W. H. Myers*).—13, *Agrostis canina* (Marsh Bent Grass); 17, *Arrhenatherum avnaceum* (Oat-like Soft Grass); 18, *Phleura pratense* (Cat's-tail or Timothy Grass), an excellent meadow grass; 22, *Triticum caninum* (Bearded Couch Grass); 25, *Trisetum flavescens* (Yellowish Oat Grass); 28, *Schlerochloa rigida* (Rigid Meadow Grass), this is a handsome little Grass of no agricultural use frequently found in the limestone and by the seacoast. (*J. P., Greenock*).—1, *Doronicum austriacum*; 2, *Veronica spicata*; 3, *Veronica rupestris*; 4, no flowers expanded, probably a *Coreopsis*; 5, *Veronica gentianoides*; 6, *Sedum spatulifolium*.

COVENT GARDEN MARKET.—AUGUST 2ND.

TRADE has been quiet during the week, our market settling down to a more steady business.

POULTRY AND PIGEON CHRONICLE.

MAXIMUM PRODUCE OF FARM CROPS.

(Continued from page 93.)

IN continuation of the subject we intend to record the growth of a crop of winter Oats grown after Wheat on a fine sandy loam soil on the Manor Farm, Durley, in the North Hants division of the county, occupied by Mr. Edward Waters, who informs us that in 1868 he grew a crop of winter Oats, which reached 9 quarters and 6 bushels per acre of fine quality. This, as compared with the common varieties of spring-sown Oats, does not seem very remarkable; it is, however, well known that winter Oats never yield so much in proportion to the bulk of straw, but we introduce this crop as the largest we have known in our own experience of this variety.

Having finished the principal records we have obtained of the different cereal crops, we shall now refer to pulse crops and seeds. Taking first a crop of common Scotch Beans grown by Mr. John Wilson of Berwickshire, who states that he grew some years previous to 1824, but cannot give the year, a field of 11 acres, which yielded 600 bushels. This information we quote from his letter to J. C. Morton, Esq., and given in the Journal of the Royal Agricultural Society in 1859. Our next record comes from the other end of the kingdom, and was given to us in 1827 by a Mr. R. Hickley, who farmed his own property at Bursledon near Southampton. He stated that he grew in the year 1812, on a field of 7 acres, the land being a very strong clay loam with a south aspect, a crop of the common sort of horse Bean of the period, of 20 sacks per acre on the average, but that upon a measured acre the produce reached 28 sacks, and this upon land which had never been manured for a period of sixty years, but farmed upon the ancient system—a fallow every fourth year, followed by Wheat, Lent corn, and pulse or Clover. We have, however, now to notice a remarkable record of a Bean crop grown in the same year, 1812, in a field within sight of the land just named, and at that time farmed by the owner, Mr. George Cleverly, it being a field of 4 acres surrounded by woodlands, with a north-west

aspect, and the soil of an exceedingly strong putty-like clay. We do not know what was the previous crop, but the Beans were sown broadcast, and the crop never hoed or cleaned in any way, and our informant stated that the Thistles which went to seed were nearly as thick as the Bean stalks, and yet the produce was 28 sacks per acre on the average. This information was obtained from various persons in the neighbourhood, but especially from a labourer of the district, who stated that when he was a lad he assisted his father in the threshing by flail and winnowing of the crop. A most curious circumstance, however, is, that the land was never afterwards cultivated, and to this day is run to waste and woodland.

We have now to notice Peas as a farm crop, although they are generally very uncertain. We shall give the only record we have of a crop of Blue Imperial Peas grown by Mr. Davis, the tenant of a farm called Otterwood in the New Forest district. This occurred, as our informant stated, in the year 1871. There was, however, no special management relating to the cultivation of the land, which was a strong clay-like gravel. The produce was 7 quarters per acre and a very bulky crop of haulm, which was unlike Pea haulm in general, the singular circumstance being that the cattle would not eat it although well harvested. This was certainly a large produce when we consider that from 5 to 6 quarters is generally the outside produce of the ordinary field Peas, such as the Early Dun, Marlborough Grey, and the Maple or Partridge.

A full crop of winter Vetches grown a chalk soil in the district of Andover in North Hants in the year 1874 next deserves notice. Our informant stated that he was not authorised to give the grower's name, but the facts could be well substantiated. The produce was 12 sacks per acre, irrespective of any special or particular cultivation or manuring. In the same district, and by the same informant, we get the produce of a yield of cow grass seed, which was verified as 12 bushels per acre. The same gentleman also gave a record of 9 bushels of Broad Clover seed grown in the same district.

We, however, have an interesting account furnished of the growth of a crop of 12 bushels per acre of red Clover seed of the old English variety as far back as the year 1815, and grown on the same field which produced the large crop of Beans in 1812, as stated by Mr. Richard Hickley, at Bursledon near Southampton. Now, when we consider that the ordinary crop of red Clover has not amounted to more than 3 or 4 bushels per acre average during the past ten or fifteen years, these three sacks per acre is an enormous crop, and as it was sold to the late Mr. C. Lipscombe, seedsman of Alton, Hants, at 1s. per lb., the value of the crop almost reached the fee simple of the land. There is, however, a point to which we desire attention being given—that, in point of fact, it is very rare now to find a sample of old English red Clover, foreign-grown seed has been so much sought for; but this foreign seed is much smaller than the old-fashioned English sort, and gives but a poor second growth either for hay or for seed.

Now we are considering the subject of seeds we will notice a crop of Mangold seed as stated in the Journal of the Royal Agricultural Society, to have been grown by Mr. John Bush of Long Sutton in Lincolnshire, in 1859, who grew 92 bushels of Mangold seed upon 3 roods of land, or equal to 120 bushels per acre. This is selected as the yield possible, no history having been given in connection with it as to soil, &c. We have now to refer to green fodder crops. There is mentioned also in the Royal Agricultural Society of England's Journal of 1859 the extraordinary growth of Italian Rye Grass obtained from a poor sandy soil at Canning Park Farm, in the neighbourhood of Ayr in Scotland, when by the use of 3 or 4 cwt. of guano, &c.,

per acre after each cutting, washed in by 100 tons of water mixed with liquid manure from the cow stalls, three or four cuttings were obtained by the end of the month of October, weighing from 40 to 50 tons of green fodder per acre.

The late Mr. Dickenson of New Park, in the New Forest, gave his statement of the growth, cultivation, and produce of Italian Rye Grass, in a paper read before the Botley and South Hants Farmers' Club in 1856, whereby upon his system of irrigation with liquid manure he obtained in 1848 seven cuttings in the year, commencing with the month of March and finishing in October, the average weight of grass being 10 tons each time, or 70 tons per acre in the year. He said any retentive soil suited for Beans, Wheat, or Oats if in high condition is suitable for this crop. Ammonia being the food for this grass, urine and water stand first, guano in wet seasons, nitrate of soda in hot dry seasons. He further stated that by artificial drying the grass in lofts 19 cwts. of grass yielded 6 cwts. of hay.

Mr. Simpson of Teawig near Beaulieu, Inverness-shire, gives the following particulars of an extraordinary crop of Potatoes, as published in Mr. J. C. Morton's essay in the Royal Agricultural Society's Journal in 1859. The crop grown was of the variety called Flukes, which produced $9\frac{1}{2}$ tons per acre, the manure used being Peruvian guano. This sort of Potatoes are considered of the finest quality. We have to record another instance of the value of a Potato crop grown in Scotland, although we cannot record the quantity grown per acre. Mr. Buttar, who farms six hundred acres of land, grew in 1879, 58 acres of the Champion Potato chiefly, and sold them for £35 per acre. We have also to record, as reported in Mr. J. C. Morton's essay as above named, "a crop of Carrots grown by Mr. Blundell of Bursledon, Southampton, an active member of the Botley Farmers' Club, and frequently a Judge at the meetings of the Royal Agricultural Society, who informs me that in 1857, on a field of light loamy soil in his occupation, he grew an extraordinary crop of the White Belgian Carrot, of which the following particulars give the history. Fallow preparation: soil, sandy loam; seed, White Belgian Carrot, 6 lbs. per acre, drilled May 14th, 16 inches apart between the rows; manure, 2 cwts. superphosphate of lime and 25 bushels of ashes per acre; the crop flat-hoed between the rows; the rows thinned by hand-pulling, which afforded 14 tons per acre of excellent food for cattle from 1st of August to 14th September. The roots we raised in the second week of November weighed 24 tons, 18 cwts., 2 qrs. per acre, there being 348 roots per pole; the tops weighed by estimate 7 tons 5 cwts. per acre. The total weight of crop per acre 46 tons, 3 cwts., 2 qrs. On a part of the same field the crop not thinned in the rows raised at the same time weighed 31 tons, 2 cwts., 3 qrs. per acre, there being 980 plants per pole, the tops weighing by estimate 6 tons 10 cwts. per acre; total weight of crop per acre 37 tons, 12 cwts., 3 qrs. With reference to these figures Mr. Blundell says that neither the thinnings of the crop nor the greens were weighed, but that having often weighed the greens from his Carrot crop up to 9 tons per acre, he is confident in the accuracy of his estimate. The main crop of roots was actually weighed."

We have next to record a crop of Yellow Globe Mangolds grown upon land in the occupation of Stewart Macnaghten, Esq. of Bitterne Manor House, near Southampton, in the year 1859. The crop being carefully weighed proved to be 55 tons per acre, and grown upon land adjoining the seashore, but to which artificial manures only were applied. Again, we quote from Mr. Morton's essay the evidence of Mr. J. Innes, Colonel North's agent, "That in 1858 they grew a crop of Long Mangolds on the ridge, farm-yard dung being applied, and also 2 cwts. guano, 2 cwts. Proctor and Ryland's Mangold manure, and 2 cwts. of salt per acre. This was upon the Wroxton Abbey Farm near Banbury. On the 25th of October the Judges of the Banbury Agricultural Association weighed a square rod, and found the average weight of the field to be $63\frac{1}{2}$ tons per acre." We must now conclude with the record of a crop of Yellow Mangolds grown by Mr. Burnett of Ashley, Hants, when he farmed in Ireland in 1851, and which he states as fairly weighed, and proved the produce to be 65 tons per acre. In quitting our subject for the present, we say in conclusion that we propose to return to it on some future occasion.

WORK ON THE HOME FARM.

Horse Labour.—This has been much delayed lately, not only in consequence of the horses being required in carting the hay to the stack from the water meadows in the early districts, and the general crop from the pastures of the midland and northern districts, but horse labour on the fallows has been seriously interfered with lately. Every opportunity should now, however, be taken to cross-plough the fallows intended for next year's Wheat land. Horse-hoeing the root crops has unfortunately been very ineffective, owing to the continued stormy weather which has prevailed. The weather has been

adapted for the planting of Cabbage, Thousand-headed Kale, and Kohl Rabi, and in those cases where the Mangold plants are deficient it is well to plant some Oxheart sort of Cabbage, which variety forms heads very quickly. They will furnish useful sound heads at the time the Mangolds are raised for storing, and especially if the plants have been set with the spade, as this opens the land and leaves it loose and favourable for the young plants to root in. When the horses cannot be worked on the land, earth-carting to heap ready for use in the cattle boxes, pig pens, &c., may be done. The odd horse or mule for carting Clover and other green fodder for cattle and horses will now have full employment, and it has always been our custom for the odd horse or horses to cart the green food for the farm horses. We do not like the plan which is too often adopted for the carters or teamsmen to cut and cart the grass required for their horses. This work prevents them being able to carry out a longer day's work than usual in a busy time, especially in the hay and corn harvest. It is yet too early for the returns as to the quality of hay stacked under the new system of exhausting the heat by the fan, although various farmers we know have tried the plan; but we must not expect to hear of the success of their endeavours or otherwise until the ricks are cut, and the quality and condition of the hay proved by appearance. We think that the new system is quite as well adapted for corn as for hay, especially in those cases where the Clover has become rank and strong in the Barley crops, and also for the crops of Oats in the lake and mountainous districts of the north of England, and particularly in the elevated highlands of Scotland.

Hand Labour.—We have recently mown over the pasture lands which have been fed by the cattle, and the coarsest grasses refused by the cattle have been made into rough cow hay suitable for young dairy cattle to eat with roots in the winter; for we find that it is desirable to get rid of the grass refused, as it improves the after growth, and at the same time lessens the probability of the formation of ergot on the grass seed heads. It has been quite impossible in those districts where the rains have been the heaviest and most continued to destroy weeds in the root crops by either horse or hand-hoeing; it remains therefore to be considered as to the propriety of hand-picking the weeds after hand-hoeing or of sacrificing the prospects of a crop. Our early white Oats have been ripe for some few days on gravelly soil, and we began cutting and tying them on Friday the 21st ult. This kind of Oat is of very delicate nature, and when ripe will fall out with the slightest wind; we find therefore the only chance to save the grain and the straw in the best condition as fodder is to cut the crop before it is quite ripe, and our Victoria White Oats are so stout and long, and much laid also, that the mowing and reaping machine could not cut, or cut and bind the crop, without serious waste and loss in the process; we have therefore resorted to the old practice, fagging and tying, as the best means of securing the crop without waste.

Thus far the root crops where hoed in time have not suffered much from the continued rains, and the price of both sheep and cattle is very high indeed. The home farmer may feel assured that if this continues he has no right to expect large profits from stock-feeding this year, and should therefore wait before buying, and even then buy sparingly, and only to supply actual necessities. Should the roots and grass continue their prosperous growth stock can be no dearer; on the other hand, should the season continue to be a wet one the price of sheep will be lower, as it will injure the healthy growth of root crops; and we have noticed in former seasons like 1853, 1860, and 1879 that the sheep became much lower as the rainy season advanced. There is another very important matter to be considered in the case of continuance of wet weather, that the sheep will be sure to suffer from the fluke rot, coathe, or bane as it is called; in fact, the serious losses of sheep in the several years of 1878, 1879, and 1880 is one of the causes of the scarcity of the sheep stock throughout England at the present time, but more particularly in certain grazing districts of the kingdom.

Live Stock.—The management of both sheep and cattle especially on low-lying meadows is most important at this time, for if sheep are trusted in meadows, or even upland parks, they would be much better and safer to have night quarters provided for them upon the arable land, and receive the produce of it either as aftermath. Clover, Sainfoin, Italian Rye Grass, or Summer Vetches, Rape, and Mustard, however, will be very suitable, and this mode of management will go far to keep them sound and healthy, particularly if they receive half a pound of linseed or cotton cake per day. We have never known sheep rot where they have been treated thus, although it is well understood that in case they had remained night and day on the pastures in a wet season they would have taken the fluke. Some of these observations apply to cattle as well as sheep; for although they would not suffer from the fluke so surely as the sheep because they do not bite the grass so close to the ground, yet they are very liable, especially if heifers or heifer calves, to suffer from the quarter-ill if they are allowed to remain entirely on pasture land at night as well as by day, but especially in low-lying grass land subject to night fogs, and particularly as the season advances from this time until when the nights get longer. Even fattening bullocks where they are fast proceeding towards good beef, if the wet weather continues, they will pay well for receiving about 3 lbs. of linseed cake and 2 lbs. of cracked beans per day; and if placed upon drier soils at night time they would still receive further benefit, for some of the best grazing

districts actually lie below the fog level, which does not make a good night lair for them.

BATH AND WEST OF ENGLAND SOCIETY AND SOUTHERN COUNTIES ASSOCIATION.—At the Council meeting held at Bristol on the 25th ult., Lord Brooke, M.P. (President), in the chair, Mr. Charles Edwards (as Chairman of the Finance Committee) brought up the quarterly statement of accounts, and reported that all prizes in connection with the Cardiff Show had been paid, and that after meeting the liabilities of the year a balance of from £700 to £800 in favour of the Society was anticipated. Letters strongly advocating the choice of Maidstone as the place of meeting were read from the Mayor of that town, Sir J. F. Lennard, Bart., and Mr. Brassey, M.P., and it was unanimously resolved that the Secretary do inform the Mayor that the Council will be prepared to visit Maidstone in 1884, on condition that the requirements of the Society are complied with.

POULTRY AND PIGEONS

EARLY CHICKEN SHOWS.

THE season has come round at which we observe one or more classes for chickens in all the many schedules of forthcoming poultry shows which are sent to us. Doubtless, many a beginner and would-be prizetaker is much interested in these. He or she may have bought a high-priced prize pen at one of last year's autumnal shows, and longs as soon as possible to test the merit of their produce. Success or failure at a first attempt brings much elation or disappointment with it in graver matters than poultry-showing. In this particular pursuit we have often seen the great mistake made of supposing that a victory with an early chicken at some small shows must inevitably lead to a series of triumphs all through the season. On the other hand, we have known a young exhibitor, whose Geese of course are all Swans, utterly disgusted because some in his eyes perfect bird has been beaten by another of a totally different kind at an early show, at once denounce all shows and judging as unfair, and never again exhibit a bird which when more developed and shown against others of its own breed where classification is more complete could not fail to become a winner.

It seems to us the time to say a little about these early shows, which are in our opinion by no means an unmixed source of good to poultry-breeding in general. Like other things they have their use and abuse, though we are inclined to fear that the latter somewhat preponderates over the former. At any rate, it is well to consider what each is. To take their disadvantages first.

1. The number of very early birds which are now fit to show and likely to be entered is necessarily small, consequently the promoters of exhibitions cannot afford to give separate classes and prizes for each variety, much less can they do so for the different sub-varieties; the result is that several breeds are shown together. Three or four schedules are now lying before us which offer very fair classification for adult poultry, but in which there are but two classes for birds of this year—viz., one for "the best cockerel and pullet, Cochin, Brahma, or Dorking;" the other for the "best cockerel or pullet of any other variety." Imagine the difficulty—we might say the impossibility—of satisfactorily judging in such classes. We need not dilate upon the number of classes into which each of these would be expanded at one of the later and better shows. The fact is self-evident that the choice of prizewinners in a large and good collection of such a miscellaneous lot of varieties must under an indifferent judge go much by chance, and under a good one much by his individual fancy. This is extremely unsatisfactory, and frequently leads, as we have already said, to false hopes on the one hand, or to unnecessary disappointment on the other.

2. We have so often written against the forcing of chickens by overfeeding and stimulants that we are not now going to repeat our remarks on this head. For the perpetuation of a vigorous and hardy race vigorous and hardy birds are necessary, and only those are such which have been reared in a natural way. But to take the fancy of a judge and to command success in a large and miscellaneous class it is almost absolutely necessary that a young pair of birds should be precocious in plumage, with bright and well-developed combs—the very points which those destined to be eventually first-rate ought not at this period to have. Of course an exhibitor wishes to win, and so is tempted to force on his young stock—no difficult thing to do with a fortnight's high feeding—to a state of blooming condition which commands attention. Now and then a very careful judge tries rather to descry the signs

of ultimate merit in undeveloped chicken-like birds than to pick out those at present the largest and most forward. This, however, is very exceptional discernment, and indeed we think on the whole that prizes should be given for birds as they are, and not as they might be.

3. These early chicken shows offer some temptation to the unscrupulous to exhibit late birds of the past year. To what extent this deception is practised we have no means of judging; but, unless we have been much misinformed, there have been yards in which Asiatics have systematically been hatched in October and November to win as chickens at the following summer's shows. We remember the dry remark of a sharp and clever poultryman standing before a stupendous prize Brahma cockerel at an early show: "Ah, he has eaten a good Christmas dinner!" On the other hand, these early shows have their purpose and their use. It is well to know what it is. To produce really fine table poultry by midsummer much care and some skill is necessary. We live in an age of competition, and those who take the pains to do anything well are not satisfied now-a-days with the bare result: they expect to display it to their neighbours. These classes, then, are useful as showing the results of care and judgment in the rearing of spring chickens. We should be very much inclined to confine them to table poultry and to pullets destined for early laying. It is something to know what breed or what cross between two breeds is specially adapted for hatching in winter. Really early spring chickens will always command an extravagant price in the markets of London and large provincial towns. Many a cottager might pay his rent by the production of a few broods, and many a farmer might manage to tide over hard times who would take the trouble to rear three or four hundred spring chickens. Some breeds and some crosses are adapted to this business, and some are not. A good early show of chickens suitable for the table is a great help to one who wishes to select a profitable breed for the purpose. Again, eggs in the late summer, autumn, and early winter are scarce and command a high price. There is consequently some use in learning from what breeds strong and early pullets ready to lay are obtainable. In both cases these birds are not destined to be used as breeding stock; in the one they are killed off as soon as fit, and their runs left to freshen up for another year; in the other they are kept for the production of eggs alone, and are probably killed subsequently. There is, therefore, no harm done by forcing them on.

Breeders of exhibition poultry, on the other hand, we advise, as a general rule, to eschew these early shows; the birds which win at them seldom win afterwards, when laurels are far more valuable, and if kept for breeding stock generally disappoint their owners or purchasers. There are, of course, some ardent fanciers who breed both for early and for late showing, and are not satisfied unless they win all the year round. Those who have space and time thus to indulge their hobby may well do so, but we would remind them not to expect too much from early success, or to be disheartened with early failure. We have known several Crystal Palace and Birmingham cup-winners which had failed to carry home a card from a village show in summer.—C.

REMARKS.

23rd.—Slight showers in morning, afterwards fine and bright with much wind.
 24th.—Heavy showers in forenoon; fine afternoon and evening, but cool.
 25th.—Very dark in west all the early part of day; showery in evening.
 26th.—Fine and bright; windy at first; calm evening.
 27th.—Morning fine and bright; afternoon cloudy.
 28th.—Overcast; very dull and oppressive; fog in evening.
 29th.—Fog in early morning; fine and bright during day; thick again in evening.

Temperature much the same as last week, but air damper.—G. J. SYMONS.

GLASS COPINGS FOR GARDEN WALLS.

THE walls surrounding the kitchen garden here are particularly good, being generally about 12 feet high, very substantial, and, considering their age, exactly a century, are in excellent preservation. Altogether, reckoning both sides, a length of 1060 yards are utilised for fruit trees; but of this extent of walls no aspect or space occupied proves half so remunerative as the 36 yards devoted to Apricots. This is entirely owing to a glass coping with the usual blinds or curtains being affixed. There is no mistaking this fact, as on the same south wall, the warmest in the garden, there is a large tree unprotected as far as copings are concerned, and other good trees on south-east and western aspects, which only occasionally produce fruit, while those under the coping have never failed since it was affixed five years ago.

The great value of the coping lies not so much in the fact of its being a sure protection at the blooming period, as it is quite possible to protect nearly as well during an average spring with doubled fish nets, mats, hay or straw bands, Spruce Fir branches, or other available material, but in the almost certain ripening of the growth. We must first secure the bloom, and then protection is a simple matter. How many employers or gardeners could during last season, without the aid of glass, boast of having gathered bushels of fine Apricots? The same thing occurred with a few branches of the tree before mentioned as adjoining the protected trees, these extending about 4 feet under the coping. On these protected branches were developed more blooms, and eventually more fruits, than all the rest of the tree—by no means a small specimen.

I may be in error in ascribing the superior floriferousness of the protected trees to the more perfect ripening of the growth, as it is quite possible the protection afforded during the winter by the coping may have resulted in the transformation of many wood buds into fruit buds. If this is possible, as suggested by "IRISH RECTOR" (page 442, last volume) in the case of Plums and other fruits, it is equally possible and extremely probable in the case of Apricots. During the whole of the winter of 1880 and 1881 the glass was not removed from the iron framework, but last autumn I had it all taken down and packed in the cases provided for that purpose. This spring we had abundance of blooms on the trees under the coping, but the blooms were equally as plentiful on all the unprotected trees. The winter being unusually mild it is very probable the glass, had it not been removed, would not have materially affected the buds, but next winter I hope to test the advisability of removing or retaining the glass. Unfortunately its retention

is apt to encourage red spider during the autumn and to ward off the rain from the border at the base of the wall. It is here where many unprotected fruit trees suffer, as it is seldom sufficient moisture reaches this position; and when it is stated the coping in our case abuts 3 feet from the wall it will be easily understood it is absolutely necessary to continue to water the trees till late in the season or remove the glass. Thanks to our improved arrangements for a good water supply, we can and do easily administer it whenever required, and the engine after the fruit is picked will check the red spider. At the same time I should greatly prefer the latest invention in the way of copings. In this case the glass is fixed to a revolving framework, thus rendering it an easy matter to admit or exclude moisture, being in addition a most undoubted improvement on the laborious practice of taking out and storing and returning the glass, and removes the only objection I have ever heard urged against glass copings.

Another advantage attending the use of copings, and this is very apparent at the present time, is the effect it has upon the ripening and quality of the fruit. Directly under the coping we pick our earliest fruit, and this season, owing to the absence of sunshine, they are clearer in colour and altogether better than the rest of the tree. According to my experience a minimum amount of sunshine does not result in absence of colour in Apricots or Peaches; on the contrary, the former are unusually red, while the Peaches under glass were never better coloured than during this season. Given plenty of light and heat, the latter artificial if you will, and highly yet naturally coloured well-flavoured fruit can be insured. This brings me to another part of my subject. The question has been asked before, and I repeat it, Why build expensive brick or stone garden walls when it is possible to secure more satisfactory returns at a less expense? These great expensive walls after all will not insure crops of fruit, whereas if a few heated or unheated glass houses were built, or even "glass walls" with copings were substituted, valuable crops of fruit of the most delicious quality could almost of a certainty be relied on. Take Pears, for instance. How often does our climate greatly assist in the production of fruit of the best quality on the open walls? Last autumn I saw and tasted a considerable number of Pears, these being grown in presumably favoured districts, but in no one case did I discover any fruit to equal either in appearance or quality those grown by an enthusiastic pomologist on pyramids in an unheated span-roofed glass structure. It is true trees of any description grown entirely under glass must receive almost unlimited supplies of water, and which is not forthcoming in many gardens. At the same time there are hundreds of places where the employers, by a moderate original outlay, could easily overcome this difficulty.

I am not in a position to contrast the respective costs of walls or houses, but I may safely assert the latter is the least costly. To build a substantial wall of the necessary height—not 8 or 9 feet high, as is too often the case, but nearer 12 feet—owing to the amount of labour involved, is a very expensive affair; whereas in this age of machinery and competition glass structures can be cheaply and yet well built. The lights could be made to un hinge, revolve, or slide off, according to the design of the house, thus insuring a moist border and clean foliage at a time when the reverse is often the case—viz., after the crops are perfected. The lights being replaced the house, whether heated or unheated, could be utilised for various pur-

poses during the winter months. I can fancy some of my readers saying, "All this looks very well on paper, but is it practicable?" and again, "What is to shelter our vegetable quarters if we dispense with garden walls?" I can confidently assert the theory (not mine alone, remember) looks still better when reduced to practice, and this there are several who could, if they would, indisputably substantiate. With regard to the vegetable quarters, it has yet to be proved that they really require so much protection; in fact, it is my firm belief they would be much better without it. Why, and also my ideas as to the best arrangements of hardy common fruit trees, I must at present leave.

If, however, a wall must be had, why not make it principally of glass, this to include a good revolving coping? Scarcity of water cannot be urged against this already adopted idea. Dr. Parker of Bath has, I am credibly informed, for several years advocated glass walls, and I also am assured Mr. White of Crediton, Devon, has arranged several, and of which after nine years' experience he can speak most highly. In this case the garden is divided by six of these glass walls, which are constructed as follows:—A brick wall is built about 18 inches high, and on this is fixed the framework, this being about 6 feet high with a coping added. Whether the framework is made of wood or iron I do not know, neither does it much matter, but most probably it is of iron, as Mr. White is a blacksmith. Wires are strained on which to train the trees, and these Dr. Parker holds "conduct the electric fluid that is naturally in the atmosphere to their nourishment." Mr. White's glass walls run from east to west, the south front being occupied by Apricots and Peaches, while on the other side can be grown Pears, Plums, and other fruits. The advantage of substituting glass for bricks is most apparent in the case of the trees on the north side, these getting the benefit of a greater amount of sunshine and light. Such dividing glass walls could be disposed any distance apart, and in the protected compartments thus formed can be grown vegetables or hardy small fruits.

The best substitutes for a brick wall I have yet seen are the unheated houses designed and erected by the late Dr. Newington of Ticehurst, Sussex. These have been fully described and illustrated in the *Journal of Horticulture*, and as managed by Mr. Salcombe, the highly respected and experienced gardener in charge, are most profitable.—W. IGGULDEN.

TUBEROUS BEGONIAS AS BORDER FLOWERS.

FOR several years Tuberos Begonias have been planted in beds and mixed borders here to a considerable extent, and this season more extensively than in any former year, there being sixteen beds of them in various gardens. Not excepting any other species or variety of plant tender or hardy—not even *Violas*—these Begonias are the only plants that have really done well this season of remarkable wet and absence of sunshine. The month of July alone gave us nearly 9 inches of rain (there being only two wholly fair days in the month), yet the more it rains the fresher and the brighter Begonias look; and at the present date (August 1st) amid torrents of rain they are a mass of bloom, while all hardy and tender-flowering plants look very poor, and vegetables being spoilt with wet. Begonias must therefore be regarded as very well adapted for wet localities, and we also found them do exceedingly well in the (here) dry and warm summer of 1880. On this account they are superseding *Pelargoniums*, and can be managed with much less labour, as a pinch of seed sown in spring with proper treatment gives plants large enough for beds and borders the same season. Then the tubers can be lifted, potted in damp soil, and placed in any cool shed till March, when they can be removed to cold frames, and from thence into the borders without being potted.—D. THOMSON.

THE LONGLEAT VINES.

So "J. S. W." would give me the honour of being one of his disciples in the matter of training and pruning, and quotes directions which he gave two years ago on the subject. He further says "it can afford them"—i.e., himself and his co-workers, "nothing but gratification to hear of that success" which has followed the carrying-out of his system. Now all this would be very flattering to me, only it so happens that in my essay I was describing what took place in 1871, and his directions appeared nine years later. My essay was written entirely without refer-

ences with the exception of two or three back numbers of this Journal containing my writings, and I am not aware that I ever saw the passages in question written by "J. S. W.," whom I may be permitted to refer to as Mr. J. Simpson of Wortley Gardens, Sheffield, till he sent me a note on the subject through the medium of the Editor. That similar ideas should be found here and there to those which other people have written is not very marvellous, but I wonder which Mr. Simpson would think is the most troublesome to one who like myself may claim to be both a practical writer and practical worker—to garble the passages written by another, or to write off-hand my own ideas and experiences.

That I should "discuss the merits of young Vine rods 12 feet long" is not to be wondered at, when it will be seen on reference to the preceding chapters I have distinctly stated that the arrangement "left not more than 12 feet for the younger Vines to run without overlapping their elder brethren," and in the Journal of March 2nd I state that the young Vines were cut to "about 12 feet." That I should mention 60 feet is also not very marvellous when it is remembered that two of the compartments are each 80 by 30 feet, and that there is a Vine near each corner running generally half the length of the compartment, and then partly or wholly across it.

My practice is to do all composition in shorthand, which enables me to write nearly as fast as I can think, and makes me altogether independent of Mr. Simpson or any other writer when I am simply describing my own work and expressing my own ideas. These shorthand notes are preserved, and are produceable. They can be made out by an expert in Pitman's style, and, with the exception of a few corrections made during transposition, are word for word the same as have appeared in the Journal.

It appears to me that Mr. Simpson is one of those unfortunate people who imagine they have invented and described everything that is good, and that every other person is incapable of doing anything higher than copying or imitating them. This form of hallucination almost amounts to a disease, and those afflicted with it are much to be pitied.

By his opening remarks I gather that he lays claim to having introduced what is called the extension system of growing Vines and other fruit-bearing plants. Now as this is the most natural system it is reasonable to suppose it is the most ancient one, and I may tell him as an indisputable fact that it was practised long before he was born—even, I have no doubt, at Wortley.

At parallel columns your correspondent is certainly an adept, and I have no doubt that were Mr. Barnum to write an essay on rearing elephants Mr. Simpson would be able to find some passages which had been borrowed from his own writings, especially if he depended on such an everyday term as "more apparent than real." But seriously, these paper parallels are becoming rather stale, and I propose a change to parallels in practice by suggesting that three Grape-growers of public repute be chosen—and that Mr. Simpson shall have a good chance and not be placed at a disadvantage, he may choose them himself—these three gentlemen to carefully examine the Vines at Wortley and at Longleat, and the grower of the second best to pay the expenses of the judges. This, it appears to me, would be more interesting to the public than mere strings of words however cleverly arranged.

If from a feeling of modesty Mr. Simpson should hesitate to select the adjudicators as I have suggested, I am quite willing that they be nominated by the Editor of this Journal.

It is not in consonance with my feelings to issue a challenge of this kind, and I would much prefer the more obscure work of steady improvement in Grape culture; yet Mr. Simpson is so persistent in his own peculiar paper methods, that I feel driven to propose an alternative plan. I now respectfully ask that he cordially concur in the proposed arrangement or what he may say can have no weight, and his tiresome accusations will not be heeded.

The shorthand text of my essay is at the disposal of the Editor.—WM. TAYLOR.

YOUR correspondent, Mr. Taylor, must by this time have ceased to wonder at Job's reflection, "Oh! that mine adversary had written a book!" He will not get much thanks for his trouble, and even I must have my little "peck" at him. The part of his treatise on Vine cultivation which has astonished my incredulous mind is the advice which he gives on manuring a Vine border. He states that his plan consists in the main of giving it "soil passed through dry closets, and also some from a dry-earth urinal, with which is mixed a little wood ashes, and occasionally a few half-inch bones."

Now, I am a firm believer in the fertilising effects of human excreta, but I cannot blind my eyes to the fact that Voelcker's opinion of the trifling value of earth-closet manure is substantially

correct, and if you will allow me I should like to place before your readers, in his own words, what this opinion is. They are taken from his report on the "Composition and Agricultural Value of Earth-closet Manure," published in vol. viii., ss., part 1, of the "Journal of the Royal Agricultural Society of England."

His first analysis is of a sample of earth "which had been used four times in succession, and been dried each time after removal from the earth closet." "It contained about $1\frac{1}{2}$ per cent. of bone phosphate, but only 0.39 per cent. of nitrogen—equal to not quite half per cent. of ammonia, and consequently was not of great fertilising value."

As this sample had been dried with fire heat, which might have caused loss of ammonia, Dr. Voeleker analysed another sample which had been used five times, and had not been dried the last time by fire heat, but "it scarcely contained more nitrogen than the preceding sample, and somewhat less phosphate of lime and potash." As the results of the preceding analysis were disappointing from the agricultural point of view, and "as he was loth to arrive at too unfavourable a view" in this respect, he "thought it well to institute further inquiries before expressing a definite opinion."

He first analysed the dry earth used in the closets of the Wakefield Prison, and found it to be "of the composition of rich garden mould," and then analysed the same earth after it had been used in the closets once, twice, and thrice. Used once the soil gained only 0.06 per cent. of nitrogen, and twice it gained 0.11 per cent., and three times 0.20 per cent.; and "after the soil had been used three times over the total increase of nitrogen amounted to only two-thirds of the small quantity originally present in the soil." The proportionate increase of phosphoric acid in the three samples of earth manure was, as might have been expected, rather larger than that of the nitrogen; but, "after all, the soil in a perfectly dry state, after having been used three times, contained only half per cent. of phosphoric acid." "Half a cwt. of bone dust would supply all the phosphoric acid which was contained in 1 ton of dry soil after it had passed" (not once, as Mr. Taylor's soil had been apparently, but) "three times through the closet."

Dr. Voeleker next refers to some trials by Dr. Gilbert, which fully confirmed his own results. "After using twice," Dr. Gilbert observes, "the soil was not richer than good garden mould." "If," says Dr. Voeleker, "the agricultural value of earth-closet manure is really so low as stated by me, how does it happen, it may be asked naturally, that market gardeners and others who have made trials with this description of manure put a value upon it varying from £1 to £3 a ton? In reply to this very pertinent question, I would say that the high estimate of the value of earth-closet manure does not rest on any solid foundation."

It is true that Mr. Taylor further supplements his supposed efficacy of earth-closet manure (to which a little wood ashes and occasionally a few half-inch bones have been added), with half a pound of Standen's manure to 10 square yards at the time of flowering, but I must be permitted to doubt whether, even with this help, a better system of manuring may not be employed for Vine borders. What does "SINGLE-HANDED" say?—INQUIRER.

NOTES ON ROSES.

As the soil in the garden of "NOVICE" is a good clay, in all probability Roses would succeed better if budded on the seedling Briar, as this stock delights in a cool moist soil. The reason why Madame Comtesse de Serenye Rose has not opened a flower during the last three years in the garden of "NOVICE" is because his good clay soil has been well manured. All Roses that produce flowers very large and full of petals which are thin and flimsy, are forced by over-culture to put forth such large buds that the slightest moisture, even a heavy dew, will cause the outer petals to stick together so firmly that the buds cannot open. There are several Roses which have this bad habit—namely Comtesse de Serenye, Capitaine Christy, Duchesse de Vallombrosa, Madame Marie Finger, Princess Beatrice, Madame Lacharme, and Souvenir de la Malmaison. With the exception of Madame Lacharme all these Roses will open here during wet weather if they have not been manured with stable manure. My gardener knows their weaknesses far too well to give them anything that would injure their health.

Three years ago Capitaine Christy manured scarcely opened a flower; this year, after having been left unmanured for two years, this Rose opened well several grand flowers, two of which remained open a week and endured two days of continuous heavy rain with scarcely any injury. My gardener gives them a Potato manure prepared by a London Co-operative Society, and occasionally some weak liquid manure, and these are quite sufficient to preserve them in health. "NOVICE" is perhaps not

aware that the very darkest Roses fade very soon, almost before they are fully expanded, and both sun and moisture seem to injure their blooms. The very best very dark Rose is, I think, an old Rose, which has been struck out of the catalogues of late years, but which was known by the name of Deuil de Dr. Jamain. I grow this Rose nearly opposite to Monsieur Boncenne, and I consider that, though this latter Rose gives a larger bloom, it is surpassed in every other point by the former.

Prinee Camille de Rohan and Pierre Notting are very dark Roses, but they are disappointing. I should prefer to grow, besides Marie Baumann and Alfred Colomb, A. K. Williams, Annie Wood, Charles Lefebvre, Countess of Rosebery, Fisher Holmes, Sir Garnet Wolseley, Harrison Weir, François Lacharme, Mons. E. Y. Teas, Lord Macaulay, Mdle. Marie Rady, Mons. Etienne Levet, Louis Van Houtte, and Senateur Vaissé; and for light-coloured varieties—Capitaine Christy, Mabel Morrison, Mdle. Bonnaire, Baronne de Rothschild, Madame Eugénie Verdier, La France, Boule de Neige, Madame Gabriel Luizet, Princess Mary of Cambridge, and Louise Darzen, and not omitting that exquisite summer Rose, Rose Celestial, and the Bourbon Emotion.—C. M.

NEWPORT AND COUNTY HORTICULTURAL SOCIETY.

AUGUST 3RD.

THE eighth annual Exhibition of this popular and deserving Society was held in the King's Hill Fields, and was in every way a decided success, the quality of the exhibits being superior to anything shown in previous years, while the weather was all that could be desired. Three large tents were set apart for the plants, fruits, and flowers staged in competition, and the whole of the arrangements were admirably carried out by the Committee and Messrs. Cox and Payne, the Honorary Secretaries.

Stove and Greenhouse Plants in Flower.—In this class the competition for first prize lay between the exhibits of Mr. R. Wattie, gardener to J. Cordes, Esq., Brynglas near Newport, and Mr. J. Cypher of Cheltenham, and notwithstanding that the latter has carried all before him both in London and the provinces, he was defeated by Mr. Wattie, who staged a grand collection of the following:—Allamanda Schottii, covered with bloom; Stephanotis floribunda, very fine; Clerodendron Balfourianum, Statice profusa, Dipladenia Brearleyana, magnificently bloomed; a grand Kalosanthes coccinea, Allamanda nobilis, and a superb Erica retorta major about 7 feet through, one mass of bloom. Mr. Cypher staged handsome plants, but smaller than Mr. Cordes', and took second prize with Erica Irbyana, Ixora Williamsii finely bloomed, Allamanda Hendersonii, Erica Aitoniana, Clerodendron Balfourianum very good, Allamanda nobilis, Anthurium Schertzerianum, and Erica Candolleana. In the amateurs' class Mr. Cordes was awarded first prize with fine specimens of Dipladenia amabilis very good, Eucharis amazonica, Statice imbricata, and a seedling Dipladenia named Wattiana. It is of a blush-white tint. Mr. J. Watts, gardener to E. J. Grice, Esq., was placed second.

Fine-foliage Plants.—In this class there was a close contest for first honours, and so even were the plants from Mr. Cordes and Mr. Cypher that the Judges were a long time before they could make their award, and even then they could not do so without calling in a third. At last, however, they gave the preference to Mr. Cypher's. He had fine examples of Cycas revoluta, Croton Sunset, Pritchardia pacifica, Croton Queen Victoria, Kentia Fosteriana, Cordyline indivisa. Mr. Cordes' collection included Croton angustifolius, Hyophorbe Verschaffeltii, Gleichenia dicarpa, Coeos Weddelliana, Latania borbonica, and Croton Weismannii.

Mr. Cordes secured the first prize for six exotic Ferns; H. J. Davis, Esq., took the first prize for well-grown Lycopods. Fuchsias were well shown by Mr. B. Evans and Mr. H. J. Davis. There was a splendid show of Roses in the open class, J. Pulley, Esq., M.P., Hereford, being first; and Mr. W. Earle, Farmwood Nurseries, second.

Fruit was also well shown by Sir G. Smythe, J. A. Rolls, Esq., M.P., J. Cordes, Esq., and C. Bailey, Esq.

SUCCESSFUL HYBRIDISING.

PASSING through the houses in the nursery at Messrs. Veitch and Sons at Chelsea, and observing that many plants were referred to as "Seden's," it occurred to me that if a list of all the plants raised by this hybridiser was obtained it would show an excellent record, and it has. Workers such as Mr. Seden should not always labour in obscurity, but should have, as they justly merit, some public recognition. Prizes are provided now-a-days most prodigally for cultivators, and there appear to be no honours at disposal for creators of plants; but the raisers, it must be remembered, are cultivators too, or they could not guide their seedlings to maturity, and far greater skill and closer attention, with much greater and prolonged watchfulness, are necessary in growing, say Orchids, from the germination of the seeds to the flowering of the plants, than are requisite in producing fine specimens for exhibition after the plants have been established. Yet for the workers in horticulture first referred to—delicate mani-

pulators and skilled cultivators—public awards are not bestowed nearly so generously as it appears meet they should be. Probably, however, this is because the magnitude of their work is not appreciated because not seen in the aggregate, or in the form in which the labours of one worker will now be presented.

SEEDLINGS RAISED BY MR. JOHN SEDEN AT MESSRS. JAMES VEITCH & SONS' NURSERIES, CHELSEA, FROM 1866 TO 1881.

NAME OF SEEDLING.	SEED PARENT.	POLLEN PARENT.
<i>Cattleya Mendellii</i>	<i>C. speciosissima</i>	<i>C. Devoniensis</i>
* <i>Marstersoniae</i>	Loddigesii	labiata
* <i>fausta</i>	"	exoniensis
radicans	"	"
superba	"	"
alba	"	"
aurea	"	"
crispa	"	"
delicata	"	"
The above seven varieties are all from one pod of seed.

* <i>Mrs. Bennett</i>	"	"
* <i>Echeverria glauca metallica</i>	<i>E. secunda</i>	<i>E. metallica</i>

To the above must be added the following Gloxinias from the percentage of Magnet, Sir Hugo, and Madame de Smet—*Gloxinia Gamos*, *Prince Leopold, *Marquis of Lorne, *Mr. Haines, *Miss Haunah de Rothschild, Madame Patti, Prince Arthur, The Hon. Mrs. York, *Aurora, *Magnet Improved, *Sunshine.

Mr. Seden is thus the originator of eighty-eight plants, fifty of which, as indicated by asterisks, have been honoured with first-class certificates, while in addition silver medals have been granted for *Begonia Sedenii* and *Alocasia Sedenii*, and a gold medal to *A. intermedia*. The question naturally arises, If the plants are worthy of the above high marks of recognition, surely the raiser of them ought not to remain ignored by, say, the Royal Horticultural Society, whose object is the promotion of horti-

culture by a system of awards to those who are worthy of recognition. But if the practice is considered of rewarding raisers and introducers of plants, the Council will ask where they are to commence and where to stop. On this point it may be submitted that they will not be frittering away their resources if they commence at the granting of fifty first-class certificates, and never stop granting medals to those who accomplish that proud feat in horticulture.—J. WRIGHT.

NOTES ON PROPAGATING BEDDING PLANTS.

A PERIOD has arrived when the propagation of many outdoor decorative plants calls for attention, and though little that is fresh can be enunciated on a subject which has been the familiar work of gardeners for many years, a few practical notes may not be unacceptable to your younger readers. Beginning with *Pelargoniums*, I may repeat the old lesson that the earlier in August the cuttings are taken the better. However, to those who, like myself, are hindered from interfering with the beds until September, when the certainty with which a strike is secured in August is liable to a considerable discount from losses unless a different process is followed, a statement of the means we find necessary to root the cuttings successfully at that time may be of use. There are two main particulars rigidly followed. One is to employ large cuttings, the other to have lights ready to place over the stock at any time necessary to do so. Both of these requirements are not always available. At one time I could command neither, but an effort procured me the first, and time brought the other. I have been laughed at on account of these large cuttings and the large plants in 5-inch pots the following spring; but the laugh was on my side when the plants came to be put out, and later on when the beds were filled with plants in flower when others were just beginning to make growth, and, especially when the recurring season of propagation came round, when I could without fear of destroying the effect of the beds secure my large cuttings at a time when others had to be content with the tips of the shoots and obliged to mutilate the whole bed. In taking the cuttings they are selected so as to thin out the plants, the cuttings themselves being cut below a joint so as to save any further work in preparation, and as a matter of course the base of the cutting is considerably hardened. A day is allowed to intervene between taking the cuttings and dibbling them into boxes. This is of importance, as the base of the cutting is so far dried as to strike almost surely under conditions where otherwise losses would occur. A cool, not too airy shed is a good place to keep them at this time. If the boxes are kept for a few days in the same place before standing out it is of advantage. One good watering must be given when the boxes are placed outdoors in a sunny position; but until roots are formed water does harm.

There are two ways of wintering the plants—the one to keep the soil in a dry condition and the temperature low enough to stop all growth; the other to keep the plants slowly growing. Little water at the roots is required for this, and a very slightly higher temperature than in the other case. If it is necessary to keep the green-leaved section in a condition at rest, the variegated kinds at least should be kept growing. *Coleuses*, *Iresines*, and *Alternantheras* we prefer from cuttings struck now. The first-mentioned is struck in small pots and wintered therein, the others in boxes. The *Iresine* roots well enough in an ordinary frame kept close, the others require a little heat; they winter best kept slowly growing. *Verbenas*, *Ageratums*, and others of that class do well in boxes placed in frames shaded from sunshine. If left till September it is advisable to employ heat in order to have them thoroughly established before winter. *Verbenas* in particular require to be kept growing all through the winter, in order to have them strong and healthy, and capable of producing good cuttings when wanted in spring.

It is not a good plan to raise *Lobelias* from cuttings at this time, a few plants saved through the summer being by far the most satisfactory way of continuing the stock. However, if cuttings must be depended on means should be taken to induce young growths to push up, and if possible to form roots before taking them off. Unless young and healthy, *Lobelias* will not strike root just now. The easily cultivated *Violas*, if produced from cuttings, should be inserted at once, so as to have roots before winter. Plants over a twelvemonth old produce many young growths, which may be removed later on with roots attached. Last November we propagated a large number by taking up old plants, pulling them into single slips of young growth, and dibbling them into cold frames thickly in a soil made of decayed leaves. *Pentstemons* make grand plants for the flower garden if properly managed. The cuttings should be taken in July, but

they will succeed even yet, though no time is to be lost now, as late cuttings sometimes do not root until the following spring. The difference between the two modes of cultivating when the plants are seen together is surprising. We dibble them into frames, and when rooted pot them, and winter them plunged in cold frames. Calceolarias we never insert before November. A layer of decayed manure is placed on a hard bottom, 3 inches of soil above that, the plants dibbled in, and the sashes kept close until roots are formed; the lights are then kept off in all favourable weather. By the beginning of April the rooted plants are transferred to their quarters in the garden, and forming good flowering plants by the beginning of July or earlier.—A NOR-EASTER.

SILKWORMS AND SILKWORM REARING.—13.

(Continued from page 63.)

ABOUT thirty-five years ago, when a "Chinese Junk" that had arrived safely in the port of London was for the time an object of general interest, the many visitors thereto were solicited to buy a variety of Chinese articles, some of which had crossed the ocean in the junk, but some in all probability had not. Amongst the articles offered there were five hundred glass cases of insects (more or less) containing butterflies, beetles, and a few insects of other tribes: many of the cases had specimens of the lantern fly. Most of the cases had a double layer of insects, butterflies or moths forming the lower one. Above these were species, beetles, flies, &c., upon tall pins, which were not unfrequently barbarously run through the wings of the plumaged insects. A large proportion of the cases had as their centre a pair of huge moths, concerning which at that time very little was known in Britain. Some collectors, indeed, regarded these as well worth the 5s. charged then for the cases and contents. Since, similar show-cases of Chinese insects have occasionally arrived here, but of late I have not seen any offered for sale, unless second-hand.

The insect in question, now familiar to naturalists by the name of *Attacus Atlas*, belongs to the group of moths referred to in our preceding article, and we believe it may claim to be the largest moth in the world. It has, however, two types or races. There is a "giant" race, the females of which have wings that expand nearly 11 inches, and a smaller race averaging two-thirds the size. Each has its locality. The Himalayan Mountains have supplied us with examples of the larger form of *Atlas*. The other has been brought from the vicinity of Bangalore. Both doubtless occur in very varied Asiatic districts, notably in China, besides India, also in the isles of the Archipelago. Our figure shows a moderate-sized specimen of the smaller race; scarcely a species belonging to the group is so remarkable for the beauty of the singular "side windows" within the wings, than is *A. Atlas*. It does not appear that, allied though this species is to *A. Cynthia* and to *A. Mylitta* (the Tussur silkworm), the silk produced by it has been much utilised in its native countries; but at the period of the temporary failure of our old friend *B. Mori*, this insect, amongst others, attracted the notice of those who were investigating the silk-yielding caterpillars. Dr. Chavannes, who made some suggestions concerning the introduction of new species into France, examined cocoons of *A. Atlas* in 1855, and commended the silk as being stronger and thicker even than that of the Mulberry worm. He believed that the cocoon was formed of one thread, which could probably be wound off; but the quantity of floss or loose silk is considerable, and this belongs, like *A. Cynthia*, to the class of open cocoons. Hence the moth extricates itself without either damaging or wetting the shode of the pupa.

Experiments in rearing *A. Atlas* have been made in Britain by Mr. Philip H. Gosse, F.R.S., and M. Wailly. The latter gentleman has for several years devoted himself to the rearing of a well-selected variety of the silkworms new to Britain. The results of their experiments, so far as they went, have been published in the "Entomologist," where also reference has been made to the energy and perseverance previously shown by M. Braine of Arras in France. He hatched out his first brood of these silkworms during June, 1869, feeding them successfully upon the common Barberry exposed to the sunshine in the open air. Cocoons of *A. Atlas* were shown by M. Braine at the Exposition des Insectes of 1872. His success in rearing was such as to encourage him to make several plantations of Barberries; but the war of 1870 and other circumstances prevented him from prosecuting silk culture in this direction, else it is likely the species might have been acclimatised

in some area of France where its conditions of life would have resembled those of its Asiatic home. Lady Gilbert, an Indian resident, seems to have been the first naturalist who reared one of the caterpillars to maturity during the autumn of 1825.

The egg of *A. Atlas* is not so large as one might expect. It is prettily granulated, and white clouded with purplish-brown. When first out of the egg the young silkworm is black and grey, having conspicuous tubercles of white. There are five moults, *A. Atlas* having thus one more moult than is general amongst the silkworms. At each while in captivity they devour the whole or the greater part of the cast-off skin. After the second moult the silkworm, until full-grown, is clothed with a farina or dust, which may be blown off the skin. Having passed the last moult the silkworm appears of a delicate pea-green, almost white in some examples, the tubercles bluish, here and there tipped with blue-black. In spinning the cocoon one of these silkworms seeks for several leaves which can be drawn together so as to form a convenient hollow. The cocoon is usually secured to a footstalk by a cord of silk. In length it varies from 2 to 3 inches; the colour of the silk is some shade of brown.

Besides the Barberry, the silkworms of this species have been fed upon Apple, Plum, and Peach by several observers, and by Mr. Gosse upon Sallow or Willow. He arranged for his newly hatched worms a saucer with the leaves of nine different plants stuck into damp sand, and found that although they nibbled several species they gave Sallow the preference. Their tardy growth proved a hindrance to success, and nearly all the brood died; the survivors reached their full size after a life of nearly eleven weeks. On the other hand, a person who placed some of

Fig. 22.—Moth of *Attacus Atlas*.

the *Atlas* worms in a plant stove reared about half his hatch within five weeks. M. Wailly found the period of his worms came between these two, but he also lost a part, and this does not seem to be a species easy to rear with us. Sprinkling their food with fine drops of water has been proposed as likely to be beneficial, and also forcing the pupæ slightly, so as to get eggs rather early in the summer, for the winter is passed by the species in the pupal state. Another noteworthy fact is that while young these silkworms are apt to turn cannibals when near each other. On the whole it may be concluded that in Britain this handsome moth and its silkworm are rather to be esteemed as a curiosity than of practical value, but it might be turned to better account in China and India.

Bombyx or *Attacus Cecropia* is a large species allied to *A. Atlas*, and one which has this fact in its favour, that the worms feed upon a variety of plants readily. It is a native of North America, bearing some resemblance to the insect just described, but it is of smaller dimensions. We cannot bestow upon it a high place upon the list of American silkworms. The silk is apparently only to be had by carding, and the cocoon belongs to the group of the open-constructed, a good deal of floss outside, and within layers of strut silk. The moths come forth in June or July, the worms hatch in a few weeks after, and spin up during the autumn. From black at infancy they pass to orange, then to blue, being at length blue and greenish yellow, with an array of tubercles or spines yellowish on the back and white on the sides of the body. Specimens of the cocoon of *A. Cecropia* have been exhibited which had been obtained in England, Belgium, France, Germany, Austria, and

Portugal. These worms have been found to thrive upon either Willow or Poplar, and they are very well satisfied with the leaves of several fruit trees—Plum, Apple, &c. Maple or Elm are less acceptable. A quantity of fertile females were liberated in a wood near London four years ago, but a colony of worms was not established.—J. R. S. C.

MYRTLES.

THOUGH so well known and admired, Myrtles are not so generally cultivated as they should be. Sometimes they are grown as window plants, and they are valuable in the greenhouse and conservatory, and in the open air bushes are always admired. Here there are some good specimens in the open, several plants being 20 feet or more against walls, and their large branches project far out, as, although they are mostly grown against walls for shelter, they are seldom trained on the rigid wall-tree system. It is only in very severe winters they require any protection here, and in most other parts of the country I am sure the weather in spring, summer, and autumn would agree with them well, protection only being needed in winter, and then only when the temperature fell below 32°. Plants which are now becoming too large for pots or boxes might be placed out in spring or about bedding-out time. Previous to planting out they would have to be gradually hardened, otherwise they might look sickly for a time. A moderately rich open soil suits them well, and when once they begin growing they push rapidly on, and soon cover a large space. In dry summer weather we often supply Myrtles out doors with liquid manure, but this only in the case of established plants. Indoors they should only be treated as cool greenhouse plants.

Cuttings may be rooted freely now; a sandy soil and a little bottom heat is needed to do this. In potting them good drainage must be given, and the compost for both young and old plants should consist of loam, a little decayed manure, and plenty of sand. Peat we never use in potting, as we find them do equally as well in loam. In making their growth they should be frequently syringed, as thrips and red spider are very likely to attack them, and this discolours the leaves and sometimes causes them to fall. Established plants, although grown for the greenhouse, may be placed in the open air for several months in the summer, when their space may be given up inside to softwooded plants of various kinds.

As Myrtles when properly treated grow fast, they may be trained into almost any shape; but a free-growing bush showing no trace of cutting or training is as pleasing as any form, but cutting need not be objected to if it is done with the object of securing choice green sprays for mixing with cut flowers, and for this purpose alone Myrtles are well worth cultivating. *M. communis* is the best known, and *M. angustifolia*, *M. latifolia*, *M. flore-pleno*, *M. tenuifolia*, and several others compose a good selection.—J. MUIR.

HERBACEOUS PLANTS IN FLOWER.

SINCE writing my notes on the above subject (page 14) so many other plants have come into flower that I am again tempted to contribute a few notes respecting them. Many species that were mentioned previously are still fresh and in good condition, thus proving the value of a good selection of hardy plants. They are not only valuable for outdoor decoration, but where cut flowers are in great demand they are also useful and well adapted for cutting, and many last long in that state.

The genus *Statice* may be mentioned as one of those that last a considerable time after being cut. There are now several species in flower, and amongst the most showy are *Statice Limonium* or Sea Lavender. The flowers vary considerably in colour, being light purple or white. This is a very free-flowering plant, and deserves to be more extensively grown. *S. dahurica* is a much dwarfer plant than the latter, not exceeding 18 inches high, and produces flowers of a light pink colour. It is a plant very suitable for near the front row of the border. *S. elata* is a very handsome species from Siberia, with bright green glabrous foliage. The flowers are blue, and last nearly two months in perfection. *S. densiflora*, *S. occidentalis*, and *S. latifolia* are all worth a place.

Many of the Labiates are now at their best, although the heavy rains that we have experienced lately have not improved them; but still there are plenty in flower, and will doubtless remain in perfection for some time. The dwarf free-flowering *Betonica officinale* and the variety *flore-albo* should certainly find a place, as also should *B. hirsuta* with its dark purple flowers. *Prunella vulgaris* should certainly be planted; large tufts when well flowered are very showy. *P. Webbiana* is dwarfer, producing flower heads of great size. *P. grandiflora* and *P. grandiflora* var. *laeniata* are desirable plants, the foliage of the latter being

finely cut and showing off the dark purple flowers to better advantage. *Nepeta grandiflora* is now flowering profusely, and should find a place in the second or third row in the border. It grows about 3 feet high, and has very showy light purple flowers. *N. maciantha* and *N. longiflora* are worth consideration if sufficient space is at hand.

The Sage family is now well represented. Many of the plants are extremely showy and well suited for the herbaceous borders. The genus *Salvia* is said to contain about four hundred species, being found in most temperate and tropical countries, many of these being strictly tropical, and numbers being not worth cultivating except in botanic gardens. *S. sylvestris* attains the height of 4 feet, and is of bushy habit; it is a very handsome plant when in flower. *S. Sclarea* and *S. Sclarea* var. *bracteata* are amongst the most showy of the hardy species, the bracts being the most conspicuous part. *S. glutinosa* is a hardy European species about 3 feet high; the younger parts are clothed with glandular viscid hairs. *S. sylvestris* forms a bush between 4 and 5 feet high; the flower spikes average a foot long. *S. Horminum* is a very showy plant, and well suited for a position near the edge of the border. The flowers are inconspicuous; the most showy part is the dark purple bracts clustered at the top of the flower spikes. *Thymus Serpyllum* var. *citriodorus* is now one mass of flowers, and although common is extremely ornamental when in flower.

Amongst ornamental-foliage and flowering plants combined the genus *Acanthus* deserves special mention. The leaves are armed with sharp spines, flowers in leafy spikes terminating the stem. *A. spinosus* has deeply cut foliage, which, with the bracts, are very prickly; the flowers are purplish and white, attaining the height of about 3 feet. *A. lucidus* is well worth cultivating, and has bold foliage and large flower spikes. *A. mollis* is a similar plant to the two preceding, but the teeth of the plant, though acute, are not prickly. Of the latter there are two or three well-marked varieties differing from the type chiefly in the colour of the flowers.

In my previous notes I mentioned two or three species of *Veronica* that were then in flower. Since then, however, other species have come into flower that are perhaps more ornamental. The species here mentioned cannot fail to give satisfaction to all who grow them. The pleasing bright blue spikes of flowers are exceedingly useful for cutting. *V. longifolia* is a tall variable plant, producing long dense terminal racemes of blue flowers. *V. longifolia* var. *rosea* with rose-coloured flowers, and *V. longifolia elegans* has pure white flowers, the latter being remarkably fine. *V. incana* var. *neglecta* is a very dwarf-growing species, not exceeding 4 inches high, and produces upright spikes of flowers a foot or more long. *V. virginica*, or Culvers Root, attains the height of 4 to 5 feet; the flowers are pure white with conspicuous yellow anthers. *V. corymbosa* is a useful plant, being intermediate in size, growing about 18 inches high, and producing spikes of purple flowers a foot or more long. *V. spicata* is another variable plant; the typical species produces flower stems from 1 to 2 feet high, and terminated by racemes of bright blue flowers. There are some well-marked varieties producing rose-coloured and white flowers.

Pentstemons are too well known and appreciated to need much comment. There are three or four species, however, that may here be mentioned, such as *P. glandulosum*, which grows about 3 feet high and produces flowers of good size. *P. gentianoides* is a very beautiful species from the higher mountains of Mexico; it grows about 3 or 4 feet high, bearing long leafy panicles of bright violet-blue or scarlet and white flowers. The latter is very distinct, the tube being much longer than in most of the other species. *P. perfoliatum* grows about 4 feet high, and bears flowers lilac and white. *P. Digitalis* is a very distinct tall-growing species, producing pure white flowers, contrasting favourably with some of the other species with more highly coloured flowers.

The *Verbascums* are now finely in flower, and are very effective if judiciously planted in the shrubbery and herbaceous borders. They may be considered by some as coarse common plants, but if care be taken in selecting suitable positions they are by no means to be despised; if planted in the shrubbery they are very effective, reaching 6 or 8 feet in height. *V. phlomoides* and *V. macrum* produce the largest and showiest flowers. There are other species that are not so rank-growing, and are more suitable for the herbaceous border proper.

One of the prettiest plants now in flower in the herbaceous border is *Omphalodes Luciliae*; it has glaucous foliage, and the flowers in shape are much in the way of the Forget-me-not, but larger. This should have a place in every border. The *Boragos* are common, but for a variety one or two plants would not be out of place. *B. officinalis* is the most showy; it is indeed a very

distinct plant, with broad leaves and large blue flowers with conspicuous black anthers. The *Symphytums* come very near the latter, *S. officinale* being the most showy. There is a very fine variegated form that is well worth growing if only for the foliage. *Gilia achilleæfolia* and *G. capitata* deserve a little attention, the latter being useful for cutting purposes, producing light purple heads of flowers.

Of late years much attention has been paid to the *Phloxes*, and well they deserve it, for what border would be complete without some varieties of *P. paniculata*? This handsome species varies in the colours of its flowers from lilac, pink, or purple to white, and being crossed with *P. maculata* has given birth to the numerous fine varieties now in cultivation. *Gentiana asclepiadca* is a remarkably handsome plant, and may be considered as one of the best for borders and general cultivation. The flowers are large and dark blue; it attains the height of about 18 inches. There is a variety with white flowers that is also worth growing. *Erythraea diffusa*, with its *Silene*-like flowers, is a little gem, and is useful for the front line; the flowers are rosy pink, showing well above the foliage. *Asclepias tuberosa* should be grown, for it produces its brilliant flowers nearly all the summer, thus increasing its value. *A. Cornuti* is also worth a place; this is a robust-growing plant 3 or 4 feet high. The flowers are fragrant, dull purple, and larger than the first-named species.

We have now reached one of the most showy and important genera of herbaceous plants—viz., *Campanula*. There are many species in flower, and some are now about their best. *C. pusilla* is of dwarf habit, not exceeding 6 inches high, producing white flowers. It is very suitable for the front of the border; being pure white is a desirable species. *C. carpatica* is another desirable form, and considered to be one of the best of the dwarf section. It produces large open flowers, and being variable many fine varieties are produced with blue, blue and white, and some with pure white flowers. *C. persicifolia* is one of the handsomest, including some very showy double-flowered varieties. If grown in good rich soil it attains the height of 3 feet, and continues to bloom from June till September. *C. coronata* grows between 3 and 4 feet, with purple flowers, and should be included in the list. *C. sarmatica* is a species well worth a place; it grows between 3 and 4 feet high, and is of free habit. *C. pulla* is a little gem. It is of spreading habit, not exceeding 3 or 4 inches high, producing single flowers freely, which rise a few inches above the foliage. Other species that may be recommended are *C. rotundifolia*, *C. latifolia*, *C. turbinata*, *C. glomerata*, *C. garganica*, and *C. rapunculoides*.

Anemone japonica is one of the most useful and effective plants now to be seen in the herbaceous border. The flowers are large rose or white, and last long in perfection. A plant known as *Anemone Honorine Jobert* is a good and distinct variety of *A. japonica*. *Tunica Saxifraga* is a very effective plant when in flower, and is now about its best; it closely approaches *Dianthus*, but is valuable for its free-flowering property. The bright pink flowers are small, but being produced in great profusion and continuing to flower throughout the summer months, should be appreciated by all. *Dianthus Seguieri* is free-flowering, growing about 18 inches high. It is especially noteworthy for the fact that it flowers at a time when the greater part of the other species of *Dianthus* are over for the season. Several species of *Hypericum* are in flower, some of which are great acquisitions, the best being *H. olympicum*, *H. calycinum*, *H. tomentosum*, *H. asperum*, *H. perforatum*, and *H. Androsæmum*. *Calandrinia umbellata* must not be forgotten; it grows about 6 inches high, the crimson flowers being borne in the form of an umbel.

The *Malvas* include several showy and ornamental plants, and are admirable subjects for the shrubbery as well as the herbaceous borders proper. *Malope trifida* and the var. *flore-alba* are showy plants about 3 feet high. *Kitaibelia vitifolia* is a tall-growing plant with handsome foliage, producing the rose or white flowers from the axils of the upper leaves the greater part of the summer. *Althæa rosea* (Hollyhock) needs no comment. *A. officinalis* (Marsh Mallow) is a capital plant for single specimens; plants about 6 feet high and as far through are noble objects. *Lychnis viscaria* is now very handsome, and when seen in masses is most striking. *L. chalcedonica*, although like the last an old garden plant, must not be left out, as for some time past has been one of the greatest ornaments of our borders. There are several varieties of this valuable plant, some with white and rose flowers, also double varieties. *Silene Armeria* is a very conspicuous plant when grown in masses, averaging about 18 inches high. Several species of *Linum* are now very fine. *L. grandiflorum* is one of the handsomest annual species; it grows about 18 inches high, and has beautiful crimson flowers. *L. luteum* should be grown for variety, and *L. narbonnense* should also find a place; it has

light purple flowers over an inch across, and when seen flowering in quantity is really a telling plant. The several varieties of *Lythrum salicaria* are great ornaments, and have been all aglow for some time past with their rosy purple flowers. The vars. known as *roseum* and *grandiflorum* are extremely showy, particularly the latter, as it produces finer spikes of flowers than the others; they also prove very useful for cutting.

Many other good plants might be mentioned, such as the *Scaebious*, *Godetia*, *Epilobiums*, *Sweet Peas*, *Clarkias*, &c. I have not mentioned any of the *Composites* in this paper, although there are many that deserve a word of praise, but perhaps a little later in the season I may contribute a few notes respecting them.—W. K.

A GOOD CROP OF POTATOES.

"A CITY MAN" is right in inferring that at least two or three profits had to be obtained for the Potatoes. I referred to page 77, but he is wrong in supposing the price quoted is too high. Since I have been obliged to market produce no fact has been more forcibly impressed on me than this one—that in order to succeed the best must be done to have your produce fine. It not only makes a difference as to price, but in a crowded market it means a sale or no sale. For example—the last consignment of Potatoes sent to market brought exactly double the price of most of the others in for sale. A different class of purchasers was to be had for ours, and they were willing to pay so much more. To satisfy your correspondent that I have not exaggerated as to price, I wrote to the salesman who acts for me to return the receipts for the week I referred to. I now send them on to you. You will see there were seventy gallons marketed, and the returns, clear of any drawback, were £5 5s. The gallon in question contains twelve imperial quarts, and is therefore two and two-thirds of a bushel, or 21 lbs. in weight; but we find that the gallon always contains over that weight, so that these seventy gallons would be more likely to weigh 15 cwt. than the statute weight of 13½ cwt. I may say that from a crop lifted later we secured a gallon off every 6 to 7 yards, exclusive of seconds and those kept for seed. All our Potato ground is again under crop, from which I expect a further £30 to the acre before the end of the twelve months from planting the Potatoes.—B.

[We do not think "A CITY MAN" doubted the accuracy of your statement, but considered the returns unusually high in comparison with London prices.]

TWO-DAYS ROSE SHOWS.

It is always an unpleasant thing to bring charges of disloyalty against those with whom one has been acting and to point out flagrant inconsistencies; but I have always thought it best to say distinctly what I mean, while, I hope, endeavouring to do so with all courtesy, and I must therefore say that I have beheld with some amazement the prize lists of the Manchester and Birmingham Rose Shows. When I see there the names of the President and many members of Committee of the National Rose Society, and when I recollect the whole history of the Society, the resolutions it has passed and the rules it has laid down, I must confess to a sense of utter amazement at the inconsistencies of which some persons can be guilty, with a light heart too.

When, now some years ago, the circular was issued to which is owing the present existence of the Society, it was distinctly stated in it that one great reason for the need of such a Society was the existence of two-days shows, and one of the resolutions proposed to the meeting was that of discouraging by every means in their power two-days shows. We know what was the condition of Rose-showing then and we know what it is now. I remember well that one or two persons said they would not give a pledge on such matters as two-days shows, but that they would do their best to discourage it. Since then several circumstances have occurred in connection with the subject which ought to be recorded. When the lessees of the Alexandra Palace proposed in 1880 a two-days show very strong remonstrances were made by the Secretaries of the National Rose Society and by some of our prominent growers against it; and the result was that they, with a laudable desire to meet the objections, abandoned their idea and confined it to one day.

When, again, the authorities at Manchester wished the National Rose Society to hold their Exhibition there, a hitch occurred because the Committee insisted on its being confined to one day. It was said it must be a failure if this was insisted on. However it was, and the result was a clear gain of £400. When, again, last year proposals were made about holding the Show at South Kensington the hitch arose, not from unwillingness to hold it there, but because their Rose shows had been for two days, and the Committee of the National Rose Society would not alter their rule. And lastly, when the regulations were drawn up afresh with regard to affiliated societies, it was laid down as a rule that no Society which held a two-days Rose show be affiliated; yet many of those who assisted in all these

cases, who voted in this matter, are found, as far as I know, without any remonstrance quietly helping to swell the exhibition tables of two-days shows.

Now I hold that this is disloyal to the Rose and to the National Rose Society, and against the interests, if they would only see it, of those who are the chief offenders—*i.e.*, the growers for sale. Disloyal I say to the Rose. Has anyone ever seen a box of Roses on the second day without mourning over its draggled and miserable condition?—not a trace of the beauty which so charmed us the day before, and instead of the delicate and delicious fragrance a faint and sickly odour of decay. Nay, does not one call to mind some of those who have thus offended fuming and fretting because the judging was a quarter of an hour late, and declaring that their flowers would not be fit to be seen? And yet—well, the inconsistency of “human nature” is very wonderful. It is disloyal to the Society, for it stultifies its very foundation, it makes its resolutions a farce, and leads to the question, If one rule may be broken why not others?

Then, again, it is against, as I have said, the interests of the growers. If all have benefited by the establishment of the National Rose Society, assuredly the growers for sale have most done so. Let us take the demand for Roses now and compare it with that which existed before the Society was established, or let us see how the culture of the Rose has penetrated into districts where it was unknown before, and the truth of this must be acknowledged. But I wonder who ever received orders from a box of Roses two days old; and must it not be seen that to let flowers for which a sale is expected be seen in this condition is “a mockery, delusion, and a snare?” Let me put one question: Would any of our growers who have a seedling which they wish to sell cut it and expose it to the light, and then at the end of the second day let it be seen?

I have thus pointedly alluded to the growers for sale, not because I think they are greater offenders than the amateurs—all who have taken part in it are “tarred with the same brush,”—but because I believe firmly the remedy lies with them. If those whom we can count on the fingers of one hand were to put their foot down and say, “No, we cannot consistently show at a two-days exhibition,” the thing would be settled. Much as amateurs have done and are doing to make our shows a success, it cannot be doubted that if the long array of boxes which are exhibited in the nurserymen’s classes were absent many shows would be a failure; and I am sure that had they done so in both of the instances to which I have alluded this year they would have gained their point and saved their consistency.

I have not alluded to another reason, although to some it is a matter of no little importance. I mean the additional expense that is entailed by it. Instead of being able to get away the same night they must remain for another, or else leave a man or have their boxes forwarded. Now when an exhibitor has taken a goodly amount of prizes this is all very well; but when one has been unsuccessful or only gained some of the smaller prizes, “the gilt is taken off the gingerbread” when another day’s sojourn is involved or when boxes have to be forwarded afterwards.

I have thus pointed out the disease and suggested the remedy. I have done so in the interest of the Rose and without any personal feeling. I have striven “naught to extenuate or set down aught in malice,” and I can only hope these observations I have made may be taken in the same spirit in which they are offered.—D., Deal.

NOTES ON STRAWBERRIES.

SHORTLY after Strawberries commenced ripening this year much fruit was noticed lying on the ground under the plants, and on examination it was apparent that mice had cut off the fruit for the sake of the seeds which they had nibbled out, the fleshy portion being left untouched. Curiously enough the only sort injured was President.

I may say that our most satisfactory varieties are President and Vicomtesse Hericart de Thury. I have tried many kinds of late years, and generally with much dissatisfaction resulting. Helena Gloede I intend to give a further trial. It has been in crop three seasons, and although not very satisfactory, another opportunity of judging its merits will be given. Elton Pine, an old late sort which was discarded, I am going to try again, a crop of it I saw last year in another garden being one of the finest. Pioneer was discarded last year, and Loxford Hall Seedling this; I have been unable to get either to ripen here. Dr. Livingstone has been so strongly pressed on me as a grand variety that a trial will be made of it for the first time.

We have been busy planting out strong-rooted runners lately. This plan I have followed so successfully that I may refer to it again. I send a plant with the soil shaken from the roots to show the kind of thing we obtain by the simple method of rooting the plants between the lines. They are lifted with balls 6 inches across, a mass of roots, and are transferred at once to the quarter set apart for them, being set out in rows 3 feet apart and 2 feet from plant to plant. The ground is just cleared of a crop of Potatoes, the only preparation for the Strawberries being levelling it down with forks. Half an ounce of chemical manure suitable for the Strawberry is worked in round each plant

as it is put out. I may say that I would prefer “SINGLE-HANDED’S” plan were we planting on a small scale, and would strongly recommend those who set out a few hundreds to follow his advice.

One-fifth of an acre is being planted with Strawberries, and notwithstanding the protest of “A NORTHERN GARDENER” the other week, I do not find that it would be advantageous to stop intercropping. Turnips are not a suitable crop, as they require the same dominating manure as do Strawberries, but provided the Turnips are drawn young no harm is done. Lettuces, Endive, Onions, or Spinach do practically no harm. A very slight dressing of nitrate of soda and sulphate of ammonia mixed in equal proportions applied to either of the four vegetables will ensure a good crop. I am taking my latest crop of Lettuces from this quarter, and intend taking the earliest crop of the same vegetable from the same ground next spring.—B.

[Such strong-rooted runners as the example sent, planted in July and well attended to, will produce an excellent crop the first season.]

CHEAP FLOWERS.

AFTER a day spent among pleasant sights and objects of great beauty, some fine statuary, an exhibition of water-colour paintings, an extensive collection of rare works of art, a public garden rich in fine trees, gay flower borders and elaborate carpet beds, the brightest sight of all clinging to the memory with a freshness born of itself was a row of common *Tropæolums* growing in a cottage garden which I passed on my way home. The garden was at an angle of the road enclosed by a low fence, along the inner side of which seed of the *Tropæolum* had evidently been sown in spring; and with the exception of keeping down weeds and slugs, no care or culture had been necessary to bring to perfection a fringe of floral beauty fit to grace the garden of a palace. Foliage was most abundant, forming a background and setting to the blossom that much enhanced its beauty, while both clustered charmingly around the neat white paling. Mine was only a passing glance, taking in the general effect and dwelling upon no colour in particular, and a closer inspection might have shown little variety; yet I may remind your readers that we now have shades of scarlet, yellow, crimson, rose, peach, and white, some ten or twelve in number, all to be had in a 3*d.* packet of seeds—no slight boon where space under glass cannot be had for wintering bedding plants. Let not the hint be thought untimely because of no avail for this year; now is the time to gain many a similar scrap of knowledge worth keeping for future use.

A packet of Belgian Pansy seed purchased for a shilling and sown last year afforded me some dozens of plants—enough, in fact, to plant a narrow border of Tea Roses along one side of my house, up which the Roses are trained. The plants grew freely, and had some flowers last year. This year they soon filled the entire border, and for months have been one mass of flowers—all beautiful, and considerably varied in colours. An enthusiastic florist who came to see the Rhododendrons in full beauty declared that the Pansy border alone was worthy of a special visit, and was rewarded as he deserved by having cuttings of all of them. It must not, however, be thought that the flowers are florist’s flowers worthy of a place in an exhibition stand; hardly any of the markings were sufficiently regular for that, but they are undeniably rich, varied, and curious.

A row of Sweet Peas upwards of 100 feet long sown last autumn in light rich soil came into bloom in April, and continued in full beauty till the middle of July. They grew 7 feet high and were quite an imposing sight, all the more enjoyable from being near to a path. The hedge of sweet flowers filled the surrounding air with its fragrance, and afforded an inexhaustible supply of cut flowers, of which huge bowls were used for corridors and other similar places. It would, of course, prove somewhat expensive to purchase enough seed for such a row, but I have been gradually extending the length of such rows for some years, and have now enough seed hanging upon this first row alone to sow some dozens of similar ones. Those who have only seen Sweet Peas in the ordinary little clumps can hardly form a true conception of the striking effect of a hedge of them, and every garden might afford space for something of the kind.

A mixed packet of Chinese Pink (*Dianthus sinensis*) sown upon a slight hotbed in March afforded enough plants for two small beds, which are now coming into bloom, large, rich, varied in colour, and abundant. The effect is charming, and tells well among surrounding beds of the ordinary bedding type. The seed bed was a very rude contrivance—a heap of leaves a yard high, four 9-inch boards nailed together for the sides, soil put in to within an inch of the top, the seed sown in rows, and a glass light

laid over it. Among the flowers so raised this year I may mention Carnations, Picotees—those so raised last year are now in bloom—a collection of Everlastings, most of which have produced flowers, which are now cut and dried for winter—Polyanthus, Pyrethrum, Potentillas, of all which there is an ample stock of seedlings; Zinnias, both single and double; Larkspurs, Asters, Nigellas, rare kinds of Papaver, Scabious, just now opening their first flowers, and other familiar annuals and perennials. The heat derived from the bed of leaves is so little that no importance is attached to it; rather is it important to sow in soil raised 2 or 3 feet upon a suitable base, well drained, covered by a glass light, and sheltered from cold winds. The advantages of the plan are abundance of light and air, inducing robust health and sturdy growth.

Need I point the moral? Will it be thought heresy if I assert that gardens may be bright with seasonable flowers the year round without the aid of costly glass houses? A border filled with choice strains of Aquilegias, Campanulas, Sweet Williams, Antirrhinums, Canterbury Bells, Polyanthus, Delphiniums, Lupins, Wallflowers, Stocks, Asters, Phloxes, Oenotheras, Pentstemons, Mignonette, Larkspurs, Hollyhocks, Pinks, and Carnations, all coming under the category of cheap flowers, easily raised from seed, and all answering well under the advantages of a generous soil and careful tending, often proves more attractive than the most costly ribbon border. My favourites may well enough be termed "old-fashioned;" but does not our heart warm to the term, and the mind involuntarily wander back to scenes of youth and to familiar objects cherished, now, alas! but too often in memory alone?—EDWARD LUCKHURST.

AN ESSAY ON THE PELARGONIUM AND ITS CULTIVATION read by Mr. C. E. Pearson of Chilwell before the members of the Nottinghamshire Horticultural and Botanical Society on June 12th of the present year, has been issued in pamphlet form. Attention is chiefly given to the Zonal varieties, the culture of which is fully described, but short select lists of Show, Fancy, and Ivy-leaved varieties are also included. Referring to the name of the genus, Mr. Pearson observes:—"There has been a good deal of confusion amongst non-botanical people between Pelargonium and Geranium, in consequence of these plants being called scarlet Geraniums, bedding Geraniums, &c.; the fact is, they are not Geraniums, but Zonal Pelargoniums, though belong to the Geranium family. Most of the Geraniums are hardy herbaceous plants, dying down in winter, several of them being amongst our native wild flowers. The best known, perhaps, are the blue Geranium found in moist meadows (*Geranium pratense*), and the small pink one which is found in every hedgerow, *Geranium Robertianum*, or, as it is commonly called, the Stinking Cranesbill. The easiest method of distinguishing the two families is by the flowers; in the Pelargonium the parts of the calyx unite to form a tube, easily found by cutting through the flower-stalk. If the Geranium be treated in the same way it will be found to be solid."

— AN Exhibition has just been held in Sherwood Park of the FRANT COTTAGERS' ASSOCIATION. This organisation, we are informed, has been of great benefit for those for whom it was established, and that the Shows are appreciated is evident from the fact that at the one in question there were five hundred competitors. Upwards of 350 prizes were provided for flowers, fruits, vegetables, neatest cottage gardens (in parishes, districts, and on estates), poultry, pigeons, geese, turkeys, rabbits, canaries, cats, bees, needlework, darning, bread-making, butter-making, and writing. We are glad to see the Society is supported by the resident gentry; and the Committee and Mr. Ware, the Secretary, are to be complimented on their labours in a work that is calculated to improve the condition of the industrial classes in those districts in which it is carried out.

— MESSRS. J. CARTER & Co., High Holborn, have now a magnificent display of PETUNIAS AT PERRY HILL, comprising over fourteen thousand plants, and representing a large number of beautiful varieties both single and double. The colours are extremely varied; from the richest crimson to the most delicate rose and pure white there is every gradation. In form, too, there is great variety, some being scalloped or fringed at the margins, others are quite even and regular. The markings also differ considerably, and there are several very distinct types. Some have a clearly defined white centre, the other portion of the corolla being coloured; some are evenly striped, and others are irregularly streaked and blotched. The double flowers are remarkable for their great size and fulness, while all the plants are characterised by a dwarf, compact, yet vigorous habit that is most satisfactory.

— A CORRESPONDENT writes as follows respecting *SALVIA FARINOSA*:—"This is a most beautiful blue-flowered species, the spikes of which when cut continue to open flowers for a long time. It is not hardy, but is very useful for planting in borders during the summer months. In habit the plant is erect, with ovate-lanceolate leaves, and its flowers in terminal spikes are of the brightest lavender blue. Another rare species flowered recently in the greenhouse, but of the same tint as *S. patens*. It is called *S. chamaedrifolia*, and makes a well-formed pot plant, freely flowering in neat spikes during summer when variety is often much wanted. Both these are grown in the Cambridge Botanic Garden, where a large number of the tender species are cultivated."

— ONE of our prettiest British species of St. John's Wort is *HYPERICUM UNDULATUM* (some regard it as a variety of *H. quadrangulum*). It is 8 inches or a foot high, with erect stems bearing small leaves, and is rendered extremely elegant by the numerous red buds, which are intermixed with bright yellow flowers. It is well worth a place in the garden. It is found growing wild near Plymouth and in Cornwall.

— "J. R. S. C." writes:—"I read with special interest the communications in the last issue of the Journal anent the STRAWBERRY-EATING BEETLES. My entomological friends cannot make it out at all; it is quite contrary to all theories that Carabi should act thus, unless their natural food run short, which could not be the case this season. However, the fact seems well authenticated. Mr. Cornhill of Byfleet speaks of several species being noticed, allied to each other he thinks. I should like to see samples of the smaller beetles he mentions, perhaps not a Carabus but an *Otorhynchus*. The weevils of that genus have been taken about Strawberry beds."

— MESSRS. H. CANNELL & SONS, Swanley, have sent us some very handsome blooms of PENTSTEMONS, extremely varied and bright in colour, of great size, and good form. Scarlet of various shades, crimson, purple, rose, and white are represented, some of the hues being particularly brilliant. In several cases the blooms are quite bell-shaped, and even in outline suggestive of small Gloxinias; some also have a white throat, with the outside of the tube purple or crimson, the same colour forming a regular margin round the lobes of the corolla; in others the throat is heavily streaked with colour. They indicate a strain of considerable merit obtained by careful selection.

— "B. S." writes:—"Now that Mr. Taylor has finished his history of the VINES AT LONGLEAT I desire to tender him my best thanks for the most valuable information he has given from beginning to end. I have gained much valuable instruction."

— ON the opening day of the British Bee-keepers' Association's Exhibition at South Kensington last week Messrs. J. Carter and Co., Holborn, contributed a large COLLECTION OF TOMATOES IN POTS, representing many excellent varieties. About three

dozen plants were staged in pots 10 inches in diameter, and some of the specimens were bearing good crops of fruit. Such well-known varieties as Hathaway's Excelsior and Trophy were particularly good, other noteworthy varieties being Dedham Favourite, Abundance, Nisbett's Victoria, Royal Cluster, and Red Currant.

— AT the same Exhibition Messrs. Sutton & Sons' SPECIAL PRIZES FOR MELONS AND CUCUMBERS were competed for. Two collections were staged, the premier award being secured by Mr. G. Goldsmith, Hollenden, Tonbridge, who staged fine fruits of the Melon Suttons' Hero of Lockinge well coloured and beautifully netted, and Suttons' Hero of Bath also in good condition. The Cucumbers were Suttons' Improved Telegraph and Marquis of Lorne, even and fresh. Mr. G. Steggle, gardener to A. W. Green, Esq., Faulkner's House, Hadlow, Tonbridge, was placed second with good examples of Hero of Lockinge and Victory of Bristol Melons, Duke of Connaught and Improved Telegraph being the Cucumbers shown in the same collection.

— A CHARMING little red-fruited shrub is RIBES OPULIFOLIUM. It forms a dense round shrub of moderate growth with pretty foliage, and is covered all over with berries in short racemes, in colour deeper than the Red Currant, and as ornamental as those of the Mezereum. They are quite insipid, and of no value for culinary purposes.

— A CORRESPONDENT informs us that "The NORTHENDEN FLORAL AND HORTICULTURAL SOCIETY'S EXHIBITION held last Saturday in Wythenshawe Park, was a great success, all the classes being well represented, though the majority were only confined to gardeners and amateurs in the district. Mr. W. Neild, gardener to W. Tatton, Esq.; Mr. G. Coulson, gardener to H. Schill, Esq.; Mr. Jackson, gardener to the Rev. E. L. Y Deacle, were some of the leading prizetakers. A collection of thirty-nine species and varieties of grasses collected in the district, neatly labelled and tastefully arranged, deservedly secured Mr. T. Entwistle of Didsbury the first prize in that class, and were much admired."

— MR. ROBERT WARNER, Broomfield, Chelmsford, writes:—"In the spring of this year for several weeks your paper contained articles on WASPS, one stating that when many queen wasps were seen early or in spring time such a circumstance did not prove that there would be many wasps in the autumn. My gardeners state they never knew so many queen wasps in spring and such a dearth of wasps now. Gooseberries are over, plenty of Plums are ready for them, and yet at present not a single wasp has been seen. Will your readers kindly state in your paper their experience this year?"

— MR. W. CONNELLY, The Gardens, Leagram Hall, near Preston, writes:—"The EARLY POTATO CROP is unusually good here this season, especially the kidneys. We have large, clean, smooth tubers, and plenty of them, but the disease is spreading very rapidly. I have dishaulmed all those that are not quite ready for lifting—a remedy that goes a long way to save the crop if done before the disease reaches the tubers. The late kinds are also looking well, particularly the Magnum Bonums, and as yet quite free from the disease; but I am afraid they will not be free long, especially if the heavy rains which we have had lately continue much longer."

— WE are requested to note that on the 2nd inst. the firm of THOMAS GREEN & SON (Limited), Smithfield Ironworks, Leeds, held the third annual meeting of the Shareholders at the offices of the Company, 96, North Street, Leeds, Mr. Green, Governing Director, nominating Mr. W. Baxter to the chair. The Chairman, in moving the adoption of the last balance sheet, said that during the three years the Company had been in existence

they had paid a dividend of 26 per cent., in addition to which they had written off nearly £6000 by way of depreciation of plant and freehold. They had every prospect of an equally successful year. He also stated that the Company were now removing from their old premises in Blackfriars Road, London, the lease of which expires next year, to those larger and more commodious premises formerly known as the Surrey Chapel. After some further observations the Chairman proposed that a dividend at the rate of 10 per cent. for the year 1881 be declared upon the capital of the Company, to be paid on the 1st of September, free of income tax. This was seconded by Mr. T. W. Green, and carried. Messrs. T. B. Jones & Co. of Albion Place, Leeds, were re-appointed auditors. The Chairman proposed the re-election of Mr. Hebblethwaite as a Director on his retirement by rotation. Mr. Thos. Green seconded it, and it was carried. The meeting then terminated.

LILIUMS.

YOUR correspondent "C. P. P." in last week's Journal desires to know the management of *Lilium lancifolium* and *L. umbellatum* after flowering in pots. We do not grow *L. umbellatum*, but have succeeded very well with *L. lancifolium* and others. The way they are treated is as follows:—After flowering they are placed outside on an ash border till the bulbs are ripe, water being gradually withheld. The bulbs are then taken out of the pots, all decayed matter picked off them, and repotted. The soil used is loam and sand, with a little leaf soil added. If the pots are the same size as we use—namely, 8 inches and 10 inches, a space of about 2½ inches or 3 inches should be left for top-dressing with loam and cowdung in the summer. When potted they may be placed in their winter quarters at once, which is any convenient border where they can be covered with 8 inches depth of ashes. They are left there till March or April, when the bulbs will commence growing, and may be taken to a greenhouse or shed safe from frost. When taken to the former they could be placed in a row on the floor, the side which is least exposed to the sun, as, in case any of them have commenced growing in the ashes, the sun's powerful rays would blacken their bleached stems. They then could be taken for forcing as required, of course taking the most forward first, and leaving the others for later batches.—A. R. P.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 8TH.

SEVERAL features of especial interest distinguished this meeting, but the most important were the fruit trees from Messrs. J. Veitch, the Gladioli from Messrs. Kelway, and the Tomatoes and Petunias from Messrs. J. Carter. The two last-named groups were arranged on tables in the vestibule, the Petunias being particularly attractive. Though not crowded the Council-room was well filled with exhibits.

FRUIT COMMITTEE.—H. J. Veitch, Esq., in the chair. Messrs. J. Veitch & Sons, Chelsea, sent a collection of seventeen varieties of Apples, including Lord Suffield, Ecklinville Seedling, and Hawthornden, very fine. They also sent four plants of Negro Largo Fig in pots, together with some well-ripened fruits of the same variety, for which a certificate was awarded. When fully ripe the fruits are of even turbinate form, 3 or 4 inches long, and dark brown or black. A silver Knightian medal was also awarded to Messrs. Veitch for a collection of fruit trees in pots; Pears, Peaches, Nectarines, and Apples being represented by specimens bearing very good crops of fine fruits. A cultural commendation was awarded to Mr. R. Gilbert, Burghley, for a collection of twelve varieties of very fine Potatoes, of good size, even, and neat. Mr. H. Eckford, gardener to Dr. Sankcy, Boreatton Park, Shrewsbury, sent a collection of eight varieties of Peas, which were characterised by the Committee as very promising. Mr. J. Broadfoot, gardener to Col. Miller, Shotover Gardens, Whatley, sent some fine Late Admirable Peaches. Messrs. J. Cheal & Sons, Crawley, Sussex, sent fruits of Early Lowfield Apple, which was, however, considered inferior to other varieties in cultivation. A bronze medal was awarded to Messrs. James Carter & Co., High Holborn, for a large collection of Tomatoes in pots, including about sixty specimens and nearly as many varieties. Some of the plants were bearing large and handsome fruits.

FLORAL COMMITTEE.—Rev. H. Harpur-Crewe in the chair. Messrs. Kelway & Sons, Langport, Somerset, exhibited a handsome collection of Gladioli, comprising sixty spikes of excellent varieties, several being new, and were honoured with certificates. The flowers were of great size, the spikes being long, massive, and compact. Some of the best varieties, exclusive of those that were certificated, were the following:—Belgica, pale mauve streaked with crimson; Argus, rich

scarlet with white streaks; Sir G. Nares, rose streaked with crimson; Lord Allington, very bright salmon scarlet; Mr. Derry, pale rosy purple; Shakspeare, white, with a crimson stripe in lower petal; Duchess of Westminster, blush, very delicate; Agricola, white, suffused with rose and streaked with crimson. A collection of single Pyrethrum blooms was also staged by the same firm, most of them being large and bright. A medal was awarded for this collection. Mr. Francis Smith, West Dulwich, contributed a collection of double Balsams in pots representing extremely varied colours, the flowers large, full, and of good form. A vote of thanks was awarded.

Messrs. H. Cannell & Sons, Swanley, contributed stands of handsome Show, Fancy, and single Dahlia blooms, the two first-named being distinguished by their size, substance, and good form, while the latter were noteworthy for the brilliancy of the scarlet, crimson, and maroon tints. Some fine blooms of Salpiglossis were also staged, several of a crimson tint streaked with yellow being very distinct and attractive. Mr. T. Ware, Tottenham, contributed a large collection of single Dahlias, for which a vote of thanks was awarded. A number of the best varieties were represented, together with several handsome unnamed seedlings. A collection of varieties of Phlox decussata was also staged, and some fine blooms of the white Clove Carnation Gloire de Nancy. Mr. H. G. Smythe, 17a, Coal Yard, Drury Lane, sent blooms of the new Carnation Mary Morris, a charming rose-coloured self of great merit. A desire was expressed that a plant be shown. A collection of blooms of Carnation Chiswick Red was also sent from the Society's Gardens at Chiswick. It is particularly remarkable for deep scarlet red of the blooms, which are, however, rather small. The General Horticultural Company, Melbourne Nursery, Anerley, sent plants of the glossy red-leaved Caladium Frederick Bause and Nepenthes superba and Hookerae, the former bearing about two dozen pitchers, and the latter having large richly blotched pitchers.

A vote of thanks was accorded to Messrs. J. Veitch & Sons, Chelsea, for a most interesting collection of flowers of ornamental shrubs and trees from their Coombe Wood Nurseries, Ceanothuses, Hypericums, Veronicas, &c., being largely represented. Many very choice shrubs were also included, one very noticeable being Eucryphia pinnatifida with rich green leaves and white flowers. Mr. H. Eckford, gardener to Dr. Sankey, Boreatton Park, Shrewsbury, sent a collection of Sweet Peas, amongst which were several fine varieties, especially one named Bronze Prince, of a rich purple hue, the standard being of a reddish bronze tint. Messrs. J. Laing & Co., Forest Hill, sent a plant of a particularly handsome Tuberous Begonia named Dr. Masters, the flowers being bright scarlet, very large, the petals broad and rounded. Mr. W. Howard, Southgate, was awarded a vote of thanks for a fine collection of Carnation blooms.

A vote of thanks was accorded to Messrs. J. Carter & Co., High Holborn, for an extensive and handsome group of single and double Petunias, which formed a highly attractive display in the vestibule. The plants were very dwarf and well flowered, the blooms large, richly and diversely coloured, and very fragrant. Of the single varieties the most noteworthy were Queen of Roses, White Pearl, Purple Prince, Stars and Stripes, and King Crimson. The best doubles being Double Rosette, Bridesmaid, A. F. Barron, Prince George, Iris, Elaine, Cetewayo, Violet Beale, and Mrs. Hathorn. A pretty and interesting group of Gesneraceous plants was sent from Chiswick, some well-grown Achimenes, Tydæas, Plectopomas, Rosonowias, Eucodonias, and Scheerias being represented.

First-class certificates were awarded for the following.

Gladiolus Bono (Kelway).—Flowers large in a close spike, rich, dark scarlet, the lower petals being tinged with rosy purple.

Gladiolus James McIntosh (Kelway).—Flowers very large, the petals broad, salmon scarlet streaked with a darker shade; lower petals crimson at the base; spike massive.

Gladiolus Ala (Kelway).—A charming variety, rich rose, the base and centre of the petals white.

Gladiolus A. F. Barron (Kelway).—Very bright scarlet, long well-formed spike, neat flowers, the petals being streaked in the centre with white.

Godetia Satin Rose (Carter).—An extremely handsome variety with large, rich, rosy flowers, possessing a satiny gloss that is very pleasing. The plants of dwarf habit and exceedingly floriferous, being one of the most showy we have seen.

Phalænopsis violacea Schröderi (Ballantine).—A beautiful and distinct variety, with large flowers of a uniform bright purple colour, the petals being broad and rounded. It was shown by Mr. Ballantine, gardener to Baron Schröder, The Dell, Egham.

Polypodium vulgare cornubiense Fowleri (Stansfield).—A graceful dwarf variety with finely divided fronds 5 or 6 inches long, and somewhat suggestive in general texture and appearance of some of the slender Trichomanes.

Scolopendrium vulgare crispum multifidum (Stansfield).—A bold distinct Fern with rich green fronds, the margin very strongly undulated, the apex being divided and crested.

Lastrea montana coronans (Stansfield).—A slender graceful Fern with pinnate fronds 1 foot to 18 inches long, the pinnæ being neatly crisped at the apex.

Sweet Pea Bronze Prince (Eckford).—A very distinct variety with large flowers, the keel and wings rich purple, the standard broad, and of a peculiar bronzy red hue.

Petunia Mrs. Dunnett (Carter).—Blooms very large and full, white, rich crimson in the centre. Very fragrant and handsome.

WHY, WHEN, AND HOW WE MANURE OUR VINES.

THERE are two statements in the article by "SINGLE-HANDED" on the above subject, given in your last number at page 95, which are to my mind somewhat misleading if not qualified. I should gather from his words (for so he states) that, "of course, urine [whether of human beings or animals, whether of horses or cows or swine] contains no phosphoric acid." Again, he says, "I used bones very sparingly for two reasons, one being that we have a tank always filled with sewage water, and *that everybody knows* (the italics are mine) *is particularly rich in phosphoric acid.*" I find, however, that although the urine of horses and cattle is practically deficient in phosphoric acid, yet the urine of sheep contains 7 grains of phosphoric acid to the gallon; that of swine contains 49 grains; and the urine of man no less than 119 grains per gallon (these quantities are deduced from Wolf's tables); whereas sewage water contains only from 1 to 1.75 grain per gallon, and "SINGLE-HANDED" mentions that the sewage water he used was "very weak." "SINGLE-HANDED" informs us that in times of drought he had no other water than sewage water, and that he "never hesitated to use it freely, with first-rate results." Few will doubt this, but many, and I among the number, should be inclined to attribute these first-rate results rather to the water than to the phosphoric acid it contains, more especially as on reading further we learn that in the opinion of "SINGLE-HANDED" "among plant foods water occupies the chief place, just as water is the chief item in every bill of fare for animals." . . . "No matter what other food is provided, unless water is used very freely first-rate results need not be expected;" and, again, "Those who have been most successful have all used water freely." I should like to know whether "SINGLE-HANDED" does not really think as I do in this matter, although his words might seem to imply differently.—INQUIRER.

ARRANGEMENT OF FLOWERING PLANTS.

HOWEVER well plants may be grown for this purpose, we often find them crowded together so as to have as much bloom as possible within a moderate space. This is a great failing with many young men, who evidently think that the more plants they can place on a stage the greater is the display, and it is often difficult to induce them to follow a different course. On the other hand, some quickly acquire the art of arranging plants effectively. Where small decorative plants are grown they are often placed so as to form an even bank which has the appearance of being clipped into shape with the shears. This ideal arrangement is carried to excess in many establishments; we cannot blame young men for ideas which they have gained from others whom they have been accustomed to regard as authorities.

In some gardens there is but little opportunity of displaying well-grown plants to advantage. The stages are often far from suitable, and the houses too small. To see flowering plants to the greatest advantage it is absolutely necessary that they be either arranged on the floor or on low stages so that the whole can be looked down upon. Where the stages are ill constructed, even if the greatest care and taste are employed, well-grown plants cannot be shown in half their real beauty. Stages should not exceed 7 to 8 inches in height above the path, and should be from 2 feet 6 inches to 3 feet wide, then elegant arrangements can be carried out with ease. It is essential that the glass be within a short distance of the stage, as with abundance of light amongst the plants the flowers last longer. Some may say, If any arrangement sloping towards the centre of the house were adopted, the pots in the back row and those employed for elevating any plants that require it could be seen from the outside and would prove objectionable. By frosting the glass to 1 foot or 14 inches above the brickwork this disadvantage will be overcome, yet abundance of light would be admitted.

Light and elegant designs can easily be carried out where fine-foliage and flowering plants are associated. To my mind Palms, Dracenas, and similar plants add a beauty and distinctive character to the whole which can scarcely be achieved when they are excluded, though flowering plants may be employed if some of very distinct and elegant habit are included. To attain real success crowding must be carefully avoided. At the same time there should be no approach to scantiness. Each plant should be placed so that its particular attractions are well displayed, and some should be elevated so as to vary the general outline.

Epacris for light arrangements during winter and spring are

invaluable; their long slender stems bearing variously coloured flowers rise well above the more sturdy growers. By growing a number of plants a long succession can be maintained. Celosias with their various shades of rich crimson and yellow combined with their lasting properties command for them a foremost place during the winter when grown in 5 and 6-inch pots. Euphorbia jacquiniæflora should be grown in numbers in small pots, their slender stems and brilliant scarlet flowers gracefully arching above other plants have a most elegant effect. Amaryllises are very handsome; *A. Johnsonii* and its varieties are moderately cheap, and strong bulbs never fail to produce two and often three spikes of flowers. With this variety the flowers are produced before the foliage is developed, and are on this account even more serviceable. They can be grown in 5 and 6-inch pots providing they are liberally supplied with liquid manure while growing.

Begonia manicata and *B. heracleifolia* are amongst the most useful plants we possess. The flowering season can be greatly prolonged by retarding some and bringing forward others in heat until their flowers are about to open, when they will stand conservatory treatment providing the temperature ranges from 45° to 50°, and the flowers will last longer than would be the case if retained in heat. These are not grown in large numbers now, but they are worth any care, and their flowers are also very useful in a cut state for vases. Young plants are best annually produced, and I consider a good batch of the utmost importance either in the stove or conservatory. *Lilium longifolium* is also useful, and if grown in pots for a season or two can be had in flower very early in the season. This *Lilium* I consider the best of all for decoration in small pots, and should be grown in every garden.

Prunus sinensis flore-pleno is scarcely excelled for the purpose mentioned. Plants in small pots with from two to six shoots are preferable to those of larger size. Their slender shoots can be had in a season nearly 2 feet 6 inches in length, and if well ripened will be laden with snow-white double flowers at this season of the year.

Many Orchids are charming for this purpose, but I will only mention one, *Odontoglossum Alexandræ*. Its delicate flowers are produced on a graceful arching spike, and when the plants are judiciously associated with other flowering plants they add considerably to the effect.

It will clearly be seen from the above that formal arrangements are by no means advocated. When plants are staged for effect it is important that they be disposed so as to present a varied as well as pleasing and striking appearance. This is readily accomplished by the exercise of taste and judgment, and a knowledge of what plants are suitable for the purpose.—W. BARDNEY.

GENOTHERAS.

ON my return from visiting several gardens in Surrey famous for their collections of hardy plants, I see no reason to change my opinion about the best hardy *Genotheras* expressed on page 101. I saw nothing to induce me to add to or detract from the list there given, but I find a want of agreement about the names. With respect to one which I received and described as *G. riparia*, I believe the name is incorrect; it is more commonly named *G. cœspitosa* or *G. linearis*, the latter being the name given to it in the garden at Kew. The true *G. riparia* is not unlike *G. fruticosa* or *G. Fraseri*, but inferior to them, and as it flowers at the same time is not often grown. With respect to the two last-named I find a want of agreement, and by gardeners they may be taken as one; but I find that some plants divide the stalk and prolong the flowering part of it, the other being generally simple-stalked and producing more of an umbel of flowers. After consulting "Loudon's Encyclopædia," I conclude that the latter is *G. Fraseri*, and the former *G. fruticosa*. He gives 3 feet as the height of *fruticosa*, and 1½ foot of *Fraseri*, but both exceed these heights in my soil according to situation; the branching species is, however, the taller. Some variation exists in the naming of the species I described as *G. marginata*, a synonym being *G. eximea*: but the former name, though sometimes applied to a species with smaller flowers, is adopted at Kew for the kind with the large white flowers. A species sent to me as *G. prostrata* and *G. acaulis* with incised leaves and medium-sized pale yellow flowers is here a rank weed.—C. WOLLEY DOD.

EXTENDED BLOOMING OF PELARGONIUMS.—I am now referring to the Show, Fancy, and Regal varieties. I have often heard different growers complain of the short time those keep in flower, especially the Show and Fancy types. Some blame the nurseryman, and, I have always thought, most unfairly. Mine are now most beautifully in bloom, but I have always maintained this is dependent on the system

of treatment. Cool treatment and partial shade from the strong rays of the sun are the secrets of extended bloom. To this I might add small pots but rich compost and occasional supplies of liquid manure. W. J. M., Clonmel.

SENECIO PULCHER.

THE Groundsels or Senecios are a very extensive family, numbering nearly one thousand species, very variable in form and size; so remarkable are they in this respect that there is a gradual passage from small fleshy annuals to tall arborescent perennials. They occur in almost every latitude, but are particularly abundant in temperate regions; very strong in Southern Africa, not less than two hundred species finding a home there, and they are very plentiful in temperate South America. In this country they are represented by several species, of which the common Groundsel (*S. vulgaris*) and the Rag-weed (*S. Jacobæa*) are perhaps the most common; and if we were to judge the merits of the family for decorative uses by the former standard we should cease to entertain anything like friendly feelings towards them. Happily, however, many of them are extremely showy, both hardy and tender kinds; many of the alpine species are very pretty rock plants, and by no means common. Of all the introduced hardy kinds perhaps the subject of these remarks is the showiest. It is a vigorous-growing perennial with large fleshy or almost leathery leaves of a deep green colour and shining; the radical or root leaves are variously dentated and lobed, while those on the stem are ragged and irregularly cut. The flower stems are from 2 to 3 feet high, very stout, freely branching at the top, and supporting numerous flowers with the rays of a brilliant purplish-crimson colour, and the disk or centre golden yellow, measuring 3 inches or more in diameter, and lasting a considerable time in beauty. It flowers during the late autumn months, when it is of special interest and very welcome; and when well cultivated it is a most attractive plant—indeed so effective is it that there is no plant in flower with the same coloration comparable to it. *S. speciosus*, more recently introduced, is also a brilliant-flowered species, but I am much afraid that it will not prove hardy with us, otherwise it would be an invaluable addition to our borders.

Cultivation.—It is one of those plants which may readily be cultivated in ordinary borders and with similar treatment, but especially does it thrive in rich loamy soil in a damp situation, as it enjoys plenty of moisture during the summer months. Some plants last season planted in almost a swampy place developed remarkably and flowered very freely; in fact a connoisseur of such plants stated he had never seen the species in finer condition. Some of the flowers measured 4½ inches across, and the rays were proportionately broad, which I consider was entirely due to the circumstances under which the plants were grown. As regards the pot culture of this plant, there is no difficulty in securing good flowering plants by that treatment in, say, 5 or 6-inch pots, using as soil good yellow loam, leaf soil, and well-decayed cow manure with some wood ashes and sand, or in lieu of the ashes fine nodules of charcoal: the latter is of decided advantage in growing the plant. Perfect drainage is also essential, and an abundance of moisture during the growing season; and it would be advisable to plunge the pots in some material such as spent hops or ashes, which would greatly assist to keep the roots cool and moist. The advantages of pot culture would be great, especially in the case of very late-flowering plants, which are liable to be ruined by the earlier frosts, as they could then be easily placed under shelter, and would be useful for the decoration of the conservatory, being well adapted for arranging with groups of plants on the floor. As the stems are tall the flowers would in that position be seen to greater advantage, and would certainly be most effective. If the flowers are very late and it is desirable to secure them from the frost it will be necessary to protect them during the night with a mat or some covering, as I have found it difficult to move the plants when established in the soil owing to the absence of fibrous roots to keep the soil together. The plant is liable to the attack of a rusty-looking fungus, which frequently affects every part of the foliage; this I think is mainly due in many instances to stagnant soil, and charcoal added to the soil appears of great benefit, or flowers of sulphur dusted on the foliage is prejudicial to its development.

Propagation.—When we possess such a valuable plant it is of great interest to know the best way to increase it and contribute in every possible way to its rapid distribution. It is not readily increased by division, but there are still two other methods by which the stock can be multiplied—viz., by seed and root-cuttings. The first plan is not to be encouraged, as, to begin with, the seed is very expensive and very slow in germination, which to the amateur frequently cause great disappointment. The other method—viz., by root-cuttings, is most expeditious though not

generally known, therefore I shall describe it in detail. When the plant is well established large fleshy roots are freely produced about the thickness of straw; these may be taken from the plant any time from early spring till autumn, and, of course, it is only advisable to remove as many roots as necessary to secure sufficient stock, or the plant will suffer severely. The roots should be cut into pieces an inch or more long with a sharp knife, and dibbled thickly in pots of soil and covered with sharp silver sand, so that the upper end of the cutting is just level with the surface of the soil, which should be made up of loam, leaf soil, and sand, with the pots thoroughly drained; and when filled with the root-cuttings the pots should be placed in a cold frame and kept close and

shaded during bright sunshine, if the pots are covered with a bell-glass so much the better. All things being equal, the upper ends of the cuttings will be well callused in a few days, and a bud or buds will be formed, while the lower end emits roots; and in due course young plants will be fully formed, which should be carefully potted in the same kind of soil with some pieces of charcoal finely broken, and placed in a cold frame kept close until they are quite established, when they may be exposed or planted out in the open ground. If kept in pots it is advisable to plunge the pots in some suitable material. By this means there is no difficulty in propagating the plant by the thousand if required. To begin with, it is preferable to purchase plants rather than seeds,

Fig. 23.—MANDEVILLA SUAVEOLENS.

as the latter more frequently cause disappointment than otherwise.—HORTUS.

MANDEVILLA SUAVEOLENS.

WHEN planted out in a border and trained to the rafters of a greenhouse or conservatory *Mandevilla suaveolens* is both attractive and useful, the pure white, exquisitely fragrant, bell-shaped flowers being produced very freely during early summer if the plant be in a satisfactory condition. A compost of two-thirds good turfy loam and one-third of peat, sand, and leaf soil suits it very well, but occasional supplies of weak liquid manure will prove beneficial when growth is advancing. The shoots must be trained in a position where they will be well exposed to light, and it is advisable to allow some of the young growths to hang free, as the plant then has a more graceful appearance. Care is needed to keep the plant clean, as insects, such as scale or mealy bug, are frequently rather troublesome. During winter comparatively little water is needed, giving only sufficient to keep the soil moderately moist.

CHLORA PERFOLIATA GRANDIFLORA.

THIS was the name under which the late Mr. G. Joad, who was a good botanist, used to grow the brilliant biennial, mentioned by

your correspondent on page 32 as being so ornamental in the plant house in the Botanic Garden at Cambridge. Mr. Joad told me that he did not know its origin, but that he believed it to be a variety of the wild British plant *C. perfoliata*. The large-flowered southern natural varieties of some native species, with their many variations in form, are so deceptive that it is seldom safe to disbelieve in identity because of difference in appearance. We are told that the grandiflora forms of *Prunella* are nothing but continental forms of *P. vulgaris*; and our common wild Bluebell (*C. rotundifolia*) is sold under at least a dozen different names, some of them being giant alpine forms, but several of them found on English and Welsh mountains. But many of us would like to know the history of this *Chlora*, which is not yet common in seed

catalogues. It certainly is far less hardy than our native plant, for I had two pans of healthy seedlings killed by frost in a frame in the winter of 1880.

I am not one of those who think that Nature is the best guide in gardening operations, where plants cannot always have their natural conditions supplied to them; but with regard to the time of sowing plants which are biennial in nature, I think the right time is always as soon as the seed is ripe. If seedlings are allowed to be crowded in pans, and are ill supplied with food and water, they are spoilt; but this *Chlora*, like all other biennials, should be transplanted early, and have plenty of room to grow. I have grown it for three years in large quantity both in pots under glass and planted out on sunny rockeries and in sunny beds, and when the sun is out it never fails to attract admiration; but, like most of the *Gentian* tribe, it closes when the sun is off. It is too slender to stand against high wind, and it looks best in a mass skilfully pegged down. I plant it out in May, and it flowers through July and August, ripening seed during the latter month. Can no one tell us its real history?—C. W. D.

LIVERPOOL SHOW.

AUGUST 5TH.

SEFTON PARK in which the Exhibition was held is without doubt the most beautiful public park in the provinces, and by the admirable manner in which it is kept by Mr. Herbert is certainly one of the most enjoyable. The Exhibition under notice was not only the best that has ever been held in the Park, but beyond question the finest early autumn show that has been seen in England this year. It is not too much to say that the specimen stove and greenhouse plants were magnificent, and not a few of them unique; and it is the more creditable to the cultivators of the district that the chief prizes in all the open classes in this section were won by local competitors. Mr. Mease was the premier exhibitor, and the splendid quality of his products entitle him to a high place of honour amongst British gardeners. Fruit was of great excellence, Black Grapes especially being superb, and Muscats fine; Peaches large, and many of them remarkably well coloured. Nectarines were similarly fine; a dish of Pine Apple staged by the exhibitor named being the richest in colour we have ever seen, and of the first size. Pines were admirably represented, but Melons were rather small. Vegetables, excepting the Peas and Potatoes, were perhaps the weakest part of the Show; still the winning collections included superior dishes, notably the cup collection of the redoubtable Mr. Mease. Cut flowers were of great excellence, there being some good stands of Roses notwithstanding the late inclement weather, while the collections of exotic and hardy flowers were of the first order of merit. Miscellaneous groups of plants were attractive, and some of them tastefully arranged, but although decided progress has been made in this section there is still room for improvement. Bouquets on the whole were not of high-class quality, and we should not give a faithful record of the Show if we did not say the epergnes were decidedly bad. Collections of ornamental trees and Conifers were of great magnitude and merit; but the award of the gold medal by no means met with general approval, and Messrs. Ker & Son were regarded by the public as the premier exhibitors. Having given a general idea of the Show we will refer to the principal classes, making no pretence to notice all the exhibits in the three large marquees—one of them a hundred yards in length.

PLANTS.

Stove and Greenhouse Plants.—In the open class for twelve specimens Mr. Mease, gardener to F. Neumann, Esq., Wyncote, Allerton, was first with such specimens as are seldom seen. *Croton variegatus* was 9 feet in diameter, excellent in colour, and faultless in form. *C. Queen Victoria* was grand; 7 to 8 feet in diameter, and, so far as we know, unequalled. The other plants were *Ericas retorta major* and *Parmenteriana rosea*, neat; *Clerodendron Balfourianum* and *Allamanda Hendersonii*, fresh; *Latania borbonica*, *Gleichenia Mendelli*, *Croton angustifolius*, and *Ixora coccinea*. Mr. Pears, gardener to R. R. Raynor, Esq., Hillside, Allerton, was a good second, his notable plants being a fresh and fine *Clerodendron*, *Croton Queen Victoria* in superb health and colour, *C. Disraeli*; fine and most creditable examples of *Calamus ciliaris*, *Latania borbonica*, *Allamanda Hendersonii*, and a fine *Dicksonia antarctica*. In the open class for six plants Mr. Mease was again first with, amongst others, *Allamanda grandiflora*, a really grand and fine *Stephanotis*, with *Vinca alba* and an *Ixora*, both good; Messrs. Caldwell & Sons, Knutsford, and Mr. Faulkner, gardener to F. R. Leyland, Esq., Woolton Hall, securing the remaining prizes with excellent plants. In the local class for ten plants Mr. Leadbeater, gardener to T. S. Timmis, Esq., Grasendale, secured the foremost position, his *Stephanotis* being of rare merit; *Ixora Dixiana* with a hundred bright trusses, *Allamanda Hendersonii*, and *Croton Queen Victoria* remarkably fine. Mr. Cox, gardener to W. H. Watts, Esq., Wavertree, followed, his best plants being *Alocasia macrorhiza variegata* and *Kalosanthes Dr. G. Regel* attracting special attention. For four plants the prizes went to Messrs. Pears and Cromwell. The best specimen stove plant was *Anthurium Andreanum* with seven spathes 5 by 4 inches in diameter, and foliage 14 inches long by 9 inches wide.

He had also the best greenhouse plant—*Kalosanthes miniata*, a semi-globe nearly 4 feet across, like a huge bouquet of rosy flowers. The best *Ericas* were staged by Mr. Cromwell, the plants exceeding 3 feet in diameter and well flowered.

Fine-foliage Plants.—In the open class for eight plants there was excellent competition, Mr. Faulkner securing the chief position with admirable examples of *Areca Baueri*, *Alocasia Lowi*, *Pritchardia pacifica* fine, *Kentia australis* splendid, *Croton Weismanni* 7 by 6 feet, *C. Queen Victoria* excellent, *Latania borbonica*, and *Cocos revoluta*. Mr. Cromwell, gardener to T. Moss, Esq., Aigburth, was a good second, his prominent plants being *Anthurium Warroqueanum* with five leaves from 3 to 4 feet long, *A. cristalinum* remarkably fine, and *Kentia Fosteriana*. Messrs. Caldwell & Sons were third. In the class for six plants Mr. Mease was first with plants of extraordinary merit. The beautiful *Croton Prince of Wales*, 4 feet in diameter at the base and 5 feet high, is with little doubt the finest plant in the country, as it was the gem of the Show; *C. Weismanni*, a grand bush 8 feet in diameter, and *C. interruptus*, 9 feet across, were the striking plants in this group. Mr. Leadbeater was second, staging *Davallia Mooreana* 9 feet across, and *Alocasia metallica* 6 to 7 feet. Mr. Mercer, gardener to Mrs. Crossfield, Aigburth, followed, *Phyllanthus nivosus* being seldom seen in such fine condition.

Ferns.—Mr. Faulkner distanced all competitors in the class for eight plants. *Adiantum lunulatum* 6 inches high and 5 feet across being quite unique, and was excellently matched with a similar mass of *Davallia humata* Tyermanni, while *Nephrolepis davallioides* furcans we have never seen so large and fine, the plant being 6 feet in diameter, with grand arching fronds. Mr. Pears was second in this class, *Davallia polyantha* being admirably grown; and Mr. Gore, gardener to T. Holder, Esq., Prince's Park, third. Mr. Whitfield, gardener to J. T. Cross, Esq., Aigburth, had the best specimen Fern, *Goniophlebium subauriculatum*, 4 feet through, with drooping fronds 5 feet long. For six plants Mr. Cromwell was first, *Lomaria zamifolia*, *Pteris scaberula*, and *Gymnogramma peruviana argyrophylla* being in superior condition. Mr. Stevenson, gardener to Mrs. Horsfall, was second, his group including a most meritorious example of *Adiantum excisum* 4 to 5 feet in diameter, all the rest being good. Mr. Foster, gardener to J. Branker, Esq., Wavertree, had third honours, his notable plant being *Todea superba*, really superb. In the class for ten hardy Ferns Mr. Faulkner was again decidedly in advance with plants of great excellence, followed by Mr. Gore.

Orchids.—Only two classes were provided for these, but the competition and quality of the plants exhibited were superior to any staged at the Society's previous exhibitions. In the class for four plants Mr. W. Sherwin, gardener to Morton Spark, Esq., Huyton, was well ahead with a grand variety of *Saccolabium Blumei majus* with two large spikes, *Cattleya Leopoldii* with eighteen flowers, *Odontoglossum Alexandræ* with one large spike, good variety, with flowers nearly 3 inches across; and a large pan of well-grown *Disa grandiflora* with fully forty flowers. Mr. Edwards, gardener to Dr. Walker, Liverpool, was a good second with *Cattleya crispa*, *Odontoglossum Pescatorei*, *Oncidium Lanceanum* (three spikes), and a good *Saccolabium Blumei majus* with three spikes; Mr. Bostock, gardener to E. Harvey, Esq., being third. For one plant Mr. E. Smith, gardener to R. D. Holt, Esq., Sefton Park, was first with *Aerides suavisimum* with six grand spikes; Mr. Lander, gardener to Mrs. H. Banner, Birkenhead, second with *Oncidium Lanceanum* with six spikes; and Mr. Sherwin third with *Saccolabium Blumei majus* with four spikes. There were eight entries in this class.

Conifers.—Three very fine groups of these were arranged—two, one on each side of the entrance to the grounds, and the other some distance in the grounds near the fruit and vegetable tent. The Society's gold medal was given for the best collection of hardy trees and shrubs, and the Judges pronounced in favour of Messrs. Caldwell & Sons' collection. That belonging to Messrs. R. P. Ker and Son included a good assortment of choice ornamental trees, Hollies, and Conifers. Messrs. J. Dickson & Son also staged a good choice group.

Fuchsias were on the whole far superior to any that have been seen at previous shows of the Society, the plants in the winning classes ranging from 6 to 7 feet high and 3 feet in diameter at the base. The most successful competitors were from Aigburth—namely, Messrs. Butler, gardener to T. Drysdale, Esq.; Leadbeater; Evans, gardener to Mrs. Lockett; Hurst, gardener to W. B. Bowring, Esq.; and Wright, gardener to E. Lawrence, Esq.

Begonias formed a brilliant feature of the Show, and it is questionable if such a large number of huge specimens have ever been seen together before. The prizes offered by Messrs. John Laing & Co. were won by Messrs. Hurst and Evans with comparatively new varieties, and consequently the plants were not large—about 2 feet in diameter, but those older forms in competition for the Society's prizes were wonderful by their size and excellence. Mr. Mease's single specimen of *Vesuvius* was 5 by 5 feet and crowded with brilliant flowers, and the second and third-prize plants of Messrs. Wright (Emperor) and Leadbeater (*Vesuvius*) were little inferior. The collections of six plants from Messrs. Stevenson and Evans were similarly remarkable by their size and quality, as were those of Messrs. Hurst and Wright in the classes for three plants. The competition was spirited, there being dozens of plants 3 to 4 feet in diameter densely covered with dazzling flowers.

Petunias were as fine as the Begonias, and that is saying a great deal; indeed we never saw any to equal those with which Mr. Littlemore, gardener to A. Wilkinson, Esq., Aigburth, won the first prize in the class for six plants. The specimens were dense bushes about 3 feet high, and exceeding that in diameter, the blooms being as regular as if arranged in bouquets, and large and of bright colour withal. Mr. Stevenson followed with smaller but very fresh and fine plants; in fact the majority of the plants staged were very far above the average in which Petunias are seen in pots.

Zonal Pelargoniums, although not equal to the grand specimens exhibited at the York and Leeds Shows, yet showed great improvement, and those in the winning collections were most creditable to the cultivators. The pyramids of Messrs. Whitfield and Evans were 3 to 4 feet high, having a basal diameter of 2 feet, fine in foliage and trusses; and the dwarf bushes of Messrs. Stevenson, Littlemore and Finnigan, were as good as plants of the size could be desired—3 feet in diameter.

Caladiums were grandly shown by Messrs. Mease, Mercer, and Warrington, several of the plants being 5 feet in diameter, admirably furnished with large well-coloured leaves of a foot and more across. The best Coleuses were staged by the last-named exhibitor, 4 feet bushes of the best varieties in excellent colour. The best Lycopods, very fresh and good, were staged by Messrs. Mercer, Wright, and Hurst.

Gloxinias were an attractive feature, and added materially to the beauty of the Show, the plants being well bloomed and the flowers bright and of good quality. Mr. Gowan took the lead with grand plants 18 inches in diameter, followed closely by Mr. Mease and Mr. W. Evans. Cockscombs were very effective, being dwarf and well-shaped. Mr. T. Gowan was placed first, Mr. Leadbeater second, and Mr. Mease third.

Table plants were admirably shown, of the right size and in good colour and condition, the prizes going to Messrs. Jones & Sons, Shrewsbury; G. Park, gardener to R. A. Harrington, Esq.; and T. S. Timmis, Esq.

Groups.—These occupied the centre of two large tents, the one being devoted to the open class and the other to the class provided for local exhibitors. The groups were circular, and arranged for effect, space not to exceed 150 square feet. Mr. A. R. Cox took the lead in the local class with the lightest arrangement in the whole, the centre being occupied with a large plant of *Dracæna Baptisti*, while others of various sizes and variety were dotted here and there, such as *Crotons Weismanni*, *Johannis*, *Disraeli*, and *Cyperus alternifolius variegatus*, the groundwork of dwarf Ferns, Coleuses, Zonal Pelargoniums, Celosias, and Gloxinias. Mr. W. Mease followed closely with choice plants, but their appearance was rather too heavy. Mr. G. Leadbeater followed closely, and was awarded the remaining prize. The groups in the open class were also circular, but not to exceed a space of 250 square feet, the premier honour being given to the Liverpool Horticultural Company (John Cowan). The group contained many valuable plants of new *Crotons*, *Dracænas*, and others freely intermixed with Orchids, *Stephanotis*, *Gloxinias*, *Begonias*, and other flowering plants, the arrangement being rather too close and heavy. Messrs. R. P. Ker and Son, Aigburth Nursery, also staged a choice collection of plants similar in every respect, for which they were placed second. As examples of good taste the gardeners' arrangements certainly surpassed those of the nurserymen, but none were equal to the best groups at southern exhibitions.

Certificated Plants.—The following were exhibited by Mr. B. S. Williams for the first time in Liverpool, and were awarded certificates. *Asparagus plumosus nanus* and *A. virgatus*; *Nepenthes Lawrenceana*, *N. Williamsii*, and *N. Stewartii*; *Capsicum Little Gem*, a valuable decorative variety; *Aralia Chabrieri*; *Areca lutescens gracilis*; and *Amaryllis Mrs. Garfield*, a distinct and beautiful variety with blush flowers veined rose, and the distinct leaf midrib of one of its parents *A. reticulata*. To Messrs. Ker & Son for *Dracæna Lindenii*; *Croton Kingianus* with leaves 17 by 9 inches; *C. flammeus*, somewhat resembling *C. majesticus*, but richer in colour; *C. Duchess*, with leaves an inch wide and 18 inches long, deep yellow; and for a bedding Pelargonium named *Silver Gem*, dense in habit and does not flower. It is presumably of continental origin, and we think was sent to Mr. Cannell under its continental name. Messrs. Kelway & Sons had similar awards for the following new and very fine *Amaryllises*:—*Gheimus*, lilac, boldly flaked with rose, purple spot, very fine; *Lady Derby*, white, bright purple spot, chaste; *Amyntas*, white, flaked rose, very broad petals; *Appianus*, white with rose spot, a smooth and charming flower; *Lord Sefton*, salmon heavily flaked with crimson, distinct; *Aquinus*, lilac blazed with rose, effective.

CUT FLOWERS.

The classes devoted to these were admirably filled, especially those devoted to stove and greenhouse and herbaceous cut flowers. Messrs. Perkins & Sons, Coventry, were the successful exhibitors in the open class for forty-eight Roses, distinct, single trusses; Messrs. James Dickson & Sons, Newton Nurseries, Chester, were good second; and Mr. R. Mack, Catterick Bridge, Yorkshire, secured the remaining prize. There was only one exhibitor in the open class for twenty-four triplets, and Mr. Gittens, gardener to T. B. Hall, Esq., Rock Ferry, was awarded the first prize. In the local class for twenty-four single blooms the same exhibitor was again first with fresh examples. The same exhibitor was also successful for twelve single blooms very fresh and bright;

second Mr. W. Mease, and third Mr. R. Brownhill. There were seven entries. Messrs. R. Dickson & Sons and R. Mack were the only exhibitors for twelve blooms of any dark Rose, and obtained the prizes in the order as named, both showing well Alfred Colomb. In the corresponding class for twelve light Roses Mr. R. Mack took the lead with *Comtesse de Serenye*, Messrs. J. Dickson & Sons second with *Elie Morel*, there being only one point between them; and Messrs. Perkins and Son third with *Capitaine Christy*. T. B. Hall, Esq., was first for the best and most tastefully arranged box of Roses, not less than twelve varieties. The box contained a good number of Tea blooms, which were freely intermixed with *Adiantum cuneatum*. Mr. R. G. Waterman, gardener to A. Tate, Esq., Woolton, was placed second with a neat box.

For eighteen varieties of stove and greenhouse cut flowers Mr. Faulkner staged a wonderful collection, the bunches being large and neat, which gained for him the premier position by one or two points. Mr. Faulkner's box contained *Kalosanthes Madam Wynes*, *Solanum jasminoides*, *Ixora Williamsii* and *Prince of Orange*, *Lapageria rosea* and *alba*, *Gloriosa superba*, *Stephanotis floribunda*, *Statice profusa*, *Dipladenia boliviensis*, *Erica Aitonii*, *E. tricolor Wilsoni*, *E. t. profusa*, and *Miltonia spectabilis*. Mr. Mease's stand contained a grand spike of *Saccolabium Blumei majus*, and the remaining bunches were of great excellence. The last-named exhibitor was first for twenty-four varieties of herbaceous cut flowers (open). The collection, a remarkably fine one, contained *Phlox Oberon*, a grand dark variety; *Lilium auratum*, fine; *Gladiolus brechleyensis*, *Phlox Le Luon*, *Alstromeria aurea*, *Achillea Ptarmica flore-pleno*, *Pentstemon Ethel*, *Lilium longiflorum*, *Galega officinalis alba*, *Agrostemma coronaria*, *Oenothera Youngii*, and *Dahlia Juarezii*. Mr. J. Bostock, gardener to E. Harvey, Esq., Riversdale, Aigburth, was a very close second. Mr. Faulkner was third with a handsome collection. In the local class for twelve Mr. Mease was again first; Mr. W. Bustard, gardener to J. Lewis, Esq., second; and Mr. A. R. Cox third. Bouquets were not numerous nor of superior quality. The prizetakers for two in the open class were Messrs. Jones & Sons, Shrewsbury; G. Downs, Prince's Park, Liverpool; and Colebrook, Dingle Head. For one the second-named exhibitor was first, Messrs. Jones & Sons second, and the same exhibitor third as in the previous class. In the local class Messrs. J. A. Williamson, Colebrook, and J. Agnew, gardener to Mrs. Watts, were the prizetakers. Mr. J. Phythan, gardener to D. Walker, Esq., West Derby, was placed first for an epergne, and needs no further comment. Carnations were neat but small, Mr. R. Brownhill being first for twenty-four blooms, and Mr. W. H. Watts second.

FRUIT

Fruit was of superior quality, and the competition keen in nearly all the classes. The Grape classes were especially well filled, and some wonderful examples of Black Hamburgs and Muscat of Alexandria Grapes were staged. The Peaches, Nectarines, and Pines were also very fine—in fact, it is seldom that such specimens of high quality and in such quantity are seen at any provincial exhibition.

Collections.—In the class for eight dishes of fruit, distinct kinds, not more than two varieties of Grapes, Mr. Joseph Ward, gardener to T. H. Oakes, Esq., Shropshire, took the lead, followed closely by Mr. Faulkner, gardener to F. R. Leyland, Esq., Woolton Hall, Liverpool, and Mr. Edwards, Nottingham. The first collection contained well-finished Muscat of Alexandria and Black Esperione Grapes, Eggleston Hybrid Melon, Queen Pine, Bellegarde Peaches, Violette Hâtive Nectarines, Brown Turkey Figs, and a good dish of Plums. Mr. Faulkner staged good examples of Madresfield Court and Muscat of Alexandria Grapes, large Princess of Wales Peaches, and well-coloured for that variety; Rivers' Orange Nectarine, Brown Ischia Figs, Eleanor Strawberries, and Scarlet Gem Melon; Mr. Edwards having good Chancellor Peaches, Violette Hâtive Nectarines, and very fair Grapes and a Pine. In the corresponding local class for six dishes Mr. W. Mease was well ahead with a grand collection, comprising fine Black Alicante and Muscat of Alexandria Grapes, both being large in bunch, berry, and remarkably well finished; Hero of Lockinge Melon, grandly netted; Violette Hâtive Peach, well-coloured; Moorpark Apricots, and the best dish of Pine Apple Nectarine in the Exhibition. Mr. Elsworthy, gardener to A. R. Gladstone, Esq., Court Hey, Liverpool, was a close second with good Grapes of Madresfield Court and Muscat of Alexandria, Dickson's Exquisite Melon, Pine Apple Nectarine, and remarkably fine examples of Bellegarde Peaches. The third prize went to Mr. Furgerson, gardener to Mrs. Paterson, Rock Ferry, who staged good Black Hamburg Grapes, Royal George Peaches, and Best of All Melon.

Pines.—In the class for two Pine Apples the competition was good, and the premier award was deservedly obtained by Mr. Edge, Cringle House, Cheadle, for really fine fruits, of large size, and well-swelled pips. Mr. J. H. Goodacre, gardener to Earl of Harrington, Elvaston Castle, Derbyshire, was a close second, and Mr. F. Faulkner followed closely. For one Pine the last-named exhibitor was first with a superior Queen, followed by Mr. S. Whitfield, gardener to J. T. Cross, Esq., Beechwood, Aigburth. Fifteen fruits were staged.

Grapes.—In the class for four bunches of Grapes, two white and two black (distinct varieties), there were eleven entries, and all remarkably good. Mr. C. Young, gardener to J. Evans, Esq., Hurst House, Prescott, was awarded the premier award with large bunches of Madresfield Court, good in shape and berry, but slightly under-

coloured; grand Black Hamburgh, with fine berries; good Muscat of Alexandria, and Foster's Seedling, weighing fully seven pounds. Mr. J. Ward was second with smaller bunches, but superbly finished examples of Buckland Sweetwater, Muscat of Alexandria, Black Hamburgh, good berry, but slightly rubbed, and good Madresfield Court. Third Mr. R. Brownhill, gardener to Mr. Hargraves, Rock Ferry, with superb Alicante and Muscat of Alexandria. There were ten entries in the class for two bunches of Black Hamburgh Grapes, which caused the Judges considerable trouble in deciding; but Mr. J. Stephenson, gardener to Major Pilkington, Windle Hall, was accorded the premier honour for superb bunches, not the largest, but remarkably even well-staged bunches, with berries of large size, good in bloom and colour. Mr. I. Barker, gardener to Alderman Raynes, Rock Ferry, was second with bunches equally good in all respects except the berries, which were a trifle smaller. Mr. Washington, gardener to I. John, Esq., Rock Ferry, took the remaining prize with large bunches, well coloured, but a little rubbed in travelling. Mr. T. Furgerson was also awarded an extra third prize for good bunches. There was the same number of exhibitors in the class for two bunches of Muscat of Alexandria, and Mr. Wm. Blomily, Oaklands, Aigburth, took the lead with grand examples, well finished, followed closely by Mr. Mease, the bunches having larger berries but not such a fine amber colour. Mr. R. Brownhill, was third. For two bunches of black Grapes Mr. Mease was first with large bunches of Alicante, grand berries, and superbly finished, Mr. Young staging Madresfield Court, which was all that could be desired in bunch and berry, but scarcely ripe; Mr. Furgerson being third with Black Hamburgh. Mr. Finnigan, gardener to W. Burnyeat, Esq., took the lead for two bunches of white Grapes with Buckland Sweetwater, remarkably fine; Mr. Wm. Blomily second with Muscat of Alexandria, and Mr. Mease third with the same variety. There being nine entries.

Peaches and Nectarines.—Peaches, as before said, were of superior quality, and Mr. Elsworthy took the lead in the open class with Bellegarde, which were the finest in the Show. Mr. J. Delworth, gardener to Mrs. Holland, New Brighton, second with the same variety, but not so well coloured. Mr. J. Pears took the remaining prize with large fruits of the pale-coloured Princess of Wales. In the corresponding class the same exhibitor was again first with the same variety, followed by Mr. F. Roberts, gardener to W. D. Holt, Esq., Sandfield Park, West Derby, with large well-coloured Violette Hâtive, and Mr. J. Pears again third with the same variety as in the preceding class. Mr. J. Wallis, gardener to Rev. W. Sneyd, was first in the open class for a dish of Nectarines with well-coloured Elruge; Mr. Elsworthy second with Pine Apple, and Mr. Furgerson third. In the local class Messrs. J. Hurst, gardener to W. B. Bowering, Esq., and J. Webster were the prizetakers.

Melons.—These were not numerous nor of superior quality. Mr. Wm. Mease took the lead for a green-fleshed kind, followed by Mr. J. Stephenson and Mr. G. Mease, gardener to W. Nichol, Esq., St. Michael Mount. For a scarlet-flesh the same exhibitor was again first with Hero of Lockinge. Mr. Foster, gardener to Mr. Barker, and J. Stephenson were second and third respectively. Messrs. W. Mease and Elsworthy were the only exhibitors for Strawberries, and took the prizes as named. Mr. Hanagan, gardener to R. C. Naylor, Esq., Hooton Hall, Cheshire, was first for Cherries with White Heart, Mr. Dallachie, gardener to Mrs. Zwelchurbart, Aigburth, and Mr. W. Evans, gardener to Mrs. Lockett, second and third. Mr. Hanagan took the lead for six dishes of hardy fruits, which was not shown in large quantities or of extra quality, his best dishes being White Heart Cherries, Early Orleans Plum, Moorpark Apricots, and Citron des Carnes Pears. Mr. W. Mease and Mr. J. Lambert, gardener to Col. Wingfield, Shrewsbury, took the remaining awards.

VEGETABLES.

On the whole we cannot speak favourably of the vegetables, neither do the exhibitors stage them to the best advantage, the Peas and Potatoes being an exception. The former were shown in large numbers and in good condition, while the latter were clean and numerous shown, but too large. The cup collection for twenty-four dishes, distinct varieties, not less than twelve kinds, given by Mr. D. Cuthbert, seedsman, Clayton Square, Liverpool, and won by that successful exhibitor Mr. Wm. Mease, were really the only vegetables worthy of special mention with the exception of those alluded to above. The best dishes in the collection being Orange Jelly and Snowball Turnips; Leicester Red Celery; Intermediate and Early Horn Carrots; Model and Telegraph Cucumbers; Potatoes Woodstock and Schoolmaster; Laxton's Supreme and Telephone Peas; Onions, Giant Rocca and White Italian; Scarlet Runner and Canadian Wonder Beans; excellent Mushrooms; good large red Tomatoes; Longpod Beans, and Globe Artichokes. Mr. J. Richardson, Boston, was first for the collection of twelve dishes (in the open class) with good Ne Plus Ultra Pea, large Tomatoes, and Favourite Potato. There was no name to the second collection, the Tomatoes and Schoolmaster Potatoes being good; Mr. A. R. Cox was third, having a good dish of Dedham Favourite Tomato and Telegraph Peas. The last-named exhibitor, gardener to W. H. Watts, Esq., was first in the corresponding class for twelve dishes; his best dishes were Model Cucumber, Hathaway's Excelsior Tomato, Canadian Wonder Beans, Defiance Red Celery, and Fingland Yellow Turnip. Mr. Faulkner and Mr. Elsworthy being the remaining prizetakers. Nine entries.

Peas were of first-rate quality and well filled considering the unfavourable season. For six dishes in the open class Mr. L. F. Turner, gardener to D. McIver, Esq., Bromborough, took the lead with Carter's Pride of the Market, Telegraph, Baron, Laxton's Supreme, Telephone, and Dr. McLean. Mr. J. H. Goodacre, Elvaston Castle, second with Stratagem, Criterion, Telephone, Williams' Emperor of Marrows, and Walkers' Perpetual. Third, Mr. J. Richardson, Boston, having Triumph good. Mr. A. R. Cox took the lead for four dishes, showing well Culverwell's Giant Marrow, The Baron, Telegraph, and Telephone. Messrs. Turner and W. Mease second and third with much the same kinds. There were eleven entries.

Potatoes were clean, and the classes devoted to them were well filled. Mr. Hanagan took the lead in the open class for six dishes (three round and three kidneys) with Woodstock Kidney, White Kemps, Schoolmaster, Myatt's Prolific, Grampian (good), and International. Mr. J. Richardson followed, having good Lye's Favourite and Breadfruit. In the local class for six dishes Mr. Dallachie took the lead with good dishes of Early Vermont and Porter's Excelsior, other kinds being such as already enumerated. Mr. T. W. Green and Mr. L. F. Turner second and third respectively; the former having good Covent Garden Perfection, and the latter Beauty of Hebron.

For three dishes of Tomatoes Mr. G. Conden, gardener to Wm. Chambers, Esq., Wallasey, was first with good examples of Wallasey Surprise, a grand corrugated variety; Orangefield and Conqueror. Mr. C. Finnigan followed with Stamfordian, Trophy, and President Garfield, very large corrugated fruit. Mr. Ward, Shropshire, third. For one dish Messrs. Sherwin, Conden, and Finnigan were the prizetakers. Mr. A. R. Cox was first for a brace of Cucumbers with Model. Mr. Buttler, gardener to T. Drysdale, Esq., second with Baldwin's Perfection; and Mr. Stephenson third with Defiance.

Miscellaneous Exhibits.—Mr. B. S. Williams, Victoria and Paradise Nursery, contributed a large and varied assortment of choice plants, including all the Holloway novelties. Messrs. R. P. Ker & Son a similar group, including some remarkably fine Crotons and Gloire de Dijon Roses in 8-inch pots, with growths fully 12 feet in length. The Liverpool Horticultural Company (John Cowan) also staged a very interesting group of stove and greenhouse flowering and foliage plants, Vines in pots, and a beautiful circular group of clean healthy Tea Roses in 6 and 8-inch pots, which added materially to the beauty of the Exhibition. Mr. Hooley, Edgley Road, was awarded a certificate of excellence for a group of well-grown Bouvardias. Similar awards being granted to Messrs. J. Laing & Co., Forest Hill, London, for a superior collection of Tuberous Begonias; and to Messrs. Cannell & Sons, Swanley, Kent, for a handsome collection of cut flowers, including double and single Petunias, Pelargoniums, an excellent assortment of Verbenas, and his new double Pansy Lord Waveney, which was certificated. Messrs. J. Dickson & Sons had a number of well-grown pot Vines and baskets of Figs, Osborn's Prolific fruiting freely in 6-inch pots. Messrs. Dickson & Robinson contributed boxes of cut Roses. Mr. James Tynden, Liverpool, staged a box of Gladiolus The Bride, which was much admired. Messrs. Kelway & Sons, Langport, had a wonderful collection of Gladioli remarkable in colour, size of spikes, and flowers, also a grand assortment of single Pyrethrums which arrested much attention. Mr. Amos Ledsham, market gardener, Wallasey, Cheshire, submitted an extraordinary example of fasciation in the Cucumber; the flattened stem exceeding 3 inches in diameter, and in the space of 3 inches a remarkable cluster of thirteen average fruits were produced.

Implements.—The following were highly commended by the Judges. Messrs. Messenger & Co., Loughborough, for garden chair and Loughborough boiler; Messrs. J. Webster & Co., Wavertree, for garden handlights; Mr. R. Rushton for edge-clipping machine; Messrs. Halliday & Co., Middleton, Manchester, for horticultural buildings; and Mr. F. Mee, Wood Street, Liverpool, for boilers and general work.

ORCHIDS IN AUGUST.

THE majority of Orchids are now ceasing flowering, and it is a good time to attend to the Lælias and Cattleyas. These will only require a top-dressing of fresh material if the plants look healthy and fresh, as they are impatient of repotting, but where they seem shrivelled and sickly it is better to repot them at once. It will be advisable also to look for white scale that appears with the young growths, which should be carefully sponged with tepid water and soft soap.

Amongst the plants now in bloom may be noticed Brassia Lawrenceana, which is at its best, bearing its deliciously scented pale yellow, brown-spotted flowers, and Brassia Wrayæ with its yellowish green, brown-spotted blooms, lasting a long time in perfection. These though not very showy are still acceptable, as they fill up the gap between the summer and winter-flowering Orchids. The spikes are very suitable for filling vases and cpergnes, and a fine specimen well flowered is by no means unornamental; they are of easy culture, and do well in an ordinary stove where room is no object. When they have flowered they

should be kept somewhat dry, but not allowed to shrivel, until the new growths produce roots, when water should be given more freely.

Cattleya crispa with its beautiful large flowers is exceedingly fine, as is also *Cattleya crispa superba*, a superior variety of the former, being larger, and the lip of a deeper crimson colour. *C. Eldorado* and its varieties bearing flowers from a pure white with orange throat and white lip, to a deep rose with yellow throat and purple lip, are now blooming finely. *C. guttata Leopoldi* is exhaling a powerful clove-like odour from its lovely brownish yellow, purple-spotted blooms with velvety purple lip. *C. labiata picta*—this beautiful variety of *labiata* is now producing its blush-coloured flowers with crimson lip elegantly margined, and remains a long time in perfection.

Disa grandiflora with its brilliant vermilion, green, and yellow flowers is exceeding attractive. *Maxillaria venusta* is bearing its charming pure white yellow-lipped flowers which are very fragrant, while *Maxillaria nigrescens* is producing its dark port-wine-coloured flowers, exhaling a Melon-like odour. *Oncidium incurvum* with its numerous pale lilac and white flowers is now in grand condition.

Saccolabium Blumci is pretty with its arching spikes of numerous white, rose-stained blooms, which remain in beauty for about three weeks.

Stanhopea insignis, *S. oculata*, and *S. tigrina* are all bearing their charmingly sweet-scented flowers; the latter being the largest and most richly coloured of the genus. *Trichopilia picta*, with its yellowish-green blooms and creamy-white lip spotted with rose, is also in flower.—ORCHIDIST.

REVIEW OF BOOK.

Report of the Experiments on the Cultivation of Different Varieties of the Potato. By THOMAS CARROLL, ESQ., Superintendent of the Agricultural Department.

THE experiments made at the farm of the Munster Agricultural and Dairy School under the superintendence of a Committee of the County of Cork Agricultural Society and embodied in the Report before us were undertaken (1) to compare a number of the Potatoes generally cultivated, in order to discover what kind or kinds would best resist disease and produce the largest amount of food, and (2) to test the merits of potash salts, phosphates, and nitrogen both in the "hydrogenised or ammonia form, and in the oxidised or nitrate form." We are told that since the reading of a paper calling attention to the necessity of improved methods of cultivation by P. W. Ogilvie—a Scotchman evidently, as well as the Chairman—that a great change for the better has taken place both in the quality and quantity of Potatoes in the south of Ireland. It would have been interesting to know in what way such a revolution has been brought about, for "a great change for the better" is exactly what the agriculturists of the whole world want. On this head nothing further is stated, but in the report that follows many valuable hints are to be found, and to a few of these we would specially direct attention.

A number of French and German varieties were grown along with American and home kinds. Some of the Americans did well, but the French and German kinds for the most part did very badly; the crops were small, and even that small quantity was much diseased. Curiously Reading Abbey, a kind sent out as a disease-resister, proved the worst. We in a very different climate have found the same thing. Victoria, at one time the foremost among disease-resisting kinds, also fared very badly. As some varieties escaped disease, although growing beside badly affected varieties, the reporter considers the disease as "non-contagious." Nothing but a profound ignorance of the nature of the disease could have led to such a conclusion. The fact proved seems to be, not that the disease is not contagious, but that "disease-resisting" is a proper epithet to apply to such varieties as escaped.

As showing the influence of good or inferior seed on the ultimate yield, it is curious to observe that seed from one firm manured with ordinary farmyard manure at the rate of 30 tons per acre produced in one instance 13 tons 16 cwt. per acre, and in another 14 tons, while that from a different firm under precisely the same conditions gave only 11 tons 18 cwt. Under the same conditions American Chili gave 14 tons 1 cwt.; Brown Rock, 14 tons 2 cwt.; and White Rock, 11 tons 16 cwt., with very little (in one instance no) disease; so that Champion (Carter's), which gave 11 tons 8 cwt., with 11 cwt. of diseased, is by no means unique either in its yield or disease-resisting powers. Indeed, in this experiment Magnum, Prince Frederick Charles, Black Apple, Redskin Flourball, Brown Black, Moray Blue, Brinkworth's Fortyfold, White Rock, and Skerry Blue are before it, for they were quite free from disease. Unfortunately not a word is said about the table quality of any of these kinds, some of which, in one district at least, are hardly fit for pigs.

In the experiments with special manure Scotch Champion was the variety fixed on. Nothing can be said against the confining of the experiments to one variety, but when that variety is perhaps the most robust in general cultivation it does not follow that the results can be trusted. Many excellent Potatoes require a strong start to enable them to "forage" with effect, whereas the Champion, in common

with a few others, possesses, as we have said, an extremely robust habit and unequalled foraging powers; so much so, in fact, as to make it an exterminator of most ordinary kinds of vegetation, and an effectual impoverisher of any but the richest soils. Should the same experiments be repeated with weaker kinds it is just possible that very different results might be the consequence.

Unless we were to reproduce the tables it would be impossible for us to go over the ground indicated in the Report. In the case of sulphate of ammonia alone we find that 2 cwt. produced 7 tons 15 cwt., but that 4 cwt. only gave 6 tons 17 cwt. Although it is not stated, we suppose the extra application had caused a too great growth of haulm, which often detracts from the underground produce. It was the same with nitrate of soda; 2 cwt. produced 9 tons 8 cwt., while 4 gave only 6 tons 17 cwt. When the ammonia salt and the nitrate were combined the same result followed—too much reduced the crop. We ourselves by sheer dint of heavy manuring have produced Champion shaws 6 feet high with hardly any produce. Sulphate of ammonia and kainit gave 12 tons 10 cwt., and kainit combined with the nitrate gave 11 tons 19 cwt. Phosphates without potash salts gave good results. Sulphate of ammonia and alta vela phosphate gave 10 tons 6 cwt.; but with bone superphosphate the result was only 3 tons 19 cwt., or more than a ton under the yield when no manure at all was given—rather a blow to the manufacturers and manufacturing chemists who put bone higher than mineral, and dissolved higher than undissolved phosphate. With nitrate of soda, however, rather a different story is told. Possibly the excess of acid might be neutralised by the soda liberated from the nitrate of soda, just as Mr. Jamieson found nitrate of soda neutralise the evil effects of chloride of potash. When sulphate of ammonia was given the evil would be increased, hence the very small crop.

In all the other experiments with phosphates sulphate of ammonia gave better results than nitrate of soda, thus showing that the mischief must be attributed to the acid in the superphosphate. Not a word is said on the subject in the Report, which is rather disappointing, for it surely came within the scope of the Superintendent's duty to find out the cause and explain such results. It is rather bewildering to find, too, that while sulphate of ammonia and bone superphosphate gave such poor results, bone superphosphate and sulphate of ammonia gave 11 tons 19 cwt.—a fact which needs an explanation, which is not vouchsafed. Bone superphosphate and kainit gave 13 tons 19 cwt., while kainit with mineral superphosphate gave 14 tons 13 cwt.—a large yield, but exceeded by kainit and alta vela phosphate, which gave 15 tons. Kainit alone (2 cwt.) gave 13 tons 19 cwt.; double the amount, 14 tons 6 cwt. Kainit and curaçoa phosphates gave 15 tons 19 cwt.—a fact which seems to prove that nitrogen may be dispensed with, although we think it a pity that nitrogen should not have been given along with both kainit and phosphates. Farmyard manure collected in the ordinary way and applied at the rate of 30 tons an acre (we presume) gave 13 tons 15 cwt. The same amount collected under cover produced 16 tons 13 cwt. This is a lesson that should be taken to heart, for less material is required to produce a given amount of manure in covered sheds, the rain washing the very best away from that which is exposed. As sulphate of ammonia along with kainit did not increase the crop very much, we hardly know whether to attribute such a remarkable increase in the produce to the greater amount of nitrogen in the manure, or the greater amount of potash salts in which urine is known to be rich, or to both; but taking into consideration the effect of kainit, possibly the potash had most to do with it. As, however, kainit itself is a complicated compound, such reasoning is not safe, even though the chemist employed by the Association tells us that the other matters have "no disturbing influence." This we know to be a mistake, as proved by the falling-off in the crops in the case of the highly scientific experiments under the auspices of the Sussex Association, when magnesia, for instance, was withheld. Kainit, we are told, was chosen because of its cheapness. Scientifically this was a blunder—different forms of pure potash salts should have been used if the object was to ascertain the value of potash for Potatoes. Practically the blunder was a happy one if anything approaching the results gained at Munster Farm can be secured generally with such a cheap compound as kainit is.

One of the things insisted on in the Report need hardly have found a place because of its fallaciousness and because of its being universally followed. We refer to changing the seed. That when Potatoes are badly cultivated and the tubers selected for seed are carelessly selected a change is beneficial we will not seek to deny, and if we did would be speedily and successfully controverted. But we have repeatedly proved, and anyone may profitably prove it, that when Potatoes are really well grown, the seed carefully selected and preserved, improvement and not degeneracy results. To our loss we have found a change of seed under such circumstances not an advantage. Even in the Cork experiments different samples from different sources gave very different results, pointing not so much to the necessity for change in seed as for quality in it. This view we know to be exactly the reverse of orthodox, but it is hardly a matter for opinion seeing anyone can test the matter for himself.

Space forbids us either quoting or further noticing more, but we recommend the Report as well worthy a perusal from which many fruitful hints may be gathered. If we have sometimes in our short notices pointed out what, in our opinion, has been done too much in a haphazard way we hope to be pardoned, for our object is to do a

little towards making such experiments more exact, more scientific, and therefore more useful, and the results more generally applicable. Out of the mass of facts that are being patiently unearthed we ought by-and-by to be able to gather something that will raise our agriculture to a higher pedestal and plant it on a securer foundation.

STRAWBERRIES IN POTS.

THESE should now be transferred to their large pots, as it is best performed when the runners have filled the small pots with roots. For early forcing 5-inch pots are most suitable, as the kinds adapted for this purpose are moderate growers, and for the successional crops 6-inch pots are ample, whilst for late forcing and for strong-growing sorts 7-inch pots may be used. The pots should be efficiently drained, and the soil can hardly be made too firm. Sufficient space should be left for watering, as copious supplies are required. The plants should be placed in an open situation, being on a bed of ashes or other material impervious to worms. Avoid crowding the plants. Each should have sufficient space for development. Good turfy rather strong loam is the most suitable material for potting, with about a fifth of well-decayed manure incorporated. Runners layered into large pots may, now they have become well established, be detached from the parent plant, and removed to a situation where they can be more conveniently watered. Keep them free from weeds, and remove all runners as they appear. When the plants have filled the pots with roots liquid manure may be advantageously applied, as the finer the crowns the stronger will be the trusses of bloom.

FRUIT HOUSES.

Pines.—The suckers, which were produced by the early summer fruiting plants, will now be started. The treatment most suitable to such plants was indicated in our last calendar under this head, which should be continued until growth in the plants is perceptible, when shading should be gradually discontinued and more ventilation given on all favourable occasions. Pine plants in all stages of growth will now advance rapidly, providing they have the necessary attention. See to the state of those beds which have been upset or renewed by the removal of the fermenting beds and replacing of plants, not suffering the heat at the roots to exceed 95° without at once raising the pots, and placing a piece of slate beneath them so that they may stand clear of the material of which the bed is composed, as the consequences resulting from inattention to this matter would be most disastrous, especially in the case of fruiting plants. Shading, which is advisable in houses or pits where the plants are grown near the glass, particularly those having large panes, for an hour or two at mid-day when the sun is powerful, is highly beneficial to both plants and fruit during May, June, and July; but this should now be discontinued, and the plants exposed to every ray of light, with a plentiful supply of air when the temperature in the house stands at from 85° to 95°. Fruiting plants must have a night temperature of 70° to 75°, and successional stock 65° to 70°.

Vines.—Muscats, Lady Downe's, and other late Grapes, to insure their keeping fresh and plump through the winter, should be ripe and well finished off by the second or third week in September. To effect this a little fire heat will be necessary to maintain a maximum temperature of 85°, and a minimum temperature of 70°, with a steady circulation of air day and night. Assuming that the roots were well supplied with water and mulchings during the swelling period, healthy Vines under this treatment will be certain to afford satisfactory results; but where there has been any neglect during the swelling process it may be expected to show itself during the ripening in imperfect colouring and shanking. Keep the laterals well stopped; and although Muscats cannot endure the direct rays of the sun through large panes of glass, they must have plenty of light to ensure the golden colour characteristic of good finish. Examine

the borders inside and out, and if at all dry soak well with tepid water. Red spider is unusually troublesome, and it is necessary to dress the pipes with sulphur upon its first appearance.

Late Hamburgs will only require fires to maintain a night temperature of 60° to 65°, and 70° to 75° in the daytime, advancing to 85° from sun heat, ventilating from 75°, and freely between 80° and 85°. See that there is no deficiency of moisture in the borders, and if necessary afford tepid water or liquid manure at 80° liberally. Moderate extension of the laterals may be allowed where the Vines are carrying heavy crops of fruit, and especially when the Vines are weakly, otherwise keep the laterals well stopped. Houses with the Grapes colouring should have a rather dry warm circulation of air day and night, giving what air moisture is needed by damping the borders in the early part of the day.

Very early Vines having the wood fully ripe may now have the laterals cut back close, and in a few days some of the longest shoots can be shortened back, but defer the final pruning until the leaves are all or nearly all down. The outside border should be protected with some waterproof material to ward off heavy rains, as a saturated condition of the soil is not conducive to early and complete rest. The borders of early houses must be renovated, as it is always desirable to keep the roots of the Vines near the surface. Remove the old surface soil without injuring the roots; supply good loam, with which has been incorporated a small proportion of crushed bones, wood ashes, and charcoal.

Vines in pots intended for very early forcing now have the wood ripe, and will rest all the sooner if moved into the open air and placed at the south side of a wall or fence, to which the canes should be secured to protect them against injury from wind. Provision should also be made to protect the roots from heavy rains, which would prove injurious by destroying the roots, and overdryness is equally so, hence extremes should be avoided. If by any means the canes are not ripening well fire heat should be applied forthwith, and be accompanied with abundance of air. All attempts at lateral growth should be checked by pinching, but all the old foliage should be retained and allowed to fall naturally. Ripe Grapes will require frequent examining for the removal of shanked or decayed berries.

Melons.—Place the last batch of plants out at once, and maintain a moist genial condition of the atmosphere with a temperature of 70° at night, and 75° to 85° or 90° in the day, with ventilation upon all favourable occasions, seeking by a firm condition of the soil and not too moist a condition of the soil and atmosphere a short-jointed, sturdy, solidified growth. Remove every alternate lateral as soon as they appear, and stop the primary growths when they have extended two-thirds across the trellis, pinching the laterals at the second joint if they do not show fruit at that on the first laterals. Commence fertilising the blossom when three or four on a plant are expanded, and do so daily until about half a dozen fruit on a plant are set and swelling, when all above that number should be removed. If the plants are weakly about three or four fruits to a plant will be sufficient. Keep the laterals closely pinched and well thinned, so as to give the principal foliage the full benefit of sun and air. Earth up the roots after giving a good watering when the fruit is fairly swelling. Dispense with fire heat as long as possible by the husbanding of a good sun heat, closing the ventilators early in houses with growing crops, maintaining a moist atmosphere to all plants not setting or ripening the fruit. Shade no more than is absolutely necessary to prevent flagging and scorching.

Cucumbers.—Plant the autumn fruiters on raised hillocks or ridges made moderately firm. Where autumn-fruiting plants are not grown, seed to raise plants for winter fruiting should be sown, so that the plants may be sturdy and fit to place out not later than the middle of September. Telegraph is one of the most reliable sorts. Let the work of trimming plants every week be regularly attended to, removing the exhausted growths to make room for young bearing wood. Maintain a healthy root-action, not allowing to become dry at the roots, supplying liquid manure. Shade only to prevent flagging and scorching. Syringe freely as early in the afternoon as the brightness of the sun will permit, closing the ventilators for an hour or two, and afterwards reopen them for a short time to allow of the

escape of rank steam and moisture, it being essential that the foliage be dry before night.

PLANT HOUSES.

Stove.—Gesneras of the zebrina section must not be placed under the shade of other plants, but must have a light position to induce stout short growth, which is essential to their free flowering and the development of their handsome foliage. They should have weak liquid manure occasionally, and not be too freely watered, nor must the foliage be allowed to flag. *G. Cooperi* and *G. Donckelaari* will, if well attended to, throw up second flowering shoots, and bloom well if encouraged with liquid manure and kept in a light position.

Gardenias from cuttings struck in spring and grown on for winter flowering should be well attended to, not allowing them to become root-bound, but shifting into the blooming pots—6 or 7-inch—at once, so as to get them well established before the short days. Every care should be taken to keep them free of mealy bug and other insect pests. They should be grown in plenty of light, so as to harden the growth and induce free-flowering.

Pancretium caribæum, *fragens*, and *ovatum* bear large umbels of pure white fragrant flowers from June to August; the flowers, of lighter appearance and greater elegance than *Eucharis*, and expanding successively, are very useful for cutting, being very chaste for bouquets. They are of easy culture, and should have a place in every stove. Turfy yellow loam with a fifth of leaf soil or well-decayed manure and a slight admixture of sand suits them perfectly. Plants that have flowered will be starting into growth, and should be well supplied with moisture both at the roots and in the atmosphere, feeding occasionally with liquid manure, as the finer the growth and bulbs the stronger they will throw for bloom. A position near the glass should be given them to insure thick leathery foliage. Being evergreen they ought not to be dried off, but have the soil always moist; lessened supplies of water, however, being necessary when at rest than during growth. *Amaryllis* having completed their growth should have a light airy position, or may be stood in a pit and have water to maintain the foliage in good condition to the last, keeping them free from red spider by syringing, or the leaves should be sponged with soapy water occasionally. A little weak liquid manure occasionally will assist in developing fine bulbs, which invariably throw the finest flower scapes.

The earliest-flowered *Gloxinias* may now be gradually dried off, not withholding water altogether, but giving sufficient to keep the foliage from flagging. Any choice varieties may have the leaves inserted in sandy loam around the sides of a 6-inch pot; and kept close, moist, and shaded from bright sun in gentle heat, they will soon form a bulbous callosity, and be available for next year's flowering.

Toxicophlæa spectabilis and *T. Thunbergi* are well worth growing for their odour, a few flowers scenting a house. The flowers are white, borne in corymbs (not unlike an *Ixora*) from the points of the shoots and axils of the leaves. They do best in an intermediate temperature or cool stove, and do not require a great amount of root space, thriving in sandy peat. *Jasminum gracillimum* promises to be one of the finest of winter-flowering plants for decorative purposes and for cutting from. It is of free growth, and blooms profusely, the flowers being borne in a cluster, pure white and very fragrant. It is of very easy culture, doing well in sandy loam with a little leaf soil. It should be now placed in plenty of light to harden up the growth, and it will flower in October through the winter. Plants well bloomed in 6-inch pots are fine for table decoration, its graceful habit peculiarly fitting it for that purpose.

Climbers trained to the rafters improve the appearance of the house, and where cut flowers are in request in quantity it is absolutely necessary to have such plants as *Clerodendron Balfourianum*, *Bougainvillea glabra*, *Allamandas Hendersoni*, *nobilis*, and *cathartica*, along with *Dipladenia Brearleyana* and the indispensable *Stephanotis floribunda*, are better planted out, but if allowed to become too large they do serious injury to the plants beneath by excluding the necessary light. Climbers in restricted borders should be well supplied with liquid manure.

THE BEE-KEEPER.

AUTUMN TREATMENT OF STOCKS.

THE present season from its beginning till now (August 5th) has been unfavourable for bees and most discouraging to young apiarians. Owing to last winter being open and warm, bees, generally speaking, consumed most of their stores, and therefore their hives were unusually light in spring, and in most cases and places have been during the spring and summer months at the doors of poverty. With scant supplies in side hives and gloomy skies above them bees are discouraged, and wisely or instinctively abstain from extensive breeding. In such circumstances bees make little progress, and move slowly up to the swarming point. This season has been a remarkable one for slow growth, drone-killing, late swarming, and unwillingness to swarm at all. In some hives that were heavy in autumn the bees have neither felt nor feared the approach of poverty, and have done better. Bee-keepers of experience know that hives with sufficient stores in them are less affected by unfavourable weather, and continue to multiply their numbers often, while weaker hives abandon breeding and cast out their drones. Bee-keepers have had abundant evidence of this during the last few years, and every year's experience strengthens and deepens our convictions on the subject. In September at latest bees should have stores enough laid up to keep them till the end of the March following, so that feeding is unnecessary during winter and early spring. About 15 lbs. of honey or syrup keep a large swarm or stock from September till March. A straw hive and board weigh about 10 or 12 lbs.; bees from 5 to 8 lbs.; combs-farina about 7 lbs., 15 lbs. of honey, thus making a good stock about 40 lbs. in weight. Boxes and bar-frame hives are considerably heavier than straw, and therefore their weight in September should be rather more.

In apiaries kept for profit autumn treatment is considered a point of the greatest importance. Hives properly treated in August and September need but little attention in winter and spring, cause no anxiety or fear, but foster hopes of a successful future. To have strong hives in autumn should be the aim of every bee-keeper. The great secret of success lies here, and therefore let us here notice some points of importance in autumn treatment. At the end of the season, when hives begin to lose weight, one of the first things to be done is to select hives for keeping another year. The best for this purpose are those that are full, or nearly full, of young sweet combs straightly built, the central combs well filled with brood and without many drone cells. The longer we practise bee-keeping the more clearly do we see the importance of having the apiary filled with stocks with young combs. This statement has been often repeated, because it cannot be too well or widely known. Old combs are objectionable from every point of view. The central and greater parts of the combs of every hive are filled with brood several times every year, and every cell becomes less by the cocoon or skin of every bee reared in it. The walls of the cells become thicker, and in this way the cells are contracted and give less space for the development of brood and for the storing of honey. Old combs often become filled with pollen, and are then worse than useless, for they occupy space and cannot be used for either breeding or storing purposes. Foul brood, the scourge of many an apiary, is very rarely found in young combs; and if the practice of changing stocks every season be followed foul brood will never do much harm and need not be feared. Hives, then, with young combs are to be preferred for stocks.—A. PETTIGREW.

(To be continued.)

FORECASTS OF VARIOUS KINDS.

THE EFFECTS OF COLD—POLLEN-GATHERING—INFERTILE QUEENS.

THE milder the winter the more complete will be the repose of the bees, and the lower will they be able to allow the temperature to become even when they have their winter quarters, whilst increasing cold stimulates them to breathe more frequently and to consume more food; in other words, it stimulates their vital powers to greater activity in order to be able to offer the necessary resistance to the cold. It will be seen from this whether it is advisable to keep bees exposed to the cold in winter. Theory and experience, as well as the last mild winter, demonstrate to us practically the fallacy of this opinion. Exposure of the bees to extreme cold certainly causes them to crowd together into as thick a cluster as possible, but it does not send them into a sleep-like state of repose. On the contrary, it startles them out of their rest,

compelling them to hum more loudly, while previously they were in perfectly silent repose. Nor does severe cold prevent premature breeding. There is generally more brood to be found in the hive in January and February, when the weather is very cold or after the temperature has been very low, than during a continuance of mild weather. Dr. Krasicke acknowledges this fact, but explains it in a peculiar manner by saying that because bees consume more food when the temperature is low, the production of chyle would also be greater. But it is a known fact that in order to create a higher degree of temperature bees consume a large quantity of honey only. The latter, however, only supplies an increased quantity of excrementitious matter as secondary product, but no chyle. The presence of much excrementitious matter in their bodies, on the contrary, renders the bees more incapable of producing chyle. It is the disturbance of their rest and incitement to activity in order to raise the temperature which also directly affects the queen, inducing her to deposit eggs sooner than she would have done if the weather had continued mild. The principal cause of early breeding, however, is the presence of much moisture, which forms inside the hive when the temperature outside is lower; water, as is well known, forming by far the largest constituent of the food of the brood, and want of water prevents or restricts breeding.

During mild weather, when the difference in the temperature of the air inside and outside the hive is but insignificant, little or no moisture is precipitated, just as the windows of our rooms condense no moisture then. At such a time the bees may be suffering from want of moisture, but as long as the suffering does not become acute it does no harm. It has rather the advantage that it keeps the bees back from breeding until they are able to fetch in sufficient quantity the water which is indispensable in the preparation of chyle. It is best that breeding should be delayed till such a time when the bees are able to gather fresh pollen in considerable quantity, as many colonies, especially young stocks, possess but a small stock or none at all of this material, which cannot be dispensed with when food is to be prepared for the brood. This is generally the case at the time of flowering of the Alder tree, so that hagsful might be collected from many trees, especially from those in isolated positions, and the bees might supply themselves from this source with pollen for the whole year. If favoured by the weather they could take full advantage of the Alder flowers, which mostly make their appearance in March. Unfortunately, however, on account of the uncertainty of the weather at that time of the year, the pollen harvest is frequently a complete failure; and should the weather happen to be favourable, the flowering time of the Alder passes too quickly to be fully utilised. The flowering season of the Alder might be artificially prolonged if branches with plenty of flower-buds were cut off and kept in a cool and shady place until the flowering time was coming to an end, when they might be put into the ground in a sunny spot near the apiary. But on account of the uncertainty of the bees being able to fully utilise these flowers, even if in the neighbourhood of the apiary, we might render them a far greater service if we took the trouble at the time of falling of the Alder flowers to collect the pollen which Nature offers in such abundance in order to supply the bees with it. We might perhaps moisten it with honey and squeeze it into the cells.

I have taken this trouble in former years, but found it rather a tedious and troublesome labour, and I have often asked myself the question whether it would not be possible to obtain the valuable substances which pollen contains—viz., the nitrogen, the essential oils, the ferments and salts from the entire buds, if these were collected before the pollen became scattered abroad by the wind, either by a process of drying or roasting, by pulverisation, or dissolved as a kind of tea, and to make them palatable to the bees by mixing them with honey. The solution of this question would be a worthy and most commendable task for bee-masters who at the same time are thorough chemists.

It would certainly be better if the various artificial contrivances to keep our bees supplied with the substances their economy requires were not needed. The weather late in last summer and in the autumn was most unpropitious for the impregnation of queens, and in this district at least rendered it altogether impossible. In former years it was a rare exception in my apiary to find queens remaining unfertilised even if reared late in the season. Even about Michaelmas, when one would naturally expect all drones to have disappeared, my queens still became fertile if only a few really fine days intervened to allow them to fly out again and again, and often far away from their hive. In the year 1867 the weather during the whole month of September was inclement and cheerless, and not one young queen became fertile, but on the 8th of October a calm, warm, and sunny day followed. After the bees had been playing joyfully I examined several hives with

young queens in the afternoon, and found that eight of them exhibited the sign of impregnation; in fact, all my queens qualified for impregnation became fertile, although the number of drones in my apiary scarcely amounted to a hundred.

All the young queens which had not become impregnated at the time of our meeting at Erfurt last year remained unfertile, and had finally to be thrown away as worthless. Warned by this experience I examined afterwards five parent hives, in which I certainly did not expect a change of queen to have taken place, and discovered either no queen at all or a virgin queen, and was obliged to unite these stocks with smaller colonies, as I had no longer any spare queens at my disposal. In this respect the mild weather which prevailed late in the autumn, and even this winter, was also very welcome, as it enabled operations to be performed which in colder weather could not very well have been attended to.—DR. DZIERZON, *Carlsmarkt, 11th January, 1882.*—(From the *Bienenzeitung*, No. 4, 15th February, 1882. Communicated by Mr. Alfred Neighbour.)

BRITISH BEE-KEEPERS' ASSOCIATION.—The annual Exhibition of this Association was held in the east and west quadrants of the Royal Horticultural Society's Gardens from Thursday the 3rd instant to Tuesday the 8th. Exhibits were numerous, hives of all the most approved forms, samples of honey, extractors, sections, artificial foundations, and other appliances useful to the bee-keeper being largely represented. A tent was also provided, in which demonstrations of the chief operations in connection with the apiary were frequently given.

TRADE CATALOGUES RECEIVED.

Wm. Cutbush & Son, Highgate and Barnet.—*Catalogue of Bulbs.*
Wm. Paul & Son, Waltham Cross.—*Catalogue of Bulbs.*

* * All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Seedling Achimenes (G. H.).—The majority of the flowers had fallen off the specimen you sent, but from what remained it appears to be a pretty and distinct variety, though the blooms are small. We doubt if it would possess any trade value, however, as there are many more showy varieties in cultivation. Its dwarf free habit is a recommendation, and you should certainly give it a good trial before discarding it.

Exhibiting (A Reader).—According to the terms of the schedule, if the gardeners you name showed produce grown in their employers' gardens they should certainly have been disqualified, but of course in any proceedings that may be taken it will be necessary to prove that point, and possibly this may be rather difficult. It is manifestly unfair and contrary to the spirit of the regulations in the schedule that the two classes of exhibitors which you term A and B should be allowed to compete together, as the latter would have greatly the advantage. Have you directed the attention of the Secretary and Committee to the matter? If not, that course would be advisable before proceeding further.

Raspberry Canes Dying (J. E.).—The most common cause of the canes dying is the wood being gross in the previous season, and consequently not well ripened. Such growths usually fail in the early part of summer during the prevalence of east winds or sharp frosts. There is no remedy except a less rich and firm condition of the soil, so as to induce shorter-jointed and more solidified growth, leaving sufficient space between the stools to admit light and air freely. The canes sometimes die through being pruned and tied during frosty weather, which injures their tissue.

Late Strawberry (Idem).—Helena Gloede is larger and later than Frogmore Late Pine, and in every way superior. It does best on heavy land, being on light soils much subject to mildew. Loxford Hall Seedling is a very fine variety; it succeeds well in heavy soil, and for travelling is one of the best. Pioneer is a fine early kind, and succeeds well in heavy soil.

Elaterium (C. L., Surrey).—The drug bearing this name is obtained from a plant related to the Cucumber, *Ecbalium agreste*, or Squirting Cucumber, which is as you state cultivated at Mitcham. The fruit is like a small oval Cucumber, about an inch and a half long and an inch in diameter, and is covered with stiff hairs or prickles. When fully ripe it separates from the stalk, and throws out its juice and seed with considerable force through an opening at the base, where it was united to the stalk; it is from this circumstance that the name is

derived. When the fruit is sliced and placed upon a sieve a perfectly limpid and colourless juice flows out, which after a short time becomes turbid, and in the course of a few hours begins to deposit a sediment. This, when collected and carefully dried, is very light and pulverulent, of a yellowish-white colour slightly tinged with green; and this is genuine elaterium, which will purge violently in the dose of one-eighth of a grain. The mode in which it is obtained at Mitcham is to slice the fruit longitudinally in halves, and then press it with considerable force, wrapped in a hempen cloth, with a common screw-press. The juice is then strained through a hair or wire sieve and set aside to deposit, which usually is completed in three or four hours. The liquor is then carefully poured off, the deposit is placed on calico cloths resting on hair sieves, and allowed to drain for about twelve hours, after which it is removed with a knife, spread over small cloths, and dried on canvas frames in a drying stove. About half an ounce of elaterium is obtained from 40 lbs. of the fruit.

Learning Gardening (Wild Rose).—There is a great difference between what you said in your previous letter and in the one now before us. There are many, we fear, who have not so much time for study as is desirable; still by utilising even odd moments diligently an earnest man will not fail. You had better work perseveringly in a small place for a year or two, not attempting what is beyond the resources of the garden, but whatever you undertake do well. First experiment with such free-growing plants as Coleuses, Fuchsias, Chrysanthemums, Pelargoniums, Balsams; then as you succeed with these you will be gathering knowledge that will enable you to grow such other plants as are within your means. Vine culture is easily learned. We do not advise at first to procure the expensive work referred to, but get the "Cottage Gardener's Dictionary" (price 7s. 6d.), our "Garden Manual" (price 1s. 6d.), our "Vine Manual" (price 3s.), "Pearson on the Vine" (price 1s.), our "Window Gardening" (price 9d.), and "Greenhouse Manual" (price 9d.). You will thus at a trifling outlay have a small gardening library of great value. But apart from the information contained in these works you must study current gardening literature. Read the *Journal of Horticulture* regularly and attentively, and never a week will pass that you will not obtain knowledge that will bring you nearer the goal you appear to be laudably desirous of attaining.

Ornamental Cucurbits (Lorrimore).—Several members of the family Cucurbitaceae, exclusive of the large Gourds, are ornamental when well grown, such as Cucumis perennis with globular green fruits streaked with white; Cucumis metuliferus with lemon-shaped yellow or scarlet fruits covered with short thick protuberances; Cucumis dipsacens with buff or bright green fruits. But one of the prettiest is Cucurbita melopepo depressa, shown in fig. 24. Of this the fruits are bright yellow, regularly striped with green from base to apex. A charming little plant of this class, when well grown, is Cucumis prophetarum, also known as C. grossularioides, the Gooseberry Gourd, as it is popularly termed from the resemblance the fruits bear to Gooseberries. They are freely produced in pairs from the axils of the leaves, and are very evenly streaked from apex to base with dark green and yellow alternately. An excellent illustration of this species was given in this *Journal*, page 181,

Fig. 24.—Cucurbita melopepo depressa.

vol. iii, new series. The seeds of all such plants should be sown in heat, afterwards affording them similar treatment to Cucumbers—namely, a good temperature and abundance of water.

Clematisses in Pots (J. E.).—The following particulars respecting the culture of Clematisses in pots were given by Mr. Bardney on page 349 in No. 45, vol. ii, new series:—If the plants are in 5-inch pots when obtained, and are well rooted, they should be transferred to 7-inch pots. The pots should be well drained, the old drainage being removed and the roots disentangled. This operation will cause no injury, as they are strong-rooting plants. Potting is best done a short time before the plants are started into growth. A shift into a larger pot every year, according to the progress they have made, is sufficient until they are placed into 10 or 12-inch pots, which are large enough for decorative purposes. When in the last-named size annual potting is still recommended—that is, by removing a portion of the old exhausted soil, renewing the drainage, and again placing them in the same sized pot with fresh soil. The soil cannot be too rich; good rich loam, a third of decayed manure, and coarse sand to render the whole porous will suit them well. While growing Clematisses require liberal applications of water at the roots, and in no stage should the soil be allowed to become very dry. When the pots are full of roots stimulants can be liberally supplied. After potting, if the plants are placed in a temperature of 45° to 50°, they soon commence growing. When the wood is nearly mature the shoot can be tied to stakes and the plants placed outside, where they may be allowed to remain until the approach of frost, and then be protected in a cold frame or house. The earliest-blooming varieties of the Patens section, of which Lady Londeshorough is the type—one of the freest, earliest, and best for forcing—will, if gently started at the commencement of the year, produce a few flowers in the spring. This section furnishes the most varieties suitable for pot culture, especially for early flowering during February, March, and April. Most of the varieties flower profusely and require no pruning, as the flowers are produced on the previous year's wood. There is but little difficulty in inducing plants to flower early; one or two seasons' early starting is sufficient. Our plants commence growth in a cold frame towards the end of November. The following varieties are arranged in the order they flower:—Lady Londeshorough, Standishii, Miss Bateman, Albert Victor, Lord Londeshorough, The Queen, Sir Garnet Wolseley, Fair Rosamond, and Sophie flore-pleno. Some further particulars are also given in the same article upon propagating Clematisses.

Layering Carnations (A Young Gardener).—Layering should be done as soon as possible after the shoots are long enough to be pegged down easily, and in the following manner, as detailed in our manual "Florists' Flowers for the Many." A layer is a branch or shoot brought down to the ground, and when rooted separated from its parent. The materials wanted for layering are a sharp small knife, a quantity of hooked pegs (the fronds of the common Brake or Fern are the best, though the pegs may be made of Birch or Hazel), and some finely sifted soil. When the shoots round each plant have made five or six joints or pairs of leaves, choose a dull cloudy day on which to perform the work; or, if

the plants are in pots under an elevated awning, they may be layered in any weather. Commence by trimming off the leaves from the bottom of a shoot, leaving the two uppermost on and entire. Trim off the lower leaves on every shoot before layering one, because when a layer is tongued it is easily broken off. When this is done take hold of the shoot, turn it up, and pass the knife blade through the third joint upwards, commencing the cut just below it; then reach a hooked peg, thrust it into the soil, catching hold by its hook of the layer as it descends, and press it gently down to the soil. Do the next in the same manner, and so on till every shoot is layered, then cover them all with the sifted mould about three-quarters of an inch deep, and that pot or plant is completed; then give a slight watering, and the layers want no further care till they are rooted, which will be in about a month or six weeks. Examine them occasionally, and as soon as roots are emitted pot them off into 5-inch pots, a pair in each; or, if your space is limited and the layers small, three may be put into each pot. After they are potted they should be placed under glass in a cold frame or pit, plenty of air being given in mild weather and shelter from severe frost when it occurs. Very little water is required through the winter months, and the air in the frame should be kept as dry as possible. Should damp prevail, the plants some fine day should be taken out and fine dry coal ashes spread on the surface. The plants should be replaced in the pit.

Rhynchospermum jasminoides not Flowering (W., Chelmsford).—Overpotting is probably the chief cause of your plant not flowering. Small pots, well-ripened wood, and a moderate temperature are three important points in the culture of this plant. Take your plant out of the hothouse at once to a sunny airy position in a greenhouse or orchard house, give only enough water from the present time till March to keep the foliage healthy, and keep the plant in the greenhouse where the usual winter temperature of 40° to 45° is maintained, thus letting the winter be a period of complete rest. In March cut off any bare old growth and thin any that is crowded, shortening the remainder to induce a plentiful growth of young shoots, at the ends of which the flowers should appear. Just as growth begins shake out the plant from its large pot and examine the roots; if they are crowded in the soil and the drainage is good replace in the same pot, but if there is much soil without roots then remove it and repot in a size or two less, picking as much of the old sour soil from among the roots as possible, ramming hard some fresh sweet soil around the ball. As the growth makes progress give more water, but do not remove the plant from the greenhouse till the flowers fade, then turn it out of doors, standing the pot upon a bed of coal ashes in any open yet shaded nook, and keep it there till the autumn.

The Cherry Plum (J. V. W.).—The fruit you send is known by the above name. It is also known as Early Scarlet, Miser Plum, Myrobalan, and Virginia Cherry. It may be used in the dessert more as an ornamental variety than for its flavour, but it makes excellent tarts. Ripe in the beginning and middle of August. The young shoots are smooth, slender, and thickly set with buds. This is the Prunus myrobalana of Linnæus. It is frequently grown in shrubberies and clumps as an ornamental tree, where in spring its profusion of white flowers render it an attractive object.

Names of Plants (Constant Reader).—We do not undertake to name varieties of Coleuses. (X. L.).—1, Fuchsia gracilis; 2, Herniaria glabra; 3, Escallonia macrantha. (W. R. S.).—1, Pteris quadriaurita; 2, Adiantum tenerum; 3, Asplenium cicutarium; 4, Selaginella Martensii. (R., York).—1, Retinospora obtusa; 2, Cupressus Lawsoniana; 3, Quercus cerris; 4, Thuia orientalis. (H. H.).—Rhus Cotinus.

Removing Supers from Hives (J. McNair).—This is the easiest and most pleasant work of the apiary. First cut the super from the hive by drawing a piece of brass wire or twine between them. If any nails or impediment prevent the wire from cutting them asunder use a thin table knife. Then raise, by using wedges of wood or slate, the super about three-eighths of an inch above the hive, so that the bees will clean out the honey from the broken cells. This they will do well in about an hour. Then get some rags or brown paper dipped in a solution—weak solution—of saltpetre and dried. A few puffs of the smoke and smell of this saltpetre blown in at the top of the super will cause all the bees to leave the super and run downward into the hive with all possible speed. In wooden supers a gimlet hole answers for the admission of the smoke. In glass globes without holes in their crowns let the smoke play on the bees by some means, and the bees will fly out quickly. It is very desirable to get the bees out of supers as soon as possible, so that their combs remain pure and unspotted, and nothing can answer for this better than using saltpetre.

COVENT GARDEN MARKET.—AUGUST 9TH.

THE market is still quiet, owing to the holidays, scarcely any business of note being transacted

POULTRY AND PIGEON CHRONICLE.

THE NORFOLK OR FOUR-COURSE SYSTEM OF CROPPING.

THIS mode of culture and cropping, which was the regeneration of West Norfolk, was introduced by Mr. Coke, afterwards created Earl of Leicester, and whose spirited farming and development of sheep-breeding and winter-feeding of cattle on an extensive scale, and the expenditure of £400,000 in the erection of superior farm buildings on his estate, which, together with permanent improvements in the use of manures, the use of oil cake, and the liberal system of general improvements in cultivation, induced the farmers of the period to boast that this system had converted West Norfolk from a Rye-growing into a Wheat-growing district. We have chosen to introduce this subject to the notice of the home farmer at this particular time of year, because as fast as the crops of this year's harvest are cleared from the land it is notoriously the best period for arranging or re-arranging any system of cropping which may be deemed advisable to be carried out in the immediate future. In consequence of the change of circumstances which have prevailed for a few years past, it will of necessity oblige the home farmer to consider his position under the altered character of agriculture, and induce him to forecast any changes which may be desirable in the system of cropping best calculated to yield a profit, instead of acting entirely under the influence of former traditions. One great point in his favour is that he is a free agent, more particularly if his employer does not interfere or recommend any special mode of conducting the business of the home farm as regards the cattle and general stock of the farm, including the rotation of cropping. It is frequently made a point that the land shall be managed upon the four-course or Norfolk rotation of cropping, simply because it is so easy to be conducted under a course of cropping laid down, whether it is the four-course or any other. The four-course, however, is the easiest and most regular mode of conducting the home farm, because the cropping is fixed; and there is then only the simple and practical details of the everyday duties to be considered, such as the cultivation, seeding, harvesting, hay-making, and manuring in connection with the rotation proper. There is, however, apart from the course of cropping, the kind of stock to be kept, the further influence of climate on the cultivation of the land, and the adaptation of certain cereals and seeds suitable to the nature of the soil as well as climate.

We will first allude to the Norfolk course of cropping as it was known upon its first introduction at the end of the eighteenth century, the rotation being (1) fallow for roots to be fed off on the land in part, and part fed off by bullocks at the homestead; (2) Barley or Oats; (3) Clovers alternated; (4) Wheat after one ploughing and manuring with yard dung, the roots being manured entirely with artificial and portable manures. In estimating the advantages of the four-course system, it must be considered when properly conducted as an improving system; for we know that in certain parts of Norfolk, Lincolnshire, and some other counties the land is of a very thin, sandy, and flinty nature, resting upon chalk, and in various districts was originally merely rabbit warrens, or at the best poor sheep walks, or downs as they are sometimes called. By the adoption, however, of the four-course rotation, the roots being consumed by sheep on the land, and in part by bullocks in the boxes, these light and originally worthless tracts

have been raised into valuable farms for the keeping of both sheep and bullocks in the winter months, and the growth of good crops of corn also, especially in those instances after having been clayed or marled. In fact when Barley is grown under the four-course rotation it is nearly sure to produce a good malting sample. Of roots we must state that they are very sure to produce abundantly, except in some severely hot summers, and even then the common varieties of Turnips will produce fair crops if sown late, for the autumn rains upon such soils have a very forcing effect; in fact fine crops of stubble Turnips are often grown after the Rye crop or early white Oats on that part of the root-lain intended for Mangolds in the next season on the root-lain.

After being farmed as nearly as may be possible on the Norfolk rotation, the land will gradually improve in letting value as time goes on if the feeding of sheep and bullocks is carried out with judgment. Now this being the case is the cause of this course being in most cases adopted as the rotation to be carried out in the last two years of a lease, for its simplicity and its easily defined rotation is sure to leave the land in a fair state as regards cropping to be entered upon by an incoming tenant. This latter point is also of some consequence in the event of a home farm being leased or let off to an occupying tenant. So far as the home farmer is concerned in the management of such soils as we have named, the system is adapted to his position, for we have numerous instances in the competition for prizes for the best-managed farms given by the Royal Agricultural Society of England. The Journal of the Society furnishing particulars of their management in several instances, states that the prize farms were conducted upon the four-course or Norfolk rotation of cropping, and at the same time remarking that the stocking with both sheep and bullocks and their feeding also was in accordance with the old Norfolk system, whereby the former consumed the roots on the land, but the latter under cover, and mostly upon the box system, both, however, having liberal allowances of cake and corn in addition to hay and roots; thus exhibiting the force of our previous observation, that when properly carried out the Norfolk system is an improving one, and certainly calculated to add to the letting value.

We are still alluding to light thin soils, and there was originally, and before the four-course came into practice, the five-course prevailed in the north-east part of Norfolk; and we find that Mr. C. S. Read, who is a great authority upon all agricultural matters, but more particularly in the county of Norfolk, states—"In the second year the seeds were broken up in July, and make a bastard fallow for Wheat. One could imagine no worse preparation for Wheat on such lands. The ground could not be consolidated, and every facility was given for the swarms of winter annuals which infest such soils to spring up and smother the plant. The farm manure was wanted for Turnips, and a one-year ley left to its own resources grew but little Wheat." The improved system is to use artificial manures for the root crop, and to apply the farm-yard dung one half to the Clover seeds in winter or early spring, and the other half on the one-year ley, ploughing it once for Wheat; and by using the presser at the same time these light soils become firm, and once ploughing only breeds no weeds. In connection with this practice it should be considered as to the necessity of sowing broadcast after the presser in preference to working the land and drilling, for upon these light soils, which are so apt to shrink after frosty weather throwing the Wheat plant out of the land, it is preferable to sow after the presser, because, not only do the plants retain a better hold upon the soil, but in the event of a dry summer they withstand drought better, the roots being in contact with the moist subsoil.

Although the four-course system originated in the county of Norfolk, it must not be supposed that it is continued as a system adapted for the better and loamy soils, and to illustrate this we

cannot do better than quote from a letter in the Journal of the Royal Agricultural Society for 1859 from Mr. Wm. Cubbit of North Waltham to Mr. J. C. Morton, wherein he states—"The land I occupy is of the finest quality, and I have come to the conclusion that to farm it unusually high, and stick to the usual four-course system, is occasionally attended with great loss and disappointment. My plan of late years has been to pursue no particular course, but to crop close and extend the rotation, as for instance, thus—First, Turnips or Mangold Wurtzel; second, Wheat or Oats; third, Barley; fourth, Clover or other seeds or Beans; fifth, Wheat; which is a kind of five-course shift, care being taken not to lay down more land in seeds than is required for the use of my horses. After Barley, therefore, I usually grow a field or two of Beans, but always grow as large a shift of roots as possible, being generally well paid by the winter grazing of sheep and cattle, and also by the means thus afforded of getting the straw made into good manure."

This Norfolk four-course system is still continued on the strong lands, generally on medium or small-sized holdings, in the county we are told; but it is difficult to see how it can be practically turned to account as a profitable rotation, for the leading point in the system is the growth of one-fourth of the arable land in roots to be fed off by sheep, but this cannot be done on cold strong land in the winter months, or at spring in time for sowing the land with Lent corn. It may, however, be done by the removal of the main crop of roots off the land for bullock-feeding under cover; but this is, if not a departure from Norfolk system, calculated to incur great expenses.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour is now of more importance than in almost any other month of the year, because they will not only be required in such work as is usual during the use of the mowing machine, as well as the reaping and binding machine; for, besides this work, as fast as the corn is cut and tied the land may be ploughed every day between the stooks of corn, such as Rye, especially of that which has now been cut for some little time, and some of it carted. All the early sorts of corn, such as winter Oats, White Victoria Oats, Rye, and Wheat in the early districts of the southern and home counties together with winter Beans and forward Peas, were commenced being cut on the 24th of July, and in all such cases where enough hands were employed, the corn or pulse may have been placed either in stook or in pook, in such a position as to leave two-thirds of the land vacant and ready for ploughing, working down and drilling Turnip seed every evening after four o'clock. In this way we for many years secured fine crops of common Turnips forward enough to be fed by sheep in the month of November following; when, however, in the absence of Turnips being required for use grown in this way there is still a sufficient reason why the land if encumbered with couch, black grass, or other weeds should be scarified and worked with Howard's self-lifting drag harrow, as the cheapest and earliest mode of commencing operations for an autumn fallow. In fact, throughout the harvest we contend that as fast as the crops of corn and pulse are cleared all the horses not required in carting corn should be constantly employed in cleaning the surface of all those fields intended for crops next year where a fallow is necessary. Not only is it necessary to do this work with the horses during the harvest period, but steam power should be employed also in the deeper stirring of the soil, so that the horses may follow after with Howard's excellent implement and complete the work of surface-cleaning. Nor is there any other period of the year when so much can be done with such beneficial effect in a given time as during and just after the harvest, nor is it any use for the home farmer to tell us that his horse power and steam is not equal to do this. We answer that he is not farming on commercial principles, nor has he any reason for complaining of his land being foul if he loses the opportunities we have just described. It is not, however, the only loss which he must expect, for if he neglects the first opportunity it may not and does not occur again in some seasons, and the crops intended to be sown are delayed.

Hand Labour.—It is very rare that farmers commence cutting their crops too soon, and should they do so in some respects, yet in others they have the advantage, for the corn of every kind when cut early if wet weather succeeds takes less injury when cut and set up in stook than it does if it takes bad weather before cutting. If loss occurs it is the worst corn or pulse which is lost, whereas losses occurring before the crops are cut it applies to the best of the grain; the straw too is more valuable as fodder when cut early. It is just the same with Beans or Peas. The haulm is more valuable if cut early, and

the pods are not likely to open and waste the grain if wet weather follows. It is frequently stated that Bean haulm is of little value, but if so it arises from not being cut soon enough. We know from experience that if the eye of the bean is turned black the crop should be cut; the haulm then will if harvested in a proper manner be fit for cutting into chaff and pulping, so as to form part of a valuable food in admixture with roots. It is only in this way that the feeding value as shown by analysis of Bean haulm can be made available as nutritious food, and the calculation of feeding value compared with straw, as shown by Dr. Voelcker, can be obtained. It is now time to consider where the corn ricks are to be placed, and we contend that much time is often wasted by carrying corn to a rick yard, especially when it is intended to sell the straw, for in that case the ricks can be threshed and the straw stacked with as much advantage nearly as though it was corn, because straw is and will be very dear in the future in all districts, but especially near towns and railway stations where carriage is easily obtained.

Live Stock.—We must not forget our sheep stock and our cattle during harvest, nor can the shepherd take part in harvest work if he has a flock of breeding ewes, especially on the large outlying hill farms. To the dairyman on the large dairy farms, the harvesting of corn is nothing; his only care is for the hay, but for this it is seldom that he can find time for assisting at haying time, especially if he has a large herd of cows, but still more so if in addition he has to look to bullocks fattening on the pastures, which should have their cotton cake about 4 lbs. each daily, and if it is given with 2 lbs. of bean meal so much the better, especially if the food is given in mixture with cut Cabbage or Mangolds held over for the purposes. It is essential for every bullock to have its proper share of food, and there is no better plan than having iron skeps, which hold a little over a bushel, each skep receiving the food for one bullock. In this way they can all feed separately without difficulty. Just in the same way yearlings and stores of any age may be fed with advantage without some having the lion's share and others getting little or none of the trough food. With respect to the health of all our live stock, it is often the case that the most in quantity and the best in quality of the grass in the pastures is found in those which lie the lowest and on the sides of brooks and rivulets; this land lies below the level of night fogs. Now as the autumn advances this is an important matter for consideration, as young animals frequently suffer from quarter-ill (especially heifers in fine condition) unless they are removed to higher and drier pastures for night-lying.

POULTRY AND PIGEONS

THE FATTENING OF FOWLS FOR THE TABLE.

OUR subjects are often suggested to us by the inquiries of correspondents. We have this week had a question put to us as to the best kind of fattening coop, which reminds us that fattening is at this time of year an important operation in many poultry yards, and that some notes on the whole subject would not be out of place. We have before now stated that generally speaking we do not think any artificial fattening necessary, that well-kept chickens of good kinds should always be ready to kill, and that we do not ourselves pen up chickens to fatten, though we are often complimented on the figure and flavour of ours on the table. There are, however, exceptions to all rules, and in this case there may be many good reasons for exceptions to our rule—*e.g.*, where circumstances compel young and old fowls to be kept on one run, and that not a very large one, an old cock will so bully cockerels that it is impossible for them to put on any flesh; or in farmyards and other places where there are necessarily impurities about, it is sometimes found that the flesh of chickens which have access to them has a disagreeable flavour. Again, there are some people who think fattened fowls, such as are sold in the London and Parisian markets, alone palatable.

We have written often enough about table poultry to give our readers some idea of the breeds of fowls crossed or pure which are suitable for fattening. It is worse than useless to attempt to improve the condition of narrow, breastless, long-legged mongrels. Such we have often seen imported from ill-managed farmyards into gentlemen's establishments, crowded into a wretched pen in a back yard, fed on oats or other grain—a diet perfectly unfit for a creature which takes no exercise, and then we have heard the family wonder why the chickens are so unpleasant on the table.

1. To begin. A chicken which is to be fattened must have a plump frame and apt to carry fat on the breast, it must also be a perfectly healthy bird; chickens which have only just been kept alive by care are not in a fit state to be fattened. Given a suitable lot of young birds, the methods of fattening them are

two. The first consists in simply restricting their liberty to a certain extent, and giving them food which improves the quality of their flesh; the second in closely confining them, and towards the end of the time cramming them forcibly if needs be. We have occasionally successfully improved chickens by the first method. A number of fine young birds of one age should be selected, put in a clean enclosed grass run, with access to a dust bath to keep their plumage clean, and a heap of gravel to help their digestion. The partial confinement and freedom from old tormentors prevent their running the flesh off their bones, and companionship tempts them to eat well. All the food of fattening fowls should be soft. When first they are put up starve them for twelve hours, and if ever they get dainty and do not seem really eager for their meals repeat the fast. This will not often be necessary, and as long as they are happy and hungry give them as much as they will take three times a day. It is needless to say that their house and run must be kept scrupulously clean; in a confined space any poultry left in dirt and discomfort soon show its ill effects by loss of appetite. Their diet should consist of various meals mixed into the crumbly state we have often described, but with milk instead of water, and rice boiled in milk. The best kinds of meal are barleymeal, Indian meal, and buckwheat meal. The latter is largely used in France, and we believe the delicious flavour of first-rate Parisian chickens is attributable to it. After three weeks of this régime any chickens of good race should be in perfection.

2. For those who wish to attempt more systematic fattening we will describe the method which we believe the best from a common-sense point of view and from observing it in the establishments of our friends, though beyond an occasional experiment, as we have said, we have not found it necessary to put it in practice. The long coops into which we have formerly seen dozens of chickens crammed are nearly exploded; if any exist we beg our readers to burn them—their use is absolute cruelty. The poor stupid birds in them invariably crowd to one end, the strong trample on the weak, and the violent scalp the timid. The existence of a bullied bird for weeks in such a purgatory is horrible to think of. How could it possibly do otherwise than waste away? If chickens are to be put into close confinement to improve their flesh each one must have a separate cell. Some of the ingenious contrivers of poultry appliances sell such pens singly and in rows, both of wood and galvanised zinc. They are, however, very dear, and a few hints may help a clever carpenter to construct some at a much less cost. Each pen should be about 1 foot wide, 1½ foot deep, and 2 feet high. They should be closed above, at the back and sides, and be barred in front and at the bottom. Some bars in front should push up to form a door, and a sliding tray should run under the barred bottom. It should be covered with dry earth for deodorising purposes, and cleaned daily. Of course, if a row of such pens are constructed together one long drawer will suffice for many. Two little earthenware pans should be placed on ledges in front of each pen, the one for water, the other for food. These are far better than wooden troughs, inasmuch as they can be frequently put into hot water. Milk much improves the flavour of chickens, and every vessel into which milk is placed requires scalding. The system of feeding should be the same as that for chickens in a semi state of confinement, save that their progress is advanced by keeping them in the dark while digesting each meal. Towards the end of the time cramming may be resorted to if the more natural method is not found sufficient. This, however, requires much care and practice, and we are strongly averse to it ourselves. For those who are inclined to try it we will in another article translate some passages from a French authority on the subject.—C.

THE POULTRY CLUB.

A MEETING of the Committee of the Poultry Club was held at the Charing Cross Hotel on Friday, the 4th inst., at 2 P.M. There were present Messrs. R. A. Boissier (in the chair), T. W. Anns, and S. Lucas.

A communication from the Secretary of Nottingham Show, as to holding the same under Club rules, was read, and a subscription of two guineas was granted in aid of the funds of the Show.

The date of the next meeting was fixed to be held on the first or second days of the Dairy Show, the exact time and place of meeting to be fixed by the Secretary, who was also empowered to summon a special meeting in the meantime should he think it desirable.—ALEX. COMYNS, *Hon. Sec.*, 47, Chancery Lane, W.C., August 8th, 1882.

THE WARWICK SHOW FRAUD.

JAMES WYNN *alias* GROUTAGE, thirty-six, described as a clerk, and William Cockerill, thirty-three, oil merchant, were on Saturday last

put on their trial at Warwick Assizes before Mr. Justice Grove for obtaining money by false pretences, and for conspiracy to obtain the same. The circumstances of the case, to which we shortly referred at the time it occurred, were as follows:—Groutage, the principal offender, in the month of April last advertised and issued schedules of prizes for a show of poultry, Pigeons, and dogs to be held at Warwick on the 10th and 11th May. The prizes offered were liberal, there being for poultry sixty-two classes, with £2, 15s., 10s., and 5s. prize money in each class, besides a few cups. Pigeons were to have thirty classes, and dogs forty-seven. We have not the Wolverhampton schedule by us, but speaking from memory we should say that with the necessary alteration of dates, Judges, Committee, &c., the whole schedule was taken bodily from an old schedule of Wolverhampton Show. Groutage announced himself as Secretary under the pseudonym of James Wynn, and took for address that of his brother-in-law the prisoner Cockerill. The Show was announced to be held under Poultry Club and Kennel Club rules, and the Corn Exchange was named as the site. A Committee of eight completed the schedule. Unfortunately for Mr. Groutage several of the Warwick police are fanciers, and among these Sergeant Hall and one or two others were inclined to exhibit at the Show. As a preliminary, however, the sergeant made a few inquiries, and the result of these was that he took up the matter in his capacity of police officer instead of as a fancier. The result of his investigations was that Groutage and Cockerill were arrested just as the former had completed his arrangements for emigrating with his family, and the sum of £200 obtained for entry fees. It appeared from the evidence given on Saturday that the prisoner Groutage had made no arrangement with the authorities of the Corn Exchange as to holding the Show there, that he had not communicated with the Poultry Club or Kennel Club as to holding the Show under their rules; that entry fees to the amount of over £200 in cheques and post office orders had been received, and that Cockerill having a banking account had changed the most of the cheques and post-office orders into cash. Evidence was also adduced that before the entries closed Groutage was in communication with Messrs. Allan Brothers, Liverpool, as to securing passages for himself and family to Canada on the 11th May. The trial occupied the entire day on Saturday, and the Jury returned a verdict of guilty of both charges in the case of Groutage, and of guilty of conspiracy only in the case of Cockerill. The latter prisoner was strongly recommended to mercy. Sentence was deferred. We may mention that through the action of Sergeant Hall in sending timely notice to all exhibitors only one or two exhibits were actually sent to Warwick for the Show. It has been suggested that the services rendered by the Sergeant throughout the case are worthy of recognition, and we entirely concur in this view. He has rendered a great service to exhibitors by bringing these defaulters to justice.—A. C.

OUR LETTER BOX.

Fowl Coops (G. S.).—We believe that coops for fattening fowls are supplied by Christy & Co., incubator manufacturers, 155, Fenchurch Street, London, E.C., also by Reynolds, manufacturer of various poultry appliances, Compton Street, Soho. The article on fattening fowls on page 141 is a general answer to your question.

TUBEROUS BEGONIAS.

THE improvement of plants during the past half century has very deservedly received much attention from horticulturists, and the grand advances that have been made in many genera afford abundant evidence of the success which has attended well-directed efforts. Careful cultivation, judicious crossing, and thoughtful persevering selection have yielded most satisfactory results, the number of usefully ornamental plants being largely increased and their beauty greatly diversified. Many instances of this could be given, but a few will suffice, one of the most striking, perhaps, being the Clematises, the progress of which was noted a short time since in these pages. Pelargoniums, especially the decorative and Zonal sections, have also advanced greatly; while amongst fine-foliage plants may be instanced the Dracenas, Crotons, and Coleuses, all of which have progressed considerably in recent years. There is, however, another genus of flowering plants—the Begonia, that has profitably employed the attention of hybridisers; but it is in one section alone—namely, that including the Tuberous species and varieties, that the most astonishing results have been obtained, and to a consideration of the means by which such success has been achieved the following notes are devoted.

All who have visited the Royal Horticultural Society's Gardens at Chiswick during the past and present months have been greatly attracted by the display of Tuberous Begonias there provided, which well illustrate the excellence that has been attained with these plants. Visitors to Messrs. J. Laing and Co.'s nurseries at Forest Hill have been similarly surprised, not only at the brilliancy of the colours and the abundance of flowers, but also at the great size of the individual blooms, the breadth of the petals, and the symmetrical form which distinguish so many handsome varieties. Contrasting these with the narrow-petalled earlier forms shows at a glance the progress that has been made, and reminds us forcibly of the similar difference between the early Zonal and bedding Pelargoniums and those finely formed varieties at present in cultivation. Attention has further been paid to the habit of these Begonias, and there are now two well-marked groups—namely, those of erect growth and those with slightly drooping stems, though gradations may be found between the extremes. The first-named may be again subdivided, according to the height of the plants, into tall, medium, and dwarf varieties, all having their particular advantages and uses. Some advance has also been made in obtaining a race with ornamental foliage, though at present this is chiefly confined to the Pearcei type with yellow or buff flowers, yet greater success is confidently ex-

pected, and will doubtlessly be attained. Hundreds of varieties, all more or less distinct and beautiful, have received names and been sent out by nurserymen; but it is now found that seed saved from a good strain yields so many excellent varieties that some firms have discontinued naming these plants, their efforts being directed to rendering the strain generally as meritorious as possible. So that now the purchaser of a packet of seed can rely upon obtaining varieties quite equal to some of the best named forms, and there is the possibility even that something superior may be secured. At the Forest Hill nurseries many thousands of seedlings are raised every year, and these are planted out in prepared beds for trial, all that are really worthless being discarded. In the autumn the young plants are lifted, the small tubers being dried and sold like other tuberous or bulbous plants. A great demand exists for these, as they come within the means of many who cannot afford the higher-priced novelties.

Having considered the present characteristics of Tuberous Begonias, it may be well to briefly allude to the means by which so high a degree of merit has been attained, and the original forms that have been employed by hybridisers in producing such satisfactory results. Although the varieties and hybrids are so numerous, the species that have contributed to their formation are comparatively few, and, moreover, are nearly all of recent introduction. The lofty Andes of South America is the chief home of these Begonias, distinguished by possessing a tuberous rootstock and herbaceous fleshy stems; but one of the latest introduced, *B. socotrana*, which also shares these characters to some extent, is, however, as the specific name signifies, a native of Socotra. Though this will doubtless play an important part in future attempts to improve or vary the Tuberous Begonias, it has at present been in this country too short a time (about two years) for any results to have been obtained in that direction. The other species—namely, *B. octopetala*, *B. boliviensis*, *B. Veitchii*, *B. Pearcei*, *B. rosæflora*, *B. Clarkei*, *B. geraniifolia*, *B. Davisii*, *B. Frœbelii*, and *B. cinnabarina*, are found on the Andes of Peru, Ecuador, or Bolivia at high elevations, frequently up to 10,000 feet above sea level. The oldest of these is the greenish white-flowered species *B. octopetala*, which appears to have been introduced from Peru about 1835, but was subsequently lost and reintroduced by M. Roezl. This is chiefly interesting as one of the oldest of the section, for it has not been of great service to hybridisers. Next in order of introduction is another rather unimportant species, *B. cinnabarina*, a native of Bolivia, with vermilion flowers, which made its appearance about ten years later than the preceding. *B. boliviensis* is well known, and has been largely employed in crossing with other forms. It is a Bolivian species, and was originally found by Mr. Weddell, but not introduced until some years after—namely about 1857.

B. Pearcei, a comparatively dwarf form with large yellow flowers, dark green velvety leaves, veined with a lighter hue, and reddish on the under surface, is also a Bolivian species, for which English cultivators are indebted to Messrs. J. Veitch and Sons of Chelsea, by whom it was sent out seventeen years ago. It was found by the traveller Mr. Pearce, whose name it bears. Most of the yellow-flowered varieties owe their origin to this species. *B. Veitchii*, also a dwarf form, has bright scarlet flowers, which are produced freely, and it has been very useful in giving rise to a race of dwarf but vigorous

habit. The petals are rounded, imparting a symmetrical appearance to the blooms; the leaves are bright green, broad, and rounded in outline. This was found in Cuzco, Peru, at the great elevation of 12,000 feet, whence it was introduced by Messrs. Veitch about 1867. Two other pretty species allied to the preceding, and resembling it in habit and form of flowers, are *B. Clarkei* and *B. rosæflora*, both from Peru; but the *B. Clarkei* inhabits rather warmer regions than *B. Veitchii*, though *B. rosæflora* is found at a similar altitude. The last-named has large rounded flowers of a fine clear rose colour, and its parentage may be traced in many of the varieties that are now grown with flowers of a like tint. *B. Clarkei*, which is named in honour of Colonel Clarke, who first brought it into general notice, has large scarlet flowers, but not quite so brilliant as *B. Veitchii*. Both these appeared in England about the same time—namely in 1866 or 1867. Later still—namely from 1874 to 1876, *B. Frœbeli* and *B. Davisi* were added to the list of species in this section, and both have contributed to some extent to the improvement of varieties and hybrids. *B. Frœbeli* is of compact habit and somewhat related to *B. einnabarina*, having scarlet flowers freely produced. It was introduced by M. Frœbel & Co. of Zurich from Ecuador. *B. Davisi* is a charming dwarf species, having neat light green leaves, red on the under surface, and rich scarlet flowers of moderate size, but good form and extremely abundant. Small plants of this are highly ornamental for cultivation in pots, and the fine double form obtained a short time since is also a most valuable plant.

The intercrossing of these species and careful selection from the numerous seedlings raised have produced with surprising rapidity the handsome race of plants which are now becoming such general favourites for decorative purposes either in pots, baskets, or for bedding-out, and their popularity is still increasing. Selections of varieties have been frequently given in these pages, and it is not necessary to repeat these now, but a glance may be given to the earliest of the hybrids obtained, though it would be almost impossible to trace the parentage of all those cultivated at present. One of the first hybrids secured and certainly the best was *B. Sedeni*, which was obtained at Messrs. Veitch's Chelsea nursery by Mr. Seden as the result of a cross between *B. boliviensis* and an unnamed species. This was subsequently employed as a parent with *B. boliviensis*, *B. Veitchii*, *B. Clarkei*, and *B. Pearcei*, giving rise to *B. Chelsoni*, *B. Stella*, *B. Vesuvius*, *B. Model*, and *B. Chambersi* respectively, the last two resulting from two crosses with *B. Pearcei*, all improvements of more or less value. *B. Veitchii* crossed with *B. boliviensis* resulted in the production of *B. Chelsoni*, and this with *B. Sedeni* produced the variety *Aeme*. Thus the first hybrids raised have been repeatedly utilised by intercrossing with each other, the diversity and excellence of the progeny being steadily and satisfactorily increased. Much is due to Messrs. Veitch's initiatory efforts, but other workers in the same field have also produced very creditable results both in England and on the continent. Messrs. J. Laing & Co. have already been mentioned as having contributed large numbers of handsome single and double varieties to the list of cultivated forms, and M. Lemoine also deserves a word of praise for the many beautiful forms he has raised. In the last year or two the double varieties have received much attention, and some of considerable excellence have been obtained, but the majority are inferior in an ornamental point of view to the leading single varieties.—L. CASTLE.

THE CHOICE OF SEEDS—SELECTION OF PEAS.

THE plan which most of our nurserymen now adopt of offering at a cheaper rate a large assortment of seeds selected by themselves has involved me this year in some difficulty. For some time past I had purchased a two-guinea selection of one of the great advertising houses, and need scarcely say that the seeds were good. I found, however, that in this way I became a mere creature of the firm from which I had purchased, and if I was asked the name of a special Pea, Lettuce, or any other vegetable I could only give the title of the firm, prefixed, as seems now the general rule. On selecting for myself this year my bill exceeded four guineas, chiefly because more seeds were sent in each packet than were required. What is my remedy? Should I order by the ounce, or what should I do? Perhaps you will tell me that I

must pay for exercising my right of private judgment, but the difference in the cost seems to me excessive. Another year I hope to induce my gardeners not to sow so thickly, but on this point it is almost useless to contend with them, particularly as they do not pay the bill.

Some of your correspondents who are learned in Peas may like to criticise the list I enclose, and if so I shall be obliged. I have tried the following:—Sangster's No. 1, Ringleader, William I., G. F. Wilson, Hundredfold, Dr. Maclean, Laxton's Fillbasket, Veitch's Perfection, and Ne Plus Ultra. My early Peas were a great success, but I complain of Hundredfold that the quality is not equal to that of many others. As a boy I was accustomed to what were called Marrowfats after the early Peas were over, and expect my gardeners now to provide Peas of first-rate quality, otherwise I may just as well do without a garden. What these Marrowfats were I cannot explain, but possibly some of your readers can, as I believe the name was a common one; their quality at any rate was excellent. The list above is probably too varied, and certainly can be improved, particularly in point of quality.—E. BARTRUM, *Berkhampstead, Herts.*

HARDY AND OUTDOOR FLOWERS—SELECTION NECESSARY TO SUCCESS.

IT is common to hear hardy flowers, especially strong herbaceous growers, described as weedy, fugacious, and mere rubbish. I fear there has been an excuse for this the present season with two months of almost continual showers. I have on several occasions advocated the extended culture of hardy flowers, but without prejudice to the ordinary summer bedders, carpet-bedding and foliage plants included. Tastes are so different. Situations are often suitable for one class of plants that will not do well for others; and lastly, even with comparatively unlimited command of money many gardeners and amateurs cannot get what they would prefer. Reasons like those might be multiplied why no hard-and-fast line can be drawn. Then, again, most people have beds and borders where no one would think of making a carpet bed or putting their choice tricolor Pelargoniums or their Tuberos Begonias, which are even more adaptable. No; the back beds and borders, especially if shaded, answer admirably for tall plants, and the shade in summer is just what suits Polyanthus, Auriculas, Pansies, &c.; and if a wall is convenient, to which Hollyhocks, tall Phloxes, Lychnises, Helianthemums, Asters, Campanulas, Aconitums, Delphiniums, Aquilegias, Rockets, Pæonies, and Lilies can be easily secured, then those plants are just where they ought to be. In central beds, open, and under the full influence of the sunshine, those and dozens of others not so generally known would be out of place.

I have twenty beds and some borders that I try to have showy and gay for about ten months out of every twelve with all I am able to procure of those flowers. From those I can cut a bouquet for any visitor or to send to a sick person almost any day in the year. Now this is the grand line of demarcation between those who confine themselves to bedding and carpet plants and those who grow hardy and herbaceous plants. What can equal for brilliancy, colouring, and sweetness a bouquet of the queen of flowers (the Rose) alone or when taken in variety? For showiness and sweetness combined in spring you can make a selection from Hyacinths, Auriculas, Pansies, Tulips, the Anemones, Narcissuses, Irises, Polyanthus, and others equally well known. The varieties of any one of those would make a varied bouquet. Later in the season and during the summer months, as already mentioned, pre-eminently stands the Rose; and if you want white for variety I should recommend *Achillea Ptarmica*, *Campanula persicifolia alba* (I do not mean what is commonly sold under that name, but the variety perfectly double and as full as a white Camellia, 1½ inch across the flowers on the spike), and *Matricaria inodora*, all three very double, blooming a long time, and exceedingly useful for cutting. The last has been blooming the past two weeks, and will continue into autumn. I should select other colours in the same way, and manage so as to have them come in succession. Granted that some perennial Lupins, Potentillas, Geums, and Scabious, especially singles, as illustrations of common perennials, are not worth the space they occupy; but selected double varieties, especially of the three last, have been blooming six weeks, and will continue yet some time.

But let me look at other beds, and consider how they promise now, always keeping in mind how small and limited my collection is, and I see opening the first blooms of Kelway's Gladioli considerably behind in another bed being two dozen others French-raised. I do not remember a better season for this favourite flower. I cannot complain so far of losses, as I only notice a few withered out of two hundred, while Sir Stafford Northcote and

Vicomtesse Glentworth are the only two certificated seedlings that are not likely to bloom. One of the showiest beds I have comprises some of the hardier tall-growing Fuchsias, such as Lye's, obtained from Mr. Cannell, Swanley Nurseries, two years since, and left out last year. Not one was lost by cold. I should have previously mentioned two of my favourites, to which I have devoted considerable space—Pyrethrums and Dahlias. Except for variety I am not sufficiently æsthetic to prefer single to double Pyrethrums. Once grown I cannot imagine any flower lover to be without the latter. I have a selection of show, fancy, single, bouquet, and the better kinds of double Dahlias, for the next three months I expect much satisfaction from seventy varieties of these. Next comes a whole bed of the white Japan Anemone—I say a "whole" bed, and this is the best way of growing it. It will "kill" any edging or other flower; but who that knows it but will say it deserves every space and attention? The first bloom opened recently; the last will come next November. I do not eschew zonals, for one of my most interesting beds is fifty seedlings, seemingly all different. Passing over others, lastly come three beds of my especial favourites, Tuberous Begonias in variety. Briefly I may say I grow them much as I would Potatoes, and they need very little more care in winter, except that in future for bedding I intend to start them earlier in a mild hotbed in February to have blooms in May. When I with limited means, limited facilities, and multifarious other duties to attend to can have flowers in this way for such a large portion of the year, what excuse is there for others to complain of growing weeds or rubbish who have no such difficulties?—W. J. M., *Clonmel*.

THE BOG GARDEN.

A WELL-MADE bog garden is an inseparable adjunct to the rock garden; no well-arranged garden where hardy plants are made a speciality should be without one. Where natural conditions do not admit, some special arrangements should be made. It too often has been my experience to see moisture-loving plants grown indiscriminately amongst alpinists; no worse mistake can be made, for some of the best plants are thus never seen to advantage. It is unadvisable to be hasty in discarding plants until given a thorough trial and their right place be found, except in cases where they are really worthless. I have seen such plants as *Cardamine trifoliata* grown amongst alpinists generally, but never so luxuriantly as in the more elevated parts of the bog, where, though not saturated, there is always an understratum of moisture. *Astrantias*, which seldom give satisfaction in the ordinary border under conditions such as those just mentioned, will be seen in their true character and be more acceptable. Some of the miniature Daisies (*Belliums*) planted amongst other alpinists dry up, so to speak, on the first short season of drought. They are generally looked upon as biennials, but in the drier parts of the bog become perennial. *Bryanthus erectus* and *Epigæa repens*, two of the best American under-shrubs, never do well planted amongst ordinary alpinists. Special preparation may be made for them, giving peaty soil; but that will not furnish them with the indispensable understratum of moisture. Some of the moisture-loving *Saxifragas*—*S. Fortunei*, *S. repanda*, *S. Hirculus*—and a great many more could be mentioned to show the necessity of making special provision for moisture-loving plants.

It has already been said the alpine and bog garden are inseparable, and they are better made together and planned to harmonise. If, however, as is very often the case, an alpine garden already exists, whatever be its qualities or defects, it must be taken into consideration—its contour studied. Simplicity is the order, and let nothing elaborate be attempted.

A bog garden may consist of a small irregular bed at the base of the alpine garden, or a more extensive one at a lower end in connection with a pond or miniature lake. In the latter case it should be irregular and have an undulating surface. If a natural stream of water can be turned so as to take a winding course, so much the better. I have, as I write, in my memory a piece of water for genuine aquatics and a bog in connection, through which a natural stream runs. It is an interesting corner, and a place to which I direct my steps almost daily to watch the progress of or attend in some way to the plants there growing. It matters little what the subsoil consists of in places where plenty of water is at hand. I have made bog gardens on a most retentive clay and also upon gravel, and have always found the desired condition as to moisture can be obtained with a little manipulation. In the case of a deficiency of water a clayey subsoil would be essential, and if a bog garden consists of a small irregular bed some artificial means ought to be adopted for flooding it in dry weather. I have seen this done by a small leaden pipe carried underground. By elevating the surface in places you are enabled

to grow a greater variety of plants. A slope from comparatively dry ground, say where that part of the rock garden terminates on the general level to a basin-like hollow irregular in shape, if the subsoil be retentive, you can here grow swamp plants, such as *Menyanthes trifoliata*, *Comarum palustre*, *Hottonia palustris*, and many others. I have seen handsome specimens of *Primula japonica* growing in such places, also *Helonias bullata* and *Pinguicula grandiflora*. By adopting an irregular curve and a slope you will be enabled to find all conditions of moisture and even partial shade.—M. J.

EUTOCA VISCIDA.

SEVERAL of those attractive little hardy allies of the *Nemophilas*, the *Eutocas*, are grown in gardens, the best being *E. viscida*, *E. Franklinoi*, and *E. multiflora*, hardy North American annuals. All these are pretty, but being of dwarf growth they

Fig. 25.—*Eutoca viscida*.

are chiefly adapted for small beds or near the margins of borders, as otherwise they appear to little advantage crowded with the taller stronger-growing perennials. They are not particular as to soil, any moderately light ordinary garden soil suiting them, and perhaps the best way to obtain them in good condition is to sow the seeds in the borders in autumn. Some may also be sown in early spring, however, and the plants so obtained will form a succession to the others.

The species represented in the woodcut (fig. 25)—*E. viscida*—is one of the prettiest and best known. The flowers have very deep rich blue five-lobed corollas, with a circular red blotch in the centre, and they are borne in curved racemes, several blooms being open at one time. The leaves are somewhat heart-shaped, but irregularly cut at the margin, and the surface of the plant

generally is covered with hairs, the points of which each bear a viscid secretion, and to this character it owes its specific name. The bright blue tint is very pleasing, and the flowers moreover last a considerable time if cut with a good length of stem and placed in water, thus rendering them valuable for vases. It was found by Mr. Douglas in California, and from the seeds he sent to the London Horticultural Society plants were raised, which first flowered in the summer of 1835.

Eutoca multiflora is also a charming species, with very abundant rosy purple flowers and pinnatifid leaves. Like the preceding this was introduced by Mr. Douglas, who found it growing in sandy places in North America. E. Franklino has small light blue flowers in short close racemes. The leaves are pinnatifid, with more divisions than the preceding, and it was first found by Dr. Richardson on the banks of the Mississippi. E. Wrangeliana has entire ovate leaves, very large purplish-blue flowers, and is one of the most handsome species in the genus. It was discovered in the Russian colony of Ross, New California, and seeds were first sent to St. Petersburg.

NATIONAL GOOSEBERRY SHOW.

THIS was held in the Royal Botanical Gardens, Old Trafford, Manchester, on the 7th inst. The respective prizewinners with the names and weights of the varieties are as follow:—

TWO GOOD BRITISH PLANTS.

AMONG the great number of British and exotic plants grown by an enthusiastic and experienced botanist and cultivator, Dr. Marsh, Egford, near Frome, there are two which are strikingly superior—viz., a Corn Marigold and a Scolopendrium. The former (*Chrysanthemum segetum*) was selected during one of the Doctor's botanical rambles, and as now grown by him quite surpasses all the Marguerites. The seed, I am informed, will not germinate in heat, but does so readily in the open ground, and rapidly grows to about 2 feet in height. The blooms are freely produced, from 2 to 3 inches in diameter, and in colour are rich yellow. They are much admired by the ladies, and the flowers last well when placed in water, some having been kept in cool weather upwards of a month.

The Scolopendrium alluded to, a remarkably broad wavy-leaved variety, was also discovered by Dr. Marsh and is named Marshii. I have frequently heard of this form, and am pleased to say rumour for once did not exaggerate its beauty. Several fine crested Scolopendriums are also grown, but these are more noteworthy as being curiosities, while Marshii must be classed as a really ornamental Fern.—W. I.

A COLOSSAL FERN.—Recently a huge Fern, *Todea barbarea*, writes Baron Von Mueller, was brought away from its seclusion in the Dandenong Ranges, near Port Philip. "After the removal of its hundreds of fronds, the stump-like trunk weighed 2900 lbs. It required to be dragged by a train of oxen out of its recess, where it may have grown for more than a century to accumulate the substance of its massive stem. The monster Fern is to be placed in the conservatory of Melbourne, where the mycologist, Rev. Heinrich Tode, so long laboured for the Church and for science also, and where his mortal remains are buried. A brisk trade in large Todeas

ought to arise, as the marvellous specimen at Kew must have attracted the attention of professional and amateur horticulturists for many years after its removal thence from the Melbourne Botanic Garden. Giant *Todeas* may be obtained from South Australia (Mount Lofty Ranges), various places in Victoria, Tasmania, New South Wales, and Queensland, but specimens weighing over half a ton (without fronds) are rare. This colossal Fern has also the recommendation of bearing a considerable amount of frost, so that in temperatures like that of Arran it could be grown in the open air. In South Africa it seems never to attain to the enormous weight of extra large Australian specimens."—(*American Gardeners' Monthly*.)

AN HOUR AT THE PRESCOT NURSERIES.

CUCUMBER-GROWING.

IT is not my intention to attempt any description of this establishment that has been referred to again and again in the pages of the Journal, but to point out some of the cultural details in Cucumber-growing and the production of plants for market without ventilation.

Gardeners visiting the neighbourhood of Liverpool should not fail to inspect this establishment during the Cucumber season, for many useful and profitable lessons may be learned. I have before stated the "express" system, as it has been termed, is practised, not in one or two houses, but in thirty or more, varying from 50 to nearly 200 yards in length. When I alluded to this establishment on page 357 last volume I estimated the weight of fruits cut at about 3 tons per week, but should have been nearer right if I had written 5 tons. I also asked if it were possible for the plants under this heavy cropping and non-ventilating system to last as long as those more judiciously cropped and brought forward more slowly. I am now convinced they last equally as long, and will produce a greater weight of fruit. For instance, plants from which Mr. Whittaker commenced cutting during the month of November were only pulled out at the end of May. At that time several dozens of saleable fruit were hanging. These plants had been in bearing for at least seven months, and could not have been expected to last much longer under the system generally practised. There need remain no doubt about the crop being heavy, or the plants would have been removed long before. I do not doubt if Mr. Whittaker had removed all the fruits and cut back the plants they would soon have pushed growth and continued fruiting for a long time, but preference was given to clearing out the whole and starting again with young plants.

It is generally believed that small houses are the best for the earliest crop, and frequently such are built or used for the purpose in private gardens. We have seen this recommended repeatedly. Mr. Whittaker has, however, found from experience that this is really a delusion, and that he can cut fruit in his large house (nearly 200 yards in length) earlier from plants placed out in February than in any house he has of a smaller size. During the past two years the plants in his large house and a number of smaller ones were all raised from the same batch of seed to test this point. The plants in the large house have produced fruits for cutting before those in the smaller houses, which from all appearance are equally as suitable as far as heat and position are concerned. The idea that small houses can be kept warmer than those of a larger size has long since been abandoned by many practical men. Small houses are more variable in temperature, while those of a larger size are more uniform and a certain temperature is more readily maintained. Regularity is a great point to be aimed at, not only in producing early Cucumbers, but plants as well as early fruits.

How frequently do we see advised that syringing is to be done early in the afternoon for the foliage to be dry before night. However beneficial this may be to plants and fruit trees generally grown inside, it should not apply to Cucumbers. Those who recommend it, if they saw the 2-inch hose with a large rose secured to the end at the Prescott Nurseries playing amongst the Cucumbers and thoroughly saturating the house after eight o'clock P.M. would at once abandon the practice of early syringing. The hose to which I allude is worked by two men. One directs the nozzle, giving the whole house and soil in which the Cucumbers are growing a thorough drenching, while the other supplies the water by means of a patent hydraulic pump from wells sunk into the earth and at certain distances along the centre path. Wells of this description rudely constructed are in all the houses. The ordinary syringe is not in use in this establishment; it was found much too laborious an operation, besides the instrument being continually out of order. In my previous article I omitted to say a little shade is used on the west side of the houses.

To achieve real success the principal object appears to be in the selection of a suitable variety when grown under the

"express" system. The majority of kinds are worthless; on some the fruits are inclined to damp in their early stages, others are not free enough, while other varieties produce too long necks, and so on. This year there is a house full of a Cucumber grown well by Mr. Harrison, Knowsley Gardens; it fruits abundantly under this close system, but is not so good for the market as Mr. Whittaker's variety.

PLANTS GROWING WITHOUT VENTILATION.

Although Cucumbers are so largely grown in this establishment, attention is paid to the production of plants in large numbers and cut flowers for the market. The plants generally occupy the houses during the winter and spring months before the Cucumbers are planted; in fact large quantities are grown under the Cucumbers until they shade the roof of the house too much. The above heading may startle some cultivators, who attach so much importance to the admission of air to their plants grown under glass. It is generally believed that ventilation is of vital importance to the production of a sturdy compact growth; but it is nevertheless a fact that thousands are produced in this establishment without any ventilation except what is provided by the spaces between the panes of glass and when the doors are opened. There are no ventilators, and the doors are only opened when passing in or out. The plants subject to this close confinement are generally those to which the majority of us give abundance of air to keep them dwarf and compact. But I can assure all who read this that the plants grown on the non-ventilating system are sturdy and compact, in fact equal in appearance to any treated in the ordinary way. Harrison's new Musk is grown early in the season by tens of thousands, and has a ready sale in the market. These are all grown in the Cucumber houses in 5-inch pots. Of Zonal Pelargoniums, *Vesuvius* and *Wonderful* are most largely represented, and these are produced for market in enormous quantities. *Happy Thought* is also grown in quantity, and is sturdy and luxuriant. A large number of both single and double Pelargoniums are included, but those mentioned appear general favourites. The doubles at the time of my visit occupied a large cool house. These doubles are principally for supplying cut flowers. *Fuchsias*, *Coleuses*, and other plants are grown under exactly the same close conditions. In one house I noticed a number of healthy *Eucharises* and two or three half-specimen plants of *Bougainvillea glabra* profusely flowered, the blooms being of a remarkably rich colour.

Chrysanthemums are cultivated in considerable numbers. Half an acre of ground is planted with them, and they will be lifted in autumn to flower inside. Thousands are grown in pots, but these appear to be principally *Elaine*. Some small plants of *Mrs. Dixon* were flowering, and Mr. Whittaker said they had scarcely been without flowers since last autumn. The young plants, although pushed forward in a close house, were strong in the spring, but are now standing outside.

The outside grounds are devoted to plantations of *Asters*, *Rhubarb*, *Mint*, *Sage*, and other herbs; the second and third named are largely forced, while whole houses are devoted to the growth of small salads during winter and spring; but in this branch of horticulture the palm must be given to our southern friends at the present. Young plants of *Tomatoes* occupied one house and were setting fruit freely.—W. B.

LONICERA SEMPERVIRENS MINOR.

WHEN at Messrs. Veitch's Chelsea nurseries about this time last year this *Honeysuckle* was pointed out as being a first-class conservatory climber. Having previously heard it well spoken of, I decided to give it a trial as a substitute for *Habrothamnus elegans*. I did not much like cutting away two plants of the latter, as this *Habrothamnus* is decidedly a most useful climber, whether for supplying cut blooms or the enlivenment of the house for several months of the year. Unfortunately they were badly infested with our greatest enemy—mealy bug, and were besides rather too coarse for the position. However, I had long since been well satisfied with the substitute. Planted out from 5-inch pots into the ordinary loamy soil of the conservatory had they quickly commenced running, and at the present time nearly cover two light archways about 15 feet high.

The plant is always flowering, and we frequently cut handfuls of the sprays of bloom for vases or packing, as the case may be. The growth is wiry, yet sufficiently strong to support the beautiful sprays of trumpet-shaped reddish-yellow flowers. It is, in fact, much more elegant and serviceable than the heavy, drooping, and weakly-stemmed sprays of *Habrothamnus*. Cutting increases the floriferousness, as every lateral, which the running growths produce very evenly, will bear a spray of flowers from the axil of each leaf.

Thrips appear to be particularly fond of it, and as fumigation is out of the question in our conservatory we had recourse on one occasion to a decoction of quassia chips and soft soap. This was made by steadily boiling half a pound of the former and 1 lb. of soft soap in a gallon of water for about an hour, and used at the rate of a pint to a 3-gallon can of water, the plants being thoroughly wetted with the aid of a syringe. This effectually checked the thrips, but also much damaged the apparently very susceptible foliage. This season we tried paraffin oil or petroleum at the rate of 2 ozs. to the gallon of hot water, adding to a 3-gallon can a lump of soft soap about the size of a hen's egg. The latter was added to assist in the difficult matter of mixing the oil with the water, and besides this it is always necessary to either forcibly return each alternate syringeful into the can or to have a second syringe constantly stirring. The water is employed heated to about 120°, and the mixture is syringed off in the course of half an hour. It is safest applied in the evening and during dull weather, as bright sunshine is apt to injuriously affect the plant operated upon. I give this well-known recipe, not because I believe it so effective as a thrips and green fly-destroyer as either the decoction of quassia chips or tobacco water, but simply because I find it invaluable as a destroyer of mealy bug. This mixture again damaged the older leaves of the *Lonicera*, and for the future we shall employ the decoction of quassia chips and soft soap more diluted.

I believe *Lonicera sempervirens minor* is commonly called the Japanese Trumpet Honeysuckle, but I have searched in vain for a description or history of it.—W. IGGULDEN.

THE MUNSTER SCHOOL POTATO EXPERIMENTS.

THE following remark occurs in the interesting review which appeared in your issue of last week (page 135) on the experiments made on the cultivation of the Potato at the farm of the Munster Agricultural and Dairy School:—"Kainit and euraçoa phosphates gave 15 tons 19 cwts., a fact which seems to prove that nitrogen may be dispensed with, although we think it a pity that nitrogen should not have been given along with both kainit and phosphates."

No doubt there are soils to be found so rich in nitrogen as to meet the wants of the Potato or any other crop without an additional supply, but this can scarcely be so common as to render it prudent to dispense with this element in manures for ordinary cases. Unfortunately the composition of the soil at Munster is not indicated in your review (perhaps it is not given in the report), but the following table taken from Ville's interesting work may keep some of your readers from being misled by these experiments in so vital a point as the value of nitrogen in the cultivation of the Potato. The table not only shows the results which may follow from the elimination of nitrogen from the manure used, but how much its value is influenced by the presence of potash:—

	Result per acre.			
	1865.		1867.	
Normal manure	11 tons	3½ cwts.	9 tons	16¾ cwts.
Manure without nitrogen ...	6 "	14 "	8 "	6¼ "
" " phosphate ..	7 "	3 "	— "	— "
" " potash	4 "	4 "	4 "	4 "
Without any manure	3 "	1½ "	3 "	0 "

The suppression of potash caused the crop to diminish from 9 tons 16¾ cwts. to 4 tons 4 cwts., the soil without manure yielding only 3 tons, and as Ville remarks—"But this is not all. You will see by the preceding table that by reducing the proportion of nitrogen in the normal manure from 103 to 67 lbs. per acre [for these were the quantities of that element used in 1865 and 1867 respectively] we only obtain with 103 lbs. of nitrogen 11 tons 3½ cwts. tubercles per acre; with 67 lbs. of nitrogen 9 tons 16¾ cwts. tubercles per acre. By suppressing the potash in the two manures the results became equal. The excess of nitrogenous matter was altogether useless, and no longer exercised any action." "When the dose of potash was doubled the result was—normal manure with 103 lbs. of nitrogen 11 tons 3½ cwts.; manure without phosphate, 7 tons 3 cwts.; ditto, but with double dose of potash, 11 tons 4 cwts." "A remarkable instance," says Ville, "of the preponderant action of the dominant constituent." These crucial experiments appear to me to put the whole case in a striking and clear light. As Ville truly remarks, they are of "exceptional interest by reason of the ill effects that attend insufficient or badly composed manure" in growing Potatoes.—INQUIRER.

PLANTS IN POTS—LILIES.—At this time of the year gardeners are very busy, and when plants have bloomed it is but too common to see them placed out of the way, often fully exposed to the sun, which treatment, excepting perhaps for Pelargoniums and a few others that

require ripening, usually causes great injury to the roots. Often Cyclamens, Begonias, and many others suffer in this way; but I principally wish to urge more careful after treatment for Lilies when grown in pots, especially *L. auratum*. Too frequently they are said to be good the first year after importation and gone the third. This is often the cause of failure, and importers are not to blame. Remove the seed pods when the flowers fall, and grow them carefully on with plenty of water until the stem becomes yellow and withered.—W. J. M., *Clonmel*.

TALL SUMMER PERENNIALS.

BEING often asked to recommend tall and showy perennials for border decoration to flower late in summer "when the family are down," I mention a few which are in full flower here now on the 12th of August, reminding the readers that Cheshire is from a week to a fortnight later than counties to the south of London. I include nothing which does not grow more than 3 feet high.

Campanula pyramidalis.—Grows 6 feet high; colour blue or white. Requires a strong moist soil to flower well out of doors, and does best treated as a biennial from seed sown early the first year; but if the bed in which the seedlings are planted is kept undisturbed, fresh plants keep coming up from fragments of roots, which may be planted in the borders in spring to flower in autumn. A showy plant where it thrives.

Verbascum nigrum.—This, though a common native in the south of England, is a good border plant for any soil, to flower in July and August. If divided in early spring the size of the flower spikes is larger in proportion to the leaves, and the height is less. Roots may be divided in autumn, and are better for it. The white variety is a very beautiful plant, but requires a little more attention than the common form, or it may be lost.

V. Chaixi.—Though *V. nigrum* is often sent from nurseries by this name, the true *V. Chaixi*, called also *V. orientale*, is an oriental form of *V. nigrum*, and is quite distinct in form and habit. The leaves are broader, the flowers larger, and the stem, which is 5 or 6 feet high, being branched for its whole length. It is a very good plant. I have never seen a white variety of it, those entered in catalogues as *V. Chaixi album* being always *V. nigrum album*.

Monarda didyma.—In a moist soil and a sheltered but not too shady position this is a truly grand August plant. It should be replanted annually in a fresh spot, two or three shoots in spring being sufficient to make a fine plant if the soil is rich. With me it grows 5 feet high in the best positions. I have never seen a white *M. didyma*, those advertised being always *M. fistulosa*, a very inferior plant with dusty white flowers.

Aster puniceus.—A large-flowered, free-flowering, mauve or slate-coloured early Michaelmas Daisy 5 feet high, having two or three distinct varieties and more names. I took great pains to get it rightly named, and hope I succeeded. It is a good back-row plant, but requires frequent division to enable the flowerheads to be properly developed.

Veronica verticillata, alias *virginica*.—A tall upright species 6 feet high or more, with stiff slender stems, branched vertically, and flowers nearly white. Leaves in regular whorls, distinct and elegant, taking little room, and not particular about situation.

Veronica spicata var. longifolia.—I venture to name a large class of Veronicas in this comprehensive way, as I am convinced that no distinctive line can be drawn to separate them. The finest is a well-known variety called *subsessilis*, growing about 4 feet high when the plant is two years old, but being more elegant and ornamental when grown from an early spring cutting, when the proportion of flower to leaves is larger. Of other forms there are blue, white, and rose-coloured varieties, ranging from 2 feet to 4 feet in height. With regard to the distinction between these very variable and confused species, it is generally thought that the large forms with deeply serrated leaves and long petioles belong to *longifolia*; but two years ago I carefully saved the seed from a dwarf native plant of *V. spicata* not more than 6 inches high. The seed produced every form from the dwarfiest *spicata* to the largest *longifolia* 4 feet high with serrated long-stalked leaves.

Astilbe rivularis.—A coarse plant, and less elegant than *Spiraea Aruncus*, though flowering a month later, and in the same style. The form of the flower spike is handsome, and the flowers dull white; but it is a robber of the soil, and spreads much at the root.

Stenactis speciosa.—Upwards of 4 feet high, extremely free-flowering, continuing in full flower for at least two months; like a Michaelmas Daisy, with very large lavender-coloured heads.

Malva Aleca.—Five feet high, with abundant flowers of clear pale rose of good substance.

M. moschata.—Both the rose-coloured and the white forms are

worth cultivating, growing 4 feet high in cultivation, and continuing in flower all July and August. Both come true to colour from seed, and may be considered full grown at two years old.

M. Moreini.—The strongest in growth of all the Mallows, exceeding 6 feet in height, and producing larger flowers of a deeper rose than the others. It ripens seed plentifully, flowering well the first year.

Aconitum Napellus.—Amongst the many names under which the Aconite is sold, none, with the exception perhaps of *A. autumnale*, a very late flowerer, surpasses the old type. *A. N. bicolor* with dark blue and white flowers is now very handsome. One, sold as *A. N. album*, has pale dull yellow flowers, but not white; it grows upwards of 6 feet high.

Leucanthemum lacustre.—Over 6 feet high, with smooth glossy leaves, and flowers resembling those of an Ox-eye Daisy, but much larger and of more substance. It is a first-rate back-row plant, though its flowers are far inferior to those of *L. atratum*, a plant with far larger flowers, but not growing half the height, and, therefore, not to be admitted in this list.

Matricaria inodora flore-pleno.—Grows fully 4 feet high, and produces white double flowers without end. Strikes readily from any part of the stalk; and though it must be renewed annually requires no shelter to strike it, and makes a good show with little trouble.

Centaurea aurea.—A tall free-flowering plant, with leaves like those of *C. montana*, but flowers like those of a large yellow Thistle. The flowering period is long, and the habit of the plant good.

Mimulus cardinalis.—Three distinct colours of this, all of them 4 feet high, and producing a dense mass of flowers, are grown here. The strongest has rich crimson flowers, and is known as Crimson King. Another has rose-coloured flowers. The third is the old type with scarlet flowers.

Achillea Ptarmica flore-pleno.—A decidedly useful plant either for show in the border as a white flower or for cutting. It increases fast by underground runners, and should be planted on that account, confined by an earthenware ring, a plan which I find to succeed very well with such plants.

Enothera fruticosa.—This grows 4 feet high, and flowers all through the summer. It requires to be frequently divided to keep it in a condition to make the best show.

Lysimachia ciliata.—The flowers of this plant, which grows about 4 feet high, are of a pale yellow and freely produced.

Catananche carulea.—This grows about 4 feet high, and bears a long succession of pretty flowers. The plants flower the same year they are sown, and are perennial. The variety called "bicolor" with white flowers and purple centre should also be grown.

Stobaea purpurea.—This, too, if sown early flowers the same year. It has leaves like a Thistle, and large flowers in outline somewhat resembling those of a Passion-flower; colour dull white tinged with purple, borne from within a foot of the ground to the tops of the stalks, which are over 3 feet high. It is a novel and distinct plant.

The most showy yellow Composites now in full flower and exceeding 3 feet high, being all perennial and hardy, are *Helianthus* (or *Harpalium*) *rigidus*, 5 feet. It requires a warm dry soil, or the flower-stalks damp off. *Helianthus pubescens*, very free-flowering, and second only to the last-named, to which the flowers bear a great resemblance, but are rather later. *H. decapetalus* 5 feet; flowers smaller, but very abundant. *H. multiflorus*, double and single, 5 feet. *Helenium autumnale*, 4 to 5 feet high, varying in size and habit of flowering. A dwarf form called *H. pumilum* is excellent, but does not exceed 2 feet. *Inula macrocephala*, 3 feet, rather a disappointing plant, as the beds seem as if the flowers meant to be much larger than they are, but the bright gold colour is good. *I. Helenium*, 6 to 8 feet high; a grand plant in a moist rich soil, if only for its foliage. *Telekia cordifolia* or *speciosa*, 4 feet high, large deep yellow disks with drooping long rays. *Silphium perfoliatum*, 6 feet high, handsome foliage, and distinct in style. *Rudbeckia laciniata* or *digitata*, 8 feet high, and very showy and free-flowering, though a coarse plant. *R. californica*, quite distinct from the last, having downy undivided leaves; flowers fewer, but much larger and deeper in colour, height seldom exceeding 6 feet. A splendid back-row plant. There are many other tall yellow late Composites, but for August-flowering these are amongst the best.—C. WOLLEY DOD.

TAUNTON DEANE HORTICULTURAL SOCIETY.

THE county town of Somerset, pleasant in itself and pleasant in its surroundings (for there can hardly be a more lovely valley for richness and wealth of foliage than the Vale of Taunton), was again the scene of one of those successful flower shows (for which it has become famous) on Thursday last; and whether one has regard to the quan-

tity and quality of the exhibits, the admirable character of the arrangement, or the hearty manner in which it was taken up by the town and neighbourhood, an example was furnished of what can be done when people put their shoulder to the wheel; and if it be true that fortune favours the brave, it was eminently so with the Committee of the Taunton Show. A fine day (although the morning had been threatening) tended, of course, largely to its success, and during the afternoon most of the leading families in the neighbourhood attended. How different this is from those parts where hardly one would even attempt to put in an appearance—would perhaps subscribe to its funds, but never use their tickets! The Exhibition was arranged in tents, one containing the open classes, one that for amateurs, one for fruit and vegetables, another for cottagers, and the fifth for table decorations and bouquets; and all were well filled, the amateurs' tent perhaps not so well as I have seen it. The outdoor fruits, as might have been expected in such a season as this, fell short; but in all other classes the entries were numerous—the vegetables especially good.

I think it is not too much to say that a finer collection of plants at this season of the year was never shown than those exhibited by Mr. Lawless of Exeter (whose gardener, Mr. George Cole, is one of the renowned Manchester firm) and Mr. James Cypher of Cheltenham. The plants in Mr. Lawless' collection were *Lapageria rosea* and *alba* trained on balloon trellises; *Ixora Prince of Orange* and *Fraseri*, *Dipladenia Brearleyana*, *Erica æmula* and *Marnockiana*, *Stephanotis floribunda*; and *Allamanda nobilis*, *A. Hendersoni*, *A. grandiflora*, and *Clerodendron Balfourianum*. Where all were good it is difficult to particularise, but I think it was impossible to imagine anything more remarkable in culture than the two plants of Heaths; they were covered with blooms, and in the very highest perfection. Mr. Cypher's plants, hardly behind his competitor's, were *Ixora Pilgrimi* (very like *Fraseri*) and *Ixora Duffii* (a remarkable though somewhat coarse-looking plant, reminding one rather of *Clerodendron fallax*, but likely to be useful as an exhibition plant); *Ixora Williamsii*, *Bougainvillea glabra*, *Erica Irbyana*, *E. Candolleana*, and *E. Austiniana*; *Allamanda nobilis*, *Stephanotis floribunda*, *Anthurium Schertzerianum*, and *Erica æmula*. For six plants Mr. Cypher was first with a remarkable specimen of *Hæmanthus magnificus*, *Erica æmula* and *E. Marnockiana*, *Allamanda grandiflora*, and *Clerodendron Balfourianum*. In the class for foliage plants the same competitors were first and second, Mr. Cypher in this instance beating his opponent. He had at the back three grand Palms—*Thrinax elegans*, *Areca lutescens*, and *Latania borbonica*; while in front were fine plants of *Cordyline indivisa*, *Croton angustifolius*, *C. Disraeli*, and *C. Sunset*; and although the first of these Crotons is an old plant, what can be more lovely than it is when it is well grown? Mr. Lawless' collection contained *Latania borbonica*, *Croton Disraeli*, *Anthurium Veitchii*, &c.

The Fuchsias, as usual in these western shows, were remarkably good, the two best collections being so evenly balanced that the Judges were compelled to place them equal. Ferns were not so well shown as usual, but there were some fine specimens of *Adiantum farleyense* and other good kinds. Amongst the new plants exhibited were *Anthurium Andreanum* and a very remarkable *Disa* by Mr. Cypher of Cheltenham. This came up in an imported clump and would seem to be a seedling. It is totally distinct in colour from *Disa grandiflora*, having a white labellum and creamy-coloured sepals. Its habit is the same, and it would therefore appear either to be a natural hybrid or sport, more probably the latter, as there are flowering stems of the type in bloom in the same pan.

As usual there was a good display of cut flowers, although Mr. Keynes did not exhibit either in Roses or Gladioli. Roses were not (as they seldom are in August) very good. The best both in twelve trebles and twenty-fours were exhibited by Messrs. Cooling & Son of Bath. The best of their blooms were *Xavier Olibo*, *Jules Finger*, *Senateur Vaisse*, *Comtesse de Serenye*, *Madame Eugène Verdier*, *Madame Fillion*, *Baron Haussmann*, *Baroness Rothschild*, *Madame Hunneville*, *Richard Laxton*, *Lælia*, *Robert Marnock*, *Pierre Notting*, *Vicomte Vigier*, *Reynolds Hole*, *Star of Waltham*, *Alfred Colomb*, and *Duchess of Vallombrosa*. Dahlias were exhibited by Mr. Latin and Mr. Harkness of Bedale in Yorkshire. Some of the best blooms in the first-prize collection (Mr. Latin's) were *Ovid*, *Vice-President*, *Flag of Truce*, *Marchioness of Bath*, *Lady Gladys Herbert*, *Alex. Cramond*, *James Service*, *Lord Chelmsford*, *Rev. J. Fielding*, and *John Bennett*.

Gladioli were well exhibited. Mr. Kelway sent a fine stand mainly composed of his own seedlings, which made a fine exhibition at the end of the tent. The two competing collections were those of Mr. Dobree, who for so many years has successfully competed here, and Mr. Harkness, who grows them so well in far-off Yorkshire. Mr. Dobree had fine spikes of *Adolphe Brongniart*, *Horace Vernet*, *Amalthie*, *Cymbal*, *Fair Maid of Taunton*, *Vagrant*, &c. Mr. Harkness' collection was remarkable for some fine spikes, but more especially for the excellent manner in which some of the very old varieties were shown, such as *Penelope*, *Velleda*, *Meyerbeer*, and *Ninon de l'Enclos*. He had besides fine spikes of *Amalthie*, *Adolphe Brongniart*, *Orphée*, *Leander*, &c. I cannot omit mentioning here a splendid stand of a new white Clove, *The Governor*, about which there has been some controversy; but about the excellence of which, I think there can be no doubt. It is large and well formed, and there is no fear of the pod bursting as in *Souvenir de la Malmaison*.

It need hardly be said that the table arrangement of Mr. Cypher left little to be desired in tasteful arrangement and effect. A Palm

in the centre springing out of a flowery base, and two glass stands at the ends, together with specimen glasses carefully placed, constituted a most beautiful arrangement. It was to be regretted that only one competitor appeared against him, and this, though a little overdone, was very good.

Nothing could have been better than the manner in which the arrangements were carried out, and much credit is due to Mr. Samson the indefatigable Secretary for the manner in which all was done.—D., Deal.

RELATIVE to the flagrant example of PLAGIARISM which was submitted on pages 99-100, we have received the following letter from Mr. George Humphrey, head gardener at Nash Court near Faversham:—

“Your issue of August 3rd contains articles on ‘Allamanda Culture.’ Kindly allow me through your columns to inform Mr. Bardney and my many friends, and the horticultural-reading public in general, that my hands are clean of the whole affair, and I think I may venture to say that those who know me also know that I could not be guilty of such a discreditable act as my foreman, ‘D. D.,’ is charged with. My foreman’s name is Daniel Dowdeswell.”

Daniel Dowdeswell has, in an exculpatory paragraph in the paper in which the abstracted article appeared, stated that he “simply recorded his own experience.” We observe he does not deny the charge against him of copying Mr. Bardney’s article and foisting it on the public as his own. Daniel Dowdeswell has made himself notorious, and has shown that he has no claim to literary ability, and he had better have left the record of his “own experience” to someone else.

— THE INJURIOUS EFFECTS OF BRICK KILNS ON VEGETATION are, as we have seen more than once, of a very serious nature, and occasionally lead to litigation. At the Gloucester Assizes a case was decided in favour of Mr. Foster, nurseryman, against Mr. Harper, a proprietor of brick kilns. The trees and shrubs of the plaintiff had sustained damage by the sulphurous vapour from the defendant’s kilns, which were some 150 yards from the nursery. The case was tried before Lord Justice Bowen and a special jury on the 5th inst. The jury adopted the very practical course of visiting the nursery and seeing the damage that had been done. The question in dispute was exhaustively argued from a legal standpoint, but his lordship put the matter very clearly when he observed—“Suppose fire comes from the chimney of the blast furnace and sets fire to a crop near. What is the difference between the sparks of fire falling and burning it and the fumes of acid gas coming and burning it?” The injury being admitted a verdict of £50 damage was recorded for the plaintiff. The next morning Mr. Matthews asked for judgment for £50, with costs, and an injunction. The Judge granted an injunction, and said the defendant would not be restrained from burning bricks, but from burning them so as to cause damage.

— THE forty-third anniversary meeting of the ROYAL BOTANIC SOCIETY was held on Thursday last at the Gardens, Regent’s Park, Dr. H. A. Pitman in the chair. The annual reports gave a satisfactory account of the finances of the Society, the receipts for the year having exceeded the expenditure by over £306. The number of subscribers joining during the year—118, exactly corresponded with that of last year, and was above the average of the last twenty years. In addition to the usual flower shows, exhibitions of special groups or classes of plants had been undertaken. These were thought useful, as enabling amateurs to compare in one view the many varieties of one class of plants. Above £800 had been awarded at the exhibitions in prizes for the encourage-

ment of the cultivation of plants, flowers, and fruit, and so large was the collection of exhibits sent in competition for these prizes that much difficulty was experienced in finding suitable accommodation for them. Medical and other students, artists, and those whose pursuits had any connection with the vegetable kingdom, had been granted free-admission tickets. The distribution of cut specimens was so highly valued that 827 tickets had been applied for and issued, and nearly 37,000 cut specimens distributed.

— MR. T. S. WARE of Tottenham sends blooms of a very promising white Clove CARNATION named GLOIRE DE NANCY, respecting which he observes:—“The white is very pure, and the scent true clove; its grass and habit are identical with the old Clove, and it has every appearance of growing equally as free. I know of no variety so well suited for outdoor growth, and feel sure it will, when known as a white Clove, eclipse the popularity the old Clove has gained.” The blooms are of good size, extremely fragrant, and are freely produced—recommendations of considerable value, which will rapidly bring it into general favour as a border plant.

— DR. C. STUART, Hillside, Chirside, N.B., writes:—“In the endeavour to cultivate single flowers such as Pyrethrums, Dahlias, &c., I send you a bouquet of SINGLE QUILLED DAISIES which I have raised this season. They may not be worth much, but are very much admired by the ladies for cutting for the glasses as something new in colour at this season.” We can readily understand that such flowers would be admired by ladies, for they are extremely bright and pretty, and somewhat suggestive at first glance of the small Erigerons. The florets are neatly quilled, deep or pale rose and white, and would undoubtedly have a charming effect arranged with other flowers.

— A CORRESPONDENT is desirous to know who was the raiser of FOX’S EARLY POTATO. It is a variety which has become of late years very scarce, but forty years ago it was a favourite early variety. We find it mentioned by Mr. T. A. Knight in 1810.

— MR. G. STEGGLES, The Gardens, Faulkner’s House, Tonbridge, writes as follows:—“TOMATO ABUNDANCE is a new variety sent out this season, and in my opinion is the finest in cultivation. It grows to a large size. I have cut fruits from half a pound to 1½ lb. in weight each. Some of the fruits are corrugated and some round, smooth, and very handsome. The flesh is solid and very agreeably flavoured. It is a free setter and rather a vigorous grower. Those who have not grown this kind will do well to add it to their collection, and I think they will not be disappointed.”

— WE have received prospectuses and regulations of the INTERNATIONAL FISHERIES EXHIBITION to be held in London in 1883 under the patronage of the Queen and the presidency of the Prince of Wales. The Exhibition, it is stated, will be opened on May 1st, and continue open for six months, the exhibits to “include specimens of all kinds of fish life, and to illustrate all the modes by which the marine and fresh-water animals of economic value are captured and utilised, together with the commercial, scientific, social, historic, and legislative aspects of such fisheries.” Medals in gold, silver, and bronze, with diplomas of honour, will be awarded to the exhibitors. All particulars, with forms of application, &c., can be obtained from the Secretary, 24, Haymarket, London, S.W.

— WRITING ON HOUSE FLIES “J. C. B.” observes:—“I can promise ‘C. A. J.’ not only ‘a few moments’ peace,’ but entire immunity from the attacks of these insects, if he were to procure a box of Myocom Fly Gum, and use it according to the directions given with it. Strings coated with the gum are suspended from the ceiling, and the fly that settles thereon is doomed, acting also as a decoy to the rest, so that in the course of a few days the

room is cleared of them. With respect to the objections that have been made to the use of this gum, I may state that there is no need to let the flies linger and die, as the strings may be taken down daily and the insects killed."

— THE fourth Exhibition of the WAKEFIELD CARNATION AND PICOTEE SOCIETY, which was held last week, exceeded all previous exhibitions. The prizetakers in the chief classes were Messrs. J. Madoek, H. Gill, G. Lamb, W. Wilson, A. Spurr, W. Mellor, J. Battersby, J. Hardwick, J. Steel, and J. Netherwood. The premier Carnation was Admiral Curzon, exhibited by Mr. H. Gill; and the premier Picotee Lady Holmesdale, staged by Mr. T. Madoek. Mr. George Rudd of Bradford was the competent Judge of the Exhibition.

— Mr. F. BEZANT, The Rectory Gardens, Aversham, sends us the following note:—"I send you an Apple of D. T. FISH from a pyramid tree which I planted two years ago last October. It is a strong grower and good cropper here, with very fine even fruit. The Apple measures $11\frac{1}{2}$ inches round, and I recommend all growers to give this variety a trial, as it is an excellent kitchen Apple." Without doubt the variety is worthy of extended culture, and probably not a few of our readers have "D. T. Fish" without knowing it under its right name—Warner's King.

— CONCERNING semi-double ZONAL PELARGONIUMS Mr. Iggulden writes:—"We have now a great, and I may say bewildering, variety of these to select from; and seeing how extremely serviceable many of them are for flowering in large or small pots under favourable circumstances nearly all the year round, they deserve to be more generally grown. Single-flowering varieties may be the most showy, but for cutting and various decorative purposes are less valuable than the semi-doubles. One of the most successful propagators of, and a good authority on Pelargoniums, recently kindly favoured me with what he considers a good well-varied selection of semi-doubles. The selection consists of Heteranthe, orange scarlet; Victor Emanuel, salmon; F. V. Raspail, deep scarlet, very fine; Henry Cannell, bright crimson; Gambetta, rosy scarlet; Jean Dolfus, magenta; Madame Thibaut, pink; Madame Thiers, white; Nymphe, white; and Guillon Mangilli, crimson."

— AN American contemporary has the following note:—"Important in reference to their value in rural economy are the ACACIA FARNESIANA, which produce the fragrant flowers so much used in perfumery, and the A. HOMALOPHYLLA, the wood of which is highly prized and dearly paid for by manufacturers of fans. In every Moorish garden in North Africa there can be seen a few trees of the A. Farnesiana, of which the flowers are gathered by women and children for family use; whilst in France and Italy it furnishes a not unimportant article of commerce. In the district of Cannes alone about 36,000 lbs. of flowers are yearly produced, for which the perfumers pay from 50 to 75 cents. per pound, which would amount to about 45,000 dols. One tree furnishes, according to age, from one to five or more pounds; and one acre planted with about eight hundred trees would produce in a few years a notable increase of income to many of our farmers, some pin money to their wives, besides making farm work and farm life both pleasant and profitable to their children. But this pleasant prospect cannot be realised as long as the extraction of perfumes is not undertaken, because the Acacia flowers, like most of those flowers whose perfume is extracted, must be treated while fresh and on the spot."

— A WRITER in the "Gardener" has the following upon AQUILEGIA CHRYSANTHA:—"This is one of the aristocrats among hardy flowers. The whole family is attractive, but there is a dignity, grace, and refinement about this one that makes it a favourite wherever it is seen, and as it is easily come by, and a

free grower and bloomer, it is an 'everybody's' flower. It may be divided, but is very much better raised from seed, from which it comes perfectly true. Possibly the best time to sow is in spring, either in a particularly favoured spot or under a handglass in light rich soil. As soon as the plants have made three or four leaves they should be pricked out in half loam, half well-rotted manure, and watered should the weather prove dry. Under such conditions the plants will be strong by midsummer, when, during showery weather, they should be planted in the places they are destined to occupy. Transplanting should be done carefully, for it resents careless handling. As old plants fail it is best always to have a young batch coming on. For cut flowers it is a gem."

WASPS.

REPLYING to Mr. Robert Warner's letter in your impression of the 10th inst., I would inform you that we had an abnormal number of queen wasps make their appearance early this spring, and fearing for the fruit crop we paid 2d. each for them up to the middle of June. In spite of the great quantity of rain, which frequently injures the nests, the young insects have appeared in great numbers, and fully a fortnight earlier than usual. We have already destroyed four large nests, and my men inform me that they know of fourteen more. I would add that our situation is about ten miles nearly due north from London.—WINCHMORE.

MY experience at the present time is just the reverse of Mr. Warner's. I think I never saw so many queen wasps in the spring—certainly not for many years past. During April I destroyed two small nests, each with eleven maggots in them; these were in some Rhubarb roots which were put in a cold frame. After that I did not see a wasp until about three weeks ago. On the 6th inst. I destroyed the first nest. Since then I have destroyed fourteen within an area of 400 square yards. This is considerably more than I have ever known in such a short time and so near each other, for as a rule there are not many wasps in this neighbourhood—not a quarter as many as there are in some of the midland and northern counties. Although the nests are very strong in numbers I do not know what the wasps live upon, for I have not seen one on any of the fruits, either Grapes, Gooseberries, Plums, or Currants.—D. WALKER, *The Gardens, Dunorlan, Tunbridge Wells.*

WHY, WHEN, AND HOW WE MANURE OUR VINES.

WHEN I wrote "Of course urine contains no phosphoric acid" I referred to what is to be had at the stables, for sheep urine is hardly ever to be obtained, or that from swine either, and human urine is generally disposed of as quickly as possible. When the words "very weak" were used in regard to the water from the sewage tank, it was more with reference to the usual strength of liquid manures than to the usual strength of sewage water. As that referred to is mixed only with the water which comes from the closets, kept distinct from what comes from bath-rooms, lavatories, pantries, sculleries, laundries, and so forth, it is not to be compared with ordinary sewage water. The sewage from towns is mixed with all these and much more, and is comparatively valueless compared with what we use here. Although a weak liquid manure as gardeners would view it, it is quite as strong as such waters ever should be used when large quantities are required. As to how many grains of phosphoric acid it contains per gallon I cannot even hazard an opinion; but applied to all sorts of vegetables and plants, including those in pots, its action is very satisfactory indeed. For giving small plants a start nothing can be better.

When I said that in seasons of drought its application to Vines was very satisfactory I did not intend to mean that the applications were made to plants suffering from drought. Under such circumstances the mistake might be made of attributing to manurial matter effects brought about by the water alone. What was meant was that here in seasons of drought the water supply is apt to fail, and the garden supply has to be brought from a distance. To give Vines nothing but liquid manure for a whole summer might look like excess; but having tested such as is used here against pure water, or as pure as is generally found in canals, the results are in favour of the sewage water. Such results, we think, may be fairly attributed to the manurial matter contained in it, and we may safely conclude that four or five thousand gallons contain more—very much more—phosphates and nitrogen than an ordinary house of Vines can possibly want in a season.

Potash is amply provided as well, and if not, the annual application of urine "maka siccar."

I study economy, and "take that which lieth nearest" if reasonably certain that the best results can be thereby attained. For this reason I think Mr. Taylor errs, not in using closet manure, but in using such an extremely costly manure as Standen's. So far as that is concerned, I certainly think a better system of manuring Vines could be adopted. It is perfectly certain that £10 properly spent will go as far, if indeed not much further, than £100 spent on any of the fancy manures which are put up in small packets. When gardeners generally get to know what plants really want, and the sources of plant food, we may expect a big national saving under this head.

As for the closet manure and its real value, very much depends upon the amount of earth with which it is diluted. Earth from those modern contrivances, when large quantities of screened ashes are used, may be very well from a sanitary point of view, but they render the excreta dear for the carriage if the distance is great. When properly dried surface soil from loamy or clay land is used, and only sparingly so, not only is a perfect state of sanitation reached, but the resulting manure is of real value. When, as is the case here, it comes from public works, where earth is very sparingly used, where the sanitary arrangements are indeed so bad that no earth at all is used often, the manure is of the most valuable character, and is worth certainly three times as much as ordinary stableyard manure for many crops. Here a piece of land was recently enclosed that was so thin and poor, and with a subsoil so hard as to be nearly impenetrable, that Oats would scarcely grow. Although not more than 6 inches deep, yet dressed at the rate of 25 tons an acre with such manure as we have described, it has produced enormous crops of Cauliflowers, &c. Many of the Cauliflowers have been over a foot in diameter, and of fine appearance and quality. Brussels Sprouts and Savoys have indeed grown much too strongly. It is only fair to say that the season has been very favourable, as the soil has never been anything but moist. In addition all our short grass was used as a mulch, for we dreaded the results that would in such a soil have followed drought. Next year Potatoes will be planted with no further manuring, and experience leads us to expect a first-rate crop. As to what value should be placed on manure from earth closets, then, it is difficult to say.

As for the best way of manuring Vines I think, for reasons given before, no better plan exists than utilising sewage and urine in some such way as we do here; the one contains all the potash, the other the phosphates, and between them everything else plants of any description require. When such can be had no more economical or satisfactory plan can be pursued; all else that is needed is occasionally a little lime and plenty of water. When neither can be had I should employ bones, or, perhaps, better because more economical and likely to be equally efficacious, mineral phosphate, or other cheap phosphate to supply phosphoric acid. Where wood ashes were to be had I would not hesitate to rely on them for furnishing potash, magnesia, and lime. Failing that I would employ kainit, or a cheap source of potash, and apply quicklime sparingly. As for nitrogen, so long as we have sulphate of ammonia or nitrate of soda that need bother none of us. Possibly combination manure might prove more suitable and in the end more cheap. For instance, guano contains plenty of everything except potash perhaps. Then such manures as "Fimus" might go far to solve the problem. The fact is there are a hundred ways whereby Vines might be cheaply supplied, but few, very few, of us are in a position to do more than glance at the subject. I wish the horticultural world could induce the Government to grant a few thousand pounds to establish a garden where these problems could be solved by someone having at once a knowledge of gardening and science to enable him to conduct such experiments to a successful issue. Some people might consider this a waste of money, but it would in the end undoubtedly lead to an enormous saving. At the worst it would only cost the price of a few puffs of gunpowder, and one or two shells more or less. It is tantalising to see how such problems could be solved and yet be unable to move towards their solution.—SINGLE-HANDED.

A WEEK IN LONDON.

IN some departments of art London may be rivalled, but in horticulture it stands pre-eminent among gardeners. The parks, nurseries, private gardens, market gardens, as well as the great markets, form a collective body of gardening attractions not to be found elsewhere. Under such circumstances it is not surprising that country gardeners should look towards this great metropolis for improvements in their art, and no one who is observant can spend a few days there without gaining knowledge which must be of the utmost advantage to him.

In summer flower garden decoration the parks afford a wide field of observation both in design and the plants employed, and as much skill is devoted to arrangement and effect by the intelligent superintendents new ideas are put into practical shape annually. To describe all that is worth seeing would require far more time and space than can be given here, but no gardener who visits London should leave again without inspecting the parks. Battersea, Hyde, Victoria, and Regent's are the best, and apart from their flower garden interest capital ideas of effective planting may be gained in all of them; indeed, it would be most difficult to find a more interesting or beautiful park in any part of the country than the one at Battersea. The freshness distinguishing it is surprising, as the air is pure and the trees quite free from the discoloration which generally disfigures many about towns. Blue and white is a favourite combination of colours at Battersea. White variegated Pelargoniums and blue Lobelias are very pretty, and Acer Negundo and blue Delphiniums are more noble and equally beautiful. Some trellises about 6 feet in height covered with the fine free-flowering Clematis Jackmanni have a fine effect, as the plants are not spoiled by being tied-in too closely. The finer specimens of Ferns and Palms which are arranged in the sheltered dells of the subtropical garden have a charming effect. Pandanus Veitchii is regarded by most of us as a tender stove plant, but during the latter half of July we saw it in some of the beds in this Park in good condition. Coleuses are much more sparingly used in the London parks now than they were a few years ago; in fact, they seem to be on their last trial, as they appear dull against the Alternantheras, which furnish the bright colours in most of the foliage beds. In Regent's Park we thought the Golden Feather Pyrethrum was too abundant, but this may have been more from compulsion than choice, as all plants appear to suffer more there than in any of the other parks.

Booking at the Victoria Station for Clapham Junction, changing there, and proceeding to Hampton Court, gives a prospect of a poorly farmed district; but the termination of the journey is most satisfactory, as of all the parks about London Hampton Court is the most enjoyable. The Palace itself is a unique structure, and the flower garden has of late years gained considerable fame. The carpet beds are perfect in arrangement and condition, and reflect the highest credit on Mr. Graham. The beds filled with flowering plants there are also grand examples of their kind. John Gibbons Pelargonium, which was the pet seedling of my lamented friend Mr. J. R. Pearson, is the best of all the scarlet varieties grown. In number and size of trusses and deepness of colour it must command the attention of all. Combinations of scarlet and white were most effective there. One bed planted with dwarf specimens of Acer Negundo variegata and a splendid scarlet seedling Verbena was charming. The Acer branches were pegged down, and the white leaves and the scarlet flowers combined most happily. A fine collection of all the best herbaceous plants is an attractive and new feature. In the garden where the large Vine is situated improvements are visible since Mr. Stirling became Superintendent. The Vine itself has now something more genial than a hard road over the principal roots, and as we knew Mr. Stirling as a good Grape-grower when at Park Wern with Sir H. H. Vivian this historic Vine is not likely to suffer in his hands. This year it is bearing about 1200 bunches, which are very evenly distributed over the house, and will weigh about 1 lb. each. The idea that this Vine owes its extent and existence to its roots feeding in the River Thames is not confirmed by a personal inspection of the ground or situation. A long row of Orange trees which line one side of the walk leading to the vinery appear as if they would be benefited by frequent applications of liquid manure.

From Hampton Court to Kew is not a great distance, and this is the only way those interested in plants and flowers should return to London. Since we last saw Kew some twelve years ago the outdoor trees and shrubs have made good progress, many of them have now gained the proportions of fine specimens, and their health is all that could be desired. The new rockwork is a valuable addition to the many attractions. The flower beds in front of the large Palm house and those along each side of the long broad walk which form the flower garden part of Kew, are tastefully filled. Under glass the plants were in excellent health, and altogether Kew is in most satisfactory condition. As a public place of resort Mr. Smith, the able and courteous Curator, assured me it is becoming annually more popular.

Chiswick, "dear old Chiswick," as it has been lovingly termed by Mr. W. Taylor and others who have gained much knowledge there, is only some two miles Londonwards from Kew, and if I were asked which garden is most worth seeing about London I should have no hesitation in answering Chiswick. The collections of plants, fruits, and vegetables are extensive, and, what is of equal or more importance, everything is well cultivated. The Tuberos Begonias were fine. I have seen collections of these at our horticultural and agricultural shows, but the Chiswick plants overshadow them all in size, bloom, and general finish. The single and double Pelargoniums were surprisingly fine, the plants being most profusely bloomed. The Grapes in several of the vineries are in excellent condition. Considering the season Pears and Apples are a good crop, and small fruits are abundant. In the vegetable quarter the Pea crop interested me much, as there were numerous varieties on trial; but after inspecting them my opinion was that if all the newest and best Peas in the country were there nothing much superior to what is now in

commerce will be offered for years to come, as I saw none to equal several of Culverwell's varieties. Culverwell's Giant Marrow as seen at Chiswick is poor, and bears little resemblance to the grand original.

Visiting Hampton Court, Kew, and Chiswick is a comfortable and instructive day's work. Another may be most profitably spent among the nurseries of Messrs. Veitch, Bull, and Williams. The name of "Veitch's" is as well known to all gardeners as the word "London," and it will hardly be necessary to advise any to visit this excellently managed establishment. The Chelsea nurseries are some 5 acres in extent, and 4 of these are covered with glass houses. The inmates of these include every kind of plant worth growing, from the choicest Orchid to the most common bedding plant. Seventeen houses are devoted to Orchids, and the collection is not more wonderful in extent than health. In fact this expression may be applied to all plants in this nursery. The Pitcher-plants are astonishing in variety, size, and numbers.

At the time of my visit the collection of Orchids in bloom in Mr. Bull's nursery was very grand, and as Lilliums of the auratum section were arranged with them the odour was most pleasing. In other houses were thousands of small Orchids, and the demand for these plants must be greatly on the increase.

At a greater distance from London the nurseries of Mr. Charles Turner of Slough, and Messrs. Cannell of Swanley, Kent, should be included in the week's work. The former has high fame for Carnations, and all kinds of choice hardy and florists' flowers, while the establishment of Messrs. Cannell is unique. It has been named "The Home for Flowers," and it really is so. Covent Garden Market must not be left out of the programme, but a few hours from 5 A.M. will suffice. As a rule country gardeners are led to believe that market growers are far in advance in the production of vegetables, and that we have only to visit Covent Garden to get our eyes opened, and they will be opened too, but not in the admiration of the quality. The quantity is certainly astonishing, and this is all that can be said about it. I know many gardeners who would blush to send such Peas, Potatoes, Cauliflowers, Beans, Vegetable Marrows, &c., to the kitchen as those which formed the bulk of the produce in Covent Garden on two market mornings in July last. Plants in pots are well grown, and fruit, especially Grapes, very good.

The large seed shops are also worth visiting, also the market gardens. The manner in which cropping is carried on in those places is very suggestive. Vacant spaces are not tolerated, crop follows crop in rapid succession, and manure is applied unstintingly. This is one of the secrets of successful cultivation in market and private gardens alike.

Apart from purely horticultural subjects there is always something occurring in the neighbourhood of London to interest strangers. In the second week of July the Royal Agricultural Show was held at Reading. Interesting as this show always is, it was doubly so this time, as the celebrated grounds of Messrs. Sutton & Sons are close to Reading, and they offered attractions which few shows excel. Tuberos Begonias and Gloxinias were their principal flowers during the royal show week, and those were to be seen in great numbers and of excellent quality. The Gloxinias especially were far in advance of any I have yet seen. Following close upon this came the Wimbledon meeting; and although at first sight this may appear to have no connection with gardening it really has, as no one can visit "the camp" without being brought close to many celebrated gardens about the Common, and the way choice plants and showy flowers are used to decorate the open spaces in front and around many of the tents gives one an excellent idea of temporary flower gardening. This season the part set apart for the Canadians was the most effective. Most of the plants were arranged in different-shaped beds, and the pots were all concealed under a covering of cocoa-nut fibre. In private gardens beds might be formed and material of the kind might be used with advantage in many parts on any special occasion.

I must conclude, as these notes will occupy much of your valuable space, but a hint may yet be given to intending visitors. Do not be afraid to ask questions. At Veitch's, for instance, it may be remarked "What little pots those fine Orchid plants are in!" and the answer is "Yes, those allow us to give them great quantities of water without any danger of stagnation at the root," and it is from being in too large pots that so many Orchids fail to succeed. The compost is important in the cultivation of all plants, and an instance of good plant-growing should never be allowed to pass without asking particularly about this and other favourable conditions. In this way a week in London may not only give pleasant impressions at the time, but much information may be secured which may be useful in years to come.—J. MUIR, *Margam*.

PRIDE OF THE MARKET PEA.

WE have from time to time seen and heard much in favour of Messrs. Carter's fine dwarf Pea Stratagem, but little of its twin rival Pride of the Market. It is questionable if the latter is not the better Pea of the two. It is true the pods are not quite so large as those of Stratagem, but they are large enough and fill well, while the peas are of a deeper green and are sweeter than the other. The plants also bear with greater freedom—in fact Pride of the Market is, in my opinion, the most profitable of dwarf Peas. I had the two sown in one row, 10 yards in length, of each

variety, and while both are undoubtedly good, Pride of the Market bears the palm. Others may have formed a different estimate, but still I am sanguine of not being alone in arriving at the verdict now recorded.—W. P. L.

GARDEN FAVOURITES.

Violet Devoniensis.—This proves a great acquisition, coming into bloom early in July, and becoming more and more floriferous as autumn approaches. Its deep purple and very fragrant flowers have long stalks, which admit of their being made up into large bunches, a few of which mixed with Maréchal Niel Roses make a stand of cut flowers for a sitting-room table that finds favour with everybody. I regard this Violet and the old Russian as quite indispensable for every garden.

Salvia tricolor.—This makes a charming pot plant, not as a dwarf bush, but with two or three shoots left to grow unshortened. It then attains a height of about 4 feet, with foliage of a lively green hue, remarkably handsome, and, including the leafstalk, fully 10 inches long. Each leaf curves gracefully downwards, and has a lateral shoot springing from its axil, imparting to the plant an air of fulness without crowding, which is very pleasing, especially while it is in bloom. Each leading shoot is crowned by a flower spike about 9 inches in length, thickly set with its bright purplish pink flowers, not of a decided self colour, but delicately shading to a lighter tone upon the lower part of the flower, and with white lips. I have not yet tried it in an open border, but believe it assumes a dwarf bushy habit there, which in its way is equally attractive.

Arundo conspicua.—A large plant of this handsome New Zealand Reed had its plumes fully developed early in July. They are fully 10 feet high, but are not so abundant as usual. I had this plant from Messrs. Veitch four years ago, a small healthy plant of the usual size that we receive such things from a nursery, and its drooping foliage now covers a circle 9 feet in diameter, which cannot be an extraordinary size, for it is in ordinary soil and has had no special treatment. A leading place must be given it among our best hardy plants, not only for its intrinsic worth, but for the earliness of its flowering. In proof of its hardiness I may add that it sustained no harm in the cold winters of 1879-80, which proved fatal to a large plant of *A. Donax* growing near it.

Cornus mascula variegata.—Is a perfect picture in miniature during summer, but its delicate foliage is liable to suffer from fluctuations of temperature, and a sudden burst of hot sunshine after dull weather destroys the broad yellow margin of the leaves, but does no harm to the green centres, which remain intact with brown shrivelled edges that are most unsightly. In favourable seasons when the foliage sustains no damage it is in its best from June till autumn, for when the midsummer growth appears clothed with its bright yellow and green foliage the yellow margins of the spring leaves have changed to a pink hue that blends charmingly with the brighter colours. Its slender dwarf growth renders it unfit for a crowded border or shrub bed, but it is precisely one of those pretty little knickknacks that find a suitable home in a cosy nook of a rock bed, and help to render it attractive.

Berberidopsis corallina.—Glad am I to say that these have fully recovered from the baneful effects of the exceedingly cold weather of the two winters preceding the late mild one, both the large plants here being just now in full beauty of foliage and blossom. The flowers are unusually abundant, and although so quiet in tone are so striking as to at once attract attention, and one is repeatedly asked for the name of "that lovely climber." The growth is wonderfully robust, exceeding the bounds assigned it by many yards, and has encroached upon its neighbours, mingling with them in a half-wild manner that is by no means unpleasing. What is the correct colour of the flowers? I have termed it a deep coral, but am told I am wrong, and that rose-pink is the true shade.

Double Arrowhead (Sagittaria sagittifolia flore-pleno).—This lovely aquatic is now in great beauty. I counted fourteen expanded flowers upon one stem a day or two ago, each of them a pure white fleecy ball some 2 inches in diameter growing loosely in tiers upon stout stems rising about 20 inches above the surface of the water among the large green arrowhead foliage. Its culture is very simple. It is an annual, reproducing itself by a bulbous growth, which is found in autumn in the form of a small egg laying in the mud at the bottom of the pond. Half a dozen of the bulbs have only to be thrust into the mud a foot apart any time during winter in about a foot or two of water to produce at this season of the year a group that, for freshness, purity of colour, and much intrinsic beauty, has few equals. Once established it requires no subsequent care other than an annual thinning of the

bulbs after the growth dies in autumn, for if this is neglected the growth becomes crowded and weak.

A few of the tall-growing aquatics tell well among a collection. *Nymphæas*, *Nuphars*, *Villarsias*, and *Aponogetons* are all good, but none of them rise much above the surface of the water, and have rather a tame appearance alone. It is well, therefore, to introduce among them with the Arrowhead a few plants or groups of *Typha*, *Richardia*, *Ranunculus*, *Butomus*, and *Lythrum*. One frequently sees *Lythrum roseum superbum* strongly recommended for ditches and pond margins, and it is so brilliant as to be worthy of a conspicuous place in any moist ground. I have it just now most beautiful mingled with *Typha minima* in a shallow stream; but *L. Salicaria* answers well in a foot of water, and either of them may be lifted with impunity when in full bloom and dropped carefully in any part of a pond that is not over 20 inches deep. *Typha minima* answers best in the moist banks of the stream; planted out in a foot or two of water it becomes so coarse and vigorous as to lose much of its beauty. This is a matter worthy of our best attention, not only in its relation to this particular plant, but as affecting all others worthy of culture. As an illustration I may mention a bold mass of *Calla palustris* clustering cosily at the foot of a vigorous clump of *Iris pseud-acorus*. The *Iris* quite fills the channel of the stream which supplies the aquatic plant pond with water, and the *Calla* spreads outwards from it to a soft semicircular outline just far enough into the pond to fill with its pretty greenery what would otherwise be an unsightly angle.—EDWARD LUCKHURST.

NOTES ON THE BOTANY OF HONG KONG.

THE botanical aspect of Hong Kong is much more interesting than the horticultural aspect. The total number of species enumerated in Bentham's "Flora Hongkongensis" is 1056, but the discoveries since that work was published has added nearly 200 additional species, 75 of which are enumerated in Dr. Hance's Supplement to the Flora. The remainder have been described when the species were new, chiefly in the "Journal of Botany." Every year adds something to the already wonderfully rich flora, and, judging from the number of additional species which have been discovered of late in localities which had been well ransacked by botanists, we may expect many more interesting "finds." Recently I have had the pleasure of discovering a new *Otanthera*, which has been named by Dr. Hance *Fordii*; a new *Sonerila*, *Asplenium lunulatum*, and two or three other species which are not yet accurately identified. The chief botanical connections with other countries are with Japan, a few with Australia, and many with Assam, Sikkim, and Nepal, and the Khasia Mountains in eastern Bengal. When the opposite mainland of China becomes better known doubtless such plants as those which are exceedingly rare and only known in Hong Kong will be discovered. Amongst these interesting plants peculiar to Hong Kong are the beautiful *Rhododendron Championi*, *Rhodoleia Championi*, and *Symplocos decora*, and the interesting *Woodwardia Harlandi*; *Ainslæa Walkeri*, several species of *Calamus*, and many others. There are nearly a dozen species of Oaks and several Hollies, some of them ornamental evergreens, but none with spiny leaves like the favourite English species of the genus *Ilex*. Of Ferns there are about a hundred species, and about the same number of Grasses, a large number of which are very common and numerous in individuals, besides being extremely beautiful.

To return to the Oaks, I might mention that the acorns of one, *Quercus cornea*, are edible, and when once extracted from their shell, which is extremely hard and about a quarter of an inch thick, are very sweet and palatable.

Hong Kong furnishes but few edible plants amongst its numerous indigenous ones. The fruit of the Myrtaceous *Rhodomyrtus tomentosus* is tolerably good and enjoyed by the natives; it is hunted for like the Blackberries in England, chiefly by the boys. Then, again, the fruit of an Anonaceous plant called *Uvaria purpurea*, although it contains many seeds, is by no means to be despised, and has sometimes supplied me with refreshment when I have been botanising in the woods on the south side of the island. The bunch of fruit looks more like a small bunch of Bananas than anything else I can think of.

A very large number of plants are used in medicine by Chinese, herbalists' shops abounding in every part of the town. Perhaps the most sought for is China-root, *Smilax* sp. A great number of plants are used in fever cases and other diseases, but in a great many instances with very doubtful results.

Besides medicinal plants Hong Kong yields but little for economical purposes if we except the grass growing on the hills, chiefly *Spodiopogon obliquevalvis*, which, when full grown, is industriously cut by women and used for fuel. The hills have

a very treeless appearance in most places, which defect, however, is now rapidly and happily being overcome by the large plantations annually made. I have just completed the plan of forest operations for 1881, which will enable us to plant upwards of 800,000 trees, covering an area of about six hundred acres. The tree chiefly used for this purpose is *Pinus sinensis*, which grows rapidly and stands exposure well. For the great strides in afforestation in Hong Kong, we have more particularly to thank the present Governor, Sir John Pope Hennessy, who, when he arrived here, was so enlightened as to see at once the great importance of tree-planting, and to obtain the necessary funds for carrying out an effective scheme for that object.—C. FORD, *Botanic Gardens, Hong Kong.*

TWO NATIVE GEMS.

THOSE who are fond of native plants should not neglect to cultivate two of the neatest and prettiest, which I mention together, because the same conditions suit both, and because in North Wales they often grow mixed up in the same sod. The names are *Anagallis tenella* (Bog Pimpernel) and *Campanula hederacea* (Ivy-leaved Bellflower). On leaving Conway station in the direction of Bangor you pass two or three hundred acres of level uncultivated ground, lying between the railway and the sea, known as Conway Marsh. The soil is sea sand mixed with fine humus, and its very small elevation above the sea level secures constant moisture rising from the subsoil, though water never stands on the surface. Over a great part of this the ground is quite full of these two plants growing amongst the fine grass. They flower together through the month of July. Unless examined the flowers are so similar in size and form that they might be taken for different colours of the same flower. The colour of the Pimpernel varies from clear rose to pinkish white; that of the Campanula is more constant, being very pale blue. The Bog Pimpernel is found in most parts of England, but I have nowhere seen it so abundant as it is in all suitable spots in North Wales; and I lately crossed some old pasture fields in the neighbourhood of Holyhead where it literally covered the ground in such a way as to give the prevailing colour to the surface. These fields could not be called boggy, being apparently dry, and were situated on a hill side; but probably the subsoil contained water at a small depth. The Ivy-leaved Campanula is more local, and is often found in drier spots than the Pimpernel; but it likes a moist climate, and is tolerably common in Wales and the west of England. I have seen and will mention several ways of cultivating these plants, and I have had both of them growing in my garden for two or three years. A plan which suggests itself to the inexperienced—to dig up a sod containing roots of both the plants and transfer it to a moist part of the garden—generally fails. The fine grass becomes coarse, hidden weeds spring up, and the delicate plants are hopelessly smothered. It is, however, difficult to extricate the fine roots and delicate hair-like stems of the Campanula; the operation requires clever fingers and patience. When it has been performed the plants should be carefully planted in small pots of sandy peat soil and kept under a handglass, and well watered. When you see that they are growing choose a moist sunny spot. Fine sandy soil which neither cakes nor dries up is indispensable. The edge of a tank, where the *Anagallis* is grown at Kew, is a good place; the base of a rockery where watering is not neglected is also good; but if there is an exposed bog bed in the garden, that is the best of all. Lay a few stones about the size of half bricks, and raise the surface a few inches with riddled peat soil and sand, and both plants will grow luxuriantly in it, and will make a show which you may safely take your most fastidious gardening friends to see. I found the Campanula hard to establish, but when once that is accomplished it lasts. Both plants may be grown in pots standing in a tub of water to within 3 inches of the rim. I have seen the *Anagallis* doing well in this way at Kew, but I think the Campanula is not grown there.—C. WOLLEY DOD.

PHALÆNOPSIS VIOLACEA.

THOUGH one of the small-flowered species of this beautiful genus *P. violacea* possesses considerable attractions for culture in baskets, for its violet purple-tinted flowers are produced very freely, the neat bright green leaves and dwarf habit also being additional recommendations. In shape and size the flowers are rather suggestive of *P. Luddemanniana*, though they have not the distinctive markings of that species, the sepals and petals being oval in form, whitish towards the tips, but deep violet purple at the base, the column being of a similar tint. They are borne several together on short racemes, but the latter are produced so

freely that the plant has a very pleasing appearance when grown in a basket suspended from the roof of the Orchid house. It was introduced about twenty years ago, but was only certificated last year when shown by Messrs. J. Veitch & Sons of Chelsea at the meeting of the Royal Horticultural Society, June 28th. A very distinct and beautiful variety was exhibited at the last meeting of the above Society, August 8th, by Mr. Ballantine, gardener to Baron Schröder, The Dell, Egham. This was named *P. violacea* Schroederi, and the Floral Committee awarded a first-class certificate for it. It is distinguished from the typical form by the

flowers being of a uniform bright purplish tint, the petals not being whitish at the points as in the species. Another pretty variety, *P. v. Murtoniana*, is also known, a yellow hue being largely present in the blooms.

ANDROSACES.

THIS is a charming little group of Alpine flowers belonging to the Primula family, the floral structure being very similar to that of the genus *Primula*, but differs in the corolla mouth, which

Fig. 26.—*PHALLENOPSIS VIOLACEA*.

is very much contracted in *Androsace*. There is a number of species, especially if we include the sub-genus *Aretia*. Regardless of them, however, the species of the genus proper are numerous, inhabiting the mountainous regions of Europe, more particularly extending from Siberia to the Pyrenees, while a few occur in the upper parts of the Himalayas; indeed, there may be several indigenous to the latter part yet undiscovered, as the flora of those regions is by no means fully worked out. There is nothing in these plants conspicuously attractive, but their very simplicity is quite sufficient to interest all lovers of Alpine plants. *A. sarmentosa* is certainly pretty, and it has been received well by the floricultural world generally, but the other species are only known

to specialists, which are comparatively few in this country. The reasons for this are manifold, the primary one being, perhaps, that there has not been sufficient care bestowed upon them under cultivation, the result of which has been frequent loss. In the cultivation of Alpine plants, it must be confessed we are far in the rear of our continental brethren, and I do not forget that their climate generally is more conducive to the well-being of such plants, and amongst English gardeners as a whole there is a great lack of knowledge respecting them. They are most studiously cultivated by many on the continent absolutely for the love of them, and, in my opinion, the absence of such enthusiasm is the chief cause why so many of our Alpines have been,

and are being lost. More intelligent work is needed among these plants than has been exercised during the last half century.

As regards the cultivation of Androsaces, they require the rock garden as a home, and to be planted in well-drained partially shaded positions, so as not to receive sunlight during the hottest part of the day, with a good depth of soil to root into. The following compost I have found suits them when suitably prepared—good turfy loam, leaf soil, sand, and broken limestone in equal parts, the latter broken up finely and well mixed with the other parts. When planting press the soil firmly about the plants and cover the surface round about them with small nodules and fragments of limestone to keep the roots cool and moist, as that will greatly prevent evaporation. They may be fully exposed during all the year except the winter months, when they should receive a slight protection, not necessarily against the cold, which they can endure with impunity, but against superfluous moisture when at rest, which is positively injurious, causing decay, especially in the case of the woolly varieties. This can be effected by a bellglass tilted so that there is free access of air, or a sheet of glass so placed that the rain can pass off. This answers a similar purpose as the coating of snow they receive under natural circumstances. It is necessary to keep a sharp look-out for slugs, as they are very partial to them, and in making a good meal would greatly reduce the size of a good established plant. The different species are increased in various ways. Some can readily be divided, which should be done carefully; and in the case of those kinds which emit runners, the latter should be pegged down, when they will readily root, after which they may be separated from the parent. Several kinds are easily increased by cuttings, which should be taken when the wood is ripe, inserted in well-drained pots of very sandy soil, and placed in a cold frame in a shady position, watering carefully. They are slow in striking, but there is no difficulty in the matter. They are also easily raised from seed, which should be sown as soon as ripe, as the longer it is kept the slower it is in germination, like most of the Primulaceous seeds. It is best to raise the seed in pots filled with carefully prepared soil, and place the pots in a cold frame or cool greenhouse, standing them upon a cool bottom. Cover the seed lightly, and cover the top of the pots with a suitable pane of glass, so as to prevent evaporation and reduce to a minimum the necessity of watering. Let the young plants remain in the seed pots until they are well established rather than pricking them off young. Finally, plant them out on the rockery in batches so as to form a clump quickly.

Old cultivators of these flowers grew them in pots, when they were given the protection of a frame during the winter, or were covered with such protecting material as bracken fronds. This plan is to be encouraged, especially where it is not practicable for want of material with which to construct a rockery, and they are easily managed this way. This method of culture is largely practised on the continent, where, however, they have not only climatal advantage, but cultivators are frequently collectors. Many young gardeners enjoy their short holiday with an alpine excursion in search of their favourites, which are taken home and carefully cultivated in pots. A few of the best species are briefly described below, and it is difficult to find many others in cultivation with us, although several others are offered by some alpine plant-cultivators in Austria and other parts of southern Europe.

A. carnea.—Very free-growing; leaves in flattish rosettes, linear, smooth; flower stems 4 to 6 inches high, forked; flowers bright pink. It flowers very early in the year, being one of the first flowers to open, and is extremely pretty. Very gritty soil is most suitable for it. It is a native of the Swiss Alps, and was introduced into this country more than a century ago, and was cultivated by Mr. Miller in the Chelsea Botanic Gardens.

A. Chamajasma.—A very small species, forming under favourable conditions dense cushions. Leaves less than an inch long, linear lanceolate, hairy, in roundish rosettes; scape 1 to 2 inches high, supporting a small umbel of white flowers about one-quarter of an inch across with yellow eyes, or rarely of a light pink colour. It is a little gem, very free-flowering, and the flowers last some time, appearing in June. It is found on the mountains of southern Europe generally, where it forms very large masses, and was introduced about the same time as the last.

A. ciliata.—A small tufted species, with light green, linear, ciliated leaves; flowers in tiny umbels, very freely produced, bright pink with pale yellow eyes. A very close and free-growing kind, enjoying a damp situation. Native of Austria, flowering in May and June.

A. glacialis.—A very dwarf species with sub-trailing branches, slender, and rather fleshy; leaves linear, blunt, smooth, 3 to 4 lines long; flowers produced at the ends of the branches, almost sessile, pink, about 4 lines across. A very curious little species, somewhat resembling some of the Stonecrops. It enjoys a well-drained posi-

tion, with a free admixture of limestone crumbs, where it thrives well. Native of the Swiss and Austrian Alps.

A. lactea.—A free-growing species with flattened rosettes; leaves 1 to 2 inches long, linear acute, smooth, light green; flower stems 4 to 9 inches high, divided at the top, bearing several flowers about 4 lines across, pure white. This requires a dry position during the winter, as it is very liable to decay without some covering. If that is afforded it is perfectly safe, multiplying itself by runners, which should be carefully pegged down. It flowers in June and July. Native of the Austrian mountains, and appears to have been cultivated by Miller.

A. Laggeri.—This is also a tufted species, very dwarf; branches sprouting, thickly covered with small subulate leaves 3 to 4 lines long, rather prickly; umbels near the extremities of the branches one to three-flowered; flowers bright pink with yellow centre, the corolla limb five-lobed. This is a little gem, and does very freely in a moist position in plenty of leaf soil and sand. I have also known it to thrive well in a small bog bed, and well remember seeing a splendid little patch of it in such a bed in Mr. Whitehead's garden at Bickley. It flowers in April and May, and comes from southern Europe.

A. lanuginosa.—A very distinct trailing species, with long reddish branches covered with white silky hairs; leaves ovate lanceolate, 1 inch or more long, thickly covered with silvery down; umbels axillary, copiously produced, many-flowered; flowers 3 to 4 lines across, white shaded with lilac, with conspicuous yellow centres. This is a most desirable plant for the rockery, the flower umbels blending so charmingly with the silvery-grey foliage, while the growth is so disposed as to render it a capital rock plant, and it should be so arranged it can ramble over the ledges of the stones. It enjoys thorough drainage in very free soil, and the cuttings will root freely if treated carefully in a cold frame. It flowers nearly all the summer, and is a native of Asia Minor.

A. obtusifolia.—A dwarf dense-growing kind, with roundish rosettes of linear, acute, very hairy leaves, resembling some of the Drabas, $\frac{1}{2}$ to 1 inch long; flowers in umbels, pink, 3 lines across. This is perhaps not more than a biennial, as it dies away very frequently; but it seeds freely, and is easily raised, flowering in April and May. Southern Europe.

A. pyrenaica.—A very dwarf tufted species, resembling some of the dwarf Saxifragas of the aretioides section; branches not more than 1 inch high, erect, covered with small narrow blunt leaves; flowers axillary, usually solitary, pink, very small, but freely produced. It requires a well-drained fissure in loam and coarse sand, surrounding it with pieces of limestone. It is not so showy as the others, but it is very distinct, and should be grown, coming from the Pyrenees.

A. sarmentosa.—A very handsome species from the Himalayas of comparatively recent introduction, forming large compact rosettes; leaves 2 to 3 inches long, strap-shaped, hairy, falling away at the end of summer, leaving dense woolly rosettes; flower stems 6 to 9 inches high, umbellate, with several flowers 5 to 6 lines across, bright rosy-pink with white centres. This is a very free-growing kind, each rosette producing several runners, which should be pegged down, when a little colony may soon be formed, and it is a very handsome plant, covering in a comparatively short time a good patch, flowering in June and July, or even later. I have known plants to vary much in the time of flowering.

A. septentrionalis.—A very free-growing annual, or, at the most, biennial species, none the less, however, worthy of cultivation. Leaves linear lanceolate, distantly serrated, in flattish rosettes; flower stems 6 inches high, forked at the top, several-flowered; flowers pure white, 4 lines across, very pretty. It flowers as early as March, frequently when the ground is covered with snow, continuing in a mass till the end of May, when it seeds freely, which falls to the soil and readily germinates, and a batch of young plants take the place of the old ones, so there is little trouble with it, and it is charming during the long blooming period. Native of Russia.

A. villosa.—A very compact-growing dwarf kind; leaves in close roundish rosettes $\frac{1}{2}$ to $\frac{3}{4}$ of an inch long, linear, acute, covered with white silky hairs; scape 1 to 2 inches high, with small umbels of flowers, white with yellow eyes, or light pink, very freely produced. This is a beautiful little plant in any state, enjoying a soil composed of crushed limestone and sand, with a little loam added, when it roots freely, the rosettes producing a number of tiny runners, which freely establish themselves. I have also taken these runners off and rooted them in a cold frame, and planted a colony of them on the rockery, where they thrived admirably. Native of the Pyrenees, flowering here during May and June.—N.

PASSIFLORA CERULEA IN IRELAND.—For the past month this beautiful Passion-flower has been blooming here against a southern

wall. I thought I had lost it in the severe winter of 1878, and until this year had not sufficiently recovered to bloom again. Hearing it described as perfectly hardy I did not in any way protect it, but shall do so with bracken or hay in future. This will prevent the stems being killed. To bloom continuously during the summer months occasional supplies of liquid manure, full exposure, and severe pruning and thinning must be resorted to.—W. J. M., *Clonmel*.

THE CATSHEAD APPLE.

UNDER the above name we have an old Apple tree that never fails to bear good crops of very large fruit. We have planted many modern varieties during the last fifteen years, but not one of them is so really useful as this. The fruit is of excellent quality when cooked—is, indeed, one of our best kitchen Apples for winter use. A local nurseryman has told us the proper name of our Apple is the Costard, but it has been known as the Catshead by three generations of the family. Whatever its true name may be, it is one of the best of orchard Apples, and ought not to be lost.—NORTH LINCOLN.

[The Catshead is one of our oldest and best culinary Apples. It is in use from October to January. The tree is a strong and vigorous grower, and attains the largest size; and though not an abundant bearer during the early period of its growth, it is much more productive as it becomes aged. In the Horticultural Society's Catalogue of Fruits, and also in Lindley's "Guide to the Orchard," this is made synonymous with the Costard of Ray, which is undoubtedly an error, the Costard being a distinct variety. The Catshead was always highly esteemed for its great size. Phillips, in his poem on Cyder, says:—

— "Why should we sing the Thrift,
Codling or Pomroy, or of pimpled coat
The Russet, or the *Cat's-Head's* weighty orb,
Enormous in its growth, for various use
Tho' these are meet, tho' after full repast,
Are oft requir'd, and crown the rich dessert."

In Ellis's "Modern Husbandman" he says the Catshead is "a very useful Apple to the farmer, because one of them pared and wrapped up in dough serves with little trouble for making an Apple dumpling, so much in request with the Kentish farmer for being part of a ready meal that in the cheapest manner satiates the keen appetite of the hungry ploughman both at home and in the fields, and, therefore, has now got into such reputation in Hertfordshire and some other counties, that it is become the most common food with a piece of bacon or pickle pork for families."]

ST. VINCENT'S, GRANTHAM.

TRAVELLING a short time ago on the main line between York and London I determined, as I neared Grantham, to visit the above establishment, which is easily recognised by the spire that rises from the mansion. It is the home of Mrs. R. Hornsby, widow of the late R. Hornsby, Esq., senior partner of the extensive firm which has long been famous for the various agricultural implements made by them. These, however, have not been the means of bringing the St. Vincent gardens prominently before the horticultural public, but the excellent exhibits staged by Mr. Mann at the London and other provincial exhibitions during recent years. I have had several opportunities of seeing his successful exhibits, and this tempted me to break my journey and again visit the gardens that I had seen, over eight years ago, prior to Mr. Mann taking charge. The improvements since then have been considerable, and the trees and shrubs which were then comparatively young have grown with such rapidity and so many glass structures have been erected that I could scarcely recognise it as the St. Vincent's once familiar to me.

The garden is situated on the side of a hill, and much excavating has been necessary where the glass houses have been erected. The drive is of moderate length, gradually curving and rising from the entrance to the mansion. To the front on each side are grand pyramidal specimens of Golden Yews, varying from 6 to 8 feet in height, and every plant is well proportioned. At intervals Thuja elegantissima, about the same height, are like pillars of gold. These are also freely employed about the grounds, and evidently do remarkably well, for I do not remember ever seeing this beautiful Conifer in better condition. In the background is a row of young standard Limes with beautiful round heads: the trees are planted sufficiently far apart to develop naturally. Between these, and rising out of the above-named shrubs, are Irish Yews, which show to advantage by the light young foliage of the Limes and the pillars of gold surrounding them. I have not seen any planting more effective, and have always regarded the Irish Yew as only fit for churchyards as it is seen in many gardens; but as employed at St. Vincent's, with taste and judgment, nothing could have been more appropriate. In every instance the shrubs have been planted a good distance apart, or have been timely transplanted to allow each individual specimen room to develop without encroaching upon its neighbour. In few places is the same wise plan carried out so well.

Although each specimen has plenty of room there appears no thinness in the borders, for the spaces between them are occupied with many hardy flowering plants. In such places herbaceous plants are shown to advantage, and not only afford abundance of flowers for cutting, but brighten the shrubbery borders. The most striking in flower were quantities of Intermediate Stocks of various colours, which were one mass of bloom, grand for borders as well as pots during the spring. Good patches of Pansies, *Narcissus poeticus* and its pure white double form *albus plenus*, were conspicuous, and should be grown in every garden where quantities of cut flowers are in request. *Iberis* in large clumps were showy, and *Pyrethrums*, *Irises*, *Pæonies*, and *Aquilegias*. These will be followed by *Phloxes*, *Delphiniums*, and many others.

Leaving the drive before reaching the mansion we traverse what is known as the Serpentine Walk, which curves through a large belt of choice Conifers and ornamental trees. On each side of this and other walks are grand Hollies—standards of the weeping kinds, with their branches sweeping the ground, and in the best of health and condition. Many silver, golden, and green varieties are seen in various parts of the grounds, and in every instance are perfect pyramids. The quantity of bloom many of them were producing rendered them attractive at the time of my visit; this applies to the former as well as the latter, the silver kinds being so laden with bloom that they were perfectly white, and added materially to the beauty of the plants. I also noticed a fine young specimen of the Weeping *Wellingtonia* doing well, and in its true character. Large patches of *Ajuga reptans purpurca* were conspicuous with numerous spikes of bright blue flowers, the plants succeeding best when undisturbed. The Serpentine Walk leads into another walk running almost parallel with the drive, and by which the mansion and flower garden is reached, the latter lying in close proximity to the former on the south side, with a fountain in the centre and the flower beds cut out in the turf. Although Mr. Mann admires and makes provision for hardy plants he also appreciates summer bedding, and I am informed he does it well.

The glass is extensive, and, as already noted, much excavating has been necessary before building the vineries and Peach houses, for the ground behind is almost level with the tops of the houses. The first and early vinery is especially noteworthy on account of some experiments conducted by Mr. Mann, and which may prove of interest to many readers. The Vines are sixteen years old, and consist of Black Hamburgs and one Royal Vineyard. The former was ripe towards the end of March, and were well finished; while the latter was far from ripe, but had set as well as would be expected of Foster's Seedling. From this Royal Vineyard two canes have been laid horizontally, Black Hamburgs being worked upon it; and two or three canes have extended three parts of the way up the rafters, and are carrying large bunches and bold foliage. The Grapes on these marched Vines were commencing colouring nearly two months later than those on their own roots and in the same house, and subject to the same treatment. The object to be attained by using the Royal Vineyard as a stock was, if possible, to produce the Black Hamburg in good condition until March instead of January. If grown in a late house this useful variety will not keep much after the latter date, but by working it on the stock alluded to there appears every chance of Mr. Mann succeeding in his object. It is readily seen from the experiment in the early house that this stock has a great influence in keeping the Black Hamburg late. This is to be further tested, as a number of Royal Vineyard stocks are in readiness for working, and a house is to be planted with them.

The extension system of Vine-growing is practised in the next house, which is being filled with Alnwick Seedling that has been planted three years, and has seven canes nearly to the top of the house, with others extending horizontally, from which the remaining canes required will be taken. In this house I noticed some Plum trees in tubs bearing fruit fast approaching ripeness. The next is a large vinery with about twenty-nine canes in it, some Vines with two and others three canes; they have been planted five years, and consist of Alicantes, Muscat of Alexandria, Gros Colman, Gros Guillaume, Black Morocco, and Golden Queen, a great favourite here. Waltham Cross is another variety much appreciated as a late Grape, and produces long tapering bunches from the young wood, but is very shy from the old spurs. To grow this Grape well no doubt the long-rod principle would be most suitable. The border is partitioned into as many compartments as there are Vines by $4\frac{1}{2}$ -inch brick walls, so that any one Vine can be taken out without disturbing the roots of its neighbours. Where a number of varieties are grown in one house this is an admirable plan, as any that may require it can be kept drier at the roots while ripening. Dryness at the roots is found here to be the secret of success with Golden Queen, and perhaps Mr. Mann's success with Black Morocco may be attributed to the same cause, as it sets well and the fruits do not crack. These Vines had been grown up to the time of my visit without fire heat, and were very healthy.

Another house of similar length has been recently planted. The old Vines planted previous to Mr. Mann's charge were never good, the fruit always shanking badly. The border was 4 feet deep, and the roots had passed into the clay. The new border is made on the old one, and provision is made to keep the roots from unsuitable material. Black Hamburgs fill the next compartment; they had been planted five years and were carrying a good crop of fair-sized

bunches, which had just commenced colouring. This border is only 18 inches deep, and has been made on the gradual system. The next and last vinery that I shall notice is filled with Muscats, which are carrying a good crop of well-set bunches. These Vines used to shank from the cause above alluded to, but have been lifted and their roots brought nearer the surface. One of the Vines of Muscat of Alexandria has been worked on Muscat Trovèren, and not only grows more luxuriantly than the rest, but produces larger bunches and berries, this difference being readily observed in their present stage. Another is on the Madresfield Court, but the growth is rather weak, and no perceptible difference can be seen in the fruit either now or when ripe from the fruit of those on their own roots.

Four or five houses are devoted to the cultivation of Peaches and Nectarines. The trees throughout are clean, healthy, and are carrying good crops of fruit. The young shoots are thinly trained, so as to admit abundance of light and air amongst the branches, which is the secret of having thoroughly ripened wood, plump buds, and fine fruit the following season, other conditions being favourable. The varieties principally grown are Peaches—Royal George, Barrington, and Violette Hâtive. Nectarines—Elruge, Victoria, Violette Hâtive, and Stanwick: the last-named cracks badly in some places, but shows none of its faults at St. Vincent's.

Melons are grown in several useful span-roofed structures, and Mann's Hybrid Green-flesh is seen true. It is a handsome fruit, round, nets well, and may be termed a small Melon. The one that attracted my attention most is a seedling named Sir G. Wolseley, and which if I remember rightly was exhibited at South Kensington last year. It was growing by the side of Eastnor Castle, Read's Scarlet-flesh, Hero of Lockinge, William Tillery, and others, all having been raised and planted at the same time. The fruits of the last-named had commenced swelling, while the seedling would have its fruit fully ripe in three weeks from the time of my visit. This Melon is round, of small size, nets splendidly, and from all appearance is a good early variety. The Melons are planted closely, and have about two or three fruits each on the first laterals.

Plants are grown as well as fruit, but not on such an extensive scale, being principally in small pots, and of a suitable size for decorative purposes. Ferns are in special request, and a large house is filled with them as well as a rockwork fernery, with the Ferns planted out amongst the rocks and round small pools of water. In one of the plant houses I noticed a new Coleus, a sport from Magic but much superior to that variety. It has light yellow leaves, which possess a transparency which will give it an effective appearance by gaslight. Round the stem and at the axils of the leaves are deep crimson markings, which render it the more effective.

In thanking Mr. Mann for his kindness, it is only fair to say the gardens were in good order, and cleanliness prevailed everywhere.—VISITOR.

THE INFLUENCE OF FORESTS UPON CLIMATE.

THE following remarks upon the above subject by Dr. R. Schomburgk are appended to his report of the Adelaide Botanic Garden and Government Plantations in South Australia for 1881.

Whether or not forests are of importance to climate is a question pretty freely ventilated of late by science; but how important they are in the household of Nature, and how closely connected with them is civilisation, I shall endeavour to prove. The green leaves and young branches of trees derive a great deal from the atmosphere by binding the carbon of the carbonic acid for the purpose of producing woody substance, amylo, fibre, &c. Likewise the soil gets the benefit by the dropping of the leaves, which, decomposing, return to it partially the material taken out of the ground by the roots. But what is equally important, the leaves also cover the surface when decaying with a rich layer of humus, the shadows of the trees keep the ground moist, so a constant decomposition takes place. Now we know that water is necessary for the existence of plants, for without water no diffusion—without diffusion, no vitality. If on one side the forests absorb a great deal of water out of the atmosphere, they also on the other side exhale humidity on a large scale. As a rule, humidity surrounds them, rain falls, and dew. The forests attract and draw down the rain clouds, which benefit themselves and likewise the neighbouring agricultural land. We therefore, as a consequence, always find good agricultural land near forests. Without doubt we are all acquainted of the fact that plants are not only nourished by their roots but also by their leaves, which are the lungs, and by their inhaling and exhaling purify the air in a great measure. It is perfectly understood that dew is nothing else but a deposit of mist or vapour on the surface of the earth, which can only be generated by having been exhaled or evaporated from the surface of the earth: but the dry sand and naked rock cannot exhale any humidity, therefore dew very seldom falls on them, and only in consequence of attraction by a neighbouring forest. The forest itself, presenting a very large surface for evaporation, returns the loss of the soil in the shape of a refreshing dew, which falls on it in abundance. If we find that very little dew falls on the soil of a very dense forest, the reason is the rays of the sun cannot penetrate deep enough and convey heat thither, consequently very little evaporation can take place and produce radiation of heat.

It is perfectly well known that most of the rivers spring from wooded mountains. The forests conserve the water of a country,

and thus nourish the rivers and springs. In a desert the rivers generally dry up. All those magnificent and powerful rivers of North America spring from primitive mountainous forests; but I doubt if they will continue to discharge the same quantities of water into the sea in the future, when their mother forests are gone. We already hear that the Mississippi is getting perceptibly lower since the last decennium. We also know that when during the winter, when snow and ice melt, great bodies of water suddenly gather in the mountains, and come rushing down with disastrous effect. But even here we perceive a great difference in the manner the waters are drained off. For instance, if such a stream springs from a dense forest a great deal of ice, snow, and water, are retained by the layer of humus acting like a sponge, and consequently the water is drained off gently and with much less danger. But when once the forests of a country are gone there is nothing to check the wild impulse of the waters, and very destructive inundations take place. With reference to this I wish to point out, as one instance only, the fearful inundations caused every year by the Rhone in France.

No doubt some countries at the present time bearing the character of a hopeless desert were always so—for instance, the Sahara; but other countries now in a similar plight were formerly in a different condition. All those vast and almost endless savannahs or plains and prairies of Australand, South Asia, were once heavily timbered; Diodorus of Sicily, at least, mentions the existence of immense forests destroyed by fire. According to Cæsar and other Latin authors, Germany was covered with immense forests; and according to Herodotus and Thucydides the same was the same with Greece, Italy, Spain, France, and England. If we believe in the testimony of Diodorus, the forests of Spain were devastated to a large extent. We know that this country, when subjugated by the Romans, was covered with large forests, especially its southern provinces; but at the present time only her coast retains the forests, and the interior presents the aspect of a vast plain covered with Heath, Lavender, and Rosemary. The forests of the Peloponnesus were burnt down by Ali Pashi, and in consequence there came famine and drought. Likewise a Russian general, in modern times, rendered his name infamous for ever by burning and destroying wholesale the forests of the Caucasus for the purpose of routing out and starving the brave Tsherkessians. The name of the man is Dibitsch Balkansky. Since the destruction of these forests the climate has entirely changed; the country has become barren, droughts and famine set in. In the islands of Mauritius, Jamaica, and the Azores, in the two former, for the purpose of extending the sugar cultivation, where the forests have been cut down, so that some parts of these islands are now totally denuded of trees, the results are felt most alarmingly. The rain has become less every year; springs and rivulets which before flowed uninterruptedly have now ceased to flow. The respective governments of those islands, convinced of the injury done to the country, have taken steps to replant the forests; especially in Mauritius the replanting has begun in full earnest, and our Gum trees are partly used for the purpose.

If anyone still feels inclined to doubt the influence of forests on the climate of a country I beg to give several instances of modern times. The Delta of Egypt, well known for its dry climate after the destruction of its forests, Olive, and other plantations, had about six rainy days every year on an average; but since so many millions of useful trees have again been planted the rainy days have increased to forty days annually. It is also mentioned that the Viceroy, Mehemet Ali, had planted on the Delta twenty millions of trees. These results are confirmed by renowned travellers in Egypt, but especially by Mons. Pouchet. Many millions of trees have been planted in the barren and swampy districts of France, also thousands of acres of the desert of Algiers have been transformed into forests with trees suitable to the climate, and with surprising results. By the last accounts these plantations, especially of the Australian species, have already reached the height of 30 to 40 feet, and with their rapid growth a great change of the climate is observable, and twice more rain and dew has fallen in the neighbourhood of these forests than before. More than sixteen geographical square miles of the swampy and unhealthy country along the coast of the Bay of Biscay, in the Department of Lands, where swamp fever prevailed, have been planted with millions of trees, especially the Cork Oak and Swamp Pine (*Pinus maritimus*), with a surprising beneficial result. Not alone that the trees have drained the land, but have changed it into a healthy country with fine forests.

In 1856 Messrs. Bequerel (father and son) in France published a series of observations on the importance of forests on climate, and the great influence they have in regard to rain and temperature, and showed at the same time the injurious effects on the climate by cutting down the forests. In consequence, to test those observations, the French Government ordered a series of meteorological observations in the neighbourhood of forests and also in plains denuded of trees to be made by the Forest Academy at Nancy. These observations were read some time ago before the Academy of Science at Paris, and the result showed that during the time the investigations had been made one-quarter more rain fell annually in the neighbourhood of forests than in plains denuded of trees. It is further stated, in regard to the temperature near forests, "The forest effects the same equal temperature as the sea does along the coast, and that a great contrast in this respect was found in the temperature of plains." Since Messrs. Bequerel's, most important observations have been

made in France by Messrs. L. Fautrat and A. Sartiaux, which were continued over a period of three years in the forests of Hallate, having an extent of surface of 5000 hectares. It is an established fact that of the rain which falls over a normal forest only about half of the quantity reaches the ground, the other parts remaining on the leaves, branches, and trunks of the trees. Mr. Fautrat, therefore, erected a platform which reached 2 metres higher above the tops of an Oak and Beech forest of twenty-six years standing. The following meteorological instruments were fixed on the platform—viz., rain gauge, psychrometer, maximum and minimum thermometer, and an evaporimeter, to learn the exact quantity of rain falling over the forest, the degree of the moisture, the temperature of the air, and the evaporation of the water. Three hundred metres from the forest, on a plain denuded of trees, another platform of the same height was erected, with the same instruments. The observations of the first six months, from February to July, the rain which fell over the forest was 7.578 in., and over the plain (300 metres distant from the forest) it was 6.956 in., or 0.610 in. less than that which fell over the forest. The hygrometrical observations proved that above the tops of the trees a large portion of vapour exists, which does not appear on the plain. From the 1st of March till the 1st of December the average of the damp atmosphere was 66°, and over the plain 61.72°. An interesting fact was observed—that the highest degree of vapour in the forest exists during the spring, when the young growth of the trees appears, and when the trees exhale the greatest quantity of carbon. These vapours are beneficial for the cultivated lands surrounding the forest; they spread over the neighbouring ground, and fall during night as a fertilising dew. Mr. Fautrat, after his observations in the Hallate forest, made similar observations in the Pine forest of Ermensville, to ascertain if a Pine forest has the same condensing property as a deciduous forest. Similar platforms like those in the forest of Hallate and the same meteorological instruments were used. The other was erected in a treeless sandy plain near by. The result of these observations during fourteen months was—viz., the fall of rain over the Pine forest was 23.098 in., and in the plain 29.832 in. Mr. Fautrat also came to the conclusion that the Pine forests possess still a greater condensation influence than the deciduous forests. The hygrometrical observations showed that the average humidity was 63°, and that of the plain 53°; but the evaporation of the Pine forest is much quicker than that of another forest.

A GOOD TOWN PLANT.

I HAVE been trying several plants in my smoke-enveloped garden, but the one that thrives the best is, I am told, a Veronica.

Fig. 27.—Veronica spicata.

It has numberless spikes of blue flowers 18 inches long, several of them branching freely. The stems are 3 feet high, the leaves somewhat like those of Willows, and rather deeply toothed. I have several plants which have afforded an abundance of flowers for months, and the spikes are most agreeable for arranging in vases in rooms. One plant produces white flowers, which are great favourites with my family. I first saw the plants growing in a London, not a suburban garden, quite surrounded by buildings, and nearly always under a cloud of smoke, and they seemed as if they liked it rather than otherwise. They certainly grow with great freedom, in this respect quite equalling Chrysanthemums as town flowers. I mention the circumstance for the benefit of those who attempt flower-growing under difficulties, and am disposed to venture the assertion that where scarcely

anything else will grow this free, hardy, and useful plant will flourish.—A CITY MAN.

[The plant is no doubt Veronica spicata, of which we submit a sketch, and we know it grows freely in town gardens.]

VEGETATION IN CEYLON AND INDIA.

A WELL-KNOWN continental naturalist, Professor Haeckel, has recently returned from an expedition to Ceylon and India, and has published a series of letters in the *Deutsche Rundschau*, recounting the chief features of interest he observed there; and as he gives some notes upon the vegetation, an abstract of this portion, recently published in *Nature*, may be interesting to some readers of the Journal.

During one portion of his stay he visited the Island of Elephanta, and after describing its interesting rock temple, he goes on to mention the impression made on him by the tropical flora:—

“In another way this excursion to Elephanta was of the greatest interest and never to be forgotten, for this day, the 9th of November, was the first on which I saw the magic of the tropic flora in all the freedom of Nature. I had occupied the afternoon of the previous day in visiting the Victoria Garden, which is a fine though not very carefully cultivated botanical garden. It cannot indeed be compared in richness and arrangement with other botanical gardens in India, but still it was there that I saw for the first time a number of the most beautiful and grandest tropical growths. But my delight was infinitely greater and more vivid when in Elephanta I saw the most important and characteristic Indian plants growing wild in an unartificial state, with a luxuriance impossible to a limited garden. There clinging creepers and climbing Ferns clothed the mighty trunks of the Teak trees; there the noble Cocoa Nut Palm bends its slender trunk and splendid feathery glittering crown above the seashore, which is bordered by bushes of the Pandanus, and secured by walls of Mangroves rooted in the water; there big parasite Figs, Convolvulus, and other climbing plants, with large gay flowers, run up the straight black stems of the mighty Palmyra Palms, the proud summits of which, with their fan-shaped leaves, are also covered with the climbing flowers. And there rise noble examples of the sacred Banyan; their mighty trunks are divided into an actual network of great roots, while from among the dark green leaves of the stout branches above hangs a mass of air roots, many of which reach the ground, and, taking root, form new supports for the mother crown. And look there! a gigantic strangler (parasite Fig) smothers a noble Palm with its network of twigs, and a few steps farther stands a brother of this strangler, like a hollow cylindrical pillar without leaves, for the Palm it had embraced had died and decayed, and the cruel murderer now suffers the same fate. The pretty Bamboo forms large bouquets; Bananas and Strelitzias spread their fresh green leaves; large gay flowers unfold their scented cups; feathery Acacias form shady roots, and prickly Cactus-like Euphorbias are woven into thick hedges. Here I saw in concrete reality a number of the most remarkable and loveliest forms of the tropic flora of which I had read and dreamed for thirty years; and in the sunny air sported thousands of the most beautiful butterflies; great golden beetles darted through the bushes; hundreds of swift lizards and snakes glided among the leaves; noisy flocks of splendidly feathered birds flew from tree to tree—all new forms which I had never seen alive, and yet seemed old acquaintance. I snatched at everything like a child, and laid my hands upon the trunks of the Palm and Bamboos to convince myself that all was not a dream of fairy-land!”

In Ceylon the Cocoa-nut and other Palms especially attracted his attention. He says—

“The number of Cocoa Palms on the island is calculated at 40,000,000, each Palm yielding from eighty to a hundred nuts (eight to ten quarts of oil). It is not found in the northern half of the island, nor on a great part of the eastern coast. Its place is here supplied by the not less useful Palmyra Palm (*Borassus flabelliformis*). This is the same which covers the hot and dry districts of Hindostan, growing in great profusion near Bombay. Even from a distance the two Palms vary greatly. The Palmyra is a Fan Palm, with a strong, very straight black stem, topped by a thick bunch of fan-shaped leaves. The Cocoa, on the other hand, is a Feather Palm; its slender white stem, 60 to 80 feet high, is gracefully curved and adorned with a bushy crown of feathery leaves. The lovely Areca Palm (*Areca catechu*) has similar but stiffer and smaller leaves, and a tapering reed-like stem; it is an invariable feature of a Singhalese garden, carefully tended for the sake of the nut, which, being chewed together with the leaf of the Betel Pepper, colours the teeth and saliva red. Another Palm, the Kitool (*Caryota urens*) is cultivated chiefly on account of its abundant sugar-sap, from which palm-sugar (Djaggeri) and Palm wine (Toddy) are prepared. Its stiff strong stem supports a crown of double-feathered leaves resembling those of the Maidenhair Fern (*Adiantum Capillus-Veneris*.) After the Palms the most important trees in the little gardens of the Singhalese are the Breadfruit and the Mango. Of the former there are two kinds, the ordinary Breadfruit (*Artocarpus incisa*), and the Jak Tree

(*Artocarpus integrifolia*), growing everywhere in great profusion. Another tree frequently cultivated by the natives is the curious Cotton Tree (*Bombax*). Mingled with these round the Singhalese huts is the beautiful Banana or Pisang Tree, well deserving the name of 'Fig of Paradise' (*Musa sapientum*). Its beautiful yellow fruit, affording excellent nourishment either raw or cooked, is here seen in numerous varieties. Magnificent clusters of its gigantic light green leaves topping a slender stem from 20 to 30 feet high overhang the Singhalese huts, and form their loveliest adornment. Scarcely less effective are the arrowy leaves of the Aroidæ, especially of the *Caladium*, cultivated for its esculent roots, the same being the case with the *Manihot*, with its lovely clusters of hand-shaped leaves (belonging to the *Euphorbiacæ*.)"

A native garden is thus described :—

"The garden of Whist Bungalow has been converted, by the care and taste of its proprietor, into a veritable earthly paradise, containing examples of almost every native plant of importance, and thus forming a valuable botanical collection, as well as a fragrant and delightful pleasure garden. On the very first morning of my stay, as I wandered in rapturous delight under the shade of Palms and Fig Trees, Bananas, and Acacias, I gained a very comprehensive idea of the flora of the plains. Here the noble Palm in all its variety of foliage and fruit rears its stately columns; Cocoa and Talipot, Areca and Borassus, Caryota and Palmyra; here the Banana spreads its great feathery leaves to the wind, and displays its clusters of precious golden fruit. As well as various kinds of the common Banana (*Musa sapientum*), a fine example of the Traveller's Tree of Madagascar may here be seen (*Urania speciosa*). It stands just at the division of the principal walk, from which the path to the right leads to the bungalow, and that to the left brings us to a magnificent specimen of the Banyan or sacred Fig Tree (*Ficus bengalensis*), forming, with its hanging air-roots and numerous stems, a very striking object; beautiful Gothic arches open out among the roots which, pillar-wise, support the main structure of the tree. Other trees of various groups (*Terminalia*, Laurels, Myrtles, Ironwood Trees, Breadfruit, &c.) are overgrown and intertwined with those lovely creeping and climbing plants which play so important a part in the flora of Ceylon. These belong to the most varied families, for in the dense forests of this magic island, and under the favourable influences of moisture and warmth, a countless multitude of climbing plants strive and cling, and grasp their way upward to the light and air.

"Among the charms of this most lovely garden must be included the large-leaved *Calla* plants or Aroidæ, and the graceful feathery Ferns, two groups of plants, which, both by their individual mass and by the beauty and size of their development, occupy an important place in the lower flora of Ceylon. Scattered among them are many of the finest shrubs and flowering plants of the tropics, partly indigenous, partly introduced from other tropical regions, especially from South America, but all perfectly at home here. Among these rises the stately *Hibiscus*, with great yellow or red flowers; the Flame Tree or *Acacia*, a mass of splendid flame-coloured clusters (*Cæsalpinia*); venerable *Tamarinds* with their aromatic blossoms; while from every branch hang clinging *Convolvuli* with gigantic bell-shaped flowers, and *Aristolochias*, yellow and brown. Rubiaceous plants, such as *Lilies*, *Orchids*, &c., bear extraordinarily large and beautiful blossoms."

Similar interesting descriptions of the fauna and scenery are also given, but need not be repeated here.

KITCHEN GARDEN.

Sow Cauliflower seed to raise plants for pricking out into hand-lights and frames to secure a supply of heads in early summer. A light open situation should be chosen, and the seed not sown too thickly, so as to insure a sturdy growth in the seedlings; the soil also should be moderately firm. Veitch's Extra Early Dwarf Forcing, from its preceding other varieties by a fortnight, is very valuable, and being of dwarf growth is suitable for planting in pits at a distance of 15 to 18 inches apart. Frost being excluded, and air admitted freely upon all favourable occasions, close heads of pearly whiteness may be cut early in May. Early London and Walcheren are excellent successional varieties.

Lettuce seed should now be sown to raise plants for placing out in late summer or early autumn to give a supply of heads for salads in spring and early summer. Stanstead Park and Hardy White Dutch are the best of the Cabbage varieties, and the Cos varieties

Hick's Hardy White, and Bath or Brown Black-seeded, are preferable. If these can be sown where they are to remain it will be an advantage, sowing in drills about a foot apart, and thinning to about 6 inches for the Cabbage sorts and 9 inches for the Cos, so as to allow of every alternate plant being drawn for early use. A moderately sheltered border should be chosen, and the soil should be rich, and where light made moderately firm, which will check the tendency to a gross growth, keeping the plants sturdy and better able to withstand severe weather. The thinnings will be available for planting out later on as suitable positions become vacant.

Radishes for winter use may now be sown, China Rose being probably the best, but Black Spanish and Californian Mammoth are excellent. The seed should be sown in rich light soil in a sheltered position, and not too thickly, as when grown well they form large roots, which are crisp, tender, and good in winter, keeping satisfactorily in damp sand when the weather precludes their being had from the open ground. Radishes of the summer kinds should be sown at intervals of about three weeks to have them in good condition.

Continue to plant Lettuces and Endive, and where the latter is in demand provision must be made accordingly by placing out a good breadth from the main crop or July sowing. A last sowing can be made at once where it is in request in spring, transplanting to the foot of south walls next month or into pits. Tie up Cos Lettuces and water copiously in dry weather, so as to have them crisp and well blanched.

Early Celery will need earthing up, watering if necessary before doing so, keeping the soil from the centre of the plants by drawing the leaves together, and firming the soil well about the heads. Later plants should have very moderate earthings, as they grow best without much soil over the roots, and should be well supplied with water or liquid manure. Any likely deficiency in the supply of green vegetables in winter and spring should be provided against at once by planting Borecoles, Coleworts, &c. Cauliflower plants may yet be placed out, choosing a sheltered situation, and if the autumn be favourable useful heads will be obtained, and for lifting to continue the supply in frames after the supply is stopped outside by severe weather. Late Peas and Dwarf and Runner Beans will need plentiful supplies of water in dry weather, and the pods should be picked as they become fit for use.

Keep weeds well under by frequently stirring the soil between growing crops, and where this is not practicable their removal by hand must be attended to in good time. Rubbish will now accumulate rapidly, and should be thrown into a heap and mixed with a little lime and a sprinkling of salt. This is very valuable as manure for many crops.

FRUIT HOUSES.

Peaches and Nectarines.—Some of the leaves of the trees in the earliest forced house will be beginning to change and fall, which should not be accelerated, as is sometimes done, by brushing over the trees; but, on the other hand, endeavour by occasional syringing to keep the leaves healthy until they fall naturally. The roof lights being withdrawn the wind will bring the leaves down quite as fast as they mature; and the foliage having fallen is not, as is too often concluded, a sign of the maturity of the wood, but rather indicative of the ripening of the foliage being accelerated by a deficiency of moisture at the roots and the presence of insects. The continuance of the leaves on the trees will tend to prevent the premature swelling of the buds.

In the house started early in the year, and from which the fruit was removed in June or early July, the trees will now have the wood ripened and the buds well plumped, in which case the roof lights should be removed; but if the trees are very vigorous the lights must not be removed so soon by three weeks or a month as is necessary for older trees having less vigorous wood: but as long as the lights are kept over them full ventilation must be given day and night. Any trees that are unduly vigorous and do not set their fruit well should have the root-action checked by judiciously shortening the roots as advised in this calendar for July 20th. The Peach scale sometimes attack the trees about the ripening period, and as the

application of an insecticide then would have an injurious effect upon the fruit it is often delayed until the fruit is gathered. Of approved insecticides the cheapest is petroleum, but it is necessary that the oil be well mixed with the water. We use a fluid ounce to a 3-gallon pot of water at a temperature of 120°. Many insecticides owe much of their potency to the temperature at which they are applied. Even water at 160° will destroy most insects, and is quite safe for plants that have the wood and foliage mature.

The trees in the house started in February will be cleared of the fruit. They should be examined and all the shoots that have borne fruit, not being extensions, may be cut away to those that have been trained in at their base as bearing wood for next season, and where the shoots are too crowded they must be thinned. Thoroughly cleanse the foliage of red spider by the forcible application of water from the garden engine or where there is sufficient pressure with the hose. If there be any doubt as to the ripeness of the wood allow the temperature to rise to 80° or 85° by day, without, however, keeping the house closed, and ventilate fully at night, but do not allow the trees to suffer from insufficiency of water at the roots. Weakly trees can be assisted to plump their buds by the application of a little liquid manure.

In the late succession houses with the fruits ripening syringing must be confined to damping the surface of the borders occasionally; at the same time a very moist condition of the soil is not desirable, as it sometimes, particularly with vigorous trees, causes the fruit to split at the stone. Trees with fruit swelling should be well supplied with water, and be syringed twice daily in sunny weather until ripening commences. Fruit on the under side of the trellis should be raised to the light so as to colour it evenly. Keep the shoots tied and regulated, and pinch laterals to one joint of growth as made.

FLOWER GARDEN.

Flower beds are now at their best, and every effort should be made to keep them as perfect as possible by removing any dead or decayed leaves or flowers, regulating the growth of such plants as Verbenas, Petunias, and Tropæolums. Seed vessels should be removed immediately they are formed, for if allowed to remain they greatly exhaust the plant and check the formation of bloom. Beds showing signs of exhaustion must be assisted with liquid manure. Pelargoniums, except such as are grown for the beauty of their foliage, should be rather sparingly watered. In all cases when water is given it should be in such quantity as to soak the whole of the soil as deep as the roots penetrate. No time should be lost in raising a stock of the different varieties of Pelargoniums, so as to allow time to get them thoroughly established before winter. In taking cuttings it is necessary to exercise some care to avoid making gaps and spoiling the effect of the beds and borders, judicious thinning when the growth is crowded being an improvement, and the flowering is thereby prolonged.

Phloxes have been and are unusually fine. They should be well supplied with water whilst developing their heads of bloom; indeed, good rich moist soil is essential to the successful cultivation of these plants. Choice varieties may now be propagated either by cuttings or division. Polyanthus, Auriculas, Primroses, Myosotises, Gentians, and Daisies may still be increased by division, and considering the great beauty of these plants in the spring and early summer months it is remarkable they do not receive more attention. Their cultivation ought to become general in all gardens.

Roses promise a fine display of bloom in autumn, but mildew is very prevalent. Sulphur and soot dusted over the foliage in the early morning, and syringing off at eventide so as to thoroughly cleanse the foliage, is an effectual remedy. Liberal supplies of liquid manure in dry weather will be necessary to enable them to make free growth. Climbing varieties, such as Maréchal Niel, Gloire de Dijon, and Cloth of Gold should have all the old flowering wood cut out, and the young shoots of the present year's growth laid in to replace them for flowering next season. Climbing Roses flower much better when not spurred or pruned too closely. All climbers must be examined frequently, tied or nailed in, and the growth thinned out and regulated.

THE BEE-KEEPER.

AUTUMN TREATMENT OF STOCKS.

(Continued from page 137.)

ANOTHER point to notice is the extent of brood in hives at the end of the season, or say in the month of August. If six or eight of the central combs of a hive contain their large sheets of brood the hatch of young bees will make it a pretty good one for keeping; but if hatches of young bees from honey hives be united to them the hive will be doubly strong, swarm earlier, and do far more work next year. We have ever found and often laid it down as an axiom in bee culture, that the stronger hives are in population in autumn the safer they are in winter, the more valuable they are to the bee-keeper. Mr. Raitt has said lately that Mr. Pettigrew's disciples wastefully use bees in uniting swarms in autumn, but the practice we recommend is now extensively followed with ever-increasing confidence and satisfaction. We have no hesitation in asserting that no other practice or discovery in apiculture is more important and valuable than the one now recommended—viz., by making hives strong by uniting swarms in autumn. We believe with Mr. Raitt in stimulating feeding when necessary, but this is more costly and troublesome and less successful.

On selecting hives for stocks the bees of the condemned hives should be shaken or driven into empty hives with a view to unite them to those selected for stock. When hives are light and easily handled the bees are more easily shaken out than by the slower process of drumming or driving. When visiting a bee-keeper in Bowdon the other day I found he had two hives he wished to unite, but dreaded the work. He was asked to find an empty hive, and when he brought one to the garden I took the old hive in my hands and shook all the bees into the empty hive and united them to the other in less than three minutes without losing a bee. Mr. Brierley, the owner of the hives, said he had read of this process in the "Handy Book of Bees," but could not believe it could be so done. Though he said it is "most astonishing," this process is simple and easily performed. In uniting swarms the oldest queens are destroyed, and it is wise to take the precaution of giving both swarms some highly scented syrup half an hour before the union is made. This syrup serves two purposes: it puts all the bees in good temper, and partly destroys the peculiar smell of each swarm. Such unions should be made late in the afternoon or evening when the other hives in the garden are not flying about, otherwise they might smell the syrup and gain access to it during the confusion of the union. The day after the union the bees will defend their hive against all comers.

If the united swarms have not food enough in their hive they should be fed up to a safe-keeping weight, and such feeding if done in August or early part of September will probably cause the bees to recommence breeding, and a good hatch of bees may be added to the community late in the season, and thus the hive would be made stronger still and more valuable. But young beekeepers should know and remember that hives so strong in bees require more food than hives with less numerous populations. Autumn feeding should be done both as soon and as rapidly as possible for two reasons—first, that the breeding and hatching of brood may be over before frosty weather come; and secondly, in order that the bees may settle down into a quiet state before winter. In honey seasons when hives become too heavy for stocks what should be done? In such seasons we drive the bees out of all the hives, take all the honey, unite the swarms in empty hives, and feed all into stocks. In this way a large harvest of honey is obtained, and excellent stocks for keeping. Such syrup-fed stocks invariably do well, none do better. They are easily created and thrive uncommonly fast.

As to the best modes of feeding stocks and swarms we have nothing to say, every bee-keeper has a way of his own which he finds to answer well enough. The best time to administer food is about sunset, and not to give more than the bees can take up before the bees of the other hives begin to stir in the morning. Feeding during the day attracts robbers.

In the creation of stocks by feeding there is one point to be considered—viz., the use of artificial comb foundations. This year we have tried swarms with and without these foundations. What are called the thick or brood foundations cost 2s. 6d. per lb., and this is what is used in creating stocks; about five sheets of these, bar-frame size, weigh 1 lb. Ten sheets costing 5s. would fill an ordinary-sized bar-frame hive. The question I wish to see ven-

tilated is this, Are they worth the 5s. in the practice of creating stocks? For 5s. we can buy 20 lbs. of good sugar; 40 lbs. or thereabouts of good syrup can be made from 20 lbs. of sugar, and from 40 lbs. of syrup a large bar-frame or other hive can be filled with natural combs in warm weather. From the experiments we made this year with the artificial foundations for brood combs we have come to the conclusion that they are not economical, and for summer use in such work they are not worth the money they cost. Let others try the experiment of putting two swarms separately into empty hives. Let one of the hives have 1 lb. of the brood foundations, and the other 10 lbs. of sugar made into syrup. Let all the syrup be given to the hive in seven days. Then examine both and see which is the better, which has most perfect comb, which the heavier of the two. The sooner this question comes to the front and is fully and widely discussed the better will it be for bee-keepers and bee-keeping. Artificial comb foundations for supering answer well. They are made much thinner; eleven or twelve sheets of them, same size, weigh 1 lb., and cost 3s. Thus we see that of a sheet foundation for brood cost 6d., and a sheet (same size), for supering cost only 3d. For the present we shall leave this important question for others to answer and discuss, with the hope that they will examine it carefully and discuss it temperately.—A. PETTIGREW.

GLASS VERSUS "TIN."

It certainly is the duty of every bee-keeper to scrupulously refrain from any action or practice whereby the purity of honey might be impaired. Now, I contend, on chemical principles, that leaving honey in contact for a certain length of time with tin so-called ordinarily, but properly speaking with the alloy of tin and lead, as is the case when honey is filled into tin pails for the retail sale, or filled into tin tanks for maturing it, or permitted to stay for some time in the extractors, must expose it to contamination with lead.

Many of the readers of the "Bee Journal" will know that the ordinary sheet-tin is in reality sheet-iron coated with a thin film of an alloy of tin and lead. For hygienic considerations it would be desirable that this film should consist of pure tin. But, unluckily, pure tin does adhere only with the greatest difficulty and rather imperfectly to iron. Thus the manufacturers of sheet-tin are compelled to use an alloy of tin and lead. Nearly everybody knows the injurious effects of lead, in all its chemical combinations, and even in the minutest quantities, if long continued, upon the human system. It is contended that a small amount of lead alloyed with tin is so thoroughly held by the latter that it cannot be attacked and dissolved by the sugars and acids, and thus cannot enter into our articles of food. Granted. But, as far as I know, hygiene has never solved the question—with the assistance of analytical chemistry—how great the amount of lead may be in the alloy without incurring the risk of injury to the human system. The great difference in the prices of tin and lead is a standing inducement for the manufacturers to increase the proportions of lead enormously, and to an injurious extent.

Some time ago I analysed, for my own satisfaction, a sample of canned Tomatoes and one of canned Peaches. The first, against my expectation, did not contain any lead; but the latter did to a considerable extent. Whether the tin (so-called) of the Tomato-can contained less lead proportionately than the other can, or whether the sugar in the Peaches could exert a greater action upon the lead than the acid in the Tomatoes, I cannot decide. In the honey the saccharine and acid principles must attack the lead in the so-called tin vessels. I could observe that, a couple of years ago, my extractor was considerably corroded by the honey that was, by mistake, allowed to stay for some time.

The French Government has, some time ago, taken measures against the indiscriminate use of tin vessels for holding preserved food containing acid and saccharine substances. And I think bee-keepers ought to store their honey in glass or wood (how would paper kegs impregnated with paraffin do?) as long as no discrimination is made in the trade between tin (rich in lead) for roofing purposes and tin for holding articles of food.—LOUIS KNORR, M.D. (in *The American Bee Journal*.)

EQUALISING COLONIES.—For the best results it is necessary that all colonies be made strong by the time the honey harvest begins. The frames of comb should be well filled with brood, and the hives full of bees. With only a few colonies, all seemingly in the same condition, we find some will far outstrip others in brood-rearing. Frames of brood should be taken from the strongest and given to the weakest, and in this way equalise the colonies before harvest commences. It will not perceptibly injure the strong colony, and will soon put the weaker one in working condition. In building up weak colonies by this method it is better to do the work in the middle of the day, when the bees adhering to the combs can also be added, as they will nearly all be young bees, and will stay where put. In all manipulations of this kind first ascertain the whereabouts of the queen, so as not to transfer her with the combs.—(*Indiana Farmer*.)

* * All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Myrtles (C. T.).—The writer of the article to which you refer resides in South Wales.

Planting Bulbs in Grass (Narcissus).—The bulbs may be planted any time during the autumn when the ground is not too wet, but it had better be done before severe frost is experienced. Those named are suitable, but you might add *Lencojum vernum* and *Galanthus nivalis* with a few clumps of *Crocuses* of different colours. Be careful not to plant the bulbs too deeply, especially in the case of the small ones; just covering the crowns will be sufficient.

A Seedling Raspberry (F. B.).—The fruit arrived in a very unsatisfactory condition, but as far as we could see the variety appears inferior to many others in cultivation. The lateness of its fruiting, too, is no recommendation, as the autumn-fruiting or double-bearing varieties as they are termed are now coming in, and all these are greatly superior in size and quality to that you sent.

Anonymous (C. T. II.).—Under ordinary circumstances we would not have departed from our invariable custom, and should have expunged the portion of the communication you refer to; but in this case there was no secrecy, as the parties had corresponded with each other through this office in their proper names. We had the less hesitation in publishing the name in full, as the writer, in a case of this kind, very properly makes no secret of his individuality. But for this your remarks are very just and meet with our approval.

Treatment of Iresine Herbata (A. B.).—To obtain a stock in spring two methods may be adopted—namely, striking a few hundreds of cuttings now and keeping them in store pots during the winter, and by preserving the old plants lifted from the borders and potted. A stove temperature is required, and a light position, preferably a shelf near the glass, is also needed to ensure their success. Sufficient water must be given to prevent the foliage flagging, but it is best not to be too liberal in the supply of moisture until spring, when growth may be freely encouraged, and cuttings can be then obtained in abundance. Both for the old plants and the autumn cuttings a sandy soil is best. Inserted in moderate bottom heat the shoots strike readily.

Climbers for a Conservatory (F. J.).—You do not state the size of the conservatory or the number of plants required, both of which points should be considered in making a selection. If you have plenty of space and desire to have a diversified collection of free-flowering plants, all the following are suitable:—*Berberidopsis corallina*, *Bignonia speciosa*, *Bomarea Carderi*, *Bougainvillea glabra*, *Clematis indivisa lobata*, *Clianthus puniceus*, *Cobaea scandens variegata*, *Cestrum aurantiacum*, *Hardenbergia Comptoniana*, *Habrothamnus fascicularis*, *Hibbertia volubilis*, *Jasminum grandiflorum*, *Kennedyia Marryattae*, *Lapageria rosea* and *alba*, *Lonicera sempervirens*, *Mandevilla suaveolens*, *Passiflora racemosa caerulea*, *Plumbago capensis*, *Rhodochiton volubile*, *Rhynchospermum jasmynoides*, *Sollya heterophylla*, *Solanum jasmynoides*, and *Taesonina Van Volkemi*. If a less number are required select from the above, giving preference to the *Bougainvillea*, *Clematis*, *Habrothamnus*, *Jasminum*, *Lonicera*, and *Plumbago*.

Select Border Plants (Item).—In Mr. Luekhurst's article upon "Cheap Flowers," page 126, last issue, you will find a list of useful hardy plants such as you appear to require, and in addition to these the following will be found useful:—*Achillea Ptarmica* fl.-pl., *Agrostemma Flos-Jovis*, *Anemone japonica* *Honorine Jobert*, *A. stellata fulgens*, *Coreopsis grandiflora*, *Campanula persicifolia alba plena*, *Chrysanthemum frutescens* varieties, *Dahlias* of the single and Pompon sections, *Erigeron alpinus*, *Geum coccineum plenum*, *Hesperis matronalis alba* and *purpurea plena*, *Lathyrus latifolius*, *Malva moschata alba*, *Matricaria inodora* fl.-pl., *Myosotis dissitiflora* and *M. palustris semperflorens*, *Orobis vernus*, *Pentstemon*, *Primula cortusoides*, *P. acaulis* fl.-pl., *P. rosea*, *Ranunculus amplexicaulis*, *R. aconitifolius plenus*, *R. acris* fl.-pl., *Senecio pulcher*, *Spiraea Filipendula* fl.-pl., *S. Ulmaria* fl.-pl., *Statice Limonium*, and *Violets*. The bulbs you mention should not be lifted until the foliage has decayed.

Guavas (A. F.).—These plants are produced by several species of *Psidium*, a genus allied to the Myrtle. They are grown in many of the chief botanic gardens, and at Kew specimens may be occasionally seen fruiting. The common Guava is *Psidium pyriferum*, a tree 10 to 20 feet high, producing fruit of a pear shape, and grown extensively in the West Indies; and this is also known as the White Guava, in contradistinction to the fruit of *P. pomiferum* or Red Guava, which has a red flesh, very acid, and much inferior to the white. The common or White Guava is about as large as a tennis ball, the rind of a russet colour, tinged with red. The pulp is sweet, aromatic, of an agreeable flavour, and interspersed with numerous small white seeds. The fruit is very extensively eaten in the West Indies, both by the natives and by the Europeans, either raw or in the state of jelly; but it possesses great astringency, and is not suited to those of costive habits. The rind, when stewed, is eaten with milk, and is preferred to any other stewed fruit. From the same part marmalade is made; and the whole fruit prepared with sugar furnishes the celebrated Guava jelly. The bnds of Guava boiled with barley and liquorice produce an excellent drink for diarrhoeas, and even dysentery, when not too inveterate. The wood furnishes excellent fuel, burns with a bright heat, and lasts a long time. The fruit of *P. Cattleianum* is about the size of a small walnut, nearly round, of a deep purple

colour. The skin is of the consistence of that of the Fig, but is thinner. The interior is a soft fleshy pulp, purplish-red next the skin, but becoming paler towards the middle, and at the centre it is quite white. It is juicy, and in consistence is much like a Strawberry, which it resembles in flavour. This is one of the best of the Guavas, and is a native of China, whence it has been introduced to Brazil, and now it is grown extensively in both countries.

The Cherry Plum (J. E.).—The description of the Cherry Plum given on page 139 was accurate as far as it went, and was sufficient for the purpose of our reply. We now add that the fruit is medium-sized, cordate, somewhat flattened at the stalk, and terminated at the apex by a small nipple, which bears upon it the remnant of the style like a small bristle. Skin very thick and pale red, covered with small greyish white dots. Stalk three-quarters of an inch long, slender, and inserted in a small cavity. Flesh yellow, sweet, juicy, and subacid, adhering to the stone. This agrees with Linnæus' description of the fruit, and any other account that differs from it in any essential particular is incorrect. The other Plum to which you refer is a different variety altogether, and probably has no existence now.

Wistaria Treatment (H. J.).—The young shoots should by timely attention to training be kept from twining round the wires, and be trained-in moderately thin, so as to expose them freely to light and air, thereby solidifying the growth and ripening it, so as to induce a free disposition to flower. Any shoots not required for training-in should be cut back to a couple of joints of growth, and to one subsequently, so as to induce the formation of spurs. The young shoots should be trained-in their full length as far as space permits, and be otherwise stopped or spurred-in. If the situation be dry supply water freely in hot weather.

Mildew on Roses (W. M.).—The measures you have already adopted will probably be useful in promoting healthy growth; at the same time we recommend you to dissolve 3 ozs. of soft soap in a gallon of water, mixing in it also a small handful of flowers of sulphur, and syringe the trees with this mixture at a temperature of 120°. This will check the growth of the mildew, if it does not destroy it altogether. We name this remedy because it is generally at disposal. Nicotine soap and Ewing's mildew composition are alike useful for the same purpose.

Earwigs Eating Nectarines (A Forest Hill Reader).—Since the fruit is ripe or nearly so it would not be safe to apply any strong insecticides for destroying the pests; but by violent syringings you could dislodge them from their lurking places, and then prevent them ascending the wall again by a barrier of coal tar spread at or near the bottom of the wall, with cotton wool wrapped round the stems of the trees also smeared with tar. The insects no doubt can fly over the barriers, but that is not their usual method of locomotion when in quest of food. If you place a little moss or hay in small flower pots, these to be laid along the bottom of the wall, and examine the pots every morning, you may destroy numbers of earwigs. Our plan is to shake them into water as near the boiling point as possible; in this way we have killed thousands instantaneously, hence painlessly.

Double Stocks (D. E.).—If you perceive any single flowers that have more than four petals choose these for producing seed, removing the others, and you will be certain to have a large per-centage of double flowers; if you have no such abnormal flowers do not let too many pods mature on the same plant, and support the plants well. You may then hope for good results if the plants are in a favourable position for ripening the seed.

Grapes not Colouring (An Amateur).—We think on the whole you have been successful with your Vines. Those in pots are probably cropped rather too heavily, and it is not uncommon for young Vines with much extension growth beyond the bunches to fail to mature satisfactorily the whole of the berries. Undoubtedly the red spider would impair the colouring process. Syringe the Vines heavily after the fruit is cut, and wash the insects off the foliage. We think we warned you against keeping the old spider-infested Cucumber plants, and you are now paying the penalty of having followed what you considered a better plan than ours. Had you carried out our suggestions you would have had more Cucumbers, less red spider, cleaner Vines, and better Grapes. We will readily give you all the aid we can at any time. You have done right by liming the border, and it will probably be advisable to syringe the Vines next year after the fruit has set.

Melons not Setting (F. C.).—It is by no means easy for us to state the cause of your failure, but we presume it would not be difficult to determine the point if we could see the plants. The small size of the flowers indicates that the plants have received a check. This may have resulted from temporary dryness of the roots, or an excess of liquid manure; and again, the atmosphere of the house, as is not unfrequently the case, may have been too wet or too dry, and in either event the fruit would not set. The bottom heat of 75° to 80° would suffice if the treatment were right in other respects; but you do not mention the top heat or temperature of the house, which is a most important matter. The upright trellis is not the cause of the evil; still the growths are better trained up the roof of a house, and about a foot from the glass—the exact angle being of no importance whatever. You have overlooked what has been written, but the subject shall be treated more fully than is possible in the form of a reply.

Peaches and Nectarines (Idem).—To our taste there is quite as much difference in the flavour of some of those fruits, Nectarines especially, as between different varieties of Strawberries. The Strawberries you sent arrived like a sample of jam—utterly shapeless, and undistinguishable for the purpose of nomenclature.

Numbers of Journal (J. E.).—The date of the number 654 is October 9th, 1873; and of 789, May 11th, 1876.

Names of Fruits (Saltmarsh & Son).—The fruit was so much decayed we could not identify it. Plums should always be accompanied with a portion of young wood.

Names of Plants (A. B.).—The plant with variegated leaves is Tradescantia discolor, the other is Isolepis gracilis. (W. H. Myers).—12 and 24, Aira cæspitosa (Tufted Hair Grass); 14, Holcus lanatus (Meadow Soft Grass); 27, Lolium italicum (Italian Rye Grass); 29, Glyceria fluitans (Floating Sweet Grass); 30, Briza media (Common Quaking Grass). (G. P., Devon).—Ceterach officinarum.

Management of Bees (M. B. D.).—So far as we understand the case—and we do not perceive how you could have made it more clear—both the old hive and the swarm are of fair strength, and the bees work actively. As regards the former, we should drive the bees into a bar-frame hive and take the honey; then feed them liberally at once. The swarm already in the bar-frame should be

fed as needed and according to circumstances, but no honey should be taken from the hive now. By carrying out this plan we think you will have two good hives next spring. See what Mr. Pettigrew says on page 161.

COVENT GARDEN MARKET.—AUGUST 16TH.

OUR market is still very quiet, and the supply of home-grown fruit has greatly fallen off within the past week.

POULTRY AND PIGEON CHRONICLE.

THE NORFOLK OR FOUR-COURSE SYSTEM OF CROPPING.

(Continued from page 141.)

AS we have previously stated all that can be said in favour of this system of cropping on light, thin, and poor soils, we will now refer to the system when carried out upon the mixed and better soils in various parts of the kingdom, and the difficulties and disadvantages in connection with its adoption thereon. In the management of the Norfolk course proper—viz., Wheat, roots, Lent corn, and Clover, there is but little opportunity for cleaning the land if the season should prove wet and unfavourable when making the fallows for roots. From sowing the Lent corn there is no time or opportunity for clearing the land of couch or twitch as it is called, until after the Wheat crop is cleared off, a period of something like twenty-eight months, without breaking in upon the rotation and system of stocking, which by its advocates is claimed as important, and must be rigidly observed and performed, especially the stock of sheep and cattle.

The provision for sheep, especially for breeding ewes, forbids the ploughing of the Wheat stubbles in the autumn in order to forward the fallow land in the spring, because these stubbles afford the only run for the in-lamb ewes until the land is fallow-ploughed in the month of December. It is especially valuable for this purpose when Italian Rye grass has been sown in the Wheat for autumn-feeding, for we have known the stubbles folded off for sheep three times between harvest and Christmas when Italian Rye grass has been grown for the purpose. Some farmers feed their sheep on Clover in the Lent-corn stubbles in the autumn, but this practice often ruins the plant of Clover; the Clover plants die from this cause during the winter months, and in

consequence the land is called Clover-sick. If the Clover had been allowed to remain without feeding the sheep on them except slightly in September, the autumn leaf produced would have protected the crowns of the plants from frost during the whole of the winter months, and have given an impulse to the early spring growth of the Clover crop. Again, however, advisable it may be to have the stubbles of the Wheat land seeded, it must be remembered that Italian Rye grass unless specially prepared by the seedsman often contains the seeds of couch and Black grass, entailing further difficulties in making the fallows in the spring before the seeding for root crops. As the fallow for roots is the foundation of the cleaning process, enabling the four-course to be carried out, it prevents autumn cultivation as well as green crops being seeded in the autumn, such as Trifolium, Vetches, and Rye. It prevents the land being autumn-fallowed, but also makes the land unkindly for the seeding of root crops after the fodder crops are disposed of; at the same time it often proves fatal to root crops of heavy weight, owing to the delay of the seed time. This is one of the objectionable points in the four-course system, because the fallowing for roots must not under any pretext be deferred or interfered with, particularly upon the mixed soils and farms where couch and Black grass prevail. Many valuable corn-producing soils are so liable to encourage these grasses, especially when they are highly farmed or are deficient in chalk, lime, and marl, for when these important substances are absent from the land it favours the growth of couch in an extraordinary degree.

We must now look to the effect of a wet season upon the fallow break, such as those of 1853, 1860, 1879, and others, causing more or less difficulty; for in those we have named it was found totally impossible to clean the land during the period usually available for that purpose—namely, from the 1st of March to the 1st of June. The root seed must be sown, whether the land is as clean as it ought to be or not, between the 1st of June and the 1st of August, which is the only period for seeding which can be attended with success and furnish full crops of roots; in fact, in the northern counties we must add the month of May to the seeding time. It is very clear that in case the land cannot be seeded within the above-named period the root crops must be abandoned and the land lie fallow until August and September, and the process of cleaning the land be continued during the autumn. In that case the land will be laid up for the winter, ready to receive the Lent corn seed without spring ploughing. Although this may not be unfavourable for the crops of Lent corn whether of Barley or Oats if early sown and properly manured, yet it has proved fatal to the growth of roots by which the sheep and cattle are to be maintained, and upon which so much value is placed and attributed by the advocates of the Norfolk system of cropping.

It is worth consideration what can be done to assist in cleaning the land when the fallow in untoward seasons has been a failure to a certain extent in completing the preparation, because under such circumstances it is frequently found that when the roots are ready for the sheep, or fit for carrying away to store heaps for bullock-feeding, couch will still be found prevailing. When this happens it is imperative that these bunches of couch, however small, should be forked out previous to the sheep entering upon the folding and feeding, because there will be no other opportunity to attack the couch or black bent grasses, until the end of the four-course rotation has been carried out—a period of twenty-eight months. If we delay forking-out the grass from the root crop, and prefer to try and clean the land in the spring by horse labour and cultivation, we are met with the serious objection that it cannot be done thus without delaying the seed time, besides incurring expensive horse tillage, which together will prove fatal to the profit and benefit generally expected in the growth of Lent corn.

We must also remember that on the mixed soils and vale land

after the root crops have been fed off by sheep eating cake, corn, and hay, that the bulk of straw in the Lent corn will be great, especially that of Barley, which frequently becomes laid, injuring the grain, and likewise destroying the young Clover plants. This is not, however, so much the case when spring Wheat or Oats are sown after the root crops fed off; still, wherever the loss of the Clover plant occurs the mischief is not confined to the loss of the Clover intended for hay, but is extended into the next course. It is sure to injure the prospect for a Wheat crop, because in the Norfolk system the Clover roots have always been considered the basis of a good Wheat crop, and so it will prove upon any light soil when neither of the spring-sown crops grown are stout enough to injure the Clover plant. Upon the home farm where the Clover hay crop may be sold off the land, and also upon farms where the lease allows of its sale, the loss of the crop is irreparable, for the substitutes under the Norfolk system are not attended with advantage unless the growth of Beans or Peas are covenanted for; the only crop to be taken is a green fodder one for feeding sheep, such as Vetches or Trifolium, or Mustard, to be either fed off or ploughed in as manure. The management of the Clover crop and the mixtures of seed are of the highest importance, for broad or red Clover cannot be taken with any safety oftener than once in eight years, therefore the alternation must be carefully considered. We know no mixtures better than red Clover and Giant Sainfoin alternated with white Dutch and Alsike Clover, both to be grown without Rye grass, as this prejudices the crop of all cereals, and in lieu of it we introduce Giant Sainfoin in red Clover to facilitate the making of the hay in the absence of Rye grass, and it is frequently advisable to grow it also in admixture with the white Dutch for the same purpose.

The next point we have to consider is the disposal of the Clover crop. It is a common practice to cut the first growth for hay and feed sheep on the latter-math; but our experience is that the second growth should be cut for hay or for seed, because of the value of the Clover roots as manure for the Wheat, for the weight of roots is much larger after two cuttings than with one cutting and one folding with sheep. We have sometimes known where the Clover lain has proved foul with couch that attempts have been made to clean the land by what is called a bastard fallow after the first cutting of Clover has been taken for hay. This in our opinion is often fatal to the Wheat crop, for it not only destroys the Clover roots so valuable in the ordinary once ploughing for Wheat, but the attempt at fallowing proves injurious to the Wheat plant, as it becomes root-false, and breaks down previous to harvest, and seriously reduces the yield of grain. We shall now refer to a very important point for the home farmer to consider in connection with the four-course rotation upon the mixed soils or vale farms, because he is not obliged to grow Turnips to any such extent as one-fourth of the land, unless the stock of sheep and cattle fed on the pastures and parklands during the summer months render it necessary to ensure a large provision for them in the winter months. We do not object to the fallowing relating to the cultivation for Turnips, as that prepares the land for future crops, but it frequently occurs that in feeding and folding the Turnips by sheep in wet seasons the land is trodden and sodden, by which it becomes unkind both for the corn and Clover plants to follow. We therefore state that not only has the crop of Turnips, to which we have never seen an exception, when passed through the cutter and ploughed in proved most beneficial to the following future crops, but even better than when the roots have been fed off by sheep eating cake and hay in addition. A few days ago we noticed when passing over a farm that one-half of a field of Turnips had been fed off, the stock eating cake, on the other half the roots had been carefully reduced and ploughed in; the latter we estimated at two quarters

per more of grain, the crop being white Oats, than the half fed off by sheep, nor have we ever seen an exception to this result when the roots have been properly ploughed in. We shall, however, return to the consideration of this matter on a future occasion, and now conclude our subject by observing upon one of the most serious evils of the Norfolk rotation—that is, when sustaining losses by adverse seasons, there is no opportunity to retrieve them by change of cropping; all losses are therefore permanent.

WORK ON THE HOME FARM.

Horse Labour.—Harvest work being now the chief employment of both men and horses, large areas of corn have been cut and stacked in good condition in all the early districts of the kingdom, especially in the southern, eastern, and home counties. We must ask the home farmer to remember the harvest of last year, for the only corn got together in good condition was previous to the rains, which commenced on the 10th of August, and adverse weather continued, with little opportunity for carting in fair condition, until the end of September. The question to be considered is this—some farmers got up all their Wheat in the southern and eastern counties and some of their Barley and early White Oats before the rain set in, whilst other farmers having equally early crops had carted no Wheat and but little else, except Peas and White Oats, up to the 10th of August. In consequence of this dilatory conduct thousands of acres of Wheat were seriously damaged, and much of it rendered unsaleable, and was actually used for the feeding of fattening cattle and milch cows. This circumstance looks very like bad farming, which might have arisen from ignorance as to when corn in sheaf was fit for stacking or from carelessness: and it is a point worth consultation amongst farmers, What indications are there noticeable which should decide the matter as to when Wheat in sheaf is fit to carry to the rick or barn?

At the early stages of harvest the straw of Wheat may be ripe as to colour, but the knots in the straw will be soft, and the grain soft enough to yield on pressure between the thumb and finger; and when it is in that condition it should remain in shock or stook for some days, although the weather may be fine. Even then there may be some doubt as to whether the sheaves will be dry enough not to heat in the stack, simply because grass or weeds may prevail in the corn when cut, which will render the question of fitness for carting doubtful. If, however, the straw is free from weeds at the time of cutting, and the weather fine, the less time the corn remains in the field the better, for we have always found the point to be decided is, Will it heat or not? for that is the turning point of the whole matter of securing corn of every sort and pulse of every kind. When we have felt assured that it would not heat in the stack or barn, the best of grain has been the result; the less the corn is left to the effects of the sun and wind the better, for it certainly is the best grain which ripens into condition in the stack if it does not heat. But this is now a question to be decided under the system of exhausting heat by the fan from the rick, and it has been pointed out as to how far corn stacks can be allowed to heat without tainting the grain as to smell and taste, and it is stated that 80° of heat may be allowed in corn ricks with safety to the value of the grain. We are not sure of this, and the circumstances connected with the management at harvest work by different farmers are various, and we do not consider this matter will be decided so that a safe and uniform practice under the action of the exhausting-of-heat process can be relied on until further experience in its use will justify a decided opinion.

The home farmer will do well to be provided with the exhaust-fan and tackle connected therewith, and the time will come when he will reap the benefit of his own care and detail in conducting its operations, for we feel thoroughly convinced that this system of saving hay and corn as practised by Messrs. Neilson & Knowles is destined to become general, and enable the home farmer to conduct his harvest both of hay and corn with far greater advantage in difficult and uncertain weather than has ever heretofore been possible. But whenever the question of details of the system has been mastered and become fully known and set forth, it will require the strictest attention to carry out the detail in all its necessities, otherwise failure will follow as certainly as that machinery must stop if one cog in a wheel is absent. Some horses will be continually employed in using the reaping and binding machine, and we recommend its being used for Barley as well as Wheat and Oats; for when Barley is cut and tied it cannot all be stabled if the weather should prove wet and stormy, but especially when the Clover is strong and rank amongst it, if not tied it must lie on the ground until the Clover is dried sufficiently to prevent heat in the stack or barn, and before it is ready if rain occurs the Barley will be seriously stained and unfit for malting purposes. The steam cultivator we have seen at work since the harvest began, and land enough has already been cleared of its crop of Wheat, so that the cultivator may work with advantage; and as the weather has been fine for the most part, we notice that the steam-cultivated land has received benefit far beyond any horse labour, even if the horses can be spared to do such work. But these have ploughing and seeding with Turnip seed to do daily, by drilling every evening, and thus finishing off the land daily as fast as ploughed whilst the ground is moist, and the seed sure to vegetate—a matter of great

importance at all times, but especially when drilling Turnip seed in the harvest, for every day is of importance.

Hand Labour.—In order that the ricks may be thatched as fast as made, it is desirable to have a thatcher attached to the staff of labourers on the farm. Straw has been very dear and scarce, and it will in consequence be well to thrash Wheat in the field in order that the straw may be available for immediate use.

Live Stock.—Since the first day of this month the sheep have required constant attention, especially the lambs, for the weather having been hot the flies have been very busy; and where the sheep have not been dipped or coloured with fly powders, the animals have been much injured in their fleeces. All the lambs intended for wintering may be shorn with great advantage, for they winter much better, and we find that this should be done by the middle of this month; but we do not wash them. The hogs when sold will then realise from seven to 6s. to 8s. each more than if they had been fattened without shearing. This hot weather will render different management necessary for the dairy cows, as they should come into the pens at daytime from 10 until 4 o'clock to avoid the flies, which disturb them greatly, and shorten the quantity of milk and the milking period also. If, however, they get a quiet lair during sunny days with a bait of second cutting of Clover in their racks, it will not only serve to increase the milk, but enable them to continue yielding a supply for a longer period, and this we consider one of the most important points in the management of dairy cows.

POULTRY AND PIGEONS

FATTENING FOWLS FOR THE TABLE.

We gave in our last article the most simple methods of improving the condition of poultry for the table. As was said, we believe them to be sufficient for the production of delicious birds. It is, however, a well-known fact that the best fowls procurable in the French markets are superior to, or at least carry a much greater amount of white flesh than those which we are used to see on English dinner tables; we will therefore fulfil our promise of translating some passages from a French author on the methods pursued by French poultry growers. There are two systems in France of artificial fattening—the one consists in the forcible cramming of the fowls by hand with balls of meal, in much the same way as they are crammed in England; the other in cramming them through funnels with farinaceous food in a more liquid state. We will first speak of the former.

The dealers and small farmers who pursue the trade in the La Flèche district buy in the markets and from their neighbours the finest pullets and cockerels which have never bred; these are not caponised, but they take a little longer to fatten than the pullets. The finest pullets are got up to 9 lbs. weight or more, the cockerels to 13 lbs., and sometimes more. "They fat (to translate at length the words of a great authority, from whose writings on this subject extracts have already been made in the pages of the Journal) from fifty to eighty and a hundred at a time. The work begins in October, and goes on till the ordinary carnival time. For it they begin by setting up all round, and on the floor of some room or other suitable place, small coops made of stakes or the roughest wood that can serve for sides and divisions. These rude contrivances are made by the fatteners, and cost, so to speak, nothing but the labour and price of a few nails. Their height should be from 18 to 22 inches; their length is optional, provided that the longest do not hold more than six chickens, and give each bird room enough to be comfortable without walking about. All light coming directly from outside is excluded, and all chinks in the doors and windows of the apartment are fastened-up to prevent too free entry of external air. To accustom the chickens to the system of forced feeding and seclusion to which they are destined for the first eight days they are confined in a somewhat dark place, and have no food but a moist rather thick dough of the same kind of meal as the fattening balls, mixed with a third part or half bran. During this preliminary trial they are allowed to eat and drink at pleasure. The mixture which serves for the feeding balls is generally made in the following proportions:—viz., half buckwheat, a third barley, and a sixth oats (the coarse husk is taken out). Every day enough of this meal is mixed in either new or sour milk to suffice for two feeds, one in the evening and the other the next morning. Some add a little hog's lard to the ingredients of this dough, specially towards the end of the process. The meal must neither be too stiff or too thin, and rolled out into pieces like an olive in shape, half an inch thick and 2 inches long. At the feeding times, which should be very regular, the poultryman or feeder takes three chickens at a time, ties them all three together by the legs,

puts them on his knees, and by the light of a lamp begins by making them swallow a spoonful of water or whey—some do not give them anything to drink—then he puts a ball of meal into the mouth of each chicken by turn, and to aid its passage into the crop slides his thumb and two first fingers gently down from the neck to the crop, and so prevents its rejection.

“By thus attending to three chickens at once they give them time enough for digestion, and the birds are taken in proper and regular order. During the early days of cramming they think it enough to fill partially the crop of each chicken, but by degrees they increase the quantity of balls till they give them twelve or even fifteen at each feed. They must be dipped in water before they are administered to help them down the throat. There is no fixed duration for the process of fattening, it depends upon the disposition of the bird and its strength. Some chickens cannot be raised to perfection without danger of accidents; the experienced feeder knows the moment when to stop. No one can entirely escape losses; they say that in spite of knowledge and pains there is such a thing as good and bad luck, seasons more or less favourable, the causes of which cannot be explained. Those who have for many years successfully carried on the process in one place experience heavy losses in another, though they pursue the same method, from being unable to bring their chickens to perfection. Some fowls are quite fat at the end of six weeks, others at two months. Sometimes if a bird still seems to take its food with avidity they continue to administer it as long as possible, and so attain marvels of weight. They calculate that some chickens consume $2\frac{1}{2}$ gallons of meal, some as much as $3\frac{3}{4}$.”

The author proceeds to say that during this process no litter is placed under them and their pens are never cleaned, and that though the odours consequent on this are necessary (!) for the fattening process they are often baneful to the fatteners, who spend all their days and parts of the night in the places, the first meal beginning at 4 A.M., and barely terminating at noon; the second beginning towards 3 P.M., and finishing towards 11. We should strongly object to this state of dirt, equally for the fowls and their breeders; however, as “the proof of the pudding is in the eating,” so we suppose must the proof of the fowl be.

He continues, “To conclude, when the feeder takes his chickens from the coop, he himself performs the work of bleeding and plucking them, and before they are cold presses them on their back on a flat board, and shapes them in the desired fashion by means of pieces of wood or stone to keep them in place; he then puts entirely over each a little damp linen cloth to refine the fat.” To sum up, the principal points to be observed in fattening are—

“1. The finest young cocks and pullets of the year must be chosen, showing all the above-named good qualities.

“2. They must not be caponised, as is the common practice in some places.

“3. A dark place must be got ready where the air changes as little as possible, and where the chickens can be confined in their coop without being too much cramped.

“4. The coops must not be cleaned during the whole time of fattening.

“5. The chickens must be accustomed to forcible feeding for from eight to ten days before the regular system is begun.

“6. They must be carefully and quickly made to swallow the balls of food.

“7. They must have two feeds at regular times in the twenty-four hours.

“8. They must not be made to take a fixed number of balls, all alike; it must depend upon an examination of their crops, which during the early days should be partially filled, and later on quite filled, but never gorged.

“9. The food described must be their sole diet, without any change, save as to the proportion of the ingredients, which may be varied according to circumstances.

“10. Discernment is necessary as to the time when fattening is finished, and watchfulness as to birds which require to be removed before they go off or die. If all these points are carefully observed the result must be good.”

Such is one of the French methods of artificial fattening. We will endeavour soon to give the other method—viz., that of funnel-feeding.—C.

HERTFORD POULTRY SHOW.

THE first Exhibition of poultry and Pigeons and dogs took place at Hertford on Wednesday and Thursday, August 9th and 10th, and was a decided success in every way, the arrangements were perfect and the weather fine. There was a most excellent Committee, all

worked harmoniously, and the attendance was large. The Kennel Club and Poultry Club rules were in force. The Judges for Dogs were Edgar Hanbury, Esq., Rev. G. L. Hodson, Harry Jones, Esq., C. S. Lindsett, Esq., F. Redmond, Esq., J. H. Salter, Esq. The Judges for poultry were Messrs. T. Coke, Burnell, and M. Leno, Esqs. For Pigeons F. Esquilant, Esq., who was assisted by Major-General Hassard, C.B. We were glad to see this old and well-known fancier before the public again.

There were 686 entries for the dog show, and 777 for poultry and Pigeons. The pieces of plate for the prizes were in good taste, and the cards to be sent to each noticed exhibitor well prepared. Messrs. Durrant and Mather were Secretaries for the Dog Show, and Messrs. Breeze and Brett for poultry, and Mr. Billett provided the necessary poultry and Pigeon pens. The dogs were exceedingly good, and fox terriers formed a very large class. Space will not allow our going into particulars of each class. The poultry and Pigeons were very superior. We particularly noticed a white Cochin cock shown by Mr. Darby, the grandest White we have seen. There were some very good Blacks, and the Buffs were excellent. In the Poland classes Mr. Beldon's second prize delighted us, as a Chamois Poland is a thing of the past, and we are glad to see it is not quite lost, the crest of the cock was quite equal to the drawings in the poultry books.

Messrs. Fowler showed Ducks well as usual. When we say Messrs. Fulton and Hammock were among the Pigeon exhibitors nothing more need be said as to the quality. Mr. Fulton winning the cup for best bird in Show, except in Classes 70 and 71, which was won by Mr. A. Allen. The county of Hertford has had such an auspicious beginning, we hope the Show will be continued annually.

THE WARWICK SHOW FRAUD.—The sentences passed in this case, the particulars of which we gave last week, were as follows:—Groutage fifteen months imprisonment, and Cockerill four months imprisonment. The Judge intimated his readiness to make an order for the restitution of the proceeds of the fraud to the rightful owners.

STAFFORDSHIRE AGRICULTURAL SOCIETY.—We would call the attention of our readers to the postponement of the date of the poultry Show to be held at Lichfield in connection with the Exhibition of the Staffordshire Agricultural Society on September 26th and 27th, instead of the 12th and 13th of that month as previously arranged.

OUR LETTER BOX.

Fowl's Tail Crooked (F. G.).—The condition of your bird indicates that it is suffering from spinal curvature which causes the tail to be carried constantly on one side. It frequently arises from over-growth when young, caused usually by too high feeding and too much confinement. Nourishing but not animal food, a good run, and abundance of green food, are in such cases the best preventives. It is sometimes also the result of too much in-breeding or inherited. Such birds should be killed.

REMARKS.

6th.—Fine, bright, hot day; bright starlight night.

7th.—Cloudy first part of day, afterwards fine and warm; cloudy evening.

8th.—Very dull at first, afterwards fine and bright; evening starlight and cool.

9th.—Cloudy morning, afterwards fine and bright; warm misty evening.

10th.—Dull and overcast throughout, very slight rain after 9 P.M.

11th.—Generally cloudy, but bright in the latter part of the day; many shooting stars at night.

12th.—Fog in early morning, fine, hot, but rather oppressive day; lightning and a slight shower in late evening.

Temperature about the average, and a little below that of the preceding week. The barometer continued high, and, as is frequently the case with a high barometer, the weather was inclined to be cloudy and dull, though no measurable quantity of rain fell.—G. J. SYMONS.

RENOVATING PEACH AND NECTARINE TREES— THE "YELLOWs."

WELL-ARRANGED and well-managed Peach houses are both a source of much pleasure and profit. The houses need not necessarily be expensive in construction, they make but little difference to the coke bill in a garden where other houses are being constantly heated, and, in addition, can be utilised for various other purposes. It is not my intention at present to discuss which is the best style of house for Peach culture and most profitable method of arranging the trees, further than expressing the opinion that the houses should be constructed to admit of a double row of trees—one on the back wall and the other on a semicircular trellis in front, rather than train the trees to a trellis near the glass, somewhat after the manner of Vines. The former is the method adopted here, and which I should be sorry to see altered, especially as our back wall is 12 feet high. The position of our houses is also particularly favourable, and the range is 190 feet long, divided into three compartments, two being heated and one unheated. I found it furnished with well-formed trees, comprising several sorts worth growing, and not merely as many as could be crowded in; there are a few, however, which are doomed.

Unfortunately the trees were in an unsatisfactory condition, being afflicted in many instances with the "yellows"—that is to say, the points of the young growths were yellow instead of a dark healthy green colour. This may be thought a rather singular name for a complaint, but those who are acquainted with the symptoms know the crops obtained from such trees are of comparatively little value till these same "yellows" are prevented. The trees when in this condition, unless too far gone, flower freely and set good crops of fruit, which appear to stone well, but the majority drop when apparently near perfection. If fruits drop before they are quite ripe they are not fit to eat, and when this dropping occurs there is of a certainty something radically wrong with the roots of the trees. It is true over-dryness or over-cropping may result somewhat similarly, but in the latter case especially, I think, we more often err in not cropping heavy enough, always supposing we have healthy vigorous trees. A fruit to every square foot of tree surface might do for older generations, but it will not satisfy either "gardeners' greed" or employers' demands of the present time, and twice that quantity have to be grown of kinds which bear moderate-sized fruit.

An over-cropped tree, and which, perhaps, has not had sufficient moisture supplied to it above and below ground, will, as a rule, be plentifully covered with insects, such as red spider

and aphides. Now, I found trees afflicted with the "yellows" were not infested with those pests, probably because of the absence of the food they prefer. This, however, was poor compensation, and drastic remedies had to be applied. It must be understood the "yellows" are caused by too deep root-action, this being the result of either an insufficient supply of moisture or poverty of surface soil, or both. If no means are taken to keep the roots of Peach, or indeed of any fruit trees, near the surface they will inevitably strike downwards in search of the necessary food, and this, it is almost needless to say, marks the commencement of the trees' decay. The roots should be near the surface to such an extent as to render it impossible to lightly point up the soil without detaching bunches of them. In this position they derive much benefit from the warm atmosphere, the soakings of liquid manure, and any fertilising top-dressings that may be applied, all of which are wasted on borders containing deep fibreless roots. Last year at this time it was a difficult matter to find any roots, but suckers were remarkably abundant. This has been completely changed, and as a consequence valuable crops of fruit have been and are being secured. The remedy for trees in the condition described is simple, and consists of either partial or wholly lifting, and placing the roots near the surface in fresh soil. Good turf, nearly or quite fresh, a sprinkling of lime rubbish and wood ashes, form an excellent compost, using also a little decayed manure.

We commenced operations early in September, and completed the late house by the end of the month. In each instance the growth was ripened and the buds plumped, this being long before the leaves dropped. At this time the root-action is most brisk, and it follows if many of the roots are carefully lifted and placed in fresh soil numbers of rootlets form long before the foliage falls. By these means a good foundation is laid for an early start the following season.

In the early house one tree was too far gone for renovation. This was removed, the soil being cleared away to a depth of about 2 feet, and a width each way of 6 feet. Fresh soil was introduced, and afterwards occupied with an overcrowded tree from the successional house. This transplanting was no easy matter, as the tree was disposed behind a double row of hot-water pipes in front of the house, and as it would have to be similarly placed in the fresh position not much earth could be moved with it. In moving we first cut a circular trench as far off the stems as we safely could without injuring the adjoining trees to a depth of about 30 inches, and then gradually forked away the soil from the roots, carefully preserving these till within 18 inches of the stem. The ball thus retained was then partially undermined and reduced to a manageable size, after which the tree was loosened and gradually brought down to the ground, while the earth and roots were drawn out from under the pipes. It was then worked through the doorway into the next compartment and replanted. Much of the foliage was unavoidably broken, but by carefully shading from bright sunshine and frequently syringing at times during the day we succeeded in preserving the majority of the healthy leaves. Prior to removal the tree was in a bad condition, but this season, although forced, it has improved wonderfully, and during June ripened five dozen excellent fruit, besides forming abundance of medium-sized well-ripened growths, ranging from 18 to 30 inches in length. The variety is the Early Grosse Mignonne, and the tree covers a space of about 12 feet by 8 feet.

I have assisted in transplanting much larger trees from a vinery, these being carried a considerable distance, disposed against a high wall and a house built over them. In every case the trees the following season were more or less forced, carried fair crops of fruit, and formed excellent growth.

It is always of importance in lifting to preserve as many roots as possible, this being best attained by opening a deep trench as far off the stem as circumstances will admit or the size of the tree necessitates, and when forking the soil from the roots to keep it thrown out of the trench. In fact, unless this is strictly practised it will be impossible to properly undermine the tree so as to admit of its being placed on a board or a flat hand-barrow, with which it is necessary to carry the great weight sometimes secured. If left to themselves the men are apt to neglect keeping the trench open and then roughly drag out the trees. This will not do. Neither should a very large ball of earth be taken, or there will be danger of large pieces falling off, carrying away many valuable roots at the same time. A moderate-sized ball made flat underneath and all unoccupied surface soil pricked off prior to the trees' removal will be found the best plan. The soil should be moist when used, and kept in that state afterwards.

Peaches and Nectarines are so accommodating in disposition that young trees can be readily prepared for the forcing houses either in the open air, or, better still, in a late house. To plant a tree newly received from a nursery direct into a forcing house is, as a rule, a mistake, being both injurious to the tree and wasteful of house space. I prefer to have the young trees in a bearing state and under my own care prior to planting in early or second-early houses, as this admits of fruiting the old trees to the last, and the young trees being moved in full leaf can then be safely forced and fruited at once. After planting a tree with foliage intact the house may be kept somewhat close for a week without injuring the older occupants, and by carefully shading and syringing the tree operated on, it soon recovers.

In the case of the "yellows" it is not necessary to completely lift the trees to restore them, but a trench should be cut as if for removing, and the old soil being picked away from the roots to within 3 feet of the stem of a moderate-sized tree, which covers, say, a space 12 feet by 8 feet. If new soil is scarce much of the old surface soil may be disposed at the bottom of the hole made, allowing a depth of 18 inches for the fresh compost, the latter, if possible, to consist of turfy loam, or, failing this, the best clayey loam procurable, adding to every four barrowloads one of short stable manure, half a barrowful of old mortar rubbish, not throwing out the small brick ends, wood ashes to be dusted about the roots as they are being covered. Charred refuse may with advantage be mixed with some soil, but it must always be remembered that neither Peach, Nectarine, nor any other fruit trees should be planted in a very loose compost. Firmness should always be insured from the bottom to the top of the border.

After the roots are trimmed always dispose them in a flat or horizontal position exactly as they start from the stems, the bottom tier to be covered with moderately fine compost; the next tier should be disposed on this, and so on till the whole are buried, the topmost tier being brought to within about 2 inches of the surface. In this manner the roots are evenly disposed throughout the fertile soil, and will form rootlets more readily than if matted together as they sometimes are when the soil is thrown in promiscuously. If properly attended to in watering and syringings the trees will be able during the following season to perfect heavy crops of superior fruit, and will also form growth of the best possible quality. Those in charge of them will never regret having taken some trouble with the trees, and will probably take every precaution to keep the roots nearer the surface in the future than they have been in the past.

Trees on the open walls would continue fruitful much longer if treated similarly, as the growth formed under more favourable conditions is healthier and ripens more certainly, and is consequently less liable to injury by severe frosts. There is no doubt the uncertainty attending open-air culture of Peaches has led many to wisely provide houses for them, but I still think it possible to grow good crops on the open walls over a

wide district of the country, provided there is sufficient labour for keeping the trees healthy by lifting them as frequently as may be needed, and the essentials are provided for protecting them in spring. The Peach crop on the open walls at Frogmore I believe seldom fails.

In concluding these notes I wish to point out emphatically that Peach and Nectarine trees cannot be lifted too soon after the crops are gathered, as then, if the foliage is kept fresh by shading and syringing, the trees become established before winter, and will bear freely the following season.—
W. IGGULDEN.

MUSHROOMS FOR THE MILLION.

(Continued from page 98.)

INTELLIGENT SUPERVISION.

THIS consists chiefly in covering the beds so as to maintain a steady and equable temperature, also in watering them at the proper time and in the right manner. As previously mentioned, sufficient straw can be shaken from the manure on its arrival from the stables for the purpose of covering the beds. There can be no better material than this—indeed, no other is so good for placing in immediate contact with the surface of a Mushroom bed. If during unusually severe weather clean straw or fern must be used, it should always be placed on the other covering, never on the soil under it, as it is somewhat strange to observe that when this has been done after Mushrooms have commenced growing considerable injury has resulted to the crop. The long litter shaken out from the manure is placed in a large heap and heats more or less; it should, however, not be turned, but be allowed to heat itself dry, and it will then be in the best possible condition for use. Its peculiar nature and smell appear to be precisely suitable for Mushrooms; at any rate they are produced far more freely under such a covering than under a layer of sweet clean straw or hay. A sufficiency of this litter should therefore be secured if possible, and it can usually be obtained if the manure is collected, long and short together, just as comes from the stables. There is a danger in gathering the manure that the long may be refused, under the impression that it will not decay sufficiently for use in the beds. It certainly will not decay to that extent, but it is of the greatest service nevertheless, for it is important to remember that, however suitable the decayed portion may be and strong the spawn, if the beds are not thickly covered with proper material satisfactory crops of Mushrooms cannot be produced.

The proper degree of thickness of the covering can only be determined by the heat in the beds and the weather. If the weather is mild and the bed comparatively new a covering of 6 inches of litter will suffice. If the bed is old and the temperature of the air remains still mild, the covering must be twice that thickness; while during severe and prolonged frost 2 feet or more in depth of straw, protected with mats, canvas, or some such material, will be absolutely necessary, and sometimes the beds are covered 3 feet thick. Beginners, however, should endeavour to have beds to come in bearing in October or April, as Mushrooms grow with freedom then, and experience would be gained for extending the period of gathering when greater care is needed. The proper temperature of a bed can be determined by the hand. If when it is placed on the surface under the straw and the slightest possible warmth is felt, that will suffice; or, for the sake of greater accuracy, if a thermometer is laid on the soil at night, and

in the morning when the straw is removed the temperature is neither many degrees below or above 50° , it will be safe. The instrument is no doubt a useful guide for the experienced, but it is certain to be dispensed with after a few crops have been gathered. Mushrooms will form and grow at a temperature of 40° when the bed is permeated with strong spawn; but their movement is slow, and a mean ranging from 10° or 15° higher should, if possible, be maintained.

WATERING MUSHROOM BEDS.

During bright weather in autumn, spring, and especially early summer, when the beds need little covering, they often require, especially those that are bearing heavily, frequent supplies of water. It is of the greatest importance that the soil is never permitted to become dry, and water must be given as often as is needed in quantity sufficient to prevent this. The time chosen for applying water should be early in the afternoon of a sunny day. The covering on the beds will be then quite warm, and on this, not under it, the water must be sprinkled in sufficient quantity to percolate through it and gradually moisten the soil. Immediately after watering the beds they should be covered with mats to prevent the moisture evaporating, and the vapour that will be generated will result in a cool humid atmosphere under the mats and straw precisely conducive to the growth of Mushrooms, the mats to be removed in the morning. Those who are not experienced in the method of culture in question cannot understand that Mushrooms can be produced in summer on account of the heat, forgetting that by using sufficient straw, and sprinkling it, permitting at the same time free evaporation, that the beds may even be made too cold for the crop, on the same principle that ice-cold water can be produced under a tropical sun by enveloping the porous vessels in which it is stored with a medium that can be kept moist when the constant evaporation, with the ever-attendant lowering of temperature, produces the effect desired; still, as a rule, the crops are not profitable after the middle of June, as the Mushrooms, owing to the nitrogen they contain, speedily decay after being gathered in hot weather, and they can then no more be eaten with safety than meat can that is in a state of decomposition. If this simple fact were impressed on the minds of those Mushroom-consumers who do not always think before they eat there would be fewer records of injury resulting from partaking too freely of this esculent.

EXHAUSTED BEDS.

Mushroom beds partially exhausted by heavy and continuous bearing may be in some measure renovated by a free application of liquid manure, sufficient being given at a temperature of 100° to penetrate the entire mass of manure. The drainings from a manure heap are good for this purpose diluted until the liquid is of the colour of pale ale, 1 or 2 ozs. of common salt being added to each gallon. When the above tank liquid manure cannot be had perfectly clear soot water of the colour indicated, with salt as directed, may be advantageously applied, or an ounce of sulphate of ammonia dissolved in four gallons of water will be found equally beneficial. These stimulants are often of great value to beds in private gardens where a steady and prolonged supply of Mushrooms has to be maintained; but when beds in the open air are once fairly

exhausted by heavy bearing they can seldom be profitably renovated by the use of stimulants.

Salt has been recommended, and lest there be any timid readers who may fear to use it at the strength named, they may take courage from the fact that Mr. Barter regularly uses it at the rate of a quarter of a pound to a gallon of water, but applied, be it remembered, over the straw covering. So beneficial is salt to Mushroom beds that it is used regularly whenever bearing beds require watering, and it was found just as the quantity was increased so the crops were improved, and the Mushrooms were rendered more white and fleshy.

GATHERING MUSHROOMS.

Different opinions are held by cultivators relative to the best method of gathering Mushrooms. Some advocate and practise cutting them, removing the stems a few days afterwards when they can be withdrawn easily; others pull them up, but usually do it in a very cautious manner as if afraid of disturbing the beds and arresting the growth of further produce. When the writer

Fig. 28.—Pulling v. Cutting Mushrooms.

received his first lessons in Mushroom culture thirty-five years ago it was regarded as little short of criminal to pull Mushrooms, the orthodox plan being to cut them. If the old practitioners who gathered the crops so tenderly and almost in fear and trembling lest no others should follow, could see the manner in which Mushrooms are gathered for market they would scarcely believe their own eyes. Not only are they torn ruthlessly from the beds, but the roots are dug out if they are not sufficiently broken in the process of pulling. It is usual to have two baskets, the large Mushrooms being placed in one and the "buttons" in the other, the soil being knocked off the roots as the work proceeds. When the stems are separated, as many are, close on the surface of the bed, leaving the stump undisturbed in the soil, this stump is at once scooped out with a knife, leaving a round open cavity in which a walnut might be placed. This to the uninitiated appears barbarous work; it looks like spoiling the beds and preventing the production of successional crops. That it has not that effect is certain, or those to whom every pound of Mushrooms is an object would not adopt it. The result of the digging-out process is the direct opposite of that indicated. Instead of impair-

ing the productiveness of the beds it increases it, and for a very good reason that is, however, not very easy to make intelligible to all. If the lines of communication—the threads of the mycelium—from the interior to the surface of the beds which terminate in clusters of Mushrooms are not broken the strength of the beds—the Mushroom-producing force, is expended on the old stumps, and very frequently, indeed almost invariably, finds expression in masses of fluff of a cauliflower-like appearance, or a gigantic mass of mould or fungus. These masses if permitted speedily attain the size of dinner plates, and no more marketable Mushrooms are produced where they occur; but on the other hand, when the stumps are scooped out and the mycelium lines are severed, small tubercles form at the end of each and speedily develop into Mushrooms. The effect of this is that rings of fine produce form round each cavity, and thus the productiveness of the beds is prolonged and increased. Hundreds of gardeners know nothing of this, and there are few probably who dare practise it boldly at first; but if they were to see the thousands of indentures or cavities made in a Mushroom ridge in removing the crop, and a week hence see the fine rings of Mushrooms springing round each cavity, they would at once perceive the soundness of the practice of digging out the roots; and if for the sake of experiment some stumps were left undisturbed, and they could also see the result—the great masses of mould and no Mushrooms—they would be still further convinced that the skilled market growers have excellent reasons for the practice described.

Endeavour has been made to show as faithfully as possible in the accompanying engraving examples of digging and non-digging the stumps out of Mushroom beds at the time of gathering the crop, and the effects in one part of Mushrooms springing round the indentures are apparent, while in the other, where the stumps were not disturbed, there is a large white mass of mould and no Mushrooms.

It may be urged against this system of gathering the crops that beds have continued bearing when a different method has been pursued. This may be the fact, as it is equally a fact that one man has travelled over the Falls of Niagara on a tight rope, and another crossed the channel in a balloon, but these are neither safe nor sure modes of transit for others to attempt. And in the subject in hand—obtaining the greatest quantity of Mushrooms from prepared beds—the object is to point out a path that shall be the safest and the best for all to traverse who may engage in the work.

(To be continued.)

STANDARD ROSES.

THERE is a cry recently raised against standard Roses which I venture to think has been taken up and pushed beyond the bounds of reason and common sense, as many a cry has been in times gone by. If I were asked, "Whence this cry?" I should answer that it has apparently been started by those who are innocent of this particular form of the Rose while abounding in dwarfs. I cannot understand why standard Roses, which in the past have been admitted on the highest authority indispensable in the composition of garden scenery and otherwise desirable in both large and small gardens, should be altogether undesirable now. Is not the cry an exemplification of the old fable of the "Fox and the Grapes?" Nevertheless, I am free to admit that the former popularity of the name, and the matchless splendour of the objects both as individuals and in groups, have led people deficient in taste to place them in unsuitable positions. But this surely tells no more against their proper employment

than the traveller's tale of the savage's use of an Englishman's wardrobe does against the proper employment by the owner of any special article of civilised dress.

One great use of standard Roses in large gardens is the elevated masses of colour they present to the eye both in near and distant views, while in small gardens the avenue of standards is often one of its prettiest features. Then what is more beautiful in the conservatory than standard Tea-scented Roses? Without following out all the uses to which they may be advantageously applied, I venture to predict that they who discard them from their gardens now will miss them greatly in the future, and seek in vain for something that will satisfactorily fill their places. With greater reason might a cry have been raised against the sorts of Roses that have been, and still are, in some instances grown as standards. Here, indeed, is the modicum of truth in the cry which gives it a temporary hold on the public mind, and renders the matter worthy of investigation.

It is beyond controversy that the natural term of life of certain sorts of Roses when grown as standards is three years, two years, or even one year only, as that of man is threescore years and ten, and that a prolongation of this term carries with it all the accompaniments of old age. What will the uninitiated say when they are told that certain sorts of Roses seen at the Rose shows are budded yearly by the exhibitors, and never cared for after they have given their first year's blooms? But it may here be asked "Why does the Rose-grower bring such ephemeral goods into the market?" His reply probably would be, "Why does the public persist in purchasing them?" and add that it is not his business to dictate to his customers what they shall buy, but to be prepared to supply what they demand. The remedy on the part of the purchaser would be to choose his sorts from trees seen growing in nurseries or gardens, and in doing so inquire (if the fact is not apparent on the surface by the age of the tree or otherwise) whether the sort has a good constitution and habit as well as a handsome flower. There is one special advantage in growing Roses as standards which was suggested to me by an old friend, a distinguished horticulturist, when discussing the subject the other day, and I will put it in his words—"I agree with all you say, and will add one reason more; in growing Roses as standards the flowers are brought near to our eyes and noses, and those who, like you and I, are growing old have not to bend the back or go on all fours to see and smell them."—WILLIAM PAUL, *Paul's Nurseries, Waltham Cross.*

A COTTAGER'S PEAS.

IT is very gratifying to observe how great is the interest that many hardworking sons of toil—the agricultural labourers, in some rural districts—take in the cultivation of their gardens, and how fine are the crops they produce. Local exhibitions of garden produce have stimulated, not to superior culture only, but to the acquisition of new varieties, which it might be imagined could only be obtained by the affluent; but when a man, however humble his position may be, has a strong and firm desire to excel and distance his neighbours in the rarity or excellence of his crops he will soon find a way to procure the best varieties obtainable "regardless of price." At the first glance it is not improbable that there may be some excellent individuals who are animated with the best possible motives, and earnestly desirous of seeing their humbler friends prosperous, who may deem it highly imprudent for a man earning not more than 2s. 6d. per day to give more than that sum for a small packet of Peas or a pound of Potatoes. But it by no means follows that the man who does that is imprudent; on the contrary, it is evidence of thoughtfulness and enterprise, which not infrequently brings a reward.

Recently in my travels I was surprised to find in the garden of a labourer one of the finest examples of Pea culture I have seen. The occupant of this garden had been a prizewinner in some cottagers' classes at a local show. He there saw some of the newer varieties of Peas, and resolved to have them and grow them as well or better than those that had arrested his attention. He purchased the new varieties in small quantities, grew them well, and saved the seed. The surplus of this he sells locally, and more than recoups himself for his original outlay, and has extremely fine and very profitable rows of Peas into the bargain.

Like a wise man he does not sow his Peas in parallel rows a few feet apart—that is to say, instead of having five rows 10 yards long each, side by side, he has one row 50 yards in length. He prefers the row at the side of a walk as economising space, the ground on the other side being planted with early Potatoes, which do not exclude the light and air from the Peas, hence the haulm is sturdy, strong, and fruitful.

The ground is prepared as if for a row of Celery to be grown

for a prize, and the trench is not quite filled when the Peas are sown and covered. Provision is thus made for applying liquid manure quickly and in large quantity as may be needed. Thin sowing is practised, as saving seed, which is costly, and the seed so saved pays for the manure that is used to make the rows so vigorous and the crop so fine.

The varieties grown freely by this cottager this year are Telegraph, Telephone, Culverwell's Giant Marrow, Stratagem, and Pride of the Market. A correspondent on page 153 last week gave the preference to the last-named variety over Stratagem; the cottager is exactly of the same opinion. He regards both as very good, but says Pride of the Market is a "better bearer and better eater." As to Telegraph and Telephone, the former he esteems the most productive and generally useful "for such folk as me," but the latter is the sweeter, and thinks it will "make a good parson's Pea;" but he says "Culverwell's Giant is the biggest of all," and he shall grow "a lot of it." Considering it is such a new Pea he has "a lot" already, and as he has tried it and found it "first-rate" when cooked, he says he shall "go in" for a lot more, and he knows he can sell every seed at a "long figure." Certainly the crop was a splendid one, the row 7 feet high being laden with huge well-filled pods, some containing thirteen peas.

Here, then, we have a farm labourer purchasing Peas at prices that well-to-do people fear to give, or they cannot indulge in "such extravagance;" but when a man gets, as this man easily will do, much more than 100 per cent. for his outlay, growing new and dear Peas indicates good judgment and commendable prudence, for those new Peas are decidedly the most profitable crop in this working man's garden. It is not enough, however, to buy the Peas, sow them without special care, and leave them to take their chance. They must, as the man says, "be forced—make a show and a noise to cause a sensation, then everybody who sees them wants a pint." Perhaps this little record of facts may be suggestive to some readers of the Journal who have a prejudice against, or think they cannot afford to purchase "new Peas."—A TRAVELLER.

THE COLOURS OF FLOWERS.

ON pages 105 and 106 you notice Mr. Grant Allen's views on the colours of flowers. It seems to me that there are many phenomena which militate against his conclusions, and which should be explained before these can be accepted. Mr. Grant Allen's theory is that all flowers were in their earliest form yellow; then some of them became white, after that a few of them grew to be red or purple, and finally a comparatively small number acquired various shades of lilac, mauve, violet, or blue. I understand his arguments to be, 1, That yellow and white flowers are the commonest and blue the rarest. 2, That stamens are commonly yellow; that petals are modified stamens; therefore that petals were yellow until some circumstance arose to change them. 3, That the smallest, simplest, and most regular flowers are yellow or white; and that as flowers advance in complexity to irregular petals, to a united corolla, and lastly to an irregular united corolla, the red and blue shades become more frequent. 4, That colours change is by no means uncommon, and that it is always—(I am commenting on the article in the January *Cornhill*; I see that your quotation is "in almost all known cases," so perhaps this is somewhat modified)—in the same direction, from yellow or white, through pink, orange, or red, to purple or blue. 5, That the colours of flowers are liable to sport back to those of their ancestors, and hence white specimens are common in the red, and red, white, or purple in the normally blue kinds.

Now to take these in order. The first may be admitted; it is, however, no proof that the blue flowers have passed through other stages. The second is perhaps Mr. Grant Allen's strongest argument. It is, however, merely a reasoning from the probable. Many botanists, indeed, suppose petals to be modifications of the leaves, not of the stamens at all; and in the very instances adduced to prove the contrary—the staminodes of the white Water Lily, the rays of the *Mesembryanthemum*, the extra petals of the double Rose, the petaloid filaments of the Star of Bethlehem—the modified organs take from the very first the colour of the outer row of petals. Was a case ever known of a double flower in which the extra petals retained the colour of the stamens instead of adopting that of the corolla?

Mr. Grant Allen shows, no doubt, that many irregular flowers are coloured blue; and he quotes the Composites, the Labiates, the Snapdragons, and the Orchids as the most profoundly modified of all existing flowers, and also those in which blue and purple flowers are commonest; but if the doctrine of regular procession be true, it seems to me that blue, the colour of the fourth stage, should prevail here, not purple and blue, the third and fourth taken together. Now, if we were asked in what families blue

colour is most prevalent, I think we should mention the Flaxes, in which the petals are regular and separate; the Violets and Spiderworts, in which they are irregular and separate; the Bell-flowers, Gentians, Nemophilas, and Borages, in which they are regular and combined. Perhaps we might add Labiates, though the blues of the order seem to be decidedly outnumbered by the purples. But of Mr. Grant Allen's other types blue is by no means a common colour in the Snapdragon family. The Speedwells are our only native examples; and in the Orchids, the most remarkably developed of all flowers, I believe that a really blue colour is unknown. There remain the Composites, among which, considering the vast number of species, the small number of blue flowers is very remarkable; while such as there are belong chiefly, as the Succory, Endive, and foreign Lettuces, to the Dandelion group, which Mr. Grant Allen considers the least advanced in the order, and which is certainly characterised by the enormous majority of yellow flowers. It must be a puzzle for the theory to account for the small number of intermediates between the yellows and the blues.

As to colour change, Mr. Grant Allen quotes one instance—a Forget-me-not—of passage from pale yellow through pink to blue. I doubt if he could name a second, and even here the white stage is omitted. Changes from white or pale pink to crimson are no doubt frequent. *Quisqualis indica* might have been added to the list, and the Rose which we call Archduke Charles. But there certainly are many instances of change in the reverse direction. *Brunfelsia americana* changes from pure white to primrose. I believe that *Solandra grandiflora* does much the same. Mr. Grant Allen himself describes a Wallflower which has a white stage before the citron yellow. Again, *Ipomæa rubro-cœrulea* fades from azure blue to reddish; an arboreal *Solanum*, I believe *S. macranthum*, is violet the first day, pale lilac the second, and silver white the third, while the changes of *Franciscea* are in the same direction. I should draw the inference that white and blue flowers often change, yellow and red scarcely ever, and that the cause is in all probability merely chemical and quite unconnected with heredity.

Lastly, the sports quoted by Mr. Grant Allen are admitted; but who ever heard of those flowers sporting back to yellow? It appears to me that this alone is almost conclusive against blue and purple flowers having passed through a yellow stage as well as a white one.—WILLIAM WATERFIELD.

THE BEST MANURE.

I MAKE no pretence to a knowledge of chemistry, and therefore cannot say whether Professor Voelcker (see page 121) is right or wrong in his analysis of earth-closet manure, but I am prepared to say, and to prove if necessary, that the estimate he places on it, supposing him to be correctly quoted by "INQUIRER," is far too low, and that most fruits, vegetables, and flowers can be grown by its aid alone quite as satisfactorily as they can be produced by any other fertiliser, either natural or artificial. I have often wondered why the earth-closet system has not been adopted to a greater extent. It seems that we have now the key to the mystery, and that the chemists are responsible for it. I do not deny the valuable aid which chemistry has rendered to agriculture and horticulture, but it would be madness on our part, when a certain manure has proved practically to be of the greatest possible value, to throw it aside simply because a professor, however eminent, cannot find the fertilising ingredients in it.

"INQUIRER" seems to have an idea that chemists are infallible, and that we are bound to take as proven everything they tell us. I hope the chemists themselves do not think so, and, indeed, I know they cannot, for every now and then there are startling discoveries which in a great measure upset their former theories, and must have the effect of forcing them sometimes to reconsider what have been supposed to be facts. That chemistry has a bright future before it I am certain, but what is wanted is original research by persons unfettered with old notions. That there are such in the field, and that we are on the eve of great discoveries, may be gathered from one or two papers which have appeared in this Journal of late, and with which I have been much interested, notably the review on the "Report of the Sussex Association for the Improvement of Agriculture," which was published in the number for August 3rd.

I would humbly suggest to Professor Voelcker, or any other chemist who may be disposed to analyse soil from an earth closet, that he obtains his sample elsewhere than from a prison or work-house, for possibly the diet and exercise enjoyed by the inmates of such institutions are not such as are best calculated to produce the most fertilising material. It may appear presumptuous, but I altogether object to the statement attributed to Dr. Voelcker

"that the high estimate of the value of earth-closet manure does not rest on any solid foundation," for even Dr. Voelcker himself, I imagine, does not deny that pure night soil contains high manurial properties; and granted this much, I would ask, What becomes of the nitrogen, &c., when simple dry earth is mixed with it? We who know the value of earth-closet manure take care that there is nothing used for deodorising which can have the effect of driving away the ammonia, also that the soil is in the best possible condition for absorbing it, so that only a small quantity is needed. To dry the soil after it has used by the aid of strong fire heat must have the effect of driving off a great deal that is valuable, and the practice can only be defended where soil is more valuable than manure—certainly it ought not to be tolerated in any but our largest cities.

"INQUIRER" must remember that my statements rested on something more than theory. I was simply telling my readers what had been used for the production of Vines and Grapes, of which a well-known writer and good gardener said in this Journal last October, that "a similar example of culture had not been attained in the time in the Queen's dominions;" and as nothing else has been used besides what was described, I would ask "INQUIRER" to suggest where the stimulant came from. That the small quantity of Standen's manure used did not produce it I have had proof this season, which I will partly describe. The earth-closet manure was used on some of the Vines, and as there was not sufficient for all it was used on those which were supposed to be most in need of it, an extra dressing of Standen's manure being given to those which had none of the favourite mixture, and the difference is so very remarkable that I am now prepared to agree with "SINGLE-HANDED" that I make a mistake in using Standen's manure for this purpose. I have used it hitherto because in a trial with several other concentrated manures a few years ago I found it to be the most satisfactory, but I have my doubts whether the quality is of so high a standard now as it once was.

I wish to tender my thanks to "SINGLE-HANDED" for his papers on manuring. I hope your readers will turn his advice to good account.—WILLIAM TAYLOR.

FORGET-ME-NOTS.

In simple unobtrusive beauty what hardy flowers can equal the Forget-me-nots? Whether they be growing in native luxuriance near some shady brook or stream, in the most humble or most elaborate garden, in the conservatory, or whether we see the flowers alone in vases or bouquets, they are invariably admired and can claim a position amongst the most general favourites. Now spring bedding is so fast growing in popularity increasing attention is being paid to these plants, for few beds are more effective than a well-filled one of Forget-me-nots with some suitable margin, say lines of red and white Daisies. Their cultivation in pots also is being greatly extended, and many growers send large quantities to market in spring and early summer, while in suitable localities, particularly under the shade of fruit trees, acres of these plants are grown to afford flowers for cutting. Such evidence of the demand existing for them is sufficient apology, if any be needed, for devoting a little attention to these charming plants, especially as the present season is a suitable one for seed-sowing to obtain a stock in spring.

Names to many persons possess considerable interest, and few plant names are invested with more romance than the Forget-me-not. Everyone knows the German legend of the unfortunate but devoted lover whose exclamation as he threw the flower to his lady on the river bank is said to have given it the popular title which it still bears. It is not, however, so generally known, as Dr. Prior has pointed out, that quite a different plant was long designated Forget-me-not both in England and on the continent. The old writers, Gerarde, Parkinson, and many others, all bestow this title upon the *Ajuga Chamæpitys*, not on account of its beauty or from any similar romantic associations to those connected with the *Myosotis palustris*, but from its possessing a nauseous flavour which is likely to dwell in the memory of those who have tasted the plant. *Veronica Chamædryas* has also been so named in Denmark and elsewhere, while it appears to have been bestowed upon some plant in the middle ages which cannot be now recognised. The English name of Scorpion Grass refers to the inflorescence, which is considered to resemble the tail of a scorpion. As a popular name, however, Forget-me-not is much preferable, and is often adopted now for the whole genus, though originally restricted to one species. The botanical title *Myosotis* is an old classical name, having been employed by Pliny and others, and signifies Mouse-ear, in reference to the shape of the leaves.

The species of *Myosotis* are rather numerous. Between fifty and

sixty are known besides some varieties; but few are in general cultivation even in large collections of hardy plants, and more than half a dozen species are rarely seen in any but botanic gardens. Of so large a number it may be readily imagined that many are unfitted for general cultivation, being wanting in the richness of colour or size of blooms which characterise the best of those now grown. The true Forget-me-not (*Myosotis palustris*) is the most common, and for general garden culture is very useful, especially in rather moist situations; and its free growth, abundant bright blue flowers, and long-continued beauty are its great recommendations. One variety named *semperflorens* continues blooming very late in the season. As this is a perennial plant, when once a stock is obtained it is little trouble afterwards, but, like other species of the same type, it is benefited by occasional lifting, the soil being freshened by the addition of a little light rich compost. It can be increased by division of the plants, cuttings, or seeds.

M. sylvatica (the Wood Forget-me-not) is also well known and thrives well in beds and borders, but appears best when grown in dense clumps. Though preferring a somewhat damp and shady situation, this will succeed in drier positions than the preceding, and its bright blue flowers are always welcome.

M. dissitiflora is an acknowledged favourite with all; the early season at which it blooms and the great size of the flowers well entitling it to its popularity. This has proved invaluable for spring bedding, and for culture in pots to afford a supply of flowers early in the season it is also greatly appreciated. The size and clear blue colour of the flowers admirably adapt them for bouquets, buttonholes, or floral decoration generally, especially as they are obtainable at a season when such are most in demand. A plentiful stock can be raised from seed sown at the present time in prepared beds outside or in pans or pots for forcing. A compost of light loam, leaf soil in equal proportions, with a little well-decayed manure and sand, suit it well, water being liberally supplied in dry weather to beds outside and to plants in pots. Most forms of *Myosotis*, in fact, except the alpines, require abundance of water, but they are impatient of any approach to stagnation, particularly when grown in pots. Varieties have been obtained with flowers greatly surpassing the ordinary type in size, two named *splendens* and *grandiflora* being similarly good in this respect.

M. azorica, a compact-growing species of branching habit, often not exceeding 6 inches in height, is one of the best for pot culture; and though its flowers are not so brilliantly blue as some of its allies, they are so freely produced that a well-grown plant appears to be literally a mass of blooms. It is on this account that the Azorean Forget-me-not is prized for pots, and when arranged in the marginal rows of groups or on stages the plants have a most pleasing effect. A white-flowered variety has been obtained, and is grown as a companion to this.

M. rupicola is a charming little alpine plant that is more at home on the rockery than in open beds, and if a suitable nook be assigned it, moderately sheltered and not too dry, it will thrive and flower as well as could be desired. In pots also it is extremely pretty, but a little attention is needed to ensure its success under that method of cultivation. It is extremely dwarf, 2 or 3 inches high, of tufted habit, and the bright blue flowers are abundantly produced, possessing, moreover, an additional recommendation—a slight but agreeable fragrance. It may be readily increased by seed, cuttings, or division of the plants.

Of the varieties grown, in addition to those mentioned above *Myosotis Weirleigh Surprise* must by no means be omitted, its pretty blue and white-striped flowers being so distinct in appearance from all others in the genus. *M. Impératrice Elizabeth*, with purplish blue flowers and of dwarf habit, well suiting it for pots, is also a useful variety, and to these may be added the variegated form *M. elegantissima*, which is so well adapted for the margins of spring beds or as clumps in the mixed border. Many more species might be enumerated, all possessing some attractions, but the above will be found sufficient in most gardens, and a few particulars regarding the general cultivation may now be given.

The quickest mode of raising a stock of Forget-me-nots, even of the perennials, is by seeds, which most produce very freely, and as these readily germinate, abundance of plants can thus be soon obtained. When preparing for a display next spring the seed should be sown at once, either in prepared beds of light moderately rich soil, from which the young plants can be afterwards transferred to the positions where they are required, or the seed can be sown in the allotted beds and the plants remain without being transplanted. Wherever there is much demand for flowers it is well to have a bed in a shady position, where the supply can be prolonged until autumn. For culture in pots similar treatment may be afforded—namely, the seeds can be either sown in the pots, or the young plants raised in beds can be pricked out when large

enough either into 60 or 48-size according to their size. Increasing the stock by cuttings or division of the plants is best attended to in spring, the first-named being inserted in light sandy soil, and the divisions need merely to be transplanted and well supplied with water.—L. C.

COLLECTIONS OF SEEDS.

MR. BARTRUM on page 114 has, it appears to me, no substantial cause of complaint. He admits the seeds he obtained in "collections" were good, and does not deny the collections were cheap. This being so, why should he object to the names of the firms which supplied the seeds being prefixed to the varieties? If any seedsman introduces a new and distinct "Pea, Lettuce, or any other vegetable," he has a perfect right to have his name attached to it, and it is obviously the same as regards a firm. If the vegetable is not new but in general cultivation the name of any particular firm prefixed to it is of no moment, and Mr. Bartrum will do no one an injustice by not naming the firm, for the variety will be the same by whomsoever supplied; and in such a case how can a purchaser properly regard himself as a "creature" of the firm who supplied the seeds?

Mr. Bartrum also complains of "paying too dearly for exercising his right of private judgment" in one sentence, and in another he states the additional cost was incurred "because more seeds were sent in each packet than he required." No doubt the quantities ordered were sent, and a seedsman can hardly be blamed for executing an order correctly. The "judgment" of the purchaser appears to have been at fault. In seeking a remedy your correspondent asks if he should "order by the ounce." Order what? An ounce of Celery seed, for instance, might be too much, and an ounce of Onion seed not sufficient for his garden and for raising produce for his family. It appears to me as a gardener that Mr. Bartrum has either said too much or not enough on the question which perplexes him. There are many, no doubt, willing to help him, but it is not easy for them to do so effectively as the matter now stands.

For many years I have had to supply a family of twenty persons with vegetables, and it has been incumbent on me to do so as economically as possible. I have twice purchased collections of seeds, but good as they were they did not satisfy me. There were too much of some and not enough of other seeds. I have found the best results from making my own selection; and by having regard to the price of the different varieties, and knowing exactly what were required of each, the aggregate cost has not been appreciably greater, while the returns have been decidedly better than by relying on "collections," and being troubled with the consequent waste of surplus seeds on the one hand and shortcomings on the other. It would have been perfectly easy for me to have spent four guineas instead of two and have no more seeds nor useful crops, but exercising my right of "private judgment" nothing of this kind occurred, or most certainly the rector would have deemed my judgment faulty.

No one can well select seeds for another, at least it would be impossible for anyone to select them in my case, for the simple reason that some things are scarcely wanted to which others attach importance; but on knowing the extent of ground and number of persons to supply with vegetables, an approximate idea can be formed of the quantity of seeds that will be needed.

My vegetable seed bill has never exceeded £3. When I tried a two-guinea "collection" it was quite insufficient, and a three-guinea one did not greatly improve matters, as there was so much seed that could not be utilised, and the varieties of Peas, for instance, were not satisfactory. I now leave the "collections" for amateurs who are not acquainted with the varieties that are sent, or are not particular about them so long as they can get as much as possible for their money. For such persons the ready-made packages are both cheap and useful.

The question of Peas, as submitted by Mr. Bartrum, is very much a question of soil. In the soil at my disposal Veitch's Perfection does not flourish, nor are any dwarf Peas profitable. With three varieties—William I., Champion of England, and Ne Plus Ultra—I can have Peas as long as they are procurable, and I think as good in quality as is producible. It is quite certain I could not obtain an equally satisfactory supply from the varieties Mr. Bartrum has submitted. Hundredfold is very productive and good in colour, but so inferior in quality that I have long since discarded it. I fail also to see the exercise of sound judgment in having three varieties of early Peas if a supply of the best quality is the only object.

Another word. Mr. Bartrum speaks about his gardeners. If I were in the fortunate position of a gentleman keeping gardeners, I should expect one of them at least to be competent to select seeds to the best advantage both in an economical and alimentary

point of view for stocking my garden. My rector once, with the object of reducing expenditure, made his own selection of seeds, but it only ended in reducing the supply of good vegetables. He has since left the selection to myself, reserving to himself his undoubted right, with which I most cheerfully comply, of discussing the list with me before the order is transmitted. It is thus, we think, we get the best return at the lowest possible cost. I have always felt it my duty to strive as earnestly as my employer to "keep the bills down," and this has proved sound policy, for since adopting it I have been encouraged by a "double rise" in wages without the payer of them, I trust, being a penny the poorer.—A PARSON'S GARDENER.

ON BUDDING AND GRAFTING: OR THE INFLUENCE OF THE STOCK UPON THE SCION AND VICE VERSA.

[Read at a meeting of the North of Scotland Horticultural Association at Aberdeen on August 18th, 1882.]

IN presenting this paper to the members of the North of Scotland Horticultural Association, I would observe that I do so with some diffidence. It must not be considered by any means to be original or even exhaustive; the subject is so vast, so full of interest, and so imperfectly understood, that I can only skim over the surface by a recitation of some facts that have come under my own observation and that of others from time to time, leaving it with you for general discussion. I have selected this subject mainly with a desire to direct the attention, especially of the younger members of your Association, to the great importance of correct observation and research, with a careful noting of facts as they may occur. It is in this way, and in this way only, that the great truths of Nature can be elucidated, and in our search after the why and the wherefore some rays of light may appear. This subject is one—if ever it will be thoroughly understood, will only be so by the careful accumulation of facts, and in this way everyone may aid. It is a subject in which I have not been altogether idle, and one in which I have for many years taken a great amount of interest.

The art of grafting seems to have been known from the very earliest times. We read in Scripture, in the eleventh chapter of St. Paul's Epistle to the Romans, twenty-fourth verse, "For if thou wert cut out of the Olive tree which is wild by nature, and were grafted contrary to nature into a good Olive tree, how much more shall these, which be the natural branches, be grafted into their own Olive tree." Pliny, Aristotle, and others of the ancient philosophers also speak of grafting; but as far as can be gleaned the principles appear to have been very imperfectly understood. The practice seems to have been to engraft the wild into the garden tree to promote fruitfulness, &c. We also read in old books absurd stories of Roses becoming black by being grafted on the Black Currant (this is even vouched for by some to the present time), and that the blood-red Oranges derive their colour through being grafted on the Pomegranate; and Virgil it is that speaks of Plum trees bearing Cornels, and Apples, Pears, &c., and in Columella it is asserted that the Vine may be grafted on the Fig—a declaration the impossibility of which had to be formally proved in the Jardin des Plantes, Paris, by the Director, M. Thouin, not a great many years ago.

It is a universal law of Nature that no plants will engraft on each other which do not belong to the same natural order. Even species which are distantly related cannot be united to each other. We cannot graft an Apple on a Plum or a Rose upon a Thorn. For any organic union to take place there must be a great similarity in the organisation and secretions of the plants to be united. That similarity exists between the Apple and the Crab and between the Peach and Plum, consequently they take on each other. It does not exist between the Apple and Plum. If, then, there is this physiological impossibility of uniting plants of the same natural order, the belonging to which necessarily implies a great similarity of structure and constitution, how can it be possible in the case of plants of different natural orders, which necessarily implies a great dissimilarity of structure, &c.? Mistletoe, being a parasite, is an exception. Animals of different species mix not together, and what is true of animals is true of plants.

The merely mechanical operations of budding and grafting need not be here discussed—the physiological principles to be studied are the same. The cutting, or portion cut off, forms the bud or scion, as the case may be, and the rooted plant on which it is worked the stock. The operations in both budding and grafting are performed whilst the sap is in motion, or, in other words, when the tissues are in a forming state. It is these tissues which are formed by the cells of the cambium, which lies between the surface of the albumen and the inner bark coming in contact that effect the union. In grafting, be it noted that wood will not join to wood however carefully fitted, neither will bark to bark, the bark being a part already

formed; not even the inner bark, although nearly all gardening books that treat of the subject say "it is on the junction of the inner barks that success depends." This is true only to the extent, that if the inner barks are fitted the substances immediately below will be also in contact.

PLANTS MAY BE GRAFTED ON ROOTS OR PIECES OF ROOTS.

Grafting may also be performed on the roots of plants, pieces of the roots being used, for that which hinders the growth of pieces of root into young branches is merely the want of buds. The difference between the internal organisation of a root and a branch is very trifling.

Mr. Knight was the first physiologist who showed the possibility of grafting on roots, an account of which was given to the Horticultural Society in 1811, and he at the same time suggested the possibility of the practice being applied to scarce herbaceous plants, Dahlias, &c. It is now much practised for Clematis, Roses, Pæonias, and similar plants.

THE OBJECTS OF BUDDING AND GRAFTING.

The direct object of either budding or grafting is—see Lindley's "Theory of Horticulture," which should be carefully studied by every gardener—to multiply a given species or variety more readily than it could be done by any other means. If this, however, were the only purpose of the cultivator the stock that is most readily procurable would be obviously the best. Thus it was the ordinary practice of nurserymen to take the common Plum as a stock for Peaches and Apricots, the wild Pear and the Crab for Pears and Apples, and so on. Mere propagation is, however, not the only object of the grafter; it is to secure a permanent union between the stock and the scion, so that the new plant may grow as freely as if it were on its own roots under the most favourable circumstances.

THE STOCK INFLUENCES THE SCION. ITS CONSEQUENT IMPORTANCE.

The influence of the stock upon the scion is manifested in a great variety of ways, arising chiefly, but not entirely so, from the stock supplying a greater or less amount of vigour to the scion than it would obtain on its own roots.

Many plants, such as the Apple and Pear, bud or graft freely, but are difficult to strike from cuttings. Others, also, that are naturally delicate become strong by being worked on robust stocks. The choice of stocks whereon to graft a given plant is therefore one of considerable importance, and the propagation of stocks for specific purposes is now, instead of being left to chance, a speciality of many nurseries. The time has gone by for using promiscuous stocks for our fruit trees, and the planter now—with the knowledge there is of stocks, and the enormous influence they exercise—should be particular in obtaining those that are most suitable for his requirements. Some pomologists, notably in America, maintain that grafting has to a certain extent extended the varieties of our fruits, and is made to account for the great variations that are so observable in some varieties.

Bearing on this part of the subject I have collected from various sources well-authenticated examples, or records of certain influences as illustrations.

A.—STOCKS INDUCE EARLY FLOWERING—*i.e.*, IMPART A TENDENCY TO FLOWER SOON.

1. In 1878 I grafted in the gardens at Chiswick corresponding stocks of the French Paradise, Doucin, and Crab Apple stocks with Blenheim Orange Apple. The following year those on the French Paradise and Doucin flowered freely, and every succeeding year. Those on the Crab did not flower until the third year. In the four years the number of flowers on the French Paradise was 189, on the Doucin 254, and on the Crab 23. There were two examples of each, and all in very good health.

2. Pears grafted on the Quince flower much sooner than do those on the Pear stock.

3. Seedling fruit trees, which frequently grow to a great size and are years old before fruiting, come into bearing much earlier by being grafted than if allowed to do so on their own roots. Mr. Rivers was thus enabled to fruit his many seedlings much earlier than he would otherwise have done.

4. A scion taken from a young tree and grafted on a mature tree bears sooner than if left to itself.

5. The Catillae Pear always bears more profusely grafted on a branch of a large tree than by itself.

B.—STOCKS RETARD FLOWERING.

1. Grafting the Pear on the Mountain Ash is practised in Nassau, and is said to retard the blossoming of the trees, thus enabling them to escape spring frosts. On the other hand, Dr. Lindley states that on the Mountain Ash the Pear bears earlier.

2. The Court Pendu Plât Apple, which is so well known for its late-flowering habit, is recommended by many as likely to prove an excellent stock for retarding the flowering of Apples in spring.

C.—STOCKS ALTER THE CHARACTER AND THE QUALITY OF THE FRUIT.

1. Pears grafted on the Quince and on the Thorn are often very different in quality to those worked on the Pear stock. Generally more gritty and drier in texture.

2. There are cases reported where a different kind of Apple has started from a grafted tree.

3. A gardener at Grenoble grafted the Pears Deux Yeux and St. Pierre on the common Hawthorn. The fruit proved very similar to Haws.

4. Mr. Knight mentions two trees of the Aeton Scott Peach, the one growing upon the native stock, the other upon the Plum. That growing upon the Plum produced fruit much larger in size, redder in colour, with coarser pulp, and of superior quality to that of the others.

5. Muscat Hamburg Grape grafted by myself on a coarse late Spanish variety produced fruit so entirely different and inferior to the original variety that the members of the Fruit Committee were unable to recognise it. It still maintains the same character.

6. Black Hamburg Grape grafted by myself on a small variety named Blussard Noir produced small bunches and berries similar to the stock—very inferior.

7. Gros Guillaume Grape grafted at Chiswick on the Frankenthal produced bunches and berries so large and so resembling Frankenthal as to be mistaken for that variety. This influence is not continued.

8. Mr. Thomson, Drumlanrig, records that the Gros Guillaume Grape grafted on the Muscat of Alexandria bears berries superior and fruits more freely than those grafted on the Black Hamburg.

9. Mr. Fenn, late of Woodstock, grafted Ribston Pippin Apples upon Blenheim Orange. The fruit produced was, both in quality and appearance, intermediate between the two varieties as exhibited before the Fruit Committee. I procured grafts, worked them at Chiswick, and submitted the produce to the Fruit Committee again, when the minute recorded was "Distinct, but inferior to both stock and scion."

10. In the "Theory of Horticulture" it is recorded of a Mr. Billington that he budded a Bergamot and a Swan's Egg Pear on a Jargonelle, which produced fruit much larger and better in quality than he had ever before seen it. Those budded on the Hawthorn produced fruit not half the size, and quite gritty.

11. Joseph Bailey of Dedham, U.S.A., states that if he wants a pleasant Porter Apple he grafts on a sweet variety. The Porter is a sour Apple.

D.—STOCKS PROMOTE A GREATER HARDINESS AND VIGOUR.

1. The Muscat Hamburg Grape has been found to fruit and grow more freely, with a less tendency to shank, &c., when grafted on the Black Hamburg.

2. The Apricot succeeds better on its own roots or upon seedling Apricot stocks than when worked on the Plum.

3. Peaches worked on the Plum are far more hardy and vigorous than those worked on the Almond; the latter suffer from the cold, and have that affection termed "the yellows."—A. F. BARRON, *Chiswick*.

(To be continued.)

LOBELIA CARDINALIS.

THIS is a very old plant, having been known in this country for over 250 years, and the first account we have of it is in Parkinson's "Paradisus," where he says he "received plants of it from France for his garden, and that it groweth neere the river of Canada where the French plantation in America is seated;" and in 1795 a figure was given of it in "Curtis's Botanical Magazine." This plant was then, as now, highly esteemed, as Parkinson calls it "the grand rich crimson Cardinal's Flower;" and this is no meaningless epithet, for the plant is a most brilliant one, and well adapted for border cultivation, quite hardy in many parts of this country, and only requires a sheltered place in the colder parts, and when in a proper position as to soil and moisture it is extremely showy and desirable, not only on account of the high colouring of the flowers, but their persistency and the freeness in which they are produced. It frequently happens that substitutes are sent out for the true plant in the form of varieties with high-coloured leaves, probably some variety of *L. fulgens* which are not hardy with us; hence we frequently hear that *L. cardinalis* is not hardy, when in reality the true form was not under treatment.

It is a hardy herbaceous perennial, growing 3 or 4 feet high under favourable circumstances, with large coarse broadly lanceolate leaves with serrated edges, green; whereas the foliage of the plant often sold for *L. cardinalis* is deep crimson. The stems are terminated with the flower spike, with flowers about $1\frac{1}{2}$ inch long from tip to tip of a peculiar form, and intensely deep red colours; lateral flower spikes are also produced, which greatly lengthen the blooming period. The flowers appear from July to October, and the plant is a native of the northern and eastern United States, being distributed over a very wide area.

It should be planted in a damp situation in good rich loamy soil, rather stiff, as it speedily dies in positions at all dry and loose. It does well in the bog garden. I have seen it finer in such than in any position, and by the margins of lakes and ponds it thrives well. This plant is easily propagated by striking the young shoots in spring, or by cuttings freely produced in the leaf axils during summer, and struck in a cold frame, or from seed, which being small should be carefully sown during May or June in pots and placed in a cold frame. I have raised seedlings fairly well, observing the following items: Fill the pots with soil and water it freely, sprinkle the seed upon the surface, slightly cover it with silver sand, and place some fresh moss upon the surface, which keeps the seed moist and shaded, removing the moss directly after germination.—N.

THE big Gooseberry season being over, we are threatened by an incursion of COLORADO BEETLES. A Colorado beetle having been found on board the Guion steamer "Wisconsin" from New York, the Privy Council were communicated with, and gave orders that the insect should at once be killed and forwarded to Whitehall.

— WE are informed that the popular work, "THE FERN WORLD," by Mr. Francis George Heath, author of "Autumnal Leaves," has just reached its seventh edition.

— MR. S. L. BOURCHIER, Crosby, near Liverpool, writes:—"Mr. Iggulden in his interesting note on DOUBLE ZONAL PELARGONIUMS has omitted the best of all—namely, Charles Darwin, very deep rich purple, with orange shade in upper petals; fine form and size, habit and freedom of blooming equal to any single. Candidissima plena is much the best white, as under no circumstances is it ever even faintly tinged pink."

— A CORRESPONDENT writes respecting ALLIUM SACCU-LIFERUM as follows:—"This is an extremely pretty pink-flowered species, received in the Cambridge Botanic Garden from Dr. Regel. The heads are perfectly globular and dense, and a number together form an attractive tuft a foot high. The leaves about equal the flowers in height, and are slender and graceful. A pure white variety has come from seed, and is being attended to. The bulb of this species is long and narrow. It appears to be rare in gardens. In the same garden the beautiful *Lilium longiflorum* is one of the most suitable Lilies for the dry soil. No other kind does better, and this without any preparation succeeds well."

— THE schedule of the SOUTH SHIELDS CHRYSANTHEMUM AND WINTER FLOWER SHOW states that the Exhibition of the present year will be held in the Public Library Hall, South Shields, on November 29th and 30th, when prizes will be offered in thirty classes for Chrysanthemums, both specimens and cut blooms, miscellaneous plants, and Grapes. In one of the regulations relating to the Chrysanthemum portion of the schedule it is stated that "for the guidance of exhibitors Cannell's catalogue will be the standard."

— MR. GEORGE BUNYARD of Maidstone has sent us a dish of BUNYARD'S BROAD-PODDED DWARF KIDNEY BEAN, which is

claimed to be "the best flavoured in cultivation." The pods were not particularly attractive, and were fully too old for cooking, the beans showing prominently; yet, notwithstanding their apparent want of crispness, they were when prepared for table of excellent quality—tender, buttery, and possessing a flavour that is not possessed by all Dwarf Kidney Beans, and which is highly agreeable. Judging by the sample sent this is not a show variety, and we know nothing relative to the habit and productiveness of the plants.

— PERHAPS nowhere is what may be termed DOMESTIC FLORICULTURE practised more earnestly than in the suburbs of London, and local societies are established to give encouragement to window gardening, and to render the surroundings of homes enjoyable. One of the best-conducted of these that we have seen is the SHAFTESBURY PARK GARDEN IMPROVEMENT SOCIETY, the annual Show of which was held last Saturday. Besides the competition in the classes, valuable contributions of plants were kindly and generously sent by Messrs. Veitch & Sons, J. Laing & Co., and of cut flowers by Messrs. C. Turner of Slough and Cannell & Son of Swanley. The single Dahlias from Slough were particularly handsome, and being arranged on stands with foliage and buds as cut they had a much better effect than when staged in the usual manner. The Swanley Petunias commanded much attention. Messrs. Veitch's plants included specimens of a number of their novelties, forming an important portion of the Show. The prizes consisted of various well-selected articles of a useful or ornamental character.

— MR. GEORGE BOOTHBY, writing from Louth, states:—"Mr. Luckhurst does not speak a word too much in praise of VIOLET DEVONIENSIS. Here in East Lincolnshire, whilst the rest of the kingdom has been complaining for some weeks past of an excess of rain, we have been almost suffering from a want of it; consequently such plants as autumn-blooming Violets are not in a very floriferous state at present, but *V. Devoniensis* is in full bloom as usual. I generally find it and a seedling of mine, *V. Floribunda*, the first to bloom, and New York has sometimes been as early."

— MR. WILLIAM CONNELLY, Leagrims, writes:—"I was glad to see the old favourite CATSHEAD APPLE brought under notice, and can fully endorse all that has been said in its favour on page 157. I have known it as long as I have known what an Apple was. It is a general favourite in Herefordshire, so much so that if a true old Herefordian had a dozen trees in his garden and one of them was a Catshead, he would prize it more than all the rest on account of its large size and good keeping qualities. It is principally used by the farmers and cottagers in country districts for making Apple dumplings and Apple bobs. An Apple bob is made exactly the same as a dumpling, only it is baked instead of boiled; and in establishments where kitchen Apples are in great demand this good old variety should be cultivated."

— RELATIVE to the HOP HARVEST, Mr. E. Doust, Hop-factor, has stated in a daily paper that "There has not been a year in the memory of any living man in which a less quantity of Hops was grown than is likely to be grown this year. It is certain that there are thousands of acres that never will be picked at all; whole plantations can bring nothing but ruin on the luckless planters. Almost the only exception to this dreary aspect is where the planters have thoroughly washed to death the insect pests; and even this effort, where it has not been efficiently done, has proved a failure, and, what is more, just now we are compelled to hear that the mould has set in even upon many of those plantations where the insect pests had been destroyed."

— A CORRESPONDENT has given the following brief but dismal account of THE IRISH CROPS:—"In the north-west of Ireland the crops are in a frightful condition, hay lying cut in

the fields soaked in water. Potatoes are suffering from blight. It is feared that unless there is dry weather shortly a famine will occur this year. The mountainous parts are in a worse condition than the lowlands."

— "E. L. R.," referring to Mr. Wolley Dod's article, says "It is no wonder he should speak of *CAMPANULA HEDERACEA* as a native gem. I purchased a small plant and placed it in a rockery, where it died; but the following year the *Campanula* was seen in our lawn, where it spreads yearly and is lovely. My only trouble is the scythe—no gardener can recollect that this portion of the lawn is not to be mown after June. It grew on a damp lawn, but this year appears plentifully in the driest part over a flue, and flowers in a dwarfer state. *Sibthorpia europæa* has naturalised itself on the same lawn, though only on the damp part. It never flowers there. I am unacquainted with the *Anagallis* named, but shall add it to the above. Where can seed be procured of the *Chrysanthemum segetum* as improved by Dr. Marsh, and named on page 146?"

— RELATIVE to our report of the BRICK-KILN CASE on page 150 Mr. Foster, the complainant, informs us that "the jury stopped the case, consequently my witnesses, Mr. Pennell, Mr. Barron, two from the Royal Agricultural College, Cirencester, and several from this neighbourhood, were not called. The chemical evidence we had would have proved that 10 tons of sulphur was burnt out of the clay used in a year in making bricks in the defendant's brickyard. It may not have had any influence on the verdict, but it would have been an interesting piece of evidence." It would not only have been interesting but important. The noxious fumes from brick-kilns are beyond question most injurious, and even deadly, to trees and shrubs near them, and Mr. Foster has done good service in persevering, even though a former verdict was against him, and winning his case. An experiment that we suggested of applying dilute sulphuric acid to the foliage produced the same results as the acid deposited on the leaves from the kilns. One part of acid to forty parts of water killed the specimens. One part acid to one hundred of water applied to one specimen, and one part acid to 150 water sprinkled on another, produced at once effect exactly similar to those produced more slowly, but not less certainly, by acid from the kilns. Mr. Matthews, the complainant's counsel, stated

"Both the clay and the coal when burnt gave off sulphur, and the effect of the burning was to cause the sulphur to combine with the oxygen of the air, and then it formed two very virulent acid gases, one called sulphuric acid, and the other sulphurous acid, the difference being that the sulphuric acid had one more atom of oxygen than the other. Sulphuric acid was commonly known as oil of vitriol, and was highly corrosive. When the wind carried this amiable gas, particularly in damp weather, it became deposited on the plants, which were burnt into holes, just as oil of vitriol would burn a coat sleeve. Repeated doses of these fumes coming from the brick kilns injured the plants so as ultimately to kill them. Some trees are more susceptible than others, and some would die while others would not. The *Coniferae*, he believed, were the most susceptible, and the Laurels suffered very severely. There were very large quantities of plants in a nursery ground, and in 1881 there were 130,000 bedded Larch, of which number no less than 40,000 were so damaged as to be unsaleable. Red Currants, Laurel, Limes, Austrian Pines, Cherries, Roses, and so on were injured in large numbers, and the damage amounted to no less than £200 in that one year."

We congratulate Mr. Foster on the results of the litigation.

— WE regret to have to record the DEATH OF MAJOR ABRAM BASS, which occurred at his residence, Moat Bank, Burton-on-Trent, on the 15th instant. Mr. Bass was a most estimable and benevolent man, and the products of his garden, which were always of superior quality, have graced the tables of his acquaintances and been of benefit in humbler homes, where such delicacies as it was in his power and disposition to give are so welcome during periods of sickness. A description of Mr. Bass's garden appeared in our issue of February 10th, 1876. The pride of the garden was the orchard house, and the pride of the house the

Apples grown in pots, which in appearance and quality have probably never been surpassed. In the condition of this house Mr. Bass, previous to the days of his infirmity, took active interest, and had a great measure of success in the production of choice fruit; in other respects, too, his garden was most enjoyable, and its pleasures were shared by many friends. He was 78 years of age.

CABBAGES, AND HOW TO GROW THEM.

THE average "Britisher" is very slow at improving upon anything. If there is work to be done he is the man to do it; but in the matter of "notions" he is considerably behind his go-ahead transatlantic cousin. These thoughts occurred to me on reading an interesting work bearing the above title, and the further thought occurred that by pointing out some of the more prominent "notions" contained therein help might be afforded to those who have an opportunity of adopting some similar ideas.

The author's description of what constitutes a Cabbage may be passed over, but it may be profitable to notice and make a running commentary on most of the other points, and just as they are set down in the little work before us.

The first thing is the selection of the soil, and our author prefers to follow Nature by either choosing a limy soil or making it so. At the same time he can grow Cabbages on any soil, but prefers that which is heavy. Wet undrained land, he says, produces "stump foot." When a choice can be made small-growing kinds are planted when the soil is thin, and any deep spot is kept for big-growing Drumheads. As the author refers only to field cultivation, possibly he may be better worth listening to than if he were dealing with the garden, especially since farmers are looking around for fresh openings.

"Should the soil be a heavy clay a deep fall ploughing is best, that the frosts of winter may disintegrate it; and should the plan be to raise an early crop, this end will be promoted by early ploughing in any soil, as the land will thereby be made drier in early spring." It should be borne in mind that this advice is given to Americans, and may not be suitable for us. To plough or dig up heavy clay in many districts in this country would have exactly the opposite effect from that described by Mr. Gregory, the author of the book. The subject is introduced here, as it is one that might be debated profitably, for many are of opinion that very great mistakes are made just in the season of digging, and much loss occasioned thereby. In America, when the frost sets in in the "fall" and continues till spring, there cannot be any doubt about the correctness of autumn turning of the soil, and the same may be said of any place where the frost is continuous during winter, or the rainfall little, but under different conditions it is a mistake.

"Any manure but hog manure for Cabbage. Barn manure, rotten kelp, night soil, guano, phosphates, wood ashes, fish, salt, glue waste, hen manure, slaughter-house refuse—I have used all these, and found them all good when properly applied. If pure hog manure be used it is apt to produce that corpulent enlargement of the roots known in different localities as 'stump-foot,' 'underground-head,' and 'finger-and-thumb.'" Has the use of this kind of manure been succeeded by like results in this country, or has the fact been overlooked? Often club-foot is to be seen, greatly to the chagrin, loss, and mystification of the cultivator. It is quite possible that such apparently inadequate causes may have been entirely overlooked, and if so, readers who have been afflicted may hereby find a clue. Recently a writer in this Journal related his success in preventing this troublesome disease by using lime rubbish freely. Mr. Gregory mentions several instances of a free use of lime and also wood ashes being a preventive, and specially notices the fact that in cottage gardens constantly treated with soapsuds Cabbages have been grown for many years quite free from "stump-foot." He considers that the alkalis present in the suds are the cause of this; but on a large scale the only safeguard is to plant yearly on a fresh spot, otherwise clubbing almost invariably follows. Considering that Cabbages naturally affect calcareous soil near the sea, we should be inclined to think that liberal applications of lime and common salt would be certain to keep off the pest. Certainly such applications are of decided advantage to Cabbage of all kinds, and Mr. Gregory's evidence inclines us to think that either or both would be found specifics.

The best manure for growing the largest and best Cabbages was a mixture of farmyard manure and night soil. This is quite in accordance with my experience, and attention is drawn to this fact, as in many densely populated districts such is to be had much below its real value. For many things it is too strong and

causes too rank a growth; but that can never be the case with ordinary Cabbages. The author sometimes ploughs in his manure, sometimes puts it on the soil and harrows it in, and, especially when the supply is short, applies it "in the hill." In this country "plowing-in" is the usual course, but we question its being equal to either of the other two plans, especially when autumn digging is practised. In the first place, even when ordinary digging is practised, the manure is put down too deep, and every drop of rain that passes through the soil carries it deeper or perhaps away altogether. Even under favourable circumstances seedlings or even strong plants may, and often do, languish and lose the season before the roots reach the manure. On the other hand, when manure is spread, preferably in frosty weather, over dug ground, and left there till the soil is dry and mixed with the upper few inches, the results are greatly different. This is especially the case with such concentrated manure as night soil, which by surface-manuring and forking afterwards are thoroughly distributed, instead of being buried in lumps so concentrated that only after the rains have dissipated their qualities can plant roots live near them, while the body of the soil suffers poverty and affords nothing. The other plan of applying the manure "in the hill" is by no means to be despised, especially when the supply is "from hand to mouth," as the saying is. It was from an old Irish labourer that I learned the lesson, and it certainly is worthy the attention of those short of manure.

In America it appears the seed is usually sown where the crop is to grow, although sometimes the seed is sown in beds, and the plants nursed on and afterwards transplanted. Sowing late Cabbages, Brussels Sprouts, &c., where they are to remain is a practice not altogether unknown in this country; but is not very widely practised, so far as I am aware. Mr. Gregory considers sowing the seed where the plants are to remain a much superior plan to nursing and transplanting. America, however, is not England, far less Scotland, in the matter of climate; and while with such usually spring-sown vegetables as Sprouts, Broccoli, or even Savoys, the system may be worth recommending and a fair trial, our summers are too short to allow of its being practised with the larger-growing Savoys and Drumhead Cabbages, and it is to the system of growing, preserving, and marketing these in America that I wish chiefly to refer.

Readers are informed that an ounce of seed "contains ten thousand seeds, but should not be relied upon to produce over two thousand plants." This is a better guide to novices than telling them that so much seed will be sufficient for sowing a bed so many feet square. We are also informed that Cabbage seed will keep good for four or five years, and that old gardeners prefer seed two or three years old.

In sowing the seed in beds the advice is to use very rich soil and to prick out the plants. This is sound advice. The difference between plants raised on rich soil—I refer, of course, to spring-reared plants—is often in the ultimate results equal to what follows a very heavy manuring, compared with what results from starvation. Generous nursing of plants and animals pays well: the opposite never does.

Planting under hot sunshine is condemned, and when it becomes absolutely necessary to plant during dry weather the making of deep holes to be filled with water, which, by capillary attraction, pervades the body of the soil without the danger of rapid evaporation, is recommended. Planting is also advised to be done towards sunset.

Attacks of the "fly" are warded off by dustings of wood ashes or quicklime; the "cutworm" is only kept at bay by being searched for and killed, or kept off by a funnel of paper round the stem of each plant, or by dropping a little wood ash round each—all rather tedious processes, and hardly applicable on the large scale. For the "louse"—aphis, I presume—there appears to be no cure except thoroughly good cultivation, irrigating if need be, and if possible. Caterpillars are to be disposed of by picking off the infested leaves and crushing the insects with the feet.

Summer cultivation consists of thoroughly hoeing, and should any heart-up prematurely "starting" is recommended—that is, loosening each plant with the fork. This is said to prevent hard-headed Cabbages bursting. As frequent loss occurs to market growers from this cause "starting" may be worthy attention; but I may be pardoned for refusing to put much faith in a process that has failed with us.

It is not necessary to say anything about the early spring or summer crop, as it is doubtful if anything is to be learned by our own growers in that direction; but there is something in the way they in America have of keeping up a winter and having a very early spring supply well worth dwelling on, for had the American practice been common here, instead of a famine of vegetables such as was experienced during some of our more recent winters,

an abundance—of Cabbages, at least—would have been forthcoming; and, instead of market gardeners and farmers losing heavily through the destruction of their winter vegetables by frost, fortunes might have been begun if not made.

The plan to which I refer is to have a regular crop of solid heads late in autumn, and to store these where they can be kept at once dry and free from frost. Drumheads are chosen for this purpose, but not the Drumheads common in this country. These, it is said, are at once too coarse, and do not produce heads of keeping quality. Among the sorts that are favourable for storing I may notice that Premium Flat Dutch, Stonemason, Marblehead Mammoth Drumhead (said to grow to the weight of 60 lbs. and to produce 60 tons an acre!) Fottler's Early Drumhead, and Cannonball. Among Savoys, Improved American.

The manner of keeping is varied according to the climate. Far south wet has to be guarded against, and consequently waterproof sheds are provided, inside of which the hard heads are packed closely after all loose leaves have been removed, but the roots retained. In the north, where frost is the enemy, furrows are made with the plough, and the Cabbages are stood heads down, stumps up, and covered over with earth, straw being added if necessary. On a smaller scale the heads are placed in pits something in the way Potatoes are kept in this country. These supplies are drawn upon during the winter or kept till spring, as best suits the market. Even Cabbages that are not headed in autumn may be turned to good account. It seems that when placed head up so deeply in the ground that the points of the leaves are level with the surface, so that no frost can reach the stems, and the tops protected, heads will form which in America sell wholesale at 4 cents (2d.) a pound. A few tons of Cabbages at that price would represent a good sum. "These refuse Cabbages realise 10 cents a piece," says Mr. Gregory. The hard heads usually sell at from 3 to 25 dollars per hundred. A shilling a-piece for Cabbages is enough to make a market gardener's mouth water!

There are many more points in the book, and all interested should refer to it for further information. The book is posted in America for 15 cents, and may be had from James J. H. Gregory, Marblehead, Massachusetts, U.S.A. To cover postage to this country an extra cent or two may be necessary.—SINGLE-HANDED.

ROYAL HORTICULTURAL SOCIETY.

FLORAL COMMITTEE MEETING AT CHISWICK.

AUGUST 16TH, 1882.

THE Committee (G. F. Wilson, Esq., F.R.S., in the chair), inspected the collections of Achimenes, Tydeas, Verbenas, Heliotropes, &c., when the following awards were made. The names of those varieties that are printed in italics were granted first-class certificates, the others, not in italics, being recommended as worthy of culture.

VERBENAS.

Phlox (Cannell & Sons).—Plant of fine vigorous growth, very free-flowering; the trusses of medium size; flowers large, rosy crimson, with mauve ring round distinct white eye.

August Reuz (Cannell & Sons).—Free habit, free-flowering; the trusses of medium size; flowers rosy scarlet with distinct yellowish eye. A showy variety.

Kentish Beauty (Cannell & Sons).—Plant of vigorous growth, free-flowering; trusses and flowers large, well displayed, of a beautiful rosy claret with pure white eye.

AGERATUM.

Malvern Beauty (Cannell & Sons).—Close compact growth, free-flowering; the flowers well displayed, pale blue. A fine variety.

IVY-LEAVED PELARGONIUM.

Rossini (Lemoine).—A free-growing variety. Stem short-jointed; the trusses of medium size; individual flowers very large, of a beautiful magenta scarlet. A very fine addition to the single-flowered section.

HELIOTROPES.

Bouquet Perfume (Lemoine).—A dwarf and compact free-flowering variety; the trusses large, well displayed; flowers dark lilac blue. A good variety for pot culture.

Madame P. Athles (Lemoine).—Vigorous habit, free-flowering; the trusses large and well displayed. Dark blue.

PENTSTEMON.

Virginale (Lemoine).—A variety of fine free habit with pure white flowers.

TROPÆOLUM.

Bedfont Rival (Dean).—A fine free-flowering variety, with flowers of an intense orange-scarlet colour.

ACHIMENES.

The collection includes about a hundred sorts, from which the

following were selected as the best in their respective classes, and received three marks of merit:—

Margarittæ (Vallerand).—Pure white, fine, large-flowered. Good habit.

Mauve Queen (Vallerand).—Mauve, with orange-spotted eye; tube shaded orange.

Longiflora macrantha (Vallerand).—Pale blue; tube shaded orange; large showy flowers.

Longiflora (Vallerand).—Blue; more compact in habit than the above; leaves reddish beneath.

Mauve Perfection (Vallerand and Van Houtte).—Mauve purple, veined with crimson; fine large flowers; very free. This was received from Van Houtte under the names of Cassiopée and Mauve Perfection.

Ambroise Verschaffelt (Vallerand).—White, shaded mauve, deeply veined with purple; lemon eye. From Van Houtte under the name of Diamond.

Sir Treherne Thomas (Vallerand and Van Houtte).—Rosy purple, with orange-spotted eye; leaves reddish beneath.

Floribunda (Vallerand).—Deep violet purple. Very dwarf.

Carl Wolfarth (Van Houtte and Vallerand).—Violet purple; pale yellow eye, spotted with red; very free-flowering. Frau Schiller (Van Houtte), Pink Perfection (Van Houtte), and Baumanni (Van Houtte), are the same as the above.

Diadem (Vallerand).—Bright rosy scarlet; yellow eye; lobes of flower serrated.

Unique (Vallerand).—Bright magenta; orange-spotted eye.

Firefly (Vallerand).—Bright scarlet, with orange eye.

The following received two marks of merit:—

Celestial (Vallerand).—White, slightly veined with mauve; mauve eye.

Cherub (Vallerand).—White, with mauve eye; dwarf habit; leaves brownish beneath.

Dentonia (Vallerand).—Pale mauve with purple veins.

Longiflora picta.—Rosy lilac; large flowers.

Tubiflora (Vallerand).—Copper red, with orange centre; long orange tube.

Georgiana (Van Houtte).—Bright scarlet; orange throat; long open tube, and small lobes.

Dr. Hopft (Vallerand).—White, with mauve centre. Dwarf and very free-flowering.

Ami Van Houtte (Vallerand and Van Houtte).—Deep violet blue; throat yellow, with dark spots; leaves pale green.

Liebmanni (Van Houtte).—Mauve purple, shaded with white in centre.

Grandiflora (Vallerand).—Rosy lilac, white centre.

Masterpiece (Vallerand and Van Houtte).—Violet purple; white throat; large brownish leaves.

Admiration (Vallerand and Van Houtte).—Rosy purple; whitish throat; rough brown leaves.

Hofgartner Neuner (Van Houtte).—Magenta rose; orange-spotted eye.

Dazzle (Vallerand).—Bright orange scarlet; small yellow eye.

Hofgartner Wendscanch (Vallerand and Van Houtte).—Violet purple; small flowers; compact habit.

TYDÆAS.

Cybèle (Vallerand).—Soft rosy carmine; lobes spotted and striped with crimson.

Magicien (Vallerand).—Deep orange scarlet; lobes spotted and striped with deep crimson.

Chiron (Vallerand).—Bright scarlet; lobes spotted and striped with crimson.

Harlequin (Vallerand).—Tube purple; lobes greenish yellow, heavily spotted with purple.

Venosa (Van Houtte).—Tube red; lobes soft carmine, spotted and striped with red.

The two following Gesneriaceous plants were also regarded as meritorious:

Rosonowia ornata (Van Houtte).—Creamy white covered with rose lines on the tube and on the two superior lobes; interior striped with purple.

Gesneria macrantha (Van Houtte).

MARKET GARDENING AND FRUIT-GROWING.—Market gardening for farmers has been strongly advocated as a partial remedy for the present distress; and within certain limits, and upon the better class of soils, this may prove a great auxiliary. But the danger of relying too much upon the production of vegetables has been shown by the autumn of 1880, when it was impossible to dispose of the produce at anything like remunerative prices. The perishable nature of the goods and heavy carriage are very much against the success of the enterprise, when attempted to be carried on in places remote from the centres of consumption. But in the direction of fruit-growing there is boundless scope for the farmer. Home-grown produce, coming fresh into the market, has always carried away the prize when opposed to the dried-up American Apples, Jersey Grapes, and the indifferent Plums of Germany and the Netherlands. Black Currants, Raspberries, Gooseberries, and some other fruits make immediate returns, and it does not require a very long lease to reap

the benefit of Plums of all kinds planted in hedgerows and in selected spots or odd corners of the farm.—(*The Agricultural Depression, and How to Meet It.*)

REVIEW OF BOOK.

A Dictionary of Economic Plants. By JOHN SMITH, A.L.S. Demy-8vo. London, Macmillan & Co.

THE veteran ex-Curator of the Royal Gardens, Kew, has added another work to those which have already gained him considerable fame as an author, and it appears probable that his latest production will become even more popular. The study of economic botany has been greatly extended in recent years, as it is a division of the science which interests a far larger proportion of persons than structural or systematic botany. In fact, a knowledge of the uses and properties of plants, or the sources of the numerous vegetable products employed in this country, has become an important part of general education; and to persons engaged in commercial pursuits, particularly in connection with the importation of colonial and other produce, it is almost indispensable. The works, however, that are available and suitable for consultation generally are by no means numerous, and it was on this account that the "Domestic Botany" published by Mr. John Smith in 1871 was well received, as it gave in a popular, concise, but clear form a description of the principal plants notable for their uses. This work principally comprised a portion of the materials collected by the late Mr. Alexander Smith, as the basis for an exhaustive treatise on economic and commercial botany, the completion of which was prevented by his early decease. Such of these as were deemed suitable for a popular work were selected by his father, and, together with a brief review of the structural characters of the vegetable world, were published, as before stated, under the title of "Domestic Botany." The lapse of ten years rendered a revision necessary; but instead of issuing another edition of the original work it was decided to give it a different form, arranging the various products for convenience of reference under their popular names in alphabetical order, instead of in the natural families, as had been previously adopted. As a result we have the work now being noticed, which in 449 pages contains descriptions and references to about 1600 subjects included in 1163 genera, thus comprising by far the greater portion of the most important plants that possess really useful properties. Though no elaborate research has been attempted, a large amount of information is conveyed in clear but concise language, and a most commendable accuracy, both as regards facts and nomenclature, distinguishes the whole work. As examples of the method adopted we submit the following quotations:—

CRANBERRY (*Vaccinium Oxycoccus* and *V. macrocarpum*), slender trailing-stemmed, small-leaved shrubs, belonging to the Cranberry family (*Vacciniaceæ*). They are natives of this country and North America, growing in boggy heaths. The fruits are berries about the size of Currants, which are collected for preserving and for making tarts. *V. macrocarpum* has the largest fruit, and is imported from North America, where it is extensively cultivated, especially near Berlin, Wisconsin, where about one-fourth of 750 acres of marsh is under cultivation. It is flooded during winter; in the spring the water is drained off, and in October picking commences. Sometimes there are as many as three thousand pickers employed. The ground is so marshy that a wooden railway is laid from the centre of the operations to convey the berries in trucks to the warehouse, where they are laid on the upper floor, and on the lower are large fanning mills, to which the berries are let down in hoppers, and are thus cleaned from leaves and other impurities. 35,000 bushels are sometimes collected from this spot in one season, the greatest quantity of which is sent to the Chicago market. This quantity is far surpassed in New Jersey, where in favourable seasons 125,000 bushels are collected, valued at £60,000.

INDIAN FIG.—*Opuntia Tuna* and *O. Ficus-indica* and other species of the Cactus family (*Cactaceæ*) have received the names of Indian Figs or Prickly Pears. They are common throughout the tropical and subtropical countries of America, and since the discovery of that continent they have become naturalised in southern Europe, many countries of Africa and Asia, even growing on the old walls of Jerusalem. Their stems when young are fleshy and nearly flat, but in age they become cylindrical, hard, and branched; the branches consist of oblong fleshy joints superposed upon one another, smooth, or more generally furnished with strong spines. They seldom exceed a height of 10 to 12 feet, but Humboldt says he saw at Cumana "erect Cactæ (*Cereus*) and *Opuntias* 30 to 40 feet high, 4 feet 9 inches in circumference, and covered with lichens, and the wood becomes so hard from age that it resists for centuries both heat and moisture." They make impenetrable hedges. Their fruits are pear or egg-shaped, flat at the top, 2 to 3 inches in length, covered with tufts of small spines, and are of a green, yellow, or red colour; they are wholesome, and are esteemed for their cooling juice. They abound on the lava slopes of Mount Etna, and are the pioneers of cultivation, their roots penetrating and breaking up the lava. They naturally decay in time,

forming a rich vegetable mould on which Vines are planted. The fruit is collected and sold in large quantities in the markets, forming an extensive article of food to the inhabitants. They contain saccharine matter; their juice is used for colouring confectionery, and in Mexico a drink called colinche is prepared from them. The plants grow abundantly in other parts of South Europe and in Algeria, from which place the fruits are imported into this country. When old the fibrous parts of the joints of the stems become hard and firm, and are made into ornamental articles.

RICE PAPER.—It might be supposed that the beautiful substance called rice paper was made of some part of the Rice plant, but such is not the case; the name is quite misleading. It was early ascertained to be a vegetable substance, but the plant producing it was long unknown to botanists, and on inquiry being made respecting it, fanciful figures and descriptions were given of it by the Chinese. Not long after the commerce of China was opened to Europe it was ascertained that it came from the Island of Formosa, which led Sir John Bowring, then Governor of Hong-Kong, to obtain plants of it from that island, one of which arrived safely at Kew in 1853, and flowered in 1855. From this it was proved to be *Aralia papyrifera*, now known as *Fatsia papyrifera*. It is a small tree of the Ivy family (*Araliaceæ*), attaining a height of 10 to 12 feet, with a stem 3 to 4 inches in diameter, the interior being full of white pith like that of the Elder. It has soft downy palmate leaves, something like those of the Plane tree, growing on long footstalks, and produces a somewhat erect paniced raceme of small flowers. The tree is cut down in order to obtain the pith, which averages, according to size, about 1 inch in diameter. It is divided into pieces about 3 inches in length, and by the aid of a lath and the use of a sharp instrument is cut into very thin rolls, and then becomes rice paper. It is extensively used by the Chinese for drawing figures of plants and animals, and also for making artificial flowers. The plant requires the protection of a greenhouse in this country, and propagates freely from suckers. It is now common in Australia and other countries.

It need only be further added that the work is excellently printed on good paper, and neatly bound in green cloth.

THE LIVERPOOL HORTICULTURAL COMPANY'S GROUNDS (JOHN COWAN, LIMITED.)

Most persons have heard of The Vineyard at Garston, formed by Mr. Meredith and long carried on by him successfully, but which some time since was bought by Mr. Cowan, and afterwards a company was formed by some Liverpool merchants to carry on the business. The nursery is pleasantly situated on rising ground overlooking the Mersey, and I was surprised to find quite a town of glass. I think there are thirty-six houses, besides pits and frames, houses from 50 to 240 feet long. I cannot trespass on the pages of the *Journal of Horticulture* to give details of every house, but may remark that Grape-growing is not so largely followed now as formerly, more attention being paid to plant-growing. Still, one of the first houses I went into was a long lean-to with a division in the centre, and planted with one *Madresfield Court* Vine, which was bearing fine Grapes not fully ripe but swelling well. This one Vine filled the two divisions, and by turning on the heat at one end first it caused the Grapes to be three or four weeks in advance of those at the other end where the Vine was planted. In another house were some magnificent bunches of *Gros Guillaume*, the true variety, as sent out in 1850 from Stratford-on-Avon. It is most distinct from another variety I often meet with under that name. In other large houses were some good *Muscats* and *Black Hamburgs*, while Vines in pots are growing in large numbers—strong healthy plants 7 and 8 feet high. In the famous large house, 240 feet long by 25 feet wide, were three thousand fine young Vines; some *Foster's Seedlings* were showing fine bunches of fruit on the laterals. On the north side of these Vines I observed two men potting some thousands of seedling Ferns—*Pteris serrulata*—one would think enough to supply the whole of the country. My guide informed me this Fern is in great demand in the Liverpool market. There were also two new houses about 150 feet long each, with glass sides over 6 feet high, built expressly for growing young Vines.

Within the last year and half attention has been paid to Roses, especially *Teas*; house after house is filled with all the best kinds. To give some idea of the fine growth they are making I may mention that some young *Gloire de Dijon*s worked last spring were over 10 feet high, and amidst the many thousands of plants not one speck of mildew was visible; but the foliage was fresh, clean, and vigorous young shoots breaking up from the bottom thick and firm, with large clusters of buds—just such growth as one would expect to see in the south or west of England. Hundreds of *Ericas* and *Cytisuses* were growing outdoors just as well as in London. In other houses were thousands of Palms, and in one of the propagating houses were several thousand *Hydrangea* cuttings in a bed, and at the end of the house a number of fine young plants in 5-inch pots. Some were 9 inches high, with a stout stem, the joints about three-quarters of an inch apart, the leaves 9 inches from the stem to the tip and 5 inches across, with large buds close, hard, and green, like small Cauliflowers. I was told that when potting them the men employed an extra quantity of the manure now being made and advertised by the Company, which is also being used for all purposes, even for their Orchids. I

noticed a fine lot of plants of the *Chimney Campanula*. So few know how to do these well in the present day, yet here they were 8 and 10 feet high, with several stems, and white, blue, and lilac flowers. *Solanums* are largely grown, also *Bouvardia Alfred Neuner*, *Tuberous Begonias*, *Fuchsias*, *Pelargoniums* (*Show and Regal*), *Zonals* for winter blooming, *Aralia Sieboldii*, with other table and foliage plants.

I was especially pleased with the packing shed; it is, in fact, a conservatory with platform all round, with a place for everything, even to a pair of scales. In the workshop the steam engine was driving the saws and other machines, and men were busy making the frames the Company advertise so much, and I was told they have large orders in for glass houses. I also visited the new nursery, some fifteen acres, at Gateacre, about four miles distant. This land was only obtained eleven months since, but several houses have been erected, in which the plants are looking well. Most of the grounds are planted, and the walks were wide enough for a carriage drive. To describe in detail all I saw would be too wearisome, but from the above notes it will be seen that The Vineyard Nursery is a large one, and all gardeners who may visit Liverpool should not omit a call at Garston.—N. J. D.

THE MOUNTAIN ROSE.

UNDER this rather pretty yet very appropriate name of the old botanists, the attractive hardy shrub *Rhododendron hirsutum* is

Fig. 29.—*Rhododendron hirsutum*.

scarcely known now. It is a native of the Alps of Switzerland, and is found near the summits of lofty mountains. When densely covered with its rosy scarlet flowers it has a glowing effect. The popular name is thus very expressive, both as regards the habitat of the plant and its appearance when flowering in its mountain home.

For planting on large rockeries this *Rhododendron* is admirably adapted, its spreading yet compact habit rendering it very suitable for such sites; and even when not flowering its dense bright green

foliage imparts to the mounds an agreeable appearance, while when in flower dwarf bushes of several feet in diameter are very beautiful. It also grows well in beds and borders, and succeeds in soil in which Rhododendrons flourish. In some gardens this Rhododendron is plentiful, and, in good condition, never fails to contribute to their attractiveness during May and June; but in others it is not represented. It is a distinct and good old flowering shrub, and ought to be grown everywhere, being extremely hardy, and always admired when covered with its small bright flowers. It has been tried as a forcing plant for the conservatory, but does not appear to like a high artificial temperature.

The woodcut (fig. 29) is a reduced representation of a small spray, and well indicates the floriferous habit of the plant.

SHREWSBURY HORTICULTURAL SHOW.

AUGUST 16TH AND 17TH.

THE above Society is one of the most flourishing in the kingdom, and the finances have enabled the Committee to greatly improve the Quarry Grounds, in which the Exhibition is held. It is now a pleasant situation for a summer show, and the inhabitants of the town and neighbourhood indicate their appreciation by visiting the grounds in thousands. The days of the Exhibition are regarded as a general holiday, and the chief approaches are festooned and draped with flags and banners. The Show, like the grounds, has steadily improved each year, while the one opened on Wednesday was considerably the best yet seen at Shrewsbury. Three years ago it was mentioned that an improvement was necessary in placing on the prize cards; and this year the South Kensington system was adopted, and the whole was done without hurry or confusion. The plants were of superior quality in the open classes except the Tuberous Begonias and Achimenes, which were poor. The amateurs' classes showed a marked improvement in the quality of the exhibits, while the groups arranged for effect were very attractive. The fruit was good, except the Muscat Grapes, many of them being far from ripe but good in other respects. The cut flowers were superb, especially the Dahlias and Gladiolus. Vegetables were of satisfactory quality, and shown in large quantities.

Stove and Greenhouse Flowering and Foliage Plants.—In the class for twenty plants, not less than ten in bloom, there were three entries. Mr. J. Cypher, Cheltenham, took the lead, followed closely by Mr. Tudgey, gardener to J. F. G. Williams, Esq., Henwick Grange, Worcester. Mr. J. F. Mould, Pewsey, Wilts, third with an uneven collection of much smaller size. The first-prize collection contained grand examples of *Ixora Pilgrimii*, *Allamanda nobilis*, *Lapageria rosea*, very good; *Clerodendron Balfourianum*, *Ixora Duffii*, a very fine plant with twenty large trusses, some more than 10 inches in diameter; *Ixora Williamsii* well bloomed, *Bougainvillea glabra*, *Erica æmula* and *E. Austiniana*, neat and in the best of health. The principal fine-foliage plants were *Croton Disraeli*, *C. majesticus*, *Thrinax elegans*, *Cycas revoluta*, *Latania borbonica*, *Dasylyrion acrotrichum*, *Gleichenia flabellata*, and *Cordyline indivisa*; while Mr. Tudgey staged good well-grown plants of *Croton Queen Victoria*, *C. Andreanus*, *C. Johannis*, *Dipladenia amabilis* well flowered, *Ixora amabilis*, *Anthurium Schertzerianum*, a large specimen and a very fine variety; *Gleichenia rupestris*, *Cycas circinalis* and *C. revoluta*, *Dipladenia hybrida*, *Erica Fairriana* and *E. ampullacea*. Mr. Mould's best plants were *Dracæna Goldiana*, *Statice profusa* and *S. Butcherii*. In the corresponding class for nine plants, not less than five in bloom, there were six entries. Mr. C. Roberts, gardener to E. Cliffe Glover, Esq., Highfield Hall, Staffordshire, took the lead with a good *Ixora Williamsii*, *Allamanda Hendersoni*, *Eucharis amazonica* 4 feet in diameter and remarkably well flowered, *Croton majesticus*, and *Clerodendron Balfourianum*. Mr. W. Pratt, gardener to Lord Hill, Hawkstone, Salop, followed closely, showing a good *Alocasia metallica* and *Nepenthes Hookerii*. Mr. Purser, gardener to J. Watson, Esq., was the other successful exhibitor, and staged a good *Vinca alba*. In the amateurs' class for six plants, not less than four in bloom, H. Owen, Esq., The Cedars, Shrewsbury, was first, having amongst others a good *Begonia metallica*. Mrs. Wace and L. Burd, Esq., were second and third respectively.

Ericas.—These were not shown in large numbers, as the schedule only provided one class, which brought out three competitors—Messrs. Cypher, Tudgey, and Mould. Those shown by the first-named exhibitor were neat, healthy, and profusely flowered plants. The varieties were *E. Marnockiana*, *E. McNabiana*, *E. Turnbullii*, *E. æmula*, *E. Austiniana*, and *E. Maidstoniensis*. Mr. Tudgey's were rather smaller but very fresh, *E. Lindleyana*, *E. insignis*, and *E. tricolor Wilsoni* being good; while Mr. Mould staged a grand *E. cerinthoides coronata*.

Palms.—There were three exhibitors in the class for six tall Palms, and the plants staged were large, well furnished, and in admirable condition. Mr. Cypher was first with *Pritchardia pacifica*, *Kentia Fosteriana*, good; *Thrinax elegans*, *Kentia australis*, and *Verschaffeltia splendida*. Mr. Tudgey second with rather smaller plants; *Geonoma gracilis* and *Thrinax elegans* were very fine. Mr. C. Roberts was third with much smaller plants.

Dracænas.—There were only three collections staged in the class for six plants, which were of good quality but not large, being dwarf and well coloured. Messrs. Pratt, Purser, and Roberts were the

prizetakers in the order named. The first-prize collection did not contain a faulty plant, the varieties being *Leopoldi*, *Reginæ*, good; *Mooreana*, very fine; *Baptistii*, *Berkeleyi*, and *Fraseri*. Mr. Purser staged grand plants of *splendens* and *hybrida*, while the third collection included good examples of *Willsii* and *Elizabethæ*.

Caladiums this year showed a marked improvement, and the first and second collections were very creditable. The prizetakers were Messrs. Pritchard & Sons, Shrewsbury; Mr. J. C. Slater, gardener to G. D. Lees, Esq.; and Mr. Farrant, gardener to Mrs. Juson.

Coleuses were well represented, and all of pyramidal shape, as stipulated in the schedule. In the class for six distinct varieties those shown by Mr. Purser were very neat. The plants were about 6 feet high and perfect in shape, while the bright colours of the foliage were all that could be desired. His plant of *Lady Burrell* had not a sportive leaf upon it, while Mrs. G. Simpson, Zanzibar, Ajax, Soliel, and Smart were very fine. Mr. J. Morris, gardener to Mrs. Shaker, and Mr. G. Pearson, gardener to Lord Berwick, were second and third with good plants, but not so neat as the first collection. Mrs. Wace, E. Burd, Esq., and H. Owen, Esq., were the successful exhibitors in the amateurs' class for three plants.

Fuchsias were also in better condition than last year; the plants were considerably larger and much more profusely flowered, although there is still room for improvement. For six plants, distinct varieties, Messrs. Pritchard & Sons were first with creditable plants well flowered, the best being *Blushing Bride*, *Charming*, and *Crimson Globe*. Messrs. R. J. Niven and A. Myers were second and third. The plants in the amateurs' class for three were even and better flowered than in the preceding class. Mr. H. Owen first with good examples of *Avalanche* and *Rose of Castile*, Mrs. Wace second with smaller but neat plants, while Mr. L. Burd was second with larger but poorly flowered examples.

Begonias, *Balsams*, *Achimenes*, and *Gloxinias* were of inferior quality, and need no further remark, except those in the amateurs' class, which were much the best flowered.

Table Plants.—These are always good at Shrewsbury, the plants generally being of small size, neat, and well-coloured. Messrs. Jones and Sons, Shrewsbury, took the lead with a grand lot, the most striking being *Croton interruptus aureus* and *C. majesticus*, *Dracæna gracilis*, *Pandanus Veitchii*, *Cocos Weddelliana*, *Aralia gracillima*, and *A. elegantissima*. Mr. Farrant was a good second, and staged a beautiful *Croton Johannis*, *Geonoma gracilis*, and *Yucca filamentosa variegata*. Mr. W. Pratt followed closely with neat and even plants. There were six competitors, all staging well.

Groups.—These occupied the left hand side of the large plant tent, and created considerable interest, as the competition was good and keen, seven or eight groups being staged. They were arranged for effect on a space not exceeding 100 square feet, and were on the whole more tastefully disposed than we have seen them at this Society's previous exhibitions. Mr. Pratt won chief honours with a light and effective group of choice plants. Most of the groups contained a number of flowering plants, but in Mr. Pratt's there was none. The principal objects of the group were *Crotons*, *Thomsonii* grandly coloured, *Disraeli*, *Johannis*, *Andreanus*, and *Evansianus*; *Aralias*, *Palms*, and *Dracænas* rising out of a groundwork of *Ferns*, small *Crotons*, *Coleuses*, *Caladiums*, and edged with *Panicum variegatum*, *Sonerilas*, and a number of well-berried *Nertera depressa*. Messrs. Pritchard & Sons, Frankwell Nurseries, were second with a rather heavier group, and Mr. J. W. Pritchard, 63, New Street, third. In the class for fifty miscellaneous plants grown in 5-inch pots, not less than thirty in bloom, there were four competitors; the exhibits were arranged on narrow stages, and added materially to the effect of the large tent. Messrs. Jones & Sons took the lead, having a number of *Odontoglossums*, *Dendrobiums*, and *Cattleyas*; several *Rhododendron Princess Royal* were also in flower. Messrs. Pritchard and Sons were second with a grand assortment of well-grown small plants, and would, but for the few *Orchids* in the first-prize collection, have had a higher position. Mr. H. Purser was awarded the remaining prize.

Zonal Pelargoniums.—These constituted an imposing feature in the large tent, the plants being of moderate size and fresh, with very large trusses of flowers. In the class for six doubles Messrs. Oldroyd and Co. were first with well-flowered examples of *Madame Thibaut*, *Prince Noir*, *Adelaide de Blanche*, *Wonderful*, and *Asa Grey*. Messrs. Pritchard & Sons were second, having a good *Sylvia* and *Victor Lemoine*. Mr. J. R. Jones third with larger but not such well-flowered plants. In the corresponding amateurs' class for three plants, Messrs. L. B. Burd and H. Owen were the prizetakers, both staging very neat plants. For six singles Messrs. Oldroyd & Co. were again first, showing *Hettie*, Mrs. Vickers, *Pirate*, *Lady Sheffield*, *Ellen*, and *Turner's Bride*, all good. Mr. J. R. Jones was second, having a good *John Gibbons* and *Arthur Rogers*, Messrs. Pritchard & Sons were third. There were four entries. For three plants H. H. Treasure, Esq., first with good plants not named; Mr. H. Owen second, having a grand plant of *White Vesuvius*; Mr. L. Burd followed, having a fresh well-flowered plant of *Henry Jacoby*.

Ferns.—Though not extensively shown the plants were large in the open classes and in excellent condition. For nine exotic *Ferns* Mr. Cypher staged large well-grown specimens of *Woodwardia radicans cristata*, *Gleichenia flabellata*, 6 feet through; *Dicksonia antarctica*, *Microlepia hirta cristata*, very fine; *Gleichenia Speluncea*, *Cibotium princeps*, *Davallia Mooreana*, and a grand *Adiantum trapeziforme*. Mr.

Tudgey was the only other exhibitor, and was placed second, having large well-grown plants of *Adiantum cuneatum*, *A. decrum*, and *Hymenophyllum demissum*. For six plants Mr. Farrant took the lead with *Adiantum pedatum*, *A. formosum*, *A. venustum*, and *Davallia Moorcana*, all good. Mr. W. Pratt was second with a large *Adiantum gracillimum* and *Asplenium bulbiferum*; and Mrs. R. S. Burton was third. In the amateurs' class for four plants there were seven entries, the prizetakers being Messrs. H. Owen, R. Cooper, and H. H. Treasure; for hardy Ferns Messrs. Pritchard & Sons, Harrison, and J. R. Jones in the order as named, staging very creditable specimens.

CUT FLOWERS.—The competition was keen in the various classes devoted to these. Roses were not shown in large numbers, but the blooms were of first-rate quality. In the class for twenty-four single trusses Messrs. Perkins & Sons, Coventry, were awarded the premier position, having good blooms of Marie Baumann, Beauty of Waltham, Belle Lyonnaise, Madame Marie Verdier, Henry Eaton, Mdle. Annie Wood, and Dupuy-Jamain. Messrs. James Dickson & Sons, Newton Nurseries, Chester, were closely second with fine flowers of Mdle. Marie Rady, Mrs. Jowitt, Duchess of Bedford, Louis Van Houtte, and Lord Beaconsfield. Mr. F. Perkins, Leamington, obtained the remaining prize with much smaller blooms. Messrs. C. M. Campbell, G. Townsend, and E. W. Pritchard were the principal prizetakers in the smaller Rose classes.

Dahlias were of fine quality, the blooms being of large size, fresh, and good colour. For thirty-six distinct blooms there were only two exhibitors, Mr. Shaw being easily first. His most striking blooms were John Bennett, Rev. J. M. B. Camm, Burgundy, Egyptian Prince, Mr. Bunn, Henry Bond, Duke of Connaught, Peacock, Prince Bismarck, J. C. Quennell, General Roberts, John McPherson, John Wyatt, John Greenaway, Pioneer (fine dark flower), Woman in White, and Countess of Pembroke, no prize being awarded the other collection. In the class for twenty-four blooms the same exhibitor was again first with even and finer blooms than his thirty-six. For nine blooms Messrs. R. J. Niven, Campbell, and Rev. J. H. Charter were the successful exhibitors.

For thirty-six single *Gladiolus* spikes Messrs. Kelway & Sons took the lead with splendidly arranged examples, even finer than generally seen from that firm. Mr. Shaw was second with a very creditable collection, but far behind those to which the first prize was awarded. A few of Messrs. Kelway & Sons' best were *Agrilus*, salmon pink; Beauty of England, *Astræa*, Bethcar, Cassino, Lady Bridport, Marcinus, Mrs. J. Eyton, Mrs. Laxton, Mrs. Reynolds Hole, Parsonii, *Plautus*, Ptolemy, Queen Mary, and Rhamnes. Mr. Lambert, gardener to Col. Wingfield, took the lead in the class for eighteen spikes, followed by Messrs. Pritchard & Sons and Mr. J. W. Pritchard.

Asters were numerous, but not up to the usual standard. In the class for twenty-four, not less than twelve varieties, Messrs. A. Myers, W. Shaw, and J. Bowen Jones were the successful competitors. In the amateurs' class for the same number, but not less than six varieties, Messrs. J. B. Jones, Harrison, and Shuker took the lead in the order as named.

Mr. Pratt was successful in the class for twelve trusses of stove and greenhouse cut flowers; second Messrs. Pritchard & Sons; and third Mr. J. C. Salter, gardener to G. D. Lees, Esq. There were five entries. Mr. Pratt's best bunches were *Lapageria rosea* and *alba*, *Ixora coccinea*, *Allamanda Wardleyana*, *Dendrobium chrysanthum*, and *Stephanotis floribunda*. For twelve trusses of herbaceous cut flowers Mr. G. Townsend, Uffington, was first with a neat collection of fair-sized bunches; Mr. J. B. Jones second; and Mr. R. W. O. Withers third, the last-named collection being very uneven. In the class for twelve spikes of herbaceous *Phloxes* there were thirteen competitors. Messrs. Pritchard & Sons and A. Myers were the fortunate exhibitors. For six Messrs. Harrison, Campbell, and Crump. The principal prizetakers for Ten-week Stocks were Messrs. Townsend, Cooper, E. W. Pritchard, Jones & Sons, and Shuker. Miss Brooks took the lead for twelve French Marigolds; and Mr. J. Mitchell for the same number of African Marigolds, with splendidly shaped flowers.

Mr. Rudge, gardener to T. S. Eyton, Esq., was first for twelve trusses of Zonal Pelargoniums, the collection being even and neat. Messrs. Pritchard & Sons, and Oldroyd & Co. second and third. For twelve bunches of Show or Fancy Pelargoniums Mr. F. Perkins, Leamington, was well first with large trusses of Captain Raikes, Madame Thibaut, Illuminator, Royalty, Beauty of Oxtou, Emperor of Russia, Ed. Perkins, Delves Broughton, Dr. Masters, and Volonté Nationale; Messrs. Pritchard & Sons second with grand Dr. Andry, Prince of Wales, and Lucy Lemoine. Messrs. Jones & Sons were awarded the remaining prize. Trusses of *Verbenas* were good, and Messrs. Pritchard & Sons, J. W. Pritchard, and W. Shaw were successful exhibitors.

Bouquets were not numerous, but good. Mr. Cypher was first for one ball or hand bouquet, which was neat, and composed of *Eucharis*, *Cattleyas*, *Lapageria alba*, and a few flowers of *Ixora* and *Rhododendron Princess Royal*. Mr. F. Perkins was second, his being composed of Hybrid Perpetual and Tea Rose buds. Messrs. Jones & Sons were third. For one bridal bouquet Mr. F. Perkins was first, followed by Mr. Cypher and Mr. Herbert Jones, all being remarkably good. Mr. Cypher was first for button-hole bouquets, and Mr. Tudgey for a stand of cut flowers for table decoration, the arrangement being very light and effective. Mr. Cypher was second, and Messrs. Jones and Sons third.

FRUIT.—In the open class for twelve dishes Mr. Pratt was well first with good Black Hamburg and Muscat of Alexandria Grapes, Queen Pine, Conqueror of Europe Melon, Brown Turkey Figs, Moorpark Apricots, Irish Peach Apples, Pine Apple Nectarine, Bellegarde Peaches, and a good dish of Cherries and Plums. Mr. R. Milner, gardener to J. D. Corbett, Esq., was second, having fine Muscat of Alexandria Grapes, Peaches, and a good Pine. Mr. Hannagan, the remaining exhibitor, was thrown out for having two dishes of Apples. The schedule merely specifies "distinct," and can be read "for distinct kinds or varieties." In the corresponding class for nine dishes, Pine excluded, open to the counties of Montgomery and Shropshire, Mr. Purser was the successful exhibitor, and staged fair Grapes but rather small, good Prince of Wales Nectarines, Grosse Mignonne Peaches, and a good Melon. Mr. Lambert was a close second with fine Grapes but scarcely ripe, and good dishes of Grosse Mignonne Peaches and Early Orange Apricots. Mr. G. Pearson obtained the other prize. For six bunches of Black Grapes, three varieties, Mr. W. Pratt was successful with neat well-finished bunches of Madresfield Court, good in berry and colour; Black Hamburg, fine in every respect except that the berries were rather undersized; and well-finished Lady Downe's. Mr. R. Milner was second with larger but looser bunches of the same kinds, except Alicante in the place of Madresfield Court. Mr. Goodhill, gardener to E. T. W. Wood, Esq., was third with good bunches but rather defective in colour. There were five entries. For three bunches of black Grapes, open to the two counties above referred to, Mr. J. Lambert took the lead with Black Hamburg, good in berry and colour, although the bunches were not large; Mr. Purser second; and Mr. C. Davies, gardener to F. S. B. Sladen, Esq., third with very fair Grapes cut from Vines over seventy years of age. Mr. R. Milner was first for four bunches of white Grapes with good Buckland Sweetwater and Muscat of Alexandria Grapes, the latter scarcely finished; Mr. W. Pratt second with Trebbiano and rather small Muscats; and Mr. Purser third. The remaining two Grape classes were devoted to amateurs. Mr. Lea, Whitchurch, took the lead with well-finished Black Hamburgs, the berries being rather small. Messrs. Watson, Lea, and Charter were first and second for two bunches of white Grapes.

Messrs. Bain, gardener to R. Broughton, Esq.; Hannagan; and J. Edwards, gardener to Sir F. Smythe, were the prizetakers for Peaches. For a dish of Nectarines Mr. C. Dawes was first with Elruge; Mr. J. Bain second with Pitmaston Orange. For Apricots Mr. Dawes took the lead; and Mr. S. Jones, gardener to W. Hazclidine, Esq., for Plums. Mr. Farrant was first for a green-flesh Melon with Eastnor Castle; Mr. Owen second. Mr. Shutte first for a scarlet-flesh with Hero of Bath; Mr. Farrant second with Read's Hybrid Scarlet Flesh; and Mr. Lambert third. Mr. Hawkesford, gardener to Sir V. R. Corbett, for Cherries, which were very fine.

VEGETABLES.—These were very numerous and of fine quality. The competition was close, there being from seven to fifteen exhibitors in each of the fourteen classes devoted to vegetables. Mr. R. Milner took the lead for the collection of twelve dishes, followed by Mr. Purser and Mr. Pratt. The first collection contained first-rate examples of Webb's Crimson Beet, Reading Onions, Canadian Wonder Beans, Autumn Giant Cauliflowers, Reading Russet Potatoes, Telegraph Peas, Manchester Red Celery very fine, Intermediate Carrots, and a dish of good Leeks. Messrs. A. Myers, R. Milner, and H. Purser were the prizetakers for six distinct dishes of Potatoes. The tubers, with the exception of one or two collections, were clean, even, and of suitable size. Mr. Myers staged Beauty of Hebron, Schoolmaster, Rector of Woodstock, and Vicar of Laleham. In the class for three dishes Mr. R. Milner was first, staging grand examples of International Kidney and Reading Russet; Mr. Purser had fine tubers of Webb's Surprise, Mr. C. Dawes took the remaining prize. Mr. Hannagan, Hooton Hall, took the lead for Tomatoes with large shapely fruits of Stamfordian, followed by Mr. Myers and Mr. G. Goodhill. For one dish of Peas Mr. Laurence, gardener to H. M. Heywood, Esq., first with Stratagem, Mr. Hawksford second with Telephone, and Mr. J. Bain third. Messrs. W. Dow, Lambert, and Pearson were the prizetakers for spring Onions, which were remarkably fine; while Messrs. Myers, Pearson, and Hannagan were successful for autumn Onions, which were of considerable size. Cauliflowers were rather coarse, those shown by Mr. Lambert excepted. Cucumbers were all that could be desired, and the same exhibitor was again first, Mr. H. Purser second, and Mr. W. Rudge third. Celery was good considering the earliness of the season, and the prizes were won by Messrs. R. Milner, H. Purser, and Rev. A. W. Brooke. Mr. Pratt was first for French Beans with Canadian Wonder, Mr. Hannagan second with Pale Dun, and Mr. Lambert third. Parsnips were clean and straight, and the same applies to the Carrots, Mr. Dawes taking the lead for the former, and Mr. Dow, gardener to J. Phillips, Esq., for the latter. Mr. Purser took the lead for Turnips, which were superb.

Miscellaneous Exhibits.—Messrs. Oldroyd & Co. exhibited a group of choice Conifers, which were arranged near the main entrance to the grounds, also a number of well-flowered single Zonal Pelargoniums. Messrs. J. Dickson & Sons, Newton Nurseries, Chester, had small Fig trees in 6-inch pots fruiting freely, and a choice collection of stove foliage plants, principally of a decorative size. Messrs. Perkins & Sons, Coventry, several boxes of Roses, which contained many very good blooms. Mr. F. Perkins, Leamington, had a similar collection. Messrs. Kelway & Sons, Langport, showed single Pyrethrum and *Gladioli*, which were very much admired. Messrs. F. and A. Dickson & Sons, The Upton Nurseries, Chester, contributed largely

to the Exhibition with a varied collection of stove, greenhouse plants, herbaceous plants, and small choice Conifers, all neatly and tastefully arranged, also Vines in pots and Figs; the latter were very fine from eyes this season, and now in 8-inch pots, carrying from twenty to thirty fruits. Messrs. Jones & Sons also exhibited Conifers and plants.

Cottagers' Exhibits.—The schedule provides some thirty-nine classes for these exhibitors—viz., twenty-one for vegetables, seven for fruits, and eleven for plants and cut flowers. The prizes offered were well contested, and the exhibits filled a large tent nearly 150 feet long and proportionately wide, with a stage down the centre and on each side. The vegetable exhibits were especially noteworthy, Potatoes, Beans, Peas, Onions, Carrots, Parsnips, Celery, and others being remarkably fine. The whole of the Turnips and Cauliflowers were

too large, and in consequence coarse. The managers of other large provincial societies will do well to follow the worthy example set them by the Committee of the Shrewsbury Society, and make liberal provision in their schedules for these classes of exhibitors, which are worthy of encouragement.

SILKWORMS AND SILKWORM REARING.—14.

(Continued from page 123.)

MORE valuable in regard to its silk, and apparently easier to rear than the *Attacus Cecropia* already mentioned, is another species also of North American parentage, *A. (or Telea) Polyphemus* (fig. 30), though I confess I see no good reason why it should

Fig. 30.—MOTH AND CATERPILLAR OF *ATTACUS POLYPHEMUS*

be named after the one-eyed giant of mythologic lore. Indeed, so highly is this estimated by several of those naturalists who have made a special study of the silk-spinners, that although there are half-a-dozen or more belonging to this tribe of moths which have been reared in the hope of turning their silk to useful account, *Polyphemus* has begun to receive the title of *the American Silkworm*. The cocoon of the species resembles that of the common silkworm, that of *Yama Mai*, and others allied to it, in being closed at both ends. In shape this is oval and compact, the fibre of the silk, which is nearly white, being very strong and glossy.

To Mr. L. Trouvelot, of Boston, U.S.A., belongs the credit, so we are informed, of suggesting that *A. Polyphemus* might be "tamed" and utilised, at the time when people were inquiring into the merits or demerits of American silkworms. Previous to 1860 scarcely a specimen of this worm had been reared in captivity, and its habits were unknown. This gentleman at once resolved to take up the matter practically, and prove, if he could, the theory he had put forth. "At first," he writes, "the undertaking seemed very simple, but who will ever know the difficulties, the hardships, and discouragements which I encountered?" The insect not being abundant, there was an unavoidable delay, owing

to the death of some of the earlier caterpillars bred and the long searches requisite to produce more. In spite of care bestowed it was not until 1865 that a really satisfactory result was attained, and Mr. Trouvelot had that season nearly 500,000 of the worms distributed over a patch of woodland five acres in extent, the bushes upon which they fed being enclosed with nets. I believe it was about three years after that date when British specimens of this silkworm were first obtained.

Both in Britain and in America the insect is single-brooded in the ordinary way, but should the cocoons be kept at too high a temperature soon after they have been spun, the moths they contain will sometimes emerge towards the end of autumn. If eggs are obtained from these they are likely, under the circumstances, to turn out unproductive. The proper season for the moths to appear is the months of June and July, when each female deposits about three hundred eggs, which hatch in twelve or fourteen days after. Selecting from a number of trees upon the leaves of which the worms have been reared, it may be noted that *A. Polyphemus* has grown well when supplied with Birch, Beech, Chestnut, Elm, Hazel, Maple, Oak, and Willow. In this, as in some other species, there is the curious circumstance that the young silkworm makes

the commencing meal off its egg-shell. There are four changes of skin, these changes or moults usually occurring at the same hour of the day, with an interval of ten or twelve days between them. Each time, as Mr. Trouvelot has observed, the silkworm spins a little pad upon a leaf to keep its position firm during the operation. He also noticed that after a moult each worm examined the body carefully, feeling especially at the openings of the spiracles or breathing tubes, evidently to remove any fragments of the old skin that might chance to be left. After the last moult the growth is more rapid, the whole life of the silkworm varying from two months to ten weeks; it is thus longer in attaining maturity than are some of the silkworms. When adult the caterpillar of *A. Polyphemus*, as may be seen in the figure, is a striking object, the delicate green ground colour being studded over with pink spines. In addition to these it has about fifty metallic spots; most of these are silvery, but eight of them situated on the front segments are of a golden hue.

The silk of the cocoon of *A. Polyphemus* is so tightly compacted and gummed together, that the perfect insect requires the aid of a solvent in order to effect its extrication. This is discharged upon the fibres by the moth some hours before it begins its struggle to make an opening, and this task is then facilitated by the acid which the fluid contains. From this fact it follows that if the cocoons are to be utilised for their silk, the chrysalids or pupæ enclosed must be previously killed, as is the practice with the Mulberry species. Nor could the thread be unwound continuously unless moistened by plunging the cocoon in water of a suitable warmth. Some of the breeders of the species in this country have found a difficulty in obtaining eggs, but practice will probably show us how this can be better managed. In the autumn of 1878 Mons. Wailly, having to leave his home, placed upon some small trees in his garden at Clapham—Hazel, Birch, and Willow—several caterpillars of *A. Polyphemus*. Upon his return he was gratified to discover that they had spun cocoons, so proving that the insect might be reared in our climate without protection, at least after a certain period of growth has passed.

Attacus Luna is another species that has been imported from America. The moth is of unusual beauty, named by some fanciful naturalist after the "queen of night." It is not unworthy of the honour, for the wings, which are adorned with long tails resembling those which bedeck our swallow-tail butterfly and others of the Papilio tribe, are of a green tint very pleasing to the eyes. Crossing them are also stripes of purple grey, and upon each of the fore wings spots resembling the lunar crescent, while the hind wings have their corresponding spots, which are rather eye-like. In Britain the caterpillars of this species, which hatch during July or August, feed well upon Walnut, Hazel, or Oak. From experiments at Clapham M. Wailly inclines to think that if let alone they would live in the open air, but his specimens placed at liberty were found out and devoured by sparrows when they became large, so failed to reach maturity. A small colony of these silkworms was reared upon Walnut leaves by Mr. Grapes in about eight weeks, the cocoons being placed in small hollows formed by drawing some leaves of the food plant together. Through their successive changes of skin they are of the same green or greenish white as when first hatched. Upon the skin are numerous irregular points and warts of red or crimson. The cocoon is long and also broad. The value of its silk remains yet to be ascertained.

Apparently more difficult to rear is the even more gorgeous and nearly allied insect, a native of India, *A. silene*, which exceeds in size its American relation. The food of the English-bred specimens has hitherto been Walnut, Willow, and Cherry, but it has succeeded better in France and Germany than on English soil as yet. This is one of the races of silkworms from which by suitable management more than one brood may be obtained in the course of a year. Cocoons obtained from Asia have yielded moths between March and August; these are similar to the cocoons of *A. Luna*, in being open, not compact. At the Westminster Aquarium those interested in silkworms may see sample cocoons of *Attacus Aurota*, only recently brought to us from French Guiana. The worms are reported to grow with great rapidity. Its general aspect has led to its being called the South American Atlas.—J. R. S. C.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 22ND.

NEITHER plants nor fruits were largely shown at Kensington on Tuesday last, the two chief collections being the handsome single Dahlias from Tottenham and the Balsams from Dulwich.

FRUIT COMMITTEE.—John Lee, Esq., in the chair. Messrs. T. Rivers & Son, Sawbridgeworth, exhibited a collection of seedling

Nectarines, which were considered of deficient flavour and tasted of the packing material—some rough moss. Some handsome samples of *Beurré de l'Assomption* Pears were shown, but to specimens of Clapp's Favourite Pear similar remarks apply to those characterising the Peaches above. Messrs. J. Cheal & Sons, Crawley, sent several Melons, one Crawley Paragon of very good flavour, similar to Turner's Scarlet Gem; it is a very neat scarlet-fleshed Melon of moderate size. Shepherd's Model and Excelsior were considered worthless. Mr. C. Fidler, 104, Friar Street, Reading, sent a seedling Potato named Fidler's No. 1, which is now being grown at Chiswick, and will there come before the Committee. Mr. A. Faulkner, Inkpen, Hungerford, sent a dish of fruits of a seedling Raspberry, considered of inferior size and flavour to others in cultivation. Mr. W. Divers, The Gardens, Wierton Hall, Maidstone, had a collection of fruits, including a seedling Peach, which was not considered worthy of special notice. Mr. J. Moore, gardener to J. Haig, Esq., Bray Court, Maidenhead, sent fruits of a seedling Tomato, for which a cultural commendation was awarded, the Committee considering it a fine strain of Excelsior.

FLORAL COMMITTEE.—G. F. Wilson, Esq., in the chair. A medal was awarded to Mr. T. S. Ware, Tottenham, for a very extensive collection of single Dahlias, comprising over three hundred blooms, and representing a great number of beautiful varieties. Some of the most distinct were the following:—Rob Roy, rich scarlet; White Queen, Mauve Queen, Ascalon, crimson shaded; Beauty, Yellow Queen, Francis Fell, crimson; Maroon, small, but rich colour; Zimapani, very deep maroon, nearly black; Merckii, small white, like *Glabrata*; Stars and Stripes, mauve, streaked with crimson; Pantaloon, small, but neat, florets rose in the centre, tipped with white and margined with maroon. Many other beautiful forms were also shown in this collection, and a great improvement was notable in the breadth of the florets, the general outline, the substance, and the purity or richness of the colours. Mr. T. S. Ware also sent a basket of the variegated Grass *Eulalia japonica zebrina*, the transverse bars of white being distinctly marked on a bright green base.

Notes of thanks were accorded to all the following exhibitors:—Mr. H. Eckford, gardener to Dr. Sankey, Boreatton Park, Shrewsbury, for a collection of Carnation and Sweet Pea blooms. The latter included samples of Blue King, Duchess of Albany, Lettie Eckford, and Grandeur, all very good varieties. Mr. Francis Smith, sen., Park Road, West Dulwich, exhibited a collection of double-flowered Balsams, mostly bearing large, full, and well-formed blooms, purple, crimson, scarlet, rose, salmon, and white, the last-named being particularly good; some of the flowers were diversely streaked or spotted. Mr. G. Young, gardener to Capt. Patton, Alpha House, Regent's Park, had a plant of *Lisianthus Russellianus*, bearing half a dozen of its large bright purple flowers. Some dwarf Cockscombs and *Adiantums* were also shown from the same garden. Mr. Woodbridge, The Gardens, Syon House, Brentford, had a plant of *Celosia compacta* Crimson Superb, an excellent form of close pyramidal habit, 2 feet high and flowering well from the base, the flowers being of an extremely rich crimson colour.

Messrs. W. & J. Brown, Stamford, sent a white *Lobelia* named White Emperor William, the flowers large and pure white; and Mr. J. S. Grimshaw, Leigham Cottage, Balham, also had a plant of *Lobelia purpurea* with brightly coloured flowers. Mr. G. F. Wilson, Weybridge, showed a cut stem of *Lilium speciosum album* bearing four expanded pure white flowers, and four or five buds. Messrs. H. Cannell & Son, Swanley, sent some large and handsome yellow and orange Marigolds. Messrs. Paul & Son, Cheshunt, exhibited a box of White Baroness Rose blooms, mostly of good form, white tinged with rose at the margins of the petals. A large group of *Tydas* and other Gesneraceous plants were shown from the Society's garden at Chiswick, including most of the forms described on another page.

First-class certificates were awarded to the following plants:—

Carnation Mary Morris.—A first-class certificate was awarded for this as a decorative variety to Mr. H. G. Smyth, 17A, Coal Yard, Drury Lane. It is a very floriferous variety, with large, full, even, blooms of a clear bright rose-pink hue.

Lilium speciosum var. Melpomene (Hovey).—This was shown by G. F. Wilson, Esq., Weybridge, who stated it was a seedling raised some time ago by Mr. C. M. Hovey of Boston, Mass., U.S. It has large flowers deeply coloured with rich rosy crimson, the edges of the petals being lighter or quite white.

Three exhibitors appeared in competition for the prizes offered by Mr. J. E. Ewing, Eaton, Norwich, for a collection of cut sprays of ornamental shrubs or trees, Mr. A. Harding, The Gardens, Orton Hall, Peterborough, securing the chief prize with a collection of fine specimens, chiefly of Conifers, including the following:—*P. Nordmanniana*, with nine large cones; *Torreya myristica*, with several of its peculiar globular fruits; *P. nobilis*, with three handsome cones; *P. lasiocarpa*, *P. amabilis*, *P. bracteata*, *P. grandis*, *Pinus Montezumæ*, *P. excelsa*, *Abies Morinda*, *Thujaopsis dolabrata*, and several *Thuias*.

Mr. J. W. Moorman, gardener to Miss Christy, Combe Bank, Kingston-on-Thames, was a close second with a diversified and creditable collection, which in the opinion of several visitors deserved a higher position. The sprays were placed in bottles, and appeared to much better advantage than the others which were simply laid upon the table. Some of the most noteworthy specimens were *Comptonia aspleniifolia*, *Berberis mucronata*, *Quercus palustris*, *Larix Kämpferi*, *Azara microphylla*, *Garrya elliptica*, *Pruminopitys elegans*, *Retinospora*

flicoides, and *Berberis japonica*. Mr. Hardie, Mayfield, Falkirk, was awarded a vote of thanks for a large collection of Conifers and miscellaneous shrubs and trees.

HARDY FRUIT GARDEN.

THE ground for fresh plantations of Strawberries should be prepared at once if not already done. Select ground in an open situation, manuring heavily and trenching as deeply as the soil will admit, for although the roots penetrate to a great depth under favourable conditions—a tendency that ought to be encouraged, as it enables the plants to better withstand the effects of dry hot weather, which so frequently proves injurious—yet to bring up much of the bad soil is not to increase its fertility, as until it becomes ameliorated by exposure and enriched by manuring it is positively injurious. The best plan to adopt when the good soil is shallow is to loosen the poor soil at the bottom of the trenches with a pick, and give a dressing of manure. The plants should be established in small pots or be carefully lifted from the ground, the soil well firmed about them, and a good watering be given, and repeated as necessary if the weather prove dry. Runners and weeds should be removed as they appear.

The Raspberry season being quite over the old bearing wood should be cut out, and the young canes thinned to four or six of the strongest and best placed, and to secure them against injury from wind in exposed situations they should be loosely tied to the stakes or trellises until they have completed their growth and well ripened the wood.

Some bushes of the Red Warrington Gooseberry or other late variety should be netted, and if there be bushes against a north wall the fruits will retain their flavour better than those in the open. Red and White Currants retain their flavour much longer, and Morello Cherries will keep good until October. They must, however, be netted to exclude birds, and if wasps and bluebottle flies are troublesome they must be excluded by hexagon netting.

Early Apples should be gathered before they become too ripe, or they will be mealy. The crop of these is unusually light, but we have on pyramids fair crops of Joanneting (white), Irish Peach, Devonshire Quarrenden, Worcester Pearmain, and Kerry Pippin; and of kitchen varieties Stirling Castle, Carlisle Codlin, Lord Suffield, and Ecklinville Seedling. Birds are often destructive to the softer-fleshed varieties, even before the fruit is nearly ripe, the only remedy being their exclusion by nets.

Apricots should have the protection of hexagon netting to exclude wasps and flies. The crop though light is of excellent quality. When the crop is all gathered examine the trees for any bare and attenuated spurs as well as long bare shoots, cutting them back to growth nearer the base or remove them altogether. Any dead or weak growth where crowded can be cut out, so as to give those remaining the full benefit of light and air to accelerate the ripening of the wood. Peaches and Nectarines will require looking over frequently for the regulation of the shoots, which are now growing rapidly, tying or nailing in the extensions; but the other shoots, those for next year's bearing, should as far as practicable be secured by twigs placed across the brauches or wires, or be otherwise kept close to the wall to prevent damage from wind, and to give them the benefit of the warmth afforded by the wall. To effect this the growths must not be allowed to become too crowded, and any foliage overhanging the fruit must be turned aside or be shortened. Trees with fruit swelling should be assisted with copious supplies of water in dry weather. Peaches and Nectarines, Figs, Plums, and Pears ripening on walls will need daily attention, such fruits not being allowed to fall from the trees, as the experienced eye will experience little difficulty in detecting the indications of maturity, and by gently raising or moving such fruit it will separate from the tree without difficulty. All ripe fruit should be handled with the greatest care, as the

slightest undue pressure or rough handling will inflict injury resulting in deterioration of quality and appearance, also speedy decay.

All wall trees must be examined frequently for the securing in position extensions, and checking the growth of laterals by stopping and removing superfluous growths. Morellos should have the shoots laid in similar to Peach trees. Espalier, pyramid, and bush trees will need timely attention in removing or stopping lateral and superfluous growths, which allowed to form unchecked at this season will accelerate root-growth and induce late growth unfavourable to the ripening of the wood and the plumping of the fruit buds.

FRUIT HOUSES.

Vines.—Late Vines started in March and assisted with fire heat in spring and summer in cold dull weather have the Grapes well advanced, and instead of having to keep the Vines excited by sharp firing, as is the case with those started late in the spring, atmospheric moisture may be gradually reduced, and well-ripened wood with highly finished Grapes will be secured with just sufficient artificial heat to keep up a circulation of dry warm air. Where, however, late Vines were not started until April the Grapes will only be commencing colouring, and will need artificial heat to maintain a minimum temperature of 70°, and 80° to 85° in the daytime, with an advance of 5° to 10° on bright days. A little air should be admitted constantly, and moisture kept from condensing on the berries by increasing the ventilation early in the day. To assist the swelling of the Grapes a good soaking of tepid liquid manure must be given the inside borders, and moderate air moisture be continued some time longer. Late Hamburgs will colour and ripen perfectly even if they do not begin to colour before the middle of September, but they will need a night temperature of 65°, and 75° by day artificially, with an advance from sun heat to 85° or 90°. In their case there must not be any lack of moisture in the inside borders, but the watering and damping should be done early, so as to allow of any superfluity passing off before night. Vines from which the Grapes have been cut should not be neglected, but have all laterals closely stopped and a dry warm atmosphere to insure the perfect ripening of the wood. Preserve the old foliage as long as possible, freeing it of any red spider or dust by an occasional syringing on fine evenings.

Figs.—The second crop on early forced trees will now or soon be all gathered, when attention must be directed to the maturation of the growths. Water must only be given to prevent the borders becoming dry, and syringing may be discontinued except for the purpose of keeping the trees free from insects. A free circulation of warm dry air should be maintained in the house until the foliage indicates signs of ripening and dies naturally. Trees that are crowded with wood should at once be well thinned, so as to admit the free action of sun, light, and air to perfect the growths retained.

Trees that afforded a crop of ripe Figs in June will now be furnishing another crop of ripe fruit, and should be encouraged by liberal supplies of tepid liquid manure, or, if the trees are too vigorous, clear water only should be given. The ripening of this crop will extend over a considerable time, during which a constant circulation of dry warm air should be secured.

Melons.—Accelerate the growth of young plants by closing early with plenty of sun heat, syringing at the same time. Shading in the case of healthy and robust plants may now be nearly, if not quite, dispensed with, and less atmospheric moisture will henceforth be needed. If the last batch of plants are weakly assist with weak liquid manure about twice a week; however, do not apply much stimulant until after the fruits are set, when earth up with a good compost. Continue to fertilise the female blossoms every day, maintaining a dry condition of the atmosphere and soil. Fruit ripening should have a warm dry atmosphere and but little water at the roots of the plants, but enough to keep the foliage from flagging. Secure a good sun heat in pits and frames by closing early, damping the foliage at the same time, and raise the fruit to the glass.

Cucumbers.—Plenty of moisture and liberal feeding, and close attention in stopping, thinning, and regulating the growths, are essential to success. A little fire heat should be turned on on cold nights, not allowing the temperature to fall below 65°, and maintain it at 70° to 75° in the day artificially, and 80° to 90° from sun heat.

Shade only to prevent flagging. Liberal attention must be given the autumn-fruiting plants just placed out, adding a little fresh soil as the roots advance, maintaining a firm condition of the bed. In pits and frames be careful not to overcrowd the foliage, removing all spotted and bad leaves.

PLANT HOUSES.

Orchids.—The weather becoming cooler and the sun less powerful the East India house must be kept moderately close. In dull weather less moisture will be needed, and recourse must be had to fire heat to maintain a temperature of 75° by day and 65° at night. The house should be damped and blocks, &c., syringed by three o'clock, withdrawing the shading as soon as all danger of the sun scorching the foliage is past. *Aerides*, *Phalænopsis*, *Saccolabiums*, and *Vandas* should receive every encouragement to growth, as any check will cause short leaf-growth and spoil the appearance of the plants. *Phalænopsis* grown in pots or baskets must not have the sphagnum made sodden, or the roots will perish and the leaves become diseased. Dispense with shading on the *Cattleya* house altogether, light being of the greatest importance for the proper ripening of all pseudo-bulbs. *Barkerias*, *Cattleyas*, *Dendrobiums*, *Epidendrums*, *Oncidiums*, and many others if not properly ripened will produce weak flowers, followed by a weakly growth. Vigorous *Cattleyas* frequently start a second growth before the first is completed, in which case the plant should be encouraged to complete its growth as soon as possible. As flowers are now becoming scarce, it is necessary to keep them free from damp so as to preserve them as long as possible, they being most affected when suspended too close to the glass. *Cattleya crispa*, *C. Harrisoni*, *C. labiata*, *C. maxima*, and the *guttata* type will flower from now up to October. *Calanthe Masuca* and *C. veratrifolia* may be repotted. If the soil has become sour they should be carefully shaken out, washing the roots in tepid water, and repot in a compost of equal parts of turfy loam and peat, adding a little decayed manure and pieces of charcoal about the size of nuts, all well mixed, giving about 2 inches of drainage, and the plants kept about an inch below the top of the pot.

THE BEE-KEEPER.

EFFECTS OF COLD AND THE CONSUMPTION OF FOOD.

How it comes that doctors differ in their opinion on points easily settled is a question rather difficult to answer. A few weeks ago I gave reasons, sound and substantial in my opinion, for differing from the views of Dr. Dzierzon on questions touching the power of the bee-keeper in prolonging the lives of queen bees, the power of queens over their own fertility, and what caused the loss of so many bees during the working season. On page 137 we have, through the kindness of Mr. Alfred Neighbour, the opinions of Dr. Dzierzon on other questions of importance. He says, "The milder the winter the more complete will be the repose of the bees, and the lower will they be able to allow the temperature to become even when they have their winter quarters, whilst increasing cold stimulates them to breathe more frequently and to consume more food; in other words, it stimulates their vital powers to greater activity in order to be able to offer the necessary resistance to cold in winter.

Theory and experience, as well as the last mild winter, demonstrate to me practically the fallacy of this opinion. Exposure of the bees to extreme cold certainly causes them to crowd together into as thick a cluster as possible, but it does not send them into a sleep-like state of repose; on the contrary, it startles them out of their rest, compelling them to hum more loudly, while previously they were in perfectly silent repose. Nor does severe cold prevent premature breeding. There is generally more brood to be found in the hive in January and February, when the weather is very cold or after the temperature has been very low, than during a continuance of mild weather. Dr. Krasieck acknowledges this fact, but explains it in a peculiar manner by saying, "that because bees consume more food when temperature is low the production of chyle would also be greater." All this and more than this seems to me to be no more than theory and speculation, and not supported by facts or experience.

My own experience, extending over a period of fifty years, and the experience of many practical and observing bee-keepers, go quite in an opposite direction, and prove that the colder the winter or weather is the less honey is consumed by bees, and this stands to reason as well as experience. In cold winters bees sit closely together for weeks and hardly move. There is in such seasons little waste and wear, and little food is required to make good the waste. In warm winters there may be heard a hum night and day in good hives—the bees set loosely together, move about amongst one another, and often take outdoor exercise. The waste of body is greater, and a greater quantity of food is required and eaten to make good the waste.

The last warm winter is referred to by Dr. Dzierzon in support of his new theory. English bee-keepers know that during the last open winter the consumption of food was great—unusually great, and hives were unusually light in the spring months of this year. That bees consume much more food in warm winters than they do in cold ones is a fact well known long ago, and every year's experience confirms it. This theory of Dr. Dzierzon reminds me of the strange notion of a Swiss clergyman, who boldly stated that two swarms of bees united do not eat more in winter than each of the swarms would do if kept separate. This was received as the truth by a large circle of apiarians, some of whom tried to explain it on scientific principles. Of course they failed, and when told years afterwards that ten thousand bees required twice as much food as five thousand, they believed this and said no more about the discovery of the Swiss clergyman.

If bees eat more food and breed sooner in a cold house and in a cold winter than they do in a warm house and winter, the system of contracting space in bar-framed hives cannot be too soon abandoned and condemned, and hives with cavity walls are quite a mistake if Dr. Dzierzon's views are correct.

In all attempts to manage bees successfully apiarians should try to keep step with the laws of Nature as nearly as possible. In Great Britain some winters are too severe for bees; in America almost all winters are. Where bees came from to this country I cannot tell, but evidently they are natives of a warmer climate than ours, and need often a little artificial treatment here—viz., protection from cold and wet, and need some feeding. By covering hives well during the winters no bee-keeper need be afraid of losing his hives in this country by frost, and if the coverings be kept on during the spring months his bees will breed sooner and faster than they would do in hives not so well and warmly covered. All this has been proved again and again, and let those of doubtful mind put the matter to the test next winter and spring, and they will lose all doubts on this point. But as we have stated, warmth and motion go hand in hand, and cause a greater consumption of food in hives to make up the wear and waste of motion. All this stands to reason, and reason will yet prevail.—A. PETTIGREW.

COMB FOUNDATION v. FEEDING BEES.

In your issue of the 17th inst., in an article referring to the autumn treatment of bees, Mr. Pettigrew makes the following suggestion:—"Let others try the experiment of putting two swarms separately into empty hives. Let one of the hives have 1 lb. of the brood foundation, and the other 10 lbs. of sugar made into syrup. Let all the syrup be given to the hive in seven days. Then examine both and see which is the better, which has most perfect comb, which the heavier of the two." According to my experience, if you were to give the hive with the 1 lb. of foundation 10 lbs. and the other 20 lbs. of sugar made into syrup, and then examine them at the end of seven days, I think you will find the one with 1 lb. of foundation to have the most perfect comb. On the 3rd of June last I had a large swarm, which I put into a 9-bar-frame hive with 6 inches of foundation to each frame. Three days afterwards, wishing to put in a Ligurian queen, I was surprised to see every foundation worked out into a perfect comb, and at the end of seven days every frame was filled. I have now a very strong stock of yellow bees, and there is scarcely a black one to be seen in the hive, although the swarm weighed 7½ lbs. I ought to have mentioned that the first and second night after swarming I gave them 1½ lb. of syrup, but none afterwards.—M.

BRITISH BEE-KEEPERS' ASSOCIATION.

We have much pleasure in publishing the prize list of the eighth annual Exhibition of this flourishing Association, held at the Royal Horticultural Society's Gardens at South Kensington on August 3rd, 4th, 5th, 7th, and 8th, and regret the delay which has arisen in consequence of the illness of our reporter, whose notes on the several classes shall appear in a future issue, together, we hope, with the class lists of the successful candidates for the diploma of the Associa-

tion (after two days' examination) as experts in bee-learning and manipulation for the various county associations affiliated to the parent society.

Class 1.—For best stock of Lignrian bees. First, Messrs. Neighbour & Son; second, T. B. Blow; third, G. Bertoli, Verallo-Sesia, Italy.

Class 2.—For the best stock of English bees. First, T. B. Blow; second, Messrs. Neighbour & Son.

Class 3.—For any other variety of bees. First, T. B. Blow, Carniolan; second, T. B. Blow, Cyprians; third, Messrs. Neighbour, Carniolan.

Class 4.—For the best observatory hive stocked with bees and queen. First, Messrs. Neighbour; second, H. Gibbons; third, T. B. Blow. Highly commended, Messrs. Abbott Brothers.

Class 5.—For the best moveable-comb hive complete for summer and winter use. First, F. Search; second, Messrs. Abbott; third, T. M. Hooker. Commended, A. Benthall.

Class 6.—For the best frame hive for general use, price limited to 15s. First, Messrs. Dines; second, J. Best; third, T. B. Blow. Commended, A. Blake.

Class 7.—For the best and cheapest frame hive for cottagers complete, price limited to 10s. 6d. First, Messrs. Dines, Maldon; second, A. Blake, Wickham Market; third, J. Best. Highly commended, Mr. Baldwin; commended, Messrs. Abbott Brothers.

Class 8.—For the best frame hive the work of an amateur or cottager. First, A. Benthall; second, J. S. Brooks; third, D. Stewart.

The three prizes in each of the above classes were:—First, silver medal; second, bronze medal; third, certificate.

Class 9.—For the best straw hive, price limited to 5s. Bronze medal. First, T. Sells. Highly commended, Messrs. Abbott Brothers.

Class 10.—For the neatest and best rack containing 1 lb. or 2 lb. sections. First, Messrs. Abbott Brothers; second, T. W. Cowan; third, A. Blacc.

Class 11.—For the best rack containing 1 lb. or 2 lb. sections for cottagers' use on a straw skep. First, T. B. Blow, Welwyn; second, T. B. Blow; third, Messrs. Abbott Brothers.

In classes 10 and 11 the prizes were silver and bronze medals and certificate.

Class 12.—For the best exhibition of super honey from one apiary; prizes, 40s., 20s., 10s. First, J. H. Brown; second, S. Thorne; third, R. Thorpe.

Class 13.—For the best super of honey; material, wood, straw, or glass in combination with either; 20s., 15s., 12s. 6d. First, H. S. Heath; second, J. Lighton; third, T. Sells.

Class 14.—For the best glass super of honey; 20s., 15s., 12s. 6d. First and third, W. Woodley; second, J. Lighton.

Class 15.—For the best twenty-four 2 lb. sections of comb honey 30s., 20s., 15s., 10s., 5s. First, J. H. Brown; second, T. Sells; third, S. Thorne; fourth, R. Thorpe; fifth, J. H. Brown.

Class 16.—For the best twenty-four 1-lb. sections of comb honey, 25s., 20s., 15s., 10s., 5s. First, A. Rusbridge; second, S. Thorne; third, J. Garratt; fourth, Rev. J. B. Hnmfrey; fifth, J. H. Brown.

Class 17.—For the best twelve 2-lb. sections of comb honey, 20s., 10s., 7s. 6d., 5s. First, Miss Gayton; second, R. Thorpe; third, J. H. Brown; fourth, A. Rusbridge.

Class 18.—For the best twelve 1-lb. sections of comb honey, 20s., 10s., 7s. 6d., 5s. First, J. W. Measures; second, Rev. A. Welch; third, S. Thorne; fourth, A. Rusbridge.

Class 19.—For the best twenty-four 2-lb. glass jars of extracted honey, 20s., 12s. 6d., 7s. 6d., 5s. First, K. Allen; equal third, J. H. Brown and R. Thorpe. Second and fourth withheld.

Class 20.—For the best twenty-four 1-lb. glass jars of extracted honey, 20s., 12s. 6d., 7s. 6d., 5s. First, Miss Gayton; second, R. Scott; third, J. Garratt; fourth, T. Sells.

COMB FOUNDATION.

Class 21.—For the best thick comb foundation, worker cells, not less than 2½ lbs., price per pound to be attached. Prize, bronze medal, Messrs. Abbott Bros. for Root's natural-based foundation.

Class 22.—For the best thin comb foundation for supers, not less than 2½ lbs., price per pound to be attached. Prize, bronze medal, Messrs. Abbott Bros. for natural-based.

Class 23.—For best, cheapest, simplest appliance for making comb foundation, to be exhibited at work. Three prizes—silver and bronze medals and certificate. Messrs. Abbott Bros. silver medal. Second and third withheld.

COTTAGERS' CLASSES.

Class 24.—For the best super of honey, sectional supers excepted. First, W. Woodley; second, J. Walton; fourth, E. C. Youens. Third withheld.

Class 25.—For the best twelve 2-lb. sections of comb honey, 20s., 15s., 10s., 5s. First, J. Walton; second, J. K. Filbee; third, G. B. Lacey. Fourth withheld.

Class 26.—For the best twelve 1-lb. sections of comb honey, 20s., 15s., 10s., 5s. First and second, W. Woodley; third, J. Walton; fourth, W. Martin.

Class 27.—For the best exhibition of extracted honey in twelve 2-lb. glass jars, 20s., 12s. 6d., 7s. 6d. First, M. Wood; second, J. K. Filbee; third, J. Walton.

Class 28.—For the best exhibition of extracted honey in twelve 1-lb. glass jars, 15s., 12s. 6d., 7s. 6d. First, M. Wood; second, G. Dossett; third, J. Walton. In the foreign and colonial classes, 29, 30, 31, and 32, there were no entries.

COMESTIBLES.

Class 33.—For the best mead, metheglin, &c., honey to be the principal ingredient, recipe attached, and to become the property of the Committee. Bronze medal and certificate. First and second, T. W. Cowan; highly commended, R. Scott.

MISCELLANEOUS.

Class 34.—For the best collection of hives, bee furniture, &c., no two articles to be alike. Silver and bronze medals and certificate. First, Messrs. Neighbour and Son; second, T. B. Blow; third, A. Rusbridge.

Class 35.—For the best honey-extractor. Silver and bronze medals and certificate. First, second, and third, T. W. Cowan.

Class 36.—For the best sample of beeswax, not less than 6 lbs., from exhibitor's own bees, 10s., 7s. 6d., 5s., 2s. 6d. First, S. J. Baldwin; second, T. Sells; third, Abbott Bros. Fourth withheld.

Class 37.—For the best and cheapest pair of honey jars, covers and fastenings complete, to contain 1 lb. and 2 lbs. each, 10s., 7s. 6d., 5s. First, T. W. Cowan; second, Abbott Bros.; third, Neighbour & Son.

Class 38.—For the best crate for conveying section honey by rail or otherwise. Silver and bronze medals and certificate. First, second, and third, T. W. Cowan.

Class 39.—For the best crate for conveying extracted honey in glass jars by

rail or otherwise. Silver and bronze medals and certificate. First, T. B. Blow; second and third, T. W. Cowan.

Class 40.—For any invention calculated to advance bee-culture. Silver or bronze medals, at the discretion of the Judges. First, T. W. Cowan, for his foundation-fixer; second, T. B. Blow, for a feeding bottle; extra second, F. Lyon, for Dr. Pine's removeable frame-ends; commended, T. W. Cowan, for foundation-fixer; commended, Captain R. N. Gilbert, for bee exhibition tent.

In Class 41, for microscopic slides illustrating natural history of the bee, no entry.

Class 42.—For the best display of dried British bee flora. Silver medal to Messrs. Abbott Bros.

In Class 43, for diagrams of honey bee, no entry.

DRIVING COMPETITION.

Class 45.—For the competitor who shall in the neatest, quickest, and most complete manner drive out the bees from a straw skep, and capture and exhibit the queen, 20s., 10s., 5s. First, J. K. Filbee; second, J. Walton; third, W. Martin.

TRADE CATALOGUES RECEIVED.

Louis Van Houtte, Ghent, Belgium.—*Catalogue of Azaleas, Rhododendrons, &c.*

F. C. Heinemann, Erfurt.—*Catalogue of Plants and Fruits.*

Barr & Son, 34, King Street, Covent Garden, London, W.C.—*List of Daffodils and Select Bulbs.*

J. Smith, Label Factory, Stratford-on-Avon.—*Illustrated List of Labels.*

James Veitch & Sons, King's Road, Chelsea.—*Catalogue of Bulbs (Illustrated).*

Thomas S. Ware, Hale Farm, Tottenham.—*A B C Bulb Guide and List of Hardy Perennials.*

B. S. Williams, Upper Holloway, London, N.—*General Bulb Catalogue.*

Dickson & Robinson, 12, Old Millgate, Manchester.—*Catalogue of Bulbs (Illustrated).*

** All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

TO CORRESPONDENTS.—In consequence of the above request (that matter for publication should not be addressed to Dr. Hogg or to anyone else on the staff of this paper) being so much disregarded, grave inconveniences frequently arise, and serious delay is caused in attending to matters that would be dealt with promptly and more satisfactorily if addressed to "the Editor." We earnestly desire that correspondents will conform strictly with our request in future, whether they are personal friends of any members of the staff or not.

A "Creeping" Fern (*Cranfordian*).—We have not received any specimen of the Creeping Fern which you ask us to name.

Violets in Frames (*C. R. W.*).—An article will shortly be published on this subject by a successful cultivator of these favourite flowers, which we think will give all the information you need.

Iconography of Azaleas (*E. L. R.*).—This work can be had from the address named, and at the price quoted in the advertisement which you have enclosed. It will make a beautiful volume. Ten numbers have been published. The first name you have employed in describing the Campanula is inaccurate.

Melons all the Year (*J. L.*).—You will not find it profitable to attempt to grow Melons as you propose, and you can devote your house to more useful purposes. You had better abandon your project, as if you attempt to carry it out the experiment will end in disappointment, while labour will be misapplied and fuel wasted. Water Melons are grown the same as other Melons, but are not so well worth growing as the best varieties in general cultivation.

Exhibiting Cut Flowers (*H. Harpenden*).—All the flowers you name are eligible for exhibiting in the class to which you direct our attention, as they are all herbaceous and usually grown for garden decoration. Some judges, however, might object to the *Eucomis*, regarding it as a greenhouse plant, and you had perhaps better try and make up the requisite number without it; still, according to the strict reading of the class it ought not to be excluded.

Pruning Fir Trees (*Susser*).—The present is a good time for shortening the branches for the purpose you have in view. It is not at all uncommon for the lower leaves of *Tropeolum speciosum* to wither when the plants commence flowering; but the tops do not usually wither if the plants have the requisite support. Although they need much water, it is possible to overwater them in adhesive and undrained soil. Perhaps the wind has injured the shoots.

Peas (*Perry Hill*).—It is impossible to determine the names of Peas from a pair of pods simply. You have not even stated the heights of the plants.

Perhaps No. 1 may be *Ne Plus Ultra*, and No. 2 resembles *Laxton's Supreme*; but we do not pledge ourselves to accuracy of these names, nor do we undertake to name such vegetables as Peas, Beans, and Potatoes.

Essay-Writing (*W. J. S.*).—If you are not in possession of botanical knowledge we fail to see how you can write an essay on the subject you name that would be creditable to yourself or convey sound and accurate information to your hearers. It would be a much safer course for you to write an essay on some practical subject that you understand, and leave scientific matters to scientific people. From these you might learn, but you cannot teach satisfactorily on a subject with which you are admittedly ill acquainted, and you would be sure to betray yourself if you made the attempt. Balfour's or Henfrey's "Manuals of Botany" if studied for a year might aid you in the preparation of such an essay as that to which you refer, as we presume you do not intend to simply copy from works and thus read an essay which would not be your own.

Ageratum (*Jack*).—We do not know an *Ageratum* having either yellow or buff-coloured flowers. There are varieties with white, flesh, and lavender-coloured flowers, some almost deepening to blue, and one variety has variegated foliage.

Removing Trees (*A Fourteen-years Subscriber*).—If you are neither a market gardener nor a nurseryman you cannot legally either remove or cut down trees, and it would be especially unwise for you to interfere with them after you have received notice to quit. Let them alone, or you may incur trouble that might prove serious.

Flanders Spinach (*C. R. L.*).—Some confusion exists in regard to the nomenclature of Spinach as sold by seedsmen. We have not a doubt that the seed you have obtained is suitable for sowing at the present time for affording a winter and spring supply of this wholesome vegetable. The true Flanders Spinach seed is more or less round, and the leaves are also roundish and very large. It is usually sown in the spring (like the ordinary round Spinach) for summer use, but is nevertheless hardy; but the prickly-seeded variety is more commonly sown in the autumn, and is undoubtedly suitable for that purpose. If the variety you have obtained is an improved form of this you may sow it with confidence. Possibly it is a selection of the firm from the Flanders Spinach, but we cannot tell in the absence of seeds and plants. The dictionaries you name are identical. There is a fourth edition of the "Vine Manual" published. We do not know of a better edition of the "Peach Pruner" than the one you possess. We cannot answer questions by post.

Exhibiting Cut Flowers (*J. N. F. W.*).—According to the strict interpretation of the wording of the class, which you quote, we think you can do what you suggest, but we should not think the plan advisable, as you would afford the judges an excuse for passing your stand in the case of close competition. Show each variety in a separate bunch. You can include two or three distinct varieties of Dahlias, Stocks, and Phloxes, and cannot be properly disqualified for doing so, as, if the authorities of the show regard distinct kinds of flowers, they should have said so, in which case you could only stage one bunch of Phloxes, one of Dahlias, and one of Stocks.

Pear Leaves Discoloured (*J. H. S.*).—The leaves arrived in a very dried state and partially crushed to powder. The Pear appears to have been attacked with the blister fly (*Tinea clerckella*), which is referred to in a reply to another correspondent, and also with the black fungus. Dissolve 3 ozs. of soft soap in a gallon of water, adding 1 or 2 ozs. of sulphur, and apply this at a temperature of 120° with a syringe, making both sides of the leaves quite wet. This will, we think, cleanse the foliage if used on three or four evenings consecutively. Are the roots of the tree working freely in good soil? The leaves sent are small and indicative of debility.

Various (*A. B.*).—Your young plants of *Iresine Herbistii* will not continue healthy if they are long subjected to a temperature of 35° or 36°. We have wintered them in a greenhouse, placing them at the warmest end where the temperature was usually about 45°, and seldom as low as 40°. Being stove plants they require more heat than *Pelargoniums* and *Verbenas*. You had better insert more cuttings than you require with the object of providing a margin for losses, which are almost sure to occur under the conditions you name. We do not cut the tops off *Carnations* when layering, and therefore do not recommend the practice. *Isolepis gracilis* is a miniature Sedge; it is a native of India, but succeeds well in a greenhouse, and is valuable for decorative purposes. The Tufted Hair Grass of this country is *Aira cæspitosa*. The annual of which you have sent flowers is *Kaulfussia amelloides*.

Duke of Buccleuch Grape (*F. J. M.*).—The above is the name of the Grape of which you have sent berries of average merit. The fruit is rather liable to be spotted, and the Vine does not always grow and bear well; we have, however, seen many healthy Vines and fine crops, the largest bunches being usually produced when the laterals have not been pruned very closely. It is essential that the growths be thinly disposed during the summer so as to insure the maturation of the wood, the Vine being somewhat succulent in its nature. Great care in ventilation is requisite during the season of growth, so that sudden transitions of temperature, and especially sharp draughts, are avoided, while the atmospheric moisture must be kept as equable as possible. It is a very fine Grape.

Caterpillars on Oaks (*Lady William*).—The appearance of the leaves proves that they have been attacked by the caterpillar of a small moth, very probably *Tinea onosinella*, or one of similar habit. This is just one of those instances where, owing to the caterpillar subsisting within the leaf hidden by a blotch or fold, applications are of little service, although some have advised that young Oaks which are likely to be attacked because they are near infested trees, should be copiously syringed with a soapy solution, or with one of the "compounds" now frequently employed. The best remedy is Nature's in this case—namely, small birds, which have been seen to split open the leaves and carry off the caterpillars, and should therefore be encouraged. We do not think, however, that the insect is so far detrimental as to endanger the life even of a young Oak, though the trees are seriously disfigured. The caterpillars may be less plentiful another year.

Applying Manure Water to Vines (*J. M. B.*).—Though your Vine leaves have done their work and the Vines are going to rest, the roots will remain active for some time yet; it will, therefore, not be wise to apply strong liquid manure to your border till the middle of November, or till the temperature of the border has fallen considerably and the roots are dormant. Should your border be the least dry, and the drainage as it ought to be, a thorough soaking of pure cold water given now and another in October will lower the temperature and also clear out any sourness, and prepare it for being manured by liquid applications. As there is "very little manure" in your border this may hardly be necessary for cleansing, but will do good. Six weeks before using the urine add to it three times its own bulk of water. Do not forget to supply lime.

Neglected Gooseberry Bushes (*A Suburban Amateur*).—If the bushes bear pretty well, as we presume they do (as you say you cannot easily gather the fruit from the centre), and are also healthy and make tolerably free growth, we should not do as you suggest, but should remove the suckers, using a spade if necessary for that purpose, and thin out the heads. But you must do this judiciously. If the bushes are really old and have not been pruned for some years, it is a mistake to prune them severely, as most of the inner branches are spurless and will remain so, the fruit being borne chiefly on the young wood. We should at once thin out the branches just sufficient for you to pass your hand between those remaining, not shortening the young shoots except for the purpose of rendering the bushes somewhat symmetrical. Old Gooseberry bushes often bear prodigiously on the young wood which is the reverse of luxuriant; indeed the finest crop we have seen this year was on bushes twenty years old, which are pruned but slightly and in the manner indicated. If you want large fruit you had better plant young trees.

Planting an Orchard House (*J. E.*).—We scarcely understand your case. We presume your house is a lean-to having a back wall 12 feet high. In our view the most profitable mode of planting such a house, 20 feet by 12, would be to make a good border the entire width of the house, and plant trees for covering the wall, parallel with, and a foot from it, having a trellised path for attending to the trees. On the opposite side of the walk we should have a trellis commencing at the front and arching over to the path, affixing it there at 3 feet from the border and the same distance from the wall. You would thus provide a trellis 9 feet wide, which, when covered, would not shade the trees on the wall. But, then, you ask if you "could plant two rows of trees (one on each side of the walk) trained to trellises across the border." This is what we cannot understand, nor do we think it is understandable without a rough ground plan of the house showing the position of the walk. We think a house so low in front and so narrow not well adapted for cross trellises, but in very large structures they can be very profitably employed. You also appear to want half a dozen trees in pots. To provide a suitable position for these we can only suggest that the trellis be 14 feet instead of 20 feet long; you would then have room for three or four trees in pots across each end. Another plan of occupying such a house is to have no trellis, but fill the house with trees in pots, covering also the back wall. This is a question of taste, cultural skill, and labour. The plan we first proposed would entail the least labour, and in all probability would result in the production of the greatest quantity of the finest fruit. Nor need this be had at the sacrifice of variety, as the trees, if desirable, can be grown as single cordons, planting them 20 inches apart along the foot of the wall and the front of the trellis. If you particularly desire cross trellises they should not be less than 4 feet apart, and they would probably answer fairly well.

Heliotropium peruvianum (*C. R. L.*).—The above is the name of the "old lilac Cherry Pie Heliotrope" to which you refer. It is a native of Peru and requires to be kept in a greenhouse during the winter, preferably where the temperature seldom falls below 40°, a minimum of 45° being better. Plants growing in flower beds do not what gardeners term "lift" well—that is, when taken up and potted most of them die. The best plan is to strike cuttings now by inserting short-jointed young shoots 3 inches long in sandy soil in pots, to be kept close, moist, and shaded in a frame until they are rooted, then removing them to a greenhouse. In a warm and light house healthy established plants continue flowering throughout the winter. There are many varieties of *Heliotropes* in cultivation, but none is sweeter and better adapted for winter flowering than the "old sort." *Miss Nightingale*, *Miss Lewington*, *White Queen*, and *Duchess of Edinburgh* may be named among other good varieties. For general information, concisely given, on fruit, flower, and vegetable culture, our "Garden Manual" would be useful, price 1s. 6d. Sutherland's "Hardy Herbaceous Plants," published by Blackwood, would also probably be of service to you. Every week you may derive sound information on a variety of subjects from our columns, and we answer questions that are submitted to us on all gardening matters.

Figs not Swelling (*L. J. K.*).—We are glad to learn you have been so generally successful with the fruit trees in your greenhouse. The reason why all the Figs did not swell is not easy to determine without an acquaintance with the condition of the trees and the circumstances under which they are grown. If the soil has been too dry on any particular occasion the growth of the fruit would be arrested, as it also would be if the soil were not kept fertile by top-dressings or applications of liquid manure. Again, if the growths were not stopped above the second crop all the fruit would not advance to maturity, and a portion would also cease swelling if the trees were overcrowded with growths and foliage. After a careful perusal of your letter we conclude that either the sap which has supported the embryo fruits has been appropriated by growths which should have been stopped, or that the soil has become impoverished. What we refer to as the fruit, and what is understood as such, is not the fruit, but the receptacle containing it. At the end an aperture forms, and usually opens before the young Figs attain half their full size; this, no doubt, is for the purpose of fertilisation, which cannot be effected if the flowers are sealed up. It is essential that the receptacles should open, and no doubt they have opened in those instances when the Figs have attained their full size and have ripened satisfactorily. You will find much that is interesting on the fertilisation of the Fig, with illustrations, in an issue of January 31st, 1878. If you do not possess this number it can be obtained from this office post free for 3½d.

Pear Tree Leaves Blistered (*Idem*).—The leaves you have sent have been attacked by the Pear Tree Blister Moth, *Tinea clerckella*. The caterpillars of this raise dark brown blisters on the leaves. The moth is active and minute, shining like pearly satin, the wings having an orange ground spotted with black and other colours. It appears in May. To check this disease it is advisable to wash the tree with soapsuds the end of May or beginning of June, when the moths are pairing and laying eggs for a future progeny; and if a very valuable tree be only partially attacked, the blistered leaves might be gathered and burnt as soon as any spots began to appear in August.

Burned Clay (*H. W.*).—The beneficial action of burned clay is mainly due to its altering the texture of the soil, and its application to heavy soils is attended with great success. It acts by rendering such soils less adhesive, consequently more permeable to air and water; and the clay in burning has its constituents changed so that the ashes contain a greater proportion of alkalies, more especially of soda and potash, than unburned clay, a considerable portion of the alkaline substances in the latter being liberated in the process of burning. Much, however, depends on the state of burning, for if the clay be exposed to a great heat it will be converted into a brick-like mass, and its alkaline substances be rendered less soluble than before, hence the burning should not be more than to cause it to readily crumble down. The best way to use it is to spread it over the surface and work it in by digging or trenching, so as to mix it with the soil to a depth of not more than 18 inches. The more thoroughly it is incorporated with the soil the better, and in no case should it be used in

layers. In the course of a few years more clay may be taken from beneath the ameliorated surface soil and burned, and more of the unburned clay brought up and mixed with the burned, so as to improve the texture and fertility of the soil by its increased depth.

Asphalt Walks (*Idem*).—To satisfactorily asphalt garden walks and carriage drives, a foundation should be formed of rubble, which for a walk should not be less than 3 inches thick, and for a drive not less than 6 inches, being coarser for the latter than the walk, and in each case the necessary incline should be given the surface of the rubble as will be required by the walk or drive, and at the sides should be at intervals drains with their covers and gratings to carry off the surface water. The rubble should be laid so that its surface will be about 5 inches below the level of the grass, or in the case of Box or other edgings it will need to be about 3 inches, so as to raise it when the asphalt is placed on to the level of the surrounding soil. Then take three parts ashes from a furnace with small clinkers, the whole being quite fine to form a smooth surface; to this add two parts old lime rubbish, but that is not necessary if the ashes be fine enough to absorb the tar. Place the materials in a heap, and mix with boiling coal tar until it is of a consistence similar to stiff mortar. Place on the rubble 3 inches thick and make it smooth, firming it well down, sprinkling fine gravel over it, pass a light roller over it, and in a few days it will be quite firm. Such walks or drives, however, are liable to become soft in hot weather and give off a disagreeable odour. The quantity of tar depends on the porosity of the ashes, and the cost varies proportionately, also depending upon the cost of material, &c., in different localities.

Fuchsias Unhealthy (*C. W.*).—Your plants are devoured with thrips. Dissolve 2 ozs. of soft soap in a gallon of water, and to this add a pint of strong tobacco water, and with this mixture syringe your plants every ten days. If the plants are small you had better dip them in the solution. If they are large lay them on their sides on a mat and drench them thoroughly. The mixture should be used at a temperature of 100° to 120°.

Hautbois Strawberry Culture (*W. M.*).—Make a fresh plantation in rich deep soil, taking well-rooted runners of the current year, planting them in rows 2 feet apart, and 18 inches from plant to plant. Next season do not remove the runners, but allow them to root between the rows, and after the crop is gathered and the runners well rooted out away the old plants, leaving the runners between the rows, keeping them to a row about a foot wide, manuring the space in autumn where the old plants have been growing. Alpine Strawberries may be planted now, but better plants are had from seed sown in gentle heat in spring, and the seedlings hardened off and planted out when ready. They will fruit in summer up to autumn; or seed sown now and the plants wintered in a frame, planting them out in spring, will give you earlier-fruited plants.

Names of Fruits (*G., Diss.*).—The striped Apple is Duchess of Oldenburgh, and the other Red Astrachan.

Names of Plants (*G. D.*).—*Centaurea suaveolens*, also known as the Sweet Sultan. (*T. F. L.*).—7, *Pteris serrulata cristata*; 9, *Adiantum trapeziforme*; 10, *Pteris erecta*; 12, *Adiantum concinnum*; 13, *Pteris longifolia*; 15, *Gleichenia pectinata*. We have repeatedly stated that we do not undertake to name more than six specimens at a time, and, moreover, the majority of those you sent were very unsatisfactory, nearly all the fronds being without spores. (*H. H.*).—1, *Solidago Virgaurea*; 2, *Reseda lutea*; 3, *Euphorbia helioscopia*; 4, Specimen insufficient; 5, *Galium aparine*. Notcutt's "Handbook of British Plants," published at this office, price 3s. 6d., post free 3s. 8d., would suit you. (*R. H.*).—1, *Lysimachia vulgaris*; 2, *Polygonum aviculare*; 3, insufficient; 4, *Lapsana communis*; 5, *Achillea millefolium*; 6, *Silene maritima*.

Standard Frame Hives (*Inquirer*).—At a meeting of the British Bee-keepers' Association, held on February 15th, 1881, it was unanimously resolved that the outside dimensions of the standard frame should be 14 inches long, 8½ inches deep; the top bar to be three-eighths of an inch thick, bottom bar one-eighth of an inch thick; side bars a quarter of an inch thick. These dimensions do not refer to anything outside of the rectangle. It was also resolved that standard frames duly stamped should be provided at 1s. each. Frames are usually made seven-eighths of an inch wide, five-eighths of an inch being allowed between them. Seasoned deal is suitable wood for bar-frame hives. Our Bee-keeping Manual, post free 4½d., and "Modern Bee-keeping," price 6d. (Longmans, Green & Co.), would be useful to you if you do not possess them; they were both, however, published anterior to the decision referred to.

COVENT GARDEN MARKET.—AUGUST 23RD.

A GOOD supply of Peaches reaching the market, but owing to the slackness of trade realising very low prices. Large quantities of French fruit still arriving.

POULTRY AND PIGEON CHRONICLE.

BREEDING HUNTERS AND ROADSTERS.

THIS is a subject which will certainly repay the home farmer and agriculturist for any attention he may devote to it. Under present circumstances connected with the occupation of land, products of various kinds which were formerly found profitable have lately proved the reverse; in consequence the landed proprietors who may have land on hand instead of being occupied by tenants will do well to carefully consider what will sell best in the market, and at the same time prove well adapted to the soil and climate on which the farm may be situated. To some gentlemen proprietors the breeding of horses adapted for hunting and as roadsters will form an interesting employment, and may also be made profitable as a farming transaction if proper attention is given to it. This subject requires to be considered in its economical as well as its scientific and practical bearings; yet it is a fact that no amount of foresight and skill will enable the breeder of hunting horses, &c., to obtain his chief object with more than a fair proportion of his produce. Therefore, in order that the breeder may realise a fair profit the average horse must pay its expenses, and in aiming to produce a horse of such a stamp as will realise the highest price for hunting purposes the breeder is operating on the safe side, and in the way most likely to exclude the chances of failure, simply in consequence of the animal which just misses the character of the best class of hunter is of a style which is available for general purposes.

When breeding is conducted upon this principle the style or type specially sought after should be that of the grand weight-carrying hunter. To explain what is understood by the term "hunter" it will be necessary to consider the character of English horses, the different breeds or classes into which they may be divided, and also into the history and progress of the race. The hunter has never constituted a distinct breed; in that respect he differs entirely from the pure blood horse, whose genealogy has alone obtained a reliable record. The long-established renown of the English and Irish hunter has depended, and must always depend, on the judicious crossing of breeds, and to which we have alluded in an article in this Journal under the heading of "Cross-breeding of Horses," in the numbers dated the 16th, 23rd, and 30th of March last, and for various and important statements relating thereto we refer our readers. But upon this occasion we propose to give some quotations from the prize essay on the subject of "Breeding of Hunters and Roadsters," written by J. Gamgee, sen., and published in the Journal of the Royal Agricultural Society of England in 1863. This essay is the best we have seen upon the subject, and contains a combination of ideas and statements which are not only eminently scientific but thoroughly practical.

It is surprising that the value and importance in the rearing of hunters, as they may be called the popular horse amongst the country gentlemen and various members of the middle classes of society, has not resulted in an attempt to form and maintain a general stud book in the same way that it has been for the blood horse during a long period. Difficulty is a word which frequently stands in the way of new measures relating to various matters in practical everyday life, but the way was never so plain and easy of accomplishment for establishing a register or stud book as at present. It is important to consider that the Royal Agricultural

Society of England, the Royal Highland Agricultural Society of Scotland, and similar institutions in Ireland, may be made to furnish the basis of an example by taking and selecting carefully the names, and as far as possible the pedigrees, of those animals which for years past have obtained the approval of the Judges, and to which the prizes have been awarded by the principal agricultural societies throughout the kingdom in the hunter classes.

Upon this matter Mr. Gamgee shall speak for himself. He states—"The example set in the establishing of herd books, and registrations of the produce of greyhounds and other dogs, encourages me to think that the difficulty in the more important case of the horse is more imaginary than real. Indeed, the longer period during which the horse lives and continues to propagate, and the relative slowness with which changes are effected in the race, render registration in their case more easy as well as more imperative. If the question be raised, How shall we get a satisfactory starting point? our past history will give the best answer. With the increased demand for exportation of the finest mares the difficulty increases of supplying their places, and even producing stallions of their class; indeed, the course of events leads rather to total dispersion than to mere deterioration or numerical scarcity. Though I submit that good blood stallions are alone reliable for the production of hunters, and that the mares should also be closely up to the required standard for speed, and whilst power and stamina should form the leading features in their character, I am in no way inclined to dogmatise on the exact amount of pure blood which affords the best promise of combining all the essentials in the clever hunter."

These observations contain one of the strongest arguments that can be used for the registration of hunters by a stud book; for whilst so many of our best class of hunting mares are exported to other countries and realise long prices, the object of the stud book may be said to be doubly beneficial, not only in maintaining by selection and pedigree the most valuable animals, but at the same time is calculated to maintain a high value and paying price to those who engage in the breeding, rearing, and feeding of choice hunters.

In another passage Mr. Gamgee says—"Greater changes have been made in the breeding and management of horses in England during the last fifty years than in any similar period on record. Few good judges, and especially among those who can remember longest, see reason for congratulation on comparing the present with the past, particularly with reference to the hunter and the high-class hack and carriage horse. Meanwhile, in those animals which multiply more rapidly—such as dogs, pigs, fowls, and even sheep—great changes have been effected by individual enterprise in a few years; whilst the horse, the favourite of princes and nobles, appears to require to be specially fostered by the patronage of the great, or by union and concert among the many."

These observations point in one direction; but on various estates the practical carrying-out of the management, however it may be supervised by noblemen and gentlemen, devolves very frequently upon the home farmer or agent. In order that not only the objects of proprietors may be followed out, but that in doing so the home farmer must look to profits; for although the breeding and parentage of the animals bred may be the result of correct principles, yet the profits of breeding cannot be fully attained without especial care and management in rearing the young animals as well as the mares in foal, for with care useful horses may be reared from indifferent stock, whilst without it the produce, though well descended, will not be worth their cost. In feeding young stock extremes should be guarded against. Liberal keep on sound grass, with corn and hay in moderation, proves the most economical, for when more food be given than the system can assimilate stout and fat animals of great bulk will be produced at the expense of strength and stamina, and the digestive organs frequently injured. Still, liberality in feeding must be the order of the day if we design to apply early maturity to horses as well as cattle, and we certainly contend that it should be so; for as regards profit, with special care and freedom from accident, which are the points of management in the hands of the home farmer, there is no better period of selling the off-going stock than at a little over two years old. To accomplish this certain rules apply in connection with exercise, shelter, and warmth. For the first, space and liberty combined with security are most essential. With respect to temperature, it may not be desirable for young animals that it should be specially equalised. It must be admitted that wet and cold are uncongenial to horses, and voluntary shelter for them should be available at all times. Not only should young horses be properly cared for in feeding, but they should have protection from rain, and they will know when to

seek it; and when they have a dry surface under foot in their yards and pastures, with space for voluntary exercise, the usual temperature of our winter months will not prove injurious to them. Although horses in a roomy paddock if well fenced do not suffer from a shower in summer, but long exposure to rain in confined spaces is injurious to them, and to guard against this shelter sheds in connection with their paddocks are desirable, and it is also essential that their sheds should have a north-west aspect to afford shade and protection from the sun and flies, as these always follow the sunlight.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—There is much work now, especially in connection with the use of the mowing, reaping, and binding machines, and in consequence it is best to use two horses at a time, but in relays, whereby each pair may work about five hours, but may be afterwards used during the day in any light tillage or carting corn or hay. Although it is frequently the case on some farms, it is bad policy to allow the horses to be idle during the early part of the harvest period, and it is too frequently the case that they are turned out to graze, and the carters and teamsmen put to assist in cutting the crops both of corn and second cutting of Clover for hay. In our opinion, however, nothing can justify such a proceeding, for even where hands are scarce reaping and binding machines can be hired in almost every part of the kingdom. We still advocate making corn ricks round, as they take less thatch and are less likely to be torn by the wind. At the same time we advise their being placed in the field where the crop is grown, unless the field happens to be near any buildings or premises where the ricks are usually placed for certain convenient purposes, such as having the straw and haulm which may be required as cattle fodder near to the yards where the cattle may be wintered. It is now time to consider the extent of autumn tillage necessary to be done; and in those cases where fallows are required to be made or partially made before Wheat-sowing commences, the home farmer should ascertain whether his animal power is sufficient for purposes of seeding for the fodder crops, such as Rye, Trifolium, and Vetches. We recently saw a sample of black winter Barley, which we previously thought had been banished the country; and we take this occasion to say that we first introduced this for early spring food for sheep or to cut up as green fodder in 1827. We found it produce fodder earlier than Rye with a much larger and more succulent stem and broader leaf, and as it originally came from Russia it will the better stand against any severe weather likely to happen in this country.

We will now refer to a plan of supplementing the horse power of the farm in the absence of steam, which we advocate for effecting with certainty the autumn fallowing during the harvest and subsequently. We recommend that oxen be used—strong animals three years old broken-in to work before purchase—either Herefords, Sussex, or Devons, which in our opinion are valuable as we have placed them, Herefords being more so than the others. For every hundred acres of arable land the farm may contain we would purchase on the approach of harvest three oxen, and continue them in work whenever the weather is favourable, using the scarifier and plough for raftering during the whole time of harvest and until the sowing of Wheat commences, up to which time the horses of the farm, having assisted the oxen in autumn tillage, the work will be in a forward state. The oxen will then assist the horses in helping forward the Wheat-seeding. After the Wheat-sowing has been completed the oxen and horses join in fallow-ploughing all the land intended for roots the following season. The work of the farm will then be sufficiently forward to dispense with the services of one horse for every hundred acres, or in other words to employ three horses instead of four. The result will be, that except under steam cultivation the land will be more forward than by any other means, and done at a less cost than by employing the usual number of horses during the year. The accounts will then stand as follows:—Three oxen for four months will cost the same in feeding as one horse for the twelve months, and when kept in this liberal manner they will each increase in value £1 during the four months, whereas the horse during the twelve months would have lost in value £3 3s. The advantages resulting from this mode of proceeding are obvious. The root land will be all tilled in the autumn and done at less cost; when the oxen have done work they will be found in improved condition, will be accustomed to the climate, and will be valuable to put into the boxes to fatten off at the end of twenty-one weeks from the time of completing the work assigned them. The odd horse or mule employed on the farm should be daily employed during the harvest in carting Clover and other green fodder for the horses and cattle of every kind requiring it, and in some cases the dairy cows, without interfering at all with any harvest operations, so that all the men and horses besides the odd one may be engaged in harvest work entirely until completed.

Hand Labour.—As soon as any men can be spared the Swedish Turnips, as well as the common Turnips, will then require another hoeing, and the late crops horse-hoeing and singling; some men will be also employed in attending the threshing machine if any Wheat or white Oats, &c., are required for immediate sale or for use on the farm.

Live Stock.—There is now abundance of food for the breeding ewes of any kind; and as the season for mating them is arrived they will now, whether of the short-woolled or long-woolled breeds, keep com-

pany with the ram which is in good time. We approve of crossing the long-woolled ewes with short-woolled rams, and *vice versa*, if the lambs resulting from the cross are to be sold as fat lambs; in fact, the Dorset horned ram is often used with advantage when mated with long-woolled ewes, as the number of twins is sure to be great, and the lambs for fattening are most approved by the butcher, the wool being short. Sheep are at present extremely dear, and will scarcely pay for the outlay of cake and corn-feeding in addition to that of hay and roots; in fact, we advise the home farmer to try the experiment by keeping a short stock for fattening, in order that some part of a crop of roots may be passed through an old cutter, greens and all, then spread and ploughed in. When the land is afterwards all sown with drege or Barley let him note the result next harvest, and we will engage that the corn will be stouter where the roots had been ploughed in than where they were fed off by sheep eating cake, hay, and roots. The dairy cows now should have Clover or any green fodder supplied to them in their racks morning and evening, as the pastures are becoming stale and short of grass, especially where they have been grazed all the summer. Breeding sows may now be fed with green fodder with advantage, as they will then eat a few Beans or Peas with avidity, which will maintain them in good condition.

BARLEY "BIGG."

A LADY submits to me some specimens of diseased Barley "Bigg," with the following information:—"It is often produced in branched stalks on one plant. The straw is like wire; the ears are erect when ripe. It will not grind up into meal, but into heavy chips. No animals will eat it. Donkeys and pigs refuse it when prepared for them." I cannot give a satisfactory reply, and therefore beg to ask your information through the medium of the *Journal of Horticulture*. Barley "Bigg" was given me as the name of the disease, but I rather take that to be the name of the variety.—L.

[The sample of winter Barley enclosed is not ripe, and the grain is therefore unusually thin; it is, however, never a full grain, like malting Barley. It is not a diseased sample. There are two varieties of winter Barley, as we call it, one being a white grain, and called "Bere;" the other a black grain, and called "Bigg." These kinds of grain are of Russian origin, and in certain districts are made into bread for peasant classes of the people. The white variety is imported into this country largely, and is used for meal purposes; but it makes light and coarse meal. In this country it is grown by itself, like Rye, for green fodder purposes. When required for meal it should stand to be dead ripe, and then the beard and husk will be broken off by threshing and hummelling, the grain will then make useful meal for feeding pigs, poultry, &c. If given to other animals it should be used after being broken and mixed with hay chaff; but for fattening sheep and cattle, or for milch cows, the meal should be mixed with cut roots. If further and full information should be required it will be found in the *Journal of Horticulture*, Oct. 16th, 1879. The straw is valuable for thatching, and is very durable.]

POULTRY NOTES.

WE have before us the schedule of the Poultry Show in connection with the Dairy Show, to be held on October 3rd to 6th. It is a great improvement that it is now held within a week, and does not, as formerly, extend over a Sunday. There seems little alteration in the classes from last year. Entry fees for the general public are the same as at the Crystal Palace, but there is a reduction for members of the "British Dairy Farmers' Association."

THE Committee of the Wolverhampton Show are to be congratulated upon having changed their date for the coming season from February to October. Their schedule is not yet in our hands, but if it be on its usual liberal scale it can hardly fail to bring a large entry of chickens at its altered date.

A THIRD show of poultry and Pigeons will be held at Newnham-on-Severn on September 21st. The former shows have had wonderful entries considering the modest dimensions of the schedule. As before, Mr. O. E. Cresswell will judge both poultry and Pigeons.

WE think it right to warn our readers against sending any of their superfluous feathered stock to unknown applicants in Ireland just at present. Several curious instances have come to our knowledge in which people, apparently ladies and gentlemen of

some position, have got pens of valuable birds from English exhibitors without prepayment. Payment does not follow, and the law, or it may be its present abeyance, seems unable to extract it.

WE should remind our Pigeon-fancying readers that the time has now fully come at which pairs of valuable Pigeons must be separated if they are required for autumn exhibitions. Where some less good stock is kept the last eggs of the better birds may be transferred to them, but where there are none such these had far better be sacrificed than the parents allowed to go on breeding through the moult.

IT must not be forgotten that sun is very detrimental to the colours of Pigeons in the moult. The better, however, the colour of the bird the less susceptible is it of harm from this source. Pigeons with an inclination to unsoundness of colour are quite spoilt by exposure.

THE multitude of poultry schedules which the post brings us just now makes it quite an embarrassing task to make our selection. For those who, ambitious of early success in the show pen, we may give a hint that it is far better to send their favourites where there are separate classes for both sexes, than in pairs.—C.

THE WARWICK FRAUDS.—I was much pleased to read "A. C.'s." communication to your pages of August 4th to the effect that the Warwick swindlers have been brought to justice. His suggestion that the vigilance and promptitude of Sergeant Hall are worthy of recognition is an excellent one. I for one shall be glad to subscribe 5s. towards this object—viz., a quarter of the entry fees which I was incautious enough to send, provided that I recover them.—O. ERNEST CRESSWELL.

OUR LETTER BOX.

White Leghorns as Layers (*C. R.*).—These birds have the reputation of being good layers, but, as in most other varieties, laying has been in many cases sacrificed to the production of fancy points. If you can get some of a family which has not been bred for exhibition they will probably answer your purpose. Their combs are single and their legs yellow and free from feathers. We have recently heard very favourable accounts of the laying qualities of a cross between Spanish and Black Hamburgs. Leghorn-Brahmas also lay well as a rule. Crosses very frequently bring out latent laying qualities which have been lost in the pure breeds through too fine breeding.

Cutting Beans (*D. O. P.*).—The best time for cutting is when the eye of the corn is turned black, the haulm being but little guide, as that will often be comparatively green, although the beans will be matured sufficiently. As, however, winter beans, particularly after a severe winter, grow very short, and are often podded close to the ground, we prefer to pull them by hand, and after being tied the sheaves stand several inches more above ground. The early cutting is of the utmost importance, because they will then take showery weather without the shedding of the corn by the shrinking and opening of the pods. In tying the sheaves we prefer tying with yarn, as the straw bonds do not answer all the purposes, as they are apt to break in stacking or in hauling to the machine at thrashing time. Formerly, instead of tying into sheaves at the time of cutting, it was the practice to set them up in loose state, tying the tops with a wisp of straw, and when dry then to tie into sheaves for stacking.

REMARKS.

13th.—Dull cloudy morning; fair afternoon, with occasional glimpses of sunshine.
 14th.—On the whole fine and bright, but occasional thunder and sprinkles of rain in the morning.
 15th.—A cloudy showery day, but with some bright sunshine.
 16th.—Rain in early morning, and a heavy shower at 1 P.M., but the day was on the whole fine and fairly bright.
 17th.—Wet early, dull cloudy day.
 18th.—Dull day, drizzle in afternoon; fine evening.
 19th.—Dull morning, slight shower about midday; dull afternoon and evening.
 Weather during the week dull and unsettled, but the amount of rain was inconsiderable. Barometer readings about one-third of an inch above the preceding week. Mean temperature rather above the average, and almost identical with that of the preceding week.—G. J. SYMONS.

THE ROSE SEASON OF 1882.

ACCORDING to my usual custom, now that the Rose season (so eagerly looked forward to and so variously estimated as to its probable character) has come to its close—for although a few good blooms may be gathered during September, yet nothing is likely to be gained then as an addition to our information, or what can in any way alter our estimate of the season—I now offer a few notes of a general character on matters of interest to all growers of the Rose.

With regard to the season itself, various conjectures were made from time to time which differed widely from one another, but the most general opinion with regard to it was that it would be a very early and a very short season; that the unusually mild winter had stimulated growth; that buds were formed in March, and we were commonly told that if we altered the date of our Rose shows and made them about a fortnight earlier we should be about right. In dissenting from this I stated that allowance was not made for what has proved an almost infallible visitor, a cold wave which comes over us in May or June. It came this year as usual, and the coldest June that we have had, I believe, for some years proved how useless it is to conjecture on this point. Buds remained *in statu quo* for weeks, and as a consequence there were very few districts where Roses were so very much earlier than usual. Show after show was held, and at all of them one heard the statement, "My Roses are not yet in flower." I have had many letters since they finished, in which the writers said, "I could cut better now than when our show was held." For the same reason, although Roses were as a general rule good, I do not think it can be said to have been exactly a good Rose season. The earlier buds were, too many of them, hard and green-eyed, owing to the cold weather to which I have alluded; and then as the exhibition season came on a great deal of wet weather marred the character of the blooms, and interfered with the hopes of the managers, although of those which I attended the greater portion were held on fine days. As with our fruits and cereals, we have not had for some years a thoroughly good Rose season; in many respects this has been better than its predecessors, but still not what we hope yet to see. It was, moreover, a very long season; trees did not all come into bloom together. Mr. Whitwell, who won the National Society's challenge trophy on July 4th, also took first prize for thirty-six at Newcastle on July 24th, defeating some of our largest nurserymen. I mention this as an example, because he has comparatively few trees, and because at that very time he said that he had fully a hundred plants that had not shown a

flower even then. Well, this is a great matter; we like to have good Roses, and we like to have them for a long time. A very hot season would doubtless prevent this, and therefore we may be contented, I think, with that through which we have passed.

That this year has witnessed a still further increase in the popularity of the Rose cannot be questioned. I have, perhaps, as good opportunities of knowing this as most people. As Secretary of the National Rose Society I am brought into contact with people in all parts of the country. I see the eagerness with which the exhibitions are looked forward to. I see also how at all of them there is an increase in the number of exhibitors. I see new Rose shows springing into existence like Minerva, full grown, and with an appearance of vitality which cannot be mistaken; and I see, moreover, the great increase both in the number of growers for sale, and also in the quantities grown. It is no uncommon thing to go into nurseries now where a quarter and sometimes half a million of stocks are prepared for budding. I know of nurserymen sending on all sides for buds, not having sufficient of their own for their own use. Now all these things are evidences of popularity. It shows that, multiply Roses as we may, the demand keeps pace with the supply—indeed, the more liberal the supply the greater seems to be the demand, and this not because of diminution of price, for in many cases, owing to the severity of the last two winters and the consequent losses, prices had to be raised.

As usual every year reputations are lost and won, both amongst exhibitors and flowers. With regard to exhibitors we have had some remarkable examples of success. The retirement of Mr. Jowitt permanently, and of Mr. R. G. N. Baker temporarily, gave hopes to Rose-growers which they might not otherwise have entertained. The possessors of such big battalions, combined with their skill and experience, made them such formidable exhibitors that in the large classes we naturally looked to see one or other of them occupying the chief places. It may seem invidious to single out any who have come forward as very successful exhibitors, but I think that Mr. Whitwell has proved himself a very successful grower, and has shown well in the large classes from only a thousand plants. Anyone who saw the careful manner in which his blooms were set up would be at once ready to acknowledge that he had taken a leading position as a grower and exhibitor. Then there was our worthy Vice-President, Mr. Baker of Reigate, whose modesty has kept him too much in the background. We who had known his flowers had always said that he was quite able to take a leading position if he would only believe it. He took heart of grace this year, and his success was a proof of the correctness of his friends' judgment, and I foresee that we may look forward to still greater triumphs. Then both Mr. Slaughter of Horsham and Mr. Grant of Ledbury have come forward as thoroughly good exhibitors, while amongst Tea Roses Mr. Davies of Aynhoe has shown what can be done by an amateur in this lovely class. Amongst the smaller exhibitors the most remarkable success has been achieved by Mr. G. Mount of Canterbury in a series of triumphs, which I look upon, considering the number of his trees, as unparalleled; but of this I hope to write more at some future time. Nor must I forget my worthy Co-Secretary Mr. Mawley, who has again from his small villa garden done wonders; while he has set an example to exhibitors by the

neatness with which he has set up his flowers, the fronds of Maidenhair laid on the moss giving them a most pleasing appearance. Other exhibitors will, of course, occur to many, such as Messrs. Hall, Hawtrey, Biron, &c.; but these have already made their mark. I am writing simply of those who have this year made their running, so as to entitle them to high commendation for their prowess.

And now with regard to Roses themselves. The most noticeable feature to my mind is the very great increase in the number of exhibits of Tea Roses, especially amongst amateurs. This I attribute in a great measure to the conviction which has forced itself on the minds of growers, that the supposed tenderness of this beautiful class was a myth; that they were within the compass of any amateur, at any rate south of the Trent, while their exquisite loveliness and the length of time they continue in bloom were passports to favour. Nor could I be sufficiently thankful that the National Rose Society had so determinately set its face against Hybrid Teas being included amongst them. The exquisite refinement of the stands would have been marred, for which the gain of colour would not have compensated—indeed, we are getting high colour amongst the pure Teas. I have seen at Mr. Cant's blooms of Madame Lambard which were of a very deep shade of rosy crimson, and we shall probably see more of these as time goes on. The greatest gain in this class has been Madame Angèle Jacquier, although Etoile de Lyon is considered to be the "topper." It has not, however, been exhibited anywhere, and therefore we have only hearsay evidence as to its merits, but that is so general that we cannot doubt its value. There is another new Rose which seems as if it would be likely to make its way, Rosicriste Jacobs, but then it may be like a great many others, afterwards found to be of little use; at present it appears to be like a vigorous Xavier Olibo. The dearth of new English-raised Roses is remarkable. Although prizes were offered at each of the National Rose Society's exhibitions for a new Rose it was not in any of the three shows awarded; but I am inclined to think that if "Her Majesty" had been exhibited in good condition at Bath it would have attained the honour. It is apparently a fine large Rose of the Capitaine Christy type, but as shown there it was decidedly confused. Of the Roses of three years ago A. K. Williams and Madame Gabriel Luizet have maintained their character, but it is unfortunate that the latter is as essentially a summer Rose as Coupe d'Hébé. I have seen a large number of plants, but I never saw a second bloom on any one of them. I think, perhaps, that the reason of this scarcity is greatly owing to the fact that raisers are more particular as to the flowers they send out. I know of two instances—one in which the £5 prize of the National Rose Society was awarded, and another in which a first-class certificate was obtained, but in both of which more mature consideration of their merits have induced the raisers not to send them out. This is as it should be, and will certainly add considerably to the value of any Rose these raisers may hereafter think fit to distribute.

It would hardly be expected that I should close this rapid survey of the Rose season without reference to the National Rose Society. Its career this year has been one of undoubted success. All its three exhibitions have been most encouraging, and happily on all three fine weather prevailed. Of that at South Kensington it may be safely said that no such exhibition of the Rose was ever held. We have fondly looked back on that at St. James's Hall as its first and best, but I have no hesitation in saying that if the Roses shown on that occasion had been placed in the arcades of South Kensington we should have said what a small exhibition it was; and as to attendance, I was informed by one of the officials there that it had been many a year since so large a number of people were present. Those at Bath and Darlington were also largely patronised. We must not forget, too, the publication of the Society's catalogue, which has been well spoken of in all quarters, and which cannot fail to exercise considerable influence on future exhibitions and on the demand for Roses. Nor is there any diminution in the interest which centres in the Rose; orders are accumulating on the growers. The success which has attended exhibitors leads to still further growth, and I think we may confidently expect that another season, if

we are spared to see it, will show a still further advance.—
D., Deal.

WINTER CUCUMBERS.

WHEN writing upon most horticultural topics it is often with the motive, expressed or implied, of advocating the more extended culture of the subject in hand, but I should not think of persuading anyone to commence cultivating Cucumbers in the winter unless there were a demand for them and a suitable structure provided for their growth. In the first place, to grow winter Cucumbers successfully a light and well-heated house is absolutely necessary, as they require abundance of both top and bottom heat and air on all favourable occasions. Neither should the young plants be cropped early in the season, and for this reason any old plants now in full bearing in a house or heated pit ought to be encouraged to continue fruiting till late in November. This they will do if at the present time the growth is thinned out, the crop materially lightened, a top-dressing of rough turfy loam and manure from an old Mushroom bed, and occasional supplies of clear liquid manure be given. This, however, will be of no avail if the plants are infested with either thrips, aphids, or red spider, and these must be destroyed. The safest and most effective destroyer of the two former is fumigation on two successive evenings with tobacco paper, while the latter may be checked by syringing freely with clear water when the house is closed, say at about 2 P.M.; and if the hot-water pipes are painted with flowers of sulphur mixed with milk, and then heated to about 130°, this will also prove an effective destroyer of red spider.

In providing plants for winter no time should be lost in raising them; in fact it will be well if they are already established in pots. Growers prefer to strike cuttings for the winter supply, but if these prove more fruitful in the first instance, which I do not admit, they are seldom equal to the seedlings either for robustness or duration of cropping, and, besides, are apt to be attacked with some kind of insect pest. If the present supply of Cucumbers is being taken from frames or pits, these plants will be useless for late bearing; and a few should, therefore, be grown in pots or as supernumeraries to give a few fruits during part of October and November, which will enable the permanent plants to become strong and better able to bear the strain of continuous cropping than they otherwise would be.

We find Telegraph and All-the-Year-Round well adapted for winter culture, but this season Pettigrew's Cardiff Castle is substituted for the latter, and I have every confidence in its proving an excellent substitute. We sow seeds singly in 3-inch pots, using light loamy soil. The seedlings are kept perfectly isolated from all other kinds of plants in order to keep them clean. They also require to be grown near the glass, and before becoming much root-bound should be planted out if the mounds of soil are ready, or be shifted into 8-inch pots, so that no check to the growth be experienced. Those to be fruited in pots may be at once transferred to 12-inch pots or larger sizes, these being well drained; the soil to consist of two parts of roughly broken turfy loam, and one of old Mushroom bed refuse. This should be warmed, and when used be pressed down rather firmly below and around the plants. It is not advisable to wholly fill the pots in the first instance, preferring rather to allow room for an occasional top-dressing with more of the same compost. Later on a rim may be made with strips of galvanised tin about 5 inches wide, and this will admit of further top-dressings. Sometimes rough turf is packed on the surface of the pot, and into this or any other top-dressings the roots quickly ramble to the great benefit of the plants.

While the plants are being raised the house should be prepared for their reception. Whatever has previously occupied it, a thorough cleansing should be given, all old soil being removed, the wood and glass washed, and the brickwork well dressed with whitewash made from quicklime. This will ensure a clean start, and the more light the glass admits the better for the Cucumbers. The bottom heat should be from either hot-water pipes or heated water tanks, and capable of maintaining a temperature of from 70° to 80°, while there should be sufficient piping for top heat to sustain a temperature ranging from 60° to 65° by night to 65° to 70° by day without hard firing, the lowest readings being recommended when severe weather be experienced outside. If a chamber is formed for the bottom heat by either boards, gratings, or, better still, slates, the soil may be laid direct on these. It should consist principally or wholly of turf roughly broken, and this should be disposed long enough to get warmed prior to planting. A bushel to a heap is sufficient, and this, with slight top-dressings and the help of clear liquid manure, such as soot water, guano, or any artificial manure, will perfect the crops.

There are different methods of training the plants, to two of which I will allude as being presumably the best. A stake will have been placed to the young plants, but this in most instances will at planting time have to be replaced with a stronger one reaching up to the trellis, which should not be more than 12 inches from the glass. With some it is the custom to stop the plants when they reach the trellis and to train three or more growths, which follow up nearly the full length of the house, by which time the plants will have gained much strength and capable of perfecting some of the fruit produced on the laterals, which the main growths push out after being stopped; in this case the plants should be disposed at least 6 feet apart. I believe it is a better plan not to stop the plants till the leading growth has reached the end of the trellis near the apex of the roof, the lateral growth following to be trained about 18 inches apart, or according to the wires, after the manner of an horizontally-trained Pear tree, stopping when the plants meet, and fruiting the sub-laterals following this second stopping; in this case the plants may be disposed from 10 to 12 feet apart. In each case all the young growth should be kept thinned out, and those retained be stopped at the first joint beyond the fruit, or undue crowding will result. The object of the cultivator should be to secure strong thinly disposed growth calculated to bear the strain of fruiting at an inclement period of the year. The supernumeraries whether in pots or planted out may be disposed between the permanent plants and trained up the trellis till about 6 feet in length, when they may be stopped and fruited from the growths following. When exhausted, which they soon will be, they should be pulled out, so as to afford space for the permanent plants. We have grown profitable crops on plants in pots disposed at the sides and back of Pine stoves and other light well-heated structures.

The foliage of winter Cucumbers must be robust, and therefore the plan sometimes adopted of rapidly growing Cucumbers in a high temperature and a close and moist atmosphere will not answer, this inevitably resulting in thin unserviceable foliage at this season of the year. Moisture either in the atmosphere or at the roots is not required in great quantities. The plants ought not to be allowed to become very dry at the roots, but they do not require half the water that is given the spring and summer crops. The foliage should be syringed only when the house is closed after air has been given on a clear day, and then only lightly. It is advisable to admit a little air during the hottest part of every clear day. In fact, we find it a good plan to admit air by a "chink" towards noon every day unless the outer temperature be extremely low or the weather prove otherwise unfavourable. Overcropping must be avoided.

Early next season I hope to be able to offer a few hints upon growing spring and summer crops of Cucumbers, also upon Melon culture in connection with Cucumbers and separately.—W. IGGULDEN.

ODONTOGLOSSUMS.

(Continued from page 107.)

COMPARATIVELY few of even the most distinct and really useful forms of this genus have been yet mentioned in these notes, and before giving an outline of the cultivation some of the best may be briefly described, commencing with that well-known Orchid

Odontoglossum vexillarium.—Though of recent introduction compared with other popular species, this has advanced very fast in general favour, and it unquestionably deserves a place amongst the most useful Orchids in cultivation. A dozen or so plants in bloom have a most beautiful effect, and such displays as may be occasionally seen in the chief Orchid-growing nurseries grandly exemplify the value of the species for decorative purposes. Arranged with Ferns, such as *Adiantum cuneatum* or small Pterises, they have a charming effect, their large rosy or delicately tinted flowers being produced in numbers by healthy plants. The great size of the flowers and their soft distinct hue render them highly attractive either alone or associated with other Orchids, and it is not surprising that their culture is being so much extended. Several distinct varieties have also been obtained, one named *superbum* being remarkable for the great size of the blooms; another (*rubrum*) is equally notable for the deep colour of the flowers; and a third termed *rubellum*, though having rather smaller flowers than the others, is notable for the period at which the rosy blooms are produced—namely, during autumn, until late in the season.

Two other species closely allied to the preceding are *O. Phalaenopsis* and *O. Roezlii*, each possessing considerable attractions when in good condition, though scarcely so showy as *O. vexillarium*, their flowers being smaller and less brightly coloured. However, when well treated they flower freely, and, like their

finer relative, are very useful for culture in pots. The leaves are narrow and grass-like, especially in the case of *O. Roezlii*, and quite distinct from *O. vexillarium* foliage, which is less firm, and when very healthy assumes a peculiar metallic hue. These three seem to form a distinct section in the genus, the striking characteristic being the great relative size of the lip as compared with the sepals and petals, which, moreover, do not spread so much as in other species, thus giving the blooms a close appearance like a good form of *O. Alexandra*. It is generally found also that they require rather warmer quarters than the majority of the *Odontoglossums*, and if only one house is at the command of the cultivator they should be placed at the warmer end or in a cool position in the stove; but it must be borne in mind that, like most other forms of the genus, these require abundant ventilation and a moist atmosphere, and a cool base upon which to stand the pots.

O. maculatum.—On the score of showiness this, perhaps, has little claim to notice, yet the neat flowers have some attraction, and wherever it is desired to form a collection of the best species it should by no means be omitted. One recommendation it possesses is that the flowers are produced during the winter and early

Fig. 31.—*Odontoglossum maculatum*.

spring, and, as they last well, a few plants are always useful in imparting diversity to the display of Orchids. The flowers are of a yellowish or brownish colour, with a tinge of purple or crimson in the lip that is very pleasing. The regular form and sharply defined outline of the floral divisions are also notable characters, and are well shown in the woodcut (fig. 31), which represents a flower of an extremely fine variety from Mr. Dorman's collection at Sydenham.

O. citrosimum.—With many Orchid-growers this is deservedly a favourite, its pretty flowers possessing an agreeable Lemon-like odour, rendering it especially noteworthy in a genus which includes few fragrant species. In outline the flowers are nearly circular, the sepals and petals being broad and rounded; the lip is also broad and circular or elliptical, its purplish rosy colour contrasting well with the white sepals and petals. It is a Mexican species, and was imported thence by Mr. G. Barker of Birmingham over forty years ago, when cultivated Orchids were far less numerous than they are now, and it was proportionately valued. It is said that the plant was given by Mr. Barker to a gentleman near Macclesfield, by whose gardener it was first shown at Chiswick in 1842. This may be successfully grown in company with *O. vexillarium*, as it does not thrive under very cool treatment.

O. cirrhosum.—Of quite recent introduction is this charming Orchid; but though only six years' trial has been accorded it, it has acquired a position amongst the most generally appreciated forms, not only of the genus but of the whole family. For bouquets, vases, and similar floral decorations a few spikes of this are very welcome additions, but unfortunately they are not quite so lasting in beauty when cut as some others, such for instance as

the queenly *O. Alexandræ*. Yet amongst the numerous flowers seen in the bouquetists' shops of Covent Garden *O. cirrhosum* is evidently a favourite, the peculiar but graceful form of the blooms and the contrast of the rich chocolate spots on the white sepals, petals, and lip rendering so distinct. The floral divisions are in most of the common and earlier-introduced forms narrow and much waved, but varieties have now been obtained differing greatly in the breadth of the petals and the size of the flowers, some exceeding 6 inches in diameter from tip to tip of the opposite sepals. As a rule, however, those forms with flowers of moderate size are the most richly coloured and therefore the most attractive, such as the variety known as *Klabochorum*, which is one of the best in cultivation, and is greatly valued by Orchid growers. The woodcut (fig. 32, page 197) represents an ordinary form of this species not remarkable for its size, but for the rich colour of the spots.—L. C.

SUNDERLAND FLOWER SHOW.

THIS was held on the 24th inst. and two following days under most unfavourable circumstances. On the opening day an incessant down-pour of rain occurred, and it was not deemed advisable to open the Show that day for the public. The plants were staged, however, but judging did not commence till 3 P.M. The plants were very good.

For six stove and greenhouse specimens Mr. Gardner, Swalwell, was first with a large *Statico imbricata*, *Lapageria rosea*, *Phenocoma prolifera Barnesi*, very good; and two fine *Ericas*, *Lindleyana* and *Austiniana*. Mr. Adams, Swalwell, was second, his best plants being *Erica Marnockiana*, *Ixora coccinea*, and an *Allamanda*. Mr. Armstrong, Elswick, was third. There were five lots staged.

For six foliage plants Mr. Noble, gardener to Theo. Fry, Esq., Woodside, Darlington, was first. He had good examples of *Dasy-lirion serratifolium*, *Crotons Veitchii*, *variegatus*, and *Andreasus*. Mr. Armstrong was second with *Croton pictus*, *Latania borbonica*, *Seaforthia elegans*, and *Cocos Weddelliana*—a very fresh even lot. Mr. Whiting, gardener to Mr. Walker, Shot Tower, was first for six table plants, including neat examples of *Pandanus Veitchii*, *Croton majesticus*, *Aralia elegantissima*, and *A. Veitchii*. For exotic Ferns Mr. Noble was well to the front with *Davallia Mooreana*, *Gleichenia Mendelli*, *G. Speluncæ*, and *Davallia bullata*. Mr. Appleby, gardener to H. Craven, Esq., The Briery, Sunderland, was second with creditable specimens.

For six stove and greenhouse plants in the gentlemen's gardeners' class Mr. Noble was first, his noteworthy plants being a good *Ixora javanica*, *Rondeletia speciosa major*, and *Erica Marnockiana*. Mr. Adams was second with *Erica Aitoniana superba*, *Vallota purpurea*, and *Phenocoma prolifera Barnesi* in good condition; Mr. Appleby being third. For six foliage plants in the same class Mr. Appleby was first with, amongst others, excellent specimens of *Croton Queen Victoria*, *Cycas revoluta*, and *Croton majesticus*. Mr. Graham, gardener to R. H. Jyne, Esq., Beechholm, took the second prize. For British Ferns Mr. Noble was first with a good collection. Three very fair groups of plants were shown, Messrs. Thompson, Noble, and Appleby winning the prizes respectively.

Cut Flowers.—Epergnes, bouquets, and cut flowers generally are usually well staged at Sunderland. This year was no exception; there was even an improvement in the epergnes, which were numerous and well arranged. For a hand bouquet Mrs. Cramont, Ashburnham, was first with a neat arrangement, consisting of *Ixoras*, white *Lapagerias*, *Forget-me-nots*, &c. Miss King, Ashburnham, second. There were seven entries. For bridal bouquet Mrs. Cramont was first, and Miss Bathensby second. In the class for epergnes Mr. Rutherford, Leases, Durham, was first. The top tier of his stand was very light and elegant. The second and third tier consisted of heavy coloured flowers, such as *Vallotas*, *Ixoras*, and *Anthuriums*, all neatly toned with Ferns, including *Adiantums* and *Davallia Mooreana*. There were nine competitors. For twelve and six Dahlias and six *Gladioluses* Mr. Harkness, Bedale, Yorkshire, was first with good collections of flowers.

Fruit was not shown extensively, the prizes not being very high; but some excellent Grapes and Peaches were staged by Messrs. Larke, Thompson, and Jenkins.

Messrs. William Fell & Co., Wentworth Nurseries, Hexham, showed an excellent stand of single Dahlias of such beautiful varieties as *Aigle d'Or*, *Paragon*, *White Queen*, *Scarlet Gem*, *Orange Scarlet*, and other leading sorts. The Secretaries, Mr. Thomas Humphrey and Mr. James R. Anderson, and the Treasurer, Mr. Blacklock, did all that was possible to achieve success, and it is to be hoped the inclement weather has not seriously affected the finances.

SEEDLING ZONALS.—There are many of your readers possibly who may have tried the experiment of raising Zonal *Pelargoniums* from seed. There is always a certain excitement in growing florists' flowers from seed, for the one among many reasons that you may succeed in having something very valuable. If you sowed early and transplanted the seedlings into borders as is usually done, and if the soil is rich and retentive of moisture, the seedlings are by this time possibly as thick as *Dahlia* stems, and very likely show not the least sign of flowering. If the soil is poor, sandy, and well drained you may have blooms the

first year; but if as indicated, to have blooms this year, I lift the seedlings this month, place them in small pots, and transfer to a close frame for a few days until the roots commence growth again. A sprinkling with the syringe will prevent the leaves falling. They can be fully exposed very soon, and a mass of flowers, perhaps all different, may reward your care all the winter.—W. J. M., *Clonmel*.

HARDY CYPRIPEDIUMS.

HARDY Orchids are much too rarely grown in our gardens. The reason for this is difficult to ascertain. To many of our cultivators, especially amateurs, the term "Orchids" conveys the idea of heavy expenditure in the first instance, and a perpetually heavy outlay afterwards; and this is so if one is enthusiastic in the cultivation of the tender species, and especially so if all the novelties which come into the field are secured. I do not wish to discourage in any way the cultivation of the tender Orchids, at the same time it is desirable not to neglect the hardy species, which now muster strongly; and although not so showy as many of the exotic kinds, yet they possess sufficient beauty to amply repay for the small amount of labour and outlay incurred in their cultivation.

Perhaps inattention to the real requirements of these plants is one of the chief causes of their absence from our gardens; for, like their favoured congeners, they have wants which must be studied in the matter of soil and situation, these being the chief considerations in attempting to grow them, about which, however, there is little difficulty. There is no doubt that, with reference to the hardy flower garden, we are but just beginning to appreciate the value of the proper plants for the work. Why should not hardy Ferns and Orchids be arranged together? This has been done in some places to a limited extent, but there is room for a greater extension in that direction. No two groups of plants could more easily be grown together, as the soils requisite are almost identical, quite so in many instances, while quite as much may be said as to the situation, and the Orchids would require as little attention as the Ferns if properly planted.

Cypripediums are especially suited for associating with Ferns both as regards their requirements in soil and position, and when in flower the effect is very striking, especially so in the case of *C. spectabile*. For the subjects of these remarks it is necessary to have a shady position with a good drainage, but moist. The soil required for most of the species is good peat, leaf soil, two-thirds of the former to one of the latter, and some good coarse silver sand; and when once they are planted they should remain undisturbed, when they will readily become established. Liberal supplies of water are beneficial in dry weather, and if the winter is very severe some of those enumerated below will require a slight protection over the crowns; or if excessively wet it will be necessary to protect them from superfluous moisture, which is very prejudicial when they are at rest. They may also be planted at the foot of the rockery, selecting as shady a position as possible, although the primary thing is in this respect to ensure them immunity from sunlight during the hottest part of the day, as the flowers are much longer preserved if this is considered.

The following method, which I adopted some years since in the cultivation of hardy Orchids, will give an idea of the small amount of trouble needed to grow them well. A large tree stump was selected and inverted so that the projecting roots were uppermost, the spaces between which were well filled with large cakes of peat, so that a good-sized basin was formed to receive the soil. I used as soil in this instance peat, leaf soil, yellow loam in equal parts, with a good addition of old mortar rubbish finely broken and sand. Among the Orchids planted in this stump garden were *Cypripedium spectabile*, *C. acaule*, *Calopogon pulchellus*, *Pogonia ophioglossoides*, *Orchis maseula*, *Arcthusa bulbosa*, *Orchis pyramidalis*, *Ophrys apifera*, and *Spiranthes cernua*, all of which flowered splendidly. In fact some of these species flowered finer than ever I had seen them before or since outside, especially *Calopogon* and *Arcthusa bulbosa*, and they thoroughly established themselves. In association with them I well remember the surface was covered with the charming little *Wahlenbergia hederacea* and *Erpetion reniforme*, while in the summer *Dionæa muscipula* flourished, as well as *Drosera rotundifolia* and *D. filiformis*. Among Ferns were *Allosorus crispus*, *Asplenium Ceterach*, *A. fontanum*, *Polypodium Dryopteris*, &c., so that all students of hardy plants will imagine the amount of interest which existed in so small an area; and one thing is certain—the plants were quite at home.

Already, as the species enumerated below will show, there are several *Cypripediums* introduced which may be regarded as hardy with us, but undoubtedly there are many others indigenous to both hemispheres which have never yet been found in our herbaria

even. I am much mistaken if there are not some grand species to come from the upper part of the Himalayas, as well as others from Eastern Asia and the western States of America. I have said nothing respecting their cultivation in pots, which is a very interesting method, and one which is to be encouraged, as they could then be easily protected during the winter by being placed in a cold frame.

C. acutilis.—A peculiar little species, with a pair of large oblong ovate hairy leaves, from the centre of which the flower stalks spring, which are usually about 4 inches high, carrying the comparatively large flowers, which are not less than 2 inches long, appearing during May and June; sepals ovate-oblong, brownish; petals much narrower and longer; labellum much inflated, varying in colour from almost pure white and veined with rose, to a beautiful rosy purple, when it is extremely showy. It is a native of the eastern States of North America, from whence it was introduced more than a century back. It enjoys a well-drained position with a liberal supply of sand.

C. arietinum.—A very scarce and curious species, with stems from 9 to 12 inches high, with ovate-oblong leaves, and a solitary flower about 1½ inch long; sepals ovate, greenish-brown; petals narrower, of the same colour; labellum whitish, veined and tinged with red. It flowers with us in May, and it is advisable to afford it some protection from excessive moisture in winter, although it enjoys an abundance in the summer months. Native of the northern United States, from whence it was introduced early in the present century.

C. Calceolus.—This is one of our rare British plants found only in a few localities, but is plentiful in other parts of Europe and North America, with a slight variation owing to distribution. It was formerly known as *Calceolus Marianus*, or Slipper of Our Lady. The stem grows a foot or more high, with a few ovate downy leaves, clasping the stem. Flowers one or two on each stem, with brown sepals and petals, the latter narrow and wavy; lip very conspicuous, pouch-like, bright yellow, similar in form to a *Calceolaria*, and a striking contrast in colour to the sepals and petals. This flowers in June and July, and is most easily cultivated, thriving even in ordinary borders in a partially shaded position, although it is sometimes described as a difficult plant to establish.

C. candidum.—Stems 9 to 12 inches high, with bluntly ovate leaves, conspicuously ribbed and downy, with a solitary flower at the top; sepals and petals narrow, greenish white; labellum pouch-like, pure white. This is a very scarce species from the western States of America, flowering with us in June and July; and although not so showy as some of the others, it is very distinct and well worth growing, enjoying a very moist position.

C. guttatum.—In this we have a very distinct and desirable kind, coming from the damp Pine woods of Siberia. It grows from 9 to 12 inches high, with a very short stem proper. Leaves large, alternately placed, two in number, ovate-oblong, shortly acuminate, very hairy. Flowers solitary, on long hairy stalks; sepals broadly ovate; petals oblong, both greenish white spotted with crimson; labellum large, bag-like, white spotted and splashed with crimson, resembling blood stains. Place it in a well-drained spot so that dryness is ensured during the winter, and give plenty of water during the growing season. It appears to have been introduced about 1820, but was lost for a long time.

C. macranthum.—A very showy species, growing about a foot high, with a few ovate lanceolate leaves clasping the stem, with a solitary flower to each stem, 2 to 3 inches long, of a rich purplish crimson shade varying in degree; the labellum being deeper in colour than the other parts; sepals broadly lanceolate; petals longer, linear, and wavy; labellum with a large mouth, slipper-like, very conspicuous. This is also a Siberian plant, and a most beautiful and distinct kind it is, flowering in May and June, enjoying similar treatment as the last, when it readily thrives. It was first introduced in 1828, but has several times been lost, but no doubt it will be kept under cultivation now that more attention is given to such plants and good supplies are secured.

C. parviflorum.—A pretty species widely distributed in the United States, growing from 1 to 2 feet high, with ovate-oblong light green leaves. Flowers one to three on each stem, with brownish purple sepals and petals, and a small inflated bright yellow labellum. The flowers about 1 to 1½ inch across and very fragrant, and very similar to those of *C. montanum*, except that the lip of the latter is whitish, while the habits of both plants are similar. This flowers in May, and is apt to suffer from excessive damp during the winter. Introduced as early as 1759.

C. pubescens.—A plant very similar in habit and the colour of the flowers to our native *C. Calceolus*. It is about the same height, but much more pubescent. The flowers, however, are larger and rather brighter in colour, but it is most likely only a varietal form

of that species. One of the easiest to cultivate, and extremely showy when in flower, forming a good kind for pot culture in the greenhouse, flowering outside in June. Introduced 1790.

C. spectabile.—This to my mind is the most magnificent of the hardy species, producing stems from 1½ to 2 feet high, clothed with several ovate-oblong, downy, light-green leaves. Flowers 2 inches or more across, with broadly-ovate sepals, and oblong blunt petals, both pure white; labellum large, nearly round, being much inflated, white, heavily tinged with delicate rose; sometimes the shade of colour is much deeper, when the flowers are particularly striking, vying with the most gaudy terrestrial Orchids. The value of this species has never been fully appreciated, although it has been known in the country for over a century. Not only is it a most valuable addition to the hardy flower garden, but it readily forces, so that it could be more largely employed for decorative uses in our greenhouses. Outside it flowers in July and August, which happily materially lengthens the blooming period of these charming flowers, so that we may enjoy one or other of the species from April to the end of August.

There are several other species which I have purposely omitted because of my partial knowledge respecting them, but they are, nevertheless, well worthy the attention of the cultivator, including *C. occidentale*, *californicum*, *helveticum*, *ventricosum*, &c., the two latter being very scarce; in fact, I am not certain if the last, which is a Siberian species, is to be found under cultivation now.—N.

NOTES FROM NORTH YORKSHIRE.

I HAVE been much interested with the articles that have appeared with regard to the Longleaf Vines, and also those on Mushrooms. I intend trying the method of culture recommended on a small scale, as I think there is no better dish for breakfast than good Mushrooms.

I send you a tin box with some leaves of *Coleus* and also some *Begonia* flowers, and two flowers of Intermediate Stock. I send the *Coleus* and *Begonias* as curious instances of cross-hybridisation by bees or flies. The *Coleus* were all raised this spring from seed saved only from one seedling of my own, which is rather a favourite, similar to the piece with blue silk tied to it. The leaves I have just cut from the seedling plants are only small, as I wanted them to go into the little tin, but you will see they vary very much; the piece with red worsted round it has made a very beautiful plant. I selected it as one of the best, and the colouring is very bright and uniform, the leaves flat and smooth, not curled, and measuring 6 or 7 inches by 3 to 4 when fully developed.

The *Begonias* were all raised from a seed pod of Emperor which I had tried to impregnate with Stella. They have varied much, though the greatest number of them have been like Emperor, but have bloomed more freely and are rather broader in their petals. Here in North Yorkshire they seem to grow well out of doors and have even ripened seed. I intend to try them on a larger scale if I can next year.

I send the Stock as a curious instance of the length of time a hardy Stock will flower. The plants began to bloom in a Rose bed near the house before any of the Wallflowers, which were more than usually early this year—I think about the first or second week in April. All the plants which were single have long since ceased flowering, but the double ones are in full bloom still, and seem likely to continue for some time longer.

It has been a cold wet summer for gardens, but there seems to be no flower that stands every kind of weather better than the hardy Phloxes, of which I have a great quantity and variety, and everybody who sees them wants plants. I have many seedlings which have done well.—C. P. P.

[There are nine distinct varieties of *Coleus*, and every one of them attractive. It is curious to observe that, without any attempt at cross-fertilisation, not only that the varieties are so dissimilar, but that some of them closely resemble if they are not identical with some of the older named sorts, such as Berkleyi, Baronne de Rothschild, Princess Beatrice, and some others. The selected variety resembles Kentish Fire, but is brighter and better. The seed parent is smooth, velvety, and effective. The *Begonias* are good, very pale rose, deep rose, orange scarlet, and crimson. The Stocks appear to be varieties of the Lothian, and are most useful for border decoration. You and the bees have been very successful.]

CARTERS' DWARF MAMMOTH CAULIFLOWER.—For several years I have tried, like many of my gardening friends, to winter some Cauliflower plants in cold frames. They are subject to so many misfortunes even though they receive almost daily attention, that last year I tried a small quantity of Early London, Walcherea, and t

above near a south wall, and without any care or attention the Dwarf Mammoth escaped through the winter unscathed, the other two in a less degree. I saw large beds in another garden that were fit for use thus treated in the end of May. I am sowing the above this week similarly, and shall expect they will escape better without any attention than those grown in cold frames.—W. J. M., *Clonmel*.

TROWBRIDGE HORTICULTURAL SOCIETY.

THE Trowbridge Society has not failed to have an Exhibition for the past thirty-three years, and to all appearances it is as popular as ever, not only in the immediate district, but for many miles around. The Society, in common with many others, has met with bad fortune in the shape of disastrously wet days for the meetings, but so liberal are the leading inhabitants in their support that these reverses do not result in a dissolution, as too often happens in other cases. On this occasion the weather was far from being favourable, frequent heavy rains preventing numbers of would-be visitors from attending, and in spite of the apparently large attendance a deficit was considered inevitable. The schedule of prizes open to all competitors was a fairly liberal one, and included awards for street and other decorations, and great encouragement is also given to the working classes to cultivate flowers, fruits, and vegetables. Horticulturally speaking nothing was wanted to insure success, classes being provided for most popular kinds of fruits, flowers, and vegetables, and these on the whole were well filled. Thanks to the experience and energy of the popular Honorary Secretary, Mr. J. Huntley, and the Committee generally, there no hitch of any kind, everything being well arranged, and the tents open for inspection at the appointed time.

The great feature in the Show was the magnificent display of pyramidal Fuchsias. These were exceptionally fine, notably the premier six specimens staged by Mr. J. Lye, gardener to the Hon. Mrs. Hay, and the first-prize four specimens by Mr. H. Pocock, gardener to J. P. Haden, Esq. The former's plants averaged 9 feet in height, were perfect in every respect, and comprised Beauty of the West, Elegance, Emily Lye, Bountiful, Hon. Mrs. Hay, and Mrs. Bright, all raised and distributed by Mr. Lye. Mr. Pocock staged grand specimens of Arabella, Maggie, Charming, and Doe's Favourite. The same exhibitor occupied the second position with six, staging among others a wonderful specimen 10 feet in height of Doe's Favourite. Mr. J. Matthews, gardener to W. R. Brown, Esq., and Mr. G. Tucker, gardener to Major P. Clarke, were respectively winners of the third prizes, and both staged creditably. In the amateurs' class for six stove and greenhouse plants Mr. H. Pocock occupied the first position, his group consisting of healthy well-flowered specimens of *Dipladenia Brearleyana*, *D. amabilis*, *Allamanda Hendersonii*, *Ixora Williamsii*, *Bougainvillea glabra*, and *Stephanotis floribunda*. The name of the exhibitor of the second-prize group we could not obtain, but Mr. W. Sharp, gardener to E. May, Esq., was deservedly awarded the third prize. The best four specimens were staged by Mr. G. Tucker, and comprised a good *Statice profusa* and a well-flowered *Allamanda Hendersonii*. Mr. J. Matthews and Mr. Pocock took the remaining prizes in the order named; the former had a fine specimen of *Erica Exquisite*. In the class for nine plants, open to all, Mr. Mould, Pewsey, easily secured the premier award, his most noteworthy specimens being *Erica cerinthoides coronata*, *E. Iveryana*, *Clerodendron Balfourianum*, *Ixora Reginæ*, and *Dipladenia Brearleyana*. Mr. J. Matthews was a creditable second, staging among others well-flowered examples of *Erica retorta*, *E. Marnockiana*, and *Lapageria rosea*. In Mr. J. Tucker's third-prize group a very vigorous specimen of *Anthurium Williamsii* and a beautifully flowered and richly coloured *Bougainvillea glabra* were noteworthy. Mr. W. Shay, gardener to C. N. May, Esq., staged the best nine fine-foliaged plants, the best of these being the examples of *Croton pictus*, *C. Veitchii*, *C. Weismannii*, and *Latania borbonica*. Good specimens of *Gleichenia rupestris* and *Cycas revoluta* were included in Mr. Mould's second-prize group.

Ferns and Lycopods were shown in excellent condition by several competitors, the groups being noteworthy for their evenness and healthy appearance, qualities not always apparent where larger specimens are staged. Fifteen varieties were required. Mr. H. Pocock worthily secured the premier position, his group comprising good examples of *Davallia Mooreana*, *Dicksonia fibrosa*, *Adiantum farleyense*, *A. concinnum latum*, *Lygodium scandens*, and *Thamnopteris nidus*. Mr. H. Tucker followed with many similar varieties, while Mr. G. Smith, gardener to J. Kemp, jun., Esq., and Mr. J. Coke, gardener to A. P. Stancombe, Esq., were deservedly awarded equal third prizes. *Microlepia hirta cristata* staged by the latter was particularly attractive, and deserves to be more generally grown. The class for a single specimen plant of any description was not particularly good, but the example of *Croton majesticus* staged by Mr. A. Shadwell, gardener to T. Chandler, Esq., fully deserved the premier award. Mr. Mould and Mr. J. Matthews exhibited *Ericas* in good condition; Messrs. J. Matthews, G. Garraway, Bath, and J. Lye staged good specimen *Coleuses*; Messrs. H. Pocock and W. Sharp staged *Achimenes*; Messrs. W. Sharp and A. Walters, gardener to T. Salter, Esq., Bath, *Gloxinias*; Messrs. Tucker and H. Pocock various *Pelargoniums*; Mr. Lye *tricolor Pelargoniums*; Messrs. J. Lye and W. J. Stokes, Hilperton Marsh, *Petunias*, taking the prizes in the order named in each instance. There were also well-filled classes for

Balsams, Cockscombs, Caladiums, and Verbenas. Amateurs not employing gardeners also exhibited well in the classes set apart for them.

The competition in the cut-flower classes was particularly good. Dahlias, both single and double, made a grand display, and the Roses, considering the season, were surprisingly fine. Messrs. Keynes & Co., Salisbury, had the best stand of twenty-four distinct Dahlias, Mr. T. Hobbs being a good second, both staging grand examples of the leading sorts. The prizewinners in the class for twelve varieties were Mr. H. Bush, Swanswick, and Mr. W. Sloper. Messrs. Keynes & Co. also gained other awards for Dahlias, and they also staged, not for competition, most brilliantly coloured single Dahlias. Messrs. Cooling & Son, Bath, and A. F. Walters, Bath, also brought attractive stands of single Dahlias, the best of these being alba, Paragon, coccinea, and lutea. Messrs. Cross & Steer, Salisbury, were awarded the premier prize for Roses in twenty-four varieties, among these being good examples of *Marquise de Castellane*, *Elie Morel*, *Senateur Vaisse*, *Alfred Colomb*, *Countess of Oxford*, and *Dupuy Jamain*. Mr. G. Humphries, Chippendale, and G. Cooling & Son, Bath, were awarded the remaining prizes. The latter exhibitor also brought some good stands of Roses not for competition; included in these were excellent blooms of *Mabel Morrison*, *La Rosière*, *Marie Baumann*, *Auguste Rigotard*, *Marie Rady*, and *Mons. Fournier*. Mr. W. Smith, Bristol, easily secured the first prize for twelve triplets; these comprising fine richly coloured blooms of *A. Colomb*, *La France*, *Niphetos*, *Marie Baumann*, *Louis Doré*, *Général Jacqueminot*, *Madame Victor Verdier*, *E. Y. Teas*, *Louis Van Houtte*, and *Bartelmy Joubert*. In a corresponding class for amateurs Mr. J. Davis, Wilton, was awarded the first prize; his best triplets were of *A. Colomb*, *Reynolds Hole*, *Lord Macaulay*, *Star of Waltham*, and *Madame Victor Verdier*. Messrs. A. R. Tanner and H. Catley, both of Bath, were respectively the second and third prizewinners. Mr. D. Shellar, Bristol, staged the best twelve single blooms, Messrs. J. Davis and G. Tanner following closely in the order named. Mr. W. Burridge staged the best twenty-four German Asters, his stand comprising all the beautiful quilled varieties he has raised. Mr. G. Garraway, Bath, had the best stands of French Asters, Mr. W. Sloper, Highworth, following closely. *Gladioli* were grandly shown by Mr. Wheeler, Warminster; and two stands of cut blooms of the *White Clove Carnation*, *The Governor*, staged by the Messrs. Cross & Steer, Salisbury, received much admiration. Mr. F. J. Frances, Weston, was first, and Mr. C. Bailey, gardener to — Phayre, Esq., second for twenty-four bunches of cut flowers, both staging choice kinds.

Hand bouquets were not extensively or particularly well shown, neither do the Judges encourage good taste, as they awarded the first prize to an enormous and closely packed example exhibited by Messrs. Cross & Steer; the second to Mr. W. C. Drummond, Bath, for a pyramid also closely packed; while the third prize went to Mr. M. Hookings, Bristol, for decidedly the lightest and most tasteful arrangement. The memorial wreaths were noteworthy, there being several tasteful examples shown. Mr. H. James had the best, this being composed largely of *Tuberose*s, *Eucharises*, white *Lapagerias*, and *Maidenhair Fern*. Mr. Hookings was a good second. Similar positions were occupied by these exhibitors with an ornamental device of flowers, the third prize going to Mr. J. Bland, Bristol. Good taste was shown in each instance. Mr. Hookings had the best centrepiece composed of fruit and flowers, being closely followed by Mr. W. H. James, gardener to A. Laverton, Esq., the third prize going to Mr. J. Cook.

To Mr. T. King, gardener to R. V. Leach, Esq., Devizes, was awarded the first prize for ten dishes of fruit; Mr. A. Millar, gardener to W. H. Long, Esq., M.P., Rood Ashton, taking second; and Mr. F. Crossman, gardener to F. O. Bennett, Esq., Bruton, the third prize. There was no limit to kinds or number of fruits constituting a dish, but Pine Apples were excluded. The consequence was the first prize went to a collection consisting of *Black Alicante*, *Black Hamburg*, and *Buckland Sweetwater Grapes*, and immense piles of *Moorpark Apricots*; *Jefferson Plums*; *Lord Palmerston*, *Barrington*, and *Exquisite Peaches*; *Pine Apple* and *Prince of Wales Nectarines*; whereas Mr. Miller staged better *Alicante* and *Hamburg*, but inferior *Muscat of Alexandria Grapes*, excellent examples of *Hero of Bath* and *Best of All Melons*, good *Barrington* and *Bellegarde Peaches*, *Moorpark Apricots*, *Kirke's Plum*, and *Balgowan Nectarines*. This was certainly the best representative collection. Mr. Miller was the only exhibitor of *Pine Apples*, and was awarded the first prize for a fair Queen. Mr. F. Crossman with beautifully coloured *Buckland Sweetwater* was first in the class for any white Grape not *Muscats*, Mr. Miller following with good bunches, but not well coloured, of *Foster's Seedling*. In the corresponding class for *black Grapes* these exhibitors gained similar positions, both staging *Black Alicante* in good condition. In the class for *Black Muscats* small well-coloured bunches of *Muscat Hamburg* secured the first prize for Mr. King; Mr. J. Loosemore, gardener to W. Cooper, Esq., following with good examples of *Trentham Black*; Mr. Clack taking the third prize for fair examples of *Muscat Hamburg*. *White Muscats* were not well shown. Mr. J. Loosemore was awarded the first prize for fairly coloured bunches. Mr. G. Hart, gardener to J. Fussel, Esq., and Mr. S. Paviour, gardener to W. Smith, Esq., were respectively the winners of first prizes for green and scarlet-fleshed *Melons*, there being fair competition in each instance. *Apricots* for the season were very good; Mr. Hart secured the first prize, the

second prize going to Mr. G. Tucker. Green Gages were not largely shown. Mr. Miller had the best, while with dessert Plums Mr. King occupied first position with clear examples of Golden Gage. Mr. Crossman had the best Cherries. Several good dishes of Peaches were shown: the best highly coloured Royal George were staged by Mr. G. Pymm, gardener to J. Goldsmith, Esq.; Mr. F. Rice, gardener to Mrs. Home, Weston, following. Mr. Pymm was also first with Nectarines, staging good Lord Napier; J. H. Lovibond, Esq., following with Elruge in good condition. In this and the preceding class Mr. H. Clack was worthily awarded the third prize. Dessert Apples in two varieties were well shown. Mr. E. Hall, Bath, was first with Peach Apple and Devonshire Quarrenden, Mr. A. T. Hall following with the same varieties. Kitchen Apples were not largely shown, but several exhibitors had Lord Suffield large and good. Mr. Pymm took the first prize, while Mr. W. E. Hall was the most successful exhibitor of Pears, and Mr. H. Sheppard of Filberts. Vegetables were extensively and well shown by gardeners and cottagers, prizes being offered for single dishes of all kinds in season, as well as for collections. Mr. H. Scott, Bath, and Mr. W. G. Tyler, Bath, were respectively winners of the first and second prizes for collections, and others were highly commended.

On the whole the Trowbridge Society must be termed a model institution, and fully deserves the support it receives, and we trust will long remain as popular as it is at present.

STANDEN'S MANURE.

IN your Journal of 24th inst., under the head of "The Best Manure," the comments made by your correspondent are scarcely, we think, fair to us. We have purchased the proprietary right of "Standen's Manure" at a very high figure, and are not only prepared to produce the most practical and impartial evidence as to the present fertilising properties of Standen's manure in comparison with others, but also to prove that the ingredients and manipulation of it are precisely the same as when introduced some twenty years ago.—CORRY, SOPER, FOWLER & Co., 18, Finsbury Street, London, E.C.

ROSES ON THEIR OWN ROOTS.

THERE is no season of the year when remarks on this subject are more seasonable than at the present time. For some years past Roses on their own roots have been ignored by the majority of Rose-growers, and worked plants advocated as capable of producing better and finer blooms. It is not my intention to condemn the use of stocks generally, for it is evident to all who study the Rose that certain strong-growing stocks are advantageous to those of poor weak growth. But stocks have been used for all, irrespective of variety or constitution, and all that has been urged again and again in their favour is not sufficiently conclusive to my mind why Roses should not be largely cultivated on their own roots. Those who use and recommend the use of the Manetti as a stock advise the union of the stock and scion to be buried that roots may form at the union, and the Rose finally to be upon its own roots independent of the stock. If the Manetti is left above the ground—as in the case of the Briar—and the variety worked upon it is of vigorous growth, how long will the Rose continue to thrive? To my mind the Manetti is useless as a stock for strong growers when such Roses as Belle Lyonnaise, Lamarque, Rêve d'Or, or Maréchal Niel are capable of exhausting it after one season's growth, and the stock is found dead. This is often the reason these strong growers do not flourish after the first season of their existence. One thing is gratifying to those who advocate Roses on their own roots, and that is—those who use the Manetti as a stock are evidently in favour of own-root Roses, or we should not be advised to plant those worked upon that stock deeply. This stock, I must admit, is easy to raise and work upon. But after all it takes a much longer time to raise plants by working than striking them by means of cuttings, and better plants can be produced in less time than by first striking the stock and budding them. This may be disputed, but it is, nevertheless, a fact, for plants can be seen here carrying at the present time as many as twenty flowers and buds, and it is only twelve months since the cuttings were inserted. This is the case more especially with La France, one of the easiest of all Roses to raise from cuttings, and undoubtedly the most floriferous Rose in cultivation.

Rose cuttings may be rooted with much greater ease and certainty than many people suppose, and neither amateurs nor cottagers need fail if only suitable wood is selected and the operation carried out at the proper time. There can be no doubt where it can be conveniently carried out the system detailed by Mr. W. Taylor in these pages is an excellent one. The method I have always adopted with marked success at this season of the year is to have ordinary handlights near a north wall, in which is placed half an inch depth of red sand at the bottom, and then about an inch depth of light soil over it. Old potting soil

is generally used and pressed moderately firm. The wood for the cuttings is then selected, and that of moderate strength being preferred, as I have always found a greater per-centage root than when strong pithy wood is employed. The cuttings are made without a heel, as they root equally well when cut just below a joint, in fact in less time than when a portion of the old or harder wood is attached to them. As a rule the cuttings only possess two buds unless the wood is very short-jointed, and are inserted in the handlights with the leaves attached. They are placed thickly together, the soil well firmed about them, and then thoroughly soaked with water. The top portion of the light is placed on, and the cuttings need no further attention until they are rooted, which they will be in about a month. They will not require watering after the first application if the lights are kept close.

Another system I have practised with success, and will detail for the good of amateurs and cottagers that do not possess handlights and are anxious to strike Roses. The same preparation of sand and soil should be made, only of a greater depth, and placed in a similar position. The cuttings should be about 6 inches long, and inserted fully half their length in the soil, or, better still, if only one eye is left out of the ground. After insertion and a good watering the cuttings should be dewed overhead on the afternoons of fine days and watered as they require it. If the weather is hot

Fig. 32.—*Odontoglossum cirrhosum*. (See page 193.)

and dry three or four good waterings will be required before they are rooted. It will be found that a great per-centage of the cuttings will be well rooted in six weeks if treated as described. The principal secret in striking Roses is to insert the cuttings before the wood becomes too hard, for the firmer the wood the longer the cuttings are in rooting and the greater the number of deaths. Hundreds of Rose cuttings die through late insertion, and many people in consequence conclude they are difficult to propagate from cuttings.

Under whichever system the cuttings are rooted the treatment afterwards should be similar where the protection of glass can be afforded them. I have found it an advantage to place the young plants at once into a moderately warm temperature after they are transferred to 4-inch pots, which induces them to form roots rapidly and abundantly and start into vigorous growth. It is necessary to shade from strong sun for a time after potting, and dew them overhead with the syringe two or three times daily. Roses do well after they are once rooted if only a cold frame or handlights can be given them for a time, but they make much greater progress in a temperature ranging from 60° to 65° at night until thoroughly established. The object in view when pushing them forward in the temperature named is to have them as large as possible before winter and in 6-inch pots. By the time they are placed in the last size they are in a cool house or frame, where they remain until the approach of very sharp weather, when they are assigned any cool position where frost can be excluded. This keeps them slowly growing during the winter, although but little will be perceptible, but the pots will become well filled with roots ready for early spring. Early in the season they are again placed in cold frames, which are ventilated abundantly on all favourable

occasions until thoroughly hardy, and then stood outside in a sheltered position, and finally planted out in beds or borders prepared for them.

Those having no glass can pot the cuttings when rooted if they choose, but it is preferable to leave them undisturbed in the position in which they have rooted until spring. To carry out this system properly the cuttings should be inserted in rows 6 inches apart, so that fine coal ashes can be placed between the rows and well round the plants, only leaving the uppermost eye exposed. Nothing will protect them better from sharp frost than ashes. These should not be placed between the rows until sharp frosts are really expected, when other protecting material, such as mats and dry straw, should also be in readiness. If a little protection only is given it will be found that the majority will survive. If the growth made in autumn from the top bud is destroyed it will prove but little detriment to the young plants if inserted in the ground a moderate length. The latter is important when they are intended to remain outside during the winter. In spring they can either be potted or planted out. If potted good fibry loam should be used, with a seventh of decayed manure and leaf soil, to give them a start, and sufficient sand to make the whole porous.

Last year about this time I made some cuttings from a shoot that had been broken off, and dibbled them into the Rose bed outside. They were lifted several times to see if they had rooted. The lifting killed all but one, which was well rooted in autumn, and stood well through the winter without any protection. This is now a vigorous plant, flowering freely with three or four strong shoots from the base. This is merely mentioned to show those who have no glass that a stock of Roses on their own roots can readily be obtained without proving an expensive operation, as only a limited amount of intelligence and care is needed to propagate Roses from cuttings.—W. BARDNEY.

BARNARD CASTLE SHOW.

BARNARD CASTLE is situated in the southern division of Durham, close on the confines of Yorkshire, and adjoining the romantic vale of the Tees, with its charming waterfall. Everywhere the scenery is enchanting, rich in woodland, and a fine pastoral country. Rokeby Park, immortalised by Sir Walter Scott, Raby Castle, Stratlam Castle, and other places are all contiguous. The town of Barnard Castle is very old, possessing an exceedingly fine specimen of an old Norman castle. It is in the castle grounds where the Committee held their Flower Show. This is close to the "King's Head," where Charles Dickens stayed during his visit, and where he portrayed so forcibly the adjoining educational establishments.

The Show was not very large, but in all classes the exhibits were of superior merit. For four plants the Society offer £5. Mr. Johnson, Darlington, was first with a fine *Erica Austiniana* and *Shannoni*, *Clerodendron Balfourianum*, and *Lapageria rosea*. Mr. Westcott, Raby Castle, was second; and Mr. W. Bowlzer, Rokeby Park, third; he had in his stand a fine plant of the old *Clerodendron fallax* over 3 feet high. For four exotic Ferns Mr. Johnson was again first with fine plants of *Davallia Mooreana*, *Gleichenias microphylla* and *Mendeli*, and *Adiantum farleyense*. Mr. Westcott was second, his best plant being *Davallia Mooreana* over 7 feet across. Mr. Westcott was first for four foliage plants; he had a grand *Alocasia Lowii* over 4 feet high, well developed. Mr. Westcott showed some excellent Cockscombs of his noted strain. Mr. Bowlzer showed fine Zonal Pelargoniums, *Lizzie Brooks*, *The Bride*, and *Mrs. Wright*.

Fruit was a great feature of the Show. For six varieties, Pines excluded, Mr. Westcott secured the chief prize with *Muscat of Alexandria* and *Black Hamburg* Grapes, fine in every respect, the bunches varying from 3 to 4 lbs., the berries large and finely coloured. *Royal George* Peaches and *Pitmaston Orange* Nectarines were also very good. Mr. Jowsey, gardener to Gilpin Brown, Esq., Ledbury Park, showed very fine *Black Hamburg* and large *Buckland Sweet-water* Grapes, *Violet Hat* Nectarine, *Colston Basset* Melon, and *Royal George* Peach. This collection was an excellent second. Mr. Bowlzer was third for two bunches of *Black Hamburg*; Mr. Westcott was first with excellent bunches. For two bunches of *Muscats* Mr. Jowsey was first followed by Mr. Westcott. *Peaches*, *Nectarines*, and *Melons* were also well shown.

Vegetables in both the open and amateur classes were very fine. The Society would do well to enforce the rule relative to the naming of exhibits, and also to have on the exhibition cards the names of the owners of the produce as well as gardeners who exhibit it. Mr. J. J. Bailey is Secretary, and with an active and efficient Committee endeavours assiduously to make the Show a success.

POTATOES.

I SHOULD be much obliged to any of your correspondents who would kindly supply me, through the Editor, with a few seed apples of the *Magnum Bonum* Potato. I have looked over acres here in several directions, and cannot obtain what I want. They flower, but produce no seed. I have only one seedling of the

Magnum Bonum, but that is so very satisfactory, possessing all the disease-resisting characteristics of the parent, that I wish to proceed further.

I find a wonderful difference in seedling Potatoes with regard to disease-resisting power. I have been carrying on seven or eight seedlings now for several years, but find the majority are so liable to disease that I have decided on discarding all but one. This one has never had the disease in the least as far as the tubers are concerned from first to last. It is a round Potato about the size of a cricket ball, and not very unlike one, but the skin is about the colour of Schoolmaster. I carried these seedlings on because some of them were wonderful croppers; but I shall not, I think, do so in future, and discard all which have the disease badly in the second year. It is not necessary to occupy much land in the trial of seedlings. About a dozen tubers are quite enough to carry on until you decide that the variety is worthy of a more extended trial.

The seeds are sown on a mild hotbed in spring, and planted out at the end of May or beginning of June. They should be put out at least 2 feet apart, and well earthed up. The produce varies very much according to circumstances and the season. You may have twenty tubers, some of them large enough for cooking the first season, or disease may come and you may only have seven or eight tubers about as large as peas, and then it takes several years to work them up to a respectable size, but it will save trouble if you discard in the second year as before mentioned. The seedlings require to be well earthed up, as they have more root-development than those raised from tubers. Here is a wide field open for private enterprise. The Committee appointed by the House of Commons recommended the establishment of stations at different parts of the country for the purpose of raising new seedlings and improving the cultivation of the Potato, but the Government have been too much occupied to be able to give any attention to the matter. I wish they would offer some prizes worth having, and we should then see what can be done in the way of new varieties.—AMATEUR, *Cirencester*.

WE are informed on good authority that the INTERNATIONAL POTATO EXHIBITION to be held at the Crystal Palace on September 20th and 21st promises to equal in interest the exhibitions of former years and to develop some new features. The Committee, aided by the generous co-operation of the Royal Horticultural Society, have been enabled to submit all seedling Potatoes sent in for competition to a very complete series of tests, and they will be finally judged on their cropping, disease-resisting, cooking, and exhibition qualities. The certificates of the International Committee are so much coveted by raisers of new varieties that they have felt bound to exercise the utmost caution, and to spare no pains in their endeavour to do perfect justice.

— WE have received from Messrs. James Dickson & Sons of Chester blooms of their new white CLOVE CARNATION DUCHESS OF WESTMINSTER. Spotless purity, smoothness and substance of petal, with excellence of form are combined in the flowers before us. We have never seen any white Carnations more charmingly beautiful, and the flowers are also highly perfumed. On inquiry we find that the plant is very hardy and continuously floriferous, early layers taken off and potted flowering until Christmas like a tree Carnation. We regard this variety as a valuable acquisition, and Messrs. Dicksons, we apprehend, will require a large stock of plants to meet the demand that is likely to arise when the merits of the Duchess become widely known. Plants of this variety will, we believe, be distributed during the present autumn.

— CRYSTAL PALACE.—Mr. G. Reay-Mackey, late Assistant-Paymaster Royal Navy and Secretary to Admiral Rice and Admiral Luard at Malta, has been appointed manager of the Crystal Palace; and Mr. G. G. Cleather, manager of the Sear-

borough Aquarium and late secretary of the Whitby and Scarborough Railway, has been appointed assistant manager.

— WE learn that Mr. B. Simonite's beautiful self AURICULA MRS. DOUGLAS is about being distributed by the raiser. This variety was certificated at the Southern Show of the National Auricula Society in 1880, and by its robust habit, fine truss, and rich violet purple colour it was much admired. It is not only a fine exhibition variety, but will be highly effective for decorating the front stage of a greenhouse or the margin of a conservatory. Mr. Simonite is sending out at the same time his beautiful light red-edged Picotee Mrs. Gorton.

— RELATIVE to the list of PLANTS CERTIFICATED AT CHISWICK, published on page 117, we are informed that the Heliotropes, Pentstemon, and Tropæolum were not certificated, but recommended by the Floral Committee as excellent varieties worthy of culture.

— A SHEFFIELD correspondent informs us that he saw at RIVERDALE the other day, the residence of C. H. Firth, Esq., one of the heaviest crops of Nectarines that has come under his notice. The fruits average six to the square foot, the variety being Victoria. The Grapes, as usual, are also excellent and finishing well.

— THE new Pea, DUKE OF ALBANY, raised by Mr. Abbot, the gardener at Riverdale, is described by the same correspondent as an immense cropper, with large well-filled pods of fine appearance, while the peas are of superior quality.

— THE NATIONAL DAHLIA SHOW, to be held on Friday and Saturday, September 8th and 9th, at the Crystal Palace, is expected to be one of unusual excellence, representing fully the several classes of Dahlias which are now cultivated both for show and decorative purposes. The time for making entries closes on Monday next, of which fact intending exhibitors should make a note. The entries should be sent to Mr. T. Moore, Botanic Garden, Chelsea.

— MR. LUCKHURST states that he first saw CAMPANULA HEDERACEA growing on the banks of a stream in a bog, and tried to establish Anagallis tenella and Parnassia palustris alongside it, but failed with both of them. Since then the Campanula has made its appearance in various parts of the lawn, and there are now several square yards of it in full bloom, some patches being specially left unmown. The shallow silicious soil is very retentive of moisture, which probably accounts for this lovely bog plant thriving so well in it.

— MR. HARKER, Epsom, sends us the following note on WINTERING ECHEVERIAS:—"All gardeners know the value of Echeverias for carpet bedding, and some find a difficulty in keeping them through the winter. The plan we adopted three years since has answered well through two sharp winters and one mild one. We use a three-light garden frame, and make up ridges of ashes from the furnace, such as you would make in ridging a piece of ground for the winter, then cut the Echeverias off level with the ground, and lay them on the ashes without soil or roots. Since adopting that plan we have scarcely lost a plant. We place a mat on the frame in frosty weather. About the end of March we take off the frame when we want it for Cucumbers, and water the ridges in April and May when the weather is very dry."

— THE same correspondent observes relative to DAHLIA HEDGES:—"I do not know if it is generally known what a fine hedge they make in the garden. Last year we sowed a packet of single Dahlia seed from Mr. Cannell, and had four dozen plants from it, some of which were very good varieties. We selected the best of them, and stored the roots in the usual way. In April we

divided the largest roots and planted them 15 inches apart in a row in the kitchen garden, as a row of Potatoes would be planted. They grew strongly, and when they were about a foot high we placed bushy Pea sticks to them, as if staking Peas, but slanting them outwards wider than for Peas. Now we can gather flowers by the hundred, and if the plants were protected from early frost they would keep flowering for a long time."

— WE are informed that the attendance at the SHREWSBURY SHOW, which was fully reported last week, numbered forty thousand people in the two days.

— THE issue of the "ICONOGRAPHY OF INDIAN AZALEAS" for August contains coloured plates of the following varieties:—Sigismund Rucker, a well-known form, which it is stated originated at Van Houtte's establishment as a sporting branch on Rachel Von Varinhagen, and which has been fixed by grafting; Concordia, a double deep red variety, raised from seed by M. Joseph Vervaene, and sent out in 1879; and Cordon Bleu, one of M. E. Vander Cruyssen's seedlings, with large flowers of good form, and possessing somewhat of a violet-blue or purplish tint.

— THE ninth annual Exhibition of the BRACEBRIDGE AND BOULTHAM HORTICULTURAL SOCIETY took place on Wednesday last in Bracebridge Park, kindly lent by the President, F. J. Clarke, Esq. Boisterous weather prevailed, but the rain held off and the attendance was satisfactory. The horticultural exhibits were staged in three marquees, and the display was equal if not superior to former years. The principal prize for plants arranged for effect was awarded to N. Clayton, Esq., for a magnificent collection, the arrangement of which reflected much credit upon the gardener, Mr. A. Wipf. Mr. H. Greenham was second, and Major Ellison third. The latter was also a successful exhibitor of flowers. Fruit was a splendid show, the majority of the prizes falling to Mr. Clayton, the Mayor of Lincoln (W. J. Warrenner, Esq.), Mr. A. Shuttleworth, and the Marquis of Ripon. Messrs. Pennell & Son contributed a superior collection of Roses, Gladioli, &c. Vegetables were especially fine; the Red Cabbages, Onions, and, in fact, all kinds grown by Mr. Bentley on the Corporation's Sewage Farm being of marvellous size and excellent quality.

— IN the last quarterly number of "La Belgique Horticole" we notice an illustrated verbatim translation of the lectures on "HORTICULTURAL BUILDINGS," delivered by Mr. F. A. Fawkes, F.R.H.S., during the last winter session to the students of the Crystal Palace School of Gardening.

— AGRICULTURAL depression would appear to have a wide field, for we find there are DISTRESSED TOBACCO PLANTERS. Owing, as it is said, to the low prices of tobacco in Europe the tobacco cultivation, once so flourishing in the island of Java, is rapidly declining, the planters being in consequence much distressed. The *Java Bode*, a Dutch local journal, states that lately in the eastern portion of that island three estates were sold collectively for the trifling sum of 5700 guilders, though only three years ago a brick tobacco shed on one of them cost 400,000 guilders.

— WE regret to announce the death of JOHN DILLWYN-LLEWELYN, ESQ., of Penllergare, near Swansea, at the age of seventy-two. Mr. Llewelyn died at Atherton Grange, Wimbledon, where he had taken up his residence during the last two years, having relinquished his residence at Penllergare in favour of his son, Mr. J. Talbot Dillwyn-Llewelyn, who is well known as an ardent florist and horticulturist, and as a member of Council of the Royal Horticultural Society. Mr. Llewelyn, sen., was a Fellow of the Royal Society, and one of the oldest surviving Fellows of the Royal Horticultural Society. He took an active

part in the prosecution of horticulture, and was ever ready to promote its best interests.

— MESSRS. CHRISTY & CO., 155, Fenchurch Street, London, E.C., have issued No. 6 of their work entitled "NEW COMMERCIAL PLANTS AND DRUGS," which is divided into two parts, one being devoted to "Fibres: their Botanical Sources, the Methods of Examining Them under the Microscope, and their Treatment by the Ekman Process, with six Coloured Plates;" and the other to "New Plants and Drugs, their Cultivation and Uses." In the first part much information is given concerning the relative merits of the different fibres, amongst which those of the following plants are represented by magnified dissections, accompanied by full description—Flax, Hemp, Jute, Cotton, China Grass, New Zealand Flax, Mudar Bark, Paper Mulberry, Nepal Paper Plant, Esparto, Pita, Manila Hemp, Tricum Palm, Bowstring Hemp, Pineapple and White Fir. In addition to these the chief fibre-yielding plants are referred to under their several natural orders, the mode of preparation, &c., being fully considered, and in some cases particulars of cultivation are also given.

— IN the part of the same work devoted to NEW DRUGS elaborate descriptive notes are given respecting the Papaw, Lycopodium clavatum, Carnuba, White Quebracho Bark, Kava Kava, Goa Powder, Coca, and many others. In reference to the culture of the last-named the following particulars are given:—

"The seeds of the Coca are sown on the surface of the soil as soon as the rainy season commences, and begin to sprout in a fortnight, being carefully watered, and protected from the sun by a thatched roof. The following year the seedlings are transplanted in a soil carefully broken up and freed from weeds. The ancient custom was to raise the plants in terraces on the hillsides, but now plantations on the level ground are resorted to, although Indians aver that plants raised under the former conditions yield a much superior quality of leaf. At the end of eighteen months the first harvest is ready, and the picking of the leaves, performed by women and children, is very carefully proceeded with, so as not to injure the young and still tender shoots. As soon as one crop of leaves is removed, if well watered, and the ground carefully weeded, another crop is ready in about forty days. A plant continues to yield for about forty years, and Dr. Poeppig gives the profit of a Coca plantation as about 45 per cent. Each picker carries a piece of cloth, in which the leaves, plucked one by one, are placed. These leaves are then taken to the drying yard, formed of slate flags. Here the leaves are spread out in thin layers, and carefully dried in the sun. Too much exposure to the sun spoils the flavour of the leaf, and if heaped too much together the leaves ferment and become foetid. As soon as dried the leaves are packed in bags made of Banana leaves with an outside covering of cloth, or packed tightly in large parcels of about 50 lbs. each."

It should be remarked that the book is printed upon paper of excellent quality prepared entirely from wood reduced to pulp by the Ekman patent process.

READING SHOW.

AUGUST 17TH.

THE second Exhibition of the year held by the above Society proved a very satisfactory one both in the number and quality of the contributions staged by nurserymen, gardeners, and amateurs, all sections of the schedule being well represented, and in some of the classes the competition was very keen. Owing to the gale on Wednesday night, which greatly damaged the large marquee erected in the Forbury Gardens, a new site had to be chosen at the last moment; and though the exhibitors suffered much unavoidable inconvenience in consequence, yet the selection of the new and old Town Halls for the purpose ultimately proved fortunate, as the unfavourable weather would have deterred many from visiting the Gardens. The new hall is particularly suitable for an autumn exhibition, being very spacious, light, and handsome, affording a striking contrast to the old hall in all respects. Both were well filled with exhibits, the former containing the groups of plants arranged for effect, the stove and greenhouse plants, Ferns, and miscellaneous plants; the other chiefly was devoted to fruit, cut flowers, and a few collections of plants not for competition, while the corridors contained the vegetables. The general arrangements were highly satisfactory, the display in the new hall being especially effective.

Stove and Greenhouse Plants.—The most important class for these was that for nine specimens, of which two very creditable collections were staged. Mr. Mould of Pewsey secured the leading position with even, well-grown, and well-flowered examples of *Ixora Reginae*, *Lantana Don Calmet* 4 feet in diameter and flowering freely; *Clerodendron*

Balfourianum, *Erica cerinthoides coronata*, neat and healthy; *Allamanda Hendersoni*, vigorous and finely flowered; *Ixora Williamsi*, *Statice Butcheri*, and *Dipladenia Brearleyana*. Second honours were accorded to Mr. Lees, gardener to Mrs. Marsland, The Wilderness, for a similarly praiseworthy collection, comprising an exceedingly good *Bougainvillea glabra* of globular form, about 4 feet in diameter, and well flowered; *Tabernamontana coronaria fl.-pl.*, healthy and fresh; and *Rondeletia speciosa* trained in globular form, and bearing abundant heads of large brightly coloured flowers. In the amateurs' class for six specimens Mr. Mortimer, gardener to Major Storer, Purley Park, took the lead with neat well-grown examples of *Allamanda Wardleyana*, *Stephanotis floribunda*, *Bougainvillea glabra*, and *Ixora Williamsi*. Mr. Hope, gardener to the Hon. R. Boyle, Purley, followed closely with a good *Tabernamontana coronaria*, *Allamanda Schotti*, and *Plumbago capensis*. Several admirable single specimens were shown, the one selected for premier honours being a globularly trained freely flowered *Erica Irbyana* from Mr. Bennett, gardener to M. Lonergan, Esq., Cressingham. Mr. Hope took the second prize with *Allamanda Hendersoni* healthy and good, extra prizes being adjudged to Mr. Ashby, gardener to W. Fanning, Esq., Whitchurch, for a specimen of *Fanny Catlin Pelargonium* of considerable size and profusely flowered; and to Mr. Lees for a plant of *Stigmaphyllon auriculatum*, evenly trained, healthy, and bearing numbers of its bright yellow flowers.

Fine-foliage Plants.—Three beautiful collections were contributed in the class for six variegated or fine-foliage plants, Mr. Ross, gardener to C. Eyre, Esq., Welford Park, securing chief honours with handsome examples of the following:—*Cyperus alternifolius variegatus*, about 4 feet high and as much in diameter, very healthy, and the variegation well marked; *Maranta zebrina*, of considerable size and good colour; *Alocasia metallica*, fresh and healthy; *Alocasia macrorrhiza variegata*, vigorous; *Croton Weismanni*, bright; and *Bonapartea gracilis*, very healthy. Mr. Mortimer followed with a collection of slightly smaller plants, but similarly well grown; *Croton majesticus*, *C. Weismanni*, *Yucca aloifolia*, and *Alocasia macrorrhiza variegata* were especially good. Mr. Mould was a third with fair examples. The best four foliage plants were staged by Mr. Bezant, and comprised *Alocasia metallica*, *Maranta zebrina*, *Croton majesticus*, and *C. variegatus*, all very well coloured. Mr. Lees was a close second, his best plant being *Alocasia metallica* in fine condition. For one new or rare plant Mr. Howe, gardener to Sir R. Sutton, Bart., Benham Park, was placed first with a large, healthy, well-coloured specimen of *Croton Truffautianus*; Mr. Ross being placed second with *Cycas circinalis* very healthy and fine, but why it was admitted in this class is by no means clear, as it can be scarcely considered as rare, and it is certainly not new.

For six Ferns Mr. Mortimer carried off the leading award for an extremely handsome collection of healthy, vigorous, but neat specimens of *Davallia bullata*, *Cibotium australe* of great size, *Dicksonia antarctica*, *Adiantum cardiochlaena*, *Davallia Mooreana*, and *Adiantum pentadactylon*. Mr. Ross, who obtained second honours, also had a praiseworthy collection, comprising *Phlebodium sporodocarpum*, *Pteris argyrea*, *Platynerium alpicorne*, *Davallia Tyermanni*, *Pteris umbrosa*, and *Davallia bullata*. Mr. Lees had the best four Ferns—very well-grown examples of *Gymnogramma pulchella*, *G. chrysophylla*, *Adiantum gracillimum*, and *A. farleyense*. As usual Mr. Mortimer had six handsome *Selaginellas* of conical form, and gained the first prize, an equal award being granted to Mr. Hope for a similar collection.

Table Plants.—A class was provided for six plants in 6-inch pots suitable for table decoration, and three excellently representative collections were staged. Mr. Ross won premier honours with neat little specimens in admirable condition, and just of the right size for such a purpose. They were *Caladium argyrites*, a well-known favourite; *Dracaenas Guilfoylei* and elegantissima, both narrow-leaved forms of good colour; two pretty seedling *Crotons*, one with narrow slightly drooping leaves, and the other with spirally twisted leaves; and *Pandanus Veitchii*, the variegated Screw Pine. Mr. Burgess took the second position with rather larger plants, chiefly *Crotons* and *Dracaenas*, an extra prize being deservedly awarded to Mr. Howe for good plants, the best being the far from common, though elegant, *Pandanus gracilis* and *Reidia glaucescens*.

Of the smaller classes the most noteworthy were those for six and three *Liliums* respectively, in both of which Mr. Bridge, gardener to J. T. Hall, Esq., gained the first prize. The specimens comprised some admirable examples of *L. speciosum* very well flowered, and *L. auratum* similarly good. Mr. Burgess had the best six *Coleuses*, small pyramidal specimens fairly well coloured. Mr. Uphill, gardener to R. Garrard, Esq., Wokingham, was the chief exhibitor of *Dahlias* in pots, having four healthy freely flowered specimens of good varieties. Mr. Ashby won the chief prize for six bedding *Pelargoniums* with profusely flowered specimens of Mrs. Moore, Lady Sheffield, Mrs. Storey, Leviathan, Lizzie Brooks, and Sophie Barkin, several of which were 5 feet in diameter.

Groups.—The centre of the new hall was devoted to these, and a very pretty effect they produced, especially when viewed from the gallery. The class provided for a group of plants arranged effectively in a space of 12 feet by 10 feet, about half a dozen exhibitors entering the competition. Although not displaying any remarkable originality most of the groups were tasteful, flowering plants being freely employed, but with sufficient Palms, Ferns, &c., to avoid an

unpleasant glare of colour. Mr. Lees was adjudged the premier prize for a free, light, and diversified arrangement, the base consisting chiefly of Adiantums and other small Ferns, from which arose taller Palms, Ferns, Aralias, and Crotons, with specimens of *Campanula pyramidalis*, Petunias, Ixoras, and Pelargoniums. The margin was very tasteful, comprising *Tradescantia multicolor*, *Panicum variegatum*, Fittonias, and Ferns. Mr. Phippen of Reading gained the second prize with a very meritorious group, in which the useful *Hydrangea paniculata grandiflora* largely predominated, the plants being all healthy and bearing very large trusses of flowers. Fuchsias, white Lilies, Gloxinias, Begonias, Coleuses, Galtonias, Ferns, and Palms were also freely and effectively employed. An extra prize was awarded to Mr. Sumner, gardener to Mr. Millard, Reading, for a bright group, in which Tropæolums were very telling. Mr. Mayne, gardener to Miss Moon, Reading, was also adjudged an extra prize, and similar recognition was accorded to Mr. Turton, gardener to J. Hargreaves, Esq., Marden-Erleigh.

Cut flowers formed an attractive feature in the old hall, Dahlias, Roses, Phloxes, and Gladiolus being particularly well shown. Messrs. Turner, Lees, Tranter, Atkins, Phippen, Burgess, Jones, Howe, and Durman, gardener to J. W. Wakman, Esq., Reading, were the principal prizewinners. Buttonholes and vases of flowers were chiefly contributed by Miss Kate Phippen, who had some very tasteful arrangements well deserving the awards secured.

Fruit.—The competition in most of the leading classes for fruit was close, the general quality being very satisfactory, especially of the collections. Grapes were also well shown, Plums, Peaches, and Nectarines being very numerous. For a collection of eight dishes, distinct kinds, Mr. Austen, gardener to Sir G. Smythe, Bart., Ashton Court, won the first prize presented by Messrs. Sutton & Sons—namely, a silver cup value five guineas, with good bunches of Madresfield Court and Muscat of Alexandria Grapes well coloured, Williams' Bon Chrétien Pears, Brown Turkey Figs, a seedling Melon from Blenheim Orange, fine Barrington Peaches, Pine Apple Nectarines, and a large Smooth Cayenne Pine Apple. Mr. Miller, gardener to W. H. Long, Esq., M.P., Rood Ashton Park, was a good second, having well-coloured Black Alicante Grapes, fine Moorpark Apricots, Kirke's Plums, and Bellegarde Peaches. Mr. Atkins, gardener to Sir R. Lloyd Lindsay, M.P., Lockinge, was third, having praiseworthy Black Hamburgh Grapes. There were also five competitors in the class for a collection of six dishes, in which Mr. Goodman, gardener to C. Hammersley, Esq., Bourne End, won the chief award, having Black Alicante and Foster's Seedling Grapes of moderate size but in good condition, Crimson Galande Peaches, Moorpark Apricots, Humboldt Nectarines, and Nectarine Plums. Mr. Lockie, gardener to Lord O. Fitzgerald, Oakley Court, Windsor, was a good second, and Mr. Mortimer third. Black Hamburgh Grapes were well shown by Messrs. Ashby, Miller, and Austen, who won the prizes in that order amongst five other competitors. For three bunches of any other black Grapes Mr. Heath, gardener to R. Ovey, Esq., Henley, gained the chief prize with grand bunches of Black Alicante, large, even, and bearing fine bloom. Messrs. Ashby and Everest followed. The best Muscats were staged by Mr. Austen, who had large bunches and berries, even and well ripened. Mr. Robinson, The Royal College, Englefield Green, and Mr. Ashby followed in that order, there being seven other collections staged. The last-named exhibitor gained the principal prize in the Any other white Grape class with fine bunches of Buckland Sweetwater; Mr. Atkins was second with Golden Queen, also good; and Mr. Wells, gardener to R. Ravenhill, Esq., Windsor Forest, was third with fair bunches of Buckland Sweetwater. Plums, Apricots, Peaches, Nectarines, and Melons were well represented, the principal prizetakers being Messrs. Osborn, gardener to the Rev. A. Golding, Sonning; Jones, gardener to Lord Calthorpe, Elvetham Park; Goodman, Atkins, Ross, Lockie, and Austen. Culinary Apples were also largely shown, Messrs. Ross, Turton, and Bennett taking the chief prizes. Messrs. J. Carter & Co.'s prizes for two fruits of Blenheim Orange Melon were gained by Messrs. Lockie, Mortimer, and Burgess, all of whom staged fruit of moderate size, even, and well netted.

Vegetables.—In addition to the prizes offered by the Society for miscellaneous vegetables, which were well competed for, Messrs. E. Webb & Sons, Wordsley, Stourbridge, and Messrs. James Carter and Co., High Holborn, contributed special prizes of considerable value. Messrs. Webb offered four prizes for collections of six distinct kinds of vegetables, and for these there were twelve competitors, all showing admirable collections. Mr. Lockie was first with clean examples of Ne Plus Ultra Peas, Reading Onions, Rivers' Ashleaf Potatoes, and Model Cucumbers, amongst others. Messrs. Bryant, Bradford, gardener to L. Cooper, Esq., Caversham, and Howe secured the other prizes in that order. Messrs. Carter's prizes for Model Cucumbers were won by Messrs. Lockie, Burgess, and Mortimer, all showing even and good fruits.

In the Society's classes Potatoes were largely exhibited, Messrs. Ross and Millen being the chief prizetakers. Cauliflowers, Celery, Onions, Tomatoes, and Cucumbers were also abundantly and well represented.

Miscellaneous exhibits were numerous and attractive, especially two handsome collections of single Pompon, Show, and Fancy Dahlias from Mr. C. Turner of Slough, which comprised a large number of beautiful varieties, the blooms in the two last named sections being extremely fine. Messrs. C. Lec & Son, Hammersmith, had a large and

interesting collection of sprays of variegated and ornamental hardy trees and shrubs, while Messrs. Cross & Steer, Salisbury, exhibited blooms of the new Clove Carnation, The Governor. This variety has creamy-white flowers of good form and substance, and was much admired. T. S. Cocks, Esq., Marlow, sent a collection of Plums grown out of doors, comprising excellent fruits of Impératrice, Coe's Golden Drop, Nectarine, Jefferson's, Belgian Purple, Washington, Victoria, Greengage, and Reine Claude Violette.

GARDEN NOTES FROM NORTH DURHAM.

A FEW fallen leaves make us look up to the trees, and their old-fashioned summer garments remind us that the time is approaching when we should make a note of what has done well with us and is worth keeping another year, and also we must make a note of failures—things not to be attempted again under the same conditions.

Foremost among our own little troubles is a bed of dwarf Tropæolums which is not at all a failure in one sense, since it has been and is yet a perfect sheet of splendid scarlet; yet is not what I should have liked, or is not what I expected it would be, which is something worse. Last year we had a bed of scarlet Tom Thumb Tropæolums which was admired by everybody for its brilliancy of colour and the compact regularity of the plants. This bed was on the side of a wide main road; on the opposite side of the road is an herbaceous border, where the tall-growing section of Tropæolums are grown in abundance for the purpose of covering the boundary wall. Such was the general admiration of the dwarfs that I determined to save some of the seeds for another display the following year. The seeds were saved in quantity and were freely distributed amongst the public, a good number being sown this spring in a cold frame. Only one bed has been exclusively planted with them, and that at the entrance, and out of the whole bed there are scarcely ten plants have not shown the unmistakable habit of the tall Tropæolums that grew opposite them last year. Instead of the small dark leaf and compact dwarf habit, they exhibit large bright green leaves with a tendency to "sprawl" all over the place. Is this degeneration, or is it the result of insect-fertilisation? Cuttings from the same plants as the seeds were saved off are quite satisfactory.

Another failure of the same sort—*i.e.*, plants turning out to be something else than they were expected to be, is a new Golden Feather sent to me by a neighbour with a flourish of trumpets that it "was to eclipse the old variety altogether." It has a long high-sounding name which I never knew, or ever cared to learn; suffice it to say that neither here nor in my neighbour's garden has it been anything at all equal as a yellow-leaved plant to the old Golden Feather. But as a white-flowered dwarf plant it is about as pretty as anything I know of; it has pure white double Daisy-like flowers which it produces in abundance, and does not exceed 8 inches in height. If it is very hardy and can be utilised for spring flower gardening there is a great future in store for it; but as a golden or yellow-leaved bedding plant it is no use at all in this neighbourhood.

Pansies have been a great success, especially Blue King, Tory, Pilrig Park, and Duchess of Edinburgh, and I had almost omitted the best—Magpie. The first and last of these I often see thriving famously in town gardens. Cloth of Gold does not do well with us, a remark which applies to all the yellows that I know. A local sort without a name is a favourite from its free-blooming properties, and its fine dark colour, splendidly relieved by a bright golden eye. Lilacea is a free and continuous bloomer but of very little substance, and nothing save that property and its remarkably sweet scent to recommend it. By keeping the seed pods and spent blooms assiduously picked off them Pansy beds and borders may be kept in good condition the whole of the summer. Some of ours that are in bloom now commenced flowering in February, and are still good.

Antirrhinums have been very good. We never sow any; there are always plenty coming up in the borders, both of them, Foxgloves, and Canterbury Bells; and by exercising a little care in saving them and transplanting them when and where necessary the stock is kept up and improved. Every year the varieties become more numerous and the flowers better. We have no great quantity of herbaceous plants, but it would be difficult to find anything more beautiful, or anything to give a greater amount of flowers over a longer period, than the red Valerian and its varieties, the white one being particularly fine. Sweet Williams were among our best flowers, large masses of them being very fine. Stocks and Asters do not do well with us, and the only few plants we had of the true *Myosotis dissitiflora* disappeared during the dry weather in May.

Manure as it is usually understood has no existence here; neither have we any approved earth closets. We have sifted ashes, refuse

soil, and night soil, and we make the most of the mixture. This native guano is applied to all sorts of crops, both flowers and vegetables, it is even used for plants in pots; and I may state here that if a sufficient quantity of it could be had instead of being sent down sewers to the sea, both farming and gardening would be immensely the better for it.—PETER FERGUSON, *Monk Wearmouth*.

THE LONDON PARKS.

PILGRIMAGES from distant parts of the country are made by many who are interested in summer garden decoration to the parks of the metropolis, where the different styles of bedding are so well represented. But after all the visitors are in the minority, and the infinitely greater number of gardeners and garden admirers have to content themselves with descriptive accounts of the beds and the plants that are employed, with the object of gaining information that may be usefully turned to account in furnishing their own gardens or those for which they are responsible. A few notes on the gardening in the London parks will, therefore, not be unacceptable at the present time.

HYDE PARK.

"Hyde Park is very good this year" is an expression that has been frequently heard this season, and not many who have examined the flower beds will dispute the accuracy of that verdict. For several weeks after the planting was done the weather was miserably cold, and the more tender plants, such as Iresines and some of the subtropicals, made slow progress; but latterly the days have been bright if not hot, the beds have filled well, and have been bright with both flowers and foliage. There are perhaps more flowers than usual—Pelargoniums—and a less number of carpet or tapestry beds, but what there are of the latter are highly finished examples.

The best route for a gardener to traverse is to enter the Park at the Marble Arch, pass along the margin to Hyde Park Corner near the Wellington Monument, and he will thus "catch" the tapestry and flower beds; then turn to the right, still near the margin, and go on to the Albert Gate. Then turning to the right again he will see the subtropical examples, which culminate in the beautiful dell near the Serpentine; a walk from there "cuts" across diagonally back to Hyde Park Corner and past some large beds filled with ornamental-foliaged plants. The route is not a long one, not much more than a mile, and a great deal more is to be seen than can be told about here; but it is to be feared all the beds cannot be seen now at their best, as the tempestuous wind of the 22nd and 23rd inst., driving with great force from the west, can scarcely fail to have been very injurious to the foliage and flowers.

From the Marble Arch onwards the ribbon border on the left has been gay, the front line of *Lobelia Blue Stone* very rich. This is an excellent variety where a dark dense colour is wanted. Amongst the Pelargonium beds on the lawn Mrs. A. Miles, a fine pink bedder; Princess of Wales, pale cerise, very pleasing; Pioneer, cherry crimson; and Little Carr, bright scarlet, attract notice. We next come to a glowing bed of the fine old nosegay variety *Fire King*, edged with the variegated *Queen of Queens*, and margined with *Lobelia Blue King*, the latter a pale bright blue, fine for large beds. A mass of Maurice Bernardin, a salmon oculated Pelargonium, is evidently one of the best bedders of its class, and contrasts well with the bright John Gibbons not far distant; but brighter still perhaps is the older—almost ancient for a Zonal Pelargonium—*Triomphe de Stella*. A bed now, very different and very attractive, compels a pause; it is a large oblong, and is planted diagonally with Pelargonium Verona, a dwarf variety with greenish-yellow foliage and pale rosy-lilac flowers, and Iresine Linden in alternate rows. It is edged with a silver-leaved Pelargonium, banded with *Alternanthera amœna* and margined with *Echeverias* set in *Sedum glaucum*: the combination is very striking. The terminal bed of this group is a round one, having several plants of *Dracœna rubra* growing from a carpet of *Alternanthera*. The edging is of *Mentha*, with *Chamæpuce diacantha* at intervals, and a margin of *Echeverias*.

We are now at Grosvenor Gate, and find another series of very fine beds to Mount Street, all edged with Robert Fish Pelargonium, yellow, banded with *Lobelia pumila* magnifica margined with *Antennaria tomentosa*. The *Lobelia* is singularly rich and fine. There are several mixed beds here, which afford agreeable relief to the Pelargoniums. For instance, a mass of *Solanum margaritaceum* with a groundwork of purple Pansies, and the variegated *Abutilon Thompsoni* springing from a mass of dark *Heliotrope*, are both pleasing. Near is a very bright deep scarlet bed of Pelargonium Sir Henry S. Stanhope, very good, and opposite a rich mass of the glowing crimson Rev. F. Atkinson. Rose Bradwardine has succumbed to the showers and is not a safe bedder, and the same may be said of William Thomson; but Ernest, orange scarlet, is free and fine, and there are also grand beds of Mrs. Holden and *Fire King*. More mixed beds follow—namely, *Abutilon Boule de Nieve* in a groundwork of *A. vexillarium*; *Melanthus major* with a carpet of *Alternanthera magnifica*, both of which are admired; while *Solanum Balbisi* mixed with *Perilla* has a singular effect, the whitish Potato-like flowers contrasting effectively with the almost black foliage. A few more fine Pelargonium beds are C. Schwind, rich glowing crimson, excellent; Sibylla, a fine pink; D. Rawson, cherry crimson, perhaps the best of its colour; but Capt. Holden is very fine; Gertrude, salmon, good; and Lady Bailey, one

of the finest pinks for pots or beds. Some mixtures of silver-variegated Pelargoniums Princess Alexandra and Miss Kingsbury—the two best—and *Violas* have a pretty effect. The end bed in this section is groundwork of *Sedum arachnoideum*, which has a curious effect dotted with large Agaves.

We are now at South Street, and onward to Stanhope Gate the edgings are *Lobelia Blue King*, free and fine as associated with variegated Pelargonium Ariosto, of the Manglesii type, but more resembling Duke of Edinburgh. Passing a bed of *Heliotrope Jean d'Amour*, a fine dark sort, a glowing crimson mass of *Calceolaria Bijou*, and a mixture of *Acacia lophantha* and Iresine, we come to some tapestry beds, which are certainly admirable examples of this style of decoration. In the first bed are central panels and circles of *Alternanthera versicolor*, surrounded with a scroll of *A. magnifica*. Then comes a band of *Sedum brevifolium majus*, between which and a string of *Kleinia repens* are angles of *Alternanthera paronychyoides aurea*, the bed being completed with marginal lines of *Mesembryanthemum cordifolium variegatum*, *Alternanthera amœna*, and *Echeverias*. The next bed is totally dissimilar in design. It is principally an association of *Alternantheras*—bars and lines of *A. amœna*, panels of *A. p. aurea*, a star set in Golden Feather on a groundwork of *A. p. major*, and a margin of *Antennaria tomentosa*. The splendid colour of the *Alternantheras* is very noticeable, and the bed is rich yet chaste. The last bed to be noticed is possibly still more striking. Two heart-shaped designs of *Alternanthera paronychyoides major* and *p. aurea* point towards the centre. These are banded with a gracefully arranged scroll of *Herniaria glabra*, the deepest green, the dwarfest, and the most hardy of all green carpet plants. There are central panels of *Pachyphyton bracteosum*, and outer crescent-shaped masses of *Alternanthera amœna* in brilliant colour, and *A. p. aurea* in the finest possible condition; the bed is margined with *Echeverias*. These beds are perhaps nearly faultless, and as regards designs, colour, and excellence of condition leave little or nothing to be desired.

Little can be said about the subtropical department, further than that the Palms, Tree Ferns, Cordylines, and other ornamental-foliaged plants are disposed with great taste, and that the dell near the Serpentine has been furnished with a masterly hand. Both Mr. Brown and his experienced assistant, Mr. Chamberlain, are to be congratulated on making this great park so attractive to the vast crowds which have visited it during the present season.

BLACK CHAMPION CURRANT.

WHEN this variety was exhibited before the Fruit Committee of the Royal Horticultural Society at South Kensington in August last, the wonderful size of the fruit and the profusion in which it was borne on the sprays commanded much attention. It appeared to be freely admitted that such a fine Currant had not previously been seen on the Committee table, which from time to time contains examples of the best fruits, new and old, that are produced in this country. It was exhibited by W. H. Dunnett, Esq., of Stour House, Dedham, Essex, and was unanimously awarded a first-class certificate. The great size of the fruit exhibited on that occasion may in a measure have been the result of generous soil, but if the variety were not of intrinsic excellence no kind of soil could have produced such remarkable results. We presume that soil equal to that in which Mr. Dunnett grew the Black Champion is to be found in thousands of gardens, and in the course of a year or two it will be reasonable to expect that many cultivators will have produced fruit equal to that first exhibited, and not unfaithfully represented in the annexed engraving. Plants of the Black Champion Currant will be distributed during the present autumn by Messrs. James Carter & Co. at prices that will be found in their autumn catalogue.

STANDARD ROSES.

I MUST confess that I rubbed my eyes when I came to the signature of the short article on this subject in last week's Journal, and found that it bore the name of so old a grower as Mr. W. Paul; but on reading it a second time the authorship was very apparent. May I, as old a rosarian as the writer, answer his question, "Whence this cry against standard Roses?" and refer to some other statements made in one of the most misleading articles on the Rose I have ever read. Why are they not more grown, then? 1, Because of their dearness. Standard Roses are generally quoted at about three times the price of dwarfs. If the advantages were three times as great this might be tolerated, but as that is not the case it must act as a deterrent. 2, Their ugliness. A mop of Roses at the top of a stick is not, in the minds of many, an ideal of beauty. 3, Their liability to injury from frost. The winters of 1880 and 1881 destroyed them in all directions by thousands, and in the neighbourhood of Brie Comte Robert by millions, and persons who have paid dearly for a thing that succumbs to a severe winter are not likely to repeat the experiment. It is for these reasons that standard Roses are not the

favourites now that they once were. Mr. Paul approves of the saying of his friend, who said they brought the Rose nearer to the

eye and nose, but I fail to see this advantage. They are only to be employed at the back rows of a rosery, and how a person is to

Fig. 13.—BLACK CHAMPION CURRANT.

get at them without walking over his borders I am at a loss to imagine.

Mr. Paul's observations about maiden plants are the most objec-

tionable and incorrect. I should like to know who are the exhibitors who grow Roses for one year and never care for them afterwards? There are a few Roses, such as Horace Vernet, Xavier Olibo, and

two or three more, which are such indifferent growers that they are best in their first year, but there are only four in the National Rose Society's catalogue that are so marked; and it may perhaps surprise not only the uninitiated but Mr. W. Paul himself to hear that Mr. Baker of Exeter, who won the challenge trophy last year, never exhibited from maidens, and that his plants were four or five years old; that Mr. Whitwell, who won the challenge trophy this year, does not grow maiden plants, and neither of them grows standards. Of course growers for sale, budding large quantities every year, have always plenty of maiden blooms, but it would be news to them that they threw away their plants!

It is not every grower who can visit large nurseries and see the plants in growth, and were he to do so he is apt to get confused by the number. He has now, if he will depend on it, a reliable guide in the catalogue of exhibition Roses issued by the National Rose Society, which has been carefully prepared, and in which every needful information is given.—ROSARIAN.

SANDY AND DISTRICT HORTICULTURAL SOCIETY.

THIS Society, which from small beginnings now holds position as the chief horticultural society of Bedfordshire and the district, celebrated its fourteenth annual Exhibition on the 25th inst. in the grounds of J. N. Foster, Esq., Sandy Place, notwithstanding the persistently intermittent showers throughout the day, and which at 4 P.M. culminated in a heavy downpour of rain accompanied by thunder, drew large numbers of visitors, who were, however, chiefly clad in sober grey and black, showing that the fair sex were largely deprived of a pleasant holiday, and it is feared that the Committee, although hacked by a good subscription list, must be financially sufferers. In every other respect the Show, which, somewhat after American fashion, embraces under its wings horticulture, farm produce, poultry, pigeons, birds, bees, and industrial work, was a repeated success.

The show of plants at Sandy, although always a good one, notwithstanding the liberal prizes offered, does not usually attract much competition extraneous from the locality, the deficiency, however, being well supplied by the district. Mr. G. Parker of the Rugby Nurseries has for several years past been the chief, if not the sole, representative of the professional large plant-growers at the Sandy Show, and on this occasion he well sustained his reputation by securing the first place in the open class for ten stove and greenhouse plants in flower, and although little novelty appeared in his collection, his plants were fine specimens, wonderfully healthy, and well bloomed for the season; Allamandas, Dipladenia, Statice intermedia, and Stephanotis being in most creditable condition. The second prize was awarded to Mr. W. Rabbitt, gardener to General Pearson, The Hazells, Sandy, for well-grown specimens, including a good example of *Lasiandra macrantha*, a beautiful Melastomaceous plant with violet-coloured flowers, but not frequently seen at exhibitions on account of the frailty of its blooms. For six stove and greenhouse plants in flower in the gardeners' class, Mr. Redman, gardener to J. H. Goodgames, Esq., St. Neots, was first with excellent specimens. In foliage plants Mr. G. Claydon, gardener to J. H. Astell, Esq., Woodbury Hall, St. Neots, had a good collection of six, containing a fine plant of *Alocasia Veitchii*, and received first honours.

In the open class for twelve Zonal Pelargoniums Mr. Rabbitt had admirably grown and profusely flowered examples. Dazzler, Col. Holden, Jealousy, Chas. Seely, bright vermilion scarlet with white eye; and a very dwarf and floriferous variety named Ernest Favre, most distinct and striking flowers, white with a well-defined red eye, sent to Mr. Rabbitt as a gratis addition to a collection by Mr. Cannell, and from which it would seem that rubbish is not always given by the trade to compensate for carriage. A seedling semi-double Zonal Pelargonium named Emily Carbon, from Mr. Carbon of Peterborough, which had deep pink flowers and an apparent white centre, seemed distinct and promising.

Fine stove and greenhouse Ferns were shown by Mr. Tillbrook, gardener to B. Brown, Esq., Hemingford, Hunts, in the collection of six varieties, and for which he was placed first, the centre plant being a grand *Dicksonia antarctica*. Mr. Claydon was second with almost equally well-grown plants. For four hardy Ferns Mrs. J. H. Astell was first with *Athyrium filix-femina plumosum* and *Victoria*, *Osmunda cristata*, and *Lomaria chilensis*, all large and well-grown plants.

Roses, considering the season and the recent rough weather, were in good form and force, Messrs. Paul & Son, Cheshunt, being placed first in the open class for forty-eight blooms, twenty-four distinct varieties, their best blooms consisting of A. K. Williams, Madame Willermoz, La Rosière, and White Baroness. Mr. J. House, Peterborough, was a good second, having A. K. Williams, Comtesse Serenye, and Madame Eugène Verdier, a good autumn Rose of the type of *Lælia*, in fine condition. Mr. G. Parker, Rugby, was third. Messrs. Paul & Son also showed a boxful of their new White Baroness, almost pure white, and of fine form. Mr. House also showed a box of the beautiful orange-apricot Rose, William Allen Richardson, a Tea-scented buttonhole variety, probably destined to be grown largely for market. In the amateurs' class for twenty-four blooms, not less than twelve distinct varieties, the Rev. W. H. Jackson, Stagsden Vicarage, Bedford, was first with fine large blooms, having

good flowers of A. K. Williams, Baroness Rothschild, and Mdlle. E. Verdier. The Rev. E. L. Fellowes, Wimpole Rectory, Royston, was second, his best flowers being Marie Van Houtte and Madame Sophie Fropot. C. E. Cuthell, Esq., Chapel Croft, Dorking, was third, Duke of Teck and Marie Van Houtte being very fine in his stand. For the six varieties, Mr. J. Burton, Sawtry, was first, his bloom of Pierre Notting being the best flower, and his stand one of the prettiest in the Show.

Dahlias, not for competition, were finely staged by Messrs. Paul and Son, some of the best being Christopher Ridley, Royal Queen (mauve), Lord Chelmsford, Jas. Vick (maroon), Mrs. Saunders (yellow with white tip), and F. Smith. An attractive stand of single Dahlias came from Mr. E. M. Jones, Cambridge, and *Gladiolus* from Mr. Parker. Asters were not good, but a fine stand of double Zinnias came from Mr. A. Chapman of Tempsford Mill, and African Marigolds, as usual at this Show, were good, the best coming from Mr. P. Meyer of Orwell.

Fruit was neither so good nor so largely shown as last year, but Mr. Tillbrook's first-prize collection of six varieties, consisting of Muscat and Black Hamburgh Grapes, Peaches, Nectarines, and Plums, were admirable examples of cultivation. In the amateurs' class for four varieties Mrs. D. Brown, Langford, was the premier prizewinner. For two bunches of black Grapes Mr. Tillbrook was placed first with fine and well-coloured Alicantes, and Mr. J. W. Shephard, Great Staughton, Hunts, second with almost equally good Black Hamburghs. For white Grapes the Judges had a difficult task in deciding between fine but not highly finished bunches of Muscats and very fine and well-finished bunches of Buckland Sweetwater. Flavour, however, carried the honours, which fell to Mr. Tillbrook, who was also first for his Alicantes; Mr. G. R. Allis, gardener to Jos. Shuttleworth, Esq., Old Warden, Beds, being second with Black Hamburghs in the same class. Peaches and Nectarines, although largely shown, were not in good colour, want of sun having evidently told on them. Apples included some very fine dishes of Lord Suffield. In Plums a fine dish of the Diamond was attractive, and Morello Cherries were well shown.

Vegetables were well represented in all the divisions, Potatoes especially so, and but slight indications of disease apparent. For the collection of eight varieties of vegetables Mr. C. Ellis, gardener to Mrs. Orr, Pemberley House, Bedford, was first, having large and handsome red Tomatoes, fine Superlative Peas, Cauliflowers, and Turnips in his tray; Mr. G. Vines, gardener to H. Thornton, Esq., Kempston Grange, being a very close second.

The best collection of Potatoes was shown in the market gardeners' tent by Mr. E. J. Darnell of Sandy, and consisted of the following varieties, all of good size, clean, sound, and correctly named—viz., Woodstock Kidney, Early Hammersmith, Beauty of Hebron, Vicar of Laleham, Schoolmaster, Radstock Beauty, Myatt's Prolific, International Kidney, Pride of Ontario, Snowflake, Grampian, Irish Flounders, Improved Peachblow, Early Shaw, Trophy, and Magnum Bonum. In this division the Judges had the good sense to give the preference to a good saleable sample of Magnum Bonum over a large and handsome dozen of International Kidney, which, although captivating as an exhibition variety, is practically useless for market garden purposes. In the single-dish classes Schoolmaster continued to hold first position in white rounds; International and Magnum Bonum chiefly in white kidneys; Mr. Bresee or Peerless Rose and Pride of Ontario in coloured kidneys; and Vicar of Laleham and Triumph as coloured rounds. Beauty of Hebron well to the front in both capacities, and from nearly all sources this is spoken of as the best of all the American type. Fillbasket seems to be a good new flat round white of the Model class. Reading Russet as exhibited is a handsome pink-tinted flattish tuber, but showed no indication of russet on the skin. Not a single dish of Regent and only one of Victoria was visible.

In Peas it is noticeable that the prizes in nearly all cases at this season were awarded for dishes of the Omega and Ne Plus Ultra types, of which some fine specimens were shown. Onions were on the whole inferior and somewhat weathered. The only good novelty remarkable in this department was Carters' Silver Ball, a good globe-shaped bulb with clear silver skin, shown sound, and having the appearance of being a better keeper than the other white varieties. The best brace of Cucumbers, a good strain of Telegraph, came from the Rev. W. H. Jackson.

The nomenclature at this Show was generally very defective and incorrect, and it is a pity that in a district where growers might be expected to profit by such an exhibition that more rigid regulations in this respect are not enforced. Some remarkable orthographical curiosities were observable amongst the Potatoes; "Trofen per Taotto" (Trophy Potato), "Buautey of Eberion" (Beauty of Hebron), "Pride of Tareor" (Pride of Ontario), "Inter Nashneiol," and "Pride-taker" being a few of the distinctions conferred on these worthy vegetables.

PACKING FRUIT.—In the report of the meeting of the Royal Horticultural Society (page 183) it is stated Messrs. Rivers & Son exhibited Nectarines which tasted of the packing material—some rough moss, similar remarks also applying to the Pears sent. Were the fruits sent first wrapped in tissue paper or packed without this? I have packed quantities in moss this season, but have heard no

complaints, but probably if I did not first enclose the fruit in tissue paper the case would be different. If Messrs. Rivers employed paper I shall have to test my present method, or at all events make inquiries of those who eat fruit.—W. I. M.

MANURE USED AT LONGLEAT.

No doubt Mr. Taylor has been harrassed with the criticisms which his valuable treatise on the culture of the Vize has produced. He "has written a book," and must take the consequences; but I hope and believe that the pleasures which he will derive from his useful work will greatly exceed the annoyances which it will entail. He must pardon me, nevertheless, if I recall to his remembrance the words with which "SINGLE-HANDED" finished his first remarks on this treatise at page 73, No. 1765, of the *Journal of Horticulture*. "In conclusion," he writes, "let me hope that Mr. Taylor will not be treated as he has treated other writers. He has, he says, never read any treatise on Vine culture, and laid down the only book he ever took up on the subject whenever he found that he could not agree to all that was in it. Of all Mr. Taylor's mistakes this was the greatest. . . ." Had he taken to heart the good advice which is given to him in this passage I am inclined to think that his remarks concerning my quotations and my implicit belief in chemists might have been suppressed.

I can assure Mr. Taylor that, at all events, I have no doubt that the high opinion which his brother horticulturists have expressed of his labour (as well as Dr. Voelcker's view of the feeble nature of earth-closet manure) "is substantially correct," and that I have every faith in the statement that "a similar example of culture" as that at Longleat "has not been attained at the same time in the Queen's dominions." But all this may be the case, and yet Mr. Taylor may be attributing to a manure that which is rather due to his skill in managing growth. He once changed his opinion as to the character of the soil he was dealing with, at another time he thought that he could grow his Vines without lime as well as he could with it, and on the 25th June last he gave us the highest testimony on the value of Standen's manure, which he now—after no greater interval than two months—recalls, and, as I venture to think, without sufficient proof that the character of the manure is no longer what it was. Now in all these cases he must have thought, when holding such confessedly erroneous opinions, that they were "based on something more than theory;" and supposing a chemist's analysis should show that he is right in his view that there has been a falling-off in the quality of Standen's manure, would it be "madness" on my part, as the manure "has proved practically to be of the greatest possible value, to throw it aside simply because a professor, however eminent, cannot find the fertilising ingredients in it," though backed up by the concurrent testimony of Mr. Taylor? Yet this is the attitude of things, in my mind, as respects the efficacy of earth-closet manure.

Like Mr. Taylor, I have often "wondered why the earth-closet system has not been adopted to a greater extent," but I confess that it had not occurred to me as an explanation that "chemists are responsible for it." I had thought that chemists had merely conclusively demonstrated, by showing that they could find but a small quantity of fertilising ingredients in it, that the conclusions already arrived at by farmers were based on grounds which could no longer be disputed; and I for one must, until Mr. Taylor can show me a reason to change my opinion, continue to hold that this admirable invention from a sanatory point of view does not, when properly carried out, supply a manure which will bear carriage, though it may be used with great advantage by gentlemen having large establishments with garden ground adjoining, or by the cottager; or, again, though it is an admirable system both from the sanatorial and manurial point of view for work-houses, reformatories, and prisons with gardens attached to them.

In conclusion, I would commend Dr. Voelcker's careful and conscientious paper on earth-closet manure to Mr. Taylor's earnest perusal. He will then learn that Dr. Voelcker's views are supported not only by the testimony of Dr. Gilbert, but by the opinion of that eminent agriculturist Sir J. B. Lawes, as well as by common sense; and he will, I trust, see that his acknowledged skill in Vine culture will not be seriously affected by his finding that his Vines, after all, have owed more to Mr. Standen's manures than he is now prepared to acknowledge.—INQUIRER.

A YEAR'S TREE-PLANTING IN GREAT BRITAIN.—Those who regard with dismay the cutting-down of trees, and believe that the area of woodland in this country is gradually disappearing, may take comfort from some of the figures stated in the return we publish elsewhere as to the prices for British timber realised during the season

1881-2. From those figures it will be seen that throughout England, Scotland, Ireland, and Wales, there were planted on various estates during the period under review no less than 3,156,826 trees! Of these, 2,175,826 were planted in Scotland, 646,200 in England, 294,800 in Ireland, and 40,000 in Wales. It is, of course, not easy to get absolutely complete returns, but those we give are well within the mark, and prove that there is at least some set-off against tree-felling and the gradual increase of bricks and mortar in these islands.—(*Journal of Forestry*.)

ON BUDDING AND GRAFTING: OR THE INFLUENCE OF THE STOCK UPON THE SCION AND VICE VERSA.

[Read at a meeting of the North of Scotland Horticultural Association at Aberdeen on August 18th, 1882.]

(Continued from page 174.)

BY GRAFTING ON CERTAIN STOCKS THE HABITS OR GROWTH OF PLANTS ARE ALTERED.

1. Pears grafted on the Quince do not grow so strongly and are more fruitful than those on the Pear stock.

2. Apples worked on the French Paradise stock do not grow so vigorously as those worked on the Doucin, and those on the Doucin are not nearly so strong-growing as those on the Crab or free stock.

3. Cherries do not grow so strongly when worked on the Mahaleb stock as they do when grafted on the wild Cherry. These are all termed dwarfing stocks.

The *Accr eriocarpum* is said in Loudon's "Horticulturist," when grafted on the Sycamore, to attain double the height of those raised from seed. The common Lilac attains a large size when grafted on the Ash.

4. Mr. Fairchild's experiments in 1721 on grafting the Evergreen Oak on the common Oak, and the Cedar of Lebanon on the Larch, rather prove the converse, both scion and stock retaining their natural character.

BY GRAFTING ON CERTAIN STOCKS WE ARE ENABLED TO GROW PLANTS IN UNCONGENIAL SOILS.

1. The Quince roots, for example, extend near the surface, and thus avoid a wet or cold subsoil. The Pear roots are sent down into the deep cold soil. For wet or moist heavy soils, therefore, it is found practicable to plant Pears worked on the Quince, and on dry shallow soils those worked on the Pear.

2. The French Paradise Apple is also a surface-rooter, hence its use in damp soils is to be recommended.

3. In strongly calcareous soils it has been found that what are termed the dwarfing stocks for fruit trees do not succeed. M. Dubreuil of Rouen found that not the Plum but the Almond was suitable for the Peach; not the Paradise or Doucin and Quince for Apples and Pears, but the Crab and wild Pear, &c.

THE SCION INFLUENCES THE STOCK.

The fact that the scion exerts a certain influence over the stock is fully more remarkable than that of the stock influencing the scion. It demonstrates that the scion supports the stock as much as the stock does the scion, and that the sap flows in every direction. The branches are, in fact, as necessary to support the root as the root is to support the branches.

1. The French Paradise Apple in the gardens at Chiswick invariably dies when about five or six years old; but when grafted with other varieties of Apples this tendency to die is averted, the grafted trees living to indefinite periods.

The peculiar power of the buds of variegated plants inoculating the stock on which they are budded has often been demonstrated.

1. The best-known instance is that of the variegated white Jasmine being budded by Mr. Anderson, of the Physic Garden at Chelsea, upon one branch only of a plant of *Jasminum revolutum*, which is green. Slight variegation appeared the first year, which increased year after year until the whole plant was variegated, although the branch which was first budded was cut away the second year.

2. Mr. Noble records in the *Gardeners' Chronicle*, 1871, the grafting of a golden variegated Weeping Ash on the common Ash. In four different cases the stock had thrown out variegated shoots.

3. Mr. Symes records in the *Gardeners' Chronicle*, 1877, the budding of a number of *Acer Negundo* with the variegated variety. The variegation affected the whole of the stocks, both above and below the point of insertion. Twenty-seven Ash stocks budded with the Aucuba-leaved variety, all of which grew and looked well for a time, the next spring the majority fell; only three grew. Two-thirds of the number were more or less inoculated with the variegation of the Aucuba, below as well as above, where they were budded.

4. Mr. Fish records in the *Gardeners' Chronicle* that a Purple Beech, grafted about 4 feet from the ground, at the base of the bole

a tuft of shoots with copper-coloured leaves appeared, and another at 15 feet above.

5. M. Carrière records the working of the variegated form of the *Pittosporum Tobira* on the green-leaved form. Though the graft did not grow the contact was sufficient to cause the production of a variegated shoot below the graft.—(*Gardeners' Chronicle*.)

6. *Passiflora Riddiana* and *Passiflora Impératrice Eugénie* were both grafted by M. Lemoine of Nancy with a variegated scion of *Passiflora quadrangularis*. The graft was inarched, so that the stocks were not cut away above the graft but allowed to remain. From this branch above the graft branchlets were produced bearing variegated leaves. The grafts did not grow well.—(*Gardeners' Chronicle*, 1875.)

7. A golden-leaved *Laburnum* was budded on a green-leaved *Laburnum* as a stock. The buds were inserted at 2 or 3 feet from the ground. In the course of a few months not only did some of the green-leaved stocks produce golden variegated branches below the point of union, but golden suckers were thrown up from the root.—(*Meeting Royal Hort. Soc.*, 1875.)

8. The variegated variety of *Castanea vesca* had been grafted standard high on the common Chestnut. The graft took, but from some cause died; but subsequently a young shoot with well-marked variegation broke out from near the base of the stem.—(*Cultivated Plants*, Burbidge, 61.)

9. The well-known blotched Breadalbane Ash was produced from buds taken from a yellow-leaved Ash in a Highland glen budded into the common Ash.

10. A Mountain Ash, upon which was budded a variety with variegated leaves, commenced to push forth young shoots from the main body of the stem below the point where the bud was inserted. In every instance these had variegated leaves.—(*Pro. Am. Pom. Soc.*, 1873.)

11. A Potato scion set into a Tomato plant induced the latter to set small tubers in the axils of its leaves, as are seen sometimes on the tops of Potatoes. The grafting of an Artichoke plant into a Sunflower caused the latter to form tubers underground.—(*Prof. Beal, Ag. Michigan*.)

12. Fruit-growers in America have noted that the scions affect the roots of the stocks. If, for example, part of the same row of stocks be grafted with Bartlett and Onondago Pears, they can be distinguished by their roots.

13. The curious *Cytisus Adami* or Purple *Laburnum* is a well-known example—three distinct sorts of flowers, all mixed on the same plant. This is, no doubt, a common *Laburnum* inoculated with a purple *Cytisus*. A fine example of this used to exist in the gardens at Crathes Castle, Banchoory. Numerous other well-authenticated examples of this strange influence of the scion over the stock might be given, but my object is attained in pointing out that it does exist.

This inoculation of the stock with the peculiar properties of the scion must not be confounded with that of "sporting," because each of these are, or have been, the direct result of the budding or grafting, as, indeed, they are true reproductions of the scion in many cases. It may be noted that in the majority of instances the buds inserted either did not grow or very soon died out after being worked, so that the potency of the contact seems to be all the more wonderful.

PECULIAR RESULTS OBSERVABLE IN BUDDING AND GRAFTING.

The vagaries of grafting and budding, if I may so term the peculiar preferences that particular varieties of fruit have for one kind of stock, are very remarkable, and in the present state of our knowledge quite inexplicable. For example, amongst Peaches it is well known in nurseries that the varieties *Grosse Mignonne* and *Bellegarde* take freely on the Brussels Plum stock, but will not take on the Muscle Plum. Other varieties, however, do so freely, and what is termed the Brompton Plum stock suits them all about equally well.

Amongst Plums, Mr. Bunyard, Maidstone, says the Belgian Purple, although of the Orleans class, will not succeed on the same stocks as the Orleans, but does well on the Muscle and Damask stocks. Rivers' Czar will not do on any but the Muscle. Damsons do not do well on the common Plum stocks. Wyedale Plum does not take freely on the Muscle, but fruits early—the first year instead of the second.

Amongst Pears the Marie Louise, for example, and many others will not succeed on the Quince. These varieties, if to be grown on the Quince, must be double-worked—*i.e.*, worked on some variety that is itself worked on the Quince. The *Beurré d'Amanlis* is often used for this purpose. Some years ago I made a number of experiments in grafting Pears on all sorts of stocks, such as *Cratægus coccinea*, *C. oxyacantha*, *C. acerifolia*, *Cotoneaster frigida* and laxi-

flora, Portugal Laurel, Quince, &c. The variety Winter Nelis appeared to take freely on all, whilst Marie Louise only succeeded on *Cotoneaster frigida*.

Apples may be grafted on a Pear, or a Plum upon a Cherry; indeed, I have done so, but such do not last above a year or two. The Orange takes better on the Lemon than on the Orange, and the little Kumquat will only grow on the *Limonia trifoliata*.

The well-known Rose *Maréchal Niel* will not grow on the *Manetti*, I am informed by Mr. Lane, whilst on other stocks it grows freely.

Mr. Noble of Sunningdale informs me that he uses the *Aucuba japonica* as a stock for *Garrya elliptica*. What affinity is existent here?

Some trees seem to have constitutions fit for anything almost; others are most fastidious—vigorous enough in their own nature, but alter that ever so little, even by the application of an uncongenial stock or scion, and it produces sickness and death.

Grafting Coniferae.—A great discussion was raised a few years ago on the merits of grafting *Coniferae*, especially those belonging to the *Abies* and *Pinus* sections, the practice being generally condemned as not being calculated to produce good or lasting trees. Magnificent examples to the contrary, *Abies nobilis* and *Picea pinsapo* 50 feet high for example, may be seen in Mr. Anthony Waterer's nursery at Knaphill; and in Mr. Noble's nursery at Sunningdale may be seen an avenue of several score of *Abies Nordmanniana* 30 feet in height—all perfect examples and all grafted on Silver Fir.

Potato Grafting, &c.—A few years ago much was written and many experiments made on grafting Potatoes, and several graft-hybrid Potatoes were supposed to have been raised, but I much doubt if such were the case. In some cases, probably, the cellular tissues of the Potato did unite, but there was little or no action between the stock and scion. An instance is recorded in the "Theory of Horticulture" of grafting the white Silesian Beet upon a root of red Beet. A complete junction was effected, but it was a mere junction of cellular matter; each grew and retained its peculiarity "without any interchange of contents through the sides of the cells in contact."

A variety of interesting topics and side issues to this great subject suggest themselves to me, and might be profitably discussed; but I refrain. I hope, if I have not been able to advance anything that may be considered new or instructive or of particular interest to many of you, you will believe in my earnest desire to do so, and in fostering a genuine love of horticulture amongst my fellow countrymen.—A. F. BARRON, *Chiswick*.

AUGUST SHOWS IN SOUTH WALES.

FEW counties surpass Glamorganshire in horticultural societies and shows. During August there have been more shows held in it than takes place in all the rest of Wales in a year. Upwards of £800 has been awarded in the county for fruits, flowers, and vegetables—a result which is creditable to all concerned, more especially as Glamorganshire is not renowned for the number and splendour of its noblemen's seats and great gardens. Certainly it contains some of the best families, and no one can complain of their want of interest in horticulture, although they do not support the shows to such an extent as is done in many parts of the country. This is not to be regretted either, as it is when all grades of Society augment the funds with their pounds, shillings, and pence, and make the shows with their products, that the most gratifying results are secured and the greatest benefits accrue. To those sources the Glamorgan shows owe their success, and it would be well for the prosperity of our art if this system were widely and generally followed.

From Cardiff to Neath, as the Great Western Railway runs, is a distance of some thirty miles, and in this distance seven flower shows were held during August. Taking them in rotation, the first was that of the MARGAM COTTAGE GARDENING SOCIETY, which took place on the 3rd of the month. The last Show was the fifth annual one. Competition is confined to the parish. As the funds have increased more money has been given in prizes. This year £5 more was taken as gate money than on any previous occasion. A good surplus has been left from every show; the reserve fund in the bank is over £40. Sunshine has been the rule at every show, but this "nest egg" will be very convenient in case of any misfortune. Prizes from £1 10s. downwards are given for the best cottage gardens, and for competition the prizes are offered chiefly for the kinds of garden produce most valuable to a cottager, such as Potatoes, Cabbage, Onions, Beans, Peas, Turnips, Carrots, Parsnips, &c. The competition in these is always very strong, and it is generally admitted that nothing has ever done so much for the good of the gardens in the parish as this Society. Certainly the majority of the parishioners now possess much practical knowledge as to which are the best kinds of vegetables, and many new sorts are tried and secured which would otherwise remain unknown.

BRIDGEND SHOW.—This was held on August 9th. Many open

classes are offered here, and cottagers are well provided for. The vegetables of the latter throughout South Wales are always a great feature, and as a whole they surpass those from the professional gardeners. Indeed the cottagers take a wonderful delight in trying to excel, and many of them are not satisfied with their own classes, but enter and do well in the open ones. Fruit and plants were very attractive at Bridgend this season, the finest coming from Ewenny Priory, the Glamorganshire seat of Col. Turberville.

NEATH SHOW.—This was held on the 10th inst., and is one of the best conducted shows in the country. Upwards of £300 is given in prizes annually. The Hon. Sec., Mr. Whittington, is a gentleman of the greatest tact and energy, and his Committee work so hard and close together that it would be well in many instances were their system adopted. Long lists of committeemen's names occur often enough, but how seldom are they all workers. The burden is generally thrown on two or three, and failure is often the result. Every department of horticulture was well represented at Neath. The principal plant prize—viz., £10, went to Mr. Cypher of Cheltenham, and it is well known that his plants give a high tone to any show. We have never as yet seen a bad specimen in one of his many collections. Golden Champion Grape was well shown, and was justly awarded the first prize as a dish of whites. Black Hamburgs were shown in prime condition from the garden of J. T. D. Llewelyn, Esq., Penllergare, Swansea, and the Carnations and Picotees from the same source were splendid. The attendance of visitors at this Show is always great, and we were more than pleased to see the crowd as bulky this season as ever. As before stated, no show could be better managed, none is worthy of greater support, and we hope this will never be wanting.

ABERKENFIG SHOW.—This was held on the 16th, and is conducted on the Margam principle, and we can only hope it will support itself as well and do as much good.

ABERAVON SHOW.—This is the name of a Glamorgan borough, and the chief members of the Corporation are on the Flower Show Committee. The Mayor, T. D. Daniel, Esq., was the originator of the movement, and is now the permanent President. This gentleman, along with the Committee, worked hard to secure success, and they were richly rewarded, as the Show itself was most notable for the great merit of the exhibits. Subscriptions came in well, and the attendance was extraordinary. The Earl and Countess of Jersey opened the Show, and before the close it was visited by many thousands of people, the receipts at the entrance gate being over £122. Mr. Cypher's plants were again conspicuous, and the collections of wild flowers were the finest I have seen at any show.

CARDIFF SHOW.—This is always a grand one. This year it was held on August 23rd. All the tents had been erected on the night of the 22nd in a field close to the town, and it was intended to have the Show in them as usual next day, but during the night the tents were all blown down, and a hurried arrangement of the exhibits had to be made in the Market Place. Notwithstanding this the Show was a most excellent one, all the classes being well filled with produce much above the average in quality. The best of the plants came from Mr. Cypher, Cheltenham, and Mr. Howells, Cardiff. Cut Roses were numerous and good. Mr. Crossling, St. Fagans, who is about to enter in the nursery business at Penarth, near Cardiff, had, as usual, some splendid stands of blooms, and secured the principal prizes for Hybrid Perpetuals and Tea varieties. Mr. Pettigrew, Cardiff Castle, also showed well in several of the Rose classes.

Fruit was better than we ever saw it here. The first-prize collection of nine dishes was superb and came from Mr. Crossling. One of his two dishes of Grapes was Alnwick Seedling, good in size of bunch and berry, and finely finished. For Black Hamburgs and Muscats Mr. Coomber, Hendre Park, Monmouth, was first, his Hamburgs being particularly fine. For any other black and any other white Grape Mr. Pettigrew was first in both instances, in one with grand Alicante and the other with well-ripened Foster's Seedling. Pines were numerous and good. Mr. Wood, Maindiff Court, Abergavenny, showed some very fine Queens and Smooth Cayennes. Mr. Hawkins, Ewenny, had also some grand dishes of stone fruits.

All the prize money was paid the day after the Show, and this is worth noting, as carelessness in this matter frequently tells sadly against a society in time to come. Exhibitors who have a difficulty in getting their prize money one year are not very anxious to do all they can for the society the following show, and we do not blame them; but this character does not apply to the shows in South Wales, and it is our opinion that they are a credit to all connected with them, and deserve to be supported in every possible way.—A SCOTCHMAN IN WALES.

LOBELIA CARDINALIS.

ATTENTION has been worthily directed to this grand old herbaceous plant. It has been described on page 175 as growing 3 or 4 feet high under favourable circumstances, but I have had quite a forest of brilliant spikes 5 feet high, and nothing in the garden was so gorgeous. They were grown in the lower pockets of a rockery at the margin of a lake, and the roots of the plants no doubt penetrated quite through the soil into the water. The compost was further prepared for them, and consisted of a mix-

ture of burnt, or rather charred, clay and cow manure, in which the growth of the plants were most vigorous. They could not, however, be safely left out all winter in such a position, and the best of them were always taken up and wintered in a cool pit, the roots being packed together and soil worked amongst them as if preparing Rhubarb roots for forcing. In drier borders plants have survived the winter, but were never so fine the following year as young plants were that had been preserved, prepared, and planted in rich fresh soil. In planting in the borders the practice was to have a barrowful of soil at hand, dig out a spadeful or two from the border and spread it, add the fresh, and insert the plants. A splendid return was always had for the little labour thus invested, and the fresh, heavy, and rich compost. Well-grown examples are grand also in pots for the conservatory in the autumn. For this purpose the dark-leaved sorts, *L. fulgens* or *L. ignea*, are well adapted; but it was the true old green-leaved species, *L. cardinalis*, that I had so fine in borders and on rockeries thirty years ago. It does not appear to be by any means plentiful now, and it ought to be increased, for no plant will better repay for good culture nor produce a more dazzling display under favourable circumstances.—A RETIRED GARDENER.

MR. TAYLOR'S ESSAY ON VINE CULTURE.

My absence from home has prevented me answering Mr. Taylor sooner. To use the words of "SINGLE-HANDED" on a former occasion in reference to Mr. Taylor and his Vines, I am "astonished he should seek to evade the responsibilities of his assertions;" but I can well understand his confessed aversion to "parallel passages." As he makes no satisfactory attempt to defend himself in regard to the last and other points raised by me, I feel I can safely leave the verdict with those of the public who understand such matters. Mr. Taylor's attempt to divert attention from the real issue by proposing to compare our Grapes is too transparent. It is not his Grape-growing that is assailed, but something else equally precious to him I should think. I should not have had the least objection to accept his challenge now, or at any time since he began (and if he had included other fruits besides Grapes I should have been still better pleased), had he been able to show how the comparative merits of our fruit was going to prove his avowed all but total ignorance of other people's writings and systems, more particularly in view of the fact that he is an expert shorthand writer and admits to using it in his notes; but he is unable to do anything of the kind, and I decline the frivolous and irrelevant contest.

I have on many occasions entered the lists among my fellows and equals and staked my chance there, and that is the course I should choose to adopt again if so disposed, and I could boast that I grew the best Grapes "in the Queen's dominions;" but I never did meet Mr. Taylor on any of these occasions, nor never heard of him meeting anybody; but that is the place I should have thought he would have chosen to exhibit his productions had he the confidence he professes. I do Mr. Taylor the justice to believe that his own account of his successful practice is true, but he must be conscious that to many readers, and certainly to me, his methods of culture are "paper methods" and no more; but I should be sorry to use that and the like expressions in an offensive sense to any man whose practice and results I was personally wholly unacquainted with.

Had Mr. Taylor been pleased to stake a benevolent wager in the hands of the Editors, and challenged me to prove from his late essay that he was perfectly well acquainted with the writings of other authors and their systems—if he is not open to the suspicion of being indebted to them for some of his words and ideas, notwithstanding his declaration to the contrary—I should have taken him up, and am ready to do that yet. I should have felt, had I been in his place, that it was *there* my "honour gripped," and should have acted accordingly.—J. S. W.

KITCHEN GARDEN.

CABBAGE as a spring crop is one of the most important, a supply being necessary in all gardens. The plants from the July sowing should as soon as fit be planted out in rich soil, choosing an open situation, but if possible sheltered from winds, as the autumn gales

often do the plants serious injury. Ground which has been occupied with Onions after it has been manured and turned answers well for this crop, the plants being placed out at about 18 inches apart, which is ample for the earliest; but plants of the main crop should be given more room, 20 to 24 inches according to the variety and size of head desired, and should have attention to keep them free from the attacks of slugs by dusting whilst damp with dry wood ashes, soot, or quicklime. Avoid keeping the plants too thickly in the seed beds, transplanting as many as will be requisite, and thin out the rest. A batch of the latest of these should be pricked out into beds to winter for planting out in the spring.

Winter Spinach will by this time require thinning, which should be done before the plants are very large. Allow sufficient space between the plants to prevent their damping off during bad weather, and keep the soil between the rows well stirred. The latter observation also applies to all other crops at this season. The whole surface of the kitchen garden where practicable should be hoed. When autumn-sown Onions are sufficiently advanced thin them to about 3 inches apart, which will admit of every alternate one being removed for early spring use as they are required. Where young Onions are in request they should be left thicker in the rows to allow of their being drawn as required; but where fine bulbs are required the plants must not be allowed to become weakly by being too thickly placed. Take up the main crop of Onions as they mature, and let them be fully exposed for a few days before storing them away.

Attend to the requirements of young Cauliflower plants, dusting them with dry wood ashes, soot, or quicklime as a preventive against the attacks of slugs, and do not allow them to stand too thickly, or they will be liable to shank. Another sowing should be made at once to obtain plants for pricking into frames or at the base of walls to stand the winter for spring planting.

Lettuces recently sown will need to be thinned as soon as the plants can be handled, and every encouragement must be afforded by stirring the surface soil in suitable weather, and dusting with quicklime. Another sowing may now be made of the hardy Cos varieties, Bath Cos (black-seeded), and Hicks' Hardy White, in a sheltered position to stand the winter in the seed bed for transplanting in spring. Maintain a good supply of salading, seeing to its being in proper condition for use by tying up at intervals, so as to secure well-blanching heads, and supply water abundantly in dry weather. Radishes should now be sown in more sheltered situations; a sowing made now will last well into autumn. Select fine days for earthing Celery, keeping the soil from the centre of the plants by drawing the stalks together and firming it well about them.

Cut away useless stems from Globe Artichokes, and remove all decayed leaves, so as to admit sun and air to ripen them at the base. Remove the leaves from over the clusters of Tomatoes outside, and keep all growths removed, so as to concentrate all the energies of the plants on the fruit in order to accelerate its swelling and ripening.

FRUIT HOUSES.

Pines.—Many of the suckers or plants started as such last autumn now have fruit swelling especially those of the free-fruiting sorts, which should be separated from the others started at the same time, as those not now in that condition will have completed their growth, and will the more readily start into fruit at the required time if subjected to liberal ventilation for about six weeks than if kept in a confined moist atmosphere. Therefore ventilate freely upon all favourable occasions, it not being possible to give too much air when the temperature is above 80°.

The suckers which were obtained from the summer-fruiting plants will soon be ready to be repotted if it be not already effected. The strongest should be shifted when they have become well rooted and before the roots are matted round the sides of the pots into 10 or 11-inch pots according to the variety. The plants should be afforded a position near the glass in a light well-ventilated house, and be kept gradually growing throughout the winter months, under which conditions the plants start into fruit the following May or June, and afford a supply of early autumn fruit. The remaining portion of the plants referred to above may be wintered in 7 or 8-inch pots, and be

transferred to the fruiting pots in spring, and these in conjunction with Smooth-leaved Cayenne and Charlotte Rothschild started as strong suckers last March will provide a successional supply of ripe fruit throughout the winter months, being supplemented by Queens and other varieties started at the same time.

Maintain the bottom heat steady at 80° to plants which are well established, and about 90° to those plants which have been recently repotted, continuing it until the roots have penetrated the fresh material, then lower it to 80°. Where fruit is swelling keep the atmosphere moderately moist, and give a little ventilation at the top of the house early in the morning to dispel superfluous moisture before the sun's rays affect the fruit. Ripe fruit required to be kept should be removed to a shady and well-ventilated house.

Peaches and Nectarines.—The fruit in all but the latest succession houses will be removed, and to ensure the proper maturing of the wood remove all shoots not required. Do not neglect to syringe the trees with the garden engine occasionally to keep red spider in check, and well water the inside borders whenever necessary, as the casting of the buds is due in a great measure to their imperfect formation, consequent on insufficient moisture at the roots of the trees after the fruit is gathered and the buds are being plumped, along with neglecting to keep the foliage healthy to the last.

Remove the roof lights from houses in which the trees have ripened their wood to induce complete rest and the cleansing of the trees from insects by the late summer and early autumn rains. Where any planting or adding fresh soil to the borders has to be done the present is a good time to procure and stack a supply. Rather strong turfy loam of a chalky or calcareous nature is most suitable, giving preference to loam overlying magnesian limestone, and this, without any admixture of manure or other substance, induces a healthy growth of the trees. Trees for early forcing should not be deferred planting later than the end of September.

PLANT HOUSES.

Stove.—*Clerodendron fallax* is most useful when grown from seed each year and flowered in 7 or 8-inch pots. For this purpose the seeds should be sown as soon as ripe in small pots, and kept shaded and moist until they have germinated, when the seedlings should have light position, a shelf near the glass being the most suitable. When the plants have a pair of leaves shift them into 6-inch pots, employing turfy loam with a fourth of leaf soil and a sixth of sharp sand. Old plants that have flowered and are intended to be kept for another year should now be cut down low, keeping them warm and damped every afternoon until they have commenced growth, when they can be partially shaken out and placed in smaller pots for winter.

Æschynanthuses now coming into flower must be well supplied with water, especially if grown in baskets, for which they are peculiarly suitable when grown in pots plunged in the baskets, the spaces being filled with sphagnum; and if a few pieces of *Selaginella cæsia* are introduced it will greatly improve their appearance.

Euphorbias that were some time ago removed into cooler quarters must not be allowed to remain there too long, or they will suffer at the roots and fail at a time when they ought to be coming into flower. A pit or house where they can have a minimum night temperature of 55°, with abundant ventilation and a light position is the most suitable.

Poinsettias must only have sufficient heat to keep them slowly growing, with a light airy position, and water as necessary to keep the plants from losing the lower leaves; but excessive watering must be avoided, as it causes the roots to perish and the head of bracts is small. *Bilbergias* are much-neglected plants, though easily grown and very beautiful. *B. Moreliana*, *B. thyrsoidea*, *B. splendida*, and *B. vittata* are worth a place in every stove, being handsome in foliage and their fine racemes of bloom are striking. The pots for these plants should be well drained. Fibrous peat with an admixture of charcoal and sand to the extent of about a sixth will suit them well. Propagation is effected by suckers, which should remain on the parent until they become strong. When detached they will root freely. Eight-inch pots are large enough for single-crowned plants.

THE BEE-KEEPER.

THE SOUTH KENSINGTON BEE AND HONEY SHOW.

IN reference to this Show, and the list of awards which we published last week, we commence our remarks at Class 24—"for the largest and best collection of hives and bee furniture applicable to modern bee keeping, no two articles to be alike"—since, generally speaking, it is the one most important to bee-keepers. Messrs. Neighbour & Son of Regent Street obtained here the highest honours. In their collection we noticed amongst a large number of other hives a pretty specimen termed the Crystal Case Hive, with sections at side and space also for chaff-packing or other warm material in winter. Root's American Chaff Hive also appeared to obtain a full share of notice; and Novice's Extractor, another American production, seemed to be generally approved. The bronze medal was obtained by Mr. T. B. Blow of Welwyn, Herts, for an excellent collection of modern bee appliances. The hives we thought especially worthy of notice, well put together, of good sound material, and involving the right principles of simplicity, ease of manipulation, and variety of use. The improved feeding-bottle on this bench, which obtained a prize in another class, appeared to leave nothing further to be desired in this all-important branch of apiculture—slow or stimulative and copious feeding. Mr. Rusbridge, whose various exhibits and apparatus, so well known to modern and scientific bee-keepers, need no description at our hands. Messrs. Tait and Wooldridge, who rank, we believe, as apiculturists of note, also worthily competed in this class.

Having briefly noticed this most important department of the Exhibition, we return now to the classes in numerical order, the first three of which are devoted to bees of the several different varieties, Messrs. Neighbour taking first in Class 1 with a finely marked stock of our old friends the Italians. This race appears to have undergone some change of late years, in appearance at least, since those we remember as being introduced by Mr. Woodbury some twenty years ago were certainly of lighter colour and smaller in size than the modern variety. We believe, however, this larger darker race is unsurpassed in the most desirable traits of honey-gathering, fecundity, and gentleness of disposition. Messrs. Blow and G. Bertoli of Varallo-sesia, Italy, well deserved their positions (second and third) for their bright specimens of this beautiful insect.

Class 2 was for English bees only, which, like the old English race, is, we fear, doomed ere long to extinction, so difficult is it even now, owing to the introduction of the foreign varieties, to obtain a stock of the pure old English black bee. There were only two competitors here—Messrs. Blow and Neighbour, first and second, and whose exhibits to our eyes were of that brownish tint which speaks of foreign blood notwithstanding their uniformity of colour.

In Class 3, for any other variety than Italian or English, Mr. Blow was again champion (first and second) with fine stocks of the too-little known Carniolians and Cyprians, the former a large black bee with white hairy bands around the abdomen, and said to be extremely prolific and an excellent worker; the latter one of the most beautiful, if not the best, of all varieties, but at present considered by many the most irritable and revengeful of all, and utterly heedless of smoke. It may be that it requires to be "educated" to English notions and manipulation, when assuredly it will become the "bee of the future," and this we say advisedly. Another beautiful stock of Carniolians secured for their owners, Messrs. Neighbour, third place. These bees were all exhibited with their queens in observatory hives.

Next on the list are the hive classes, of which there were six. First, Observatory (Class 4), there being seven entries, and nothing requiring special notice except Messrs. Neighbour's first-prize hive, embracing both novelty and a new principle, of which we give an engraving (fig. 34). The hive proper consists of a mahogany box about 2 feet long, and of the usual width for frames. These frames slide on metal runners, and can be moved backwards and forwards with the hands at the openings along the sides. Across the centre is an open oblong space about 2 inches wide, surmounted by a glass case to allow of the ascension of one frame of comb. Any one of the frames separately can be brought under this glass case. Two rods are then lowered, and catch two hooks with which each frame is provided. By turning the windlass above, the frame of comb with bees adhering is slowly raised for observation and as quietly lowered and passed to the other side of the centre, thus providing space for the examination of the next comb in a similar manner. The queen may thus be readily "interviewed" and the bees remain in a perfectly natural state.

The glass case revolves, in order that the light may be caused to fall upon the object desired. The bees may be kept in this hive all

the year round, since a division-board is used for contracting space during the winter months, and in summer frames containing sections are placed near the brood nest.

The remaining hives in this class demand no special notice, as involving any new principle or novelty of construction. The second and third-prize hives, and Messrs. Abbott's highly commended one were rightly placed. We regret that the same remark will not apply to Class 5, "Moveable-comb Hives, with facilities for harvesting honey, and arrangements for winter use, price unlimited." We have always imagined that utility was the object to be kept in view in the selection of a hive for general use, and that the prizes should go to those hives best calculated to advance apiculture and to create an impetus in its favour; but upon what principle the first-prize hive in this class was awarded the silver medal we are at a loss to conceive. For ourselves we should have placed it last in the class of seventeen entries. First, its principle was that of the old and exploded Giotto system with its closed frame ends, so well calculated for receiving propolis and cruelly crushing its inmates, a principle which has long been discarded on the continent of America and in other countries—wherever, indeed, bee culture has advanced beyond the state of infancy. Placed upon a lofty iron stand—while advanced bee-keepers place their hives, if not upon the ground, as near to it as possible—most complicated in all its parts, with no price attached, we were not surprised on inquiry at the Secretary's office on the last day of the Show at being unable to learn either the price at which or the maker of whom we could procure a specimen, and at being informed that no previous inquiries had been made as to price or maker. May we suggest to the Committee the desirability of an increased staff of Judges on future occasions? It was evidently impossible for two gentlemen to do full justice to eleven classes, six of them being large hive classes, in the time assigned to them. The second-prize hive was remarkable for its simplicity of construction. Mr. Hooker's third-

Fig. 34.—Neighbours' Prize Observatory Hive.
